The lesson of the mass society theory, in brief, was that if the masses overthrew the traditional leaders, things would be much worse. The “successes” of liberalism, the destruction of traditional social structures, the elimination of stable communities, and the resulting individualism (also called “egoism”) could only worsen an already precarious situation. The theory, accordingly, counseled acceptance or acquiescence.

It is easy to see such claims as ideological, as pretense, as justifications for old-regime privilege. Such claims were (and are) given short shrift in the opposite liberal dramaturgy and, still later, in the dramaturgy of the left. In those opposite accounts, the old regime is portrayed as powerful. The rulers, after all, had vast wealth and influence; they controlled the police and the ultimate force, the army.

In private accounts, however, the leaders of the old regime reported a sense of powerlessness. Their “hold” on power, they felt, was tenuous; they stood on the edge of the abyss. Chateaubriand, the French ambassador, congratulated Lord Liverpool on the stability of British institutions. Liverpool pointed to the metropolis outside his windows and replied: “What can be stable with these enormous cities? One insurrection in London and all is lost.” The French Revolution itself proved the flimsiness of “established” rule. In 1830, the restored monarchy in France collapsed after only a week of fighting in the capital. In 1848, Louis Philippe's regime fell after only two days of struggle. A month later, the Prussian king and queen, effectively prisoners of the revolution, were forced to do obeisance to the fallen insurgents. The queen's comment—“Only the guillotine is missing.” More than a century later, the historian J. R. Jones

declared that “during long periods of this time, many conservatives felt that they were irretrievably on the defensive, faced not with just electoral defeat but also doomed to become a permanent and shrinking minority, exercising a dwindling influence on the mind and life of the nation.”

Early in the twentieth century, sociologists in Europe and North America developed an extensive literature that also argued a loss-of-community thesis. Among the Europeans, we have Ferdinand Tönnies, Georg Simmel, and, with a difference, Emile Durkheim. Simmel’s essay, “The Metropolis and Mental Life,” had considerable influence in North America, especially in the development of sociology at the University of Chicago. The Chicago “school” was founded by Robert Ezra Park who had studied under Simmel. Park’s essay, “The City: Suggestions for Investigation of Human Behavior in the Urban Environment,” provided the agenda for generations of sociologists. Another central work in the Chicago tradition was Louis Wirth’s 1938 article, “Urbanism as a Way of Life.” The city, Wirth wrote, is “characterized by secondary rather than primary contacts. The contacts of the city may indeed be face to face, but they are nevertheless impersonal, superficial, transitory, and segmental Whereas the individual gains, on the one hand, a certain degree of emancipation or freedom from the personal and emotional controls of intimate groups, he loses, on the other hand, the spontaneous self-expression, the morale, and the sense of participation that comes with living in an integrated society. This constitutes essentially the state of *anomie*, or the social void, to which Durkheim alludes” (p. 153).

Writing almost a half-century after Wirth, sociologist Barrett A. Lee and his coworkers—in an important challenge to those claims—commented on this tradition as follows: “Few themes in the literature of the social sciences have commanded more sustained attention than that of the decline of community In its basic version, the thesis exhibits a decidedly antiurban bias, stressing the invidious contrast between the integrated small-town resident and the disaffiliated city dweller” (pp. 1161–1162). Those sociologists do not appear to have had any clear political direction. Their work was value-neutral. It was pointing to what they took as a basic fact about modern societies without proposing any specific remedies.

Later in the twentieth century, a new version of the mass society theory made its appearance. This may be termed the *left variant*. All three versions of the theory, right, neutral, and left, agree on “the basics,” on the underlying root causes of the modern condition, all agreeing on the “decline of community.” But the right and left differ sharply in their portraits of the rulers, of the elites, the upper classes, or the bourgeoisie. In the rightist version, the rulers face a serious threat from below, from the demagogues and their mass followings. Their control is said to be very tenuous. In the left version, the rulers are portrayed as skillful controllers of the society. The key to their successful domination is to be found in their adept use of the mass media.

The bourgeoisie, the ruling class, or its executive agency, the “power elite,” is said to control the mass media of communication, the press, magazines, motion pictures, radio, and television, using them for their purposes. News and commentary, much of it, is said to be self-serving. It is essentially ideological, material designed to justify and defend “the status quo.” The entertainment provided is diversionary in character, intended to distract people from their real problems. Advertising in the media serves the same purposes—distraction, creation of artificial needs, and provision of false solutions. The bourgeoisie, it is said, owns and controls “the media.” With their vast resources, they are able to hire specialists of all kinds, market researchers, psychologists, and so forth, to aid in this manipulative effort. The near-helpless audience (as ever, atomized, powerless, and anxious) is psychologically disposed to accept the “nostrums” provided.

Elements of this position appeared in the writings of the Italian Marxist, Antonio Gramsci, with his concept of ideological hegemony. Some writers in the “Frankfurt school,” most notably Herbert Marcuse, also argued this position. It appeared also in the work of C. Wright Mills, in his influential book, *The Power Elite*. Many others have offered variants of this position.

The left mass society theory provided a third “revision” of the Marxist framework, that is, after those of Bernstein and Lenin. It is the third major attempt to explain the absence of the proletarian revolution. Marx and Engels assigned no great importance to the mass media. They occasionally

referred to items in the “bourgeois” press, adding sardonic comments about its “paid lackeys.” But newspaper reports were treated as of little importance. They could not stop or reverse the “wheel of history.” But in this third revision, “the bourgeoisie” had found the means to halt the “inevitable” course. The controllers of the media were able to penetrate the minds of “the masses” and could determine the content of their outlooks. The masses were said to be drugged or, to use a favored term, they were “narcotized.”

In the 1950s, in the Eisenhower era, the mass media were unambiguously affirmative about “society” and its major institutions. Families were portrayed as wholesome and happy; the nation’s leaders, at all levels, were honorable and upstanding. It was this “affirmative” content that gave rise to the argument of the media as manipulative, as distracting. In the late 1960s, media content changed dramatically. Programs now adopted elements of the mass society portrait, dwelling on themes of social dissolution. Families, neighborhoods, and cities were now “falling apart.” Many exposés, in books, magazines, motion pictures, and television, in the news and in “investigative reports,” told tales of cunning manipulation. Unlike the right and left versions of the mass society theory, these critics do not appear to have any clear political program. They appear, rather, to be driven by an interest in “exposure.” No evident plan, directive, or call for action seems to be involved. Studies indicate that most of the participants are modern-day liberals, not socialists or Marxists.

The mass society theory has had a peculiar episodic history, a coming-and-going in popularity. It had a wave of popularity in the 1940s when Karl Mannheim, Emil Lederer, Hannah Arendt, and Sigmund Neumann, all German exile-scholars, attempted to explain the major events of the age. A sociologist, William Kornhauser presented an empirically based synthesis in 1959, but this effort, on balance, had little impact. In the 1960s, the wave of “left” mass society theorizing appeared, beginning with the influential work of Herbert Marcuse. In 1970, Charles Reich’s *The Greening of America* appeared, a book destined to have, for several years, an enormous influence. It provided a depiction of the nation that was entirely within the mass society framework: “America is

one vast, terrifying anti-community. The great organizations to which most people give their working day, and the apartments and suburbs to which they return at night are equally places of loneliness and isolation. Modern living has obliterated place, locality, and neighborhood” (p. 7).

Few research-oriented social scientists have given the mass society theory much credence in the last couple of decades, this for a very good reason: virtually all the major claims of the theory have been controverted by an overwhelming body of evidence (Campbell et al. 1976; Campbell 1981; Fischer 1981; Fischer 1984; Hamilton and Wright 1986).

The mass society portrait is mistaken on all key points. Most migration is collective; it is serial, chain migration, in which people move with or follow other people, family and friends, from their home communities. Most migration involves short-distance moves; most migrants are never very far from their “roots.” Cities do grow through the addition of migrants; but they also grow through annexation, a process that does not disturb established social ties. The typical mass society account, moreover, is truncated, providing an incomplete narrative. The “lonely and isolated” migrants to the city supposedly remain that way for the rest of their lives. Those lonely people presumably have no capacity for friendship; they are unable to get together with others to overcome their powerlessness, and so forth.

Many academics in other fields, however, continue to give the theory considerable credence. It is a favorite of specialists in the literary sciences, of those in the humanities. The theory, as noted, is also a favorite of journalists, of social affairs commentators, of writers, dramatists, and poets.

This paradoxical result requires some explanation. The literature dealing with “the human condition” has a distinctive bifurcated character. The work produced by research-oriented scholars ordinarily has a very limited audience, most of it appearing in limited-circulation journals for small groups of specialists. Those specialists rarely attempt to bring their findings to the attention of larger audiences. Attempts to correct misinformation conveyed by the mass media are also infrequent. The producers of mass media content show an opposite neglect: they rarely contact academic

specialists to inquire about the lessons found in the latest research.

Those who argue and defend mass society claims, on the whole, have an enormous audience. Writing in 1956, Daniel Bell, the noted sociologist, stated that apart from Marxism, the mass society theory was probably the most influential social theory in the Western world. Four decades years later, the conclusion is still valid. The intellectual productions based on this theory reach millions of susceptible members of the upper and upper-middle classes, most especially those referred to as the “intelligentsia.”

The mass society theory proves well-nigh indestructible. It continues to have wide and enthusiastic support in some circles regardless of any and all countering evidence. Some people know the relevant evidence but engage in various “theory-saving” efforts, essentially ad hoc dismissals of fact. Some people, of course, simply do not know the available evidence, because of the compartmentalization of academia. Some academics do not make the effort required to find out what is happening elsewhere. Some others appear to be indifferent to evidence.

MATE SELECTION THEORIES

Social scientists who study the family have long been interested in the question “Who marries whom?” On one level, the study of mate selection is conducted from the perspective of family as a social institution. Emphasis is placed on the customs that regulate choice of mates. A counterperspective views the family as an association. This perspective centers instead on the couple and attempts to understand the process of marital dyad formation. Both of these perspectives generate an abundance of knowledge concerning mate selection. Beginning primarily in the 1920s, theoretical and empirical work in the area of mate selection has made great advances in answering the fundamental question “Who marries whom?”

INSTITUTIONAL PERSPECTIVES ON MATE SELECTION

The purview of anthropologists has centered on kinship structures as they relate to mate selection in arranged marriage systems. Sociological inquiry that sees the family as a social institution in the context of the larger society focuses instead on the

evolution of courtship systems as societies modernize. In this respect, it is important to note the contributions of scholars such as Bernard Murstein (1974, 1976) who have pointed out the importance of cultural and historical effects on courtship systems that lead to marriage.

Historical evidence suggests that, as a society modernizes, changes in the courtship system reflect a movement toward autonomous courtship systems. Thus, parentally arranged marriages diminish in industrialized cultures, since arranged marriages are found in societies in which strong extended kinship ties exist or in which the marriage has great significance for the family and community in terms of resources or status allocation. As societies modernize, arranged marriages are supplanted by an autonomous courtship system in which free choice of mate is the preferred form. These autonomous courtship systems are also referred to as "love" marriages, since the prerequisite for selection of a mate has shifted from the need to consolidate economic resources to that of individual choice based on love. Of course, family sociologists are quick to point out that the term "love marriage" is somewhat of a misnomer, since many other factors operate in the mate selection process.

Family social scientists have tried to understand the human mate selection process by using a variety of data sources and theoretical perspectives. The most global or macro approaches have made use of vital statistics such as census data or marriage license applications to study the factors that predict mate selection. Attention has been placed on social and cultural background characteristics such as age, social class, race, religion, and educational level.

THEORY BEHIND THE MARRIAGE MARKET

Before considering individual background characteristics and interpersonal dynamics of the mate selection process, it is important to note the increasing attention given to the marriage market and the marriage squeeze. The term "marriage market" refers to the underlying assumption that we make choices about dating and marriage partners in a kind of free-market situation. Bargaining and exchange take place in contemporary selection processes, and these exchanges are based on

common cultural understandings about the value of the units of exchange. The basis for partner selection plays out in a market situation that is influenced by common cultural values regarding individual resources, such as socioeconomic status, physical attractiveness, and earning potential. Numerous studies have concluded that gender roles play a significant part in the marriage market exchange process, with men trading their status and economic power for women's attractiveness and domestic skills. But changes in contemporary gender roles suggest that as women gain an economic viability of their own, they are less likely to seek marriage partners (Waite and Spitze 1981). Thus, the marriage market and the units of exchange are not constant but subject to substantial variation in terms of structure and selection criteria.

The premise that marital partners are selected in a rational choice process is further extended in the study of the effects of the marriage squeeze. The "marriage squeeze" refers to the gender imbalance that is reflected in the ratio of unmarried, available women to men. In theory, when a shortage of women occurs in society, marriage and monogamy are valued. But when there are greater numbers of women, marriage as an institution and monogamy itself take on lesser importance. Similarly, when women outnumber men, their gender roles are thought to be less traditional in form (Guttentag and Secord 1983).

The marriage squeeze has important effects for theoretical consideration, especially in studying the lower rates of marriage among African-American women in today's society. Due to a shortage of African-American men, coupled with greater expectations on the part of African-American women of finding mates with economic resources (Bulcroft and Bulcroft 1993), the interplay between the marriage squeeze and motivational factors to marry suggest that future research needs to disentangle the individual and structural antecedents in mate selection. These studies also point to the complexity of mate selection processes as they take place within both the social structure and cultural gender role ideologies.

The marriage squeeze is further exacerbated by the marriage gradient, which is the tendency for women to marry men of higher status. In general, the trend has been for people to marry within the

same socioeconomic status and cultural background. But men have tended to marry women slightly below them in age and education (Bernard 1982). The marriage gradient puts high-status women at a disadvantage in the marriage market by limiting the number of potential partners. Recent changes in the educational status of women, however, suggest that these norms of mate selection are shifting. As this shift occurs, one can speculate that the importance of individual characteristics such as physical attractiveness, romantic love, and interpersonal communication will increasingly come to play important roles in the mate selection process in postmodern society (Beck and Beck-Gersheim 1995; Schoen and Wooldredge 1989).

Norms of endogamy require that people marry those belonging to the same group. Concomitantly, exogamous marriages are unions that take place outside certain groups. Again, changes in social structures, ethnic affiliations, and mobility patterns have dramatically affected the modern marriage market. More specifically, exogamy takes place when marriage occurs outside the family unit or across the genders. Taboos and laws regulating within-family marriage (i.e., marriages considered to be incestuous that occur between brother and sister, mother and son, etc.) and marriage to same-sex partners are examples of the principle of endogamy. Recent attempts have been made to legally recognize same-sex marriages, thus suggesting that norms of endogamy are tractable and subject to changes in the overall values structure of a society or social group.

In addition to endogamy and exogamy, the marriage market is further defined by norms of homogamy and heterogamy. Mate selection is considered to be homogenous when a partner is selected with similar individual or group characteristics. When these characteristics differ, heterogamy is evidenced. The norm of homogamy continues to be strong in American society today, but considerable evidence suggests we are in a period of change regarding social attitudes and behaviors with regard to interracial and interfaith unions.

Recent data suggest that the number of interracial marriages for African-Americans has increased from 2.6 percent in 1970 to 12.1 percent in 1993 (Besharov and Sullivan 1996). But African-American mate selection operates along lines of

endogamy to a larger degree than do the mate selection processes of Asian-American, Native American, or other nonwhite groups. Nearly one-half of all Asian-Americans marry non-Asians (Takagi 1994) and over half of all Native-Americans marry non-Native Americans (Yellowbird and Snipp 1994).

Similarly, rates of interfaith marriage have increased. For example, only 6 percent of Jews chose to marry non-Jewish partners in the 1960s. Today nearly 40 percent of Jews marry non-Jewish partners (Mindel et al. 1988).

The background characteristics of age and socioeconomic status also demonstrate norms of endogamy. The Cinderella story is more of a fantasy than a reality, and self-help books with titles such as *How to Marry a Rich Man (Woman)* have little basis for success.

The conditions of postmodern society are shaping mate selection patterns as they relate to endogamy and homogamy. The likelihood of marrying across social class, ethnic, and religious boundaries is strongly affected by how homogeneous (similar) the population is (Blau et al. 1982). In large cities, where the opportunity structures are more heterogeneous (diverse), rates of intermarriage are higher, while in small rural communities that demonstrate homogeneous populations, the norm of endogamy is even more pronounced.

Again, the complex interplay between the marriage market and individual motives and preferences is highlighted. The extent to which marriage outside one's social group is the result of changing preferences and attitudes or largely the result of shifting opportunity structures, known as marriage market conditions, is not clear at this time (Surra 1990).

The factors that operate in the selection process of a mate also function in conjunction with opportunity structures that affect the potential for social interaction. The evidence suggests that proximity is an important factor in determining who marries whom. Thus, those who live geographically proximate to each other are more likely to meet and marry. Early work by James Bossard (1932) shows that at the time of the marriage license application, about 25 percent of all couples live within two city blocks of each other.

Bossard's Law, derived from his empirical findings, states "the proportion of marriages decreases steadily and markedly as the distance between the consenting parties increases." Or, put more simply, "Cupid's wings are best suited for short flights." Of course, current American society has changed since the time Bossard studied mate selection patterns in Philadelphia, and there is a tendency to think that as society becomes more mobile propinquity plays less of a role in the choice of a mate. Propinquitous mate selection does not mean nonmobility, however. It is simply the case that the influence of propinquity shifts as the individual geographically shifts. Thus, one is likely to marry someone who is currently near than someone previously propinquitous. The overriding effect of propinquity is that people of similar backgrounds will meet and marry, since residential homogamy remains a dominant feature of American society. However, changing marriage patterns, such as delaying age of first marriage, will impact the strength of propinquity in the mate selection process by expanding the opportunity structures and breaking down homogenous marriage markets.

One interesting area of research that often goes overlooked in discussions of the correlates of mate selection concerns homogamy of physical attractiveness. Based on the equity theory of physical attractiveness, one would expect that persons who are similar in physical attractiveness levels would marry. Many experimental designs have been conducted to test the effects of physical attractiveness on attraction to a potential dating partner. In general, the experimental conditions have yielded the findings that the more highly attractive individuals are the most desired as dating partners. But studies of couples actually involved in selecting a mate or who are already married support the notion that individuals who are similar in attractiveness marry on their own level. Thus, while attractiveness is a socially valued characteristic in choice of a mate, the norms of social exchange dictate that we select a partner who is similar in attractiveness and is thus attainable. It is only when other highly valued factors such as wealth, wit, or intelligence compensate for deficits in attractiveness that inequity of physical attractiveness in mate selection might occur.

In review, theories of mate selection are more often applied to the study of personality characteristics or process orientations than to marriage

market conditions. It is important to note, however, that the basic assumption is that the marriage market operates in a social exchange framework. Men and women make selections under relative conditions of supply and demand with units of exchange. The market is further shaped by cultural norms such as endogamy and homogamy that can further restrict or expand the pool of eligibles.

NEED COMPLEMENTARITY

While earlier work on the correlates of mate selection focused on homogamy of background characteristics, the work of Robert Winch (1958) set the stage for further investigation into the hypothesis that "opposites attract." That is, persons of dissimilar values or personality traits would marry. While value theorists speculated that similarity of values and personality would lead to great affiliation and propensity to marry, Winch posited that persons select mates whose personality traits are complementary (opposite) to their own. Inherent in Winch's theoretical work is the notion that certain specific trait combinations will be gratifying to the individuals involved. For example, a submissive person would find it gratifying or reciprocal to interact with a mate who had a dominant personality. Winch developed twelve such paired complementary personality traits, such as dominant-submissive and nurturant-receptive, for empirical testing using a very small sample of recently married couples. In Winch's work, as well as the work of others, the notion that complementarity of traits was the basis for marriage was not supported by the data.

Although empirical support for need complementarity is lacking, the concept remains viable in the study of mate selection. The appeal of the concept rests in its psychological origins, as work prior to Winch's focused primarily on structural and normative influences in mate selection. The work of Winch set the stage for research commencing in the 1960s that began to examine the processes of mate selection on the dyadic level.

PROCESS THEORIES OF MATE SELECTION

The process of selecting a mate received considerable attention beginning in the 1970s. The basic form these theories take follows the "filter theory"

of Alan Kerckhoff and Keith Davis (1962). Kerckhoff and Davis found empirical support that individuals, having met through the channels of propinquity and endogamy, proceed through a series of stages or steps in the development of the relationship. According to their theory, social status variables such as social class and race operate early on in the relationship to bring people together. The next stage involved the consensus of values, during which time the couple determines the degree of similarity in their value orientations. Couples who share similar values are likely to continue to the third stage, need complementarity. However, the data collected by Kerckhoff and Davis offered only weak support for need complementarity as part of the process of mate selection.

Development of process theories of mate selection continued into the 1970s and is exemplified in the work of Ira Reiss (1960), Bernard Murstein (1970), Robert Lewis (1973), and R. Centers (1975). While these theoretical perspectives differ in terms of the order and nature of the stages, they have much in common. Melding these theories of mate selection, the following assumptions can be made concerning the stages of dyad formation that lead to marriage:

1. There are predictable trajectories or stages of dyadic interaction that lead to marriage.
2. The social and cultural background of a couple provides the context for the interpersonal processes.
3. Value similarity leads to rapport in communication, self-disclosure, and the development of trust.
4. Attraction and interaction depend on the exchange value of the assets and liabilities that the individuals bring to the relationship.
5. Conditional factors such as age, gender, or marital history may influence the order or duration of the stages, or the probability that the relationship will end in marriage.

All the studies of the mate selection process have struggled with methodological difficulties. Most studies have relied on small, volunteer samples of couples. Most have used college-age, never-married couples. Finally, most studies have made extensive use of retrospection in assessing the

process of dyad formation rather than collecting longitudinal data. These methodological difficulties may, in part, account for the recent decline in the number of studies examining the process of mate selection.

Furthermore, these stages may or may not result in marriage, but the primary focus of the research is on relationships that endure or terminate in marriage. Therefore, relatively little is known about the mate selection process as it pertains to rejection of a potential mate or how such terminations of relationships affect subsequent mate selection processes.

More current research has begun to shift away from antecedents that lead to legal marriage and turn instead to disentangling the trajectory of relationship development over the life course. More attention will turn to the formation and development of interpersonal relationships that may move through stages of romance, cohabitation, friendship, marriage, divorce, and so forth. Emphasis on relationship quality and durability, gender role negotiations, commitment processes, and romantic love have recently taken on increased importance in social science studies of mate selection (Surra and Hughes 1997; Houts et al. 1996; Surra 1990).

Many of the theories have also overlooked the influence of peer groups and family members in the mate selection process. The theoretical and empirical inquiry that has paid attention to peer and kin influences is restricted to studies of dating. Unfortunately, studies of dating and studies of mate selection have not been sufficiently integrated to provide the field with adequate data concerning the interrelationships between dating and mate selection processes.

Yet another area of research that has the potential for contribution to further understanding of the mate selection process is studies of romantic love. Process theories of mate selection seldom examine love as the basis, or even as a stage, in the development of a heterosexual relationship. While there is a large body of empirical and theoretical work on romantic love, conceptually the studies of love have been treated as quite distinct from the research on mate selection. Contrary to popular opinion, the relationship between love and marriage is not well understood.

FUTURE DIRECTIONS

As the family system changes in American society, so too the direction of research on mate selection shifts. As more couples delay first marriage, examination of courtship cohabitation becomes more salient. Future studies of courtship cohabitation will most likely examine the association between increasing rates of cohabitation and decreasing rates of marriage. On the individual level, the effects of the cohabitation experience on the decision to marry also warrant attention.

Research is just beginning on the mate selection process of remarriage (Bulcroft et al. 1989; Rodgers and Conrad 1986; Spanier and Glick 1980). While some factors that predict first marriage may remain constant in remarriage, such as endogamy and propinquity, other factors may come into play in remarriage. For example, age homogeneity may be less of a factor in remarriage since the pool of eligible mates is impacted by sex ratio imbalance. The exchange relationship in the mate selection process also differs in remarriage, since presence of children, prior marital history, and the economic liabilities of child support and alimony bring new dimensions to considerations of remarriage. Of particular interest are barriers to remarriage in the middle and later years of the life cycle, such that cohabitation or serious dating may offer more long-term rewards to the couple than legal marriage might provide. Thus, the strong profamilial norms that encourage the younger members of society to marry dissipate at mid and later life. Low rates of remarriage for individuals over the age of 50, in part, indicate that societal pressure to marry is greatly reduced.

Last, it has generally been assumed that homogamy of background characteristics leads to similarity of values, shared marital role expectations, rapport, and intimacy in the process of mate selection. But due to changing gender role expectations, this assumption may no longer be valid. As a result, more attention needs to be given to the process of role negotiation as part of the mate selection process.

In summary, studies of mate selection began with understanding the correlates of mate selection. Social scientists began by studying demographic data on homogamy in religion, social class, age, and other factors as these variables related to who married whom. For a brief period in the

1960s through the early 1980s, attention was turned to theories and data that examined the process of mate selection. Current research in the 1990s has not abandoned the study of the correlates and theories of mate selection, but as the nature of the family system changes, researchers have begun to consider that the generalizability of theories and findings may be limited when a researcher is trying to explain mate selection at a point later than young adulthood. Recent studies on the courtship processes of divorced (O'Flaherty and Workman 1988) and later life mate selection (Veevers 1988) point to the future focus of theories and research on mate selection processes.

KRIS BULCROFT

MATERIALISM

Materialism posits the epistemological primacy of matter over ideas, mind, values, spirit, and other incorporeal phenomena. Philosophical perspectives stressing the fundamental importance of physical conditions and needs have grown more elaborate with the increasing differentiation and autonomy of secular knowledge from religion. Materialists oppose magical, religious, and metaphysical explanations of worldly affairs, criticizing their role as mystifications and socioeconomic or political legitimations. The enduring debate over materialism and idealism (which gives primacy to ideas) centers on the two approaches' relative effectiveness as guides to scientific, technical, and sociopolitical practices. In social science, materialism refers to often tacit metatheories, or heuristic devices, which frame distinctive types of research problems, hypotheses, concepts, and theories stressing the causal force of physical realities on sociocultural matters.

Two contrasting threads of the materialist tradition have divergent consequences for the behavioral and social sciences. *Reductionists* posit that phenomena are determined strictly by physical causes. Their view that existential knowledge is a reflection of corporeal conditions denies the autonomy of psychological and sociocultural factors and, thus, suggests that the behavioral and social sciences have no distinct content. *Nonreductionists* hold that psychological and sociocultural phenomena arise from and are dependent upon physical substrata. They also accord "primacy" to physical realities and corporeal impulses, motives, values, representations, and interests, seeing them as basic constraints that "determine," or channel, the direction of human practices. By contrast to reductionists, however, they treat the sociocultural realm as an "emergent," "sui generis," "relatively autonomous" domain having distinct properties, processes, and laws and exerting reciprocal causality with the material realm. Implying interpenetrating sociocultural and material spheres, they include socially constituted entities and processes (e.g., technology and labor) as prime "material" determinants.

Modern materialism is rooted in ancient Greek conceptions of elementary bodies. Atomistic philosophers held that all existing things are composed of indivisible, ultimate objects of the same

material in perpetual motion in empty space. They argued that perceptible objects derive from atoms of various sizes and shapes colliding, getting entangled, and forming different combinations, and that sensations arise from atoms passing through the sense organs and impacting on the soul (also composed of atoms). From the start, materialists considered knowledge to be a “subjective” manifestation of “objective” reality, holding that physical realities ultimately determine individual experiences and sociocultural constructions. However, claims about the scope of this determination varied widely with the degree to which the thinker adhered to reductionist or nonreductionist presuppositions.

Atomistic materialism reemerged as a major cultural force during the Renaissance science revolution. Galileo and Newton again portrayed physical reality as ultimate particles moving in empty space, but their distinction between precisely measurable, primary sensory qualities (i.e., length, width, weight, figure) and nonmathematizable secondary qualities (e.g., color, smell, taste, texture) established a sharp boundary between objective and subjective experience and decisive methodological standard for distinguishing science from metaphysical, aesthetic, or sociocultural thought. The capacity of diverse observers, employing the same experimental techniques, to arrive at similar findings supported materialist claims about the primacy of the physical world and certainty of objective knowledge.

The extraordinary success of Newtonian science contributed greatly to an extensive secularization of knowledge that reduced barriers to materialist approaches in human affairs. For example, Hobbes argued that social actions are also effects of matter in motion; material primacy is manifested in the dominant drive for self-preservation, all-pervasive power struggles, and subsequent need for absolute monarchy. Locke’s Newtonian theory of mind held that primary sense qualities reflect external objects and that complex ideas merely combine the simple ones received directly from sense experience. However, Descartes’ dualistic vision of a materialist physical world and an autonomous mind blessed with innate ideas of divine origin exemplifies the seventeenth century tendency to provide separate grounds for science, which avert direct subversion of religion. The power of the Roman Catholic Church and its censors, who saw

materialism as a subversive force, was already inscribed powerfully in the earlier trial and conviction of Galileo and in his concession to dualism. Even Hobbes left space for spiritual realities. The strong subjectivist currents and subject-object dualism in Western philosophy derived from its earlier religious roots and its lack of autonomy in relation to the Church.

Enlightenment thinkers fashioned a new cultural space for free inquiry and autonomous science, subverting the power of religion and paving the way for modern materialism. La Mettrie, D’Holbach, and Diderot held that all experience has material causes. Idealizing Newtonian mechanics, the philosophes believed that naturalistic explanation of all phenomena would demystify religious and metaphysical superstition, limit the rule of the Church and nobility, and animate scientifically guided social reform. Revolutionary advances in eighteenth-century medicine, chemistry, and biology upheld their faith in materially based rationality, disenchantment, and progress. The later social revolutions against the ancien régime, secularization of political power, and gradual rise of liberal democracy favored the spread of materialist thinking in new social domains.

Manifesting Enlightenment culture, Karl Marx set the agenda for modern materialism. Even today’s debates about the topic center on different interpretations of his work. Following Feuerbach, Marx charged that religion and its secular, idealist substitutes (e.g., Hegelian philosophy) are “inverted,” or “alienated,” projections of human capacities and potentialities. As “natural beings,” he argued, people must satisfy their needs by appropriating and shaping physical objects. Although he attacked Hegel’s speculative history of “spirit,” Marx retained his view that people create themselves and their societies through their labor. Young Marx called for a “true” materialism, or a new science of humanity focusing on “social relationships.” He wanted to illuminate ideologically obscured forms of socially structured production and exploitation, which, in his view, constitute the “real history” of “corporeal” human beings.

Divergent strains of Marxian materialism—“dialectical materialism” and “historical materialism”—are rooted ultimately in tensions between the political and scientific sides of Marx’s and

Engels' works. The terms were coined after Marx's death and codified into a variety of schematic orthodoxies. *Dialectical materialism* is a philosophy of nature developed first by Engels, elaborated by Plekhanov and Lenin, and fashioned by Marxist-Leninists into an eschatology of the communist movement. Serving primarily as a political ideology and metalanguage that justified communist states and insurgencies, it did not have much impact on social science outside the communist regimes and movements. By contrast, *historical materialism*, Marx's main metatheory of social development, has much relevance for sociology. Yet even this approach was stated variously by him, and gave rise to conflicting interpretations. The elder Engels ([1890–1894] 1959, pp. 395–400), who earlier helped Marx frame his theories, berated first-generation “Marxists” for using materialism “as an excuse for *not* studying history,” or as a dogmatic Hegelian “lever for construction,” instead of as “a guide to study.” Accepting partial responsibility for the later vulgar interpretations, he admitted that Marx and he, in the heat of political battle, often spoke with too much certainty. However, he insisted that Marx and he opposed the idea of all-encompassing, mechanistic causality by narrowly conceived economic factors and that their materialism meant nothing more than that “the production and reproduction of real life” is “the *ultimately* determining element in history.”

Engels implied a problematic split in Marx's thought. On the one hand, Marx sometimes implied, in Hegelian fashion, progressively unfolding stages of history, animated by relentless technological advance and ever more unified classes rationally taking account of material factors, controlling them, and speeding history to an “inevitable” emancipatory conclusion. Such points were warranties for his political program. On the other hand, the scientific side of Marx's work breaks from teleological thinking. His *historical* materialism stresses empirical inquiry about specific material conditions and practices and their sociocultural consequences among particular groups in finite space and time, and calls for reconstruction of theory and practice in light of the findings. This approach has more affinity for the empirical and secular thrust of the Darwinian revolution than for earlier Enlightenment ideas of progress and science, which implied a new faith or civil religion. After the failed revolutions of 1848 and the rise of

the new Napoleonic dictatorship in France, Marx qualified his formerly highly optimistic views about “making history,” holding that we do not make it in accord with circumstances or outcomes that we freely choose. This insight was precursory to his mature work on capitalism, which, although retaining certain Hegelian taints, manifested clearly his historical materialism.

Following Adam Smith, Marx held that a specialized division of labor enhances productive powers geometrically. However, by contrast to Smith, he specified that capitalism's exceptional productivity derives expressly from its historically specific forms of complex cooperation, which end the relative isolation of peasants and other independent producers. Marx charged that economists mystify this process by obscuring the fundamental role of labor and portraying capitalist growth as if it were animated by a “fantastic . . . relation between things,” rather than by a specific type of “social relation” (Marx [1887] 1967, pp. 71–83). He saw the unequal relationship between capitalists and workers as the “secret” of capitalist accumulation. Treating associated labor and related forms of social organization, extraction, and domination as the decisive “material” forces in human affairs, Marx averted the reductionist physicalism of the early atomists, awkward dualism of the Renaissance thinkers, and mechanistic determinism of the dialectical materialists.

Marx and Engels ([1845–1846] 1964, pp. 31–32) said that the “first premise of all human history” is the production of “the means of subsistence” and a characteristic “*mode of life*.” As productive forces are refined, they held, growing surpluses offer provision beyond subsistence and allow certain individuals and strata to be freed from direct production for other activities, including the creation of fresh technical knowledge and new productive forces. Marx and Engels contended that incremental advances in production generate increasingly elaborate socio-cultural differentiation, class structure, and domination and more universal “class struggles” over the productive forces. In their view, material determination in the “last instance” means that socially structured patterns of production, extraction, and disposition of surplus shape social development. A materialist sociology focuses on these processes and their consequences.

The central tenet of historical materialism is that the “base,” or “mode of production,” determines “superstructure,” or “the forms of intercourse.” The base is composed of “productive forces,” which contribute directly to production for material needs (i.e., natural resources, tools, technical knowledge, labor power, and modes of cooperation), and “property relations,” which provide certain “classes” effective control over production and relegate others to direct labor. “Superstructure” is composed of nonproductive types of social intercourse (i.e., noneconomic forms of public organization, private association, and thought), which are determined by and, in turn, maintain, or reproduce, the base.

There is a core technological root to Marx’s materialism, but he also implied reciprocal causality between the physical and sociocultural realms. Thus, he was not a reductionist. Although granting productive forces ultimate theoretical primacy, his historical analyses dwelled more on property relations and class dynamics. Moreover, he did not hold that material determination operated with the same intensity throughout society. Rather, he emphasized that its strongest force is exerted in institutions that play a direct role in reproducing the mode of production and that the rest of society and culture has much more autonomy. For example, under capitalism, mainstream public discourses about property rights or free trade are central to ideology, but most music and fiction, as well as Marx’s critical writings, bear only the broad imprint of the level and form of productive development. Marx envisioned society as composed of interdependent social structures and cultural forms, implying that each element has a distinct impact on the whole. Yet he still saw the base as the most decisive factor shaping overall society and its internal relations. He treated the productive activities of subordinate producers and surplus extraction by superordinate classes as the most central and obscured processes in social life and the root of the most major institutions, conflicts, and transitions.

In a much-debated argument about the capitalist mode of production, Marx held that the rate of profit would fall under highly mechanized production. He believed that the trend toward automation in heavy industry reduces the proportion of direct laborers to fixed capital, diminishing the ultimate source of capitalist profit and requiring hyperexploitation of remaining workers to pay for

vastly increased technical investment. Marx argued that the classes would be compressed into a tiny monopoly stratum of owners and a huge impoverished mass of de-skilled workers and permanently unemployed people. However, he also held that science and technology, having replaced direct labor as the leading productive force, would provide the material basis for proletarian revolution and an emancipated, postcapitalist order (i.e., scientific production and administration, greatly reduced work and material necessity, and uncoerced cooperation). This hopeful scenario about collective agency and planning as replacing blind history, and material determinism as becoming truly “in the last instance,” went beyond the scientific thrust of historical materialism and reflected the Hegelian residue in his thought.

By the early twentieth century, pathbreaking ideas about electromagnetic fields, relativity theory, and quantum mechanics relativized space and time, eroded the borders between energy and mass, and fashioned a new relational cosmology that undermined Newtonianism. Similarly, Nietzsche, James, Dewey, Heidegger, and Wittgenstein subverted the foundations of modern Western philosophy. Major social changes accompanied the intellectual shifts. A more complex system of classes and subclasses, new types of workplaces, indirect forms of ownership and control, and state intervention altered the structure of capitalism and blurred the line between base and superstructure. Stalinism; fascism; resurgent irrationalism; and persistent racial, ethnic, gender, and religious splits also cried out for new types of theory. In this climate, Marxists tended to drift toward new types of cultural theory or to embrace dialectical materialism, which remained the official ideology of global communism.

In the 1930s, when sociology was being transformed into a professionally specialized discipline in the United States, Talcott Parsons relegated Marx to the status of a footnote in the history of social theory and gave a strong primacy to values and ideas that turned Marx on his head. Parsons’s leading role in post-World War II sociology helped harden mainstream opposition to materialism. Claiming that class was no longer a prime basis of association, a determinant of political and cultural beliefs, or a source of major social conflicts, numerous North American sociologists and many

thinkers from other liberal democracies argued that materialism did not come to terms with the nascent “postindustrial society.” Although certain critics dissented, most mainstream sociologists dismissed materialism as a crude ideology, or simply ignored the approach.

Materialist themes appeared much more prominently in later 1960s social theory, animated, in part, by New Left attacks on functionalism and positivism. Very influential among European theorists, Lewis Althusser’s “structuralist” interpretation of Marx radically revised materialism. However, G. A. Cohen’s *Karl Marx’s Theory of History* (1978) helped stimulate wider efforts to reconstruct historical materialism (e.g., Anderson 1974a, 1974b; Shaw 1978; McMurtry 1978; Roemer 1982; Bhaskar 1989). Dispensing with overt political facets and overcoming conceptual gaps, the new works were more systematic versions of the original approach. However, they did not have much impact on mainstream sociology.

Materialist theory fell on hard times in a climate where “post-materialist” identity politics were ascendent over labor-centered or class politics, and failed communism and resurgent neoliberalism seemed to doom the socialist “alternative” (Anderson 1983; Antonio 1990). In this climate, a new “cultural sociology” blossomed as part of a broader interdisciplinary turn to “representation” and “discourse.” Postmodern arguments about the primacy of culture were often pitched directly against Marxian materialism, which they declared moribund. These new cultural theories tended to shift the focus among “critical sociologists” from “structural determinants” (i.e., production and labor) to “cultural surfaces,” especially mass entertainment and other signifiers of mass consumption. Many of these theorists argued that a defining feature of postmodern culture is its increased, or, even, total autonomy from material underpinnings.

Although materialist theory has declined in recent years, historical-comparative and empirical work, manifesting tacit materialism and clear connections to nondoctrinaire forms of Marxism, was well established in North American sociology by the 1980s. It still flourishes among significant subgroups in the discipline. These thinkers do not directly employ the base-superstructure model

(which is now associated with dialectical materialism and dogmatic Marxism), but they share historical materialist presuppositions, albeit often fused with other traditions. Recent historical changes are intensifying interest in materialist themes. First, neoliberal globalization and restructuring stimulate heated debates over multinational firms, international finance, socioeconomic dislocations, and related public policy initiatives. Second, the collapse of eastern European communism and global decline of communism raise major questions about socioeconomic reconstruction in postcommunist society and detach materialism from communist politics. Third, new materialist critiques counter claims about the primacy of culture and representation in interdisciplinary theory circles. Historical materialism is a heuristic device that poses problems and hypotheses, and is perhaps best judged on this account. Consider the current “materialist” issues below.

MATERIALIST ANALYSES OF THE NEW PHASE OF CAPITALISM

As in Marx’s time, today’s materialism arises in a climate of perceived rupture, or the end of the post–World War II socioeconomic system and its distinctive patterns of growth, regulation, and geopolitics. Materialists focus on the shifts in the system of production and their impacts on other aspects of social life, especially on inequality, conflict, and politics.

Globalization and Restructuring. Recent materialist work focuses on the new “flexible” forms of production, network firms, international division of labor, and multinational economic blocs—for example, the North American Free Trade Association (NAFTA) and the European Union (EU). The core debates among these analysts concern the shape, permanence, and consequences of the new global economy and the degree to which it departs from postwar capitalism (i.e., they ask whether a new multinational, or “post-Fordist,” phase of capitalism has replaced “Fordism,” or simply modified it.) (e.g., Harvey 1989; Harrison 1994; Gordon 1996).

Income and Wealth Inequality. Neoliberal deregulation, free trade, and recommodification of public goods have increased global disparities

of wealth, income, jobs, and life chances (Braun 1997; Davis 1992). Inequality is most extreme between the richest and the poorest nations, but it has also grown considerably within societies, including wealthy ones, such as the United States. Materialists debate the scope of economic inequality, its relation to global restructuring, and its consequences.

Class, Labor, and Politics. Materialists also focus on the impact of restructuring and polarizing labor markets on organized labor. For example, they ask: Are new types of unions arising among formerly unorganized low-wage service workers and professional groups? Will transnational labor organizations arise in the emergent economic blocs? Are new fusions of class politics and cultural politics arising?

The State. Materialists raise questions about the impact of capital mobility and new forms of international financial and labor markets on the state's capacity to protect and regulate its various environments and maintain public goods (e.g., health, education, welfare, retirement). They also study the role of the state's police and military arms in the global political economy.

Environmental Issues and Sustainability. Increasing threats of resource depletion, global warming, hazardous waste, and overall environmental destruction, the need for alternative forms of energy and technologies, and the communist regimes' dismal environmental records have stimulated sharp criticism of earlier materialism's "productivism" and inattention to the costs, risks, and limits of growth. They pose questions about sustainable growth and material limits to political aspirations.

Communication and Information Technologies. These industries play a major role in globalization and restructuring and, thus, are a central focus in fresh materialist inquiries.

FOUNDATIONAL ISSUES IN MATERIALIST THEORY

Although certain thinkers (e.g., Wallerstein 1991; Postone 1993; Wood 1995; Wright 1997) have begun reframing materialism in light of the recent historical changes, more fundamental rethinking

of the tradition is likely, especially in the two broad areas discussed below.

The Role of Technology. This area has long been a central focus of materialism. In the late nineteenth century, Marx held that science and technical knowledge were already becoming the primary productive force, altering fundamentally the capitalist mode of production and materialist dynamics of all preceding epochs. Certain contemporary theorists argue that information and communication technologies are giving rise to an "informational society" (e.g., Poster 1990; Castells 1996). These thinkers raise basic questions about previous ideas of production, property, labor, organization, and other aspects of earlier materialism, which could lead to a new generation of theories framed around a knowledge-driven logic of material development.

Materialism and Politics. The effort to unify theory and practice, and the consequent fusion of science and politics, generate distinct resources (i.e., they provide a "critical" thrust) as well as major sources of tension (i.e., between science and ideology) in Marxian materialism. As "critical theorists," materialists focus on the contradictions between democratic ideology's claims about freedom, equality, abundance, and participation, on the one hand, and actual conditions of capitalist and state socialist societies, on the other. They claim to illuminate the determinate, historical possibilities for progressive social change (i.e., "emancipatory" structural factors, cultural conditions, and social movements), which favor reconstructing modern societies according to revised versions of their own democratic ideals. However, the failure of proletarian revolution and communism have blurred materialist political aims. Some materialists abandon critical theory completely, fashioning a strictly empirical sociology, while others substitute highly generalized ideals of "discursive" or "radical" democracy and cultural politics for socialism. It is hard to predict the fate of critical theory, but increasing inequalities in wealth, polarizing labor markets, and declining social benefits raise major questions about unmet needs and the material bases of inclusive democratic citizenship. The bankruptcy of soviet-style regimes and the erosion of social democracies make materialist political goals an open question, but the consequent loss of certainty undercuts the tradition's

dogmatic side and increases chances for theoretical reconstruction and restored vitality.

MATHEMATICAL SOCIOLOGY

Mathematical sociology means the use of mathematics for formulating sociological theory more precisely than can be done by less formal methods. The term thus refers to an approach to theory construction rather than to a substantive field of research or a methodology of data collection or analysis; it is also not the same as statistical methods, although it is closely related. Mathematical sociology uses a variety of mathematical techniques and applies to a variety of different substantive research fields, both micro and macro.

Theory involves abstraction from and codification of reality; formulation of general principles describing what has been abstracted; and deduction of consequences of those formulations for the sake of understanding, predicting, and possibly controlling that reality. When social phenomena can be described in mathematical terms, the deductive power of mathematics enables more precise and more detailed derivations and predictions based on original premises.

Mathematical expression also enables sociologists to discover that the same abstract forms and processes sometimes describe what seem to be diverse social phenomena. If the same type of formulation describes both the spread of a disease and the adoption of an innovation, then a common type of process is involved and the theorist

can search further for what generates that commonality. Ideally, therefore, mathematics provides the basis for very general and powerful integrative theory.

The vigor of mathematical sociology varies widely over the different subfields of sociology. Precise formulation requires precise observations and careful induction of general patterns from those observations. Some sociologists have rejected any attempts to quantify human behavior, either on the grounds that what is important is in principle not subject to precise measurement or from a philosophical unwillingness to consider human behavior to be in any way deterministic. That issue will not be addressed here, but clearly it is much easier to obtain precise information in some areas of inquiry than in others. For example, census data provide reasonably precise counts of many sociological interesting facts, with the consequence that mathematical demography has long flourished.

Mathematics can be thought of as an elegant logic machine. Application of mathematics to any substantive discipline involves careful translation of the substantive ideas into mathematical form, deriving the mathematical consequences, and translating the results back into a substantive interpretation. There are three key aspects to the process: (1) finding a satisfactory way of expressing the substantive ideas in mathematical terms, (2) being able to solve the mathematical puzzle, and (3) eventually being able to compare derivations from the model with data from the substantive application.

The mathematical expression of a substantive theory is called a *model*. Often, models are created with primary emphasis on their being tractable, or readily solved. Some types of models appear frequently in substantive literature because they are widely known, are relatively simple mathematically, and have easy solutions. Basic models and applications can be found in Coleman (1964), Fararo (1973), and Leik and Meeker (1975). Mathematics and sociological theory are discussed in Fararo (1984). A wealth of more complex models can be found in specialized volumes and in periodicals such as the *Journal of Mathematical Sociology*.

Simple models have the advantage of presenting an uncluttered view of the world, although derivations from such models often do not fit

observed data very well. When the goal is heuristic, a simple model might be preferable to one that matches more closely the reality being modeled. However, when the goal is accurate prediction and possible control, then more complex models are typically needed.

There are two general questions to be raised in deciding whether developing a mathematical model has been useful. One is whether the mathematics of the model lead to new ideas about how the system being modeled operates. This is purely a theoretical question, concerned with understanding reality better by creating an abstraction of it that enables us to think more clearly about it. The second question concerns how well the model fits that reality, and is a statistical question.

Statistical models are concerned solely with fitting an underlying mathematical model to data from a sample of real-world cases. The underlying model may be complex or simple, but the statistical concerns are whether the sample can be assumed to represent adequately the population from which it was selected and whether the parameter (equation constant) estimates based on that sample can be considered accurate reflections of how the variables of the underlying model are related in that population.

A HISTORY OF RECENT APPROACHES TO FORMAL THEORY

During much of this century, there has been concern in sociology over the relationship between theory and research. Whereas theory was abstract and typically discursive, research increasingly employed statistical methods. The gulf between verbal statements about theoretical relationships and statistical tests of empirical patterns was great. Beginning in midcentury, some sociologists suggested that one way to bridge this gulf is to translate theoretical ideas into mathematics. Proposals for ways that theoretical ideas could be represented mathematically included those by Simon (1957) and several summarized by Berger et al. (1962).

Another approach to more formal presentation of theories that seemed to offer a bridge over the chasm between verbal statements and statistical tests was Zetterberg's concept of axiomatic theory (1965). The popularized result was *axioms*

in the form of monotonic propositions (“The greater the X , the greater the Y ”) and hypotheses derived solely from concatenating (multiplying) the signs of the relationships. For example, the axioms “As A increases, B increases” and “As B increases, C decreases” lead to the hypothesis that “As A increases, C decreases.” Standard statistical tests of the deduced hypotheses were presumed to be proper tests of the theory that generated the axioms. The approach was quick, convenient, and readily understood, and did not require expertise in mathematics or statistics. Consequently, it quickly became popular.

Numerous inadequacies with such theories soon became apparent, however (see for example critiques in Hage 1994), and interest turned to *path models* based on earlier work by Wright (1934). Path models assume that empirical measurements coincide exactly with theoretical concepts; that all variables are continuous (or reasonably close to continuous); that all relationships (paths) are bivariate, linear, and causal; that there is no feedback in the system (the recursive assumption); and that all relevant variables have been included in the model (the “closed-system” assumption). The underlying theoretical model is therefore very simplistic but does allow for the introduction of assumptions about multiple causal paths, and for different types of causal relationships including intervening, spurious, modifying, and counteracting.

If the assumptions are reasonable, then the causal effects, or path coefficients, are equal to ordinary multiple regression coefficients. That is, the underlying mathematical model feeds directly into a well-known statistical model, and the tie between theory and research seems well established. Are the assumptions reasonable?

The closed-system assumption, for example, implies that there is no correlation between the prediction errors across the various equations. If error correlations appear, then path coefficient estimates based on the statistical model will be in error, or biased, so the theory will not be tested properly by the statistics. Only two solutions are possible: (1) add more variables or paths to the model or (2) develop a statistical model that can accommodate correlated errors.

The assumption that measurement equals concept poses a different problem whenever various

scales or multiple indicators are used to represent a theoretical concept not readily assessed in a simple measure. Traditionally, the statistical model called *factor analysis* has been used to handle this measurement-concept problem, but factor analysis was not traditionally linked to the analysis of theoretical systems.

Recent years have seen very extensive development and elaboration of statistical models for linear systems, and these models address both the correlated error and the measurement-concept problems while allowing departure from recursiveness. They are called *linear structural models* (Joreskog 1970; Hayduk 1987). The underlying mathematical model still said that all variables are continuous and all relationships bivariate, linear, and causal. This development focused entirely on technical statistical questions about bias in parameter estimates. Furthermore, although the theory generally supposed that one variable affects another over time, the data are normally from only one or a very few points of time. From a general theory point of view, the underlying linear model’s assumptions, which were imposed for tractability, are highly restrictive.

MOVING BEYOND LINEAR MODELS

Consider the assumption of linearity. If a dynamic process is being modeled, linear relationships will almost always prove faulty. How change in some causal factor induces change in some consequent system property is typically constrained by system limits and is likely to be altered over time through feedback from other system factors.

As a disease like acquired immune deficiency syndrome (AIDS) spreads, for example, the rate at which it spreads depends on how many people are already infected, how many have yet to be infected, and what conditions allow interaction between the not-yet-infecteds and the infecteds. With very few infected the rate of spread is very small because so few cannot quickly infect a very large number of others. As the number of infecteds grows, so does the rate of spread of the disease, because there are more to spread it. On the other hand, if nearly everyone had already been infected, the rate of spread would be small because there would be few left to spread it to. To complicate

theoretical matters further, as the disease has generated widespread concern, norms governing sexual contact have begun to change, influencing the probabilities of transmission of the virus. In mathematical terms, the implication is that the rate of change of the proportion infected (i.e., the rate of spread of the disease) is not constant over time, nor is it a constant proportion of change in any variable in the system. In short, the process is inherently nonlinear.

Nonlinear models in mathematics take many forms. If the variables are conceived as continuous over time, and the primary theoretical focus is on how variables change as a consequence of changes in other variables, then the most likely mathematical form is differential equations. The substantive theory is translated into statements about rates of change (Doreian and Hummon 1976). Most diffusion and epidemiology models, like the AIDS problem just noted, use differential equations. So do a number of demography models. Recently some of the numerous differential equations models dealing with topics such as conflict and arms control have been applied to theoretical questions of cooperation and competition in social interaction (e.g., Meeker and Leik 1997).

For relatively simple differential equations models, once the model is developed it is possible to determine the trajectory over time of any of the properties of the system to ascertain under what conditions the covariation of system properties will shift or remain stable, and to ask whether that system will tend toward equilibrium or some other theoretical limit, oscillate in regular patterns, or even “explode.”

None of these questions could be asked of a linear model because the mathematics of the linear model leaves nothing about the model itself to be deduced. Only statistical questions can be asked: estimates of the regression coefficients that fit the model to the data and the closeness of that fit. To the extent that sociology addresses questions of process, appropriate theory requires nonlinear models.

What about the assumption of continuous variables? For cross-sectional data, or data from only two or three time points, new techniques of statistical analysis suitable for categorical data have been developed. However, these focus once again

on technical statistical problems of bias in estimation of parameters and generally rely on assumptions of linearity. Within mathematical sociology, other approaches exist. If time or time-related variables were to be treated in discrete units, there are at least three different approaches available. For handling dynamic systems without the calculus of differential equations, difference equations are the appropriate form. Huckfeldt and colleagues (1982) provide a convenient overview of this approach.

For extensive time series with relatively few variables, there are Box-Jenkins and related types of models, although these have seen relatively little use in sociology. Because they are closer to statistical models than general theoretical models, they are only mentioned in passing.

Many theories treat systems as represented by discrete states. For example, over a lifetime, an individual is likely to move into and out of several different occupational statuses. Are certain status transitions more likely than others? In simplest form, the implied theoretical model involves a matrix algebra formulation that specifies the probability of moving from each of the states (occupational statuses for this example) to each of the other states. Then the mathematics of matrix algebra allows deduction of a number of system consequences from this “transition matrix.” Such a treatment is called a *Markov chain*. An early application by Blumen and colleagues (1955) demonstrated that certain modifications of a Markov chain were needed for the theory to fit the data they had available on occupational transitions. Their work was the initial inspiration for a distinguished string of mathematical models of social mobility. Another classic is by White (1970), who conceptualized mobility of vacant positions as well as of individuals into and out of positions.

Another type of substantive problem that deals with discrete data is the analysis of social networks such as friendship structures. These can be modeled using the mathematics of *graph theory*, the basic concepts of which include *nodes* (or *points*) and *relationships between pairs of nodes* (or *lines*). One of the most vigorous modeling areas in sociology, network analysis has produced a rich and elaborate literature addressing a wealth of substantive issues. Typically, network data consists of

whether or not any two cases (nodes in the network) are linked in one or more ways. The resulting data set, then, usually consists of presence or absence of a link of a given type over all pairs of nodes.

Early network analyses concerned friendships, cliques, and rudimentary concepts of structurally based social power. With the introduction of directed graph theory (Harary et al. 1965), random or probabilistic net theory, and block modeling, powerful tools have been developed to approach social structure and its consequences from a network point of view. As those tools emerged, the range of questions addressed via network analysis has greatly expanded. Over the past twenty years, numerous articles in the *Journal of Mathematical Sociology* have dealt with networks. The journal *Social Networks* also publishes work in this area. Overviews and examples can be found in Burt and Minor (1983), and in Wellman and Berkowitz (1988).

Graph theory may be applied to other theoretical issues; for example, a graph-theoretic model developed by Berger and colleagues (1977) helps explain the processes by which people combine information about the various characteristics of themselves and others to form expectations for task performance.

Small group processes have also generated a variety of mathematical formulations. Because observations of groups often generate counts of various types of acts (for example amount of talking by members of a discussion group) that display remarkable empirical regularity, these processes have intrigued model builders since the early 1950's. Recent developments, combining network analyses with Markov chains, include Robinson and Balkwell (1995) and Skvoretz and Fararo (1996).

At the most micro level of sociology, the analysis of individual behavior in social contexts has a long tradition of mathematical models of individual decision making. Recent developments include the satisfaction-balance decision-making models of Gray and Tallman (Gray et al. 1998).

An exciting aspect of these different levels of development is that, increasingly, inquiries into microdynamics based on social exchange theory are working toward formulations compatible with the more general network structural analyses. These

joint developments, therefore, promise a much more powerful linking of micro-system dynamics with macro-system structural modeling (Cook 1987; Willer 1987). Recent work on power as a function of the linkages that define the exchange system is an example. The use of mathematics to express formal definitions has enabled researchers to pinpoint where there are theoretical differences, leading to productive debate (Markovsky et al. 1988; Cook and Yamagishi 1992; Friedkin 1993; Bonacich 1998).

There are other examples of work in mathematical sociology involving attempts to develop appropriate mathematical functions to describe a theoretically important concept. One is Jasso's innovative work on models of distributive justice (e.g., 1999). Similarly, affect control theory (e.g., Smith-Lovin and Heise 1988) represents mathematical formulation in an area (symbolic interaction and sociology of emotions) typically considered not subject to such treatment.

One other area of vigorous development deserves attention; the treatment of strings of events that constitute the history of a particular case, process, or situation (Allison 1984; Tuma and Hannan 1984; Heise 1989). Event history analysis has some of its origins in traditional demographers' life tables, but methods and models have experienced a great deal of attention and growth in recent years. If one had lifetime data on job placements, advancements, demotions, and firings (i.e., employment event histories) for a sample of individuals, then event history methods could be used for examining what contributes to differential risks of one of those events occurring, how long someone is likely to be in a given situation ("waiting time" between events), and so forth.

An important recent development is the use of complex computer simulations for developing and exploring mathematically expressed theories. We have noted above the tension between simple models that are mathematically tractable and more complex models that may be more realistic as for example including feedback loops and random processes. Computer simulation is a way of showing what can be derived from the assumptions of a model without an analytic mathematical solution; examples include Macy and Skvoretz (1998), Carley (1997), and Hanneman (1995).

Like many other areas of social and behavioral science, mathematical sociology has been influenced by developments in game theory, from early work by Rapoport (1960) to the more recent idea of evolutionary games introduced by Axelrod (1984) and extensive interest in problems of collective action (Marwell and Oliver 1993). These consider how actions of individuals may produce unintended outcomes because of the logic of their interdependence with actions of others. The related theoretical area of rational choice theory also has a strong mathematical component (Coleman 1990); see also recent issues of the journal *Rationality and Society*.

A notable feature of current work in mathematical sociology is that the development, testing, and refinement of mathematical models is located within substantive research programs. Mathematical formulations appear in mainstream sociology journals and are becoming accepted as one component of continuing programs of research along with development and refinement of theory and collection and analysis of empirical data (several examples can be found in Berger and Zelditch 1993).

One indication of continuing interest in mathematical sociology is the recent formation of the Mathematical Sociology Section of the American Sociological Association. There is also a large amount of work internationally, including in Japan (Kosaka 1995) and in England and Europe (Hegselmann et al. 1996). Mathematical work in sociology is alive and vigorous. It truly does promise a higher level of theoretical precision and integration across the discipline.

MEASUREMENT

There are many standards that can be used to evaluate the status of a science, and one of the most important is how well variables are measured. The idea of measurement is relatively simple. It is associating numbers with aspects of objects, events, or other entities according to rules, and so measurement has existed for as long as there have been numbers, counting, and concepts of magnitude. In daily living, measurement is encountered in myriad ways. For example, measurement is used in considering time, temperature, distance, and weight. It happens that these concepts and quite a few others are basic to many sciences. The notion of measurement as expressing magnitudes is fundamental, and the observation that *if something exists, it must exist in some quantity* is probably too old to attribute to the proper authority. This notion of quantification is associated with a common dictionary definition of *measurement*: "The extent, capacity, or amount ascertained by measuring."

A concept such as distance may be considered to explore the meaning of measurement. To measure distance, one may turn to a simple example of a straight line drawn between two points on a sheet of paper. There is an origin or beginning point and an end point, and an infinite number of points between the beginning and the end. To measure in a standard way, a unit of distance has to be arbitrarily defined, such as an inch. Then the

distance of any straight line can be observed in inches or fractions of inches. For convenience, arbitrary rules can be established for designating number of inches, such as feet, yards, and miles. If another standard is used—say, meters—the relationship between inches and meters is one in which no information is lost in going from one to the other. So, in summary, in the concept of measurement as considered thus far, there are several properties, two of which should be noted particularly: the use of arbitrary standardized units and the assumption of continuous possible points between any two given points. The case would be similar if time, temperature, or weight were used as an example.

There is another property mentioned above, a beginning point, and the notion of the beginning point has to be examined more carefully. In distance, if one measures 1 inch from a beginning point on a straight line, and then measures to a second point 2 inches, one may say that the distance from the beginning point of the second point is twice that of the first point. With temperature, however, there is a problem. If one measures temperature from the point of freezing using the Celsius scale, which sets 0 degrees at the freezing point of water under specified conditions, then one can observe temperatures of 10 degrees and of 20 degrees. It is now proper to say that the second measurement is twice as many degrees from the origin as the first measure, but one cannot say that it is twice the temperature. The reason for this is that the origin that has been chosen is not the origin that is required to make that kind of mathematical statement. For temperature, the origin is a value known as absolute zero, the absence of any heat, a value that is known only theoretically but has been approximated.

This problem is usually understood easily, but it can be made more simple to understand by illustrating how it operates in measuring distance. Suppose a surveyor is measuring distance along a road from A to B to C to D. A is a long distance from B. Arriving at B, the surveyor measures the distance from B to C and finds it is 10 miles, and then the distance from B to D is found to be 20 miles. The surveyor can say that the distance is twice as many miles from B to D as from B to C, but he cannot say that the distance from A to D is twice the distance from A to C, which is the error one

would make if one used the Celsius temperature scale improperly. Measuring from the absolute origin for the purpose of carrying out mathematical operations has become known as *ratio level measurement*.

The idea of “levels of measurement” has been popularized following the formulation by the psychologist S. S. Stevens (1966). Stevens first identifies scales of measurement much as measurement is defined above, and then notes that the type of scale achieved depends upon the basic empirical operations performed. The operations performed are limited by the concrete procedures and by the “peculiarities of the thing being scaled.” This leads to the types of scales—nominal, ordinal, interval, and ratio—which are characterized “by the kinds of transformations that leave the ‘structure’ of the scale undistorted.” This “sets limits to the kinds of statistical manipulation that can legitimately be applied to the scaled data.”

Nominal scales can be of a type like numbering individuals for identification, which creates a class for each individual. Or there can be classes for placement on the basis of equality within each class with regard to some characteristic of the object. *Ordinal* scales arise from the operation of rank ordering. Stevens expressed the opinion that most of the scales used by psychologists are ordinal, which means that there is a determination of whether objects are greater than or less than each other on characteristics of the object, and thus there is an ordering from smallest to largest. This is a crucial point that is examined below. *Interval* scales (equal-interval scales) are of the type discussed above, like temperature and these are subject to linear transformation with invariance. There are some limitations on the mathematical operations that can be carried out, but in general these limitations do not impede use of most statistical and other operations carried out in science. As noted, when the equal-interval scales have an absolute zero, they are called *ratio* scales. A lucid presentation of the issue of invariance of transformations and the limitations of use of mathematical operations (such as addition, subtraction, multiplication, and division) on interval scales is readily available in Nunnally (1978).

What is important to emphasize is that how the scales are constructed, *as well as how the scales*

are used, determines the level of measurement. With regard to ordinal scales, Nunnally makes a concise and precise statement that should be read carefully: "With ordinal scales, none of the fundamental operations of algebra may be applied. In the use of descriptive statistics, it makes no sense to add, subtract, divide, or multiply ranks. Since an ordinal scale is defined entirely in terms of inequalities, only the algebra of inequalities can be used to analyze measures made on such scales" (1978, p. 22). What this means is that if one carries out a set of operations that are described as making an ordinal scale, the moment one adds, subtracts, divides, or multiplies the ranks, one has treated the scale as a particular type of interval scale. Most commonly, the type of scale that is de facto created when ordinal data are subject to ordinary procedures like addition, subtraction, division, and/or multiplication is through the assumption that the difference between ranks are equal, leading to sets like 1, 2, 3, 4, 5, 6, and thus to the treatment for ties such as 1, 2, 4, 4, 4, 6. This is sometimes called a flat distribution with an interval of one unit between each pair of ordered cases. Effectively, this is the same kind of distribution in principle as the use of ordered categories, such as quartiles, deciles, or percentiles, but it is a more restrictively defined distribution of one case per category. To repeat, for emphasis: The use of addition, subtraction, division, and/or multiplication with ordinal data automatically requires assumptions of intervals, and one is no longer at the level of ordinal analysis. *Thus, virtually all statistical procedures based on collected ordered or rank data actually assume a special form of interval data.*

ISSUES ON LEVEL OF MEASUREMENT

A number of issues are associated with the notion of levels of measurement. For example, are all types of measurement included in the concepts of nominal, ordinal, interval, and ratio? What is the impact of using particular statistical procedures when data are not in the form of well-measured interval scales? What kind of measurement appears (epistemologically) appropriate for the social and behavioral sciences?

The last question should probably be examined first. For example, are measures made about attributes of persons nominal, ordinal, or interval?

In general, we cannot think of meaningful variables unless they *at least* imply order, but is order all that one thinks of when one thinks about characteristics of persons? For example, if one thinks of heights, say of all males of a given age, such as 25, does measurement imply ordering them on an interval scale? We know that height is a measure of distance, so we assume the way one should measure this is by using a standard. For purposes of the example here, an interval scale is proposed, and the construction is as follows. The shortest, 25 year-old male (the category defined as 25 years and 0 days to 25 years and 365 days of age) and the tallest are identified. The two persons are placed back to back, front to front, and every other possible way, and the distance between the height of the shortest and the tallest is estimated on a stick. Many estimates are made on the stick, until the spots where agreement begins to show discretely are evident; and so, with whatever error occurs in the process, the locations of beginning and end are indicated on the stick. Now the distance between the beginning and the end is divided into equal intervals, and thus an interval scale has been created. On this scale it is possible to measure every other male who is 25 years old, and the measure can be stated in terms of the number of intervals taller than the shortest person. Note that all possible values can be anticipated, and this is a continuous distribution.

Now if a million persons were so measured, how would they be distributed? Here the answer is on the basis of naive experience, as follows. First, there would be very few people who would be nearly as short as the shortest or as tall as the tallest. Where would one expect to find most persons? In the middle of the distance, or at some place not too far from it. Where would the next greatest number of persons be found? Close to the biggest. With questions of this sort one ends up describing a well-distributed curve, possibly a normal curve or something near it.

It is proper now to make a small diversion before going on with answering the questions about the issues associated with level of measurement. In particular, it should be noted that there are many sources of error in the measurement that has just been described. First, of course, the age variable is specified with limited accuracy. At the limits, it may be difficult to determine exact age

because of the way data are recorded. There are differences implied by the fact that where one is born makes a difference in time, and so on. This may seem facetious, but it illustrates how easily sources of error are bypassed without examination. Then it was noted that there were different estimates of the right location for the point of the shortest and the tallest person as marked on the stick. This is an error of observation and recording, and clearly the points selected are taken as mean values. Who are the persons doing the measuring? Does it make a difference if the person measuring is short or tall? These kinds of errors will exist for all persons measured. Further, it was not specified under what conditions the measurements taken or were to be taken. Are the persons barefoot? How are they asked to stand? Are they asked to relax to a normal position or to try to stretch upward? What time of day is used, since the amount of time after getting up from sleep may have an influence? Is the measurement before or after a meal? And so forth.

The point is that there are many sources of error in taking measures, even direct measures of this sort, and one must be alert to the consequences of these errors on what one does with the data collected. Errors of observation are common, and one aspect of this is the limit of the discriminations an observer can make. One type of error that is usually built into the measurement is rounding error, which is based on the estimated need for accuracy. So, for example, heights are rarely measured more accurately than to the half-inch or centimeter, depending on the standard used. There is still the error of classification up or down, by whatever rule is used for rounding, at the decision point between the intervals used for rounding. Rounding usually follows a consistent arbitrary rule, such as "half adjusting," which means keeping the digit value if the next value in the number is 0 to 4 (e.g., 24.456 = 24) or increasing the value of a digit by 1 if the next value is 5 to 9 (e.g., 24.789 = 25). Another common rounding rule is simply to drop numbers (e.g., 24.456 = 24 and 24.789 = 24). It is important to be aware of which rounding rule is being used and what impact it may have on conclusions drawn when the data collected are used.

The use of distribution-free statistics (often called nonparametric statistics) was popularized beginning in the mid-1950s, and quickly came to

be erroneously associated with the notion that most of the measurement in the social and behavioral sciences is of an ordinal nature. Actually, the use of the distribution-free statistics was given impetus because some tests, such as the sign test, did not require use of all the information available to do a statistical test of significance of differences. Thus, instead of using a test of differences of means, one could quickly convert the data to plus and minus scores, using some arbitrary rule, and do a "quick-and-dirty" sign test. Then, if one found significant differences, the more refined test could be carried out at one's leisure. Some of the orientation was related to computing time available, which meant time at a mechanical calculator. Similarly, it was well known that if one used a Spearman rank correlation with larger samples, and if one were interested in measuring statistical significance, one would have to make the same assumptions as for the Pearson product moment correlation, but with less efficiency.

However, this early observation about distribution-free statistics suggests that measures can be thought of in another way. Namely, one can think of measures in terms of how much they are degraded (or imperfect) interval measures. This leads to two questions that are proper to consider. First, what kind of measure is implied as appropriate by the concept? And second, how much error is there in how the measure is constructed if one wants to use procedures that imply interval measurement, including addition, subtraction, multiplication, and division?

What kind of measure is implied by the concept? One way of answering this is to go through the following procedure. As an example, consider a personal attribute, such as aggressiveness. Is it possible to conceive of the existence of a least aggressive person and a most aggressive person? Obviously, whether or not such persons can be located, they can be conceived of. Then, is there any reason to think that persons cannot have any and all possible quantities of aggressiveness between the least and the most aggressive persons? Of course not. Thus, what has been described is a continuous distribution, and with the application of a standard unit, it is appropriately an interval scale. *It is improper to think of this variable as intrinsically one that is ordinal because it is continuous. In fact, it is difficult to think of even plausible examples of*

variables that are intrinsically ordinal. As Kendall puts it, “the essence of ranking is that the objects shall be orderable, and the totality of values of a continuous variate cannot be ordered in this sense. They can be regarded as constituting a range of values, but between any two different values there is always another value, so that we cannot number them as would be required for ranking purposes” (1948, p. 105). While a few comments were published that attempted to clarify these issues of measurement in the 1960s (Borgatta 1968), most methodologists accepted the mystique of ordinal measurement uncritically.

Often measures of a concept tend to be simple questions with ordered response categories. These do not correspond to ordinal measures in the sense of ordering persons or objects into ranks, but the responses to such questions have been asserted to be ordinal level measurement because of the lack of information about the intervals. So, for example, suppose one is attempting to measure aggressiveness using a question such as “When you are in a group, how much of the time do you try to get your way about what kinds of activities the group should do next?” Answer categories are “never,” “rarely,” “sometimes,” “often,” “very often,” and “always.” Why don’t these categories form an interval scale? The incorrect answer usually given is “because if one assumes an interval scale, one doesn’t know where the answer categories intersect the interval scale.” However, this *does not* create an ordinal scale. It creates an interval scale with unknown error with regard to the spacing of the intervals created by the categories.

Thus, attention is now focused on the second question: How much error is involved in creating interval scales? This question can be answered in several ways. A positive way of answering is by asking how much difference it makes to distort an interval scale. For example, if normally distributed variables (which are assumed as the basis for statistical inference) are transformed to flat distributions, such as percentiles, how much impact does this have on statistical operations that are carried out? The answer is “very little.” This property of not affecting results of statistical operations has been called robustness. Suppose a more gross set of transformations is carried out, such as deciles. How much impact does this have on statistical operations? The answer is “not much.” However,

when the transformations are to even grosser categories, such as quintiles, quartiles, thirds, or halves, the answer is that because one is throwing away even more information by grouping into fewer categories, the impact is progressively greater. What has been suggested in this example has involved two aspects: the transformation of the shape of the distribution, and the loss of discrimination (or information) by use of progressively fewer categories.

CONSEQUENCES OF USING LESS THAN NORMALLY DISTRIBUTED VARIABLES

If one has normally distributed variables, the distribution can be divided into categories. The interval units usually of interest with normally distributed variables are technically identified as standard deviation units, but other units can be used. When normally distributed variables are reduced to a small number of (gross) categories, substantial loss of discrimination or information occurs. This can be illustrated by doing a systematic exercise, the results of which are reported in Table 1. The data that are used for the exercise are generated from theoretical distributions of random normal variables with a mean of 0 and a standard deviation of 1. In the exercise, one aspect is examining the relationship among normally distributed variables, but the major part of the exercise involves the data in ordered categorical form, much as it is encountered in “real” data. The exercise permits reviewing several aspects associated with knowledge about one’s measurement.

As noted, the exercise is based on unit normal variables (mean = 0, standard deviation = 1) that are sampled and thus are subject to the errors of random sampling that one encounters with “real” data. The theoretical underlying model is one that is recommended in practice, specified as follows: (1) A criterion variable is to be predicted, that is, the relationships of some independent (predictor) variables are to be assessed with regard to the criterion variable.

(2.) For each sample in which the relationship of the independent variables is assessed, the theoretical underlying relationship of the independent variables is specified, and thus for the purposes of the exercise is known. For the exercise, four levels of underlying theoretical relationship are product

Median Correlation of Scores with Criterion Variable, Range of 9 Samples (N=150) of Unit Normal Deviates, Additive Scores Based on Four Items with Theoretical Correlations of .8, .6, .4, and .2 with the Criterion Variable in the Population

Table 1

moment correlation coefficients of .8, .6, .4, and .2, between the predictor variables and the criterion variable. This represents different levels of relationship corresponding to magnitudes commonly encountered with “real” social and behavioral data.

(3.) For each sample that is used in the exercise, totally independent distributions are drawn from the theoretical distributions. That is, each sample in the exercise is created independently of all other samples, and in each case the criterion and independent predictor variables are drawn independently within the definition of the theoretical distributions.

(4.) Corresponding to a common model of prediction, assume that the independent variables are of a type that can be used to create scores. Here we will follow a common rule of thumb and use four independent variables to create a *simple additive score*; that is, the values of the four independent variables are simply added together. There are many ways to create scores, but this procedure has

many virtues, including simplicity, and it permits examining some of the consequences of using scores to measure a concept.

(5.) The independent variables are modified to correspond to grouped or categorical data. This is done before adding the variables together to create scores, as this would be the way variables encountered in research with “real” data are usually defined and used. The grouped or categorical independent variables are modified in the following ways:

A. Four groups or categories are created by using three dividing points in the theoretical distribution, -1 standard deviation, the mean of 0, and +1 standard deviation. The values for four variables, now grouped or categorical data, are added to give the score used in the correlation with the criterion variable. Thus, looking at Table 1, the row SumA.8 involves samples in which four independent variables based on data having four categories as defined above, and

having an underlying theoretical correlation coefficient for each independent variable to the criterion variable of .8, have been used to create a score. The variables defined by these cutting points correspond to a notion of variables with response categories, say, such as “agree,” “probably agree,” “probably disagree,” and “disagree,” and as it happens the responses theoretically are well distributed, roughly 16 percent, 34 percent, 34 percent, and 16 percent.

B. Three groups or categories are created by using two dividing points in the theoretical distribution, -1 and +1, corresponding to a notion of variables with response categories, say, such as “agree,” “don’t know or neutral,” and “disagree,” and these are again theoretically well distributed, but in this case the center category is large (about 68 percent of responses). The scores for these samples are identified as SumB.8 for the case of the underlying theoretical distribution of the independent variables having a correlation coefficient with the criterion variable of .8.

C. Two groups or categories are created by using one dividing point at the mean of the theoretical distribution, and this corresponds to variables with response categories such as “agree” and “disagree,” or “yes” and “no.” Division of a variable at the midpoint of the distribution is usually considered statistically to be the most efficient for dichotomous response categories.

DL. Two groups or categories may be created that are not symmetrical, unlike the case of C above. Here we create two sets of samples, one identified by Sum DL with the cutting point at -1 standard deviation, or the left side of the distribution as it is usually represented. Presumably, when variables are not well distributed, more information is lost in the data collection if the skew is due to the way the question is formulated.

DR. Two groups or categories are created with the skew on the right side of the distribution at +1 standard deviation. SumDR scores are created in parallel to the SumDL scores.

Finally, the rows of SumX are those where scores are computed and no conversion of the variables has been carried out, so the independent variables are drawn from the theoretically formulated unit normal distributions at the level of correlation coefficient between the independent variables and the criterion variable.

In summary, for each sample the predictor score is an additive score based on four variables, each related to the criterion variable in a theoretical distribution at a given level, with the examples in the exercise the levels chosen as product moment correlation coefficients of .8, .6, .4, and .2.

The rationale for the choice of four variables in each score is drawn arbitrarily from the theoretical distribution of reliability coefficients, which, for variables of equal reliability, is a curve of diminishing return with each increment of the number of variables. At four variables a score is usually considered to be at an efficient point, balancing such things as time and effort needed to collect data, independence of variable definitions, and the amount of improvement of reliability expected. Using more variables in the “real” world usually involves using less “good” items progressively from the point of view of content, as well as the diminishing efficiency even if they were equally as good as the first four.

With regard to the criterion variable, the dependent variable to be predicted, we have generated three as follows: First, the variable is drawn from a theoretical unit normal distribution without modification, and this involves correlation coefficients reported in column XO. Second, the dependent variable is drawn from the theoretical distribution dichotomized at the mean of 0, creating a symmetric dichotomous variable (two categories), and this involves correlation coefficients reported in column XOA. Third, the variable is drawn from the theoretical distribution dichotomized at -1 standard deviation, creating an asymmetrical dichotomous variable and this involves correlation coefficients reported in column XOB.

As noted above, we are dealing with generated data from theoretical distributions, so all that is done is subject to sampling error, which permits in a limited way for variation of results to be shown. This is useful in illustrating the variation that occurs simply by random processes in the study of variables. For the exercise there were 648 samples

of 150 cases each. The choice of 150 cases was selected for several reasons, convenience in the data set generated being one, but also because 150 cases was, as a rule of thumb, a reasonable number of cases proposed for doing research at an earlier time in the discipline when a Guttman scale was anticipated, and too much “shrinkage” in the subsequent use of the Guttman scale was to be avoided. Shrinkage referred to the experience of finding out that the scale in a subsequent use did not have the same characteristics as in the first (generating) use. The samples are grouped in the six procedures, as noted above, of the full normal data and of five created sets of categories, each with nine repetitions (i.e., samples) carried out to permit examination of distribution of results for each theoretical level of correlation coefficient and for each of the three criterion variable definitions.

A sense of the stability of the relationships involved is provided by using many samples, and *the values that are in columns XO, XOA, and XOB are the median product moment correlation coefficients between a Sum score and a criterion variable.* In the table there are two other sets of columns. XOR, XOAR, and XOBR are the actual range of values for the product moment correlation coefficients between a Sum score and the criterion variable for nine independently drawn samples of 150 cases each. The additional (last three columns) at the right of the table are the squared values of XO, XOA, and XOB, and these values represent the amount of variance that is accounted for by the correlation coefficient.

The table is somewhat complex because it includes a great deal of information. Here we will only review a number of relatively obvious points, but with emphasis. First, note the relationship between SumX.8 and XO, which is .94. Recall that the theoretical correlation coefficient between each independent predictor variable and the criterion variable was defined as .8 in the exercise. Thus, we illustrate rather dramatically the importance of building scores rather than depending on a single predictor variable. The actual improvement in prediction is from a theoretical value of 64 percent of the variance being accounted for by a single predictor variable to the median value of 88 percent of the variance in the median sample of the exercise, an extremely impressive improvement! Examining the correlation coefficient between SumX.6, SumX.4, and SumX.2, it is seen that the

advantage of using scores rather than single items is actually even more dramatic when the relationship between the criterion and the predictor variables is weaker.

Now, examine the relationships between all the Sum variables and XO. It is noted that having the SumA.8 as a well distributed categorical variable lowers the correlation to XO somewhat (.92) compared to the full normal SumX.8 (.94), and, indeed, with SumB.8 and SumC.8 the correlation coefficients are still lower. This illustrates that the more information that is available in the categorical data, the more variance can be predicted for a criterion variable. Note further, that for SumDL.8 and SumDR.8, which are based on dichotomous but skewed variables, the correlation coefficients are still lower. Note that the results for the weaker variables SumX.6 to SumDR.6, for SumX.4 to SumDR.4, and for SumX.2 to SumDR.2 are in general roughly parallel to the results noted, but some irregularity is noted when the relationship between the criterion and the predictor variables is weaker.

The results we have been examining are the median values of nine samples in each case. It is appropriate to look at column XOR and to note that there is quite a bit of variation in the correlation coefficients based on the nine samples of size 150 cases each.

One additional finding needs to be pointed out and emphasized. Compare the correlation coefficients of SumDT.8 and XOB, and of SumDR.8 and XOB. In the former case, the criterion variable and predictor variables are both asymmetric but matched (at the same cutting point), and the median correlation coefficient value is .72. In the latter case they are asymmetric but unmatched, and the median correlation coefficient is .26. This indicates the need to know how cutting points (difficulty levels) of variables can affect the values of correlation coefficients that are encountered.

The reader is urged to examine this table in detail, and it may be useful to keep the table as a guideline for interpreting results. How? If the researcher finds as a result a correlation coefficient of a given size, where does it fit on this table, taking into consideration the characteristics of the criterion variable and the scores based on the predictor variables? Doing this type of examination should help the researcher understand the

meaning of a finding. However, this is but one approach to the issues of measurement. The articles in this encyclopedia that are vital for researchers to consider are those on *Reliability*, *Validity*, and *Quasi-Experimental Research Design*. Additionally, measurement issues are discussed in a variety of types of texts, ranging from specialized texts to books on research methods to general statistics books, such as the following: Agresti and Finaly 1997; Babbie 1995; De Vellis 1991; Knoke and Bohrnstedt 1994; Lewis-Beck 1994; Neuman, 1997; and Traub 1994.

OTHER MEASURES

The consideration of measurement thus far has concentrated on interval measurement, with some emphasis on how it can be degraded. There are many other issues that are appropriately considered, including the fact that the concepts advanced by Stevens do not include all types of measures. As the discussion proceeds to some of these, attention should also be given to the notion of nominal scales. Nominal scales can be constructed in many ways, and only a few will be noted here. By way of example, it is possible to create a classification of something being present for objects that is then given a label A. Sometimes a second category is not defined, and then the second category is the default, the thing not being present. Or two categories can be defined, such as male and female. Note that the latter example can also be defined as male and not male, or as female and not female. More complex classifications are illustrated by geographical regions, such as north, west, east, and south, which are arbitrary and follow the pattern of compass directions. Such classifications, to be more meaningful, are quickly refined to reflect more homogeneity in the categories, and sets of categories develop such as Northeast, Middle Atlantic, South, North Central, Southwest, Mountain, Northwest, and Pacific, presumably with the intention of being inclusive (exhaustive) of the total area. These are complex categories that differ with regard to many variables, and so they are not easily ordered.

However, each such set of categories for a nominal scale can be reduced to dichotomies, such as South versus “not South”; these variables are commonly called “dummy variables.” This

permits analysis of the dummy variable as though it represented a well-distributed variable. In this case, for example, one could think of the arbitrary underlying variable as being “southernness,” or whatever underlies the conceptualization of the “South” as being different from the rest of the regions. Similarly, returning to the male versus female variable, the researcher has to consider interpretatively what the variable is supposed to represent. Is it distinctly supposed to be a measure of the two biological categories, or is it supposed to represent the social and cultural distinction that underlies them?

Many, if not most, of the variables that are of interest to social and behavioral science are drawn from the common language, and when these are used analytically, many problems or ambiguities become evident. For example, the use of counts is common in demography, and many of the measures that are familiar are accepted with ease. However, as common a concept as city size is not without problems. A city is a legal definition, and so what is a city in one case may be quite different from a city in another case. For example, some cities are only central locations surrounded by many satellite urban centers and suburbs that are also defined as cities, while other cities may be made up of a major central location and many other satellite urban centers and suburbs. To clarify such circumstances, the demographers may develop other concepts, like Standard Metropolitan Areas (SMAs), but this does not solve the problem completely; some SMAs may be isolated, and others may be contiguous. And when is a city a city? Is the definition one that begins with the smallest city with a population of 2,500 (not even a geographical characteristic), or 10,000 population, or 25,000 population? Is city size really a concept that is to be measured by population numbers or area, or by some concept of degree of urban centralization? Is New York City really one city or several? Or is New York City only part of one city that includes the urban complexes around it? The point that is critical is that definitions have to be fixed in arbitrary ways when concepts are drawn practically from the common language, and social concepts are not necessarily parsimoniously defined by some ideal rules of formulating scientific theory. Pragmatic considerations frequently intervene in how data are collected and what data become available for use.

An additional point is appropriate here: that in demography and in other substantive areas, important measures include *counts* of discrete entities, and these types of measures do not easily fit the Stevens classification of levels of measurement. A discussion of several technical proposals for more exhaustive classifications of types of measures is considered by Duncan (1984).

CONSTRUCTING MEASURES

There are obviously many ways that measures can be constructed. Some have been formalized and diffused, such as Louis Guttman’s cumulative scale analysis, so popular that it has come to be known universally as Guttman scaling, a methodological contribution that was associated with a sociologist and had an appeal for many. An early comprehensive coverage of Guttman scaling can be found in Riley and colleagues (1954). The essence of Guttman scaling is that if a series of dichotomous items is assumed to be drawn from the same universe of content, and if they differ in difficulty, then they can be ordered so that they define scale types. For example, if one examines height, questions could be the following: (1) Are you at least five feet tall? (2) Are you at least five and a half feet tall? (3) Are you at least six feet tall? (4) Are you at least six and a half feet tall? Responses to these would logically fall into the following types: a + to indicate yes and a - to indicate a no:

1	2	3	4
+	+	+	+
+	+	+	-
+	+	-	-
+	-	-	-
-	-	-	-

The types represent “perfect” types, that is, responses made without a logical error. The assumption is that within types, people are equivalent. In the actual application of the procedure, some problems are evident, possibly the most obvious being that there are errors because in applying the procedure in studies, content is not as well specified as being in a “universe” as is the example of height; thus there are errors, and

therefore error types. The error types were considered of two kinds: unambiguous, such as - + + +, which in the example above would simply be illogical, a mistake, and could logically be classed as + + + + with “minimum error.” The second kind is ambiguous, such as + + - +, which with one (minimum) error could be placed in either type + + - - or type + + + +.

Experience with Guttman scaling revealed a number of problems. First, few scales that appeared “good” could be constructed with more than four or five items because the amount of error with more items would be large. Second, the error would tend to be concentrated in the ambiguous error type. Third, scales constructed on a particular study, especially with common sample sizes of about one hundred cases, would not be as “good” in other studies. There was “shrinkage,” or more error, particularly for the more extreme items. The issue of what to do with the placement of ambiguous items was suggested by an alternative analysis (Borgatta and Hays 1952): that the type + + - + was not best placed by minimum error, but should be included with the type + + + - between the two minimum error locations. The reason for this may be grasped intuitively by noting that when two items are close to each other in proportion of positive responses, they are effectively interchangeable, and they are involved in the creation of the ambiguous error type. The common error is for respondents who are at the threshold of decision as to whether to answer positively or negatively, and they are most likely to make errors that create the ambiguous error types.

These observations about Guttman scaling lead to some obvious conclusions. First, the scaling model is actually contrary to common experience, as people are not classed in ordered types in general but presumably are infinitely differentiated even within a type. Second, the model is not productive of highly discriminating classes. Third, and this is possibly the pragmatic reason for doubting the utility of Guttman scaling, if the most appropriate place for locating nonscale or error types of the common ambiguous type is not by minimum error but between the two minimum error types, this is effectively the same as adding the number of positive responses, essentially reducing the procedure to a simple additive score. The remaining virtue of Guttman scaling in the logical placement of unambiguous errors must be

balanced against other limitations, such as the requirement that items must be dichotomous, when much more information can be gotten with more detailed categories of response, usually with trivial additional cost in data collection time.

In contrast with Guttman scaling, simple addition of items into sum scores, carried out with an understanding of what is required for good measurement, is probably the most defensible and useful tool. For example, if something is to be measured, and there appear to be a number of relatively independent questions that can be used to ascertain the content, then those questions should be used to develop reliable measures. *Reliability* is measured in many ways, but consistency is the meaning usually intended, particularly internal consistency of the component items, that is, high intercorrelation among the items in a measure. Items can ask for dichotomous answers, but people can make more refined discriminations than simple yeses and nos, so use of multiple (ordered) categories of response increases the efficiency of items.

The question of whether the language as used has sufficient consistency to make refined quantitative discriminations does not appear to have been studied extensively, so a small data collection was carried out to provide the following example. People were asked to evaluate a set of categories with the question "How often does this happen?" The instructions stated: "Put a vertical intersection where you think each category fits on the continuum, and then place the number under it. Categories 1 and 11 are fixed at the extremes for this example. If two categories have the same place, put the numbers one on top of the other. If the categories are out of order, put them in the order you think correct." A continuum was then provided with sixty-six spaces and the external positions of the first and the last indicated as the positions of (1) always and (11) never. The respondents were asked to locate the following remaining nine categories: (2) almost always (3) very often; (4) often; (5) somewhat often; (6) sometimes; (7) seldom; (8) very seldom; (9) hardly ever; and (10) almost never. It is not surprising that average responses on the continuum are well distributed, with percent locations respectively as 9, 15, 27, 36, 48, 65, 75, 86, and 93; the largest standard deviation for placement location is about 11 percent. Exercises with alternative quantitatively oriented

questions and use of a series of six categories from "definitely agree" to "definitely disagree" provide similar evidence of consistency of meaning. In research, fewer than the eleven categories illustrated here usually used, making the task of discrimination easier and faster for respondents. The point of emphasis is that questions can be designed to efficiently provide more information than simple dichotomous answers and thus facilitate construction of reliable scores.

MEASUREMENT IN THE REAL WORLD

Many variations exist on how to collect information in order to build effective measurement instruments. Similarly, there are alternatives on how to build the measuring instruments. Often practical considerations must be taken into account, such as the amount of time available for interviews, restraints placed on what kinds of content can be requested, lack of privacy when collecting the information, and other circumstances.

With the progressive technology of computers and word processors, the reduced dependence of researchers on assistants, clerks, and secretaries has greatly facilitated research data handling and analysis. Some changes, like Computer Assisted Telephone Interviewing (CATI) may be seen as assisting data collection, but in general the data collection aspects of research are still those that require most careful attention and supervision. The design of research, however, still is often an ad hoc procedure with regard to the definition of variables. Variables are often created under the primitive assumption that all one needs to do is say, "The way I am going to measure XXX is by responses to the following question." This is a procedure of dubious worth, since building knowledge about the measurement characteristics of the variables to be used should be in advance of the research, and is essential to the interpretation of findings.

A comment that is commonly encountered is that attempting to be "scientific" and developing a strict design for research with well-developed measures forecloses the possibility of getting a broad picture of what is being observed. The argument is then advanced that attempting to observe and accumulate data in systematic research is not as revealing as observing more informally (qualitatively) and "getting a feel" for what is going on.

Further, when systematic research is carried out, so goes the argument, only limited variables can be assessed instead of “getting the complete picture.” This, of course, is the ultimate self-delusion and can be answered directly. If positive findings for the theory do not result from more rigorous, well-designed research, then the speculative generalizations of more casual observation are never going to be any more than that, and giving them worth may be equivalent to creating fictions to substitute for reality. *The fact that attempted systematic empirical research has not produced useful findings does not mean that more intuitive or qualitative approaches are more appropriate.* What it means is that the theory may not be appropriate, or the design of the research may be less than adequate.

Further, this does not mean that there is anything wrong with informal or qualitative research. What it does mean is that there is a priority order in the accumulation of knowledge that says that the informal and qualitative stages may be appropriate to produce theory, which is defined as speculation, about what is being observed, and this may then be tested in more rigorous research. This is the common order of things in the accumulation of scientific knowledge.

If a sociological theory has developed, then it must be stated with a clear specification of the variables involved. One cannot produce a volume on the concept of anomie, for example, and then use the word “anomie” to mean twenty different things. The concept on which one focuses *must* be stated with a clear specification of one meaning, and there are two elements that go into such a definition. The first is to indicate how the concept is to be measured. The second is more commonly neglected, and that is to specify how the concept is differentiated from other concepts, particularly those that are closely related to it in meaning.

The development of well-measured variables in sociology and the social sciences is essential to the advancement of knowledge. Knowledge about how good measurement can be carried out has advanced, particularly in the post-World War II period, but it has not diffused and become sufficiently commonplace in the social science disciplines.

It is difficult to comprehend how substituting no measurement or poor measurement for the best measurement that sociologists can devise can

produce better or more accurate knowledge. Examples of the untenable position have possibly decreased over time, but they still occur. Note for example: “Focus on quantitative methods rewards *reliable* (i.e., repeatable) methods. Reliability is a valuable asset, but it is only one facet of the value of the study. In most studies, reliability is purchased at the price of lessened attention to theory, validity, relevance. etc.” (Scheff 1991). Quite the contrary, concern with measurement and quantification is concern with theory, validity, and relevance!

Finally, it is worth emphasizing two rules of thumb for sociologists concerned with research, whether they are at the point of designing research or interpreting the findings of a research that has been reported. First, check on how the variables are specified and ask whether they are measured well. This requires that specific questions be answered: Are the variables reliable? How does one know they are reliable? Second, are the variables valid? That is, do they measure what they are supposed to measure? How does one know they do? If these questions are not answered satisfactorily, then one is dealing with research and knowledge of dubious value.

MEASURES OF ASSOCIATION

Long before there were statisticians, folk knowledge was commonly based on statistical associations. When an association was recognized between stomach distress and eating a certain type of berry, that berry was labeled as poisonous and avoided. For millennia, farmers the world over have observed an association between drought and a diminished crop yield. The association between pregnancy and sexual intercourse apparently was not immediately obvious, not simply because of the lag between the two events, but also because the association is far from perfect—that is, pregnancy does not always follow intercourse. Folk knowledge has also been laced with superstitions, commonly based on erroneously believed statistical associations. For example, people have

believed that there is an association between breaking a mirror and a long stretch of bad luck, and in many cultures people have believed that there is an association between certain ritual incantations and benevolent intervention by the gods.

Scholarly discussions sometimes focus on whether a given association is actually true or erroneously believed to be true. Is there an association between gender and mathematical ability? Between harsh punishment and a low incidence of crime? Between the size of an organization and the tendency of its employees to experience alienation? In contemporary discussions, questions and conclusions may be expressed in terms of "risk factors." For example, one might seek to find the risk factors associated with dropping out of school, with teen suicide, or with lung cancer. "Risk factors" are features that are associated with these outcomes but that can be discerned prior to the outcome itself. Although a reference to "risk" suggests that the outcome is undesirable, researchers may, of course, explore factors that are associated with positive as well as negative outcomes. For example, one could examine factors associated with appearance in *Who's Who*, with the success of a treatment regimen, or with a positive balance of international trade.

Referring to a "risk factor" entails no claim that the associated factor has an effect on the outcome, whereas a statistical association is sometimes erroneously interpreted as indicating that one variable has an effect on the other. To be sure, an interest in the association between two variables may derive from some hypothesis about an effect. Thus, if it is assumed that retirement has the effect of reducing the likelihood of voting, the implication is that retirement and non-voting should be statistically associated. But the reverse does not hold; that is, the fact that two variables are statistically associated does not, by itself, imply that one of those variables has an effect on the other. For example, if it is true that low attachment to parents encourages involvement in delinquency, it should be true that low attachment and delinquency are statistically associated. But a statistical association between low attachment and delinquency involvement might arise for other reasons as well. If both variables are influenced by a common cause, or if both are manifestations of the same underlying tendency, those variables will be statistically associated with each other, even if there is no effect of

one on the other. Finding a statistical association between two variables, even a strong association, does not, in itself, tell the reason for that association. It may result from an effect of one variable on another, or from the influence of a common cause on both variables, or because both variables reflect the same underlying tendency. Furthermore, if the association is transitory, it may appear simply because of an accident or coincidence. Discovering the reason for a statistical association always entails inquiry beyond simply demonstrating that the association is there.

WHY MEASURE ASSOCIATION?

The focus here is on measures of association for categorical variables, with brief attention to measures appropriate for ordered categories. Quantitative variables, exemplified by age and income, describe each case by an amount; that is, they locate each case along a scale that varies from low to high. In contrast, categorical variables, exemplified by gender and religious denomination, entail describing each case by a category; that is, they indicate which of a set of categories best describes the case in question. Such categories need not be ordered. For example, there is no inherent ordering for the categories that represent region. But if the categories (e.g., low, medium, and high income) are ordered, it may be desirable to incorporate order into the analysis. Some measures of association have been designed specifically for ordered categories.

The degree of association between categorical variables may be of interest for a variety of reasons. First, if a weak association is found, we may suspect that it is just a sampling fluke—a peculiarity of the sample in hand that may not be found when other samples are examined. The strength of association provides only a crude indication of whether an association is likely to be found in other samples, and techniques of statistical inference developed specifically for that purpose are preferred, provided the relevant assumptions are met.

Second, a measure of the degree of association may be a useful descriptive device. For example, if the statistical association between region and college attendance is strong, that suggests differential access to higher education by region. Furthermore, historical changes in the degree of

association may suggest trends of sociological significance, and a difference in the degree of association across populations may suggest socially important differences between communities or societies. For example, if the occupations of fathers and sons are more closely associated in Italy than in the United States, that suggests higher generational social mobility in the latter than in the former. Considerable caution should be exercised in comparing measures of association for different times or different populations, because such measures may be influenced by a change in the marginal frequencies as well as by a change in the linkage between the variables in question. (See Reynolds 1977)

Third, if a statistical association between two variables arises because of the effect of one variable on the other, the degree of association indicates the relative strength of this one influence as compared to the many other variables that also have such an effect. Unsophisticated observers may assume that a strong association indicates a causal linkage, while a weak association suggests some kind of noncausal linkage. But that would be naïve. The strength of association does not indicate the reason for the association. But *if* an association appears because of a causal link between two variables, the strength of that association provides a rough but useful clue to the relative importance of that particular cause relative to the totality of other causes. For example, income probably influences the tendency to vote Democratic or Republican in the United States, but income is not the only variable affecting the political party favored with a vote. Among other things, voting for one party rather than another is undoubtedly influenced by general political philosophy, by recent legislative actions attributed to the parties, by specific local representatives of the parties, and by the party preferences of friends and neighbors. Such multiple influences on an outcome are typical, and the degree of association between the outcome and just one of the factors that influence it will reflect the relative “weight” of that one factor in comparison to the total effect of many.

Fourth, if a statistical association between two variables arises because both are influenced by a common cause, or because both are manifestations of the same underlying tendency, the degree of association will indicate the relative strength of the common cause or the common tendency, in

comparison to the many other factors that influence each of the two variables. Assume, for example, that participation in a rebellious youth subculture influences adolescents to use both alcohol and marijuana. If the resulting association between the two types of substance use is high, this suggests that the common influence of the rebellious youth subculture (and perhaps other common causes) is a relatively strong factor in both. On the other hand, if this association is weak, it suggests that while the rebellious youth subculture may be a common cause, each type of substance use is also heavily influenced by other factors that are not common to both types.

Fifth, the degree of association indicates the utility of associated factors (“risk factors”) as predictors, and hence the utility of such factors in focusing social action. Assume, for example, that living in a one-parent home is statistically associated with dropping out of high school. If the association between these two variables is weak, knowing which students live in a one-parent home would not be very useful in locating cases on which prevention efforts should be concentrated for maximum effectiveness. On the other hand, if this association is strong, that predictor would be especially helpful in locating cases for special attention and assistance.

In summary, we may be interested in the degree of statistical association between variables because a weak association suggests the possibility that the association is a fluke that will not be replicated, because changes in the degree of association may help discern and describe important social trends or differences between populations, because the degree of association may help determine the relative importance of one variable that influences an outcome in comparison to all other influences, because the degree of association may reflect the degree to which two variables have a common cause, and because the degree of association will indicate the utility of associated factors in predicting an outcome of interest.

MEASURING THE DEGREE OF ASSOCIATION

The degree of statistical association between two variables is most readily assessed if, for a suitable set of cases, the relevant information is tallied in a cross-classification table. Table 1 displays such a

College Attendance by Race in a Sample of 20-Year-Olds in Centerville, 1998 (Hypothetical Data)

ATTENDING COLLEGE?	WHITE	BLACK	ASIAN-AMERICAN	TOTAL
Yes	400	60	80	540
No	300	140	20	460
Total	700	200	100	1,000

Table 1

table. For a contrived sample of young adults, this table shows the number who are and who are not attending college in each of three racial groupings. Hence the two variables represented in this table are (1) race (white, black, Asian-American) and (2) attending college (or not) at a given time. The frequencies in the cells indicate how the cases are jointly distributed over the categories of these two variables. The totals for each row and column (the “marginal frequencies” or simply the “marginals”) indicate how the cases are distributed over these two variables separately.

If young adults in all racial groupings were equally likely to be attending college, then there would be no association between these two variables. Indeed, the simplest of all measures of association is just a percentage difference. For example, blacks in this set of cases were unlikely to be attending college (i.e., 30 percent were enrolled), while Asian-Americans were very likely to be attending (80 percent). Hence we may say that the percentage attending college in the three racial groupings represented in this table ranges from 30 percent to 80 percent, a difference of 50 percentage points. In this table, with three columns, more than one percentage difference could be cited, and the one alluded to above is simply the most extreme of the three comparisons that could be made between racial groupings. Generally speaking, a percentage difference provides a good description of the degree of association only in a table with exactly two rows and two columns. Even so, citing a percentage difference is a common way of describing the degree of statistical association.

Leaving aside the difference between percentages, most measures of association follow one of two master formulas, and a third way of assessing

association provides the basis for analyzing several variables simultaneously. The oldest of these master formulas is based on the amount of departure from statistical independence, normed so that the measure will range from 0 (when the two variables are statistically independent and hence not associated at all) to 1.0 or something approaching 1.0 (when the cross-classification table exhibits the maximum possible departure from statistical independence). The several measures based on this master formula differ from each other primarily in the way the departure from statistical independence is normed to yield a range from 0 to 1.

The second master formula is based on the *improvement* in predictive accuracy that can be achieved by a "prediction rule" that uses one variable to predict the other, as compared to the predictive accuracy achieved from knowledge of the marginal distribution alone. The several measures based on this master formula differ from each other in the nature of the "prediction rule" and also in what is predicted (e.g., the category of each case, or which of a pair of cases will be higher). When such a measure is 0 there is no improvement in predictive accuracy when one variable is predicted from another. As the improvement in predictive accuracy increases, these measures of association will increase in absolute value up to a maximum of 1, which indicates prediction with no errors at all.

A third important way of assessing association, used primarily when multiple variables are analyzed, is based on the difference in *odds*. In Table 1, the odds that an Asian-American is attending college are "4 to 1"; that is, 80 are in college and 20 are not. If such odds were identical for each column, there would be no association, and the ratio of the odds in one column to the odds in another would be 1.0. If such ratios differ from 1.0 (in either direction), there is some association. An analysis of association based on *odds ratios* (and more specifically on the logarithm of odds ratios) is now commonly referred to as a *loglinear analysis*. This mode of analysis is not discussed in detail here.

Departure from Statistical Independence. The traditional definition of statistical independence is expressed in terms of the probability of events; that is, events A and B are statistically independent if, and only if:

$$P(A/B) = P(A) \quad (1)$$

" $P(A)$ " may be read as the probability that event A occurs. This probability is usually estimated empirically by looking at the proportion of all relevant events (A plus not- A) that are A . Referring to Table 1, if event A means attending college, then the probability of event A is estimated by the proportion of all relevant cases that are attending college. In Table 1, this is .54 (i.e., 540 were attending out of the table total of 1,000).

" $P(A|B)$ " may be read as the conditional probability that event A occurs, given that event B occurs, or, more briefly "the probability of A given B ." This conditional probability is usually estimated in a manner parallel to the estimation of $P(A)$ described above, except that the relevant cases are limited to those in which event B occurs. Referring to Table 1 again, if event A means attending college and event B refers to being classified as Asian-American, then $P(A|B) = .80$ (i.e., 80 are attending college among the 100 who are Asian-American).

As indicated above, the traditional language of probability refers to "events," whereas the traditional language of association refers to "variables." But it should be evident that if "events" vary in being A or not- A , then we have a "variable." The difference between the language used in referring to the probability of "events" and the language used in referring to a statistical association between "variables" need not be a source of confusion, since one language can be translated into the other.

If we take as given the "marginal frequencies" in a cross-classification table (i.e., the totals for each row and each column), then we can readily determine the probability of any event represented by a category in the table; that is, we can determine $P(A)$. Since $P(A|B) = P(A)$ if statistical independence holds, we can say what $P(A|B)$ *would be* for any A and B in the table if statistical independence held. Otherwise stated, if the marginal frequencies remain fixed, we can say what frequency would be *expected* in each cell if statistical independence held. Referring again to Table 1 and assuming the marginal frequencies remain fixed as shown, if statistical independence held in the table, then 54 percent of those in each racial grouping would be attending college. This is because, if statistical

independence holds, then $P(A)$ (i.e., .54) must equal $P(A|B)$ for all B (i.e., the proportion enrolled in each of the columns). Hence, if statistical independence held, we would have 378 whites in college (i.e., 54 percent of the 700 whites in the table), 108 blacks in college (i.e., 54 percent of the 200 blacks in the table), and 54 Asian-Americans in college (i.e., 54 percent of the 100 Asian-Americans in the table.) Evidently, the number *not* enrolled in each racial grouping could be obtained in a similar way (i.e., 46 percent of each column total), or by subtraction (e.g., 700 whites minus 378 whites enrolled leaves 322 whites not attending college). Hence, the frequencies that would be “expected” for each cell if statistical independence held can be calculated, not just for Table 1 but for any cross-classification table.

If the “expected” frequencies for each cell are very similar to the “observed” frequencies, then the departure from statistical independence is slight. But if the “expected” frequencies differ greatly from the corresponding “observed” frequencies, then the table displays a large departure from statistical independence. When the departure from statistical independence reaches its maximum, an ideally normed measure of association should then indicate an association of 1.0.

A quantity called *chi square* is conventionally used to reflect the degree of departure from statistical independence in a cross-classification table. Chi square was originally devised as a statistic to be used in tests against the null hypothesis; it was not designed to serve as a measure of association for a cross-classification table and hence it does not range between 0 and 1.0. Furthermore, it is not well suited to serve as a measure of association because it is heavily influenced by the total number of cases and by the number of rows and columns in the cross-classification table. Even so, calculating chi square constitutes the first step in calculating measures of association based on departure from statistical independence. For a cross-classification table, this statistic will be zero when the observed frequencies are identical to the frequencies that would be expected if statistical independence held, and chi square will be progressively larger as the discrepancy between observed and expected frequencies increases. As indicated below, in the calculation of chi square, the differences between the frequencies observed and the

frequencies expected if statistical independence held are squared and weighted by the reciprocal of the expected frequency. This means, for example, that a discrepancy of 3 will be more heavily weighted when the expected frequency is 5 than when the expected frequency is 50. These operations are succinctly represented in the following formula for chi square:

$$\chi^2 = \sum \frac{(O_i - E_i)^2}{E_i} \tag{2}$$

where χ^2 = chi square

Σ is the instruction to sum the quantity that follows over all cells

O_i = the frequency observed in the i th cell

E_i = the frequency expected in the i th cell if statistical independence holds

To illustrate equation (2), consider Table 2, which shows (1) the observed frequency (O) for each cell as previously shown in Table 1; (2) the frequency expected (E) for each cell if statistical independence held (*in italics*), and, (3) for each cell, the squared difference between observed and expected frequencies, divided by the expected frequency (in bold type). When the quantities in bold type are summed over the six cells—in accord with the instruction in equation 2—we obtain a chi square of 76.3. There are various ways to norm chi square to create a measure of association, although no way of norming chi square is ideal since the maximum possible value will not be 1.0 under some commonly occurring conditions.

The first measure of association based on chi square was Pearson’s *Coefficient of Contingency* (C), which is defined as follows:

$$C = \sqrt{\frac{\chi^2}{\chi^2 + N}} \tag{3}$$

This measure can never reach 1.0, although its maximum possible value approaches 1.0 as the number of rows and columns in the table increases. For Table 1, $C = .27$.

An alternative measure of association based on chi square is Cramer's V , which was developed in an attempt to achieve a more appropriately normed measure of association. V is defined as follows:

$$V = \sqrt{\frac{\chi^2}{(N) [\text{Min} (r-1, c-1)]}} \tag{4}$$

The instruction in the denominator is to multiply the table total (N) by whichever is smaller: the number of rows minus 1 or the number of columns minus 1 (i.e., the "Min," or minimum, of the two quantities in parentheses). In Table 1, the minimum of the two quantities is $r - 1 = 1$, and the denominator thus becomes N . Hence, for Table 1, $V = .28$.

While this measure *can* reach an upper limit of 1.0 under certain conditions, it cannot be 1.0 in some tables. In Table 1, for example, if *all* of the 540 persons attending college were white, and all blacks and Asian-Americans were not in college, chi square would reach a value of approximately 503 (and no other distribution that preserves the marginals would yield a larger chi square). This maximum possible departure from statistical independence (given the marginal frequencies) yields a V of .71.

In the special case of a cross-classification table with two rows and two columns (a "2 x 2 table") V becomes phi (Φ), where

$$\Phi = \sqrt{\frac{\chi^2}{N}} \tag{5}$$

The maximum possible value of phi in a given table is 1.0 if and only if the distribution over the two row categories is identical to the distribution over the two column categories. For example, if the cases in the two row categories are divided, with 70 percent in one and 30 percent in the other, the maximum value of phi will be 1.0 if and only if the cases in the two column categories are also divided, with 70 percent in one and 30 percent in

College Attendance by Race: Observed Frequencies (from Table 1), Expected Frequencies Assuming Statistical Independence (in *Italic*), and $(O-E)^2/E$ for Each Cell (in **Bold Type)**

ATTENDING COLLEGE?	WHITE	BLACK	ASIAN-AMERICAN	TOTAL
Yes	400 <i>378</i> 1.3	60 <i>108</i> 21.3	80 <i>54</i> 12.5	540
No	300 <i>322</i> 1.5	140 <i>92</i> 25.0	20 <i>46</i> 14.7	460
Total	700	200	100	1,000

$$\chi^2 = 1.3 + 21.3 + 12.5 + 1.5 + 25.0 + 14.7 + 76.3$$

$$C = 0.27$$

$$V = 0.28$$

Table 2

the other. Some consider measures of association based on chi square to be flawed because commonly encountered marginals may imply that the association cannot possibly reach 1.0, even if the observed frequencies display the maximum possible departure from statistical independence, given the marginal frequencies. But one may also consider this feature appropriate because, if the degree of statistical association in a cross-classification table were perfect, the marginal distributions would not be disparate in a way that would limit the maximum value of the measure.

A more nagging concern about measures of association based on the departure from statistical independence is the ambiguity of their meaning. One can, of course, use such measures to say that one association is very weak (i.e., close to zero) and that another is relatively strong (i.e., far from zero and perhaps close to the maximum possible value, given the marginals), but "weak" and "strong" are relatively crude descriptors. The measures of association based on chi square may also be used in making comparisons. Thus, if a researcher wished to compare the degree of association in two populations, C or V could be compared for the two populations to determine whether the association was approximately the same in both and, if not, in which population the association was stronger. But there is no clear interpretation that can be

attached to a coefficient of contingency of precisely .32, or a Cramer's V of exactly .47.

Relative Reduction in Prediction Error. We shift now to measures of association that reflect the relative reduction in prediction error. Since such measures indicate the proportion by which prediction errors are reduced by shifting from one prediction rule to another, we follow common practice and refer to them as *proportional reduction in error* (PRE) measures. Every PRE measure has a precise interpretation, and sometimes it is not only precise but also clear and straightforward. On the other hand, the PRE interpretation of some measures may seem strained and rather far removed from the common sense way of thinking about the prediction of one variable from another.

The basic elements of a PRE measure of association are:

1. a specification of what is to be predicted, and a corresponding definition of prediction error. For example, we might say that what is to be predicted is the row category into which each case falls, and a corresponding definition of prediction error would be that a case falls in a row category other than that predicted. Referring again to Table 1, if we are predicting whether a given case is attending college or not, a corresponding definition of prediction error would be that our predicted category (attending or not) is not the same as the observed category for that case.
2. a rule for predicting either the row variable or the column variable in a cross-classification table from knowledge of the marginal distribution of that variable alone. We will refer to the prediction error when applying this rule as E_1 . For example, if what is to be predicted is as specified above (i.e., the row category into which each case falls), the rule for predicting the row variable from knowledge of its marginal distribution might be to predict the modal category for every case. This is not the only possible prediction rule but it is a reasonable one (and there is no rule based only on the marginals that would have higher predictive accuracy). Applying this rule to Table

1, we would predict "attending college" (the modal category) for every case. We would then be wrong in 460 cases out of the 1,000 cases in the table, that is, each of the 460 cases not attending college would be a prediction error, since we predicted attending college for every case. Hence, in this illustration $E_1 = 460$.

3. A rule for predicting the same variable as in step (2) from knowledge of the joint distribution of both variables. We will refer to the prediction error when applying this rule as E_2 . For example, continuing with the specifications in steps (1) and (2) above, we specify that we will predict the row category for each case by taking the modal category for each column. Thus, in Table 1, we would predict "attending college" for all whites (the modal category for whites), "not attending college" for all blacks (the modal category for blacks), and "attending college" for Asian-Americans. The prediction errors are then 300 for whites (i.e., the 300 not attending college, since we predicted attending for all whites), 60 for blacks (i.e., the 60 attending college, since we predicted nonattending for all blacks), and 20 for Asian-Americans, for a total of 380 prediction errors. Thus, in this illustration $E_2 = 380$.
4. The calculation of the proportion by which prediction errors are reduced by shifting from the rule in step (2) to the rule in step (3), that is, the calculation of the proportional reduction in error. This is calculated by:

$$\text{PRE} = \frac{E_1 - E_2}{E_1} \tag{6}$$

The numerator in this calculation is the amount by which error is reduced. Dividing this amount by the starting error indicates what proportion of the possible reduction in prediction error has actually been achieved. Utilizing the error calculations above, we can compute the proportional reduction in error.

$$\text{PRE} = \frac{460 - 380}{460} = \frac{80}{460} = .174 \quad (7)$$

This calculation indicates that we achieve a 17.4 percent reduction in prediction error by shifting from predicting the row category that is the marginal mode for all cases to predicting the column-specific modal category for all cases in a given column.

The PRE measure of association with prediction rules based on modal categories (illustrated above) is undoubtedly the simplest of the many PRE measures that have been devised. This measure is called lambda (λ), and for a given cross-classification table there are two lambdas. One of these focuses on predicting the row variable (λ_r), and the other focuses on predicting the variable that is represented in columns (λ_c). In the illustration above, we computed λ_r ; that is, we were predicting college attendance, which is represented in rows. Shifting to λ_c (i.e., making the column variable the predicted variable), we find that the proportional reduction in error is 0. This outcome is evident from the fact that the modal column for the table ("White") is also the modal column for each row. Thus, the prediction errors based on the marginals sum to 300 (i.e., the total who are not "white") and the prediction errors based on row-specific modal categories also sum to 300, indicating no reduction in prediction error. Thus, the proportional reduction in prediction error (as measured by lambda) is not necessarily the same for predicting the row variable as for predicting the column variable.

An alternative PRE measure for a cross-classification table is provided by Goodman and Kruskal's tau measures (τ_r and τ_c) (1954). These measures are based on prediction rules that entail distributing predictions so as to recreate the observed distributions instead of concentrating all predictions in the modal category. In doing so, there is an expected number of misclassified cases (prediction errors), and these expected numbers are used in calculating the proportional reduction in error. In Table 1, $\tau_r = .25$ and $\tau_c = .05$. Although λ_c was found to be zero for Table 1 because the modal column is the same in all rows, λ_r is not zero because the percentage distributions within rows are not identical.

Other PRE measures of association have been developed, and some have been designed specifically for a cross classification of ordered categories (ordinal variables). For example, if people were classified by the highest level of education completed (e.g., into the categories pre-high school, high school graduation, bachelor's degree, higher degree) we would have cases classified into a set of ordered categories and hence an ordinal variable. If the same cases were also classified into three levels of income (high, medium, and low) the result would be a cross classification of two ordinal variables. Although several measures of association for ordinal variables have been devised, the one now most commonly used is probably Goodman and Kruskal's gamma (γ). Gamma is a PRE measure, with a focus on the prediction of order within pairs of cases, with order on one variable being predicted with and without knowledge of the order on the other variable, disregarding pairs in which there is a tie on either variable.

These and other PRE measures of association for cross-classification tables are described and discussed in several statistics texts (See, for example, Blalock 1979; Knoke and Bohrnstedt 1991; Loether and McTavish 1980; Mueller et al. 1977). In some instances, the prediction rules specified for a given PRE measure may closely match the specific application for which a measure of association is sought. More commonly, however, the application will not dictate a specific kind of prediction rule. The preferred measure should then be the one that seems likely to be most sensitive to the issues at stake in the research problem. For example, in seeking to identify "risk factors" associated with a relatively rare outcome, or with a very common outcome, one of the tau measures would be more appropriate than one of the lambda measures, because the modal category may be so dominant that lambda is zero in spite of distributional differences that may be of interest.

MEASURES OF ASSOCIATION IN APPLICATION

When the initial measures of association were devised at the beginning of the twentieth century, some regarded them as part of a new mode of inquiry that would replace speculative reasoning

and improve research into the linkages between events. At the end of the twentieth century, we now recognize that finding a statistical association between two variables raises more questions than it answers. We now want to know more than the degree to which two variables are statistically associated; we want also to know why they are associated: that is, what processes, what conditions, and what additional variables are entailed in generating the association?

To a limited degree, the measures of association discussed above can be adapted to incorporate more than two variables. For example, the association between two variables can be explored separately for cases that fall within each category of a third variable, a procedure commonly referred to as "elaboration." Alternatively, a new variable consisting of all possible combinations of two predictors can be cross-classified with an outcome variable. But the traditional measures of association are not ideally suited for the task of exploring the reasons for association. Additional variables (e.g., potential sources of spuriousness, variables that mediate the effect of one variable on another, variables that represent the conditions under which an association is weak or strong) need to be incorporated into the analysis to yield an improved understanding of the meaning of an observed association—not just one at a time but several simultaneously. Additional modes of analysis (e.g., loglinear analysis; see Goodman 1970; Knoke and Burke 1980) have been developed to allow an investigator to explore the "interactions" between multiple categorical variables in a way that is roughly analogous to multiple regression analysis for quantitative variables. Computer technology has made such modes of analysis feasible.

The same technology has generated a new use for relatively simple measures of association in exploratory data analysis. It is now possible to describe the association between hundreds or thousands of pairs of variables at very little cost, whereas at an earlier time such exhaustive coverage of possible associations would have been prohibitively expensive. Measures of association provide a quick clue to which of the many associations explored may identify useful "risk factors" or which associations suggest unsuspected linkages worthy of further exploration.

MEDICAL SOCIOLOGY

Over the past several decades medical sociology has become a major subdiscipline of sociology, at the same time assuming an increasingly conspicuous role in health care disciplines such as public health, health care management, nursing, and clinical medicine. The name *medical sociology* garners immediate recognition and legitimacy and, thus, continues to be widely used—for instance, to designate the Medical Sociology Section of the American Sociological Association—even though most scholars in the area concede that the term is narrow and misleading. Many courses and texts, rather than using the term “sociology of medicine,” refer instead to the sociology of health, health and health care, health and illness, health and medicine, or health and healing. The study of medicine is only part of the sociological study of health and health care, a broad field ranging from (1) *social epidemiology*, the study of socioeconomic, demographic, and behavioral factors in the etiology of disease and mortality; to (2) studies of the *development and organizational dynamics* of health occupations and professions, hospitals, health maintenance and long-term care organizations, including interorganizational relationships as well as interpersonal behavior, for example, between physician and patient; to (3) the *reactions of societies* to illness, including cultural meanings and normative expectations and, reciprocally, the reactions of individuals in interpreting, negotiating, managing, and socially constructing illness experience; to (4) the *social policies, social movements, politics, and economic conditions* that shape and are shaped by health and disease within single countries, as well as in a comparative, international context.

The rise of contemporary medical sociology can be traced back to the immediate post-World War II period, when science and medicine were dominant cultural forces, fueling a modern optimism that many of society’s ills could be eliminated. Several key contributions during the 1950s gave credibility and spurred scholarly interest in the newly developing subfield. Koos’s *The Health of Regionville* (1954) and Hollingshead and Redlich’s

Social Class and Mental Illness (1958) addressed the connections between social circumstances and health status, and were instrumental in establishing a strong tradition of sociological research focusing on the social determinants of health. The finding that individuals in the lower socioeconomic levels of society experience greater morbidity and mortality has turned out to be one of the most consistent of these patterns. Also during this time, a number of sociology’s most prominent theorists turned their attention to health and health care. They approached the topic not because their primary interest was in health care or medicine, but out of a generic interest in authority and the maintenance of social order. Robert Merton, Everett Hughes, and Anselm Strauss all studied professional organizations and socialization during the 1950s, focusing primarily on physicians and the process of medical education (Merton et al. 1957; Becker et al. 1961).

The theoretical work of the 1950s most influential for medical sociology was undoubtedly Talcott Parsons’s *The Social System* (1951). In it, Parsons recognized illness as a major threat to the stability and productivity of societies and introduced the “sick role” concept to describe the social regulation of sickness and explain the mechanism through which individuals are induced to return to productive activity. Parsons argued that because sick persons were unable to perform their expected social roles, they were subject to being negatively sanctioned. On the other hand, if they had not intended to become ill and were motivated to get well, then, according to Parsons’s analysis, they could claim and be granted temporary exemption without blame from normally expected role responsibilities. Rather than being held accountable for failure to perform, they would be excused as sick. Parsons’s work generated enormous sociological interest because of its analysis of illness and medical care in terms of their broad social consequences and because of its focus on the structure and functions of social roles. His work also expanded the theoretical foundations of medical sociology by provoking equally compelling work from contrasting perspectives. Elliot Freidson in *Profession of Medicine* (1970) analyzed the dominance of the medical profession, suggesting that power relations in health care were fundamentally contentious. He saw physicians as rising to dominate health care through a process of

struggle with competitors in which they prevailed largely because they gained the support of political institutions, limiting the role of competing occupations. In contrast to the fixed roles in structural-functional theory, Freidson argued that illness definitions and illness behavior were socially constructed through a process of negotiation. The debate over structure and agency represented in these early contributions laid theoretical pathways for subsequent scholarship and solidified medical sociology's ties to some of the central issues of the discipline.

Medical sociology became established in only a few sociology departments during its early years, typically in elite universities. It was not until the 1970s that most graduate departments of sociology began to offer medical sociology. Today, sociology courses on health and medicine can be found in nearly every graduate program in the United States as well as in many other nations, notably the United Kingdom and Germany (Bloom 1986). Research funding to support the growth of medical sociology in many countries has come from government sources. In the 1960s and 1970s, U.S. medical sociology expanded in part because social science research was held in favor by the federal government as well as by influential private foundations. Major funding sources at that time included the National Institute of Mental Health (NIMH) and, later, the National Center for Health Services Research (NCHSR).

It has been argued that the fortunes of medical sociology have shifted in relation to the social-medical environment (Pescosolido and Kronenfeld 1995). Until the 1980s, medical sociology experienced relatively fertile conditions due in part to the fact that the health care system was dominated by professional medicine. Access to health care was the primary health policy concern, while research funding priorities focused on the biomedical and psychosocial aspects of disease, disease prevention, and patient care. This environment encouraged medical sociologists to pursue quantitative research, including surveys, national-level studies, and multivariate statistical models that predicted utilization of health services and the effects of risk factors and other variables. Two particular lines of medical sociology research gained prominence as a result of this focus. The first involved researchers studying utilization patterns for health services. There were two groups, each

using a somewhat different explanatory model. Marshall Becker and his colleagues employed the Health Belief Model, a cognitive framework originated by Rosenstock (1966) and eventually applied in research, to explain a wide variety of preventive and health-related behaviors (Becker and Maiman 1975). Ronald Andersen developed the somewhat broader sociobehavioral model (1995), which included health beliefs but also emphasized economic factors and health needs. The second line of research concerned quantitative studies of social stress. David Mechanic, one of the founders of medical sociology, pioneered sociological research on stress and mental health as early as the 1960s (Mechanic and Volkart 1961). The "stress process" group that emerged in the late 1970s, however, was closer to an interface of psychology and sociology. Using multivariate analyses, they examined the relationships among stress (Aneshensel 1992), social support (Turner and Marino 1994), and coping (Pearlin and Schooler 1978). Much of this research was published in the American Sociological Association's *Journal of Health and Social Behavior*, beginning in the late 1970s and continuing into the present (Thoits 1995).

The social-medical environment in the United States changed dramatically in the 1980s, threatening the autonomy and authority of physicians (Starr 1982). The federal government's increasing role in financing health care (through the Medicare and Medicaid programs) combined with rapidly escalating health care costs and the concern expressed by business, leading to a major federal policy shift. Rather than inequality in access and social factors in illness, public policy attention was now placed on cost control and the cost effectiveness of care. NIMH support for medical sociology was weakened, and soon afterward, the NCHSR became the Agency for Health Care Policy and Research with an agenda of research focused on managed care and evidence-based medicine. Research funding priorities gravitated from the behavioral and social sciences to economics and clinical medicine and epidemiology. No doubt these changes contributed to critical claims in the late 1980s and the 1990s, that medical sociology research had become fragmented.

The significance of health system changes for the profession of medicine became a hotly debated topic among medical sociologists during the

1980s. The controversy was sparked in 1985 with the publication of McKinley and Arch's "Toward the Proletarianization of Physicians," in which the authors argued that historical processes of bureaucratic rationalization were finally reaching medicine, irreversibly eroding the functional autonomy of physicians. This directly challenged Freidson's medical dominance perspective (1970). Also part of the debate was the hypothesis, introduced by Marie Haug (1976), that physicians had lost authority due to the increasing knowledge and medical sophistication of patients. A plethora of articles appeared, identifying and discussing at length various hypothesized changes in medical dominance and authority and culminating, though by no means ending, with a special issue of the *Milbank Quarterly* in 1988.

Much of the early growth of medical sociology can be attributed to scholars located outside sociology departments in medical schools, nursing schools, schools of public health, and health administration programs. These individuals addressed research concerns and questions that were of paramount importance in their respective settings, such as the reasons people engage in health-promoting behavior, define themselves as sick, use health services, and comply with medical treatment. They contributed to medical and health care disciplines by bringing attention to the significance of culture and human interaction in producing the *meaning* of illness and shaping illness-related behavior (Zola 1966; Mechanic 1995). They dispelled the image of the physician as a purely rational scientist. Sociologists also contributed to the development of social epidemiology, mapping the social patterns of disease, and adding social factors to the causal understanding of mortality and chronic diseases (Berkman and Syme 1979). A third group studied hospitals and health care organizations, bringing an organizational sociology perspective into the field of health services research (Flood and Fennell 1995).

Robert Straus, a medical school sociologist, introduced in 1957 what became for many years a popular way of dividing the subfield. Sociologists such as those described above were designated "sociologists *in* medicine" in contrast to sociologists *of* medicine who were typically based in sociology departments. According to Straus, sociologists *of* medicine used medical settings to address

questions of sociology while sociologists *in* medicine used sociological knowledge to address questions of medicine. Today, the boundaries between those working in health care settings and those in academic departments of sociology are blurred; sociologists in both venues conduct applied research as well as research that contributes to basic sociological theorizing. In fact, it is quite common for medical sociologists to have multiple academic appointments. On the other hand, the distinction remains valid in the pressure to conduct research that reflects the priorities of the dominant group. Medical sociologists in medicine often engage in research shaped by medical issues and a biomedical approach, whereas those in sociology have an easier time posing sociological questions grounded in sociological theory. In its early years, medical sociology was sometimes dismissed by other academic sociologists as "applied" sociology, based on the rather elitist assumption that its research did not contribute to the basic body of knowledge of the discipline and that it lacked a theoretical body of its own. Today, there is greater understanding of the links between basic sociological theory and medical sociology (Gerhardt 1989). Medical sociology concepts such as "medicalization" have added to the broader understanding of social order and social control (Conrad 1992). Medicine and the other health care disciplines recognize sociology as a valuable discipline that can contribute much to the understanding and application of health care. Academic sociology has come to regard the sociology of medicine as a fruitful area of specialization.

It is in their role of social critic that medical sociologists encounter the greatest resistance from mainstream medicine and health care. Critical medical sociology emerged from both Marxist and social constructionist traditions within the discipline (Waitzkin 1989; Brown 1995). Symbolic interactionists and labeling theorists in the 1960s saw that, despite the Parsonian notion of the sick role, many types of illness and disability were responded to socially as forms of deviance. Goffman's concept of stigma (1963) explored the relationship between labeling and identity as a process of managing spoiled identity. One of the most powerful explanatory concepts in medical sociology, stigma has been used for decades to capture the experience of mental illness, alcoholism, physical disability, and many types of chronic illness. Goffman

(1961) and Zola (1972), among others, turned the standard notion of medical care as a service on its head by arguing that medicine functions as an institution of social control. Despite strong microsociological interest in the social construction and social consequences of medical labels (i.e., diagnoses), the professional power of physicians made it exceedingly difficult for sociologists to study these processes until the 1980s. What could be studied, however, using the broader, cultural meaning of social construction, were processes of medicalization. Building on the social control perspective of Zola and others, a number of studies examined the processes through which nonmedical phenomena—such as childbirth, excessive drinking, children’s active behavior, and menstrual distress—became medical phenomena, with diagnostic criteria and specific medical treatments.

Bias in medicine and social inequality in health care have been concerns of critical medical sociology as well as of corresponding social movements initiated to improve health care. Gender analyses, especially those from a feminist perspective, offered a critical, alternative perspective on the medical profession (Lorber 1984) and the health care system (Zimmerman and Hill 1999), as did research on the women’s health movement (Ruzek 1978; Weisman 1998). This work examined the relationship between cultural ideas about gender, medical knowledge, and gender stratification systems; pointed out that the division of labor in medicine is also a gendered division of labor; and observed that the factors that often make women sick are linked to their social roles and disadvantaged social circumstances. Other critical perspectives were offered by disability researchers (Zola 1982) and by researchers focusing on the health and health care of racial and ethnic minorities (Hill 1992; Williams and Collins 1995).

The critical perspective in medical sociology was fortified by Mishler’s (1981) critique of the biomedical model, in which he argued that medicine was itself a culture, based as much on customs, social norms, and values as on scientific fact. Mishler’s view of medicine as socially constructed led to a concern with medical discourse analysis (1984) and, for some researchers, to the study of illness narratives. Departing from the political and critical concerns of the 1980s and 1990s, these

scholars have conducted in-depth, qualitative studies of illness experience, incorporating aspects ignored by their predecessors, such as emotions and the body (Charmaz 1991; Weitz 1991). The “postmodern turn” that swept over academic humanities and social science departments in the latter decades of the twentieth century influenced a number of symbolic interactionist and social constructionist medical sociologists. Working at the interface of constructionism and postmodernism, these scholars created new ways to explore the relationship between illness and identity (Frank 1995; Hall 1998).

Reviewing the literature of medical sociology reveals an unusually broad range of topics, theoretical perspectives, and research methodologies. Beyond the contributions reviewed above, medical sociologists are also active in international comparative research studying health systems or specific health care sectors within them. They are involved in health policy research both at the federal and at the local community level; they are studying alternative health care providers and their clients as well as various forms of folk medicine and lay care; and they are doing research on informal caregivers and the process of care work. Even these additions do not exhaust the parameters of the field. Medical sociology has enriched and continues to enrich the discipline of sociology, as well as making unique and valuable contributions to important policy issues and to the needs of health care professionals, managers, and patients.

MARY K. ZIMMERMAN

MEDICAL-INDUSTRIAL COMPLEX

The concept of the medical-industrial complex was first introduced in the 1971 book, *The American Health Empire* (Ehrenreich and Ehrenreich 1971) by Health-PAC. The medical-industrial complex (MIC) refers to the health industry, which is composed of the multibillion-dollar congeries of enterprises including doctors, hospitals, nursing homes, insurance companies, drug manufacturers, hospital supply and equipment companies, real estate and construction businesses, health systems consulting and accounting firms, and banks. As employed by the Ehrenreichs, the concept conveys the idea that an important (if not the primary) function of the health care system in the United States is business (that is, to make profits) with two other secondary functions, research and education.

Since that time, a number of authors have examined the medical-industrial complex: Navarro (1976, pp. 76, 80), Relman (1980), Estes and colleagues (1984), Wohl (1984), and McKinlay and Stoeckle (1994). Himmelstein and Woolhandler (1990) argue that health care facilitates profit making by (1) improving the productivity (health) of workers, (2) ideologically ensuring the social stability needed to support production and profit, and (3) providing major opportunities for investment and profit (p. 16). The last function, profit, is now "the driving force," as health care has fully "come into the age of capitalist production" (p. 17).

Arnold Relman (1980), Harvard medical professor and editor of the *New England Journal of*

Medicine, was the first mainstream physician to write about the medical-industrial complex, observing that the corporatization of medicine is a challenge to physician authority, autonomy, and even legitimacy for the doctors who become health care industry owners. Ginzberg (1988) and others (Andrews 1995; Estes et al. 1984; Himmelstein and Woolhandler 1990) have written about the monetarization, corporatization, and proprietarization of "health" care. By the mid-1980s, the author of a book appearing with the title *The Medical Industrial Complex* (Wohl 1984) did not see the need to define it but, rather, began with "the story of the explosive growth of . . . corporate medicine" and focused on "medical moguls," monopoly, and a prescription for profit.

While the health care industry has certainly contributed to improvements in the health status of the population, it has also strengthened and preserved the private sector and protected a plurality of vested interests. In U.S. society, the medical-industrial complex functions economically as a source of growth, profit accumulation, investment opportunity, and employment (Estes et al. 1984, pp. 56-70). It also contributes to the human capital needed for productivity and profit by preserving an able-bodied workforce whose work is not sapped by illness (Rodberg and Stevenson 1977), although another interpretation suggests that private capital's stability is built upon the appropriation of the working-class population's health (see Navarro 1976, 1982, 1995).

STRUCTURE OF THE HEALTH CARE INDUSTRY

Industry Components Today's medical-industrial complex consists of more than a dozen major components: hospitals; nursing homes; physicians (salaried and fee-for-service); home health agencies; supply and equipment manufacturers; drug companies; insurance companies; managed care organizations (HMOs, PPOs, IPAs); specialized centers (urgi, surgi, dialysis); hospices; nurses and all other health care workers; administrators, marketers, lawyers, and planners; and research organizations. In addition to these entities, thousands of other organizations are springing up in long-term care (e.g., case management, respite care, homemaking/chore, independent living center) and other

services for the disabled and aging, including social services that have incorporated health care components such as senior centers.

Changes in the Structure of the Industry.

There were a number of significant changes in the structure of the health care industry between the 1970s and 1990s, including (1) rapid growth and consolidation of the industry into larger organizations; (2) horizontal integration; (3) vertical integration; (4) change in ownership from government to private, nonprofit, and for-profit organizations; and (5) diversification and corporate restructuring (Starr 1982; McKinlay and Stoeckle 1994). These changes occurred across the different sectors, which are dominated by large hospital, insurance, and managed care organizations.

Rapid Growth and Consolidation Health care has long been moved from its cottage industry stage with small individual hospitals and solo physician practitioners to large corporate enterprises. Health care corporations are diverse and growing in terms of size and complexity. Hospitals are the largest sector of the health care industry, and while the growth rate in hospital expenditures was increasing rapidly, the number of community hospitals actually declined from 5,830 in 1980 to 5,194 in 1995 (a decrease of 11 percent) (American Hospital Association 1996) (see Table 1). The number of community hospital beds also began to decline going down to 988,000 in 1980 and continuing so that by 1995 there were only 873,000 (a decrease from 12 percent) (AHA 1996).

Nursing homes grew rapidly in numbers of facilities and beds after the passage of Medicaid and Medicare legislation. In 1996, there were 17,806 licensed nursing facilities with 1.82 million beds (Harrington et al. 1998). The number of facilities increased by 25 percent and the number of beds increased by 37 percent between 1978 and 1996. More recently, their overall growth has leveled off, so that growth is not keeping pace with the aging of the population (Harrington et al. 1998).

Relatively new and influential corporate forces in the health industry are the managed-care organizations such as health maintenance organizations (HMOs), preferred provider organizations (PPOs), and independent practice associations (IPAs). There has been a large growth in HMOs, which provide health care services on the basis of fixed monthly charges per enrollee. In 1984, there

were only 337 HMOs with 17 million enrollees. By 1988, there were 31 million members enrolled in 643 HMOs (InterStudy 1989). Managed-care enrollees grew to more than 50 million in 1996 and are expected to reach 100 million by the year 2002. Nearly 75 percent of U.S. workers with health insurance now receive that coverage through an HMO, a PPO, or a point of service plan (PSP) (McNamee 1997). There have been numerous rounds of mergers and acquisitions among HMOs, and some nonprofit HMO corporations have established profit-making operations (Gallagher 1999).

PPOs are modified HMOs that provide health care for lower costs when the enrollee uses participating providers who are paid on the basis of negotiated or discount rates (U.S. DOC 1990). In 1988 there were about 620 PPOs with about 36 million members.

Private health insurance companies constitute another large sector of the health industry. In 1988, the United States had over 1,000 for-profit, commercial health insurers and 85 Blue Cross/Blue Shield plans (Feldstein 1988). These private insurance organizations, along with HMOs, PPOs, and other third-party payers, paid for 32 percent (\$348 billion out of \$1,092 billion) of the total expenditures in 1997 (Srinivasan et al. 1998).

Physician practice patterns changed rapidly between the 1970s and 1990s, moving toward larger partnerships and group practices. Eighteen percent of physicians were in group practices (with three or more physicians) in 1969, compared to 28 percent in 1984 (Andersen and Mullner 1989). It is estimated that about 75 percent of all practicing physicians are part of at least one qualified health management organization (U.S. DOC 1990). Thus, physicians are moving toward larger and more complex forms of group practice. In addition, physicians are actively involved in the ownership and operation of many of the newer forms of HMOs, PPOs, IPAs, and other types of corporate health care activities (Relman 1980; Iglehart 1989).

Horizontal Integration The major changes in corporate arrangements have been the development of multiorganizational systems through horizontal integration. The formation of multihospital systems has grown tremendously within the industry. Ermann and Gable (1984) estimated there

Community Hospitals and Beds by Ownership, 1980, 1990, and 1995

Type of Ownership	1980		1990		1995	
	Hospitals	Beds	Hospitals	Beds	Hospitals	Beds
Nonprofit	3,322 (57%)	692 (70%)	3,191 (60%)	657 (71%)	3,092 (60%)	610 (70%)

were 202 multihospital systems controlling 1,405 hospitals and 293,000 beds in 1975 (or 24 percent of the hospitals and 31 percent of all beds). In 1997, there were 280 multihospital systems controlling 1,514 hospitals, and 543,588 beds (Table 2). This represents a 39 percent increase in the number of multihospital systems, a small (7 percent) increase in the number of hospitals, and an 86 percent increase in the number of beds between 1975 and 1997.

Multihospital corporations are becoming consolidated, with large companies controlling the largest share of the overall hospital market. Most of the recent increase in these systems has been the result of purchases or leases of existing facilities and mergers of organizations, rather than of construction of new facilities.

Vertical Integration Vertical integration involves the development of organizations with different levels and types of organizations and services. One such type of integration has involved the linkage of hospitals and health maintenance organizations and/or insurance companies. For example, National Medical Enterprises owned hospitals, nursing homes, psychiatric hospitals, recovery centers, and rehabilitation hospitals (Federation of American Health Systems 1990). There has also been an increase in the number of academic medical center hospitals that have relationships with proprietary hospital firms (Howard S. Berliner and Burlage 1990, p. 97). Many of the major investor-owned

health care corporations are diversified, with many different types of health care operations.

Changes in Ownership Between the 1970s and the 1990s the organizational side of health care witnessed a surge in the growth of both for-profit and not-for-profit health care delivery corporations, initially in hospitals and later extending to other types of health organizations. The ownership of hospitals shifted from public to nonprofit and for-profit organizations (see Table 1). The percentage of government-owned community hospitals dropped from 30 percent of the total community hospitals in 1980 to 26 percent in 1995, and the percentage of total beds declined from 21 percent to 18 percent during the same period (AHA 1996). In contrast, the percentage of proprietary facilities increased from 13 percent to 14 percent, and the percentage of proprietary beds increased from 9 percent to 12 percent, of the total during the 1980-1995 period. The percentage of total U.S. hospitals owned by nonprofit corporations increased from 57 percent to 60 percent during the period, while the percentage of beds remained at 70 percent (AHA 1996). Of the total 280 multihospital systems in 1997 (down from 303 systems in 1988), investor-owned systems controlled 40 percent of the hospitals and 27 percent of the beds, compared to nonprofit facilities (AHA 1997). The federal government controlled 9.8 percent of hospitals and 13 percent of beds, while nonprofit organizations controlled 50 percent of hospitals and 59 percent of beds (AHA 1997). We note that this represents a 3 percent decrease in the number

Hospitals and Beds in Multihospital Health Care Systems, by Type of Ownership and Control, 1997

Type of Ownership	TOTAL NOT-FOR-PROFIT		INVESTOR-OWNED		ALL SYSTEMS	
	Hospitals	Beds	Hospitals	Beds	Hospitals	Beds
Owned, leased, or sponsored	1,343 (53%)	309,216 (62%)	887 (35%)	119,466 (24%)	2,525 (100%)	501,724 (100%)
Contract-managed	171 (36%)	12,901 (31%)	301 (64%)	28,963 (69%)	472 (100%)	41,864 (100%)
Total	1,514 (50%)	322,117 (59%)	1,188 (40%)	148,429 (27%)	2,997 (100%)	543,588 (100%)

of hospitals and a 6 percent decrease in the number of beds in multihospital systems controlled by investor-owned systems since 1988.

Nursing homes have the largest share of proprietary ownership in the health field (except for the drug and medical supply industries). In 1997, some 65 percent of all nursing homes were profit-making, 28 percent were nonprofit, and 7 percent were government-run (Harrington et al. 1999). By 1997, chains owned 54 percent of the total nursing home facilities.

For-profit companies dominate the health maintenance organization (HMO) market. Between 1981 and 1997, for-profit HMOs grew from representing 12 percent to 62 percent of total HMO enrollees and from 18 percent to 75 percent of health plans (Srinivasan et al. 1998). Investor-owned corporations have also established themselves in many other areas of health care, ranging from primary-care clinics to specialized referral centers and home health care. The number of proprietary home health corporations is increasing rapidly, while the number of traditional visiting nurse associations is declining (Estes et al. 1992). In 1982 it was estimated that 14 percent of the Medicare home health charges were by proprietary agencies, 26 percent by nonprofit organizations, 32 percent by visiting nurse associations, 15 percent by facility-based agencies, and 14 percent by other agencies (U.S. Department of Health and Human Services 1989). By 1996, proprietary agencies accounted for 44 percent of total Medicare agencies, nonprofit care for 37 percent, and government and others for 19 percent (U.S. DHHS 1997).

Forty-four percent of home health agencies were part of a multifacility chain. This represents a dramatic shift in ownership structure within a six-year period. The changes brought about by the for-profit chains are more extensive than their proportionate representation among health care providers might suggest (Bergthold et al. 1990; Estes and Swan 1994). By force of example and direct competition, for-profit chains have encouraged many nonprofit hospitals and other health entities to combine into chains and convert to for-profit status (Dube 1999).

Diversification, Restructuring, and Growth.

Diversification of health care corporations is continuing to occur. Some large hospital corporations have developed ambulatory care centers (such as Humana, which later sold its centers), while others have developed their own HMOs or insurance. By the mid-1980s, many experts expected America's health care system to be dominated by the four largest for-profit hospital chains: Hospital Corporations of America (HCA), Humana, National Medical Enterprises, and American Medical International. By the late 1990s, only Humana and HCA were left standing, and HCA had already merged with Columbia. Eventually HCA Columbia almost collapsed as the result of a scandal over fraud during the late 1990s (*Multinational Monitor* 1998). Economic problems in the late 1980s resulted in some industry restructuring, by scaling down operations and spinning off substantial segments (Ginzberg 1988).

In the 1990s, this cycle repeated itself, as the frenzy of mergers and acquisitions has produced

ever-greater desires for cost cutting and restructuring. One report states that much of this drive for cost containment stemmed from drug companies' raising prices and from an increase in patient visits to doctors (utilization costs) (Hayes 1997). High stock values and the desire to improve market share have catalyzed many health care firms to seek growth through mergers and acquisitions. The number of mergers among health services (483) and HMO companies (33) peaked in 1996. These mergers were valued at \$27 billion and \$13.3 billion, respectively (Hayes 1997).

As HMOs grow, it has become clear that their primary goals are market control, profit making, and cost containment (through capitation and other mechanisms). For example, the merger of Aetna and U.S. Health care in 1996 put a "corporate giant in control of the care of 1 in 12 people in the United States" (Slaughter 1997, p. 22). In the years 1994–1999 a dozen companies were merged or acquired by six of the biggest firms: Aetna, Cigna, United HealthCare, Foundation Health Systems, Pacificare, and Wellpoint Health Networks.

As managed-care organizations became the dominant player in the health care industry in the 1990s, both doctors and patients began to voice complaints about the system. Many patients felt that they were no longer able to receive the quality time and personal care of a primary physician, because the physicians had to provide hurried treatment to patients in order to maintain efficiencies demanded by HMOs (Managed Care Improvement Task Force 1998). For their part, many doctors argued that capitation and other structures introduced by HMOs limited their freedom to make treatment decisions.

Many doctors and patients argued that these trends were producing lower-quality care (Dao 1999, p. A1). Additionally, registered nurses were increasingly being used in place of doctors to lower labor costs. Registered nurses, in turn, were also being replaced with less skilled and lower-paid personnel. In response, both doctors and nurses have begun a fervent effort to unionize (Slaughter 1997). While some critics argue that the impacts of this growth at all costs by both for-profit and nonprofit organizations are often devastating to communities (Bond and Weissman 1997; Kassirer 1997), others find few negative effects (Fubini and Limb 1997).

Financial Status and Profits. The private health care sector was marked by great volatility and growth in the 1990s. *Forbes's* annual report on investor-owned health corporations shows that the median five-year average return-on-equity for health corporations was 14.6 percent, well above the 10.5 percent for all U.S. industries (Condon 1998) (see Table 3). Median health industry sales for investor-owned companies grew 8.8 percent for 1997 and at a 11.1 percent rate for the five-year average. Earnings per share were 15.5 percent in the most recent twelve months, compared with 8.6 percent for the five-year average. The earnings per share were higher than the 14.9 percent earnings for all U.S. industries in the most recent twelve months in 1997 (Condon 1998).

The *Forbes* financial reports for the largest health corporations are shown in Table 3 for three different sectors of the industry: health care services, drugs, and medical supply companies (Condon 1998; Hayes 1998). The most profitable health care service corporation in 1989 was Humana, which owns both hospitals and insurance companies. In 1989 its group health insurance division had almost 1 million members and a \$4 billion operating profit (Fritz 1990). The most profitable health care service corporation in 1997 was HBO and Company, while Oxford Health Plans had the strongest five-year average.

While large investor-owned HMOs are growing each year, the 1990s were tumultuous financially. As *Forbes* Annual Report on American Industry put it, "Health care providers are supposed to make people well, but many of these companies are very sick themselves" (Hayes 1998, p. 180). Although Oxford Health Plans had the higher five-year average, between July 1997 and January 1998 its stock lost over 80 percent of its value. Similarly, the number two-ranked company, Mid Atlantic Medical Services, saw its stock drop by more than 50 percent of its value in a year's time. Rapid growth, through mergers, acquisitions, and internal sales, "eventually outstripped management's ability to run these companies" (Hayes 1998, p. 180).

Earnings per share of drug companies were at 15.8 percent in 1997, which was up from the five-year average of 11.9 percent (Condon 1998). Return on equity reported for drug companies was at 11.7 percent in 1997, significantly less than the 14.3 percent on average over the previous five

years (Condon 1997). On the other hand, earnings per share of medical supply companies were doing well at 15.5 percent in 1997, far better than their five-year median earnings of 4.7 percent. In 1989 a number of large drug company mergers occurred, particularly between U.S. firms and foreign corporations such as Genentech, Inc., and Roche Holding, Ltd., of Switzerland (Southwick 1990). These international mergers continued into the 1990s.

Although the biotechnology industry did not show overall profits in 1989, the sales growth rates were strong, and some companies had high profit rates, such as Diagnostic Products, with a 22.3 percent earnings per share and 23.6 percent return on equity in 1989 over the previous year (Clements 1990, p. 182). Biotechnology saw an upsurge of economic growth and media coverage when several new developments emerged in the 1990s. The first was the introduction of “gene therapies” whereby scientists could modify a person’s genetic makeup to fight against otherwise deadly or incurable diseases such as cancer and Alzheimer’s. The second was the launching of the Human Genome Project, a massive effort by scientists in government and industry to “map” the structure of the human genetic code. The third, was the announcement, by a Scottish scientist in 1997, that he had successfully cloned a sheep from another sheep’s DNA.

While all these developments signaled the importance of biotechnology in the future of health care research and policy, some observers were critical of these technological “advances.” First, the cloning of animals like sheep leaves open the distinct possibility that human beings might soon be cloned. The prospect of this event raised dire concerns among bio-ethicists, politicians, scientists, and religious leaders during 1997, and President Bill Clinton issued a worldwide call asking scientists to voluntarily refrain from any such activities. Second, some critics have noted that the Human Genome Project has been associated with efforts to “locate” genes believed not only to be the cause of certain diseases like breast cancer, but also those genes believed to be associated with certain types of deviant, or criminal, behavior. Focusing on the genetic “causes” of certain diseases and social behaviors raises many problematic scenarios for public policy (for example, defining breast cancer as genetically based, rather than

being rooted in social structures and the production of toxins by industry). Third, some biotechnology companies have been associated with efforts to patent life forms around the globe, including parts of the human body—prompting some critics to label this practice “biopiracy” or “biocolonization” (Kimbrell 1996). Taken together, these charges suggest that, through biotech, the medical-industrial complex is charting revolutionary territory that has allowed private interests to define, claim ownership over, and even create life on this planet. Despite these criticisms, biotechnology stocks continue to rise. As noted, the pharmaceutical industry alone traded upward of \$110 billion globally in 1997, while the overall health expenditures topped \$1 trillion by the end of the 1990s. Some analysts project health costs to more than double by 2015 to \$2.3 trillion, of which the government share will be between 25 and 50 percent (Pardes et al. 1999).

In summary, the 1970s, 1980s, and 1990s were decades of enormous growth in health care spending and the rationalization of health care service delivery, with the formation of large, complex, bureaucratically interconnected units and arrangements that reached well beyond the hospital and permeated virtually all sectors of the health care industry. At the same time, new sectors emerged (e.g., genetic research and subacute care), bringing additional industry developments. This vertical and horizontal integration of medical organizations and industries, combined with the revival of market ideologies and government policies promoting competition and deregulation, have profoundly altered the shape of U.S. health care delivery. As we enter the new millennium, these changes continue to signal a fundamental transformation of American medicine and a rationalization of the system under private control that was described by Paul Starr (1982).

The Need for Regulation. The federal government has been playing and continues to play a crucial role in the development of the medical-industrial complex. After World War II, the federal role expanded as Congress enacted legislation and authorized money for research, education, training, and the financing of health services. The passage of Medicare and Medicaid in 1965 was pivotal in expanding the medical-industrial complex, as government became the third-party payer for health care services (Estes et al. 1984). As a consequence, public demand for health care among

the aged, blind, disabled, and poor (all previously limited in access) was secure. Medicare and Medicaid provided the major sources of long-term capital financing for hospitals and contributed to the marked increase in service volume and technology, as well as to the continued oversupply of physicians (McKinlay and Stoeckle 1994). Thus, federal financing of health care has performed the very important functions of sustaining aggregate demand through health insurance programs, protecting against financial risks, subsidizing research and guaranteeing substantial financial returns, supporting the system's infrastructure through training subsidies and capital expansion, and regulating competition through licensure and accreditation (LeRoy 1979).

In addition to government spending, third-party insurance offered by Blue Cross/Blue Shield and private commercial companies covered most of the remaining inpatient hospital expenditures and a significant proportion of physician costs. The cost-based service reimbursement by private insurers, Blue Cross, and Medicare created and sustained strong cash flows in the hospital industry (Ginzberg 1988). With public and private sector third-party payments covering 90 percent of all inpatient hospital expenditures, the hospital business had become virtually riskfree.

In the 1980s and 1990s, two other forces were responsible for the dramatic changes in the medical-industrial complex: a change in the ideological climate with the election of President Ronald Reagan, President George Bush, and later President Bill Clinton, and changes in state policies to promote privatization, rationalization, and competition in health care (Estes 1990). These changes contributed to increases in the proportion of services provided by proprietary institutions (Schlesinger et al. 1987).

While policies of the 1960s and 1970s encouraged a form of privatization built on the voluntary sector (Estes and Bergthold 1988), President Reagan, President Bush, and President Clinton shifted the direction and accelerated privatization. In the 1980s and 1990s, the form of privatization was government subsidy of a growing proportion of for-profit (rather than nonprofit) enterprises (Bergthold et al. 1990). There was also privatization in the form of a transfer of work from the formal sector of the hospital to the informal sector of

home and family with ambulatory surgery and shortened lengths of hospital stays (Binney et al. 1993). Regulatory and legislative devices were important in stimulating and accelerating privatization in the health and social services. The Omnibus Reconciliation Act of 1980 and the Omnibus Budget Reconciliation Act of 1981 contributed to competition and deregulation, private contracting, and growth of for-profits in service areas that were traditionally dominated by nonprofit or public providers (e.g. home health care).

President Clinton introduced a health care reform plan in 1993 that ultimately failed, giving way to a private sector-driven market reform managed care, promoting a system that many contend benefits investors over patients, doctors, and community hospitals (Andrews 1995). Given the long-term historical role of the private, nonprofit sector in U.S. health and social services since the earliest days of the republic and the rapid organizational changes of the 1980s and 1990s, vertical and horizontal integration have blurred boundaries between the nonprofit and for-profit health care sectors. For-profit entities have nonprofit subsidiaries, and vice versa, and conceptual and structural complexities have multiplied, rendering impossible the simple differentiation of public from private. It is noteworthy that government-initiated privatization strategies did not reduce public sector costs (see the section entitled "Financial Status and Profits").

The distinction between for-profit and nonprofit is less meaningful when both organizational forms appear to be pursuing greater revenues through cost cutting and mergers. Eight of the ten largest health care systems (by net patient revenues) in 1997 were nonprofits; that same year, four out of the ten largest health care systems (by number of hospitals owned) were also nonprofits (Bellandi and Jaspen 1998, p. 36). Whether not-for-profits are still oriented toward the needs of the community is unclear, as many of these organizations (both insurance plans and hospitals) are undergoing "conversions" to for-profit status (Marsteller et al. 1998).

The concern that many communities have is that these conversions may mean less attention to the health needs of local residents. The increase in conversions has "heightened the need for accountability regarding the accurate determination and

disposition of assets developed with the assistance of tax subsidies for nonprofit medical entities such as Blue Cross” (Estes and Linkins 1997, p. 436). Federal and state laws require that their assets remain in the charitable sector and continue to be used for the community’s benefit. Twenty-three states now have conversion laws clarifying the authority of attorneys general to regulate these conversions. Conversion laws mandate varying degrees of public participation and public disclosure, but often are best implemented when there is an active community-based activist presence to monitor the organization’s practices.

From social movements to the federal government, institutions across the nation are recognizing the increasing need for monitoring and regulation of the myriad branches of the medical-industrial complex. As noted earlier, physicians are advocating new legislation and even beginning to unionize against HMOs. Unfortunately, often when regulation exists, it is easily circumvented. For example, the Health Insurance Portability and Accountability Act of 1996 was intended to protect Americans who change or lose their jobs by assuring portability of plans across groups and into the individual market. It was also intended to protect people against denial of coverage for preexisting conditions. However, many insurers have skirted this law by denying commissions to their agents who sell insurance to people with medical problems (Pear 1997).

In other cases, there is little to no regulation of purchasers, such as large employers who self-insure under the Employment Retirement Income Security Act (ERISA) of 1974. These employers are exempt from state insurance laws and are bound by no federal regulation in this area. More than 125 million Americans who have HMO coverage cannot sue their providers for punitive damages. As *Time* magazine recently reported, this represents a “clear subordination to corporate interests” (Howe 1999, p. 46). Furthermore, the continuing rapid pace of mergers and acquisitions in the health care industry has created a consolidation of markets that raise questions about the need for antitrust policies directed at this sector.

At the federal level, the President’s Advisory Commission on Consumer Protection and Quality in the Health Care Industry has called for a “consumer bill of rights,” while others clamor for

“patient’s bill of rights.” These proposals would provide, for example, the right to sue HMOs for damages, prohibitions against negative financial incentives, and external reviews of patient complaints. Whether this proposal will ever become national legislation is unclear. But as, under the “New Federalism,” previously federal responsibilities are “devolved” to the states, it is certain that fifty separate governments will have great difficulty coherently regulating a health care system for the entire nation. This is especially troublesome because of the growing numbers of the uninsured and those in need of long-term care (Estes and Linkins 1997).

Long-term care (LTC) is an area of health policy in need of greater attention as the age distribution of the population changes, so that the number of persons over 65 and over 85 is increasing rapidly. Medicare, Social Security and other entitlement programs affecting the elderly have been the focus of the “devolution revolution” (Estes and Linkins 1997) and raise serious questions about the quality and accessibility of LTC under managed care. There are profits to be made in this sector of the industry as well. One publication referred to 1997 as the “year of assisted living” because seven of the top ten health care provider organizations were assisted-living companies and half of them posted returns of 50 percent or greater (*SeniorCare Investor* 1998). LTC will have to meet the “bottom line” criterion of “cost-saving” or “profit generation,” and this is likely to produce problems for those in need of these services. Indeed the needs of all less powerful groups—the elderly, the poor, the working and middle classes, women, and people of color—are increasingly being confronted by these business directives as well. Regulation of health care institutions in the interests of these marginalized groups is especially difficult when the American Medical Association is second to none in money spent on lobbying the Congress and state legislatures (Jaspen 1999).

The U.S. Medical-Industrial Complex in a Global Context. The U.S. health and health care systems rank near the bottom of all industrialized nations on a number of key dimensions. By comparison, the health of U.S. citizens is poorer and the number of underinsured and uninsured individuals is greater than in any other industrialized nation. Among the top 24 industrialized nations,

the United States ranks sixteenth in life expectancy for women, seventeenth for men, and twenty-first in infant mortality (Andrews 1995, p. 38). A Harris poll indicated that the citizens of Canada, western Europe, the United Kingdom, and Japan report much higher satisfaction with their health care systems than do Americans (Isaacson 1993). Additionally, compared with other nations, doctors in the United States receive much higher incomes relative to the average worker. For example, in 1987 the income ratio of doctors to the average worker in the United States was 5.4, while in Canada it was 3.7 and in Japan and the United Kingdom it was 2.4 (Isaacson 1993). This poor performance of the United States on health indicators is ironic, given that the United States spends more money on its health care system than any other nation in the world.

Multinational health enterprises are an increasingly important part of the medical-industrial complex, with investor-owned and investor-operated companies active not only in the United States but also in many foreign countries. In 1990 a report showed 97 companies reporting ownership or operation of 1,492 hospitals with 182,644 beds in the United States and 100 hospitals with 11,974 beds in foreign countries (FAHS 1990, pp 16–17). The four largest for-profit chains owned two-thirds of the foreign hospitals (Berliner and Regan 1990). Pharmaceutical firms have also become major global corporate players. In 1990, foreign control over pharmaceutical production was 72 percent in Australia, 61 percent in the United Kingdom, 57 percent in Italy, and 30 percent in the United States (Tarabusi and Vickery 1998). The total value of global pharmaceutical exports and imports is estimated to be in excess of \$110 billion (Tarabusi and Vickery 1998). The effects of these developments in foreign countries and the profit potential of these operations are not clearly understood (Berliner and Regan 1990).

Because of the pluralistically financed health care system in the United States, administrative costs are much higher than those of the national and publicly financed health care systems of virtually all other Western industrialized nations, with the exception of South Africa. U.S. health care expenditures were increasing at an alarming rate until around 1993, when the rate of growth in expenditures began to slow. However, this trend is expected to reverse itself, and one study projects

that “health spending is expected to rise as a share of gross domestic product (GDP) beginning in 1988, climbing from 13.6 percent in 1996 to an estimated 16.6 percent by 2007” (Smith et al. 1998, p. 128).

Examining the U.S. medical-industrial complex in a comparative context provides an understanding of the role of the welfare state and government vis-à-vis civil society and private capital. What has become clear is that the unique problems the U.S. medical-industrial complex has created are rooted in the subordination of the state and civil society to corporate interests. Other nations whose health care systems are much more effective are marked by the state’s taking an active role to restrict the profit motive in health insurance, “or they simply never let a commercial market develop” (Andrews 1995, p. 36). This is because voluntary insurance in many other countries historically preceded public legislation, and these insurance funds were linked to labor unions, political groups, and religious groups—not to private companies and health care providers, as in the United States. In these cases, government policy was, and remains, heavily influenced by nongovernmental organizations (NGOs), namely religious and labor groups. The medical-industrial complex in particular and corporate-civil society relations in general in the United States are much less democratic largely because of the lower levels of mobilization by trade unions and other NGOs. Government agencies in the United States can learn from other nations and begin to implement policies that leverage the power of the state and NGOs in ways that bring a greater balance among the stakeholders in the medical-industrial complex.

Issues Raised by the Medical-Industrial Complex
Commodification. Commercialization, proprietarization, and monetarization are terms used to describe an increasingly salient dynamic in the medical-industrial complex: the potentially distorting effects of money, profit, and market rationality as a (if not *the*) central determining force in health care. After three decades devoted to market rhetoric, cost containment, and stunning organizational rationalization, the net result is the complete failure of any of these efforts to stem the swelling tide of problems of access and cost. For example, while national health care expenditures make up around 15 percent of the GDP, the number of uninsured

Americans was fully 43.4 million, or 16.1 percent of the population in 1997—the highest level in a decade (Kuttner 1999). Moreover, there are alarming increases in the uninsured population among African-Americans, Latinos, and the middle class (Carrasquillo et al. 1999). Of those Americans who do have insurance, a recent study found that the number of persons insured by the private sector is much less than previously believed. While many studies had estimated that 61 percent of the insured received coverage through the private sector, Carrasquillo and colleagues (1999) found that the public sector subsidizes much of this coverage so that, in fact, only 43 percent of the population receives insurance through the private sector. Thus, not only is the burden on the state greater than previously thought because of this subsidy to the private sector, but the general decline in private insurance coverage will also produce further strains on the government's budget.

The rapidly growing health care industry is creating strains on the economic system while it also is creating a financial burden on government, business, and individuals through their payments for health services. These strains are occurring simultaneously when, in 1999, a huge federal deficit has been turned into a surplus, an event of historic significance. The budget surplus has produced a combination of euphoria and vigorous debate over what the government should do with it. This surplus emerged against the backdrop of an unusually high economic growth rate and strong general U.S. economy as we enter the new millennium. Responses to these deficit strains and fluctuations have included cutbacks in services and reimbursements; cost shifts onto consumers; and alterations in the structure of the health care system itself to accord better with a competitive, for-profit model. The competition model as a prescription for the nation's health-care woes has restricted access to health care and raised questions of quality of care (Bond and Weissman 1997; Harrington 1996; Kassirer 1997). Cost shifting to consumers is increasingly limiting access to needed services for those with less ability to pay. Managed care has not delivered the cost savings it promised, and the Health Care Financing Administration acknowledges that Medicare does not benefit from cost reductions from HMO enrollment of elders due to continuing adverse risk selection (DePearl 1999).

The juxtaposition of the commercial ethos familiar in fast-food chains with health care collides with traditional images of medicine as the embodiment of humane service. Investor-owned health care enterprises have elicited a number of specific criticisms. It has been argued that commercial considerations can undermine the responsibility of doctors toward their patients; can lead to unnecessary tests and procedures; and, given other financial incentives, can lead to inadequate treatment. The interrelationships among physicians and the private health care sector, particularly for-profit corporations, raises many issues about the effects on quality of care and health care utilization and expenditures. Many have argued that the potential for abuse, exploitation, unethical practices, and disregard of fiduciary responsibilities to patients is pervasive (Iglehart 1989). Legislation has even been introduced in Congress that would prohibit physicians from referring patients to entities in which they hold a financial interest and from receiving compensation from entities to which they refer patients (Iglehart 1989). In the late 1990s several versions of a "patient's bill of rights" were considered at the state and federal levels of government.

Critics of for-profits argue that such ownership drives up the cost of health care, reduces quality, neglects teaching and research, and excludes those who cannot pay for treatment. Opponents of the market model for health care reflect diverse interests, including members of the medical profession seeking to preserve their professional autonomy, advocates for access to health care for the poor and uninsured, those concerned about the impact of profit seeking on quality of care, and many others. As government and business attempt to restrain health care spending, cutting into profits and forcing cost reductions, these concerns intensify.

The medical-industrial complex is an inherently fascinating topic for sociological analysis because it underscores many of the less obvious dimensions of health care. Profits, power, and market control are not terms that have traditionally come to mind when the average person in the United States talked about their health care provider (although this is changing as we observe the managed-care "backlash"). Yet, these are some of the primary goals of those organizations administering our medical care. Sociology itself arose as

an effort to wrestle with the myriad social impacts of nineteenth century industrialization (Durkheim [1893] 1984; Marx [1867] 1976). Early sociologists were especially concerned about how changes in communities were created by industrial production. Over the last century, sociologists have maintained a particular interest in the connection between advanced capitalism and the emergence of specific types of work, formal organizations, political systems, families, and cultural beliefs. An examination of the medical-industrial complex is therefore one of the more recent attempts to refocus core sociological questions about community, power, stratification, and social change.

Underlying this early sociological research on the impact of industrialization was an interest in power. How does power get accumulated and applied in a market-based society? How does it get distributed unevenly to social groups? To what ends do empowered social groups apply their power? One school of thought has been that industrial production skews power to an elite class (Domhoff 1998; Gramsci [1933] 1971). Max Weber's theory of bureaucracy, for example, suggested that this was an organizational form that pervades all social institutions. Its emphases on rationality, efficiency, predictability, calculability, and control (Weber [1921] 1961) were in part seen as a social advance over arbitrary religious, charismatic, and personalized forms of authority. Later analysts of bureaucracy, in contrast, saw this formalization of organizations as a dehumanizing and antisocial mechanism.

Issues for sociological investigation include the systematic identification of the ways in which the new commercial practices and organization of health care affect health care delivery. Organizational studies are needed to disentangle the effects of organizational characteristics (e.g., tax status and system affiliation) on the outcomes of equity, access, utilization, cost, and quality of care. The effects on provider-patient interactions of these structural and normative changes in health care require investigation as well. A general sociological theory of the professions will emerge from understanding the ways in which the dominant medical profession responds to the ongoing restructuring of health care and accompanying challenges to its ability to control the substance of its own work, erosions in its monopoly over medical knowledge, diminishing authority over patients

resulting from health policy changes, major technological and economic developments, and changes in the medical-industrial complex. Finally, sociologists must confront the coming biotechnological revolution and its impacts on society, human health, and the environment. The corporatization of health care and health-related research and the medical industrial complex are topics of great interest to scholars studying social movements, organization behavior, stratification, health and illness, and science and technology.

MENTAL ILLNESS AND MENTAL DISORDERS

After years of empirical research and theoretical activity, social scientists still do not agree about what mental illness actually is, let alone about what its primary causes are or about the efficacy of various treatments. Sociologists disagree about whether or not mental disorder is truly a disease that some people have and other people do not have, thus fitting a medical model of health and illness. They disagree about the relative importance of genetics, biochemical abnormalities, personality characteristics, and stress in the onset and course of psychiatric impairment. Most sociologists do, however, agree that definitions of mental illness are shaped by the historical, cultural, and interpersonal contexts within which they occur. They argue that the significance of any particular set of psychological or behavioral symptoms to a diagnosis of mental disorder lies in part with the actor and in part with the audience. Given this understanding of mental illness, sociologists are often as interested in understanding the consequences of being labeled mentally ill as they are in understanding the causes. Sociologists do, indeed,

study the social distribution and determinants of mental disorder. However, they also study social reactions to mental illness and the mentally ill and investigate ways in which mental health professionals and institutions can come to serve as agents of social control.

CLASSIFICATION AND DIAGNOSIS

Although psychiatrists themselves have difficulty defining mental illness, the official system for classifying and diagnosing mental disorder in the United States is produced by the American Psychiatric Association (APA). It is known as the *Diagnostic and Statistical Manual of Mental Disorder* (DSM) and was first published in 1952. In its earliest form, DSM-I included a list of 60 separate mental illnesses. By the second edition in 1968, psychiatric definitions of mental illness had changed so markedly that 145 different types of mental disorder were included. Despite the attempt in DSM-II to define the parameters of mental illness more precisely, critics from inside and outside psychiatry pointed out that diagnoses of mental disorder were extremely unreliable. When different psychiatrists independently used DSM-II to diagnose the same patients, they did so with substantially different results. Studies conducted during the 1960s and 1970s indicated that there was poor agreement about what disease classification was appropriate for any given patient; studies also found that clinicians had difficulty in differentiating normal persons from mental patients and that they frequently disagreed about prognosis and the clinical significance of particular symptom patterns (Loring and Powell 1988).

After years of debate, some of which was quite heated, the APA published a third edition of DSM in 1980. *Mental disorder* was defined in DSM-III as "a clinically significant behavioral or psychological syndrome or pattern that occurs in an individual and that is associated with either a painful symptom (distress) or impairment in one or more areas of functioning (disability)" (APA 1980, p. 6); deviant behaviors and conflicts between individuals and society were specifically excluded from this definition *unless* they were symptoms of another diagnosable disorder. DSM-III took a purely descriptive approach to diagnosis, outlining the essential and associated features of each disorder but making no attempt to explain the etiology of

either symptoms or illnesses. At the time of the most recent revision (DSM-IV) in 1994, there was considerable debate about whether or not to actually retain the phrase “mental disorder” in the title of the DSM. The argument was that doing so implied a false distinction between mind and body, and between mental disorders and physical or general medical conditions. For lack of a better term, however, DSM-IV retained the same terminology and definition of mental disorder that had been used in DSM-III. DSM-IV contains hundreds of mental diagnoses, including such disorders as caffeine intoxication, circadian rhythm sleep disorder, and hypoactive sexual desire disorder. It also contains a section on “other conditions that may be a focus of clinical attention” but that are not mental disorders themselves. Included here are such conditions as relational problems connected with a family member’s mental disorder, noncompliance with treatment, religious or spiritual, academic, occupational, acculturative, and phase-of-life problems.

The use of DSM-III and DSM-IV criteria has vastly improved the overall reliability of psychiatric diagnoses, thereby enabling psychiatry to meet one of the major criticisms of the medical model of mental disorder. The inclusion of more and more categories of illness in each succeeding version of DSM has led to more precise and consequently more reliable diagnoses. However, some scholars have argued that this expansion of mental diagnoses has less to do with problems of disease classification than with “problems” of third-party reimbursement (Kirk and Kutichins 1992; Mirowsky and Ross 1989). Each increase in the number of disorders listed in DSM has increased the scope of psychiatric practice. As the number of patients with recognized illnesses increases, so too does the amount of compensation that psychiatrists receive from insurance companies.

Even the firmest supporters of DSM-IV recognize that the classification of mental disorder is influenced by nonmedical considerations. In fact, DSM-IV itself includes a discussion of specific culture, age, and gender features which should be taken into account for each diagnosis. Pressures from outside psychiatry also influence diagnostic classifications. In order to reduce their payment liabilities, insurance companies have lobbied the APA to reduce the number of diagnoses. Changes in public attitudes toward sexual preference issues

led, in 1974, to dropping homosexuality from the list of mental disorders, and veterans’ groups successfully pressed for the inclusion of posttraumatic stress syndrome (Scott 1990). The storm of controversy that surrounds the issue of whether premenstrual syndrome is a medical or a psychological condition, or whether it is socially unacceptable behavior, is another example of the intersection of political, social, economic, and diagnostic concerns (Figert 1994); at the insistence of feminists inside and outside psychiatry, premenstrual dysphoric disorder has been relegated to an appendix of DSM-IV on the basis that there is currently little scholarly evidence to support such a diagnosis and that its social implications dangerously feed “the prejudice that women’s hormones are a cause of mental illness” (Tavris 1993, p. 172). In sum, there is a less than perfect correspondence between some disease-producing entity or syndrome and the diagnosis of mental disorder; psychiatric diagnosis is based partly in the reality of disordered behavior and emotional pain, and partly in the evaluations that society makes of that behavior and pain. Thus, questions about the validity of psychiatric diagnosis are as troubling for DSM-IV as they were for DSM-I. As one observer has noted, “We have learned how to make reliable diagnoses, but we still have no adequate criterion of their validity” (Kendell 1988, p. 374). Given the problems scholars have in defining “mental disorder” and given the validity problems that ensue, it is not surprising that epidemiologists have used a number of different strategies to estimate rates of psychiatric impairment. These different research methodologies often have led to quite different interpretations of the role of social factors in the etiology of mental illness.

MEASUREMENT

The earliest sociological research on mental disorder relied on data from individuals receiving psychiatric care. In a classic epidemiological study, Faris and Dunham (1939) reviewed the records of all patients admitted to Chicago’s public and private mental hospitals between 1922 and 1934. They found that admission rates for psychosis were highest among individuals living in the inner city. Several years later, researchers used a similar design to study the social class distribution of mental disorder in New Haven. In contrast to the

Chicago study, which focused only on individuals who had been hospitalized, Hollingshead and Redlich (1958) included individuals receiving outpatient care from private psychiatrists in their study. Results from the New Haven study confirmed the earlier findings; the lower the social class, the higher the rate of mental disorder. More recent studies have also used information on treated populations. Studies of patient populations provide useful information to be sure; findings shed light on the social factors that influence the course of mental health treatment. Individuals receiving treatment for mental disorder, however, are not a random subset of the population of individuals experiencing psychological distress. Everybody who has potentially diagnosable mental disorder does not receive treatment. Furthermore, pathways to mental health care may be systematically different for individuals with different social characteristics. Consequently, research based on treated rates of mental disorder seriously underestimates the true rate of mental illness in a population. (In 1994 the Institute of Medicine Committee on the Prevention of Mental Disorders estimated, for instance, that only 10–30 percent of those with a mental disorder receive any treatment.) Furthermore, such research may confuse the effects of variables such as social class, gender, place of residence, and age on psychiatric treatment with the impact of those same variables on the development of psychiatric impairment.

An alternative strategy for studying the epidemiology of mental disorder is the community survey. Early studies such as the Midtown Manhattan study (Srole et al. 1962) used symptom checklists with large random samples to estimate the amount of psychiatric impairment in the general population. Although such studies provided less biased estimates of the prevalence of psychological distress than did research on patient populations, they were subject to a different set of criticisms. The most serious limitation of the early community studies was that they used impairment scales that measured global mental health. Not only did the scales fail to distinguish different types of disorders, they confounded symptoms of physical and psychological disorder (Crandall and Dohrenwend 1967), measured relatively minor forms of psychiatric impairment, and frequently failed to identify the most serious forms of mental illness (Dohrenwend and Crandall 1970). Since it

was not clear what relationship psychological symptom scales bore to cases of actual psychiatric disorder, it was also not clear how results from those studies contributed to an understanding of the social causes of mental illness.

Since the early 1980s, symptom scales that measure specific forms of impairment have largely replaced the early global scales with the consequence that the reliability and validity of community survey research has been vastly improved. The CES-D, for instance, is a twenty-item depression scale that can accurately distinguish clinical from normal populations and depression from other psychiatric diagnoses (Weissman et al. 1977). Consistently with the overall improvement in diagnostic reliability that has accompanied the development of DSM-III and DSM-IV, methods have been developed that provide reliable psychiatric diagnoses of many disorders among community residents. The most widely used diagnostic instrument of this sort was developed by a team of researchers at Washington University as part of the National Institute of Mental Health (NIMH) Division of Biometry and Epidemiology's Catchment Area Program. Called the Diagnostic Interview Schedule (DIS), the instrument can be administered by nonpsychiatrists doing interviews with the general population. Using DSM-IV criteria, it provides both current and lifetime diagnoses for many adult psychiatric disorders (Eaton et al. 1985). Enormous amounts of time and money have been devoted to the development of the DIS, and research that makes use of it promises to provide a vital link between studies of clinical and community populations. Nevertheless, even instruments like the DIS have shortcomings.

Mirowsky and Ross (1989) have challenged the DIS and the DSM upon which it is based on the grounds that psychiatric diagnosis is a weak form of measurement and that it is of questionable validity. These authors claim that psychiatric disorders are dimensional, not categorical. By collapsing a pattern of symptoms into a single diagnostic case, valuable information is lost about the nature of the disorder. As a result, the causes of mental, emotional, and behavioral problems are obscured. Mirowsky and Ross go on to suggest that the reliance on diagnosis does not give a true, that is, a valid, picture of psychiatric distress. Instead, psychiatrists use diagnosis because it allows them to

receive payment from insurance companies who will pay only for cases and because it establishes mental distress as a problem that can be treated only by a physician. Although their criticisms are harsh, these authors reestablish the important distinction between the social construction of psychiatric diagnoses and the social causes of psychological pain. It is the latter issue, however, that most sociological research has addressed.

THE EPIDEMIOLOGY OF MENTAL DISORDER

Socioeconomic Status. The inverse relationship between socioeconomic status and mental disorder is now so well established that it has almost acquired the status of a sociological law. The relationship is surprisingly robust; it holds for most forms of mental disorder, no matter how socioeconomic status is measured, and for both patient populations and community samples. The relationship is strongest and most consistent for schizophrenia, personality disorders, and medically based syndromes. Findings for the major affective disorders are somewhat less consistent. Studies tend to report weak to moderate inverse relationships between social class and the incidence of major affective disorders such as anxiety and depression (Kessler et al. 1994). However, studies sometimes report no relationship (Weissman et al. 1991) or a positive class gradient (Weissman and Myers 1978). Evidence on the class distribution of minor depression is more clear-cut, with studies almost universally showing higher levels of depressive symptomatology among the lower strata. Similarly, research consistently shows that the highest levels of general distress are also found among those with the lowest income, education, or occupational status.

There are two general qualifications to the pattern outlined above. First, even though socioeconomic status is negatively associated with most types of mental disorder, the relationship is probably not linear. Extremely high rates of disorder are typically found in the lowest stratum. Higher strata do have progressively lower rates, but variation is considerably less between them than between the lowest and next-to-lowest tier. Some scholars have claimed, therefore, that serious mental illness is primarily an underclass phenomenon. Second, the inverse relationship between social

class and mental disorder may be stronger in urban than in rural areas and is probably stronger in the United States than in other societies. (For a comprehensive review of this literature, see Ortega and Corzine 1990.)

Most, if not all, of the major sociological theories of mental illness begin with the empirical observation that psychological disorder is most prevalent among those individuals with the fewest resources and the least social power. Until recently, researchers focused almost exclusively on one dimension of inequality—social class. Indeed, the dominant paradigms in the sociology of mental health have derived primarily from the attempt to explain this relationship; hypotheses regarding the effects of gender, age, or marital status on psychological distress are often simple elaborations of models derived from the study of social class and mental disorder. Three general models of the relationship between social resources and mental illness have been suggested. These are (1) the “social causation” hypothesis; (2) the “social selection” or “drift” hypothesis; and (3) the “labeling” or “societal reaction” approach.

Social Causation. *Social causation* is a general term used to encompass a number of specific theories about the class-linked causes of mental disorder. Perhaps the most common version of social causation explains the higher rates of mental disorder among the lowest socioeconomic strata in terms of greater exposure to stress. According to this perspective, members of the lower class experience more stressful life events and more chronic strains (Turner et al. 1995). In addition, they are more likely to experience physical hazards in the environment, blocked aspirations, and status frustration (Cockerham 1996). Taken together, these stresses produce elevated rates of psychiatric impairment. In another version of social causation, scholars have argued that class differences in coping resources and coping styles are at least as important in the etiology of mental disorder as are class differences in exposure to stress (Pearlin and Schooler 1978). In this view, poverty increases the likelihood of mental illness because it (1) disrupts precisely those social networks that might effectively buffer the effects of stressful events and (2) inhibits the development of an active, flexible approach to dealing with problems. For both social and psychological reasons, then,

the lower classes make use of less effective coping strategies. Finally, part of the class difference in mental disorder, especially rates of treated disorder, may stem from class differences in attitudes toward mental illness and psychiatric care. Because of more negative attitudes toward mental illness and because of inadequate access to appropriate psychiatric care, the lower classes may be more seriously ill when they first come in contact with the mental health care system, and thus they may be more likely to be hospitalized (Rushing and Ortega 1979).

Social Selection and Drift. This perspective implies that, rather than causing mental disorder, low socioeconomic status is a result of psychological impairment. Two mobility processes can be involved. According to the drift hypothesis, the onset of mental disorder adversely affects an individual's ability to hold a job and generate income. As a result of psychological disorder, then, individuals experience downward intragenerational mobility and physical relocation to less socially desirable neighborhoods (Eaton 1980). Social selection, on the other hand, occurs when premorbid characteristics of the mentally disordered individual prevent him or her attaining as high a social status as would be expected of similar individuals in the general population. Here, the focus is on intergenerational mobility (Kendler et al. 1995).

Labeling or Societal Reaction. Based on the work of Thomas Scheff (1966), this approach holds that much of the class difference in mental disorder stems not from any real difference in mental illness but rather from a tendency to diagnose or label a disproportionate number of lower-class individuals as psychologically impaired. According to Scheff, the process works as follows. Psychiatric symptoms have many different causes and many people experience them. Only a few individuals, however, are ever labeled as mentally ill. People who are so labeled are drawn from the ranks of those least able to resist the imputation of deviance. Once an individual is identified as mentally ill, a number of forces work to reinforce and solidify a mentally ill self-identity. Once labeled, individuals are encouraged by family and mental health professionals to acknowledge their illness. They are rewarded for behaving as "good" patients should, a task made easier by virtue of the fact that individuals learn the stereotypes of mental illness in early childhood. When individuals are

discharged from the mental hospital, or when they otherwise terminate treatment, they may be rejected by others. This rejection has psychological consequences that simply reinforce a mentally ill identity. The process is self-fulfilling, leading Scheff to conclude that attachment of the mentally ill label is the single most important factor in the development of chronic mental disorder.

An Assessment. After two decades or more of acrimonious debate, the search for unitary explanations of the relationship between mental disorder and social class has largely been abandoned. Sociologists seldom claim that mental illness is derived only from medical factors, is caused only by features of the social environment, or stems purely from societal reaction. Most scholars now believe that different types of disorders require different types of explanations. Genetic and other biomedical factors are clearly involved in schizophrenia, and certain forms of depression. However, genetics, brain chemistry, and other medical factors do not provide the entire answer since, even among identical twins, concordance rates for mental illness fall only in the range of 30 to 50 percent. Thus, the causes of mental disorder must also be sought in the social environment. Research does suggest a modest relationship between the social stressors attendant to lower-class status and the onset of some forms of mental disorder. The evidence is clearest, however, for anxiety, substance abuse, and relatively minor forms of depression or psychological distress. For the more severe forms of mental illness and for conduct disorders, the drift and selection hypothesis appears to have the most empirical support. (See Miech et al. 1999 for a comprehensive review and data bearing on these points.) Although labeling is not the only cause of chronic mental illness, it is clear that the mental illness label does have negative consequences. In what has come to be called modified labeling theory, researchers have demonstrated that the status of ex-mental patient and the discrimination that follows from it, coupled with the ex-patient's expectation of rejection by others, adversely affects earnings, work status, and subsequent mental health (Link 1987; Markowitz 1998). Thus, labeling is one of the processes through which drift occurs. As researchers continue to refine the definitions and measurement of various mental disorders and as they more clearly delineate the processes of social causation, drift, and

labeling, it is likely that further theoretical convergences will be identified.

Gender. It is not yet clear whether there are significant gender differences in overall rates of mental illness. There is little doubt, however, that certain types of disorders occur more frequently among women than among men. Research clearly shows that women are more likely to suffer from major and minor depression and anxiety than are men (Kessler et al. 1994); men, however, are usually found to have higher rates of antisocial personality disorders and the various forms of substance abuse and dependence (Aneshensel et al. 1991). The sex ratio for some forms of mental disorder may be age dependent; males have higher rates of schizophrenia prior to adolescence and females have higher rates in later adulthood (Loring and Powell 1988). Studies also find that male-female differences in levels of depression are most pronounced among young adults (Dean and Ensel 1983). Furthermore, gender effects appear to interact with those of marital, occupational, and parental roles.

Scholars continue to disagree about the precise form of the interaction effects of gender and marital status on mental illness. Virtually all studies report that gender differences are most pronounced among married persons; married women consistently show higher levels of depression and anxiety than married men. Evidence on the unmarried, however, is mixed. Research based on treated populations often finds higher rates of disorder among single men. Studies based on community samples more frequently report higher distress levels among unmarried women. The interaction between gender and marital status is further complicated by the presence of children, work outside the home, or both.

Some research on married persons finds that gender differences are reduced when both husbands and wives are employed. Studies comparing groups of women often find that employment has modest, positive effects on mental health. However, other studies report no difference between employed women and housewives (Carr 1997) and a few report that married, full-time homemakers with children have fewer worries and more life satisfaction (Veroff et al. 1981). These apparently contradictory findings stem, in part, from the

different measures of mental health and illness used. It is possible, for instance, that small children can simultaneously increase their mothers' life satisfaction and their overall levels of anxiety and distress. However, two substantive factors also appear to be involved. First, it is the demands created by children and employment, rather than by parental or employment status per se, that cause elevated levels of distress among married women (Rosenfeld 1989). The level of demands varies, of course, depending upon the level of male responsibility for child care and housework. Second, employment decreases gender differences in distress only when it is consistent with both the husband's and the wife's desires. Married men's distress levels may, in fact, surpass married women's when wives work but their husbands prefer them not to (Ross et al. 1983).

As is true for social class, explanations for gender differences in mental disorder fall into three broad classes: social causation, social selection, and labeling. Because of the consistency of gender effects (at least for depression and anxiety) and improvements in the reliability of psychiatric diagnoses, most recent work has focused on the ways in which the social and psychological correlates of male and female roles cause variation in rates of mental disorder. Some have argued that differences in sex-role socialization make females more likely to direct frustration inward, toward themselves, rather than towards others, as males might. Thus, women are more likely to develop introjective disorders, whereas men are more likely to behave in antisocial ways (Loring and Powell 1988). Others have argued that women are more attached to others and are more sensitive to others' needs than are men. As a result, not only is women's mental health influenced by their own experiences but, also in contrast to men, they are more psychologically vulnerable to the stresses or losses of loved ones (Kessler and McLeod 1984). Although the empirical literature is far from clear on this point (cf. Umberson et al. 1996), according to this perspective, women experience more stressful events and are more psychologically reactive to them than are men. Other explanations—for both direct and interactive effects—of gender on mental illness have focused on male-female differences in power, resources, demands, and personal control. Insofar as employment increases women's

power and resources, it is likely to have positive effects on mental health. Well-educated employed women have fewer mental symptoms than nonworking women; among working-class and lower-class women, however, employment may actually increase anxiety and depression because it elevates demands at the same time that it produces only marginal increases in resources (Sales and Hanson Frieze 1984). Since employed women generally retain full responsibility for children, the demands of caring for children, particularly those under the age of 6, exacerbate work-related stress. Thus, male-female differences in power and resources produce differences in ability to control demands. Gender differences in control, in turn, shape perceptions of personal mastery; personal mastery is the psychological mechanism that connects gender differences in resources and demands to gender differences in mental illness (Rosenfield 1989).

The social selection perspective is valid only for explaining male-female differences in the relationship between marital status and mental disorder. The argument is that mental illness is more likely to select men out of marriage than women. (See Rushing 1979 for a related discussion.) According to this perspective, male forms of mental disorder—psychosis and antisocial personality, for example—prevent impaired men from satisfactorily discharging the traditional male obligation to be good economic providers, making them ineligible as marriage partners. In contrast, female forms of psychiatric impairment may go undetected for long periods of time and may not seriously interfere with a woman's ability to fulfill the traditional housekeeping role. Thus, the higher rates of female disorder among the married may be a partial artifact of the differing probabilities of marriage for mentally disordered men and women.

The labeling explanation for male-female differences in psychiatric impairment begins by challenging the notion that women actually experience more symptoms and disorders than men do. Labeling theorists argue that women are overdiagnosed and overmedicated because of biases on the part of predominantly male psychiatrists and because of the male biases inherent in psychiatric nomenclature. Coupled with the greater willingness of females to admit their problems and to seek help for them, these biases simply

produce the illusion that women are more likely to be disordered than men. Scholars using the labeling–societal reaction–critical perspective argue that the effects of gender biases are not benign and that they have consequences at two levels. First, individual women are unlikely to receive appropriate services for their real mental health problems. Second, and at a societal level, critics argue that psychiatry simply legitimates traditional gender roles, thereby buttressing the status quo (Chesler 1973).

A Theoretical Assessment. With the development of DSM-IV and with increases in the number of female mental health professionals, concern over the issues raised by labeling theorists has diminished somewhat. Trusting that the most blatant instances of sexism have been eliminated, researchers have turned their attention toward specifying the social psychological dynamics of the gender–mental health equation; considerable progress has been made in elucidating the circumstances under which women are most likely to experience symptoms of mental disorder. Nevertheless, it may be premature to close the question of gender bias in psychiatric disorders. In one study, male clinicians appeared to overestimate the prevalence of depressive disorders among women, a tendency that is certainly consistent with gender stereotypes. In the same study, black males were most likely to be diagnosed as paranoid schizophrenics, a view consistent with both gender and racial stereotypes (Loring and Powell 1988). In yet another study, male and female psychiatrists made similar diagnoses of male and female patients presenting severe Axis I conditions but made significantly different diagnoses for male and female patients with Axis II conditions, such as personality disorders (Dixon et al. 1995). Thus, advances of DSM-III (and IV) notwithstanding, the authors of these studies conclude that sex and race of client and psychiatrist continue to influence diagnosis even when psychiatric criteria appear to be clear-cut.

Age. Among adults, and with the exception of some types of dementia and other syndromes due to general medical conditions, rates of mental illness decrease with age. Rates of schizophrenia, manic disorder, drug addiction, and antisocial personality all peak between the ages of 25 and 44 (Robins et al. 1984). Furthermore, an older person

with a serious mental disorder is likely to have had a first psychiatric episode in young or middle adulthood. At least 90 percent of older schizophrenics experienced the onset of the disorder in earlier life. Similarly, about two-thirds of older alcoholics have a long history of alcohol abuse or dependence (Hinrichsen 1990). Depression is the disorder most likely to occur among the elderly, and a substantial proportion of older community residents do report some of its symptoms. In general, the relationship between age and depression appears to be curvilinear, with depression lowest among the middle aged, higher among younger and older adults, and highest among the oldest (Mirowsky and Ross 1992). Nevertheless, relatively few of these older individuals meet criteria for clinical depression (Blazer et al. 1987), and rates of major depression are lower among older adults than in younger age groups. Some older persons, however, are more vulnerable to depression than others. As is true throughout the life cycle, women, individuals with health problems, the unmarried, and those with lower socioeconomic status are at greater risk of depression in late life than their peers. Estimating the true prevalence of depression among the elderly is especially problematic because its symptoms are frequently confused with Alzheimer's disease or other forms of dementia.

According to some estimates, two to four million older Americans suffer some form of mental disorder due to a general medical condition. Of these, roughly half are diagnosed with Alzheimer's, a disease that involves an irreversible, progressive deterioration of the brain. Approximately half of all nursing home residents are estimated to suffer from some form of dementia. Because there is no known treatment for most of these disorders, older mental patients receive little psychiatric care. Critics suggest, however, that many older persons are improperly diagnosed as having disorders of general medical origin. A sizable minority may actually be depressed; others may have treatable forms of dementia caused by medications, infection, metabolic disturbances, alcohol, or brain tumors. In some instances, then, the stereotype that senility is a concomitant of the aging process prevents appropriate diagnosis, intervention, and treatment.

Most explanations of the age-mental health relationship have focused on specific age groups.

Clinicians suggest, for instance, that anxiety and depression in middle age are a consequence of hormonal change or of changes in family and occupational roles. The personality disorders of young adulthood are often explained in terms of the stresses produced by the transition from adolescence to full adult roles. Among the elderly, explanations have focused on either organic or environmental factors. The dementias have recognized organic causes. Although neither is a normal part of the aging process, the two major causes of these disorders are (1) the deterioration of the brain tissue that is associated with Alzheimer's disease and (2) cerebral arteriosclerosis. However, environmental factors also contribute to the onset of the dementias. They do so, in part, by increasing the likelihood of stroke or heart attack. In contrast, primary mental disorders, such as depression, personality disorders, and anxiety, depend more directly upon environmental factors. Some types of depression appear to have a genetic component, but the genetic link appears to be stronger in early- than in late-onset cases. Individuals who have their first episode of clinical depression prior to the age of 50, for instance, are more likely to have relatives with depression than those who become depressed in later years (Hinrichsen 1990). Consequently, losses typical of late life—losses of health, occupation, income, and loved ones—appear to be the primary causes of mental health problems among older adults.

Clearly, no single theory can adequately explain the etiology of mental disorder; at each stage of the life cycle, variables that are relevant to the onset of one type of disorder may be insignificant in the onset of other illnesses. Similarly, no single variable or set of variables is likely to explain age differences in overall rates of mental disorder. Nevertheless, efforts are under way to systematically explain the inverse relationship between age and primary psychiatric impairment. Gove and his associates have suggested that psychological distress decreases with age because individuals are able, over time, to find and settle into an appropriate social niche; as individuals move through life, they become less emotional and less self-absorbed, function more effectively in their selected roles, and generally become more content with themselves and with others. As a result, rates of mental disorder decrease from late adolescence through late life (Gove 1985; Gove et al. 1989).

Place of Residence. Sociologists have commonly assumed that rates of mental disorder are higher in urban than in rural areas. However, this assumption is based more on the antiurban bias of much sociological theory than it is on empirical research. In a thoughtful and systematic review, Wagenfeld (1990) has argued that there is little evidence in the mental health literature to suggest the superiority of rural life. In several of the rural community studies Wagenfeld cites, researchers report a “probable” case rate of depression and anxiety of 12 to 20 percent. Studies that explicitly compare rural and urban communities generally find that rates of psychosis are higher in rural communities and that rates of depression are somewhat higher in urban areas. Residents of metropolitan communities also appear more likely to have multiple diagnoses than do rural residents, leading Kessler et al. (1994) to conclude that urban-rural differences in the prevalence of mental disorder probably reflect differences in comorbidity rather than differences in rates of individuals having a psychiatric condition. Differences in case definition and diagnosis, differences in how “rural place of residence” is defined and measured, and differences in the time period during which studies were conducted make it difficult, overall, to assess whether rural communities have significantly higher overall rates of pathology than urban areas. Results are sufficient, however, to suggest that rural life is not as blissful as it is often claimed to be. Recent declines in the rural economy, the out-migration of the young and upwardly mobile, and the relative paucity of mental health services are likely to be major contributing factors in the etiology of rural mental health problems.

Other factors. Epidemiologists have also explored the relationships between the incidence or prevalence of mental disorder and such variables as race and ethnicity, migration, social mobility, and marital status. In each case, results generally support the view that individuals with the fewest resources—both economic and social—are most likely to experience psychiatric impairment. However, most research has adopted a rather static view; few studies have assessed the extent to which relationships between each of these variables and mental disorder have changed over time. Given the significant changes in diagnostic practices and in the mental health professions over the last decades, this is a striking omission.

AN AGENDA FOR FUTURE RESEARCH

Since the early 1960s, psychiatric sociology has undergone enormous changes. During the 1960s and 1970s, much of the literature was sharply critical of psychiatry and of medical models of madness. Although sociologists were divided about the relative importance of labeling processes in the etiology of mental illness, most agreed that psychiatric diagnoses were unreliable and were influenced by social status and social resources, that long-term institutionalization had detrimental effects, and that at least some patients were hospitalized inappropriately. Such criticisms provided one impetus for the substantial change that took place in psychiatric care during the same period; laws were changed to make involuntary commitment more difficult; steps were taken to deinstitutionalize many mental patients; and a major effort was made to improve the reliability of mental diagnoses. By the time DSM-III was published in 1980, the most flagrant abuses and the sharpest criticism of psychiatry seemed to have disappeared. Consequently, many sociologists shifted their attention from concerns about the lives of people with serious mental disorder to the social correlates of psychological distress among the general population (Cook and Wright 1995). Using what is basically a medical model of impairment, researchers have focused on delineating the relationship between social variables (such as gender, age, race, social class, place of residence, life events, and stress) and specific diagnoses (most often depressive symptoms, anxiety, and substance abuse). Indeed, the psychiatric view of mental disorder is so well established in sociology that the growing literature on homelessness has generally accepted the assertion of mental health professionals that most of the homeless are simply individuals who have fallen through the cracks of the mental health care system. (For notable exceptions, see Bogard et al. 1999; Snow, Baker, and Anderson 1986.) It is surprising that sociologists have been so uncritical in their acceptance of this position; it is also surprising that in the decade of the 1990s, declared by the National Institute of Mental Health to be the “Decade of the Brain,” they have been so ready to accept the view that mental illness is primarily a problem of genetics or brain chemistry and that it can be treated just like any other disease. It is certainly true that enormous strides have been made in the diagnosis and psychopharmacological

treatment of mental disorder. It is also certainly true that biomedical factors are causally involved in some types of mental illness. Sociologists must, therefore, continue their efforts to develop a model of mental disorder that integrates medical, psychological, and social factors.

As some critics point out, however, the current emphasis on diagnoses, cases, and the medical model of mental illness has limitations. Acceptance of the psychiatric view of mental disorder leads to the acceptance of policy recommendations that are not yet firmly grounded in empirical research. It is far from clear, for instance, that deinstitutionalization of the mentally ill is the primary cause of homelessness in America. As Bogard et al. (1999) point out, conventional wisdom notwithstanding, very few homeless mothers are mentally ill; it can be reasonably argued, then, that the enormous resources that have been directed toward providing them with mental health care might more appropriately and effectively be used to provide safe, affordable housing. In a similar vein, Link and Phelan (1995) note that current attention to individual risk factors in disease gives rise to "personal policy" recommendations that leave totally unaddressed the fundamental social conditions that cause differential exposure to risk.

Furthermore, few studies have assessed the extent to which changes in psychiatric diagnosis or changes in the civil rights guarantees of mental patients have affected the delivery and quality of mental health services. Consumers and families have voiced concern that the powerful new psychopharmacological drugs are being inappropriately used as forms of social control and chemical restraint at the same time that research continues to show that it is racial and ethnic minority consumers who are most likely to be so restrained (Cook and Wright 1995). Aside from the field trials used in their formulation, few studies have assessed the reliability and validity of DSM-IV diagnoses. However, results from several studies show that nonclinical factors such as gender, race, the availability of viable community housing and the presence of reliable caretakers significantly affect not only diagnosis but treatment protocols and outcomes. (See Cook and Wright [1995] for a review of these studies and these concerns.) It is far from clear, then, that lower-class women are any more likely to receive

appropriate care in 1999 than they were in 1950 or 1970. It is unclear whether urban-rural differences in rates of mental disorder have changed over time and, if so, to what extent changes in diagnostic systems or service availability are implicated. Evidence that rural residents may actually experience mental illness at approximately the same rates as urban residents coupled with an acute shortage of rural mental health providers suggest the importance of understanding the diagnostic practices of primary-care physicians and of providing appropriate training to them.

Research in the next century must adopt a more dynamic or process view of mental health issues. The consequences of changes in psychiatric diagnosis, of the increased reliance on drug therapies, of changes in mental health law and policy, and in the availability of mental health services must be assessed. Changes in the mental health system must be linked to changes in the composition of the pool of "potential clients" and to issues regarding the development of gender, age, class, and culturally appropriate systems of care.

META-ANALYSIS

Meta-analysis is the practice of statistically summarizing empirical findings from different studies, reaching generalizations about the obtained results. Thus, "meta-analysis" literally refers to analysis of analyses. Meta-analysis, a term coined by Glass (1976), is also known as *research synthesis* and *quantitative reviewing*. Because progress within any scientific field has always hinged on cumulating empirical evidence about phenomena in an orderly and accurate fashion, reviews of studies have historically proved extremely influential (e.g., Mazela and Malin 1977). With the exponential growth in the numbers of studies available on a given social scientific topic, the need for these reviews has increased proportionally, meaning that reviews are potentially even more important each day. The empirical evidence, consisting of multiple studies examining a phenomenon, exists as a literature on

the topic. Although new studies rarely replicate earlier studies without changing or adding new features, many studies can be described as conceptual replications that use different stimulus materials and dependent measures to test the same hypothesis, and still others might contain exact replications embedded within a larger design that adds new experimental conditions. In other instances, repeated tests of a relation accrue in a less systematic manner because researchers sometimes include in their studies tests of particular hypotheses in auxiliary or subsidiary analyses.

In order to reach conclusions about empirical support for a phenomenon, it is necessary to compare and contrast the findings of relevant studies. Therefore, accurate comparisons of study outcomes—reviews of research—are at the very heart of the scientific enterprise. Until recently these comparisons were nearly always made using informal methods that are now known as *narrative reviewing*, a practice by which scholars drew overall conclusions from their impressions of the overall trend of the studies' findings, sometimes guided by a count of the number of studies that had either produced or failed to produce statistically significant findings in the hypothesized direction. Narrative reviews have appeared in many different contexts and still serve a useful purpose in writing that does not have a comprehensive literature review as its goal (e.g., textbook summaries, introductions to journal articles reporting primary research). Although narrative reviewing has often proved useful, the method has often proved to be inadequate for reaching definitive conclusions about the degree of empirical support for a phenomenon or for a theory about the phenomenon. One indication of this inadequacy is that independent narrative reviews of the same literature often have reached differing conclusions.

COMMON PROBLEMS WITH NARRATIVE REVIEWS

Critics of the narrative reviewing strategy (e.g., Glass et al. 1981; Rosenthal 1991) have pointed to four general faults that frequently occur in narrative reviewing: (1) Narrative reviewing generally involves the use of a convenience sample of studies, perhaps consisting of only those studies that the reviewer happens to know. Because the parameters of the reviewed literature are typically

not explicit, it is difficult to evaluate the adequacy of the definition of the literature or the thoroughness of the search for studies. If the sample of studies was biased, the conclusions reached may also be biased. (2) Narrative reviewers generally do not publicly state the procedures they used for either cataloging studies' characteristics or evaluating the quality of the studies' methods. Therefore, the review's claims about the characteristics of the studies and the quality of their methods are difficult to judge for their accuracy. (3) In cases in which study findings differed, narrative reviewing has difficulty in reaching clear conclusions about whether differences in study methods explain differences in results. Because narrative reviewers usually do not systematically code studies' methods, these reviewing procedures are not well suited to accounting for inconsistencies in findings. (4) Narrative reviewing typically relies much more heavily on statistical significance to judge studies' findings than on the *magnitude* of the findings. Statistical significance is a poor basis for comparing studies that have different sample sizes, because effects of identical magnitude can differ widely in statistical significance. Because of this problem, narrative reviewers often reach erroneous conclusions about a pattern in a series of studies, even in literatures as small as ten studies (Cooper and Rosenthal 1980).

As the number of available studies cumulates, the conclusions reached in narrative reviews become increasingly unreliable because of the informality of the methods they use to draw these conclusions. Indeed, some historical scholars have attributed crises of confidence in central social scientific principles to apparent failures to replicate findings across studies (e.g., Johnson and Nichols 1998). Clearly, there will be practical limitations on the abilities of scholars to understand the vagaries of a literature containing dozens if not hundreds of studies (e.g., by 1978, there were at least 345 studies examining interpersonal expectancy effects, according to Rosenthal and Rubin 1978; and by 1983, there were over 1,000 studies evaluating whether birth order is related to personality, as reported by Ernst and Angst 1983). From this perspective, the social sciences might be considered victims of their own success: Although social scientists have been able to collect a myriad of data about a myriad of phenomena, they were forced to rely on their intuition when it came to assessing

the state of the knowledge about popular topics. Since the 1980s, however, as scholars have gained increasing expertise in reviewing research literatures, literatures that once appeared haphazard at best and fragile at worst now frequently are shown to have substantial regularities (Johnson and Nichols 1998). For example, although scholars working in the 1950s and on through the 1970s frequently reached conflicting conclusions about whether men or women (or neither) are more easily influenced by others, reviewers using meta-analytic techniques have found highly reliable tendencies in this same literature. For example, Eagly and Carli's meta-analysis (1981) showed that men are more influenced than women when the communication topic is feminine (e.g., sewing), and that women are more influenced than men when the topic is masculine (e.g., automobiles). Moreover, contemporary meta-analysts now almost routinely move beyond relatively simple questions of whether one variable relates to another to the more sophisticated question of *when* the relation is larger, smaller, or reverses in sign. Thus, there is, indeed, a great deal of replicability across a wide array of topics, and inconsistencies among study findings can often be explained on the basis of methodological differences among the studies.

META-ANALYTIC REVIEWS OF EVIDENCE

Because of the importance of comparing study findings accurately, scholars have dedicated considerable effort to making the review process as reliable and valid as possible and thereby circumventing the criticisms listed above. These efforts highlight the proposition that research synthesis is a scientific endeavor—there are identifiable and replicable methods involved in producing reliable and valid reviews (Cooper and Hedges 1994). Although scientists have cumulated empirical data from independent studies since the early 1800s (see Stigler 1986), relatively sophisticated techniques for synthesizing study findings emerged only after the development of such standardized indexes as r , d , and p -values, around the turn of the twentieth century (see Olkin 1990). Reflecting the field's maturation, Hedges and Olkin (1985) presented a sophisticated version of the statistical bases of meta-analysis, and standards for meta-analysis have grown increasingly rigorous. Meta-analysis is now quite common and well accepted because scholars realize that careful application of

these techniques often will yield the clearest conclusions about a research literature (Cooper and Hedges 1994; Hunt 1997).

Conducting a meta-analysis generally involves seven steps: (1) determining the theoretical domain of the literature under consideration, (2) setting boundaries for the sample of studies, (3) locating relevant studies, (4) coding studies for their distinctive characteristics, (5) estimating standardized effect sizes for each study, (6) analyzing the database, and (7) interpreting and presenting the results. The first conceptual step is to specify with great clarity the phenomenon under review by defining the variables whose relation is the focus of the review. Ordinarily a synthesis evaluates evidence relevant to a single hypothesis; the analyst studies the history of the research problem and of typical studies in the literature. Typically, the research problem will be defined as a relation between two variables, such as the influence of an independent variable on a dependent variable (e.g., the influence of silicon breast implants on connective tissue disease, as reported by Perkins et al. 1995). Moreover, a synthesis must take study quality into account at an early point to determine the kinds of operations that constitute acceptable operationalizations of these conceptual variables. Because studies testing a particular hypothesis typically differ in the operations used to establish the variables, it is no surprise that these different operations were often associated with variability in studies' findings. If the differences in studies' operations can be appropriately judged or categorized, it is likely that an analyst can explain some of this variability in effect size magnitude.

The most common way to test competing explanations is to examine how findings pattern across studies. Specifically, a theory might imply that a third variable should influence the relation between the independent and dependent variables: The relation should be larger or smaller with a higher level of this third variable. Treating this third variable as a potential moderator of the effect, the analyst would code the studies for their status on the moderator. This meta-analytic strategy, known as the moderator variable approach, tests whether the moderator affects the examined relation across the studies included in the sample. This moderator variable approach, advancing beyond the simple question of *whether* the independent variable is related to the dependent variable,

addresses the question of *when* the magnitude or sign of the relationship varies. In addition to this moderator variable approach to synthesizing studies' findings, other strategies have proved to be useful. In particular, a theory might suggest that a third variable serves as a mediator of the critical relation because it conveys the causal impact of the independent variable on the dependent variable. If at least some of the primary studies within a literature have evaluated this mediating process, mediator relations can be tested within a meta-analytic framework by performing correlational analyses that are an extension of path analysis with primary-level data (Shadish 1996).

Clearly, only some studies will be relevant to the conceptual relation that is the focus of the meta-analysis, so analysts must define boundaries for the sample of studies, the second step in conducting a meta-analysis. Decisions about the inclusion of studies are important because the inferential power of any meta-analysis is limited by the methods of the studies that are integrated. To the extent that all (or most) of the reviewed studies share a particular methodological limitation, any synthesis of these studies would be limited in this respect. As a general rule, research syntheses profit by focusing on the studies that used stronger methods to test the meta-analytic hypotheses. Nonetheless, it is important to note that studies that have some strengths (e.g., manipulated independent variables) may have other weaknesses (e.g., deficiencies in ecological validity). In deciding whether some studies may lack sufficient rigor to include in the meta-analysis, it is important to adhere to methodological standards within the area reviewed. Although a large number of potential threats to methodological rigor have been identified (Campbell and Stanley 1963; Cook and Campbell 1979), there are few absolute standards of study quality that can be applied uniformly in every meta-analysis. As a case in point, although published studies are often thought to be of higher quality than unpublished studies, there is little basis for this generalization: Many unpublished studies (e.g., dissertations) have high quality, and many studies published in reputable sources do not. It is incumbent on the analyst to define the features of a high-quality study and to apply this definition to all studies in the literature, regardless of such considerations as the reputation of the journal.

Analysts often set the boundaries of the synthesis so that the methods of included studies differ dramatically only on critical moderator dimensions. If other, extraneous dimensions are thereby held relatively constant across the reviewed studies, moderator variable analyses can be more clearly interpreted. Nonetheless, an analyst should include in the sample all studies or portions of studies that satisfy the selection criteria, or, if an exhaustive sampling is not possible, a representative sample of those studies. Following this principle yields results that can be generalized to the universe of studies on the topic.

Because including a large number of studies generally increases the value of a quantitative synthesis, it is important to locate as many studies as possible that might be suitable for inclusion, the third step of a meta-analysis. To ensure that a sufficient sample of studies is located, reviewers are well advised to err in the direction of being extremely inclusive in their searching procedures. As described elsewhere (e.g., Cooper 1998; White 1994), there are many ways to find relevant studies; ordinarily, analysts should use all these techniques. Because computer searches of publication databases seldom locate all the available studies, it is important to supplement them by (1) examining the reference lists of existing reviews and of studies in the targeted literature, (2) obtaining published sources that have cited seminal articles within the literature, (3) contacting the extant network of researchers who work on a given topic to ask for new studies or unpublished studies, and (4) manually searching important journals to find some reports that might have been overlooked by other techniques.

Once the sample of studies is retrieved, analysts code them for their methodological characteristics, the fourth step in the process. The most important of these characteristics are potential moderator variables, which the analyst expects on an a priori basis to account for variation among the studies' effect sizes, or which can provide useful descriptive information about the usual context of studies in the literature. In some cases, reviewers recruit outside judges to provide ratings of methods used in studies. Because accurate coding is crucial to the results of a meta-analysis, the coding of study characteristics should be carried out by two or more coders, and an appropriate index of interrater reliability should be calculated.

To be included in a meta-analysis, a study must contain some report of a quantitative test of the hypothesis that is under scrutiny in order to convert summary statistics into effect sizes, the fifth step of the process. Most studies report the examined relation by one or more inferential statistics (e.g., *t*-tests, *F*-tests, *r*-values), which can be converted into an effect size (see Cooper and Hedges 1994b; Glass et al. 1981; Johnson 1993; Rosenthal 1991). The most commonly used effect size indexes in meta-analysis are the standardized difference and the correlation coefficient (see Rosenthal 1991, 1994). The standardized difference, which expresses the finding in standard deviation units, was first proposed by Cohen (1969) in the following form:

$$g = \frac{M_A - M_B}{SD} \quad (1)$$

where M_A ; and M_B ; are the sample means of two compared groups, and SD is the standard deviation, pooled from the two observations. Because this formula overestimates population effect sizes to the extent that sample sizes are small, Hedges (1981) provided a correction for this bias; with the bias corrected, this effect estimate is conventionally known as d . Another common effect size is the correlation coefficient, r , which gauges the association between two variables. Because the sampling distribution of a sample correlation coefficient tends to be skewed to the extent that the population correlation is large, it is conventional in meta-analysis to use a logarithmic transform of each correlation in statistical operations (Fisher 1921). The positive or negative sign of the effect sizes computed in a meta-analysis is defined so that studies with opposite outcomes have opposing signs. When a study examines the relation of interest within levels of another variable, effect sizes may be calculated within the levels of this variable as well as for the study as a whole. In addition to correcting the raw g and r because they are biased estimators of the population effect size, analysts sometimes correct for many other biases that accrue from the methods used in each study (e.g., unreliability of a measure; see Hunter and Schmidt 1990). Although it is unrealistic for analysts to take into account all potential sources of bias in a meta-analysis, they should remain aware of biases that may be important within the context of their research literature.

Once the effect sizes are calculated, they are analyzed, the sixth step of the process, using either fixed- or random-effects models. Fixed-effects models, which are the most common analysis used, assume that there is one underlying, but unknown, effect size and that study estimates of this effect size vary only in sampling error. Random-effects models assume that each effect size is unique and that the study is drawn at random from a universe of related but separate effects (see Hedges and Vivea 1998 for a discussion). The general steps involved in the analysis of effect sizes usually are: (1) to aggregate effect sizes across the studies to determine the overall strength of the relation between the examined variables; (2) to analyze the consistency of the effect sizes across the studies; (3) to diagnose outliers among the effect sizes; and (4) to perform tests of whether study attributes moderate the magnitude of the effect sizes. Although several frameworks for modeling effect sizes have been developed (for reviews, see Johnson et al. 1995; Sánchez-Meca and Marín-Martínez 1997), the Hedges and Olkin fixed-effect approach (1985) appears to be the most popular and therefore will be assumed in the remainder of this discourse. These statistics were designed to take advantage of the fact that studies have differing variances by calculating the nonsystematic variance of the effect sizes analytically (Hedges and Olkin 1985). Because this nonsystematic variance of an effect size is inversely proportional to the sample size of the study and because sample sizes typically vary widely across the studies, the error variances of the effect sizes are ordinarily quite heterogeneous. These meta-analytic statistics also permit an analysis of the consistency (or homogeneity) of the effect sizes across the studies, a highly informative analysis not produced by conventional, primary-level statistics. As the homogeneity calculation illustrates, analyzing effect sizes with specialized meta-analytic statistics rather than the ordinary inferential statistics used in primary research allows a reviewer to use a greater amount of the information available from the studies (Rosenthal 1991, 1995).

As a first step in a quantitative synthesis, the study outcomes are combined by averaging the effect sizes with each weighted by its sample size. This procedure gives greater weight to the more reliably estimated study outcomes, which are in general those with the larger sample sizes (see

Hedges et al. 1992; Johnson et al. 1995). As a test for significance of this weighted mean effect size, a confidence interval is typically computed around this mean, based on its standard deviation, $d_{\pm} \pm 1.96 \sqrt{v_{\pm}}$, where 1.96 is the unit-normal value for a 95 percent confidence interval (CI) (assuming a nondirectional hypothesis). If the CI includes zero (0.00), the value indicating exactly no difference, it may be concluded that aggregated across all studies there is no significant association between the independent and dependent variables (X and Y). For example, Perkins and colleagues (1995) found no evidence across thirteen studies that silicone breast implants increased risk of connective tissue disease. In a different literature, He and colleagues (1999) found that, across eighteen studies, nonsmokers exposed to passive smoke had a higher relative risk of coronary heart disease than nonsmokers not exposed to smoke.

Once a meta-analysis has derived a weighted mean effect size, it, and other meta-analytic statistics, must be interpreted and presented, which is the seventh step of conducting a meta-analysis. If the mean effect is nonsignificant and the homogeneity statistic is small and nonsignificant, an analyst might conclude that there is no relation between the variables under consideration. However, in such cases, it is wise to consider the amount of statistical power that was available: If the total number of research participants in the studies integrated was small, it is possible that additional data would support the existence of the effect. Even if the mean effect is significant and the homogeneity statistic is small and nonsignificant, concerns about its magnitude arise. To address this issue, Cohen (1969, 1988) proposed some guidelines for judging effect magnitude, based on his informal analysis of the magnitude of effects commonly yielded by psychological research. Cohen intended “that medium represent an effect of a size likely to be visible to the naked eye of a careful observer” (1992, p. 156). He intended that small effect sizes be “noticeably smaller yet not trivial” (p. 156) and that large effect sizes “be the same distance above medium as small is below it” (p. 156). As Table 1 shows, a “medium” effect turned out to be about $d = 0.50$ and $r = .30$, equivalent to the difference in intelligence scores between clerical and semiskilled workers. A “small” effect size was about $d = 0.20$ and $r = .10$, equivalent

Cohen's (1969) Guidelines for Magnitude of d and r

Size	Effect size metric		
	d	r	r^2
Small	0.20	.10	.01
Medium	0.50	.30	.09
Large	0.80	.50	.25

Table 1

to the difference in height between 15- and 16-year-old girls. Finally, a large effect was about $d = 0.80$ and $r = .50$, equivalent to the difference in intelligence scores between college professors and college freshmen.

Another popular way to interpret mean effect sizes is to derive the equivalent r and square it. This procedure shows how much variability would be explained by an effect of the magnitude of the mean effect size. Thus, a mean d of 0.50 produces an R^2 of .09. However, this value must be interpreted carefully because R^2 , or variance explained, is a directionless effect size. Therefore, if the individual effect sizes that produced the mean effect size varied in their signs (i.e., if the effect sizes were not all negative or all positive), the variance in Y explained by the predictor X , calculated for each study and averaged, would be larger than this simple transformation of the mean effect size. Thus, another possible procedure consists of computing R^2 for each individual study and averaging these values.

When the weighted mean effect size and the CI are computed, the homogeneity of the d 's is statistically examined, in order to determine whether the studies can be adequately described by a single effect size (Hedges and Olkin 1985). If the effect sizes can be so described, then they would differ only by unsystematic sampling error. If there is a significant fit statistic, the weighted mean effect size may not adequately describe the outcomes of the set of studies because it is likely that quite different mean effects exist in different groups of studies. Further explanatory work would be merited, even when the composite effect size is significant. The magnitude of individual study outcomes would differ systematically, and these

differences may include differences in the direction (or sign) of the relation. In some studies, the independent variable might have had a large positive effect on the dependant variable, and in other studies, it might have had a smaller positive effect or even a negative effect. Even if the homogeneity test is nonsignificant, significant moderators could be present, especially when the fit statistic is relatively large (for further discussions, see Johnson and Turco 1992; Rosenthal 1995). Nonetheless, in a meta-analysis that attempts to determine the relation of one variable to another, rejecting the hypothesis of homogeneity could be troublesome, because it implies that the association between these two variables likely is complicated by the presence of interacting conditions. However, because analysts usually anticipate the presence of one or more moderators of effect size magnitude, establishing that effect sizes are not homogeneous is ordinarily neither surprising nor troublesome.

To determine the relation between study characteristics and the magnitude of the effect sizes, both categorical models and continuous models can be tested. In *categorical models*, analyses may show that weighted mean effect sizes differ in magnitude between the subgroups established by dividing studies into classes based on study characteristics. In such cases, it is as though the meta-analysis is broken into sub-meta-analyses based on their methodological features. For example, He and colleagues (1999) found that risk of coronary heart disease was greater for women than for men nonsmokers who were exposed to passive smoke. If effect sizes that were found to be heterogeneous become homogeneous within the classes of a categorical model, the relevant study characteristic has accounted for the systematic variability between the effect sizes. Similarly, *continuous models*, which are analogous to regression models, examine whether study characteristics that are assessed on a continuous scale are related to the effect sizes. As with categorical models, some continuous models may be completely specified in the sense that the systematic variability in the effect sizes is explained by the study characteristic that is used as a predictor. Continuous models are least squares regressions, calculated with each effect size weighted by the reciprocal of its variance (sample size). For example, He and colleagues (1999) found that risk of coronary heart disease was greater to the extent that nonsmokers had greater exposure to passive

smoke. Goodness-of-fit statistics enable analysts to determine the extent to which categorical or continuous models, or mixtures of these models provide correct depictions of study outcomes.

As an alternative analysis to predicting effect sizes using categorical and continuous models, an analyst can attain homogeneity by identifying outlying values among the effect sizes and sequentially removing those effect sizes that reduce the homogeneity statistic by the largest amount (e.g., Hedges 1987). Studies yielding effect sizes identified as outliers can then be examined to determine whether they appear to differ methodologically from the other studies. Also, inspection of the percentage of effect sizes removed to attain homogeneity allows one to determine whether the effect sizes are homogeneous aside from the presence of relatively few aberrant values. Under such circumstances, the mean attained after removal of such outliers may better represent the distribution of effect sizes than the mean based on all the effect sizes. In general, the diagnosis of outliers should occur prior to calculating moderator analyses; this diagnosis may locate a value or two that are so discrepant from the other effect sizes that they would dramatically alter any models fitted to effect sizes. Under such circumstances, these outliers should be removed from subsequent phases of the data analysis. Alternatively, outliers can be examined following categorical or continuous models (e.g., finding those that deviate the most from the values predicted by the models).

TRENDS IN THE PRACTICE OF META-ANALYSIS

Although the quality of meta-analyses has been quite variable, it is possible to state the features that compose a high-quality meta-analysis, including success in locating studies, explicitness of criteria for selecting studies, thoroughness and accuracy in coding moderators variables and other study characteristics, accuracy in effect size computations, and adherence to the assumptions of meta-analytic statistics. When meta-analyses meet such standards, it is difficult to disagree with Rosenthal's conclusion (1994) that it is "hardly justified to review a quantitative literature in the pre-meta-analytic, prequantitative manner" (p. 131). Yet merely meeting these high standards does not

necessarily make a meta-analysis an important scientific contribution. One factor affecting scientific contribution is that the conclusions that a research synthesis is able to reach are limited by the quality of the data that are synthesized. Serious methodological faults that are endemic in a research literature may well handicap a synthesis, unless it is designed to shed light on the influence of these faults. Also, to be regarded as important, the review must address an interesting question. Moreover, unless the paper reporting a meta-analysis “tells a good story,” its full value may go unappreciated by readers. Although there are many paths to a good story, Sternberg’s recommendations to authors of reviews (1991) are instructive: Pick interesting questions, challenge conventional understandings if at all possible, take a unified perspective on the phenomenon, offer a clear take-home message, and write well. Thus, the practice of meta-analysis should not preclude incorporating aspects of narrative reviewing, but instead should strive to incorporate and document the richness of the literature.

One reason that the quality of published syntheses has been quite variable is that it is a relatively new tool among scholars who practice it. Yet, as the methods of quantitative synthesis have become more sophisticated and widely disseminated, typical published meta-analyses have improved. At their best, meta-analyses advance knowledge about a phenomenon by explicating its typical patterns and showing when it is larger or smaller, negative or positive, and by testing theories about the phenomenon (see Miller and Pollock 1994). Meta-analysis should foster a healthy interaction between primary research and research synthesis, at once summarizing old research and suggesting promising directions for new research. One misperception that scholars sometimes express is that a meta-analysis represents a dead end for a literature, a point beyond which nothing more needs to be known. In contrast, carefully conducted meta-analyses can often be the best medicine for a literature, by documenting the robustness with which certain associations are attained, resulting in a sturdier foundation on which future theories may rest. In addition, meta-analyses can show where knowledge is at its thinnest, to help plan additional, primary-level research (see Eagly and Wood 1994). As a consequence of a carefully conducted meta-analysis, primary-level studies can

be designed with the complete literature in mind and will therefore have a better chance of contributing new knowledge. In this fashion, scientific resources can be directed most efficiently toward gains in knowledge. As time passes and new studies continue to accrue rapidly, it is likely that social scientists will rely more on quantitative syntheses to inform them about the knowledge that has accumulated in their research. Although it is possible that meta-analysis will become the purview of an elite class of researchers who specialize in research integration, as Schmidt (1992) argued, it seems more likely that meta-analysis will become a routine part of graduate training in many fields, enabling students to develop the skills necessary to ply the art and science of meta-analysis and to integrate findings across studies as a normal and routine part of their research activities.

METATHEORY

Metatheory in sociology is a relatively new specialty that aims to describe existing sociological theory systematically, and also, to some degree, to prescribe what future sociological theories ought to be like. It leaves to other specialties—most notably the sociology and history of sociology and the logic of theory construction—the problems of explaining and predicting how such theories have been, and can be, formulated.

There are two broad varieties of metatheory. One variety, *synthetic*, classifies whole theories according to some overarching typology; the other variety, *analytic*, first dissects theories into their underlying constituents and then classifies these constituents into types.

Some typologies encountered in synthetic metatheory refer to the time periods when the theories were originated, for example, forerunner, classical, and contemporary (Timasheff and Theodorson 1976 and Eisenstadt 1976 provide examples). Some refer to the places where the theories were originated, for example, France, Germany, Italy, and the United States (Bottomore and Nisbet 1978 and Gurvitch and Moore 1945 provide examples). Some refer to the substantive themes of the theories, for example, structural-functional, evolutionist, conflict, and symbolic interactionist (Turner 1986 and Collins 1988 provide examples). Some refer to the ideologies supported by the theories, for example, pro-establishment and anti-establishment (Martindale 1979 provides an example). Some refer to various combinations of all the above differences (Wiley 1979 and Ritzer 1983 provide examples).

Analytic metatheory is divisible into two broad classes: one in which the constituents of theories are required to have empirical referents, either directly or indirectly, and another in which these constituents are required or permitted to have nonempirical referents. Thus, one sociologist claims our theory should be brought "closer to nonempirical

standards of objectivity" (Alexander 1982), while another claims "sense-based inter-subjective verification is indispensable [to sociology]" (Wallace 1983). (This difference in kind of analytic metatheory reflects an applicability of the synthetic-analytic distinction to *metamethod* in sociology: In the synthetic variety of metamethod, whole methods are characterized as *empirical* or *nonempirical*, *positivistic* or *hermeneutical*, *experimental* or *participant-observational*, and so on. In the analytic variety, such methods are dissected into their underlying constituents, which are then classified as *measurement*, *interpretation*, *speculation*, *comparison*, *test*, *generalization*, *specification*, *deduction*, *induction*, and so on.)

Some types of underlying constituents encountered in empirical analytic metatheory are "control" (Gibbs 1989); "individual actors," "corporate actors," "interests," and "rights" (Coleman 1990); "rational action," "nonrational action," "individualist order," and "collectivist order" (Alexander 1982); "social and cultural structures," "spatial and temporal regularities," "instinct," "enculture," "physiology," "nurture," "demography," "psychical contagion," "ecology," and "artifacts" (Wallace 1983, 1988); and general causal images like "convergence," "amplification," "fusion," "fission," "tension," "cross-pressure," "dialectic," and "cybernetic" (Wallace 1983, 1988). Some types of underlying constituents encountered in nonempirical analytic metatheory have been called (so far, without further explication or specification), "moral implication," "moral commitments," and "moral preferences" (Alexander 1982).

Metatheory in general has been sweepingly condemned as a dead end leading only to the study of "the grounds of other people's arguments rather than substantive problems" (Skocpol 1987), and as holding "little prospect for further developments and new insights" (Collins 1986). Against such characterizations, however, certain unique and indispensable contributions of both synthetic and analytic metatheory to sociology should not be overlooked.

Synthetic metatheory plays obviously central roles in descriptive classifications of sociological theory (e.g., textbooks and course outlines), but they are no less central to the sociology and history of sociology, where efforts to account for the rise and fall of schools, or perspectives, in sociological analysis require systematic conceptualization of

such groupings. The contributions of nonempirical analytic metatheory remain unclear (as mentioned, the kinds of ideological commitment and moral foundation to which it refers, and their consequences for sociological theory, have yet to be specified) and, therefore, will not be examined here. The contributions of empirical analytic metatheory will occupy the rest of this article.

THREE CONTRIBUTIONS OF EMPIRICAL ANALYTIC METATHEORY

Empirical analytic metatheory can aid (1) systematic cumulation of the *end product* of sociological investigation (namely, collectively validated empirical knowledge about social phenomena); (2) systematic construction of new versions of the principal *means* employed in generating that end product (namely, collectively shared theory and method); and (3) a sense of discipline-wide *solidarity* among sociologists of all theoretical traditions, all specializations and, eventually one hopes, among all social scientists.

Cumulation of Sociological Knowledge Knowledge can only cumulate when new knowledge of a given phenomenon is added to old knowledge of that same phenomenon (or, rather, insofar as no phenomenon is ever repeated exactly, that same *type* of phenomenon). The key to holding such objects of investigation constant is, of course, communication. That is to say, only the communication to investigator B of the identity of the exact phenomenon investigator A has examined, together with the exact results of that examination, can enable investigator B systematically to add new knowledge to A's knowledge.

Disciplinary Communication Now it may be imagined that we already possess such communication in sociology, but we do not. Consider the terms *social structure* and *culture*. One can hardly doubt that, by denoting the substantive heart of our discipline, they indicate what the entire sociological enterprise is about. By virtually all accounts, however, each term signifies very different kinds of phenomena to different sociologists.

Thus, *social structure* has been authoritatively said, at various times for over two decades, to be "so fundamental to social science as to render its uncontested definition virtually impossible" (Udy 1968); to attract "little agreement on its empirical

referents" (Warriner 1981); and to possess a meaning that "remains unclear" (Turner 1986). "Few words," it has been said, "do sociologists use more often than 'structure,' especially in the phrase 'social structure.' Yet we seldom ask what we mean by the word" (Homans 1975). In a more detailed statement, one analyst asserts that

The concept of social structure is used widely in sociology, often broadly, and with a variety of meanings. It may refer to social differentiation, relations of production, forms of association, value integration, functional interdependence, statuses and roles, institutions, or combinations of these and other factors.
(Blau 1975)

Indeed, we can still read that "sociologists use the term ['social structure'] in diverse ways, each of which is either so vague as to preclude empirical application or so broad as to include virtually all collective features of human behavior" (Gibbs 1989). As recent evidence of this diversity, it is noteworthy that, where one sociologist claims that "for sociologists, the units of social structure are conceived of . . . as *relational* characteristics" (Smelser 1988), another refers, without explanation, to a type of "social structure" in which the participants "have *no relations*" (Coleman 1990).

The situation is no different with the term *culture*. Some years ago it was said that "by now just about everything has been thrown into 'culture' but the kitchen sink," and the author of this remark then reflected that "The kitchen sink has been thrown in too" as part of "material culture" (Schneider 1973). Years later, it has again been pointed out that "Theorists of culture remain sorely divided on how best to define culture" (Wuthnow et al. 1984) and "values, orientations, customs, language, norms, [and religion]" have been referred to as though they were all somehow different from "culture" (Coleman 1990). No wonder at least one sociologist has simply given up: "[A]ny definition" of culture, he claims, "will be (1) inclusive to the point of being meaningless, (2) arbitrary in the extreme, or (3) so vague as to promise only negligible empirical applicability" (Gibbs 1990).

More recently still, Gilmore affirms that "there is no current, widely accepted, composite resolution of the definition of culture," and claims that as a result "the contemporary concept of culture

in sociology does not exclude any particular forms of [collective] activity.” This difficulty notwithstanding, there has arisen, Gilmore says, “a new appreciation of the salience of culture as an explanatory perspective in contemporary sociological research” (1992). To the extent that these judgments are true, one can only wonder what contribution an explanatory perspective that lacks even a rudimentary and tentative definition of its own central variable (and which expresses a kitchen-sink inclusiveness that “does not exclude any particular empirical forms of activity”) can possibly make to social science.

Regarding social structure, Rytina asserts his conviction that “Social structure is a general term for any collective social circumstance that is unalterable and given for the individual” and that such social structure “is the same for all and is beyond the capacity for alteration by any individual will” (1992). Apart from noticing, again, the kitchen-sink inclusiveness of this claim (“*any* collective social circumstance”), one wonders what good can come of conceptualizing social structure in a way that rules out the possibility of variable individual *power* (i.e., “the probability that one actor within a social relationship will be in a position to carry out his own will” [Weber 1978]). See, however, Sewell (1992) for explicit inclusion of “power” in structure—although Sewell lumps “resources” and “schemas” (i.e., what others would distinguish as components of social structure and culture, respectively) together into a single undifferentiated “structure” concept.

Some other discussions of the ongoing social structure versus culture problem may be found in Emirbayer and Goodwin (1994), Hays (1994), Holmwood and Stewart (1994), Wallace (1986), and Whitmeyer (1994). It will also be noticed that in addition to “social structure” and “culture” the concept “agency” appears in some of these discussions, and a brief comment on it may be useful. Human “agency” is said, by Sewell, to refer to “the efficacy of human action,” and to arise from the actor’s “ability to apply [known schemas] to new contexts” and to act “creatively” (1992, pp. 2, 20). It is not easy to understand, however, why a special anthropocentric term is needed for such a phenomenon inasmuch as *all* action, by *whatever* agent, is (by any physical definition of “action”) efficacious, and *all* “applications,” by definition, occur in “new” contexts and are thus “creative.”

In response to such expressions of disciplinary decline (and acknowledging their strong evidential basis), empirical analytic metatheory falls back on Durkheim’s argument that insofar as “Every scientific investigation concerns a specific group of phenomena which are subsumed under the same definition,” it follows that “[the] sociologist’s first step must . . . be to define the things he treats so that we may know—he as well—exactly what his subject matter is. This is the prime and absolutely indispensable condition of any proof or verification” (1982).

Empirical analytic metatheory, then, seeks a common disciplinary language for sociologists everywhere, regardless of their specializations. Its proponents believe that only with the adoption of some such language can our discipline begin solving its central problems, namely, systematic knowledge cumulation, theory innovation, and solidarity enhancement.

WALTER L. WALLACE

MEXICAN STUDIES

Mexican history since the country achieved its independence from Spain in 1821 is marked by a set of dramatic events that created the context for fundamental social and economic changes. These events shaped contemporary Mexican society and established much of the current agenda of Mexican social and political studies. Three issues in particular have long historical antecedents. These are the ethnic question, the role of the state in development, and relations with the United States. Despite these continuities, social trends and pre-occupations in Mexico have also differed according to historical period. In order to handle both

continuity and change, we will organize the discussion in terms of four main periods, each initiated by major events, and will consider the dominant trends and intellectual orientations of each period. The time between Mexican independence and the Mexican-American War, the first period is marked by economic stagnation and political fragmentation. The second period lasts from the aftermath of the Mexican-American War until the Mexican Revolution of 1910. Rapid but uneven economic development and political unification distinguish the second period. The third period begins with the consolidation of the Mexican Revolution and goes through the 1920s and on into the debt crises of the early 1980s. Nationalism, political centralization, and high rates of urbanization and industrialization characterize this period. Finally, we consider the two last decades of the twentieth century, shaped by the external opening of the economy with its accompanying economic and political liberalization.

This historical context and the unevenness of Mexico's development make U.S.-Mexican relations different, in significant respects, from relations between other neighboring countries. The U.S.-Mexican border is the only international frontier that divides a developing country and a highly developed country. The contradictory trends of Mexico's development shape U.S.-Mexican relations (Weintraub 1990). The two populations have been brought closer to each other in terms of trade, tourism, labor migration, and consumer aspirations. This increasing proximity can also create social distance as each population develops opposing images of the other. These are often based on the misunderstandings that result from wide disparities in income, standards of living, and political and family culture (Pastor and Castañeda 1988). For many Mexicans, the history of conflictive relations with the United States continues to negatively color perceptions of U.S. political and economic intentions toward Mexico.

Independence from Spain left Mexico an impoverished and fragmented nation. The main sources of external revenue—mining and specialized plantation agriculture—declined substantially. Internal markets were not strongly developed and were mainly concentrated in a few major cities. Thus, neither internal nor external trade provided enough stimuli to expand local agricultural or

industrial production. The economy was organized on a local and regional basis rather than on a national one. Within this context, politics was dominated by a decentralized system of *caudillos* (regional leaders, often military) and *caciques* (local bosses and power brokers). The formal government alternated between a centralist and a federalist republic, after the short-lived Empire of Iturbide. The proponents of a centralist republic tended to be conservatives, supporting the maintenance of corporatist institutions such as the church, the army, the guilds, and the indigenous communities. In a sociological account of the processes shaping the Independence movement, the intellectual leader of the conservatives, Lucas Alamán ([1847] 1942), advocated a strong central power, economic protectionism, the remedying of class inequality, and populating the empty spaces to the north through European Catholic colonization. In contrast, the federalists tended to be economically and politically liberal, arguing for individual property rights, free markets, and individual civil and political equality. The radical liberal parliamentarian, José María Luis Mora, went so far as to argue for the complete incorporation of the indigenous population into the market as a means to remedy backwardness and poverty (Lira Gonzalez 1984). A leading liberal politician and intellectual, Lorenzo de Zavala, admired the United States and considered it a model to emulate. He also viewed favorably the colonization of the northern territories by Protestant colonists from the United States (Lira Gonzalez 1984). Later, Zavala became the first vice president of the independent Republic of Texas. In order to govern, both the federalists and centralists relied on the *caudillo-cacique* power structure. Thus, the paradigmatic *caudillo* of this period, Santa Anna, was president several times, under both centralist and federalist banners.

The loss of half of the national territory, first in the Texas War of Independence of 1835–1836 and then in the Mexican-American War of 1846–1848, demonstrated dramatically the costs of Mexico's political and economic fragmentation. The conservatives entrenched themselves further in their corporate and hierarchical beliefs, leading finally to the ill-fated, conservative-backed empire of Maximilian of Hapsburg (1864–1867). The aftermath of the Mexican-American war was perhaps more traumatic for the liberals. They saw themselves as betrayed by the United States, which

they had regarded as a friend and an ally in modernizing Mexico. Thereafter, particularly with the experiences of the French intervention, Mexican liberals, while supporting market and individual freedoms and the abolition of corporations, were to become the main proponents of a strong state and of nationalism in Mexico.

Beginning with Benito Juárez (president, 1861–1863 and 1867–1872), liberals were to dominate the politics of Mexico until the Mexican Revolution, even in the paradoxical guise of the dictator, Porfirio Díaz (president, 1877–1880, 1884–1911). In face of the difficulties of achieving spontaneous economic and social progress, liberalism was modified, however, in an authoritarian and positivist direction. A disciple of Comte, Gabino Barreda, reorganized the educational system of the country to ensure a uniform and centralized system (Zea 1974). Justo Sierra (1969 [1901–1903]), one of Díaz's ministers, wrote a new version of Mexican history as a political evolution that needed a period in which political rights would be limited. He saw economic progress as depending on civic education, as well as individualizing property rights in agriculture, industrial modernization, foreign investment, and trade. Though corporate rights to land had been abolished under Juárez, Díaz made this effective, particularly for the indigenous communities. Railways were built and roads improved. Political control was centralized through a bureaucratic system of patronage that gave the central government a more effective control of state and local governments. For the first time in fifty years, Mexico experienced a long period of peace and stability.

The Díaz period was one of considerable economic expansion in Mexico, but the style of development resulted in a series of social and economic dislocations that were to contribute to the Mexican Revolution of 1910. Commercial haciendas expanded, depriving many peasants of access to land. The new economic opportunities and improvements in communication affected communities throughout Mexico, encouraging villagers to give up traditional livelihoods for wage labor in mines, plantations, or as sharecroppers. As dependence on the market grew, so too national and regional economic downturns caused increasing discontent and hardship. Advocates of progress, such as Andrés Molina Enríquez ([1909] 1978), one of the intellectual leaders of the Mexican

Revolution, denounced the economic inequities produced by land concentration. Instead, he placed his hopes on the emerging *mestizo* middle class of medium-scale farmers, merchants, manufacturers, and professionals. With Molina Enriquez, there is a clear statement of the ethnic basis of social change. Both the European-origin upper class and the indigenous peasantry are seen as incapable of progress. He sees the *mestizo* as the crucial Mexican identity capable of achieving economic development and social equity. By the time of the Mexican Revolution, the indigenous population, defined in census terms by "race" and non-Spanish-language use, constituted nearly half the Mexican population.

In spite of political centralization, the economy remained regionalized during the Díaz regime. The Mexican Revolution was essentially a set of regional movements and leaders, that responded to the particular economic problems and possibilities that the Porfirian expansion brought to local economies. These regional contexts included the sugar economy of Morelos; the *henequen* economy of Yucatan; the sharecropping, ranching, and mining economy of Chihuahua and Coahuila; and the emerging commercial farming economy of Sonora (Knight 1986).

The years from after the Mexican Revolution until approximately 1980 transformed Mexico from a society in which three-quarters of the population was agricultural and lived in small villages, to one in which less than a quarter of the population worked in agriculture and most people lived in large cities. This transformation was shaped by two outcomes of the revolution. One was an agrarian reform that destroyed the *hacienda* system, replacing it with small and medium-scale commercial farming and a system of social property (the *ejido*) that reinstated and, at times, extended the rights to land of peasant communities. In the first thirty years after the Revolution, Mexican peasant agriculture was sufficiently strong to feed the growing urban population and help the country's industrialization.

The second major legacy of the revolution was the consolidation of a centralized, modern political system around the official party of the revolution, known as the PRI (*Partido Revolucionario Institucional*) since 1948. The PRI based its control on corporate affiliations by industrial and peasant

unions. Also, the massive extension of state employment in education, health, social and administrative services modernized the country and served to create an extensive web of government patronage (Eckstein 1977). Part of the program of social incorporation was the movement known as *Indigenismo*, which was founded by the anthropologist Manuel Gamio ([1935] 1987). Though the movement sought to protect the indigenous population, its final objective was to incorporate them into the dominant *mestizo* culture through education, health campaigns, and local development programs sponsored by specialized government agencies. By 1940, the indigenous population, defined in terms of those who speak an Indian language, had declined according to the census of that year to just over 14 percent of the population. In general, the indigenous population remained poorer than the *mestizo* peasant population.

Economically, the PRI was nationalist, protecting local industries and restricting foreign investment. The state intervened in the economy, managing industries in sectors which were considered vital to the national interest, such as the oil industry, railroads, certain branches of transport, and telephones. However, it tolerated and, at times, promoted private ownership in many industrial sectors, by including entrepreneurs in the corporate alliances through which the PRI governed. For Mexico, the 1940–1970 decades were the “golden years” of development, when annual rates of gross domestic product (GDP) growth of 6 percent and more were common (Leopoldo Solís, 1970). It was also a period in which a strong political nationalism accompanied economic nationalism. Under various presidents, Mexico made clear its independence from U.S. political and economic influence, as in the nationalization of oil and as in its continuing relations with Castro’s Cuba.

The understanding of these processes was aided by the development of social sciences in Mexico, stimulated by an interest in issues of national identity and culture in face of rapid modernization. Anthropology developed under the auspices of official nationalism in the National Institute of Anthropology and History and the National Indigenist Institute, promoting the restoration and preservation of the pre-Hispanic archaeological patrimony as symbols of Mexican nationality (Vazquez 1995). Gamio’s ([1931] 1969) interest in national identity led him to document

the living and working conditions of Mexican labor migrants in the United States. He and the American anthropologist Paul Taylor (1928–1934) demonstrated that the experiences of these migrants would often reinforce Mexican nationalism through ill treatment, prejudice, and summary deportations.

Within Mexico, anthropologists undertook empirical studies of acculturation and cultural integration, viewed as irreversible trends (Aguirre Beltrán 1957). By the 1970s, sociologists and political scientists working at the National University and at El Colegio de México were questioning the Mexican style of development, focusing on issues of class and ethnic inequality (Stavenhagen 1969; Instituto de Investigaciones Sociales 1970–1973; Benítez Zenteno 1977). Some openly questioned the institutional authoritarianism of the political system and the vertical control that the government exercised over the peasantry and industrial workers through the PRI’s corporatist structure (González Casanova, 1972). The critical tone of Mexican social science increased after the student movements of 1968 and their repression by the government.

The anthropologists and economists who concentrated on the rural sector showed that, despite the propeasant rhetoric of the Mexican Revolution and of its successor governments, the lot of the small, subsistence-oriented farmer—the peasant farmer—did not significantly improve (Bartra 1974; Esteva 1983; Warman 1980; Hewitt de Alcantara 1976). Mexican and foreign social scientists demonstrated that agrarian reform had only limited success in creating employment opportunities in agriculture, in diversifying the rural economy, and in stimulating development of rural market and service centers. The expense of producing efficiently for high-risk markets deterred many members of the *ejido* from continuing in agriculture (de la Peña 1981). The deterrence increased with the advent of new technological packages that offered substantially improved yields, but which indebted the small producer and created dependence on state bureaucracy or on private sector agro-industries (Barkin 1990). Agricultural modernization in Mexico meant the displacement of the peasant farmer and the increasing importance of commercial cultivation, often linked to agro-industry (Arroyo 1989; Sanderson 1986).

One major factor that changed the pattern of political incorporation was the extension of government bureaucracy from the 1960s onward (Grindle 1977). In agriculture, this resulted in a considerable increase in government personnel administering various programs of rural development, credit, and technical advice. Direct contacts with government officials enabled peasants to bypass local power brokers, thus weakening the broker's position; but it created a new issue, the interface between bureaucracy and the peasant. Bureaucratic officials implemented central government policy but pursued their own career goals, and both objectives often came into conflict with the strategies of peasant farmers.

Demographic factors also conditioned the processes of social change, geographical mobility, and concentration of wealth. The Mexican population has had high rates of growth as a result of significant declines in mortality without offsetting declines in fertility (Alba and Potter 1982). High rates of population growth combined with the lack of economic opportunities in the countryside result in substantial rural-urban and international migration (Massey et al. 1987; Arroyo 1986). The urban growth rate of Mexico between 1940 and 1980 averaged 4.7 percent a year, with approximately a third of urban growth due to migration from rural areas. This rapid increase and the high urban primacy that resulted in Mexico City having a population six times larger than the next-largest city, Guadalajara, attracted the attention of many researchers, often in collaboration with U.S. or European social scientists. Led by Luis Unikel (1977), researchers at the Colegio de Mexico focused on the "urban bias" of Mexican development policies in which subsidies encouraged urban concentration. Garza (1985) showed that without these subsidies the profitability of Mexico City enterprises would have been less than that of enterprises in smaller cities. Other researchers focused on rural-urban migration showing the high social mobility of rural migrants in the urban labor markets, despite the importance of the informal economy (Balán et al. 1973; Muñoz et al. 1977; Escobar 1986). However, other studies looked at the social and political implications of this rapid urban growth in the spread of squatter settlements, the aggravation of poverty, and the beginnings of urban social movements in demand for

basic services (Montaño 1976; Lomnitz 1977; Alonso 1980; Cornelius 1985; Ward 1998).

The last period is that following the debt crises of the early 1980s. These crises reflected the exhaustion of the import-substituting model of development in Mexico. The national industries were not competitive internationally and Mexico desperately needed foreign investment to continue its modernization. From the mid-1980s onward, under strong pressure from international agencies and the United States, the Mexican government adopted a free market approach to development, marked by its accession to the General Agreement on Tariffs and Trade (GATT) in 1985 and its joining with the United States and Canada in the North American Free Trade Agreement (NAFTA) in 1993. Commercial interests in Mexico saw *ejidal* property rights as discouraging foreign and national investment in agriculture and in the cities where *ejidal* land hemmed in city boundaries. In 1992, laws were passed that permitted the private sale of *ejidal* land, thus effectively dismantling the agrarian reform system (de Janvry et al. 1997).

Accompanying these economic policies was a political liberalization, which included electoral reform and a greater role for opposition parties. The regime's new economic policies undermined much of its corporate political support. The abolition of the *ejido* effectively weakened the power of PRI's National Peasant Confederation in the countryside. Deregulation, particularly of labor markets, weakened the main industrial unions. The political challenge to the PRI became greater in this period because economic liberalization also created economic instability (Otero 1996). Income inequality grew and employment became unstable, as indicated by the growth of the urban informal economy.

The growth of the urban population continued, but less rapidly than earlier as a result of declines in fertility and in a diminishing pool of rural migrants (Demos 1997). According to the population count of 1995, 63 percent of Mexico's 91 million inhabitants live in places of more than 10,000 people. The fastest growing cities in the period 1990–1995 (3.1 percent growth annually) were the ones that began the period with between 100,000 and 1 million inhabitants (Solís 1997). An important component of the new population dynamic is a gradual change in the pattern of internal

migration in Mexico. From a predominantly rural-urban migration focusing mainly on Mexico City, Mexican migration patterns have become increasingly interurban, with a movement of population from the center and south of the country toward the cities of the north (Lozano et al. 1997).

The changes in migration patterns reflect the changing economic geography of Mexico resulting from the development of export-oriented manufacturing mainly in the north of the country along or close to the U.S. border. By 1999, the in bond industry (*maquiladora*) sector generated over a million jobs, mainly in the cities of the north. In contrast, in the 1980s manufacturing lost jobs in the old industrial regions of the center of the country, although industrial restructuring in the Federal District of Mexico in the 1990s has reasserted Mexico City's importance in industrial production. The industrial transformation is a complex one. There are assembly-line operations that use cheap, mainly female labor (Fernández-Kelly 1983; Young and Fort 1994). There are also plants with high levels of technology that require workers with high levels of qualification and that are prepared to offer attractive conditions of work. The Mexican car industry has shifted to northern Mexico as part of an integrated North American production system, with Mexico shipping cars as well as parts to the U.S. market (Carrillo 1989). These processes are creating a distinct border region straddling the frontier, neither fully Mexican nor fully American (Bustamante 1981; Tamayo and Fernandez 1983).

The Mexican economy is not only highly regionalized and predominantly urban, but is increasingly based on service employment (García 1988). By 1995, the majority of employment (53 percent) was in services and commerce, with manufacturing and construction contributing 21 percent and agriculture 25 percent (Pacheco 1997). The same source shows that these shifts in sectoral employment have also been accompanied by increasing rates of female economic participation, growing from 21.5 percent in 1979 to 34.5 percent in 1995. Also, after 1979, the employment categories associated with the urban informal economy—self-employed and unpaid family workers—increased from 33.7 percent to 38.3 percent of employment, whereas employees declined from 62.9 percent to 57.2 percent (Pacheco 1997).

New intellectual tendencies are emerging in face of these realities. There is now less emphasis on rural studies than in the past, although there is a growing focus on the consequences for rural areas of economic integration with the United States, including international migration (Cornelius and Myhre 1998). Mexican and U.S. scholars are studying the impact of the U.S. market on production and commercialization in Mexico with respect to crops such as avocados, mangos, and tomatoes (González Chávez 1991). Particular focuses are the difficulties faced by small-scale farmers, given the capital and technology needed to compete in the U.S. market. Also, there is a greater concern with environmental issues than in the past as market development puts greater competitive pressures on local agriculture or creates incentives to develop ecologically fragile areas for tourism (Tudela 1989; Moreno 1992; Toledo 1994).

Studies of international migration have become increasingly numerous, showing how migration to the United States has become the major means by which poor rural households complement inadequate incomes, attracting even the skilled and better educated (Massey et al. 1994). The existence of large Mexican-origin communities in cities throughout the United States, but particularly in Los Angeles and other cities of the Southwest, provides bridgeheads facilitating immigration. The importance of the U.S. migration experience has led scholars to document extensively the life histories of migrants, sometimes explicitly comparing their experiences with those recorded by Gamio and Taylor in the 1930s (Durand 1996). Mexican and U.S. researchers have also focused on the significance for U.S.-Mexico relations of transnational migrant communities where migrants settled in the U.S. maintain active links with their Mexican communities of origin, even to the extent of participating in local politics and development projects (Roberts et al. 1999).

In the realm of urban research, there is now considerable attention given to studies of family, gender and female economic participation (Benería and Roldán 1987; García and Oliveira 1997). These studies began with an emphasis on household coping strategies in face of poverty, particularly the pooling of resources and placing more members in the labor market (González de la Rocha

1994; Chant 1991; de la Peña et al. 1990; Selby et al. 1990; Roberts 1989). They have increasingly taken up issues of the changing role of women within the household as they gain a certain economic independence. The researchers question assumptions about the strength of the Mexican family and its ability to cope on its own with the fragmenting pressures coming from economic adjustment and migration. Domestic violence has become an important topic of research. In contrast with these demythifying visions of the Mexican family, other studies that focus on elites and entrepreneurial groups show that family cooperation and hierarchy are crucial for upper-class social mobility and business success, particularly among foreign immigrants and innovators willing to take risks (Lomnitz and Pérez Lizaur 1987; Ramírez 1994; Padilla Dieste 1997).

There has also been considerable research on the impact of international economic integration and “neoliberal” policies on two phenomena: poverty and political participation. The new faces of poverty and inequality have been examined through the analysis of representative surveys and case studies, but also from the perspective of the state’s retreat from welfare and social services (González de la Rocha and Escobar 1991; Cortés and Rubalcava 1991; Boltvinik 1994; Brachet-Márquez 1996; Escobar 1986). The changing political scene has been studied particularly through electoral studies and the analysis of emerging political cultures. Widespread social discontent from the magnitude of fraud in the 1988 elections, as well as the government’s search for international legitimacy in the context of economic globalization, led to the strengthening of opposition parties and the reform of electoral legislation (Molinar 1989, 1992; Azíz and Peschard 1993; Crespo 1993). The process of Mexican democratization is also related to the decline of clientelistic practices, which nowadays proves to be ineffective for handling demands in both urban and rural situations (Middlebrook 1995). The political awakening of an increasingly active civil society is reflected in new social movements that in addition to their demands for services and social justice nowadays challenge the official party and focus on issues of citizenship (Krotz 1996). Middle-class actors, whose standard of living is also declining rapidly, have a considerable presence in such movements (Sergio Tamayo 1994).

The quest for democracy and citizenship is crucial for the understanding of ethnic movements in Mexico. Their importance was dramatically highlighted by the eruption of the Chiapas rebellion on January 1, 1994—the very date of the formal enactment of NAFTA—but urgent ethnic demands have been put forward by dozens of nonviolent indigenous organizations since the 1970s (Campbell 1994; Zárate 1993). Such organizations criticized official Indigenista policies because of their ineffectiveness in eradicating poverty but also because of their assimilationist practices and their blatant disregard for the cultural and political rights of the indigenous population (Arizpe 1978). This critique was reinforced by a new anthropological literature emphasizing persisting ethnicity and cultural resistance instead of acculturation and national homogeneization (Bonfil 1981; Boege 1988). A radical statement of this position argues for the existence of an Indian “deep Mexico”—the real Mexico that has been artificially covered and repressed by authoritarianism and a spurious imitation of European modernity (Bonfil 1996). Even the National Indigenist Institute adopted a discourse of cultural plurality, and the Ministry of Education reinforced its programs of bilingual education (Instituto Nacional Indigenista 1988). In 1991, the National Congress surprisingly passed a constitutional reform that recognized multiculturalism as an essential component of the Mexican nation. If this reform may be explained as related to the government’s search for international legitimacy when NAFTA was being negotiated, it nevertheless opened the way to new indigenous demands and to a widespread discussion of the issue of autonomy for autochthonous peoples, where the participation of Indian representatives and authors is as important as that of non-Indian scholars (Warman and Argueta 1993; Díaz-Polanco 1997; Villoro 1998).

MIDDLE EASTERN STUDIES

In the closing decades of the twentieth century, successive crises and cataclysmic events in the Middle East, though obviously not unique to this region, have been widely publicized by the American mass media. The 1973 Arab-Israeli War and the subsequent oil crisis, the civil war in Lebanon, the Iranian revolution of 1978–1979 and the ensuing hostage crisis, the Iraq-Iran War of 1980–1988, the Intifadah in the West Bank and Gaza, the Gulf War, the continued bombing of Iraq, the Oslo Agreement between Palestinians and Israelis, and the World Trade Center bombing have increased Americans’ awareness of the Middle East but not necessarily their understanding of its culture and society. Unfortunately, the ways in which the media describe and interpret these events have created negative stereotypes about this region which are reinforced by movies such as *The Siege*. On the other hand, extensive research by anthropologists, historians, and political scientists has provided many insights into Middle Eastern societies and cultures that help counteract these stereotypes. What has been the contribution of sociologists?

More than twenty years ago, a review of a few sociological journals led me to conclude that “with the possible exception of demographers, the scholarly output of American sociologists on the Middle East is still very modest” (Sabagh 1976, p. 523). For the period 1963–1973, of the twelve articles on the Middle East published in the *American Sociological Review* and the *American Journal of Sociology*, eight were on Israel, three on Egypt, and one on Turkey. For the same period *Sociology and Social Research* had even fewer articles on the Middle East, but they were more evenly distributed (two on Israel, two on Turkey, two on Iraq, and one on Israel and Jordan).

One interpretation of this situation, which is still valid today, is that “as long as the research

findings tend to be area-oriented rather than hypothesis-oriented they are not likely to be published in American sociological journals" (Sabagh 1976, p. 523). Is the state of Middle Eastern studies in sociology today any better than in the early 1970s? The objective of this review is to assess the changes that have occurred since the mid-1970s, more particularly in the 1980s and the 1990s. Four topics will be considered: (1) an overview of the salient socioeconomic and demographic characteristics of Middle Eastern countries and their implications for sociological analysis, (2) trends and distributions in the number of sociologists in the United States specializing in the Middle East, (3) a brief review of the main substantive or methodological concerns of these sociologists, and (4) some of their theoretical contributions studies to American sociology. Contributions to the sociological study of Islam will not be reviewed here since they are extensively discussed in the article "Sociology of Islam."

SOCIOECONOMIC AND DEMOGRAPHIC CHARACTERISTICS OF THE MIDDLE EAST

The Middle East includes Iran, Israel, Turkey, and the Arab countries of North Africa and southwest Asia. As shown in Table 1, countries in this vast region vary greatly, not only in population but also in levels of income, education, urbanization, and stages of demographic transition. The most telling differences are those between rich and poor countries, unmatched by the experience of any other Third World region. The range in gross national product (GNP) per capita in 1997 was from \$169 for Somalia to \$17,360 for the United Arab Emirates (UAE) and to \$22,110 for Kuwait, which approaches the figure for the United States. This gap was even greater before the decline in oil prices in the mid-1980s. The least-populated countries (Kuwait, UAE, and Qatar) have the highest incomes, exceeding \$10,000, and two of the most populous countries (Egypt and Iran) have lower incomes, in the range \$1,000–\$2,000. This income differential is in part responsible for a massive labor migration from the poor Arab countries, particularly Egypt and Yemen, to the rich Arab countries (Amin and Awny 1985; Owen 1989). One measure of the importance of this migration is provided by the figures on the share of workers' remittances in the

GNP of labor-exporting countries. In 1992, net workers' remittances constituted 19.5 and 16.5 percent of the GNP of Jordan and Egypt, respectively. Estimates of the size of the Arab labor migration streams vary widely (Amin and Awny 1985; Ibrahim 1982), but it increased rapidly in the 1970s and was substantial in 1980. For Egypt alone, one estimate places the number of workers abroad at over one million in 1980, compared with around 400,000 in 1975 (Amin and Awny 1985; Fergany 1987). There was also a considerable migration from the poor countries of southern Asia and eastern Asia to Gulf countries, with an estimated 700,000 contract workers migrating in 1987 (Stahl and Asam 1990). Prior to the Iraq-Kuwait War in 1990, there were an estimated 2.6 millions migrants in these two countries, but at least 1 million of them left within two months after the outbreak of this war (United Nations, 1996, p. 209). In addition, there was a massive exodus of Yemenis from Saudi Arabia, leading to a sharp drop of net worker remittances for Yemen within a fairly short period. There is no doubt that this massive exodus of labor migrants from Iraq, Kuwait, and Saudi Arabia created new economic problems for Arab labor-exporting countries.

The characteristics and implications of the massive labor migration of Middle Easterners and Asians to the rich Arab oil-producing countries have been analyzed by a few American demographers and sociologists (Arnold and Shah 1984; Sabagh 1993; Sell 1988). These and other studies (Amin and Awny 1985; Fergany 1987) have contributed to the analysis of (1) the process of migrant settlement in countries with stringent legislation against settlement, (2) the impact of this migration on social mobility, and (3) the consequences of labor migration on countries of origin.

While a few North Africans and Turks emigrated to the Gulf, most were attracted by expanding economic opportunities in the European community. In 1996, there was an estimated 2.6 million Turks, 1.1 million Moroccans, and about 1 million Algerians and Tunisians in Europe (OECD 1998, p. 34). Most of the Turks were in Germany, and most of the Algerians and Tunisians and half of the Moroccans resided in France.

Migration streams from the Middle East to the United States go back to the 1980s, but political

Selected Indicators: Middle Eastern Countries and the United States, 1995–1998

upheavals such as the Iranian revolution, the Arab-Israeli wars of 1967 and 1973, and the Lebanese civil war as well as changes in American immigration legislation in the 1960s have led to substantial and more recent immigration to the United States. Thus, of the 1.3 million persons of Middle Eastern origin (including those of Arab, Armenian, Assyrian, Iranians, Israelis, and Turkish origins) in the United States in 1990, half were immigrants and 325,000 were very “new” immigrants who had arrived between 1980 and 1990. (U.S. Bureau of the Census 1993). As indicated by Bozorgmehr (1998, p. 5) “The Iranian revolution and its aftermath have contributed to the growth of the Iranian diaspora worldwide,” so that by 1990 the United States had

285,000 Iranians “defined as persons born in Iran or Iranian ancestry.” This represents a substantial growth from “small beginning of perhaps no more than 15,000 individuals in 1965” (Bozorgmehr and Sabagh 1988, p. 32).

In almost all Middle Eastern countries, rates of population growth of urban areas are higher, and in some cases much higher, than total population growth. This means that rural-urban migration constitutes an important feature of both rich and poor Middle Eastern societies. This rural exodus is most marked in some of the poorest countries but tends to be lower in poor countries with substantial international labor migration.

Differences in secondary school enrollment levels are as wide as income differences. Enrollment ratios in secondary schools in 1996 varied between a minimum of 6 for males and 4 for females in Somalia to a maximum 91 for males and 98 for females in Bahrain, almost equal to the United States (Table 1). While Bahraini's high enrollment ratios could be partly attributed to its relatively high income, wealth is no guarantee of higher education. For Kuwait, which has the highest income level, male secondary enrollment is noticeably lower (65) than it is for Egypt (80) and the Islamic Republic of Iran (79), which have much lower income. The ratios for females are about the same for these three countries, but the female-male gap is greater in Egypt and Iran. It should be noted that in 15 of the 25 Middle Eastern countries in Table 1, the female-male gap in secondary enrollment ratios is 10 percent or less. In Bahrain and Lebanon, females have a higher secondary school enrollment. These findings suggest gender equalization in education. Nevertheless, in some countries, notably Somalia, Yemen, and, surprisingly, Turkey, the gender gap is substantial. Since educational opportunities are fewer in rural areas, particularly for women, this gap could partly reflect the greater importance of these areas. Even in Middle Eastern countries where the educational gender gap is almost nil, women are still much less likely to have gainful employment outside the home than men. Nationwide data on women's employment, however, have to be interpreted carefully, since they include rural areas and also reflect different definitions of employment. Women in Israel, Turkey, and Morocco are the most likely to be employed, but even in these countries the ratio of women's to men's employment is in the range 50–60 percent (Table 1). The ratios between 40 percent and 50 percent in Kuwait, Tunisia, and Mauritania and between 30 percent and 40 percent in seven other Middle Eastern countries. By contrast, with the noticeable exception of Kuwait, in the rich Arab oil-exporting countries with little or no gender inequality in access to education, the ratio is much lower and is mainly around 15 percent. Increasing gender equality in education combined with continued gender inequality in employment in the Middle East have many consequences for women's roles and have been the subject of many analyses (Hatem 1994; Moghadam 1995; Obermeyer 1996). These analyses reveal the complex ways in which family structure, religious

tradition, economic development, and state policies affect the education and employment of women.

It should be noted that even in countries with high labor-force participation by women, there is a glaring gender gap in earned income. Thus, in the United States, while there are 82 gainfully employed women for every 100 gainfully employed men, these women receive only 40 percent of men's earnings. The comparable figures are 50 women and 22 percent for Israel, 57 women and 35 percent for Turkey, and 53 women and 28 percent for Morocco. Surprisingly, this lag in working women's income is less marked in some Middle Eastern countries than in the United States (for sources, see Table 1).

During the last twenty years, fertility and mortality trend in the Middle East indicate that parts of in this region have experienced a rapid demographic transition. In 1980, all countries in this region, except Israel, Lebanon, and Turkey, had total fertility rates (TFR) of 5 or more children per women, often reaching a level above 6 children. Mortality had already declined but was still relatively high. By the end of the twentieth century, life expectancy for males had increased to about 63 years at birth and, even higher, to 74–75 years in Kuwait, Israel, and the UAE, equal to that of the United States (Table 1). There was a similar trend among females, most of whom outlive men by as much as 6 years. In nine Middle Eastern countries there was a marked decline in TFR to fewer than 3.5 children per woman, reaching as low as 2.5–2.7 in Israel, Lebanon, and Turkey in 1997 (Table 1). This is only slightly higher than the TFR for the United States. Clearly some Middle Eastern countries are rapidly undergoing a demographic transition to noticeably lower fertility and mortality, but in some other countries, even though mortality is low, fertility remains high. This is a challenge to the demographic transition theory and has been extensively analyzed by demographers and sociologists (Obermeyer 1992 and 1995).

Clearly, the Middle East is a region worthy of consideration in any analysis of the social and demographic impact of economic modernization and rising levels of income. The sudden increase in the wealth of some Arab countries is part of what Ibrahim (1982) has called the "new Arab social order," which involves the appearance of new social forces, new values, and new behavior

patterns. This has resulted in a great deal of social chaos and the emergence of new social problems. Partly as a result of this social chaos, there have been significant political and social movements and revolutions that need to be analyzed from a comparative sociological perspective.

By making systematic and comparative analyses of various features of Middle Eastern societies, American sociologists could provide a foundation for a better understanding of these societies. This assumes, however, that these sociologists have incorporated the history and experience of Middle Eastern countries into their substantive concerns and theoretical models. The sections that follow will review the trends in the number of sociologists of the Middle East and in the United States, and the substantive focus of their work.

NUMBER OF SOCIOLOGISTS OF THE MIDDLE EAST IN THE UNITED STATES

It is significant that an American sociologist, Monroe Berger of Princeton University, was active in the formation of the Middle East Studies Association of North America (MESA) in 1964 and was elected its first president. Nevertheless, in the mid-1970s there were only nine sociologists teaching courses on the sociology of the Middle East in American departments of sociology (Sabagh 1976, p. 524). While growth was slow, the 1980s and 1990s were marked by a noticeable increase in sociologists teaching or doing research on the Middle East. Sociologist members of MESA, including students, increased from 12 in 1968 to 25 in 1972, 37 in 1984, 52 in 1986, 90 in 1990, and 121 in 1998 (Sabagh 1976; Bonine 1986; MESA 1998; and special tabulation by MESA). Not all these sociologists, however, resided in the United States. In 1986 only 3 percent of MESA members were sociologists, compared to 32 percent who were historians and 21 percent who were political scientists (Bonine 1986, p. 159). In the mid-1980s Bonine could still state that "compared to Latin America, for instance, there are few sociologists and demographers specializing on the Middle East" (1986, p. 160).

While an increasing number of Middle Easterners have come to the United States to obtain Ph.D.'s in sociology, most of them have gone back home; but, as a result of the Iranian revolution and its negative effect on the teaching of Western-type

sociology in Iran, many Iranians who obtained Ph.D.'s in sociology have remained in the United States as intellectual exiles. The Iranian revolution also provided a real impetus for Iranian students to major in sociology so as to gain a better understanding of the revolution.

Dr. Anne Betteridge, executive secretary of MESA, and Nancy B. Dishaw, also of MESA, kindly provided a special tabulation of the countries of birth of 1998 MESA members who indicated sociology as their discipline. There were 62 members who were residents of the United States or Canada with Ph.D.'s in sociology, of whom 44 had received their degrees since 1980, indicating a noticeable increase in the number of sociologists actively interested in Middle East studies. Most of this increase, however, may be attributed to sociologists born in the Middle East, whose numbers more than doubled, from 10 to 25. A comparison of the later and earlier Ph.D. cohorts shows that the number of sociologists born in Iran quadrupled from 3 to 12, the number of those born in Turkey increased from 0 to 7, and the number born in the United States increased more slowly from 8 to 15. By contrast, the number of sociologists born in an Arab country decreased from 7 to 6. The creation of the Association of American University Graduates in 1967 may be partly responsible for this decline.

About half of the 62 sociologists who are members of MESA and who reside in the United States or Canada are in graduate departments of sociology. By contrast, nearly all the 24 sociology student MESA members are in graduate departments of sociology. Not all sociologists with a research or teaching interest in the Middle East are members of MESA. A search of the *Guide to Graduate Departments of Sociology* of the American Sociological Association (ASA) (1999) shows that there were at least 12 who were not members of MESA.

SUBSTANTIVE FOCUS OF SOCIOLOGISTS OF THE MIDDLE EAST

It is safe to assume that sociologists who belong to MESA will focus some of their research and theoretical interest on the Middle East. The directory of ASA members (ASA 1990) provides information on fields of specialization. Unfortunately, there

are no tabulations available that would allow comparisons with all sociologists or sociologists who have an interest in other world areas. There were 26 nonstudent and 9 student members of ASA in 1989 who were also members of MESA. Of the 26 nonstudent members, 15 were in graduate departments of sociology. Members were asked to check four substantive or methodological areas of sociology in order of priority, of which the first and second are below.

The three most important areas of specialization are (1) development and social change, (2) comparative sociology/macro, and (3) political sociology. Next in importance are (1) demography, (2) race/ethnic/minority, (3) sociology of sex roles, and (4) social movements. Unfortunately, no questions were asked about the extent to which sociologists focused on a given region, country, society, or community. For this, it would be necessary to analyze the publications and papers of the 35 scholars who were members of both the ASA and MESA. A survey was made of publications and papers by these scholars that were cited in *Sociological Abstracts* for the period 1985–1990. The three most frequent substantive or theoretical topics were (1) the Iranian revolution, (2) historical-sociological analyses of Turkey and Iran, with an emphasis on dependency or world system approaches, and (3) Iranian immigrants in the United States. Other topics included (1) Egyptian international migration, (2) social distance in Egypt, (3) child nutrition, (4) a review of Arab sociology, and (5) the Intifadah. It is likely, however, that there are many more contributions to Middle Eastern studies by sociologists who are not members of MESA. The task of assessing this literature is clearly beyond the scope of this article. One way to obtain this information is through a survey of these sociologists. In 1983–1984 such a survey was carried out for Arab sociologists or sociologists studying the Arab world (Sabagh and Ghazalla 1986). Ten of the sociologists residing in the United States considered social change and development and the role of Islam to have the highest priority for research on the Arab world.

One issue that needs to be considered is the extent to which sociological research on the Middle East is cited in major American sociological journals. An analysis was made of articles on the Middle East cited in *Sociological Abstracts* for the years 1985–1990 and published in the general and

more specialized sociological journals. Since the number of papers on Israel was substantial, they were left out of the analysis. The results of this analysis showed that the situation was even worse now than it was in the period 1963–1973 (Sabagh 1976). On the other hand, in the 1980s a substantial number of articles on the Middle East were published in the newer or more specialized sociological journals.

An analysis of *Sociological Abstracts* for the period 1985–1990 showed that 31 specialized journals had published 104 articles pertaining to the Middle East or to Middle Easterners. The distribution of articles by country or region (exclusive of Israel) was as follows: Iran, 31; Turkey/Ottoman Empire, 14; Arab world/Middle East, 15; Egypt, 14; other Middle Eastern countries, 19; Palestinians, 5; Arab and Iranian immigrants in the United States, 6. The large number of articles on Iran may be explained by the analyses of the Iranian revolution and by the increasing number of Iranian sociologists in the United States. One issue of *State, Culture, and Society* (1985) included 8 articles devoted to “The Sociological and Ideological Dimensions of the Iranian Revolution.” There were four articles on the Iranian revolution (or comparing the Iranian revolution with other revolutions) in *Theory and Society*. Five specialized journals published 10 articles on marriage and the family and the status of women, 5 of which were on Iran. The period 1985–1990 was also characterized by a substantial number of articles on the Ottoman Empire and Turkey published in the Fernand Braudel Center’s *Review*. The winter 1985 issue of the *Review* included 3 articles on “From Ottoman Empire to Modern State,” and the spring 1988 issue was devoted to the “Ottoman Empire: Nineteenth-Century Transformations.” These articles present critical analyses of the process of incorporation of the Ottoman Empire/Turkey into the world economy. Clearly, sociologists whose research focuses on the Middle East or Middle Easterners have a better chance of getting their articles accepted in specialized sociological journals than in the major and mainstream sociological journals.

In 1996, the editor and board of *Contemporary Sociology* decided to “make a greater effort to cover sociology around the world” (Clawson 1997, p. vii). As a consequence, this journal published assessments of the development of sociology in Egypt and the Arab World (Ibrahim 1997; Naim-Ahmed

1998), Turkey (Oncu 1997), Israel (Ben-Yehuda 1997), and Palestine (Hammami 1997). Earlier, in a section of *Contemporary Sociology* entitled "Journals in Review," Mirsepassi (1995) presented an analysis of Middle Eastern journals. This is perhaps the most promising development of the 1990s, and it is hoped that it will lead to a greater impact of Middle Eastern studies on American sociology in the twenty-first century.

Although the numbers are still small, there has been a surprising increase in articles devoted to the Middle East (excluding Israel) published in the 1990s in the three major sociological journals. From 1990 to 1997, there were 7 articles, all of them devoted to Iran or the Ottoman Empire, in the *American Sociological Review*, the *American Journal of Sociology*, and *Social Forces*. This compares to only 1 article in the same journals in the 1980s.

THEORETICAL AND METHODOLOGICAL CONTRIBUTIONS OF MIDDLE EASTERN STUDIES TO SOCIOLOGY

There are two major ways in which Middle Eastern studies can contribute to sociology: (1) dramatic events in the Middle East, such as wars and revolutions, present a puzzle to sociologists studying such events, and (2) sociologists specializing in Middle Eastern studies focus on substantive issues that have consequences for sociological theory and methodology. Examples of both types of contributions will be given and discussed.

The Iranian Islamic revolution is clearly one of the most dramatic events of the last decades of the twentieth century. For Arjomand, it is a "cataclysm as significant and as unprecedented in world history as the French revolution of 1789 and the Russian revolution of 1917" (1988, p. 3). As could be expected, American sociologists of Iranian origin have contributed many important insights into the causes and consequences of this revolution, and these insights have been and will be incorporated into sociological theories about revolutions (see, e.g., Arjomand 1988; Ashraf and Banuazizi 1985; Ashraf 1988; Dabashi 1984; Moghadam 1989; Parsa 1989). For other sociologists who have studied the nature and sources of revolution, the Iranian revolution presents a real challenge. This is expressed as follows by Theda Skocpol:

The recent overthrow of the Shah, the launching of the Iranian revolution between 1977 and 1979, came as a sudden surprise to outside observers. . . . All of us have watched the unfolding of current events with fascination and, perhaps, consternation. A few of us have also been inspired to probe the Iranian sociopolitical realities behind those events Its unfolding . . . challenged expectations about revolutionary causation that I developed through comparative-historical research on the French, Russian and Chinese revolutions. (1982, p. 265)

Skocpol applied her earlier structural analysis of the causes of revolutions to the Iranian case, pointing to the involvement of urban masses in this revolution, the role of the rentier state, and the structural consequences of Shia Islam. When challenged by Nichols to the effect that she is "ready to concede the potentially revolutionary content of traditional religious teachings" (1986, p. 182). Skocpol replied that "far from offering a 'subjectivist' or 'ideational' analysis, I point out that Shi'a religion had the cultural potential to facilitate either a rebellion against or passive acquiescence to secular authority" (1986, p. 193). Arjomand criticizes Skocpol for not recognizing the normative factor of legitimacy" (1988, p. 191).

Arjomand, Ashraf, and other sociologists indicate the importance of analyzing the 1977-1979 revolution by considering its historical roots, particularly the structural, ideological, and leadership factors in previous uprisings and rebellions. Thus, for Ashraf, "The urban uprising of 1963 combined the leadership of a militant charismatic leader, the political resources of the bazaar-mosque alliance, and the sympathy of activist university students . . . a prelude to the Islamic revolution of 1977-79" (1988, p. 550). Arjomand (1988) points to the involvement of "high-ranking members" of the Shiite "clergy" or hierocracy in the constitutional revolution of 1905-1906. Arjomand (1984a, 1984b, 1988) not only traces the history of the relationship between the Shiite hierocracy, the state, and other social groups but also places his analysis of the Iranian revolution in a comparative perspective. With passage of time, one might expect a decline in the number of sociological analyses of the Iranian revolution. In fact, the opposite is true, and this revolution continues to fascinate some

American sociologists challenged by its implications for theories of revolution, social protests, and social movements. There is also increasing interest in the consequences of this revolution. Kurzman (1994) uses the material about the Iranian revolution to raise some important theoretical questions about resource mobilization theory. In a later paper (1996) he also uses this revolution to challenge the theory about structural and perceived opportunities. His argument is based on a number of interviews he carried out with Iranian expatriates in Turkey. Moaddel (1992) uses the Iranian revolution to test a the role of ideology, suggesting that ideology is a language that is used to express ideas about social problems and their solution. What is probably the first quantitative analysis of events preceding the Islamic revolution was carried out by Karen Rasler, in which she tests a number of hypotheses about the effects of governmental repression and concessions on the number of political protests from December 1, 1977, to February 14, 1979 (1996, p. 138).

Studies of other political protest movements and revolutions in Iran have been brought together in a book edited by John Foran (1994). This book includes analyses of the Tobacco Movement of 1890–1892, the constitutional revolution of 1905–1911, the nationalist movement in Azerbaijan and Kurdistan of 1941–1946, the oil nationalization movement of 1939–1953, and social conflict in the 1960s. American historians of Iran such as Nikki Keddie and Ervand Abrahamian are, of course, very familiar with these events, but the book should inform and hopefully challenge sociologists interested in social movements and revolutions. In one chapter Foran provides an analysis of the 1977–1979 revolution, showing the importance of comparing it to those that occurred in other countries. He concludes that “its deep causes are to be sought in the same processes of dependent development, state repression, political cultures of resistance, economic downturn, and world-systemic opening that underlay other successful revolution in Mexico, Cuba, and Nicaragua” (Foran 1994, p. 181). Foran and Goodwin (1993) and Parsa (1995a) have published studies comparing the Iranian and Nicaraguan revolutions. Parsa (1995a) shows that ideological conversions and tactical considerations explain the support that entrepreneurs and workers gave to the Iranian and Nicaraguan revolution. In another paper, Parsa (1995b) presents a critical

analysis of the role of the bourgeoisie in supporting the process of democratization in Iran under the shah and in the Philippines under Marcos. Moaddel (1996) analyzes the rise of Islamic fundamentalism in Iran and Syria. Sohrabi (1995) has carried out an extensive comparative analysis of the constitutional revolutions in Iran, the Ottoman Empire, and Russia in the early 1990s. Systematic comparisons between the Iranian and other revolutions and their outcomes are the most promising development of the 1990s.

One interesting development of the last twenty years has been the application of the world system theoretical model to the Ottoman Empire and Turkey. An early issue of the Fernand Braudel Center's *Review* includes three articles on the Ottoman Empire and the world economy, one of which provides a program of research delineated by Immanuel Wallerstein (1979). The objective of this program was to analyze the process of incorporation of the Ottoman Empire into the world economy, the consequences of this incorporation, and the degree and nature of the peripheralization of the Ottoman Empire and Turkey. This program was carried out by the Research Working Group on the Ottoman Empire and was coordinated by Caglar Keyder and Immanuel Wallerstein. The work of Kasaba (1987, 1988); Keyder and Tabak (1986); Keyder (1988); Pamuk (1988); and other sociologists, economists, and historians with a world-system perspective has documented the timing and the process of incorporation of the Ottoman Empire into the world economy, the role of the Ottoman bureaucracy, and the emergence of a minority non-Muslim bourgeoisie. Kasaba (1987, p. 842) argues that “between ca. 1750 and ca. 1820 the Ottoman Empire as a whole was incorporated into the capitalist world-economy . . . [and] the history of the Ottoman Empire after the 1820's was that of its peripheralization” (Pamuk's p.). However, analysis of various indexes of foreign trade and investment (1988) shows that until 1914 the degree of integration of the Ottoman Empire into the world economy was noticeably lower than that of Latin America or that of Algeria and Egypt. Also, within the Ottoman Empire different sectors of the economy were incorporated in different periods (Cizacka 1985).

One consequence of the process of incorporation into the world economy was the emergence of

a new bourgeois class of non-Muslim merchants (Kasaba 1987; Keyder 1988). While there was a social class conflict between these merchants and the Ottoman bureaucracy, this conflict “appeared on the Ottoman agenda to be acted out as Moslem-Christian ethnic-religious conflict” (Keyder 1988, p. 162). The periphery-core status of Safavid Iran and the Ottoman Empire in the seventeenth century is analyzed by Foran, who concludes that these states “were far too strong to be colonized and dominated by the core, *and* yet too weak to compete with Europe in the new peripheries of Asia, Southeast Asia, and Africa, not to mention Latin America” (1989, p. 113; *italic in original*). Thus, these states were neither core nor periphery.

The Fernand Braudel Center *Review* continues to publish studies of the Ottoman Empire and Turkey with a world-system perspective. Of particular interest to sociologists interested in the application of this model to urbanization is the special issue of the *Review* (fall 1993) devoted to the role of port cities in the process of incorporation of the Ottoman Empire in the nineteenth century. Included are studies of Izmir by Kasaba, Trabzon by Turgay, and Beirut by Ozveren. Keyder’s study of Istanbul in the 1940s (1993) was also published in *Review*, later in the same year.

One important theoretical and methodological addition to the socio-historical studies of the Ottoman Empire is the research by Karen Barkey on conflict and contention in Turkish villages in the seventeenth century (1997). Barkey statistically analyzes court records about contentions pertaining to taxes and land. She argues that “local and small, are the most basic and common form of contention, closely linked to discontent, often preceding and underlying collective form of discontent (1997, p. 1346).

Studies of Arab immigrants in the United States provide important insights into the process of ethnicity maintenance among immigrants, showing, for example, the importance of minority status in the country of origin, religion, and entrepreneurship in the United States (Abu-Laban 1989; Abraham et al. 1983; Hagopian and Paden 1969; Sawaie 1985; Sengstock 1982; Suleiman and Abu-Laban 1989; Swan and Saba 1974). Pulcini (1993) provides a detailed review of this extensive literature.

The recent immigration from Arab countries, from Israel, and particularly from Iran, documented above, has stimulated sociological studies of the adaptation patterns of these immigrants. Bozorgmehr and Feldman (1996) edited *Middle Eastern Diaspora Communities in America*, which includes chapters on all Middle Easterners, Iranians, Israelis, and Arab Muslims. It is significant that a volume edited by Waldinger, Der-Martirosian, and Bozorgmehr, which is devoted to analyses of the social and economic trajectories of major immigrant groups in the Los Angeles metropolitan region, includes a chapter entitled “Middle Easterners: A New Kind of Immigrants” (Bozorgmehr et al. 1996). It is also notable that *Iranian Studies*, which publishes only articles on Iran, devoted an entire recent issue, edited by Bozorgmehr, to the “Iranian diaspora” (1998). The articles by Bozorgmehr, Ali Modarres, Hamid Naficy, Shideh Hanassab, and Ali Akbar Mahdi cover a wide range of topics, including demographic and socioeconomic trends, patterns of settlement, music videos, sexuality and dating, and ethnic identity.

The high socioeconomic status of Iranian immigrants in the United States and their ethnoreligious diversity provide a theoretical challenge for the study of the process of immigrant adaptation. Iranian immigrants include Christian Armenians and Assyrians, Baha’is, Jews, Muslims, and Zoroastrians. A challenge for the sociological analysis of immigrant adaptation is the fact that some of these groups have their non-Iranian religious counterparts in the United States. This diversity was the focus of the first extensive study of the adaptation of Iranian immigrants in Los Angeles, which has the largest concentration of Iranians in the United States (Bozorgmehr and Sabagh 1989). Bozorgmehr (1997) has developed the concept of “internal ethnicity” for the analysis of the process of adaptation of ethnically diverse immigrant groups. This concept is applicable not only to Iranians but also to many other early and recent immigrant groups. He shows that the neglect of internal ethnicity in the literature has led to the simplification of a complex process of immigrant adaptation.

Bozorgmehr’s recent comprehensive review of the studies of first- and second-generation Iranians (1998) shows the wide range of topics covered by this literature, including comparisons between immigrants and exiles, ethnicity and ethnic identity, professionals and entrepreneurs, gender, and

assimilation. As the sons and daughters of Iranian immigrants are reaching adulthood, it is time for "research to direct its attention" to this second generation (Bozorgmehr 1998, p. 26). It is also time to compare the experiences of the Iranian second generation to the sons and daughters of other immigrants with equally high human and social capital, whether they are from the Middle East or from other regions of the world.

CONCLUSION

One unexpected consequence of the Iranian revolution has been an increase in the number of Iranian sociologists in the United States who have developed extensive and theoretically relevant analyses of this revolution—which, analyses in turn, have stimulated other sociologists to study this revolution. Studies of the Iranian revolution are now appearing in the mainstream sociological journals.

The world-system theoretical model has greatly benefited from extensive studies of the Ottoman Empire, especially by sociologists of Turkish origin. Ottoman archival documents are also being used to test other theoretical perspectives.

The rapid growth in the numbers of Middle Eastern immigrants in the United States in the last twenty-five years has led to the development of new concepts and insights that help us better understand the adaptation of high-status immigrants.

Still, there is much progress to be made. A continuing need exists for incorporating the experiences of this region into sociological models of wars and revolutions, of social and demographic change, of social movements, of gender roles, and the impact of religion on society. As suggested by Miresepassi (1995, p. 324), accomplishment of this work should also lead to the sociology of Middle Eastern studies becoming more relevant.

MILITARY SOCIOLOGY

Military sociology has been a relatively minor field in American sociology. Few sociologists conduct research and write on military topics, and few university departments offer courses of study in this field. To the layperson this circumstance may seem rather curious, given the sheer size and complexity of the military enterprise and the effects of war on individual societies and on the world order as a whole. The Vietnam War of the 1960s and the Persian Gulf War of 1991 are reminders of the impact that military institutions and operations have on American society.

There is no single reason for this lack of emphasis. One reason may be ideological aversion to military matters. Most sociologists fall on the

liberal side of the political spectrum, which has tended to emphasize the peace rather than the war aspect of international relations. Another reason may be that support for most military research requires clear policy applications, and applied research is of less interest to the majority of sociologists. Unlike other social sciences, sociology has not developed a sizable cadre of practitioners who conduct research and policy studies in those nonacademic settings where most military research takes place.

There are notable exceptions. One is the classic work of Samuel Stouffer and colleagues during World War II, *The American Soldier* (1949). Its studies of cohesion, morale, and race relations among combat units made critical contributions to both sociological theory and military personnel policies. The work of Morris Janowitz on organizational and occupational changes in the military is also a significant exception to the rule (Janowitz 1960). Charles Moskos at Northwestern University and David and Mady Segal at the University of Maryland are upholding this tradition today, and their universities are among the few that offer courses on military sociology.

In recent years most of the studies that could be classified as military sociology have been carried out in private research institutes or in military agencies, such as the Rand Corporation, the Brookings Institute, the Human Resources Research Organization (HumRRO), the Army Research Institute, and the Office of the Secretary of Defense. Study teams are generally interdisciplinary, with the fields of psychology, economics, political science, and management frequently represented. While these studies have a sociological complexion, they are not limited to sociological concepts or theory, and they usually have a military policy focus.

Much of the published work in this field consists of reports from these various organizations and agencies. No journal is devoted specifically to military sociology, although there is an American Sociological Association Section on Peace and War. *Armed Forces and Society* is an interdisciplinary journal that focuses on social science topics in the military, and *Military Psychology*, published by the Division on Military Psychology of the American Psychological Association, also covers topics of sociological interest.

This review emphasizes contemporary issues and studies in military sociology, most of which focus on the American military. For reviews that include historical perspectives the reader is referred elsewhere (D. R. Segal 1989; D. R. Segal and M. W. Segal 1991).

THE BASIS OF SERVICE

Without question the most significant issue in American military sociology following World War II is the shift from conscription to voluntary service in 1973. Indeed, many contemporary issues in military sociology—recruiting policies, social representation, and race and gender concerns—flow directly or indirectly from this change in the basis of service.

The notion of voluntary service is not new; indeed, compulsory military service has been the exception rather than the rule in the history of most Western societies, although the meaning of “involuntary” and the nature of service has changed over time. Until the Civil War, U.S. military manpower was raised through state militias, which technically encompassed all “able-bodied men” and hence might be thought of as involuntary. The raising and maintenance of militia was left to the discretion and policies of individual states, and they varied greatly in their representation and effectiveness. Although the desirability and feasibility of national conscription has been debated since the beginning of American history, until 1948 it was employed only during the Civil War and during the World Wars I and II. At all other times enlistment was voluntary (Lee and Parker 1977).

The peacetime conscription adopted in 1948 was a significant and historic departure for U.S. military policy. It was prompted by a combination of factors, including Cold War tensions with the Soviet Union, the critical role being played by the United States in defense alliances, and a perception that America had been inadequately prepared for World War II. These conditions led to proposals for a large standing, or “active-duty,” military force that most believed could not be maintained by voluntary methods. The policy was supported by the American public at that time, and it was consistent with the longstanding value that all “able-bodied men” should serve their country.

The end of the peacetime draft occurred in 1973 at the end of the Vietnam War. The debate over draft policies had been intensifying during the 1960s, particularly over the issue of equity. Given the growth in the American youth population (from the post-World War II baby boom), not all men were needed for the military, and a succession of draft-exemption policies—college, occupational, marriage—fueled the debate over the fairness and equity of the draft. Not only were all able-bodied men not serving, but those exempted from service tended to be from more affluent classes. In an attempt to solve the equity problem, nearly all exemptions were eliminated during the late 1960s, and a national lottery system was adopted in 1969. These changes did not quell the debate; indeed, they probably doomed the draft, since they coincided with one of the most unpopular and unsuccessful wars in America's history. Ending exemptions for college students at a time when college students were leading the movement against the Vietnam War simply fanned the flames of opposition.

On the other side of the issue, most defense and military leaders, including many members of Congress, initially opposed ending the draft. The conditions leading to a large peacetime military force (over two million active-duty personnel) were unchanged and were not under debate. If such a large force was maintained by voluntary means, it was argued, it would be either (1) a mercenary force lacking patriotic motivation, which might be either adventuresome or ineffective in large-scale combat; or (2) socially unrepresentative, thereby placing the burden of combat on minorities, the poor, and the uneducated; or (3) too costly and therefore unaffordable (D. R. Segal 1989).

The shift to voluntary service followed definitive recommendations from a presidential commission, known as the Gates Commission, which concluded that a large peacetime force could be adequately maintained with an all-voluntary force (AVF), provided that basic pay was increased to be competitive with comparable civilian jobs. The commission argued that paying enlisted personnel below-market wages not only was unfair but entailed "opportunity" costs in the form of lost productivity of persons who are compelled to work at jobs they would not voluntarily perform. If military pay and benefits were competitive, the commission's studies concluded, a volunteer force would be socially representative and would be as

effective as a drafted force. Although some attention was given to the social costs of the draft, there is little question that economic analysis and arguments formed the central basis of the commission's report (President's Commission 1970).

THE ALL-VOLUNTEER FORCE

The AVF seemed to work well for the first several years, and the dire predications of those who opposed ending the draft did not materialize. Enlistment requirements were met, and neither quality nor representation appeared much different from draft-era enlistments. The predictions of the Gates Commission seemed to be valid (Cooper 1977).

During the late 1970s, however, this positive picture faded. Military pay and benefits did not keep up with the civilian sector, and post-Vietnam War antiwar attitudes contributed to a generally negative image of the military among youth. The number and quality of new recruits began declining, and the services were forced to enlist more applicants with low aptitude scores and without high school diplomas. To make matters worse, a misnorming error was discovered in the military aptitude test (the Armed Forces Qualifying Test [AFQT]), and the quality of personnel was even lower than had been thought. By 1980 the Army was severely affected, with enlistments falling significantly below requirements and with the proportion of low-aptitude recruits—those reading at fourth- and fifth-grade levels—reaching 50 percent (Eitelberg 1988).

Some claimed that the Gates Commission had been wrong after all, and called for a return to the draft. Others, including the Secretary of the Army, proposed eliminating the aptitude and education standards that had been used since the draft era, arguing that they were not important for military job performance and were potentially discriminatory. Yet others argued that both the AVF and quality standards could be maintained but only by increasing pay and benefits to enable competition with the civilian sector. Critical to this third argument were the policy studies led by the Rand Corporation showing a relationship between aptitudes and military job performance and the feasibility of economic incentives for enlistment (Armor et al. 1982; Polich et al. 1986).

Substantial increases in pay and other benefits in the early 1980s, as well as changes in recruiting techniques including advertising, had a dramatic impact on recruiting success. By the late 1980s, all military services, including the Army, were not only meeting requirement quotas but setting new records in the quality of personnel, surpassing even the draft years in the proportion of recruits with high school diplomas and with higher aptitudes. Most military leaders, many of whom had been skeptical about ending the draft, became strong supporters of the AVF and claimed that morale and skills were at all-time highs and discipline problems were at all-time lows. Although this success did require significant increases in the military personnel budget, both the Congress and the public seemed prepared to pay this cost (Bowman et al. 1986).

The one argument against voluntary service that had never been tested empirically was the combat effectiveness of a market-motivated military. The dramatic success of the American forces in the 1991 Persian Gulf War put an end to any doubt about the ability of a volunteer military to operate successfully. Although high-technology weapons systems received much of the publicity during the war, most military leaders gave as much credit to the skill and morale of their troops, especially in comparison to the poorly trained and demoralized Iraqi soldiers.

Two major events, the collapse of the Soviet Union and the U.S. budget deficit crisis, combined to force major reductions in the size of the active military, which also meant fewer new recruits needed to sustain the smaller force. In spite of lower recruiting targets, recruit quality began edging downward again after the Persian Gulf War. The main causes were thought to be a combination of less positive attitudes toward military on the part of youth, and an increase in the proportion of youth deciding to attend college (Office of the Assistant Secretary of Defense 1998). Although some concerns have surfaced in the military community about these downward trends, by 1998 overall recruit quality was still similar to the successful levels seen during the late 1980s. A mitigating factor is the trend in the number of 18-year-olds, which declined between 1980 and 1992 but has been increasing since then and is expected to continue to grow until 2010.

SOCIAL REPRESENTATION AND ACCESS

Social representation is the degree to which an armed force represents the population from which it has been drawn. Although representation has been a longstanding issue in the United States, concerns were heightened during the AVF era, especially since that era happened to coincide with increasing emphasis on ethnic and gender diversity throughout American society. Racial representation was an issue in both the Vietnam War and the Persian Gulf War, when some civil rights leaders alleged that African Americans were overrepresented in armed forces and hence carried an unfair burden of casualties. Gender representation has developed as a major issue in concert with the women's rights movement, generating major policy changes concerning the participation of women in the military. Finally, with the election of President Bill Clinton and his campaign commitment to overturn the military ban on gays and lesbians, for the first time the issue of sexual orientation became the focus of a major military policy debate.

Debates about social representation usually divide over positions on three basic principles: equity, effectiveness, and responsiveness. The equity principle has two aspects. One is the equity of obligation, meaning that the burden of service and the risks of combat should be borne by all segments of the citizenry. Since a national military force defends the interests of an entire country and entails the risk of casualties, this obligation should be shared uniformly by all citizens, or at least all able-bodied persons. Placing this burden unequally upon certain socioeconomic or racial groups not only violates the canons of fairness in democratic societies but also potentially undermines troop morale and motivation if they perceive the disproportion as unfair (Congressional Budget Office 1989). The other aspect is the equity of access, which often means that racial minorities, women, and homosexuals should be allowed to serve in the military according to their abilities and interests, without artificial restrictions or ceilings.

The principle of effectiveness is raised because most military experts believe that the quality of military personnel in terms of education and aptitude directly influence training and combat effectiveness, and therefore a force that

underrepresents quality personnel will be less effective than a representative force. Although the armed services have attained their quality goals since the late 1980s, there is no guarantee that they can always do so, particularly if military pay and benefits do not keep up with civilian compensation. The effectiveness principle is also invoked by some military experts as a counterargument to the equity position, arguing that allowing women in combat units or open homosexuals in any type of unit will undermine unit morale and cohesion, thereby reducing military effectiveness.

Finally, a representative armed force is sometimes seen as a requirement for military acceptance of civilian control as well as respect for democratic values and institutions. A military force that overrepresents particular social strata or groups (not necessarily lower strata) might place parochial interests or values over the interests and values of the society as a whole. A force drawn proportionately from all major sectors of a society—all regions, races, and social classes—is viewed as one most likely to respect and advance the shared values and goals of the total society.

Racial Representation. One of the most frequently expressed concerns about representation during the AVF era has been the overrepresentation of African Americans and lower socioeconomic groups in the armed services, especially in the Army. Given the early experience with the AVF, this concern is not without some justification, although the situation improved considerably during the 1980s.

Table 1 shows the percentage of black recruits for selected years since the end of the draft in 1973. Black overrepresentation reached its peak in 1979, before the aptitude misnorming error was discovered. Black representation declined during the early 1980s after the military corrected its screening test. It edged back up during the late 1980s, but it declined again during the early 1990s, when recruiting was scaled back in response to the smaller permanent force. Even during the draft years, black representation exceeded the black proportion of the youth population, due in part to higher voluntary enlistment and—prior to the Vietnam War—in part to college exemption policies that applied disproportionately to white youth. During most of the 1990s, black representation in the total active forces was only a few points higher

than a comparable civilian population, although the trend was moving upward again toward the end of the decade, particularly in the Army.

It should not be inferred from these data that black soldiers have a risk of death or injury in combat that is disproportionately higher than that of white soldiers. In fact, black enlisted members in the active-duty forces tend to be underrepresented in combat occupations such as infantry, gun crews, and combat ships and overrepresented in administrative, clerical, and supply occupations. As a result, black casualty rates in wartime are in rough proportion to their share of the general civilian population. For example, in the Vietnam War black fatalities were approximately 12 percent of all American fatalities (Moskos and Butler 1996).

Some argue that these differences in representation present a policy problem, although there is no consensus on what, if anything, should be done about it. While some see black overrepresentation as a problem of burden, others see it as an opportunity for advancement in one of the best-integrated occupational sectors in American society. Higher black representation reflects a greater interest in military careers among African Americans, and any attempt to limit black enlistments could be viewed as a denial of equal opportunity. Indeed, the military in general, and the Army in particular, has been held up as a model for racial integration that should be emulated by other institutions (Moskos and Butler 1996).

Women in the Military. Another topic that has received considerable attention from military sociologists is the role of women in the military. Until 1967 women's participation in the military was limited to 2 percent by law, and most military jobs were closed to women. Even after the restriction was lifted by Congress, the representation of women did not change until the AVF policy and the opening of more noncombat jobs to women. After 1973 the percentage of women enlistees increased steadily, reaching a plateau during the 1980s of about 12 percent. Following major policy changes regarding combat restrictions in the early 1990s, the percentage of women recruits rose again, reaching a second plateau of about 18 percent during the late 1990s. This representation of women in the U.S. military is the highest among all NATO countries (Office of the Assistant Secretary of Defense 1998; Stanley and Segal 1988).

Percentage of Black Recruits, Active Forces

Fiscal Year	Army	Navy	Marine Corps	Air Force	Total Active Forces	U.S. Population, Ages 18–24
1973	19	11	22	14	17	12
1979	37	16	28	17	26	13
1983	22	14	17	14	18	14
1989	26	22	18	12	22	14
1991	20	17	14	11	17	14
1993	20	17	12	13	17	14
1995	22	20	13	14	18	14
1997	23	20	14	17	20	14

Table 1

The growing participation of women in the military reflects several forces, including the need for manpower in the AVF era as well as the increased demands for equity in the treatment of men and women in the workplace. Although all military services recruited more women to help alleviate shortfalls during the 1970s, the Department of Defense has also been pressured by Congress and various interest and advisory groups to enlarge the opportunities for women. The primary barriers to expanding the role of women were statutory restrictions on the assignment of women to combat units and missions. These statutes were repealed by Congress in 1993, and by 1994 the Department of Defense had substantially modified combat restriction regulations. All combat aircraft and combat ships were opened to women (except submarines, for privacy reasons), and the only units that could be closed to women were those that involved "direct ground combat" such as infantry, armor, field artillery, and special forces (Armor 1996).

In spite of the increased participation of women, gender representation continues to be a topic of debate. Arguments against allowing women in combat jobs include physical and emotional differences, privacy and sexual behavior, impacts on unit cohesion and morale, and a basic moral position that women should be protected from the high risk of death, injury, capture, or torture faced by those in ground combat units. Proponents of opening combat jobs to women counter that (1) women should be evaluated individually and not as a group for physical and emotional suitability for combat; (2) experience with women in noncombat jobs has shown no serious adverse impacts on unit cohesion or morale; and (3) women currently

serve in jobs and units that are exposed to increased risks of death, injury, or capture, thereby rendering the moral argument moot and in conflict with current policies (M. W. Segal 1982). Consistent with this latter view, recent reviews on the integration of women in the military report substantial progress (Harell and Miller 1997).

A second major issue involving women in the military is sexual harassment. This problem is obviously not unique to the military; it continues to be an issue throughout American society. It may be more acute, however, in a traditional male institution like the military where women constitute small minorities in many types of jobs. Little hard evidence was available on the extent of sexual harassment in the military until a comprehensive survey was conducted at the request of a 1988 Task Force on Women in the Military. The results indicated rather serious levels of sexual harassment; altogether, 64 percent of women experienced some form of sexual harassment during a one-year period, and 5 percent reported actual or attempted rape or sexual assault (Martindale 1990). These rates of harassment were considerably higher than those found in surveys of federal civilian employees, and they presaged several serious incidents during the 1990s involving sexual harassment or other sexual improprieties in three of the four services: the 1991 Navy Tailhook incident; the 1996 Army Aberdeen Proving Grounds scandal; and the 1997 Air Force dismissal of Kelly Flinn, its first female bomber pilot, for adultery with the husband of an enlisted woman.

A follow-up survey on sexual harassment was conducted in 1995 after the military services had tightened regulations, clarified policies and practices, and increased training with regards to sexual

harassment. The new survey showed some improvement, but rates of sexual harassment were still high, with 55 percent of women reporting some form of unwanted sexual behavior or advances and 4 percent reporting actual or attempted rape or some other form of sexual assault (Bastion et al. 1996).

These high rates of sexual harassment may be due to a number of factors, but are most likely associated with the increased presence of women in a traditional male workplace, and a workplace where a traditional "male" culture may be insensitive if not hostile to women. Another factor may be the attitudes and actions of military leaders and supervisors. Only about half of the women responding to the 1988 survey believed that the senior leadership of their service and their installation made "honest and reasonable" attempts to prevent sexual harassment, and only 60 percent said their immediate supervisor did so. In 1995 these rates had increased by only a few percentage points. Whether or not these figures truly reflect the behavior of military leaders, there is a perception among many military women that the military leadership is still not giving enough emphasis to the problem of sexual harassment.

Policies on Sexual Orientation. Since World War I, persons who acknowledge homosexual status or behavior have been excluded from U.S. military service, either by antisodomy provisions of the Uniform Code of Military Justice or by explicit Department of Defense regulations. This policy was challenged by President Bill Clinton in 1993, who directed the secretary of defense to prepare a "draft of an Executive Order ending discrimination on the basis of sexual orientation in determining who may serve in the Armed Forces" (Rostker and Harris 1993, p. 1). Most senior military officers opposed the change, expressing beliefs that open homosexuals would hamper maintenance of good order and discipline and would undermine unit cohesion and combat effectiveness. Various studies were commissioned, including a major study by the Rand Corporation which concluded that, based on experience in other countries and on certain U.S. police and fire departments, the homosexual ban could be lifted without serious adverse effects on unit cohesion and military performance (Rostker and Harris 1993). The Rand study also noted that nondeclared homosexuals had always served in some number in the

United States and foreign militaries without undue consequences.

The center of the debate shifted to Congress, and particularly to Democratic Senator Sam Nunn, Chairman of the Armed Services Committee, who had made it clear before the 1992 election that he was skeptical about this change and would hold hearings on the matter. Based on these hearings, including testimony from both civilian experts and military leaders, a compromise proposal was crafted, which became known as the "Don't ask, don't tell" policy; this proposal became a federal statute in 1994. The statute states that sexual orientation is a private and personal matter, and is not a bar to military service. It prohibits routine questions about sexual orientation on recruiting forms, but also says that engaging in homosexual conduct is grounds for discharge, and that a voluntary statement by a person acknowledging a gay or lesbian orientation is considered homosexual conduct (Office of the Under Secretary of Defense 1998).

Needless to say, gay and lesbian activists were not satisfied with this compromise, and especially with the provision that service members continue to be discharged for merely telling someone that they are homosexual (Rimmerman 1996). The "Don't ask, don't tell" policy has been challenged in federal courts, but with the exception of several cases where a discharged gay or lesbian has been reinstated because information was obtained improperly, the statute itself has been upheld by several appellate courts.

OTHER ISSUES

There are a number of other topics that are studied by military sociologists or that raise important sociological issues. While they have not received the same degree of attention as the topics reviewed above, they deserve mention.

Sociology of Combat. A major focus of *The American Soldier* studies during World War II, the sociology of combat deals with the social processes involved in combat units, such as unit cohesion and morale, leader-troop relations, and the motivation for combat. Recent works include studies of the "fragging" incidents in the Vietnam War and the role of ideology in combat motivation (Moskos 1988).

Family Issues. The proportion of the military personnel who are married increased from around 40 percent during the draft years to 57 percent by 1995. The current active force also has a higher proportion of career personnel than the draft-era forces (50 percent compared to 25 percent), which means more families and more family concerns. Much of the increase in military benefits is related to families—housing improvements, medical insurance, overseas schools, child care. Family policy issues include the role and rights of spouses (especially officer spouses) and the issue of child care when single-parent members are deployed in a conflict (M. W. Segal 1986).

The Military as Welfare. Somewhat at odds with the social representation issue, some argue that the military should provide opportunity for educational and occupational advancement to the less advantaged in society. The most dramatic example was Project 100,000, begun in 1966 as part of President Lyndon Johnson's War on Poverty, whereby 100,000 men (mostly black) who did not meet education and aptitude requirements were offered enlistments. According to recent follow-up studies of this group as well as a group of low-aptitude recruits who entered the AVF during the misnorming era, military training and experience do not appear to offer advantages when compared to civilian experiences (D. R. Segal 1989).

Military Social Organization. Given changes in military organization at several levels—from draft to AVF, from combat-intensive jobs to technical and support jobs, and from leadership to rational management—some have argued that the military is changing from an institution or “calling” legitimized by normative values to an occupation legitimized by a market orientation (Moskos and Wood 1988). While some of these changes apply to the military as well as to many other American institutions, others suggest that the role of institutional values and traditions is still a dominant characteristic of the American military (D. R. Segal 1989).

War and Peace. The most profound impacts of national security policies and their associated military forces are on the relations between whole nations. There is very little sociological work at this level, although some of the issues would seem to be fairly critical for sociological theory (e.g., the effectiveness of deterrence policies during the

Cold War; the role of effects of military alliances; the consequences of war for societal changes). One of the few sociological discussions of these broader issues is found in D. R. Segal (1989).

Comparative Perspectives. As in many other fields of sociology, comparative studies of sociomilitary issues across nations are relatively scarce. Exceptions are some comparative studies of whether the military is an institution or an occupation (Moskos and Wood 1988) and of women in military forces (Stanley and Segal 1988).

CONCLUSION

Although military sociologists are few in number, it is not a small field. The military is the largest single government agency, and it truly represents a microcosm of the larger society. The types of military issues that can be addressed by social scientists have important ramifications for military policy as well as for the development of sociology as a discipline. On the one hand, sociological concepts and perspectives have contributed to rationalizing the basis of service, studying the problems of social representation, and improving the role of women in the military. On the other hand, studies of the structure and processes of military institutions and policies can enhance sociological understanding and insights about important forms of social behavior, thereby contributing ultimately to advances in social theory.

DAVID J. ARMOR

MODERNIZATION THEORY

Modernization theory is a description and explanation of the processes of transformation from traditional or underdeveloped societies to modern societies. In the words of one of the major proponents, "Historically, modernization is the process of change towards those types of social, economic, and political systems that have developed in Western Europe and North America from the seventeenth century to the nineteenth and have then spread to other European countries and in the nineteenth and twentieth centuries to the South American, Asian, and African continents" (Eisenstadt 1966, p. 1). Modernization theory has been one of the major perspectives in the sociology of national development and underdevelopment since the 1950s. Primary attention has focused on ways in which past and present premodern societies become modern (i.e., Westernized) through processes of economic growth and change in social, political, and cultural structures.

In general, modernization theorists are concerned with economic growth within societies as indicated, for example, by measures of gross national product. Mechanization or industrialization are ingredients in the process of economic growth. Modernization theorists study the social, political, and cultural consequences of economic growth and the conditions that are important for industrialization and economic growth to occur. Indeed, a degree of circularity often characterizes discussions of social and economic change involved in modernization processes because of the notion,

embedded in most modernization theories, of the functional compatibility of component parts. The theoretical assumptions of modernization theories will be elaborated later.

It should be noted at the outset that the sociological concept of modernization does not refer simply to becoming current or “up to date” but rather specifies particular contents and processes of societal changes in the course of national development. Also, modernization theories of development do not necessarily bear any relationship to more recent philosophical concepts of “modernity” and “postmodernity.” Modernity in philosophical and epistemological discussions refers to the perspective that there is one true descriptive and explanatory model that reflects the actual world. Postmodernity is the stance that no single true description and explanation of reality exists but rather that knowledge, ideology, and science itself are based on subjective understandings of an entirely relational nature. While their philosophical underpinnings place most modernization theories of development into the “modern” rather than the “postmodern” context, these separate uses of the term *modernity* should not be confused.

Also, modernization, industrialization, and development are often used interchangeably but in fact refer to distinguishable phenomena. Industrialization is a narrower term than modernization, while development is more general. Industrialization involves the use of inanimate sources of power to mechanize production, and it involves increases in manufacturing, wage labor, income levels, and occupational diversification. It may or may not be present where there is political, social, or cultural modernization, and, conversely, it may exist in the absence of other aspects of modernization. Development (like industrialization) implies economic growth, but not necessarily through transformation from the predominance of primary production to manufacturing, and not necessarily as characterized by modernization theory. For example, while modernization theorists may define development mainly in terms of economic output per capita, other theorists may be more concerned about development of autonomous productive capacity, equitable distribution of wealth, or meeting basic human needs. Also, while modernization theories generally envision democratic and capitalist institutions or secularization of belief systems as components of modern society,

other development perspectives may not. Indeed, dependency theorists even talk about the “development of underdevelopment” (Frank 1966).

Each of the social science disciplines pays particular attention to the determinants of modern structures within its realm (social, political, economic) and gives greater importance to structures or institutions within its realm for explaining other developments in society. Emphasis here is given to sociological modernization theory.

Although there are many versions of modernization theory, major implicit or explicit tenets are that (1) societies develop through a series of evolutionary stages; (2) these stages are based on different degrees and patterns of social differentiation and reintegration of structural and cultural components that are functionally compatible for the maintenance of society; (3) contemporary developing societies are at a premodern stage of evolution and they eventually will achieve economic growth and will take on the social, political, and economic features of western European and North American societies which have progressed to the highest stage of social evolutionary development; (4) this modernization will result as complex Western technology is imported and traditional structural and cultural features incompatible with such development are overcome.

At its core modernization theory suggests that advanced industrial technology produces not only economic growth in developing societies but also other structural and cultural changes. The common characteristics that societies tend to develop as they become modern may differ from one version of modernization theory to another, but, in general, all assume that institutional structures and individual activities become more highly specialized, differentiated, and integrated into social, political, and economic forms characteristic of advanced Western societies.

For example, in the social realm, modern societies are characterized by high levels of urbanization, literacy, research, health care, secularization, bureaucracy, mass media, and transportation facilities. Kinship ties are weaker, and nuclear conjugal family systems prevail. Birthrates and death rates are lower, and life expectancy is relatively longer. In the political realm, the society becomes more participatory in decision-making processes,

and typical institutions include universal suffrage, political parties, a civil service bureaucracy, and parliaments. Traditional sources of authority are weaker as bureaucratic institutions assume responsibility and power. In the economic realm, there is more industrialization, technical upgrading of production, replacement of exchange economies with extensive money markets, increased division of labor, growth of infrastructure and commercial facilities, and the development of large-scale markets. Associated with these structural changes are cultural changes in role relations and personality variables. Social relations are more bureaucratic, social mobility increases, and status relations are based less on such ascriptive criteria as age, gender, or ethnicity and more on meritocratic criteria. There is a shift from relations based on tradition and loyalty to those based on rational exchange, competence, and other universally applied criteria. People are more receptive to change, more interested in the future, more achievement-oriented, more concerned with the rights of individuals, and less fatalistic.

Underlying the description of social features and changes that are thought to characterize modern urban industrial societies are theoretical assumptions and mechanisms to explain the shift from traditional to modern societal types. These explanatory systems draw upon the dominant theoretical perspectives in the 1950s and 1960s, growing out of classical evolutionary, diffusion, and structural-functionalist theories.

The evolutionary perspective, stemming from Spencer, Durkheim, and other nineteenth-century theorists, contributed the notion that societies evolve from lower to higher forms and progress from simple and undifferentiated to more complex types. Western industrial society is seen as superior to preindustrial society to the extent that it has progressed through specialization to more effective ways of performing societal functions. Diffusionists added the ideas that cultural patterns associated with modern society could be transferred via social interaction (trade, war, travelers, media, etc.) and that there may be several paths to development rather than linear evolution. Structural functionalists (Parsons 1951; Hoselitz 1960; Levy 1966) emphasized the idea that societies are integrated wholes composed of functionally compatible institutions and roles, and that societies

progress from one increasingly complex and efficient social system to another. This contributed to the notion that internal social and cultural factors are important determinants or obstacles of economic change.

Research by Smelser (1969) draws on all three traditions in describing modernization of society through processes of social differentiation, disturbances, and reintegration. In a manner similar to other conceptions of modernization, Smelser emphasizes four major changes: from simple to complex technology, from subsistence farming to commercial agriculture, from rural to urban populations, and, most important, from animal and human power to inanimate power and industrialization.

Parsons's later theoretical work (1964) also combines these perspectives in a neo-evolutionist modernization theory that treats societies as self-regulated structural functional wholes in which the main processes of change are social differentiation and the discovery (or acquisition through diffusion) of certain "evolutionary universals" such as bureaucratic organizations and money markets. These, in turn, increase the adaptive capacity of the society by providing more efficient social arrangements and often lead to a system of universalistic norms, "which, more than the industrial revolution itself, ushered in the *modern* era of social evolution" (Parsons 1964, p. 361). A similar neo-evolutionist social differentiation theory of modernization is provided by Eisenstadt (1970).

Another early influence on modernization theory was Weber's work on the Protestant ethic. This work stressed the influence of cultural values on the entrepreneurial behavior of individuals and the rise of capitalism. Contemporary theorists in the Weberian tradition include Lerner, McClelland, Inkeles, and Rostow. Lerner's (1958) empirical studies in several Middle Eastern societies identified empathy, the capacity to take the perspective of others, as a product of media, literacy, and urbanization and as a vital ingredient in producing rational individual behavior conducive to societal development. McClelland (1961) felt that prevalence of individuals with the psychological trait of high "need for achievement" was the key to entrepreneurial activity and modernization of society. In a similar vein, Inkeles and Smith (1974) used interview data from six societies to generate a set

of personality traits by which they defined “modern man.” They felt that the prevalence of individual modernity in society was determined by such factors as education and factory experience and that individual modernity contributed to the modernization of society. Finally, Rostow’s (1960) well-known theory of the stages of economic growth, which he derived from studying Western economic development, emphasized the importance of new values and ideas favoring economic progress along with education, entrepreneurship, and certain other institutions as conditions for societies to “take off” into self-sustained economic growth.

All of these versions of modernization theory depict a gradual and more or less natural transition from “traditional” social structures to “modern” social structures characteristic of Western European and North American societies. More specifically, these theories tend to share to one degree or another the views that (1) modern people, values, institutions, and societies are similar to those found in the industrialized West, that is, the direction of change tends to replicate that which had already occurred in Western industrial societies; (2) tradition is opposite to and incompatible with modernity; (3) the causes of delayed economic and social development (i.e., underdevelopment) are to be found within the traditional society; (4) the mechanisms of economic development also come primarily from within societies rather than from factors outside of the society; and (5) these internal factors (in addition to industrial development) tend to involve social structures, cultural institutions, or personality types.

In keeping with this orientation, empirical studies of sociological modernization tend to deal with the internal effects of industrialization or other economic developments on traditional social institutions or with the social, political, and cultural conditions that facilitate or impede economic growth within traditional or less-developed societies. Examples might include research on the impact of factory production and employment on traditional family relations or the effects of an indigenous land tenure system on the introduction of cash crop farming in society.

Even though modernization theory since the 1960s has been dominated by and sometimes equated with Parsons’s neo-evolutionary theory, it is

clear that there is no single modernization theory but rather an assortment of related theories and perspectives. In addition to those mentioned, other important contributors of theoretical variants include Hagan (1962), Berger, Berger, and Kellner (1973), Bendix (1964), Moore (1967), Tiryakian (1985), and Nolan and Lenski (1999). Useful reviews include Harrison (1988), Harper (1993), and Jaffee (1998).

Since the 1960s, many critiques of modernization theory and the emergence of competing theories of development have eroded support for modernization theory. Foremost among these are dependency, world systems, and neo-Marxist theories, all of which criticize the ethnocentricity of the modernization concept and the bias in favor of dominant capitalist interests. The focus of these theories is on explaining the contemporary underdevelopment of Third World countries or regions of the world in terms of colonization, imperialist interference, and neocolonial exploitation of developing countries since their gaining of independence. In these counterperspectives, both development and underdevelopment are viewed as part of the same process by which certain “center” countries or regions become economically advanced and powerful at the expense of other “periphery” areas. Rather than explaining development and underdevelopment by the presence or absence of certain internal institutions or personalities, these alternative theories argue that both result from unequal exchange relations and coalitions of interests associated with the structural position of societies in the global economy. Rather than interpreting underdeveloped societies as traditional or archaic, both underdeveloped and developed societies are contemporary but asymmetrically linked parts of capitalist expansion. Both are relatively “modern” phenomena.

Attention to modernization theory in sociology has declined as a result of the theoretical and empirical weaknesses raised especially during the 1970s. Nevertheless, it is still the dominant perspective among government officials and international agencies concerned with third world development. Hoogvelt has noted its influence on development policies as follows:

Because modernisation theories have viewed the total transformation, that is westernisation, of

developing countries to be an inescapable outcome of successful diffusion of the Western economic/technological complex, by methodological reversal it is argued that a reorganization of existing social and cultural as well as political patterns in anticipation of their compatibility with the diffused Western economic/technological complex may in fact facilitate the very process of this diffusion itself. This monumental theoretical error—which to be fair was not always committed by the theorists themselves—has in fact been made and continues to be made by modernisation policy-makers such as those employed by Western government, U.N. organizations, the World Bank, and so forth. (1978, pp. 60–61)

Thus, various indicators of social, political, and cultural development (such as degree of urbanization, high literacy rates, political democracy, free enterprise, secularization, birth control, etc.) have frequently been promoted as “conditions” for development.

Interestingly, as modern structures and institutions have spread around the world and created economic, political, social, and cultural linkages, an awareness of global interdependence and of the ecological consequences of industrial development and modern lifestyles has grown. It is now clear that finite natural resources and the nature of the global ecosystem could not sustain worldwide modern conditions and practices of European and North American societies even if modernization theory assumptions of evolutionary national development were correct. Thus, new visions and interpretations of national and global development have already begun to replace classical modernization theory.

JOHN KATSILLIS

MONEY

Sociologists treat money paradoxically: On the one hand, money is considered a central element of modern society, and yet it remains an unanalyzed sociological category. In classic interpretations of the development of the modern world, money occupies a pivotal place. As “the most abstract and ‘impersonal’ element that exists in human life” (Weber [1946] 1971, p. 331), it was assumed that money spearheaded the process of rationalization. For Georg Simmel and Karl Marx, money revolutionized more than economic exchange: It fundamentally transformed the basis of all social relations by turning personal bonds into calculative instrumental ties.

But by defining money as a purely objective and uniform medium of exchange, classical social theory eclipsed money’s sociological significance.

If indeed money was unconstrained by subjective meanings and independent social relations, there was little left of sociological interest. As a result, economists took over the study of money: There is no systematic sociology of money. Significantly, the *International Encyclopedia of the Social Sciences* devotes over thirty pages to money but not one to its social characteristics. There are essays on the economic effect of money, on quantity theory, on velocity of circulation, and on monetary reform, but nothing on money as a “réalité sociale,” using Simiand’s apt term (1934).

The sociological invisibility of money is hard to pierce. For instance, the current resurgence of interest in economic sociology has led to a serious revamping of the neoclassical economic model of the market, firms, and consumption (see, e.g., Smelser and Swedberg 1994). But despite the stimulus, no full-fledged sociology of money as social process has emerged. Consider the recent literature on the culture of consumption, which boldly reverses our understanding of modern commodities. The new revisionist approach uncovers the symbolic meanings of what money buys, but, curiously, the cultural “freedom” of money itself is seldom directly challenged (see, e.g., Appadurai 1986; Bronner 1989; Brewer and Porter 1993).

A sociology of money must thus dismantle a powerful and stubborn utilitarian paradigm of a single, neutral, and rationalizing market money. It must show that money is a meaningful, socially constructed currency, continually shaped and redefined by different networks of social relations and varying systems of meanings. There is some evidence that the sociological conversion of money has begun. (See, e.g., Doyle 1992; Carruthers and Espeland 1998; Dodd 1994; Lane 1990; Mizuchi and Stearns 1994; Reddy 1987; Singh 1997; Wuthnow 1996; Mongardini 1998; Neary and Taylor 1998; Zelizer 1994, 1996.) And in anthropology, psychology, political science, geography and history there are also scattered indications that the economic model of money is starting to lose its hold. (See, e.g., Berti 1991; Bloch 1994; Cohen 1998; Guyer 1995; Heath and Soll 1996; Helleiner 1998; Kahneman and Tversky 1982; Lane 1990; Parry and Bloch 1989; Leyshon and Thrift 1997; Thaler 1990; Shafir, et al. 1997; Shell 1995.) The following two sections will first discuss the classic approach

to money and then propose the basis for a sociology of money.

MARKET MONEY: A UTILITARIAN APPROACH TO MONEY

Many eighteenth-century thinkers saw the monetization of the economy as compatible with or even complementary to the maintenance of a morally coherent social life (see Hirschman 1977; Silver 1990). But the transformative powers of money captured the imagination of nineteenth- and early twentieth-century social theorists. Money turned the world, observed Simmel ([1908] 1950, p. 412), into an “arithmetic problem.” On purely technical grounds, the possibility of money accounting was essential for the development of impersonal rational economic markets. But traditional social thinkers argued that the effects of money transcended the market: More significantly, money became the catalyst for the generalized instrumentalism of modern social life. As Simmel ([1900] 1978, p. 346) observed: “The complete heartlessness of money is reflected in our social culture, which is itself determined by money.”

The task of social theory was thus to explain the uncontested revolutionary power of money. Presumably, it came from money’s complete indifference to values. Money was perceived as the prototype of an instrumental, calculating approach; in Simmel’s ([1900] 1978, p. 211) words, money was “the purest reification of means.” Unlike any other known product, money was the absolute negation of quality. With money, only quantity mattered. That “uncompromising objectivity” allowed it to function as a “technically perfect” medium of modern economic exchange. Free from subjective restrictions, indifferent to “particular interests, origins, or relations,” money’s liquidity and divisibility were infinite, making it “absolutely interchangeable” (pp. 373, 128, 441). Noneconomic restrictions in the use of money were unequivocally dismissed as residual atavisms. As money became nothing but “mere money,” its freedom was apparently unassailable and its uses unlimited. With money, all qualitative distinctions between goods were equally convertible into an arithmetically calculable “system of numbers” (p. 444).

This objectification of modern life had a dual effect. On the one hand, Simmel argued that a

money economy broke the personal bondage of traditional arrangements by allowing every individual the freedom of selecting the terms and partners of economic exchange. But the quantifying alchemy of money had a more ominous chemistry. In an early essay, Marx ([1844] 1964, p. 169) had warned that the transformational powers of money subverted reality: “Confounding and compounding . . . all natural and human qualities . . . [money] serves to exchange every property for every other, even contradictory, property and object: it is the fraternization of impossibilities.” As the ultimate objectifier, money not only obliterated all subjective connections between objects and individuals but also reduced personal relations to the “cash nexus.” Half a century later, Simmel ([1908] 1950, p. 414) confirmed Marx’s diagnosis, dubbing money a “frightful leveler” that perverted the uniqueness of personal and social values. And Max Weber ([1946] 1971, p. 331) pointed to the fundamental antagonism between a rational money economy and a “religious ethic of brotherliness.”

The prevailing classic interpretation of money thus absolutized a model of market money, shaped by the following five assumptions:

1. The functions and characteristics of money are defined strictly in economic terms. As a qualityless, absolutely homogeneous, infinitely divisible, liquid object, money is a matchless tool for market exchange.
2. All monies are the same in modern society. Differences can exist in the quantity of money but not in its meaning. Thus, there is only one kind of money—market money.
3. A sharp dichotomy is established between money and nonpecuniary values. Money in modern society is defined as essentially profane and utilitarian in contrast to noninstrumental values. Money is qualitatively neutral; personal, social, and sacred values are qualitatively distinct, unexchangeable, and indivisible.
4. Monetary concerns are seen as constantly enlarging, quantifying, and often corrupting all areas of life. As an abstract medium of exchange, money has not only the freedom but also the power to draw an

increasing number of goods and services into the web of the market. Money is thus the vehicle for an inevitable commodification of society.

5. The power of money to transform nonpecuniary values is unquestioned, while the reciprocal transformation of money by values or social relations is seldom conceptualized or else is explicitly rejected.

As the classic view reasons, the monetization of the economy made a significant difference to the organization of social life. For example, it facilitated the multiplication of economic partners and promoted a rational division of labor. But a link is missing from the traditional approach to money. Impressed by the fungible, impersonal characteristics of money, classic theorists emphasized its instrumental rationality and apparently unlimited capacity to transform products, relationships, and sometimes even emotions into an abstract and objective numerical equivalent. But money is neither culturally neutral nor socially anonymous. It may well “corrupt” values and social ties into numbers, but values and social relations reciprocally corrupt money by investing it with meaning and social patterns.

TOWARD A SOCIOLOGY OF MONEY

The utilitarian model has had a remarkable grip on theorizing about money. Coleman (1990, pp. 119–131), for example, builds an extremely sophisticated analysis of social exchange yet continues to treat money as the ultimate impersonal common denominator. Even when analysts recognize the symbolic dimension of modern money, they stop short of fully transcending the utilitarian framework. Parsons (1971a, p. 241; 1971b, pp. 26–27), for instance, explicitly and forcefully called for a “sociology of money” that would treat money as one of the various generalized symbolic media of social interchange, along with political power, influence, and value commitments. In contrast to Marx’s definition of money as the “material representative of wealth” ([1858–1859] 1973, p. 222), in Parsons’s media theory, money was a shared symbolic language; not a commodity, but a signifier, devoid of use-value. Yet Parsons restricts the symbolism of money to the economic sphere. Money,

Parsons (1967, p. 358) contends, is the “symbolic ‘embodiment’ of economic value, of what economists in a technical sense call ‘utility.’” Consequently, Parsons’s media theory left uncharted the symbolic meaning of money outside the market: money’s cultural and social significance beyond utility. Giddens (1990) complains that Parsons incorrectly equates power, language, and money, whereas for Giddens money has a distinctly different relationship to social life. As a “symbolic token,” money, in Giddens’s analysis, serves as a key example of the “disembedding mechanisms associated with modernity,” by which he means the “‘lifting out’ of social relations from local contexts of interaction and their restructuring across indefinite spans of time-space” (1990, pp. 22, 25, 21). Giddens’s interpretation still ignores the fact that despite the transferability of money, people make every effort to embed it in particular times, places, meanings, and social relations.

Anthropologists provide some intriguing insights into the extraeconomic, symbolic meaning of money, but mostly with regards to primitive money. For instance, ethnographic studies show that in certain primitive communities, money attains special qualities and distinct values independent of quantity. How much money is less important than *which* money. Multiple currencies, or “special-purpose” money, using Polanyi’s term (1957, pp. 264–266), have sometimes coexisted in one and the same village, each currency having a specified, restricted use (for purchasing only certain goods or services), special modes of allocation and forms of exchange (see, e.g., Bohannan 1959), and, sometimes, designated users.

These special moneys, which Douglas (1967) has perceptively identified as a sort of primitive coupon system, control exchange by rationing and restricting the use and allocation of currency. In the process, money sometimes performs economic functions serving as media of exchange, but it also functions as a social and sacred “marker,” used to acquire or amend status, or to celebrate ritual events. The point is that primitive money is transformable, from fungible to nonfungible, from profane to sacred.

But what about modern money? Has modernization indeed stripped money of its cultural meaning? Influenced by economic models, most interpretations establish a sharp dichotomy between

primitive, restricted “special-purpose” money and modern “all-purpose” money, which, as a single currency, unburdened by ritual or social controls, can function effectively as a universal medium of exchange. Curiously, when it comes to modern money, even anthropologists seem to surrender their formidable analytical tools. For instance, twenty years ago, Douglas (1967), in an important essay, suggested that modern money may not be unrestricted and “free” after all. Her evidence, however, is puzzlingly limited. Modern money, argues Douglas (p. 139), is controlled and rationed in two situations: in international exchange and at the purely individual personal level, where “many of us try to primitivize our money . . . by placing restrictions at source, by earmarking monetary instruments of certain kinds for certain purposes.”

Modern money, however, is marked by more than individual whim or by the different material form of currencies. As François Simiand, one of Durkheim’s students, argued, the extraeconomic, social basis of money remains as powerful in modern economic systems as it was in primitive and ancient societies (1934). Indeed, Simiand warned against an orthodox rationalist approach that mistakenly ignores the persistent symbolic, sacred, and even magical significance of modern money. In recent work, sociologists, as well as anthropologists, psychologists, historians, and political scientists, have finally heeded the warning, proposing long-overdue alternatives to the standard utilitarian model of money.

Impatient with their former theoretical blinders, some anthropologists are now claiming modern money for their disciplinary terrain, casting off the fallacy of a single, culturally neutral currency. Parry and Bloch’s important collection of essays (1989) demonstrates the heterogeneity of money, showing how the multiple symbolic meanings of modern money are shaped by the cultural matrix. In psychology, new studies reject the notion that money is psychologically general, maintaining that instead money involves “multiple symbolizations” (Lea et al. 1987, p. 335). An exciting literature on “mental accounting” challenges the economists’ assumption of fungibility by showing the ways individuals distinguish between kinds of money. For instance, they treat a windfall income much differently from a bonus or an inheritance, even when the sums involved are identical.

A sociological accounting of money goes even further. Anthropologists reveal the multiple symbolic representations of modern money in societies outside the centers of capitalism, and psychologists explore individual or household-based differentiations between monies. A sociological model, on the other hand, must show how, even in the most advanced capitalist societies, different networks of social relations and meaning systems mark modern money, introducing controls, restrictions, and distinctions that are as influential as the rationing of primitive money. Special money in the modern world may not be as visibly identifiable as the shells, coins, brass rods, or stones of primitive communities, but its invisible boundaries emerge from sets of historically varying formal and informal rules that regulate its uses, allocation, sources, and quantity. How else, for instance, do we distinguish a bribe from a tribute or a donation, a wage from an honorarium, or an allowance from a salary? How do we identify ransom, bonuses, tips, damages, or premiums? True, there are quantitative differences between these various payments. But surely, the special vocabulary conveys much more than diverse amounts. Detached from its qualitative differences, the world of money becomes undecipherable.

The sociological model of money thus challenges the traditional utilitarian model of market money by introducing different fundamental assumptions in the understanding of money:

1. While money does serve as a key rational tool of the modern economic market, it also exists outside the sphere of the market and is profoundly shaped by different networks of social relations and varying systems of meaning.
2. Money is not a single phenomenon. There is a plurality of different kinds of monies; each special money is shaped by a particular set of cultural and social factors and is thus qualitatively distinct. Market money does not escape extraeconomic influences but is in fact one type of special money, subject to particular social and cultural influences.
3. The classic economic inventory of money’s functions and attributes, based on the assumption of a single general-purpose

type of money, is thus unsuitably narrow. By focusing exclusively on money as a market phenomenon, it fails to capture the complex range of characteristics of money as a social medium. A different, more inclusive coding is necessary, for certain monies can be indivisible (or divisible but not in mathematically predictable portions), nonfungible, nonportable, deeply subjective, and therefore qualitatively heterogeneous.

4. The assumed dichotomy between a utilitarian money and nonpecuniary values is false, for money under certain circumstances may be as singular and unexchangeable as the most personal or unique object.
5. Given the assumptions above, the alleged freedom and unchecked power of money become untenable assumptions. Culture and social structure set inevitable limits to the monetization process by introducing profound controls and restrictions on the flow and liquidity of money. Extraeconomic factors systematically constrain and shape (a) the uses of money, earmarking, for instance, certain monies for specified uses; (b) the users of money, designating different people to handle specified monies; (c) the allocation system of each particular money; (d) the control of different monies; and (e) the sources of money, linking different sources to specified uses.

Exploring the quality of multiple monies does not deny money's quantifiable and instrumental characteristics but moves beyond them; it suggests very different theoretical and empirical questions from those derived from a purely economic model of market money. In fact, a utilitarian theory of money had a straightforward task: explaining how money homogenized and commoditized modern social life. Its critics have a much more complex empirical agenda. The illusion of a fully commoditized world must be rectified by showing how different social relations and systems of meanings actively create and shape a plurality of qualitatively distinct kinds of money. Specifically, a sociological theory of money must come to grips with the remarkably

different ways in which people identify, classify, interpret, organize, and use money.

Consider for instance the family economy. Domestic money—which includes wife's money, husband's money, and children's money—is a special category of money. Its meanings, uses, allocation, and even quantity are partly determined by considerations of economic efficiency, but domestic money is equally shaped by ideas about family life, by power relationships, age, gender, and social class (Zelizer 1994; Pahl 1989; Singh 1997). For instance, a wife's pin money—regardless of the amount involved—was traditionally reserved for special purchases such as clothing or vacations and kept apart from the “real” money earned by her husband. Or consider the case of gift money. When money circulates among friends or kin as a personal gift for ritual events such as weddings, christenings, bar mitzvahs, or Christmas, it is reshaped into a sentimental currency expressing care and affection. It matters who gives it, when it is given, how it is presented, and how spent. Within formal institutions, money is again redefined this time partly by bureaucratic legislation (Goffman 1961).

These cases are not anomalies or exceptions to valuefree market money but typical examples of money's heterogeneity in modern society. In fact, money used for rational instrumental exchanges is simply another socially created currency, not free from social constraints, but subject to particular networks of social relations and its own set of values and norms. A sociological theory of money must explain the sources and patterns of variation between multiple monies. How, for instance, do personal monies, such as domestic and gift monies, which emerge from the social interaction of intimates, differ from the imposed institutional money of inmates? How does the social status of transactors affect the circulation of monies? What determines the relative rigidity or permeability of boundaries between monies? And what are the patterns of conversions between them?

Developing a sociological model of multiple monies forms part of a broader challenge to neoclassical economic theory. It offers an alternative approach not only to the study of money but to all other aspects of economic life, including the market. In the long run, a proper sociological

understanding of multiple monies should challenge and renew explanation of large-scale economic change and variation. It should illuminate such phenomena as aggregate expenditures on consumer durables, rates of saving, response to inflation, income redistribution, and a wide range of other phenomena in which individual consumer actions make a large macroeconomic difference. In the sociological model, economic processes of exchange and consumption are defined as one special category of social relations, much like kinship or religion. Thus, economic phenomena such as money, although partly autonomous, intertwine with historically variable systems of meanings and structures of social relations.

VIVIANA ZELIZER

MORAL DEVELOPMENT

Morality refers to the set of values that people use to determine appropriate behavior, that is, what is right versus what is wrong. Determining which behavior is morally appropriate, or “right,” is

essentially a cognitive decision-making process called *moral judgment*.

Moral judgment is but one component of the process leading to the actual performance of morally appropriate behavior (Rest 1986). However, research on moral development over the past forty-five years has focused primarily on the development of moral judgment. This is due in large part to the influence of psychologists Lawrence Kohlberg (1969, 1971, 1976) and Jean Piaget ([1932] 1948).

Both Piaget and Kohlberg maintained that moral behavior largely depends upon how one perceives the social world and oneself in relation to it. Furthermore, they viewed moral decision making as a rational process and thus linked the development of moral judgment to the development of rational cognition. In this way, moral development is seen largely as changes in one’s *way of thinking* about questions of morality as he or she gets older.

The present discussion will provide a brief historical description of the theoretical foundation laid down by Piaget and Kohlberg; the method used by Kohlberg to assess moral development as well as alternative methods that have emerged more recently; some of the major criticisms and reconceptualizations of Kohlberg’s theory of moral development; and recent research that has pursued those criticisms in the areas of cultural differences, gender differences, and continued adult development.

THEORETICAL FOUNDATION

Kohlberg built on Piaget’s theory of cognitive development to hypothesize a sequence of six specific stages of moral judgment in individual development. This theory of moral development is based on a fundamental idea from Piaget that the way people think about the physical and social world is the result of an “interactional” process between the human organism’s innate tendencies and influences from the environment.

This “cognitive-developmental” approach is thus distinguished from both maturational and environmental theories of development. Maturational theories (Gesell 1956) maintain that patterns of behavior express the organism’s inherent

tendencies. Development is seen as the natural unfolding of a process determined by hereditary factors. In contrast, environmental theories argue that behavior is determined primarily by external influences. From this point of view, behavior is not innately patterned but is essentially learned, whether as a result of conditioning processes that associate the behavior with particular stimuli, rewards, and punishment, or as a result of observing (and subsequently modeling) the behavior of others.

Social learning theory (Bandura 1977) has produced considerable research on how observational learning explains a variety of behaviors relevant to morality, including prosocial behavior (e.g., sharing, cooperation), aggression, resistance to temptation, and delayed gratification. More recent developments have pursued the question of how individuals exert control over their behavior, thus providing some balance to the theory's focus on environmental influences. Bandura's self-efficacy theory (1982), for example, emphasizes the individual's expectations as important to the successful performance of a behavior. However, social learning theory has not addressed moral action and moral character in terms of a broad developmental course (Musser and Leone 1986).

Cognitive-developmental theory, on the other hand, focuses on the developmental process by which people come to understand and organize, or "cognitively structure," their experience. It attempts to resolve the "nature-nurture" controversy by emphasizing the development of these cognitive structures as the result of the interaction between organismic tendencies and influences from the outside world. While particular ways of understanding experience may reflect innate tendencies, they develop in response to the individual's specific experiences with the environment.

Thus, development is not seen as primarily maturational, because experience is necessary for cognitive structure to take shape. However, neither is development thought to be primarily determined by the environment. Rather, cognitive developmentalists argue that, because the underlying thought organization at each stage is qualitatively different, cognitive development is more than the progressively greater acquisition of information. Furthermore, at any given stage, the current cognitive structure can influence how the world is perceived. Thus, cognitive structure is

seen to be "the result of an interaction between certain organismic structuring tendencies and the structure of the outside world, rather than reflecting either one directly" (Kohlberg 1969, p. 352).

THE DOCTRINE OF COGNITIVE STAGES

Piaget's theory of cognitive development maintains that cognitive structures are periodically transformed or restructured as they become unable to account for (or assimilate) new information from the external world adequately. These periods of restructuring result in new ways of understanding that are different from the earlier mental structures as well as from those to be developed later. This allows for the differentiation of distinct cognitive stages each identifiable by a characteristic approach to processing and organizing one's experience of external reality.

Piaget (1960) identified four main characteristics of cognitive stages. Kohlberg (1969) maintains that these characteristics accurately describe his stages of moral development. The characteristics identified by Piaget are as follows:

1. Stages refer to distinct qualitative differences in the way a person thinks about an experience or solves a problem. Although the focus of attention may be the same, the mode of thinking about it is very different.
2. The progression of stages follows an invariant sequence in the development of individuals. That is, the order in which the stages occur is universal for all human beings. It is possible that the speed or timing at which one progresses through the stages may vary with individual or cultural environments—or even that development may stop at one point or another. However, a given stage cannot be followed by any other stage than the one that is next in the sequence. Conversely, the earlier stage must first be achieved before its inadequacies become apparent and the subsequent transformation to the next stage can occur.
3. The characteristic mode of thinking represents a structured whole. Specific cognitive responses to specific tasks depend upon

the overall organizational framework within which one processes information. It is this underlying cognitive structure that produces a logical consistency to one's responses. Thus, the stage is not identified by specific responses to specific stimuli, but it is the pattern in one's responses that indicates a particular underlying cognitive structure.

4. The sequence of stages is hierarchical. At each stage, the underlying structure represents a more integrated and more complex organizational system, one that adequately accounts for information that had created discrepancies within the previous structure. For example, children in the preoperational stage of cognitive development (Piaget's second stage) cannot understand that equal-sized balls of clay formed into two different shapes still have equal amounts of clay. However, children who have achieved concrete operational thinking (Piaget's third stage) understand the principle of conservation and thus recognize that the amount of clay remains the same (is conserved) for both pieces, even though the pieces have changed in shape (Piaget and Inhelder 1969). The underlying cognitive structure of concrete operational thinking differentiates between amount and shape and integrates the information to achieve a more complex understanding of the phenomenon. It is thus logically superior to preoperational thinking. That the later stages in cognitive development are also more comprehensive and more advanced introduces a hierarchical element to the sequence. The stages of cognitive development are not just different but also hierarchical, in the sense that they provide a progressively more differentiated and more integrated—and hence more adaptive—understanding of one's interaction with the environment.

KOHLBERG'S STAGES OF MORAL DEVELOPMENT

Kohlberg's six stages of moral reasoning are divided into three levels, each consisting of two stages. The three levels are differentiated according to

what serves as the basis for the person's moral judgment, specifically the significance given the prevailing, or "conventional," social expectations and authority. Briefly, the *preconventional* level, which is the level of most children under 9 years old, occurs prior to the individual's achievement of a full understanding of what is expected or required socially. The *conventional* level, which characterizes most adolescents and adults, refers to an understanding of the social conventions and a belief in conforming to and maintaining the established social order. The *postconventional* level is reached only by a minority of adults, who understand and generally accept the social rules and expectations but recognize that these have been established for the larger purpose of serving universal moral principles. Should the social conventions conflict with these principles, then moral judgment at this level will support the principles at the expense of the conventions.

Within each level, the second stage is a more advanced form than the first. More specifically, the preconventional level refers to judgment based not so much on a sense of what is right and wrong as on the physical consequences that any given act will have for the self. Accordingly, at the first stage within this level, characterized by the *punishment and obedience* orientation, the child will make judgments on the basis of avoiding trouble. This includes obeying authorities to avoid punishment.

At Stage 2, still in the preconventional level, the individual has a sense of the needs of others but still makes judgments to serve her or his own practical interests. This is called the *instrumental* orientation. Although the person is beginning to understand that social interaction involves reciprocity and exchange among participants, moral judgment is still determined by the significance that the action has for oneself. Thus a child may share candy to get some ice cream.

Next, in the conventional level, moral judgment is determined by what is considered "good" according to conventional standards. At this level, the individual has an understanding of what kind of behavior is expected. The first stage at this level (Stage 3) is characterized by the *good boy-good girl* orientation. Judgment as to what is right is based on living up to the expectations of others. It involves a trust in established authority and conformity for the sake of approval.

At Stage 4, the orientation is toward doing one's duty. This is called the *law-and-order* orientation. The individual personally subscribes to the existing social order and thus believes that obeying authority and maintaining the social order are good values in their own right. Whereas behaving according to the social conventions is desirable at Stage 3 because it produces approval from others, at Stage 4 the individual has successfully "internalized" these conventions, so that proper behavior is rewarding because it reinforces one's sense of doing one's duty and therefore produces self-approval.

At the postconventional level, one's understanding of what is right and wrong is based on one's personal values and a sense of shared rights and responsibilities. Morality is no longer determined simply by social definition, but rather by rational considerations. Stage 5 is characterized by the *social contract* orientation, which recognizes that conventions are determined by social consensus and serve a social function. There is an emphasis on utilitarian agreements about what will serve the most good for the most people. Here the person recognizes that rules or expectations are essentially arbitrary. The focus on agreement or contract produces an emphasis on what is legal and on operating "within the system" to achieve one's goals.

Stage 6, however, places the responsibility of a given moral decision firmly on the shoulders of the individual. The basis for moral judgment is found in *universal ethical principles* rather than socially established rules or expectations. One is guided by one's own conscience and recognizes the logical superiority of principles such as respect for human dignity. At Stage 6, it is thus possible to adopt a position that is in conflict with the prevailing social order, and to maintain this position as morally correct.

In Kohlberg's last theoretical paper, he and his colleagues attempt to articulate Stage 6 more completely (Kohlberg et al. 1990). They describe it as fundamentally characterized by a "respect for persons," specifically one that successfully integrates a sense of justice that is universal and impartial with an attitude of "benevolence" that is empathic and understanding of the individual (see also Lapsley 1996).

MEASURING MORAL JUDGMENT

Kohlberg's procedure for assessing moral judgment involves presenting a hypothetical "dilemma" that requires the subject to make a moral choice. The most famous example refers to "Heinz," a man whose wife is dying of cancer. The woman could possibly be saved by a new drug, but the druggist who discovered it is charging an exorbitant amount of money for it, ten times what it costs him to make it. Heinz tried but could not raise enough money, so he steals the drug. Should he have done this?

Because Kohlberg's scheme emphasizes cognitive structure, an individual's stage of moral development is indicated not by the actual behavior that is advocated but rather by the pattern of reasoning behind the decision. Thus, two people may arrive at the same decision (e.g., that Heinz should steal the drug to save the life of his dying wife) but for two entirely different reasons. An individual at the preconventional Stage 2, operating within the instrumental orientation, might recommend stealing the drug because any jail term would be short and worth saving his wife. An individual at the postconventional Stage 6 might also recommend stealing the drug but with a different understanding of the dilemma: Although stealing would violate the law, it would uphold the higher principle of valuing human life and allow Heinz to maintain his self-respect.

The difference between the actual behavioral content of a decision and the cognitive structure of the decision is also illustrated when two people arrive at different decisions but for similar reasons. Thus, the decision not to steal the drug because Heinz would go to jail and probably not be released until after his wife died is also Stage 2 thinking. Even though the ultimate decision advocates the opposite behavior of what was indicated above, it is similarly based on the consideration of what would be most instrumental to Heinz's own self-interest. On the other hand, an individual at Stage 6 might recommend not stealing the drug because, although other people would not blame Heinz if he stole it, he would nonetheless violate his own standard of honesty and lose his self-respect.

Because the stage of moral development is demonstrated not by the behavioral content but

by the form of the moral judgment, the subject is allowed to respond freely to these moral dilemmas, and is asked to explain and justify his or her answer. The interviewer can probe with specific questions to elicit more information about the basis of the subject's decision. Interviewers are trained to collect relevant information without directing the subject's responses.

The subject's answers are then transcribed and coded for stage of moral development. Kohlberg identified twenty-five aspects of moral judgment, basic moral concepts that refer to such matters as rules, conscience, one's own welfare, the welfare of others, duty, punishment, reciprocity, and motives. Each of the twenty-five aspects was defined differently for each of the six stages of moral development. Originally, Kohlberg used an aspect-scoring system, whereby every statement made by the subject was coded for aspect and rated as to stage ("sentence scoring"). The subject's usage of any given stage of moral reasoning was indicated by the percentage of his or her statements that was attributed to that stage. Aspect scoring also included an overall "story rating," whereby a single stage was assigned to the subject's total response.

Coding difficulties led to the abandonment of the aspect-scoring system. Because the unit of analysis for sentence scoring was so small, coding often became dependent upon the specific content and choice of words and did not lend itself to identifying the general cognitive structure underlying the statement. Conversely, whereas story rating referred to the total response as the unit of analysis, it created some uncertainty when the subject's answer included conflicting themes.

Kohlberg and his colleagues recognized these scoring difficulties and devoted considerable attention to developing a more reliable and valid scoring system. This led to "standardized issue scoring," which relies on the use of a standardized interview format. The subject is presented with three standard dilemmas, and the interviewer probes for only two issues that are specified for each dilemma (e.g., life and punishment in the Heinz dilemma). Scoring of the subject's responses refers to a manual that describes the patterns of reasoning for Stages 1–5 on each issue (Colby et al. 1987). Stage 6 was dropped from the coding procedure, due to its empirically low incidence, but

was retained as a theoretical construct (Kohlberg et al. 1990).

Because the focus of the new scoring system is directed more toward the abstract mode of reasoning, the unit of analysis is considered larger and less concrete than the single sentence. However, because this approach focuses on specifically identified issues, norms, and elements, it is considered more precise than the global story rating. Despite the qualitative nature of this approach and its potential vulnerability to rater bias, its developers report that long-term study of its inter-rater reliability, test-retest reliability, internal consistency, and validity has produced favorable results (Colby and Kohlberg 1987).

Validity has been a major concern regarding Kohlberg's moral judgment interview. Kurtines and Grief (1974) criticized the low utility of moral judgment scores for predicting moral action. Other questions have been raised about the validity of the data collected, even for the purposes of assessing moral judgment. For one, use of the "classical" dilemmas in this research has been criticized on grounds that they are not representative: Not only do they address hypothetical—as opposed to real-life—circumstances, but they refer to a limited domain of moral issues (e.g., property and punishment). Assessment may fail to indicate the extent to which the person's moral judgment is influenced by the particular context provided by the dilemma. A related matter is whether responses are affected by the characteristics (e.g., the gender) of the story's protagonist. Also the effect of differences in interviewing style, as interviewers interact with subjects and probe for further information, needs to be considered. Of particular importance is this method's dependence on the subject's verbal expression and articulation skills for the information that is collected. To the extent that the rating might be affected by either the amount of information that is provided or the manner in which it is expressed, the validity of the scoring system is called into question. (See Modgil and Modgil 1986 for discussion of these issues.)

An alternative to Kohlberg's Moral Judgment Interview is the Defining Issues Test (DIT) (Rest 1986). This is a standardized questionnaire that presents a set of six moral dilemmas and, for each dilemma, specifically identifies twelve issues that

could be considered in deciding upon a course of action. The subject's task is to indicate, on a five-point scale, how important each issue is in deciding what ought to be done in the given situation. The subject also ranks the four most important issues.

Here, the term "issue" is used differently than it is in Kohlberg's new scoring procedure. The items are prototypical statements designed to represent considerations (e.g., "whether a community's laws are going to be upheld") that are characteristic of specific stages of moral reasoning as they are described in Kohlberg's theory. The importance assigned by the subject to items that represent a particular stage is taken to indicate the extent to which the subject's moral judgment is characterized by that stage's mode of thinking.

There are advantages and disadvantages to the DIT compared with the open-ended interview. Whereas the interview is helpful for originally identifying the considerations that may be relevant to resolving moral dilemmas, the DIT provides a more systematic assessment of the relative importance of such considerations. In the open-ended interview, it is never clear whether a specific concern is not identified because it is not important or because the subject failed to articulate it. Similarly, interviews are less comparable to the extent that subjects do not all address the same issues. These problems are avoided by the more structured DIT, because the task requires the subject only to recognize what is important rather than to identify and articulate it spontaneously. However, because recognition is an easier task than spontaneous production, it tends to allow higher-level responses. Another important difference is that the DIT measures the maturity of moral judgment as a continuous variable rather than in terms of the holistic step-by-step sequence of cognitive-developmental stages. Researchers must be aware of such differences when interpreting results.

A third instrument, the Moral Judgment Test (MJT) (Lind et al. 1981; Lind and Wakenhut 1985) similarly attempts to measure moral reasoning by the subject's endorsement of specific items. Hypothetical moral dilemmas are presented, and subjects respond to a series of twelve statements for each dilemma. Each of Kohlberg's six stages is

represented by two statements, one in favor of and one against the particular action in question. Subjects indicate how acceptable they find each of the statements.

Citing Lind's paper (1995) extensively, Rest and colleagues (1997) focus on an important distinction between the MJT and the DIT. Instead of adding ratings to indicate how much the subject prefers a particular stage's statements (*stage preference*)—as most DIT studies do—Lind emphasizes how consistently the subject responds to different statements from the same stage (*stage consistency*). Lind argues that stage consistency is a more accurate measure of true cognitive structure, whereas stage preference is more indicative of an affective (like versus dislike) response.

Rest and colleagues (1997) use the DIT statements to construct a consistency measure that is similar to the one developed by Lind. They conclude that the stage-preference measure shows greater construct validity than the stage-consistency measures in differentiating groups with different expertise and different education. The stage-preference measure correlates more highly with moral comprehension—indicating longitudinal development—predicts both prosocial and antisocial behavior, and correlates with political attitudes.

The question of scoring for preference or consistency and what construct is measured by each approach is a legitimate methodological concern with important implications for our understanding of moral development. However, both the DIT and the MJT can be scored for preference and for consistency. Thus, they each remain a viable alternative for attempting to empirically measure moral judgment.

Another measurement tool is the Sociomoral Reflection Measure (SRM) (Gibbs and Widaman 1982; Gibbs et al. 1982), and a more recent variation is the Short Form (SRM-SF) (Gibbs et al. 1992; Basinger et al. 1995; Communion and Gielen 1995; Garmon et al. 1996). This is an open-ended, group-administrable instrument that asks subjects to rate the importance of such topics as keeping promises, affiliation, life, property, and law. It does not present specific dilemmas, but instead uses "lead-in statements" that instruct subjects to generate their own example, such as "Think about when

you've made a promise to a friend," prior to providing their rating of importance. The short form consists of eleven items that can produce a score ranging from 100 (exclusively Stage 1) to 400 (exclusively Stage 4).

Proponents argue that not only is the SRM-SF suitable for assessing stages of moral judgment, but because examples are self-generated, items also can be used to assess differences in content emphasis (Basinger et al. 1995; Garmon et al. 1996). As such, it is suggested as especially useful for research on cultural differences, gender differences, everyday life (versus hypothetical) experience, and the relationship between moral judgment and moral behavior (Communian and Gielen 1995).

As discussed below, perhaps the single most influential criticism of Kohlberg's theory is Carol Gilligan's contention that it fails to describe the moral development of females (1982). Her articulation of a more female-oriented "morality of care," complete with its own sequence of stages, has led to the development of the Ethics of Care Interview (ECI) (Skoe and Marcia 1991). Similar to Kohlberg's methodology, the ECI assesses stage differences, but specifically as they are relevant to the development of care-based morality. Research with the ECI has recently been reviewed by Skoe (1998), demonstrating that the morality of care has important application to human development in general and to the development of personality in particular.

CRITICISMS AND FURTHER RESEARCH

Besides the methodological problems discussed above, Kohlberg's theory of moral development has been criticized on a number of points. The major criticisms include the following:

1. The sequence of stages is more representative of Western culture and thus not universal or invariant across all cultures. Moreover, it is culturally biased in that it maintains the ideals of Western liberalism as the highest form of moral reasoning.
2. Like many theories of personality development, Kohlberg's theory fails to describe the development of women accurately but provides a much better understanding of

male development. This is a specific variation of the first criticism, suggesting that the theory itself reflects the sexism of Western culture.

3. Kohlberg's theory fails to describe adult development adequately. In particular, its emphasis on abstract principles fails to recognize how adult moral judgment is more responsive to the specific practical matters of everyday, real-life contexts. Also, its emphasis on cognitive structure fails to recognize that changes in the content of moral reflection may be the most important aspect of adult moral development.

Cultural Bias. A cornerstone of cognitive-developmental theory is invariant sequence, the notion that the given developmental progression is universal for all human beings within all cultures. Because the conceptual organization of any given stage is considered logically necessary before the cognitive structure of the next stage can develop, each stage is said to have logical priority to subsequent stages. Shweder and LeVine (1975) take issue with both the notion of logical priority and the doctrine of invariant sequence, although they do not address the development of moral judgment per se. Specifically, they analyze dream concepts among children from the Hausa culture in Nigeria and conclude that there are multiple sequences by which such concepts develop.

Shweder (1982) follows up this initial skepticism with a fuller critique of what he sees as Kohlberg's failure to recognize cultural conceptions of morality as relative to one another. He disagrees with the assertion that there is a rational basis upon which morality can be constructed objectively. Rather, he argues that the postconventional morality that Kohlberg maintains as rationally superior is simply an example of American ideology.

Similarly, others (Broughton 1986; Simpson 1974; Sullivan 1977) argue that Kohlberg's theory is necessarily culture-bound, reflective of the Western society from which it originates. Simpson suggests that the specific moral dilemmas used in the testing situation may not have the same meaning for people of different cultures and thus the scoring system may not adequately detect legitimate

cultural variations in moral structures. Thus, she maintains that the claims to universality are not valid. Sullivan goes even further, suggesting that Stage 6 reasoning is so rooted in the philosophical rationale for current Western society that it serves to defend the status quo. In doing so, it distracts attention from the injustices of such societies.

In an early response to the charge of cultural bias, Kohlberg and colleagues (1983) acknowledge the influence of Western liberal ideology on the theory. They agree there is a need to be more sensitive to cultural differences in the meaning attributed not only to the various elements of the research protocol but, consequently, also to the responses of the subjects themselves. However, they defend the claim to universality for the six-stage sequence of moral development and maintain that empirical research using the scientific method will help to determine to what extent this position is tenable.

They also maintain that, while it is appropriate to remain impartial in the study of moral judgment, this does not make it necessary to deny the relative value of certain moral positions. They assert that some positions are rationally superior to others. They thus continue to subscribe to the ideal that any given moral conflict can be brought to resolution through rational discourse.

Kohlberg's position on invariant sequence has been supported by a number of cross-cultural studies, although postconventional reasoning (Stages 5 and 6) may occur less frequently in nonurbanized cultures (Snarey 1985). However, in a sample of subjects from India, Vasudev and Hummel (1987) not only found stage of moral development to be significantly related to age, but also found postconventional thinking to occur among a substantial proportion of adults. Concluding that commonalities exist across cultures, Vasudev and Hummel also suggest there is cultural diversity in the way moral principles are expressed, interpreted, and adapted to real life.

More recent research has increasingly acknowledged the significance of cultural influences on moral development. In another study with a sample from India, Moore concludes that "the notion of justice, as defined by Western social scientists, was rarely used as a moral rationale" (1995, p.

286). Rather, results indicated moral judgment to be dependent on one's religious ideology or social status. Similarly, Okonkwo's study of Nigerians (1997) concludes that moral thinking and moral language are culture dependent. While some parallels to Kohlberg's scheme were found, some "well-articulated moral expressions could not be scored" (Okonkwo 1997, p. 117) due to the inability of Kohlberg's instrument to adequately assess certain concepts that served as the basis for subjects' moral judgments.

Ma and Cheung (1996), studying samples of Chinese, English, and American adolescents and young adults, likewise found cultural differences in the way subjects interpreted specific items on the Defining Issues Test. However, after they deleted some of the items used to indicate Kohlberg's Stage 4, their samples demonstrated a consistent hierarchical structure across the three cultures. They thus conclude that, while different cultures may encourage different perceptions of specific moral statements, there is some support for the idea of a fundamentally universal development.

Markoulis and Valanides (1997) similarly addressed the cultural bias controversy in a conciliatory fashion. Comparing students from Greece and Nigeria, they found stage differences between the two cultures, but nonetheless found that the sequence of development was similar. Again, while cultural environment is recognized as a factor, invariant sequence in development is supported.

A related concern that has been receiving more attention from researchers is the question of whether differences in political ideology within a single, larger culture may be inaccurately represented as developmental variation. Specifically, Gross (1996) compared Americans who are pro-life on the abortion issue with others who are pro-choice, and also compared Israelis who disagree on how to handle the West Bank settlement issue. As long as socioeconomic status was similar, he found no difference between the relevant ideological groups and thus concludes that there is no evidence that ideological bias is built into the stages of moral development.

Conversely, Emler and colleagues (1998) argue that differences in moral development as assessed by the DIT more accurately reflect differences in political ideology. Thoma and colleagues

(1999) acknowledge overlap between political thinking and moral judgment, but argue that Emler and colleagues and St. James (1998) provide no evidence to discount the DIT as a valid measure of moral development. Narvaez and colleagues (1999) attempt to resolve the issue with a model of moral judgment and cultural ideology as engaged in parallel development, each influencing the other to produce specific moral thinking.

Whereas recent times have been characterized by an increased sensitivity to cultural diversity and political "correctness," more attention has been drawn to the consideration of possible cultural and political bias in the theory of moral development. While some researchers have identified cultural differences in moral reasoning, this has led to an increased recognition of sociocultural factors in moral development (Eckensberger and Zimba 1997).

Shweder and colleagues (1987), for example, propose the social communication theory, which maintains that the learning of morality depends largely on the transmission of cultural ideology to children, by virtue of the evaluation and judgments that parents and others make. The point, of course, is that morality is socially constructed, not self-constructed (Emler 1998).

However, other researchers continue to maintain that, while we must make specific adjustments to our understanding of moral development, it is not necessary to abandon the general consideration of a single, universal pattern to human moral development. This area of inquiry thus promises to remain a controversial yet productive focus for several years.

Gender Bias. Carol Gilligan (1982) argues that the major theories of personality development describe males more accurately than females. She includes Kohlberg's theory in this assessment and points to the prevalence of all-male samples in his early research as a partial explanation. Gilligan contrasts two moral orientations. The first is the morality of justice, which focuses on fairness, rights, and rules for the resolution of disputes. The second is the morality of care, which focuses on relationships, a sensitivity to the needs of others, and a responsibility for others. Gilligan asserts that the orientation toward morality as justice is especially characteristic of males and, conversely, that

morality as care and responsibility is especially relevant to females. To the extent that Piaget, Freud, and Kohlberg each address morality as justice, they accurately represent male moral development but inadequately represent female moral development.

Gilligan argues that women are more likely to rely on the orientation of care to frame personal moral dilemmas. Furthermore, whereas the morality of care focuses on interpersonal relationship, it resembles the Stage 3 emphasis on satisfying the expectations of others. Gilligan believes this resemblance results in a high number of female responses being misrepresented with Stage 3 ratings.

Gilligan thus argues that Kohlberg's theory and scoring system are biased to favor men. However, Walker (1984), after systematically reviewing empirical studies that used Kohlberg's method, concludes that men do not score higher than women, when samples are controlled for education, socioeconomic status, and occupation. Similarly, Thoma (1986) reports that sex differences on the Defining Issues Test actually favor women but that the differences are trivial.

Kohlberg and colleagues (1983) address Gilligan's criticisms and agree that the care orientation is not fully assessed by their measurement but disagree that this leads to a biased downscoring of females. They suggest that care and justice may develop together and that Stage 6 nonetheless represents a mature integration of the care and justice moralities (see also Vasudev 1988).

Walker and colleagues (1987) found that both the care and the justice orientations were used by both males and females. Furthermore, the orientation used was related to the type of dilemma being discussed. If the dilemma was focused on personal relationships, both men and women tended to use the care orientation. If the dilemma was impersonal, both men and women tended to express a justice orientation. This suggests that observed gender differences in moral judgment may be more a reflection of the particular kind of dilemma they choose to discuss. Perhaps females tend to report more relationship-oriented dilemmas, the kind that pull for care-based judgments (Yussen 1977).

Wark and Krebs (1996) show just this pattern: Females did not score lower than males on

Kohlbergian dilemmas; however, females were more likely to report care-based dilemmas when asked to recall and describe moral conflicts from real life; this difference in the type of moral dilemmas accounted for differences in moral orientation from males and females.

Using the Sociomoral Reflection Measure-Short Form (SRM-SF), which does not rely on specific dilemmas provided by the researcher, Garmon and colleagues (1996) found support for gender differences in moral orientation, with females more likely to refer to a morality of care. However, they reject Gilligan's claim of a bias against females. In fact, results (Basinger et al. 1995) have indicated a possible female advantage in early adolescence. As measured by the SRM-SF, moral judgment was found to be higher among young female adolescents than among their male counterparts. No gender difference was found in late adolescence or young adulthood. Communian and Gielen (1995) found similar results in an Italian sample, with early adolescent girls scoring higher than early adolescent boys, but no gender differences in adults. In another study of seventh and eighth graders, Perry and McIntire (1995) found that subjects used a care mode, a justice mode, and a third narrowly concerned "selfish" mode to make moral decisions. The girls were more likely to use both the care and the justice modes, while the boys were more likely to choose the less developed selfish mode. Contrary to a bias against females, this research suggests that, at least in early adolescence, girls are more advanced in their moral development. Silberman and Snarey (1993) relate such a cognitive advantage to the earlier physical maturation of girls.

Consistent with the lack of evidence for a bias against females, Skoe (1995) found that Kohlberg's justice-based moral reasoning was unrelated to sex-role orientation, as measured by the Bem Sex Role Inventory (Bem 1974). However, this research indicates an interesting pattern for care-based moral reasoning. Using the Ethic of Care Interview (ECI), Skoe found that care-based reasoning was higher in women who were more androgynous and who indicated higher levels of ego identity. Skoe concludes that women who relinquish the traditional female gender role are more likely to develop a mature care-based morality than are women who retain this role.

This would seem to be inconsistent with Gilligan's argument (1982) that the morality of care depends on traditional female socialization. While this morality may be rooted in the traditional female role, Skoe's findings suggest that its advanced development may require a more integrated, androgynous identity.

Current researchers seem to be recognizing that the different moralities go beyond simple gender role differences. Woods (1996) argues that both Kohlberg and Gilligan represent polarized, sexist views, limited to a focus on gender differences. She suggests that researchers need to take a more comprehensive view of the multiple biological and cultural variables that impact moral development, without reducing it to a discussion of sexism. Gilligan's morality of care identifies a vital approach to morality that may have its origin and strength in feminine ideals, indeed that may be more salient in females than in males. However, women are not confined to it, nor is it confined to women, especially as gender roles become more relaxed.

Adult Development. A third major issue concerning Kohlberg's theory is whether or not it accurately addresses continued adult development. This issue reflects a more general concern in lifespan developmental psychology regarding the inapplicability of Piaget's model for cognitive development beyond adolescence, leading to a consideration of what has come to be called "postformal" development (Commons et al. 1984). Murphy and Gilligan (1980) found that college and postcollege subjects not only indicated a greater tendency to appreciate the importance of specific contexts in real-life dilemmas but also indicated a slight tendency to regress from Stage 5 moral reasoning on the classical dilemmas. They suggest that a more mature recognition of the significance of contextual particulars leads one to question the validity of abstract moral principles (hence the regressed score). This argument is consistent with other work suggesting that adult cognitive development in general is marked by a greater appreciation of the practical realities of day-to-day living (Denney and Palmer 1981; Labouvie-Vief 1984; W. G. Perry, Jr. 1970). Related to this emphasis on the practical is the finding of Przygotzki and Mullet (1997) that elderly adults, when attributing blame,

give more importance to the consequences of an action than to the intention of the perpetrator.

Finally, Gibbs (1979) argues that adult development is characterized more by increased reflection on such existential matters as meaning, identity, and commitment than by any structural change in the way the person thinks. Similarly, Nisan and Applebaum (1995) suggest that older adults give more weight to identity-related personal considerations when considering moral choices, unless they conflict with "a moral demand" from an "unambiguous law." Gibbs (1979) suggests that Kohlberg's postconventional stages are not structural advances over the earlier stages but would be more appropriately described in terms of existential development. In response, Kohlberg et al. (1983) maintain that Stage 5 represents a legitimate cognitive structure. However, they acknowledge the possibility of further nonstructural development in the adult years with regard to both specific contextual relativity and existential reflection. They suggest that such development could be described in terms of "soft" stages that do not strictly satisfy Piaget's formal criteria for cognitive stages.

SUMMARY

In spite of the formidable criticisms that have been levied against it, Kohlberg's theory of moral development remains the centerpiece to which all other work in this area is addressed, whether as an elaboration or as a refutation. At the very least, Kohlberg has formulated a particular sequence of moral reasoning that adequately represents the prevalent sequence of development in traditional Western society. To that extent, it serves as a model, not only for building educational devices (see Modgil and Modgil 1986; Nucci 1989; Power et al. 1989), but also for comparing possible alternatives. Whether or not this sequence is in fact universal or relative to the particular culture—or a particular socialization process within the culture—is a debate that continues. Nonetheless, the scheme remains the prototype upon which further work in this area is likely to be based.

MULTIPLE INDICATOR MODELS

A primary goal of sociology (and science in general) is to provide accurate estimates of the causal relationship between concepts of central interest to the discipline. Thus, for example, sociologists might examine the causal link between the amount of money people make and how satisfied they are with their lives in general. But in assessing the causal relationships between concepts—such as income and life satisfaction—researchers are subject to making errors stemming from a multitude of sources. In this article, we will focus on one common and especially large source of errors in making causal inferences in sociology and other social and behavioral sciences—specifically, “measurement errors.” Such errors will produce biased (under- or over-) estimates of the true causal relationship between concepts.

Multiple indicator models are a method of testing and correcting for errors made in measuring a concept or “latent construct.” Multiple indicators consist of two or more “alternative” measures of the same concept (e.g., two different ways of asking how satisfied you are with your life). Before examining models that use multiple indicators to assess and correct for measurement error, however, the reader should become familiar with the terms and logic underlying such models. “Latent constructs” (also described as a “latent variables”) are unobservable phenomena (e.g., internal states such as the amount of “satisfaction” a person experiences) or more concrete concepts (e.g., income) that represent the hypothetical “true” or “actual” score persons would provide if we could measure a given concept without any error (e.g., a person’s actual income or actual satisfaction, as opposed to their reported income or reported satisfaction).

Additionally, an “indicator” is simply another name for the empirical measure (“observed” score)

of a given construct. For instance, researchers might measure income through a single “indicator” on a questionnaire that asks people “How much money do you earn per year?”—with the response options being, say, five possible income levels ranging from “income greater than \$200,000 per year” (coded as “5”) to “income less than \$10,000 per year” (coded as “1”). Similarly, researchers might provide a single indicator for life satisfaction by asking persons to respond to the statement “I am satisfied with my life.” The response options here might be: “strongly agree” (coded as “5”), “agree” (coded as “4”), “neither agree nor disagree” (coded as “3”), “disagree” (coded as “2”), and “strongly disagree” (coded as “1”).

Social scientists might expect to find a positive association between the above measures of income and life satisfaction. In fact, a review of empirical studies suggests a correlation coefficient ranging from .1 to .3 (Larson 1978; Haring et al. 1984). Correlation coefficients can have values between 1.0 and -1.0, with 0 indicating no association, and 1.0 or -1.0 indicating a perfect relationship. Thus, for example, a correlation of 1.0 for income and life satisfaction would imply that we can perfectly predict a person’s life satisfaction score by knowing that person’s income. In other words, individuals with the highest income (i.e., scored as a “5”) consistently have the highest life satisfaction (i.e., scored as a “5”); those with the next-highest income (i.e., “4”) consistently have the next-highest life satisfaction (i.e., “4”), and so on. Conversely, a -1.0 suggests the opposite relationship. That is, people with the highest income consistently have the lowest life satisfaction; those with the second-highest income consistently have the second-lowest life satisfaction, and so on.

Furthermore, a correlation coefficient of .2, as possibly found, say, between income and life satisfaction, suggests a relatively weak association. A coefficient of this size would indicate that individuals with higher incomes only *tend* to have higher life satisfaction. Hence, we should expect to find many exceptions to this “average” pattern. (More technically, one can square a correlation coefficient to obtain the amount of variance that one variable explains in another. Accordingly, squaring the $r = .2$ correlation between income and life

satisfaction produces an r^2 of .04—i.e., income explains 4 percent of the variance in life satisfaction.) In sum, given a correlation of .2, we can predict life satisfaction better by knowing someone's income than if we did not have this information (we reduce our errors by 4 percent) but we will still make a lot of errors in our prediction (96 percent of the variance in life satisfaction remains unexplained).

These errors in prediction stem in part from less-than-perfect measures of income and life satisfaction analyzed (a topic covered in the next section). However, they also occur because there are many other causes of life satisfaction (e.g., physical health) in addition to income. The more of these additional causes there are, and the stronger their effects (i.e., the stronger their correlation with life satisfaction), the weaker the ability of a single construct such as income to predict life satisfaction. The same principles apply, of course, to any construct used to predict other constructs (e.g., using people's level of stress to predict the amount of aggression they will display).

Correlation coefficients and "path coefficients" are part of the "language" of causal modeling, including multiple indicator models. Like a correlation coefficient, a path coefficient describes the strength of the relationship between two variables. One can interpret a (standardized) path coefficient in a manner roughly similar to a correlation coefficient. Readers will increase their understanding of the material to follow if they familiarize themselves with these measures of strength of association. (For more information on interpreting correlation and path coefficients, see Blalock [1979]; Kline [1998].)

RELIABILITY AND VALIDITY OF MEASURES

As noted earlier, measurement errors can bias estimates of the true causal associations between constructs of interest to sociologists and other researchers. Accordingly, it is important to use measures of high quality. Specialists in the field of measurement (often labeled "psychometricians") describe high-quality measures as having strong *reliability* and *validity* (Nunnally and Bernstein 1994). Reliability concerns the consistency with

which an indicator measures a given construct; validity assesses whether one is measuring what one intends to measure or something else.

Reliability A common method of assessing reliability is to determine the strength of the correlation (consistency) between alternative (multiple) indicators of the same construct—for example, the correlation between two different measures of life satisfaction. A correlation of 1.0 would suggest that both indicators are perfectly reliable measures of life satisfaction. Conversely, a correlation of, say, .3 would suggest that the two indicators are not very reliable measures of life satisfaction.

Given the subjective nature of indicators of life satisfaction (and many other constructs found in the social and behavioral sciences), we should not be surprised to find fairly low correlations (consistency) among their many possible multiple indicators. The ambiguity inherent in agreeing or disagreeing with statements like "I am satisfied with my life," "The conditions of my life are excellent," and "In most ways my life is close to my ideal" should introduce considerable measurement error. Furthermore, we might anticipate that much of this measurement error would be *random*. That is, relative to respondents' actual ("true") scores for life satisfaction, they would provide answers (observed scores) to the subjective questions regarding life satisfaction that are likely to be nonsystematic. For example, depending on the degree of ambiguity in the multiple indicators for subjective construct like life satisfaction, a person is likely to display a random pattern of giving too high and too low scores relative to the person's true score across the set of measures.

This "noise"—unreliability due to random measurement error—will reduce the correlation of a given indicator with another indicator of the same construct. Indeed, "pure" noise (e.g., completely random responses to questions concerning respondents' life satisfaction) should not correlate with anything (i.e., $r = 0$). To the extent that researchers can reduce random noise in the indicators (e.g., by attempting to create as clearly worded self-report measures of a construct as possible) the reliability and corresponding correlations among multiple indicators should increase. Even where researchers are careful however, to select the best available indicators of constructs

that represent subjective states (like life satisfaction), correlations between indicators frequently do not exceed r 's of .3 to .5.

Not only does less-than-perfect reliability reduce correlations among multiple indicators of a given construct, but, more importantly, this random measurement error also reduces the degree to which indicators for one latent construct correlate with the indicators for another latent construct. That is, unreliable measures (such as each of the multiple indicators of life satisfaction) will *underestimate* the true causal linkages between constructs of interest (e.g., the effect of income on life satisfaction). These biased estimates can, of course, have adverse consequences for advancing our scientific knowledge (e.g., perceiving income as a less important source of life satisfaction than it might actually be). (Although unreliable measures will always underestimate the true relationship between two constructs, the bias of unreliable measures is more complex in "multivariate" situations where important control variables may exhibit as much unreliability as [or more unreliability than] do the predictor and outcome variables of interest.)

Psychometricians have long been aware of this problem of "attenuated correlations" from unreliable measures. In response, traditional practice is to combine each of the multiple indicators for a given construct into a single *composite* scale (e.g., sum a person's score across each life satisfaction indicator). The random errors contained in each individual indicator tend to "cancel each other out" in the composite scale (cf. Nunnally and Bernstein 1994), and the overall reliability (typically measured with Cronbach's alpha) on scale ranging from 0 to 1.0 can improve substantially relative to the reliability of individual items within the scale. Although composite scales are a definite step in the right direction, they are still less than perfectly reliable, and often much less. Consequently, researchers are still faced with the problem of biased estimates of the causal linkages among constructs of interest.

Validity. Unreliable indicators are not the only source of measurement error that can bias estimates of causal linkages among constructs. Invalid indicators can also create biased estimates. As we shall see in subsequent sections, bias from invalid measures stems from different sources and

is more complex and difficult to detect and control than bias from unreliable measures.

Valid measures require at least modest reliability (i.e., correlations among indicators of a given construct cannot be $r = 0$); but reliable measures are not necessarily valid measures. One can have multiple indicators that are moderately to highly reliable (e.g., r 's = .5 to .8), but they may not measure the construct they are supposed to measure (i.e., may not be valid). For example, life satisfaction indicators may display at least moderate reliability, but no one would claim that they are valid measures of, say, a person's physical health.

This example helps clarify some differences between reliability and validity, but at the risk of obscuring the difficulty that researchers typically encounter in establishing valid measures of many latent constructs. Continuing with our example, researchers may select multiple indicators of life satisfaction that critics could never plausibly argue actually measure physical health: Critics might make a very plausible argument, however, that some or all the indicators of life satisfaction also measure a more closely related concept—such as "optimism."

Note, too, that if the life satisfaction indicators do, in fact, also measure optimism, then the correlation that income has with the life satisfaction indicators could stem entirely from income's causal links with an optimistic personality, rather than from income's effect on life satisfaction itself. In other words, in this hypothetical situation, invalid ("contaminated") measures of life satisfaction could lead to *overestimating* income's effect on life satisfaction (though, as we will see in later sections, one can construct examples where invalid measures of life satisfaction could also lead to *underestimating* income's effect).

Given the many subjective, loosely defined constructs that form the core concepts of sociology and other social and behavioral sciences, the issue of what the indicators are actually measuring (i.e., their validity) is a common and often serious problem. Clearly, our scientific knowledge is not advanced where researchers claim a relationship between constructs using invalid measures of one or more of the constructs.

The sections, below, on single-indicator and multiple-indicator models will elaborate on the

bias introduced by measurement error stemming from unreliability and invalidity, and how to use the multiple indicators and “path analysis” of structural equation modeling (SEM) to test and correct for the bias. This discussion continues to use the example of estimating the effect of income on life satisfaction in the face of measurement error.

SINGLE-INDICATOR MODELS

Figure 1 depicts the hypothesized causal link (solid arrow labeled “ x ”) between the latent (unobservable) constructs of income and life satisfaction (represented with circles), and the hypothesized causal link (solid arrows labeled “ a ” and “ b ”) between each latent construct (circle) and its respective empirical (observed) indicator (box). The D (disturbances) in Figure 1 represents all potential causes of life satisfaction that the researcher has not included in the causal model (stressful life events, personality characteristics, family relationships, etc.). The E ’s in Figure 1 represent random measurement error (and any unspecified latent constructs that have a “unique” effect on a given indicator).

Because each latent construct (circled “ I ” and “ LS ”) in Figure 1 has only one indicator (boxed “ I_1 ” or “ LS_1 ”) to measure the respective construct, researchers describe the diagram as a causal model with *single* (as opposed to multiple) indicators. Additionally, Figure 1 displays a dashed, double-headed arrow (labeled “ r_1 ”) between the box for income and the box for life satisfaction. This dashed, double-headed arrow represents the empirical or *observed* correlation between the empirical indicators of income and life satisfaction. Following the logic diagramed in Figure 1, this observed correlation is the product of actual income affecting both measured income through path a , and actual life satisfaction through path x . In turn, actual life satisfaction affects measured life satisfaction via path b . Stated in more formal “path equations,” $a*x*b = r_1$.

Note, that researchers can never directly observe the *true* causal effect (i.e., path x) of actual income (I) on actual life satisfaction (LS). Researchers can only *infer* such a relationship based on the *observed* correlation (r_1) between the empirical indicators for income and life satisfaction— I_1 and LS_1 . In other words, social scientists use

an observed correlation— r_1 —to estimate an unobservable true causal effect—path x .

Notice also that in the presence of random measurement error, the observed correlation r_1 will always be an *underestimate* of the unobservable path x representing the hypothesized true effect of income on life satisfaction. Of course, researchers hope that r_1 will equal path x . But r_1 will only equal x if our empirical measures of income and life satisfaction (I_1 and LS_1) are *perfectly reliable*—that is, have no random measurement error.

The phrase “completely reliable measures” implies that each person’s observed score for income and life satisfaction indicators reflect exactly that person’s actual or “true score” for income and life satisfaction. If the indicators for income and life satisfaction are indeed perfect measures, then researchers can attach a (standardized) path coefficient of 1.0 to each path (i.e., a and b) between the latent constructs and their indicator. Likewise, researchers can attach a path coefficient of 0 to each path (i.e., d and e) representing the effects of random measurement errors (E_1 and E_2) on the respective indicators for income and life satisfaction.

The path coefficient of 1.0 for a and b signifies a perfect relationship between the latent construct (i.e., true score) and the measure or indicator for the latent construct (i.e., recorded score). In other words, there is no “slippage” between the actual amount of income or life satisfaction people have and the amount of income or life satisfaction that a researcher records for each person (i.e., there is no random measurement error). Therefore, people who truly have the highest income will report the most income, those who truly have the lowest income will report the lowest income, and so on. Likewise, people who, in fact, have the most life satisfaction will always record a life satisfaction score (e.g., “5”) higher than those a little less satisfied (e.g., “4”), individuals a little less satisfied will always record a life satisfaction score higher than those a little bit less satisfied yet (e.g., “3”); and so on.

Under the assumption that the measures of income and life satisfaction are perfectly reliable, social scientists can use the *observed* correlation (r_1) between the indicators I_1 and LS_1 to estimate the *true* causal effect (path x) of actual income (I) on actual life satisfaction (LS). Specifically, $r_1 = a*x*b$;

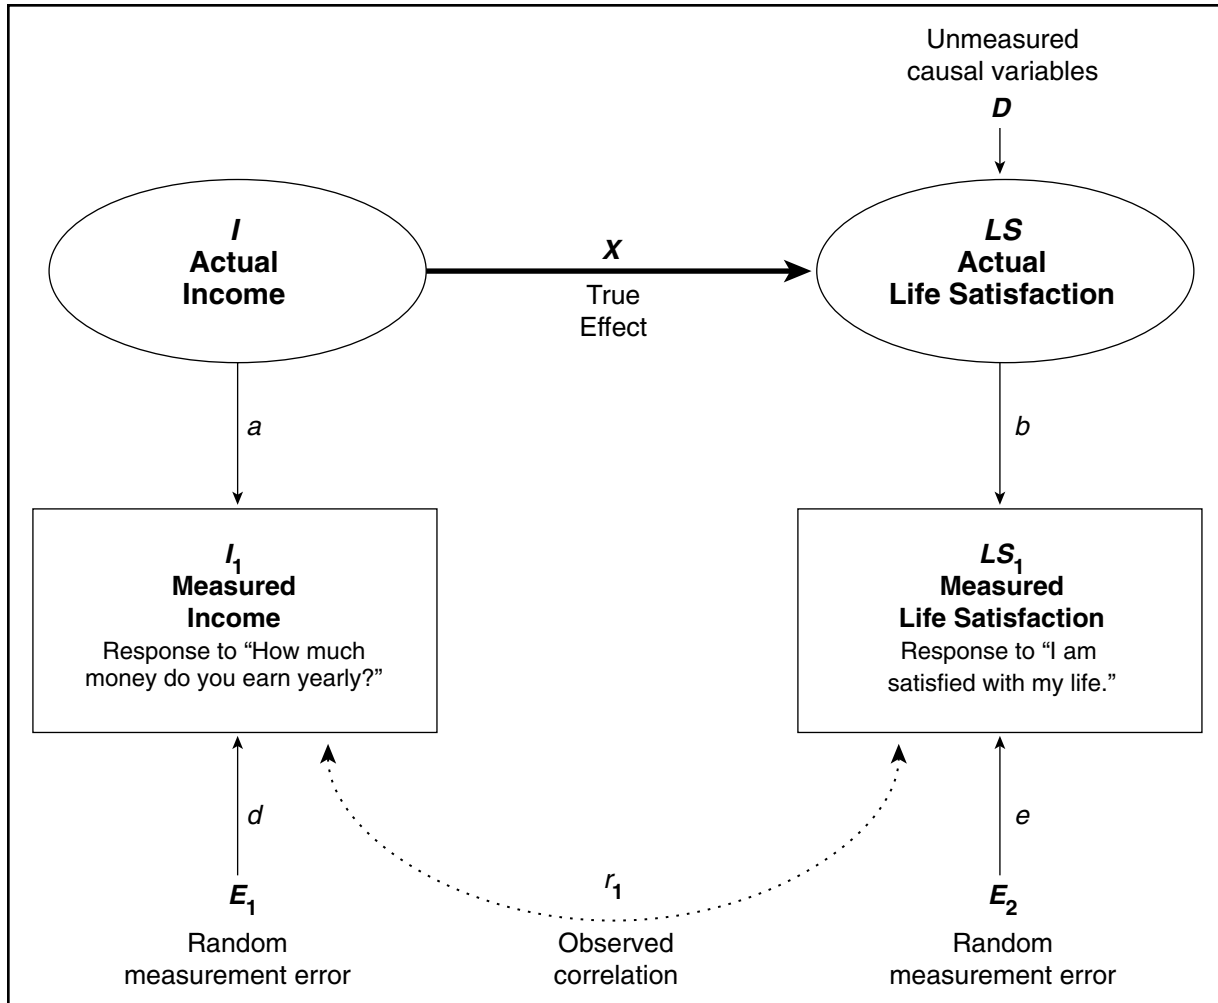

Figure 1. Single-Indicator Model for Estimating the Effect of Income on Life Satisfaction.

hence, $r_1 = 1.0 * x * 1.0$, or $r_1 = x$. Thus, if the observed correlation between income and life satisfaction (i.e., r_1) is, say, .2, then the true (unobservable) causal effect of income on life satisfaction (i.e., path x) would also be .2. (For more detailed explanations of how to interpret and calculate path coefficients, see Sullivan and Feldman [1979]; Loehlin [1998].)

Of course, even if researchers were to measure income and life satisfaction with perfect reliability (i.e., paths a and b each equal 1.0), there are other possible errors (“misspecifications”) in the model shown in Figure 1 that could bias researchers’ estimates of how strong an effect income truly has on life satisfaction. That is, Figure 1 does not

depict other possible “misspecifications” in the model such as “reverse causal order” (e.g., amount of life satisfaction determines a person’s income) or “spuriousness” (e.g., education determines both income and life satisfaction and hence only makes it appear that income causes life satisfaction). (For more details on these additional sources of potential misspecification, see also Blalock [1979].)

How realistic is the assumption of perfect measurement in single indicator causal models? The answer is, “It depends.” For example, to assume a path coefficient of 1.0 for path a in Figure 1 would not be too unrealistic (the actual coefficient is likely a little less than 1.0—say, .90 or .95). That is, we would not expect many errors in

measuring a person's true income. Likewise, we would expect few measurement errors in recording, say, a person's age, sex, or race. As noted earlier, the measurement of subjective states (including satisfaction with life) is likely to occur with considerable error. Therefore, researchers would likely *underestimate* the true causal link between income and life satisfaction, if they assumed no random measurement error for the life satisfaction indicator—that is, if they assumed a coefficient of 1.0 for path *b* in Figure 1.

How badly researchers underestimate the true causal effect (i.e., path *x*) would depend, of course, on how much less than 1.0 was the value for path *b*. For the sake of illustration, assume that path *b* equals .5. Assume also that income is perfectly measured (i.e., path *a* = 1.0) and the observed correlation (r_1) between the indicators for income and life satisfaction is .2. Under these conditions, $1.0 * x * .5 = .2$, and $x = .4$. In other words, researchers who report the observed correlation between income and life satisfaction ($r_1 = .2$) would substantially *underestimate* the strength of the true effect ($x = .4$) that income has on life satisfaction. Recall that an *r* of .2 represents an r^2 of .04, or 4 percent of the variance in life satisfaction explained by income, whereas an *r* of .4 represents an r^2 of .16, or 16 percent of the variance explained by income. Accounting for 16 percent of the variance in life satisfaction represents a much stronger effect for income than does 4 percent explained variance. Based on this hypothetical example, income goes from a weak to a relatively strong predictor of life satisfaction, if we have the appropriate information to allow us to correct for the bias of the unreliable measure of life satisfaction.

But how do researchers know what values to assign to the unobservable paths (such as *a* and *b* in Figure 1) linking a given latent construct to its single indicator? Unless logic, theory, or prior empirical evidence suggests that the constructs in a given model are measured with little error (i.e., the path between the circle and the box = 1.0) or indicate what might be an appropriate value less than 1.0 to assign for the path between the circle and box, researchers must turn from *single* indicator models to *multiple* indicator models. As noted earlier, multiple indicator models allow one to make corrections for measurement errors that would otherwise bias estimates of the causal relationships between constructs.

MULTIPLE INDICATOR MODELS

For researchers to claim that they are using multiple indicator models, at least one of the concepts in a causal model must have more than one indicator. "Multiple indicators" means simply that a causal model contains alternative measures of the same thing (same latent construct). Figure 2 depicts a multiple indicator model in which income still has a single indicator but life satisfaction now has three indicators (i.e., three alternative measures of the same life satisfaction latent construct). In addition to the original indicator for life satisfaction—"I am satisfied with my life"—there are two new indicators; namely, "In most ways my life is close to my ideal" and "The conditions of my life are excellent." (Recall that the possible response categories range from "strongly agree" to "strongly disagree." See also Diener et. al. [1985] for a fuller description of this measurement scale.)

As in Figure 1, the dashed, double-headed arrows represent the *observed* correlations between each pair of indicators. Recall that these observed correlations stem from the assumed operation of the latent constructs inferred in the causal model. Specifically, an increase in actual income (*I*) should produce an increase in measured income (I_1) through (causal) path *a*. Moreover, an increase in actual income should also produce an increase in actual life satisfaction (*LS*) through (causal) path *x*, which in turn should produce an increase in each of the measures of life satisfaction (LS_1 , LS_2 , and LS_3) through (causal) paths *b*, *c*, and *d*. In other words, these hypothesized causal pathways should produce observed correlations between all possible pairs of the measured variables (I_1 , LS_1 , LS_2 , and LS_3). (We are assuming here that the underlying measurement model is one in which the unobserved constructs have a causal effect on their respective indicators. There are some types of multiple indicators, however, where a more plausible measurement model would suggest the reverse causal order—i.e., that the multiple indicators each drive the latent construct common to the set of indicators. See, Kline [1998] for a discussion of these "cause" indicator measurement models, as opposed to the more traditional "effect" indicator measurement model described here.)

The use of a single indicator for income means that researchers must use logic, theory, or prior

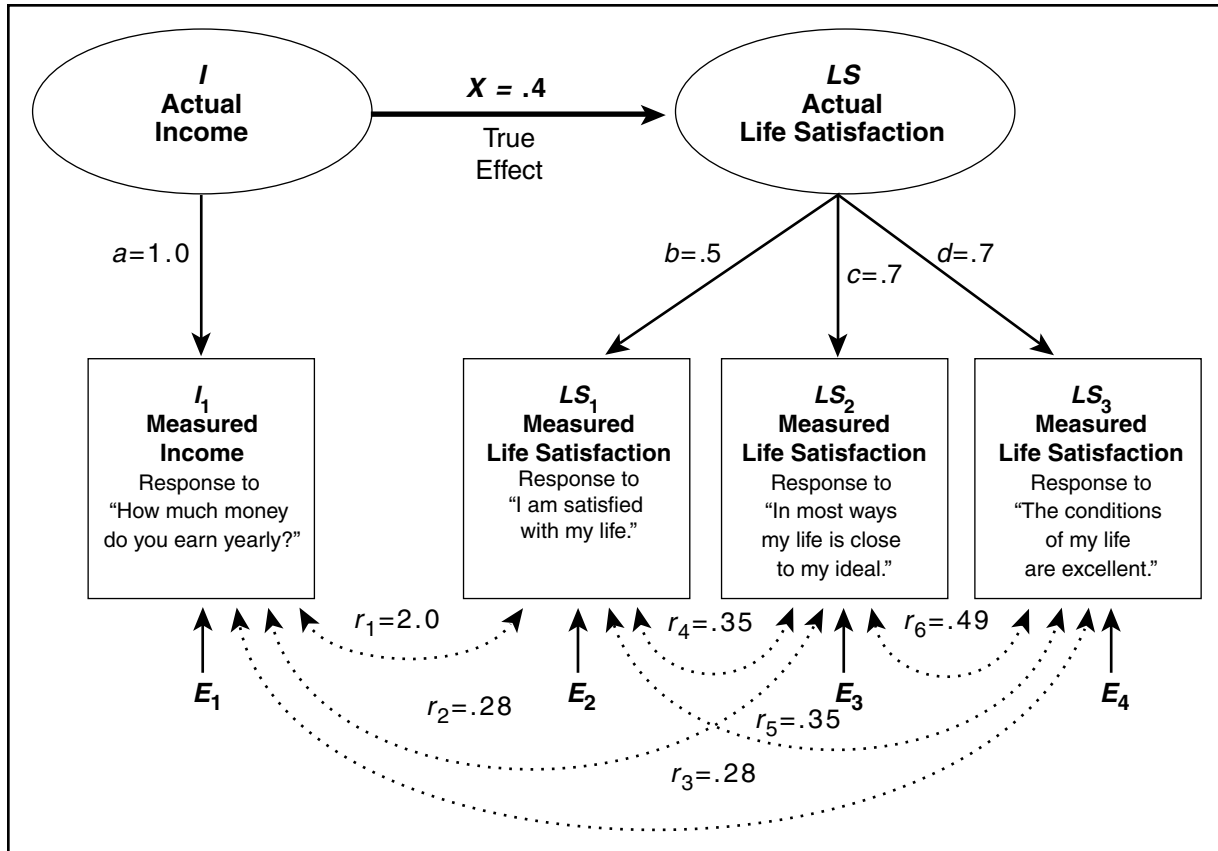

Figure 2. Multiple-Indicator Model for Estimating the Effect of Income on Life Satisfaction.

empirical evidence to assign a path coefficient to represent “slippage” between the true score (I) and the measured score (I_1). For income, path $a = 1.0$ (i.e., no random measurement error) seems like a reasonable estimate, and makes it easier to illustrate the path equations. (Although a coefficient of say, .95, might be more realistic, whether we use 1.0 or .95 will make little difference in the calculations that follow.) As noted earlier, however, indicators of life satisfaction are not as easily assigned path coefficients of 1.0. That is, there is likely to be considerable random error (unreliability) in measuring a subjective state such as life satisfaction. Fortunately, however, the use of *multiple indicators* for the life satisfaction construct permits researchers to provide reasonable estimates of random measurement error based on the *empirical data in the current study*—namely, the observed correlations (i.e., consistency) among the multiple indicators. Because measurement error can vary so much from one research setting to

another, it is always preferable to provide estimates of reliability based on the current rather than previous empirical studies. Likewise, reliability estimates based on the current study are much better than those estimates obtained from logic or theory, unless the latter sources can provide a compelling case for a highly reliable single indicator (such as the measure of income used in the present example).

If the multiple indicator model in Figure 2 is correctly specified, then the observed correlations among the several pairs of indicators should provide researchers with information to calculate estimates for the hypothesized (unobservable) causal paths b , c , and d (i.e., estimates of how much “slippage” there is between actual life satisfaction and each measure of life satisfaction). Researchers can use hand calculations involving simple algebra to estimate the causal paths for such simple multiple indicator models as depicted in Figure 2 (for

examples, see Sullivan and Feldman 1979 and Loehlin 1998). But more complicated models are best left to “structural equation modeling” (SEM) computer software programs such as LISREL (Linear Structural Relationships; Joreskog and Sorbom 1993), EQS (Equations; Bentler 1995), or AMOS (Analysis of Moment Structures; Arbuckle 1997). Kline (1998) provides a particularly excellent and comprehensive introduction to the topic. There are two annotated bibliographies that represent almost all work related to SEM up to about 1996 (Austin and Wolfe 1991; Austin and Calderon 1996). Marcoulides and Schumacker (1996) and Schumacker and Marcoulides (1998) cover even more recent advances. Smallwaters software company has a Web site that gives a wealth of information, including other relevant Web sites: <http://www.smallwaters.com/weblinks>.

In essence, these SEM computer programs go through a series of trial-and-error “iterations” in which different values are substituted for the hypothesized causal paths—in Figure 2, paths *b*, *c*, *d*, and *x*. (Recall that we assigned a value of 1.0 for path *a*, so the SEM program does not have to estimate a value for this hypothesized path.) Ultimately, the program reaches (“converges on”) a “final solution.” This solution will *reproduce* as closely as possible the *observed correlations*—in Figure 2, r_1 , r_2 , r_3 , r_4 , r_5 , and r_6 —among each of the indicators in the proposed causal model. In the *final solution* depicted in Figure 2, the path estimates for *b*, *c*, *d*, and *x* (when combined with the “assigned” or “fixed” value for path *a*) exactly reproduce the observed correlations. (Note that the *final* solution will reproduce the observed correlations better than will the *initial* solutions, unless, of course, the SEM program finds the best solution on its first attempt—which is not likely in most “real-world” data analyses.)

More technically, the SEM program builds a series of (simultaneous) equations that represent the various hypothesized causal paths that determine each observed correlation. In Figure 2, the correlation ($r_1 = .20$) for I_1 and LS_1 involves the “path” equation: $a*x*b = .20$; for the correlation ($r_2 = .28$) of I_1 and LS_2 : $a*x*c = .28$; for the correlation ($r_3 = .28$) of I_1 and LS_3 : $a*x*d = .28$; for the correlation ($r_4 = .35$) of LS_1 and LS_2 : $b*c = .35$; for the correlation ($r_5 = .35$) of LS_1 and LS_3 : $b*d = .35$; and for the correlation ($r_6 = .49$) of LS_2 and LS_3 : $c*d =$

.49. The SEM program then uses the *known* values—observed correlations and, in the causal model for Figure 2, the fixed (predetermined) value of 1.0 for path *a*—to simultaneously solve the set of equations to obtain a value for each of the causal paths that initially have *unknown* values.

Except in artificial examples (like Figure 2), however, the SEM program is unlikely to obtain final values for the causal paths such that the path equations exactly reproduce the observed correlations. More specifically, the program will attempt through its iterative trial-and-error procedures to find a final value for each of the causal paths *b*, *c*, *d*, and *x* that will *minimize* the “average discrepancy” across each of the six model-*implied* correlations (i.e., predicted by the path equations) versus the six empirically *observed* correlations.

For example, to reproduce the observed correlation ($r_4 = .35$) between LS_1 and LS_2 (recall that empirical correlations among indicators of subjective states like life satisfaction often range between .3 and .5), the SEM program would have to start with values for causal paths *b* and *c* (i.e., estimates of “slippage” between actual life satisfaction and measured life satisfaction) considerably lower than 1.0. In other words, the software program would need to allow for some random measurement error. If, instead, the initial solution of the SEM program assumed perfect reliability, there would be a substantial discrepancy between at least some of the implied versus observed correlations among the indicators. That is, multiplying the path $b = 1.0$ by the path $c = 1.0$ (i.e., assuming perfect reliability of each indicator) would imply an observed correlation of 1.0 (i.e., perfect consistency) between LS_1 and LS_2 —an implied (i.e., predicted) correlation that far exceeds the $r_4 = .35$ correlation we actually observe. (Keep in mind that, as depicted in Figure 2, the *best values* for *b* and *c* are .5 and .7, respectively, which the SEM program will eventually converge on as it “iterates” to a final solution).

If, at the next iteration, the SEM program were to substitute equal values for *b* and *c* of about .59 each (to allow for less than perfect reliability), this solution would exactly reproduce the observed correlation of .35 (i.e., $.59*.59 = .35$) between LS_1 and LS_2 . But using a value of .59 for both *b* and *c* would *not* allow the program to reproduce the observed correlations for LS_1 and LS_2 with I_1 (the indicator for income). To obtain the observed

correlation of .20 between I_1 and LS_1 , the program needs to multiply the paths $a*x*b$. Accordingly, r_1 (.20) should equal $a*x*b$ —that is, $1.0*x*.59 = .20$. Solving for x , the program would obtain a path value of about .35. Likewise, to obtain the observed correlation of .28 between I_1 and LS_2 , the program needs to multiply the paths $a*x*b$. Accordingly, r_2 (.28) must equal $a*x*c$ —that is, $1.0*x*.59 = .28$. Solving for x , the program would obtain a path value of about .47. In other words, the program cannot find a solution for the preceding two equations that uses the *same value* for x . That is, for the first equation $x \approx .35$. But for the second equation $x \approx .47$.

Given the SEM program's need to come up with a *unique* (i.e., single) value for x (and for all the other causal paths the program must estimate), a possible compromise might be to use a value of .41. Substituting this value into the preceding two equations— $a*x*b$ and $a*x*c$ —would provide an *implied* correlations of about .24— $1.0*.41*.59 = .24$ —for both equations. Comparing this implied correlation with the *observed* correlations of .20 and .28 for I_1/LS_1 and I_1/LS_2 , respectively, the discrepancy in these two situations is +/- .04.

Although this is not a large discrepancy between the implied and the observed correlations, the SEM program can do better (at least in this hypothetical example). If the SEM program subsequently estimates values of .50 and .70 for causal paths b and c , respectively, then it is possible to use the same value of x (specifically, .40) for each path equation involving I_1/LS_1 and I_1/LS_2 , and reproduce exactly the observed correlations for r_1 (i.e., $1.0*.40*.50 = .20$) and r_2 (i.e., $1.0*.40*.70 = .28$). By using these estimated values of .5 and .7 for paths b and c in place of the .6 and .6 values initially estimated, the program can also reproduce exactly the observed correlation ($r_4 = .35$) between LS_1 and LS_2 —that is, $.5*.7 = .35$. Furthermore, by using an estimated value of .7 for causal path d , the program can exactly reproduce *all* the remaining observed correlations in Figure 2— $r_3 = .28$, $r_5 = .35$, and $r_6 = .49$ —that involve path d , that is, $a*x*d$, $b*d$, and $c*d$, respectively. (We leave to the reader the task of solving the equations.)

In sum, by using the fixed (a priori) value of $a = 1.0$ and the estimated values of $x = .4$, $b = .5$, $c = .7$, and $d = .7$, the six implied correlations exactly

match the six observed correlations depicted in Figure 2. In other words, the hypothesized causal paths in our model provide a “perfect fit” to the “data” (empirical correlations).

Reproducing the observed correlations among indicators does not, however, establish that the proposed model is correct. In the logic of hypothesis testing, one can only disconfirm models, not prove them. Indeed, there is generally a large number of alternative models, often with entirely different causal structures, that would reproduce the observable correlations just as well as the original model specified (see Kim and Mueller 1978 for examples). It should be apparent, therefore, that social scientists must provide rigorous logic and theory in building multiple indicator models, that is, in providing support for one model among a wide variety of possible models. In other words, multiple indicator procedures require that researchers think very carefully about how measures are linked to latent constructs, and how latent constructs are linked to other latent constructs.

Additionally, it is highly desirable that a model contain more observable correlations among indicators than unobservable causal paths to be estimated—that is, the model should be “overidentified.” For example, Figure 2 has *six* observed correlations (r_1, r_2, r_3, r_4, r_5 , and r_6) but only *four* hypothesized causal paths (x, b, c , and d) to estimate. Thus, Figure 2 is overidentified—with *two* “degrees of freedom” (df) By having an excess of observed correlations versus hypothesized causal paths (i.e., by having at least one and preferably many degrees of freedom), a researcher can provide tests of “model fit” to assess the probability that there exist alternative causal paths not specified in the original model. (Where the fit between the implied vs. observed correlations is poor, researchers typically seek to revise their causal model to better fit the data.)

Conversely, “just-identified” models will contain exactly as many observable correlations as hypothesized causal paths to be estimated (i.e., will have 0 degrees of freedom). Such models will *always* produce estimates (solutions) for the causal paths that *exactly* reproduce the observable correlations—no matter how badly misspecified the proposed causal pathways may be. In other words,

“perfect” fit is inevitable and provides no useful information regarding whether the model is correctly specified or not. This result occurs because, unlike an overidentified model, a just-identified model does not have any degrees of freedom with which to detect alternative causal pathways to those specified in the original model. Accordingly, just-identified models are not very interesting to SEM practitioners.

Finally, the worst possible model is one that is “underidentified,” that is, has fewer observable correlations than unobservable causal paths to be estimated. Such models can provide no single (unique) solutions for the unobservable paths. In other words, an infinite variety of alternative estimates for the causal paths is possible. For example, if we restricted Figure 2 to include only LS_1 and LS_2 (i.e., dropping LS_3 and I_1), the resulting two-indicator model of life satisfaction would be underidentified. That is, we would have *two* causal paths to estimate—from the latent construct to each of the two indicators (i.e., paths b and c)—but only *one* observed correlation ($r_4 = .35$). Under this situation, there is no *unique* solution. We can literally substitute an infinite set of values for paths b and c to exactly reproduce the observed correlation (e.g., given $b*c = .35$, we can use $.7*.5$ or $.5*.7$, or two values slightly less than $.6$ each, and so on).

The number of indicators per latent construct helps determine whether a model will be overidentified or not. In general, one should have at least three and preferably four or more indicators per latent construct—unless one can assume a single indicator, such as income in Figure 2, has little measurement error. Adding more indicators for a latent construct rapidly increases the “overidentifying” pieces of empirical information (i.e., degrees of freedom). That is to say, observable correlations (between indicators) grow faster than the unobservable causal paths (between a given latent construct and indicator) to be estimated.

For example, adding a fourth indicator for life satisfaction in Figure 2 would require estimating *one* additional causal path (linking the life satisfaction latent construct to the fourth indicator), but would also produce *four* more observed correlations (LS_4 with LS_3 , LS_2 , LS_1 , and I_1). The modified model would thus have *three* more degrees of freedom, and correspondingly greater *power* to

determine how well the model fits the empirical data (observed correlations). Including a fifth indicator for life satisfaction would produce *four* more degrees of freedom, and even more power to detect a misspecified model. (The issue of model identification is more complicated than outlined here. The requirement that an identified model have at least as many observed correlations as causal paths to be estimated is a necessary but not sufficient condition; cf. Kline [1998].)

Some additional points regarding multiple indicator models require clarification. For instance, in “real life” a researcher would never encounter such a perfect reproduction of the (noncausal) observable correlations from the unobservable (causal) paths as Figure 2 depicts. (We are assuming here that the causal model tested in “real life,” like that model tested in Figure 2, is “overidentified.” Recall that a “just-identified” model always exactly reproduces the observed correlations.) Indeed, even if the researcher’s model is correctly specified, the researcher should expect at least *some* minor discrepancies in comparing the observed correlations among indicators with the correlations among indicators predicted (implied) by the hypothesized causal paths.

Researchers can dismiss as “sampling error” (i.e., “chance”) any discrepancies that are not too large (given a specific sample size). At some point, however, the discrepancies do become too large to dismiss as “chance.” At that point, researchers may determine that they have not specified a proper model. Poor model fit is strong grounds for reevaluating and respecifying the original causal model—typically by adding and (less often) subtracting causal paths to obtain a better fitting model. Just because an overidentified model can detect that a model is misspecified does not mean, however, that it is easy to then tell where the misspecification is occurring. Finding and correcting misspecification is a complex “art form” that we cannot describe here (but see Kline 1998 for an overview).

The next section will describe how nonrandom measurement error can create a misfitting multiple indicator model and corresponding bias in estimates of causal pathways. Additionally, we will demonstrate how a just-identified model, in contrast to an overidentified model, will fail to detect

and thus correct for this misspecification, resulting in considerable bias in estimating the true effect of income on life satisfaction.

MULTIPLE-INDICATOR MODELS WITH NONRANDOM MEASUREMENT ERROR

We have discussed how poor quality measures—low reliability and low validity—can bias the estimates of the true effects of one latent construct on another. Our specific modeling examples (Figures 1 and 2), however, have focused on the bias introduced by unreliable measures only. That is, our causal diagrams have assumed that all measurement error is *random*. For example, Figure 2 depicts the error terms (*E*'s) for each of three multiple indicators of life satisfaction to be *unconnected*. Such random measurement error can occur for any number of reasons: ambiguous questions, coding errors, respondent fatigue, and so forth. But none of these sources of measurement error should *increase* correlations among the multiple indicators. Indeed, as noted in previous sections, random measurement error should *reduce* the correlations (consistency) among multiple indicators of a given latent construct—less-than-perfect correlations that researchers can then use to estimate reliability and thereby correct for the bias that would otherwise occur in underestimating the true effect of one latent construct on another (e.g., income on life satisfaction).

Conversely, where measurement error *increases* correlations among indicators, social scientists describe it as systematic or *nonrandom*. Under these conditions, the measurement errors of two or more indicators have a common source (a latent construct) other than or in addition to the concept that the indicators were suppose to measure. The focus now becomes the *validity* of measures. Are you measuring what you claim to measure or something else? (See the section above entitled “Reliability and Validity of Measures” for a more general discussion.)

Failure to include nonrandom—linked or “correlated”—errors in a multiple-indicator model will bias the estimates of other causal paths in the model. Figure 3 depicts such a linkage of error terms through the personality variable “optimism” (*O*). Based on the hypothetical model in Figure 3,

the observed correlation (r_6) between the indicators LS_2 and LS_3 would not be entirely the consequence of the effects of life satisfaction (LS) operating through the causal paths c and d . In fact, part of this observed correlation would occur as a consequence of the causal paths e and f (which in this hypothetical example, we have constrained to be equal). In other words, the indicators LS_2 and LS_3 measure some of life satisfaction but also optimism. That is, they measure something in addition to what they were intended to measure. Stated in still other words, the two indicators are not “pure” (completely valid) measures of life satisfaction because they are “contaminated” by also tapping optimism.

Note that r_6 is the only observed correlation that differs in strength in comparing Figures 2 and 3. For Figure 2, this correlation equals .49; for Figure 3, this correlation equals .85. The higher observed correlation for r_6 in Figure 3 stems from the “inflated” correlation produced by the effects of optimism through paths e (.6) and f (.6). Note, also, that $.6 \times .6$ equals .36. If we add .36 to the original observed correlation for r_6 (i.e., .49) in Figure 2, we obtain the observed correlation of .85 in Figure 3. All other paths estimates and observed correlation remain the same across the two figures. Furthermore, like Figure 2, Figure 3 depicts path estimates for a final solution that exactly reproduce all observed correlations.

Note, too, if we had not added the causal paths (e and f) to represent the hypothesized effect of optimism on two measures of life satisfaction, we could not obtain a “good fit” for the observed correlations in Figure 3. Indeed, *without* these additional paths, the SEM computer program would have to increase the path coefficients for c and d —say, to about .92 each—in order to reproduce the observed correlation of .85 for r_6 . But then the program would fail to reproduce the observed correlations involving LS_2 and LS_3 with the other indicators in the model (LS_1 and I_1). For example, the observed correlation between I_1 and LS_2 ($r_2 = .28$) would now be *overestimated*, based on the product of the causal paths— $a \times x \times c$ —that the model in Figure 3 suggests determines r_2 . That is, $1.0 \times .4 \times .92$ results in an implied (predicted) correlation of about .37, which leaves a discrepancy of .09 relative to the correlation (.28) actually observed.

Figure 3. Multiple-Indicator Model for Estimating the Effect of Income on Life Satisfaction with Nonrandom Measurement Error for Optimism*.

NOTE: *To obtain an overidentified model, paths *k* and *l* are “constrained” to have equal path coefficients.

In the absence of good fit—as a consequence of not allowing paths *e* and *f* to be included in the model to be tested (i.e., not specifying the “correct” model)—the SEM program might continue to “iterate” by substituting new estimates for *c* and the other causal paths in Figure 3—*b*, *d*, and *x*—which initially have unknown values. No matter what values are estimated for each of these causal paths, however, the program will not be able to eliminate a discrepancy between the implied and

the observed correlations for at least some of the pairs of indicators—a discrepancy that, as noted previously, the program will attempt to minimize based on the criterion of finding path estimates that result in the lowest average discrepancy summed across all possible comparisons of implied versus observed correlations in the model.

Indeed, a misspecification in one part of a model (in this instance, failure to model nonrandom

measurement error in LS_1 and LS_2 indicators) generally “reverberates” throughout the causal model, as the SEM program attempts to make adjustments in all path coefficients to minimize the average discrepancy. In other words, estimates for each path coefficient are most often at least slightly biased by misspecified models (the greater the misspecification, the greater the bias). Most importantly, the failure to model (and thus correct for) nonrandom measurement error will typically result in the SEM program’s estimating a value for the true effect of one construct on another—in the present example, the true effect (path x) of income on life satisfaction—that will be biased (either over- or underestimated). For example, when we use a SEM program (EQS) to calculate estimates for the hypothesized causal paths in Figure 3 (excluding the paths for the contamination of optimism), we obtain a final solution with the following estimates: $b = .38$, $c = .92$, $d = .92$, and $x = .31$. Thus, in the present example, the failure to model nonrandom measurement error has led to an underestimate ($x = .31$) of income’s true effect ($x = .40$) on life satisfaction. Interestingly, by far the largest discrepancy in fit occurs between I_1 and LS_1 (the implied correlation is .08 less than the observed correlation), not between LS_2 and LS_3 (where there is 0 discrepancy)—demonstrating that misfit in one part of the model can produce misfit (reverberate) elsewhere in the model.

The hypothetical model depicted in Figure 3 is necessarily artificial (to provide simple illustrations of SEM principles). In real-life situations, it is unlikely (though still possible) that sources of contamination, when present, would impact only some of the multiple indicators for a given construct (e.g., only two of the three measures of life satisfaction). Furthermore, researchers would be on shaky ground if they were to actually claim that the correlated measurement error modeled in the present example stemmed from an identifiable source—such as optimism. (Indeed, to avoid specifically labeling the source of the inflated correlation between LS_1 and LS_2 , researchers would most likely model a curved, double-headed arrow between E_3 and E_4 in Figure 3, and have the SEM program simply estimate the appropriate value—.36—for this new path representing correlated measurement error.) To make a legitimate claim that a construct like optimism contaminates a construct such as life satisfaction, researchers

would also need to provide traditional measures of the suspected source of contamination (e.g., include established multiple indicators for optimism).

As a final example of the need to use *overidentified* multiple indicator models in order to detect misspecified models, consider a modification of Figure 3 in which we have access to the single indicator for income (I_1) but have only two indicators for life satisfaction available to us— LS_2 and LS_3 . Assume, further, that we are unaware that optimism contaminates the two life satisfaction indicators. Note that this new model is *just identified*. That is, there are three observed correlations (r_2 , r_3 , and r_6) and three hypothesized causal paths to estimate (x , c , and d). Accordingly, this model will perfectly fit the data, despite the fact that we have not modeled (i.e., misspecified) the correlated measurement error (.36) that we’ve built into the .85 observed correlation (r_6) between LS_2 and LS_3 .

More specifically, in order to reproduce the .85 correlation, the SEM program will increase the estimate of reliability for the LS_2 and LS_3 life satisfaction indicators by increasing the c and d paths from their original (true) value of .7 each to new (biased) values of about .92 each. To reproduce the observed correlation of .28 for both I_1/LS_2 and I_1/LS_3 (r_2 and r_3), the program can simply decrease the x path (i.e., the estimate of the true effect of income on life satisfaction) from its original (true) value of .40 to a new (biased) value of about .30—that is, for both path equations $a*x*c$ and $a*x*d$: $1.0*.3*.92 = .28$.

In sum, our just-identified model perfectly fits the data despite the fact our model has failed to include (i.e., has misspecified) the correlated measurement error created by optimism contaminating the two life satisfaction indicators. More importantly, the failure to model the nonrandom measurement error in these two indicators has led us to a biased underestimate of the true effect of income and life satisfaction: Income explains $.3^2 = 9\%$ of the variance in life satisfaction for the current (biased) model, but explains $.4^2 = 16\%$ variance in life satisfaction for the earlier (correctly specified) model.

As noted earlier, the debilitating effects of nonrandom measurement error are extremely diverse in their potential forms and correspondingly

complex in their potential bias in under- or overestimating causal links among latent constructs. The present discussion only touches on the issues and possible multiple indicator models for detecting and correcting this type of measurement error. The reader is encouraged to consult other sources that provide additional details (starting with Kline 1998).

STRENGTHS AND WEAKNESSES OF MULTIPLE-INDICATOR MODELS USING SEM

As we have seen, by incorporating multiple indicators of constructs, structural equation modeling procedures allow more rigorous tests of causal models than possible when using single indicators. With sufficient multiple indicators to provide an overidentified model, SEM procedures are particularly powerful in detecting and correcting for the bias created by less than perfectly reliable and valid measures of latent constructs of interest. In other words, by building a more accurate *measurement model*—that is, providing a more correct specification of the causal linkages between latent constructs and their indicators—SEM researchers can obtain more accurate estimates of the causal linkages in the *structural model*—that is, the effect of one latent variable on another.

A correct specification of the measurement model is, then, a means to the ultimate goal of obtaining accurate path estimates (also described as “parameter estimates”) for the structural model (e.g., obtaining the true effect of income on life satisfaction by correcting for measurement error). Some research, however, makes the measurement model the central focus (e.g., whether the three indicators of life satisfaction correlate with each other in a manner consistent with their measuring a single latent construct). In this situation, the SEM procedure is known as “confirmatory factor analysis” (CFA). The CFA uses the typical SEM principle of positing a measurement model in which latent constructs (now described as “factors”) impact multiple indicators (the path coefficient now described as a “factor loading”). Unlike a “full-blown” SEM analysis, however, the CFA does not specify causal links among the latent constructs (factors), that is, does not specify a structural model (e.g., there is no interest in whether income affects life satisfaction). Instead, the CFA treats

potential relationships among any two factors as simply a “correlation” (typically represented in diagrams with a curved, double-headed arrow between the factors); that is, the causal ordering among latent constructs is *not specified*.

Researchers have developed especially powerful CFA procedures for establishing the validity of measures through significant enhancements to traditional construct validity techniques based on multitrait/multimethods (MTMM), second-order factor structures, and testing the invariance of measurement models across diverse subsamples (again, see Kline 1998 for an introduction). CFA has also been at the vanguard in developing “nonlinear” factor analysis to help reduce the presence of “spurious” or “superfluous” latent constructs (referred to as “methods” or “difficulty” factors) that can occur as a consequence of using multiple indicators that are highly skewed (i.e., non-normally distributed) (Muthen 1993, 1998). These nonlinear factor analysis procedures also provide a bridge to recent advances in psychometric techniques based on item-response theory (cf. Reise et al. 1993; Waller et al. 1996).

CFA provides access to such powerful psychometric procedures as a consequence of its enormous flexibility in specifying the structure of a measurement model. But this strength is also its weakness. CFA requires that the researcher specify all aspects of the measurement model a priori. Accordingly, one must have considerable knowledge (based on logic, theory, or prior empirical evidence) of what the underlying structure of the measurement model is likely to be. In the absence of such knowledge, measurement models are likely to be badly misspecified. Although SEM has available particularly sophisticated techniques for detecting misspecification, simulation studies indicate that these techniques do not do well when the hypothesized model is at some distance from the true model (cf. Kline 1998).

Under these circumstances of less certainty about the underlying measurement model, researchers often use “exploratory factor analysis” (EFA). Unlike CFA, EFA requires no a priori specification of the measurement model (though it still works best if researchers have some idea of at least the likely number of factors that underlie the set of indicators submitted to the program). Individual

indicators are free to “load on” any factor. Which indicators load on which factor is, essentially, a consequence of the EFA using the empirical correlations among the multiple indicators to seek out “clusters” of items that have the highest correlations with each other, and designating a factor to represent the underlying latent construct that is creating (is the “common cause” of) the correlations among items. Of course, designating these factors is easier said than done, given that the EFA can continue to extract additional factors, contingent on how stringent the standards are for what constitutes indicators that are “more” versus “less” correlated with each other. (For example, does a set of items with correlations of, say, .5 with each other constitute the same or a different “cluster” relative to other indicators that correlate .4 with the first cluster and .5 with each other? Extracting more factors will tend to separate these clusters into different factors; extracting fewer factors is more likely to combine the clusters into one factor.) The issue of the number of factors to extract is, then, a major dilemma in using EFA, with a number of criteria available, including the preferred method, where possible, of specifying a priori the number of factors to extract (cf. Floyd and Widaman 1995).

A potential weakness with EFA is that it works best with relatively “simple” measurement models. EFA falters in situations where the reasons for the “clustering” of indicators (i.e., interitem correlations) stem from complex sources (see Bollen 1989 for an example). As an aspect of this inability to handle complex measurement models, EFA cannot match CFA in the sophistication of its tests for validity of measures. On the other hand, because CFA is more sensitive to even slight misspecifications, it is often more difficult to obtain satisfactory model “fit” with CFA.

Exploratory and confirmatory factor analysis can complement each other (but see Floyd and Widaman 1995 for caveats). Researchers may initially develop their measurement models based on EFA, then follow that analysis with CFA (preferably on a second random subsample, in order to avoid modeling “sampling error”). In this context, the EFA serves as a crude “first cut,” which it is hoped, results in a measurement model that is close enough to the “true model” that a subsequent CFA can further refine the initial model,

using the more sophisticated procedures available with the confirmatory procedure.

Even though researchers use EFA and CFA to focus exclusively on *measurement models*, these psychometric studies are really a preamble to subsequent work in which the measures previously developed are now used to test causal linkages among constructs in *structural models*. Most of these subsequent tests of causal linkages among constructs (e.g., the effect of income on life satisfaction) use data analytic procedures, such as ordinary least squares (OLS) regression or analysis of variance (ANOVA) that assume no underlying latent structure. Accordingly, these traditional analyses of structural models work with measured (observable) variables only, can accommodate only a *single indicator* per construct of interest and, therefore, must assume (in essence) that each single indicator is perfectly reliable and valid. In other words, in the absence of a multiple indicators measurement model for each construct, there is no way to make adjustments for less-than-perfect reliability or validity.

In an attempt to enhance the reliability of the single-indicator measures that traditional data analyses procedures require, researchers often combine into a single *composite* scale the set of multiple indicators (e.g., the three indicators of life satisfaction) that prior EFA and CFA research has established as measuring a given latent construct (factor). Although, as noted earlier, a single-indicator composite scale (e.g., summing a respondent’s score on each of the three life satisfaction indicators) is generally preferable to a noncomposite single indicator (at least when measuring more subjective and abstract phenomena), a composite scale is still less than perfectly reliable (often, much less). Accordingly, using such an enhanced (more reliable) measure will still result in biased parameter estimates in the structural model.

Validity also remains a concern. Even if prior psychometric work on measures has rigorously addressed validity (though this is often not the case), there is always a question of how valid the measure of a given construct is in the context of other constructs in the current structural model (e.g., what sort of “cross-contamination” of measures may be occurring among the constructs that might bias estimates of their causal linkages).

SEM remains a viable alternative to the more traditional and widely used data analysis procedures for assessing causal effects in structural models. Indeed, SEM is so flexible in specifying the structural, as well as measurement part of a causal model, that it can literally “mimic” most of the traditional, single indicator, data analysis procedures based on the general linear model (e.g., Analysis of Variance [ANOVA], Multivariate Analysis of Variance [MANOVA], Ordinary Least Squares [OLS] regression), as well as the newer developments in these statistical techniques (e.g., Hierarchical Linear Modeling [HLM]). SEM can even incorporate the single-indicator measurement models (i.e., based on observable variables only) that these other data analysis procedures use. The power to adjust for random and nonrandom measurement error (unreliability and invalidity) is realized, however, only if the SEM includes a multiple-indicator (latent variable) measurement model.

A multiple-indicator measurement model also provides SEM procedures with a particularly powerful tool for modeling (and thus adjusting for) correlated measurement errors that inevitably occur in analyses of *longitudinal* data (cf. Bollen 1989). Likewise, multiple-indicator models allow SEM programs to combine latent growth curves and multiple subgroups of cohorts in a “cohort-sequential” design through which researchers can examine potential cohort effects and developmental sequences over longer time frames than the period of data collection in the study. By also forming subgroups based on their pattern of attrition, (i.e., at what wave of data collection do respondents drop out of the study), SEM researchers can analyze the “extended” growth curves while adjusting for the potential bias from nonrandom missing data (Duncan and Duncan 1995)—a combination of important features that non-SEM methods cannot match. Furthermore, although SEM is rarely used with *experimental* research designs, multiple-indicator models provide exceptionally powerful methods of incorporating “manipulation checks” (i.e., whether the experimental treatment manipulates the independent variable that was intended) and various “experimental artifacts” (e.g., “demand characteristics”) as alternative causal pathways to the outcome variable of interest (cf. Blalock 1985).

Although this article has focused on strengths of the SEM multiple indicator measurement model, the advantages of SEM extend beyond its ability to model random and nonrandom measurement error. Particularly noteworthy in this regard is SEM’s power to assess both contemporaneous and lagged *reciprocal* effects using nonexperimental longitudinal data. Likewise, SEM has an especially elegant way of incorporating maximum likelihood full-information imputation procedures for handling missing data (e.g., Arbuckle 1996; Schafer and Olsen 1998), as an alternative to conventional listwise, pairwise, and mean substitution options. Simulation studies show that the full-information procedures for missing data, relative to standard methods, reduce both the bias and inefficiency that can otherwise occur in estimating factor loadings in measurement models and causal paths in structural models.

So given all the apparent advantages of SEM, why might researchers hesitate to use this technique? As noted earlier in discussing limitations of confirmatory factor analysis, SEM requires that a field of study be mature enough in its development so that researchers can build the a priori causal models that SEM demands as input. SEM also requires relatively large sample sizes to work properly. Although recommendations vary, a minimum sample size of 100 to 200 would appear necessary in order to have a reasonable chance of getting solutions that “converge” or that provide parameter (path) estimates that are not “out of range” (e.g., a negative variance estimate) or otherwise implausible. Experts often also suggest that the “power” to obtain stable parameter estimates (i.e. the ability to detect path coefficients that differ from zero) requires the ratio of subjects-to-parameters-estimated be between 5:1 and 20:1 (the minimum ratio increasing as variables become less normally distributed). In other words, more complex models demand even larger sample sizes.

Apart from the issue of needed a larger N to accommodate more complex causal models, there also is some agreement among SEM experts that models should be kept simpler in order to have a reasonable chance to get the models to fit well (cf., Floyd and Widaman 1995). In other words, SEM works better where the total number of empirical indicators in a model is not extremely large (say 30 or less). Accordingly, if researchers wish to test

causal models with many predictors (latent constructs) or wish to model fewer constructs with many indicators per construct, SEM may not be the most viable option. Alternatively, one might consider “trimming” the proposed model of constructs and indicators through more “exploratory” SEM procedures of testing and respecifying models, possibly buttressed by preliminary model trimming runs with statistical techniques that can accommodate a larger number of predictors (e.g., OLS regression), and with the final model hopefully tested (confirmed) on a second random subsample. Combining pairs or larger “parcels” from a common set of multiple indicators is another option for reducing the number of total indicators, and has the added benefit of providing measures that have more normal distributions and fewer correlated errors from idiosyncratic “content overlap.” (One needs to be careful, however, of eliminating too many indicators, given that MacCallum et al. [1996] have shown that the power to detect good-fitting models is substantially reduced as degrees of freedom decline.)

An additional limitation on using SEM has been the complex set of procedures (based on matrix algebra) one has had to go through to input the model to be tested—accompanied by output that was also less than user-friendly. Fortunately, newer versions of several SEM programs can now use causal diagrams for both input and output of the structural and measurement models. Indeed, these simple diagramming options threaten to surpass the user-friendliness of the more popular mainstream software packages (e.g., Statistical Package for the Social Sciences [SPSS]) that implement the more traditional statistical procedures. This statement is not meant to be sanguine, however, about the knowledge and experience required, and the care one must exercise, in using SEM packages. In this regard, Kline (1998) has a particularly excellent summary of “how to fool yourself with SEM.” The reader is also encouraged to read Joreskog (1993) on how to use SEM to build more complex models from simpler models.

As the preceding discussion implies, using multiple-indicator models requires more thought and more complicated procedures than does using more common data analytic procedures. However, given the serious distortions that measurement errors can produce in estimating the true causal links among concepts, the extra effort in

using multiple-indicator models can pay large dividends.

KYLE KERCHER

MUSIC

From the earliest days of the discipline, music has been a focus of sociological inquiry. Max Weber, for example, used the development of the system of musical notation as a prime illustration of what he saw as the increasing rationalization of European society since the Middle Ages (Max Weber 1958). Like Weber, many since have used music

and music making as a strategic research site for answering sociologically important questions. Nevertheless, music has not become the focus of a distinctive fundamental approach in sociology comparable to topics like "socialization," "organization," "deviance," and "culture." That is why the subject of this entry is the "sociology of music" and not "musical sociology" and why it takes such a long bibliography to suggest the range of work in the field.

While no musical sociology has developed, over the decades numerous aspects of music making or appreciation have been the substantive research site for addressing central questions in sociology. Broadly, these can be grouped together as six ongoing research concerns, and together they can be said to constitute the scattered but rich sociology of music. These six focuses will be considered in turn.

MACROSOCIOLOGY

Many sociologists have been concerned with the relationship between society and culture. Talcott Parsons, among others, believed that there was a close fit between the two, so that it would be possible to compare societies and changes taking place in society by studying elements of their cultures including music. This is what led Max Weber (1958) to focus on music as an example of the rationalization of Western society and led another early sociologist, Georg Simmel ([1882] 1968), to see music as a mirror of socio-psychological processes. The most ambitious cross-national attempt to directly link the structure of society with musical expression has been that of Lomax (1968).

Contemporary scholars see the links between social structure and music not as natural but as deliberately constructed, and they focus on the circumstances of that process. For example, Cerulo (1999) has found an association between the circumstances of a nation's founding and its national anthem. Whisnant (1983) examined the politics of culture involved in constructing the idea of Appalachian folk culture, and Cloonan (1997) examines how "Englishness" is constructed in contemporary British pop music.

Another line of contemporary studies exploring the society-music link focuses on the globalization

of music culture. The specific focuses and methods of these researchers vary widely, but together they show the resilience of local forms of musical expression in the context of the globalization of the media. See, for example, Wallis and Malm (1984), Nettl (1985, 1998), Hebdige (1987), Guilbault (1993), and Manuel (1993).

THE SOCIAL CONSTRUCTION OF AESTHETICS

In line with the constructivist orientation just mentioned, a number of scholars have examined the processes by which aesthetic standards are set and changed. The seminal works in this line are by Meyer (1956) and Becker (1982). Hennion (1993) studies the evolution of standards in the Paris music world. Monson (1996) carefully examines the conventions of jazz improvisation. Ellison (1995) shows the close interplay between country music artists and their fans in defining the country music experience, and Frith (1996) examines many of the same issues in the world of rock music.

Alternative kinds of aesthetic standards have been contrasted. The most widely compared are "fine art," "folk," and "popular" aesthetics (Gans 1974). Using the example of jazz, Peterson (1972) shows that music can evolve from folk to pop and then to fine art. Frith (1996) perceptively shows that all three standards are used simultaneously in the rock world and elsewhere.

THE STUDY OF MUSIC WORLDS

In his early studies of interaction among dance-hall musicians, Becker pioneered the study of the conventions that musicians use in making their kind of music together (summarized in Becker 1982). This line of activity has been continued in musical scenes varying from a group of coldly calculating recording session musicians (Peterson and White 1979; Faulkner 1983) to an impassioned gay community (DeChaine 1997). See also Zolberg (1980), Etkorn (1982), Gilmore (1987), MacLeod (1993), Rose (1994), Monson (1996), Devereaux (1997), and Nettl (1998).

A related and often overlapping line of studies focuses on the socialization of performers. See, for example, Bennett (1980), Kingsbury (1988), Freeman (1996), DeChaine (1997), and Levine and

Levine (1996). The socialization of audiences has also been the focus of considerable attention. The focus of inquiry has included popular music fans (Hebdige 1979, Frith 1981, 1996), the Viennese supporters of Ludwig van Beethoven (DeNora 1995), country music fans (Ellison 1995), and hip-hop fans (Rose 1995).

THE INSTITUTIONALIZATION OF MUSIC FIELDS

While the art-world perspective focuses on the interaction of individuals and groups in making and appreciating music, research on institutionalization has to do with the creation of the organizations and the infrastructure that support distinctive music fields. DiMaggio (1982), for example, shows the entrepreneurial processes by which the classical music field was established in the United States. Menger (1983) and Hennion (1993) show the structure of the contemporary art music fields of France. Peterson (1990) and Ennis (1992) trace the reconfiguration of the pop music field into rock in the 1940s and 1950s, and Peterson (1997) traces the institutionalization of the country music field and its articulation with the larger field of commercial music in the mid-1950s.

Based on the production of culture perspective, some researchers have shown how elements of the production process, including law, technology, industry structure, industrial organization, careers, and market structures, profoundly shape the sort of music that is produced. The interplay between these processes is traced by Peterson (1990) to show why rock music emerged in the mid-1950s. For other examples of work in the production of culture perspective, see Keil (1966), Ryan (1985), Lopes (1992), Jones (1992), Frith (1993), Manuel (1993), Freeman (1996), and Levine and Levine (1996).

A number of studies have traced the development of specific music organizations and organization fields. Ahlquist (1997) shows the structure of the early-nineteenth-century entrepreneurial opera world, and Martorella (1982) shows the remarkably different field of opera that emerged following the American Civil War. Arian (1971) and Hart (1975) focus on the classical music orchestra. Peterson and White (1979) and Faulkner (1983) discuss the organization of the apparently

purely competitive world of recording studio session musicians. Gilmore (1987) focuses on three distinct contemporary classical music fields in New York City. MacLeod traces the field of club-date musicians in the same city. Guilbault (1993) shows the shaping of World Music in the West Indies. Negus (1999) compares the very different methods the major music industry corporations use in exploiting country music, rap, and reggae.

One specific line of studies focuses on the "concentration-diversity" hypothesis. Peterson and Berger (1975) show that periods of competition in the popular music field lead to a great diversity in the music that becomes popular, while concentration of the industry in a few firms leads to homogeneity in popular music. Using later data, Burnett (1990) challenges this finding, and Lopes (1992) shows how large multinational firms are able to control the industry while at the same time producing a wide array of musical styles.

MUSIC FOR MAKING DISTINCTIONS

All known societies employ music as a means of expressing identity and marking boundaries between groups (Lomax 1968), and a number of authors have shown the place of music in social class and status displays. DeNora (1995) shows the role that Beethoven's music played in the Vienna of 1800 by marking off the rising business aristocracy from the older court-based aristocracy that championed the music of Haydn and Mozart. DiMaggio (1982) shows how the rising commercial elite of nineteenth-century Boston used support for classical music as a status marker, and recent survey research studies show how music preferences have been used in making social class distinctions. See, for example, Bryson (1996) and Peterson and Kern (1996).

Numerous studies have explored issues of racism in the meanings ascribed to music and its creators. Reidiger (1991), for example, shows how immigrant Irish, Germans, Jews, Swedes, and the like developed the "black-faced" minstrel show to satirize African-Americans and show their own affinity with the dominant English-speaking class as part of what they came to call the "white race." Leonard (1962) and Peterson (1972) show the evolving attitudes of whites toward jazz and African-American culture. The most extensive line of work on race focuses on how jazz was created and

interpreted by African-American intellectuals as a form of resistance to the dominant white culture. See especially Jones (1963), Kofsky (1970), Vincent (1995), Devereaux (1997), and Panish (1997). The racial shaping of blues, gospel, and rap have been explored, respectively, by Keil (1966), Heilbut (1997), and Rose (1994).

Music is gendered in many ways. Men are more likely to be producers, women consumers; women are often demeaned in the lyrics of rock, rap, and heavy metal, but they are characterized as strong in country music lyrics. Yet, compared to other topics, there has not been much research on gender in music and music making. Four different books suggest the range of topics that could be explored: McClary (1991) on the gendering of opera in which strong female leads do not succeed; Buffwack and Oermann (1993) on the decades of struggle of female country music entertainers for equality with men; Lewis (1990) on the gendered nature of rock videos; and Nehring (1997) on gender issues in pop music.

At least since the "jazz age" of the 1920s, music has been one of the primary ways in which generations are defined and define themselves. In the 1990s, for example, one slogan of the young was "If it's 'too loud,' you're too old." Hebdige (1979), Frith (1981), Laing (1985), Liew (1993), Lahusen 1993, Epstein (1994), Weinstein (1994), Shevory (1995), and DeChaine (1997), among many others, show how specific contemporary youth groups use music to state distinctions not only between themselves and their parents but between themselves and other youth groups as well.

THE EFFECTS OF MUSIC

As just noted, new musical forms are identified with each new generation, and adults have tended to equate the music of young people with youthful deviance. Jazz, swing, rock, punk, disco, heavy metal, and rap, in turn, have been seen as the causes of juvenile delinquency, drug taking, and overt sexuality. See, for example, Leonard (1962), Hebdige (1977), and Laing (1985). Jazz was under attack for most of the first half of the twentieth century, and more recently heavy metal music has come in for the most sustained attention (Raschke 1990; Walser 1993; Weinstein 1994; Binder 1993; and Arnett 1996).

One of the most persistent research topics involving music has been the content analysis of song lyrics, on the often unwarranted assumption that one can tell the meaning a song has for its fans by simply interrogating lyrics (Frith 1996). Content analyses can be divided roughly into two types, holistic and systematic.

Systematic content analyses identify a universe of songs, draw a systematic sample from the universe, and analyze the lyrics in terms of a standard set of categories, typically using statistics to represent their results. Examples of systematic content analysis include Horton (1957), Carey (1969), Rogers (1989), and Ryan et al. (1996). Most such content analyses have focused on popular music, but one of the most remarkable is John H. Muller's study of the changing repertoire of classical music over the first half of the twentieth century (1951)—a study that clearly deserves updating. Kate Muller (1973) makes a start. Holistic content analyses typically involve selecting songs that fit the research interest of their author and making judgments of the meaning of a song, or groups of songs, as a whole (Lewis 1990; McLurin 1992; Lahusen 1993; Ritzel 1998).

Finally the "effects" focus in social movements research returns the sociological study of music full circle to more macro-sociological concerns. Music has been an integral part of most social movements, as has been shown by a number of studies. For example, Denisoff and Peterson (1972) provide a collection of essays that describe the place of music in movements ranging from the International Workers of the World, Nazi youth groups, and folk protest music to avant-garde jazz, country music, rock, and religious fundamentalism. Denisoff (1971) has made an analysis of the use of music in the political protest movement of the 1960s and 1970s, and Neil Rosenberg (1993) has assembled a set of essays on the politicization of folk music in that same era. Treece (1997) describes the role of bossa nova in Brazil's popular protest movement, and Eyerman and Jamison (1998) examine the place of music in more recent social movements.

Something approaching one-half the works cited here are by scholars who research music topics relevant to sociology, but who are not themselves sociologists. This openness and diversity is

important to the continuing vitality of the sociology of music. It is to be hoped that, in forthcoming decades, self-conscious efforts to bring more order to the scatter will facilitate the systematic articulation of research questions, stimulate research on more diverse music worlds, and encourage more cumulation of research findings. These efforts may also show the ways in which music can become a fundamental perspective in sociology similar to socialization, organization, deviance, culture, and the like.

RICHARD A. PETERSON

N

NATIONAL BORDER RELATIONS

Are the processes commonly described as globalization presenting us with a borderless future? Are borders, the limits of state authority, traditionally the instrument by which states and nations define themselves, changing beyond recognition at the threshold of the twenty-first century? Are borders, in the classical sense of the age of the nationstate, being abolished, as part of the erosion of the nation-state itself? Are they withering, or are they undergoing functional change? Are there regional differences between the developments in Europe (EU), America (NAFTA), Asia, and Africa?

A full answer to such very practical questions would perhaps benefit from a grounding in a “general theory of boundaries” conceived as an integral part of the “general theory of systems” (Strassoldo 1976–77, 1979, 1982). States and nations are just a genus of social (societal) systems, and it can be argued that social systems are just a specific kind of (general) systems. For instance, the study of boundary (or interface, as they are sometimes also called) processes, osmotic processes taking place through cell membranes, is one of the frontiers of biological research. In fact, the boundary became a basic concept in system theories in the 1960s and 1970s (Miller 1977). The boundary has an important place in several other disciplines, beginning perhaps with Gestalt psychology (boundary as the line that activates *Gestalten*) and philosophical anthropology, according to which

the drawing of neat boundary lines—around concepts, in the definition of categories, in the classification of phenomena, in staking out domains and setting rules—is one of the hallmarks of formal, rational discourse (Bateson 1972). That most elusive concept, form, can best be defined as a “marked space” (Brown 1969). We can only conceive objects, that is, chunks of reality that have a form, a line around them: “Epistemology is about where you draw the line” (Wilden 1972).

Restricting our view to sociological system theories, we find the concept of boundary (“boundary maintenance,” “boundary articulation,” etc.) recurring throughout Parsons’s voluminous works. He seems to have borrowed the idea from earlier anthropologists; and it was another anthropologist, Barth, who has given it renewed popularity in more recent times (Barth 1969).

The logical and ontological primacy of boundaries over any other system element has been emphasized by Luhmann, arguably the sociologists who has most systematically grappled with this problem. For him, any system first emerges as a difference—that is, a boundary—between the inside and the outside, the system and the environment. Later, a difference between a center and a periphery emerges within the system (Luhmann 1982).

It must be admitted, however, that run-of-the-mill sociology has not paid much attention to the concept and problem of boundaries, although

every time one meets such dichotomies and expressions as “in-out,” “internal-external,” “backstage-frontstage,” “cross-cutting,” “center and periphery,” “marginality,” “stranger,” “distinction,” “identity,” “closure,” and so on, a boundary is implied. Several hypotheses have been suggested for this widespread blindness of sociologists to such a pervasive reality. One is the necessity, typical of all sciences, to isolate phenomena in order to make them manageable for study; this leads researchers to focus on the “core” of social objects, dismissing their margins as though they just “die out” in a surrounding vacuum. Alternatively, it may well be that it is just the inevitable interconnectedness of social phenomena, the generally overlapping, uncertain, and fuzzy character of empirical social boundaries that has kept sociologists clear of them.

On the other hand, it is always possible to find forerunners and prophets for every sociological concept and theory. So one can be referred to Simmel’s fascinating musings on the “criss-crossing of social circles,” on the “door,” the “bridge,” and the “handle” as different means of overcoming the boundary-line between different domains. In fact, his whole “formal” approach to sociology is built on the notion that social life is a system of “frames”—that is, boundaries—that are an essential part of its dynamics. This notion, of course, has fed many other, later theorists, from Schutz to Goffman. In the case of territorial borders, one can refer to what Sorokin (1928) called the “geographic school” of nineteenth-century sociology (Le Play, Des Moulins) and to Durkheim’s claim that “frontiers” are a central feature of “social morphology.” The fullest early sociological treatise on borders is by a follower of Durkheim, the Belgian sociologist and social reformer De Greef, who developed a complex and suggestive theory of an evolutionary interaction between national, political, and territorial (“horizontal”) borders on one side, and social (“vertical”) boundaries (between groups, classes, organisations etc.) on the other (De Greef, 1908).

Borders—or frontiers, or boundaries—can be studied in a variety of ways: as limits of state sovereignty or as limits of administrative units within states, but also as cultural markers—markers of ethnicity, group or individual identity, and as form. Here, we are predominantly interested in the political borders between nations and states

rather than substate boundaries or cultural and anthropological concepts of boundaries (Cohen 1986). Borders, thus, are products of human attempts at organizing territories. They may change location as well as function. “Frontiers are inseparable from the entities which they enclose” (M. Anderson 1996, p. 178); they are “a geographical instrument . . . for the organization of space” (Guichonnet and Raffestin 1974, p. 9). Political borders are human constructs, not natural givens. “Frontiers between states are institutions and processes.” (M. Anderson 1996, p. 1).

Borders are institutionalized in legal texts and international agreements, and as such are the expression of political will and social organization. They mark the limits of political decision making, the limits of a legal space, the limits within which state identities and rights and duties of citizenship operate. Looking at borders as processes, Malcolm Anderson defines four dimensions (M. Anderson 1996, p. 2): (1) They are instruments of state policy, protecting and promoting interests; (2) the de facto control states exercise over their borders is indicative of the nature of the state; (3) frontiers are markers of identities of “imagined communities” (B. Anderson 1983); and (4) the “frontier” is a term of discourse, affecting “not only the physical flow of goods and persons, which can be measured; much more important, they affect the culture and consciousness of people, which is much more difficult to assess” (Strassoldo 1998, p. 87).

Historically, the development of the idea of the border has been closely linked to the idea of the development of the state (Breuille 1993). As the idea of the state changed, so did the functions of borders. Ancient empires, like the Greek or the Roman, had clearly defined boundaries within them—to define citizenship rights and duties—but the outer limits were ‘fuzzy’. The claim was that the limits of the empire were the limits of the (civilized) world; the empire could not be bounded. In practice, the Romans developed the idea of the *limes*, a frontier line well within the boundaries within which Roman authority ruled, with a zone of influence beyond, which would act as a buffer against the “barbarians.” Even in the Middle Ages, empires preferred to be separated by spaces—“marches” (lat. *margo*)—rather than by fixed lines. In premodern times, feudal, vertical bonds of fealty were of greater importance than territorial

frontiers, and local borders—city limits, customs and toll collection points—exceeded state borders in their practical impact on everyday life. Only the decline of the feudal and the rise of the absolutist order, and then of the nation-state, necessitated greater reliance on clearly defined and defensible boundaries.

Borders became the defining feature of the emerging territorial states, as fixed in the Westphalian system (1648), following the Thirty-Years' War, with its "permanent and unalterable" international frontiers. They were neither permanent nor unalterable. The next attempt to achieve and fix a balanced international state system was undertaken in the Treaty of Utrecht (1713); and then again at the Congress of Vienna (1815) after the Napoleonic Wars.

Social contract theories highlighted the right to exit a territory (if an individual or a group found that the territorial government had broken the contract)—a stipulation closely linked with the discovery of "uninhabited" lands, particularly in the New World. Right of entry, on the other hand, rested solely with the sovereign (with the emerging exception of diplomatic immunity).

Of particular importance was the concept of borders for the emerging European nation-states in the wake of the French Revolution: Homogenization within (i.e., erosion of cultural and linguistic boundaries) and "rational" or "natural" external frontiers exactly delineated frontiers to mark the limits of exclusive authority and sovereignty, guaranteeing and safeguarding the modern state's claim to be the "sole, exclusive fount of all powers and prerogatives of rule" (Poggi 1978, p. 92).

Nation-states established the "classical" functions of frontiers—limits of state jurisdiction, fiscal limits, lines of military protection and defense, customs borders, and sociocultural boundaries. Borders serve to safeguard stability within and protect against external threats. All these functions aim at differentiating between inside and outside, between "us" and "them"; they are means of inclusion and exclusion. In this sense, they are, first and foremost, barriers, enclosing a "security community" (Deutsch et al. 1957). Wilson and Donnan define borders as "political membranes through which people, goods, wealth and information must pass in order to be deemed acceptable by the state. Thus," they argue, "borders are agents

of a state's security and sovereignty, and a physical record of a state's past and present relations with its neighbours." In their view, borders consist of three elements: (1) "the legal borderline which simultaneously separates and joins states;" (2) "the physical structures of the state which exist to demarcate and protect the borderline, composed of people and institutions which often penetrate deeply into the territory of the state;" and (3) "territorial zones of varying width which stretch across and away from borders, within which people negotiate a variety of behaviours and meanings associated with their membership in nations and states." (Wilson and Donnan 1998, p. 9).

In the late nineteenth and early twentieth centuries, concepts of the border assumed, under the auspices of "geopolitics," a Darwinian—biological or organic—interpretation. Friedrich Ratzel (1897) argued that states were living organisms, with frontiers as their skins. And as the organism grew (or shrunk), the skin would adapt, or have to be adapted. States, in his view, were striving to secure the necessary "living space" (*Lebensraum*) for their people and the most effective borders to safeguard them. While Lucien Febvre (1922) rejected such ideas of a "natural" border, seeing it closely linked to the militarization of the modern state, Ratzel's disciple Karl Haushofer paved the way for the Nazi interpretation of the state ruthlessly pursuing the frontiers deemed necessary for expansionist policies based on racial superiority (Haushofer 1986; Murphy 1997).

In the United States, Frederick Jackson Turner, from the perspective of the settlement of the North American continent, saw the "frontier" as a moving section where wilderness and civilization meet, having profound implications for an American "frontier mentality" (Turner 1894). This dynamic concept of frontier as a moving space led to purchase of territory (Louisiana, 1803, from France; Florida, 1819, from Spain) and territorial conquest through war (New Mexico, Arizona, Nevada, Utah, California, part of Colorado, 1848, from Mexico), creating the Rio Grande border. The northwestern frontier with Canada was settled, after decades of controversy with Britain, in 1846, following the 49th parallel.

Frontiers in South America have been products of European colonialism. Yet, in contrast to

Africa, they developed over a longer period of time. South American independence, on the other hand, preceded African decolonization by about 150 years. According to the principle of *uti possidetis*, the administrative boundaries of the Spanish colonial government were generally accepted, but disputes about the exact location of frontiers have led to military conflicts up to the present day (Peru and Ecuador signed a peace treaty in 1998).

African boundaries were mostly drawn by the colonizing European powers in the late nineteenth century (Berlin Conference 1884–1885) in the “scramble for Africa,” largely ignoring ethnic, tribal, and linguistic structures on the continent (Asiwaju 1985). These artificial boundaries, sometimes modified in the implementation process *in loco*, were accepted by the Organization of African Unity (OAU) at their first postcolonial conference in Cairo, in 1964, in order to guarantee stability. Recent events, such as those in Rwanda and Somalia, have given rise to fundamental questioning of these colonial frontiers and the state system exported from Europe along with them.

The literature relating to frontiers and boundaries in recent times is extensive (M. Anderson 1983; Anzaldúa 1987; Barth 1969; Brownlie 1979; Day 1987; Foucher 1988; Herzog 1990; Heyman 1991; Koptoff 1987; Kratochwil 1986; Lamb 1968; Luard 1970; Martínez 1994a; Prescott 1987; Sahlins 1989; Strassoldo 1973; Strassoldo and Delli Zotti 1982; Tägil 1977). Particularly since the fall of the Berlin Wall, frontiers have increasingly returned to the political and academic discourse in Europe (M. Anderson 1996; M. Anderson and Bort, eds. 1998; Blake 1994; Brunn and Schmitt-Egner 1998; Donnan and Wilson 1994; Eger and Langer 1996; Eskelinen et al. 1998; Foucher 1990; Ganster et al. 1997; Kramer 1997; Martínez 1994b; Murray and Holmes 1998; Neuss et al. 1998; O’Dowd and Wilson 1996; Raich 1995; Rupich 1994; Wilson and Donnan 1994–1998a).

New international frontiers have been created (e.g., the Baltic states, the former Yugoslavia, the Czecho-Slovakian “velvet divorce,” Moldova); other boundaries have changed their function fundamentally, particularly in the case of the former Iron Curtain. Resurgent nationalisms in the former Soviet Union and in the Balkans, emulating the classic European claim to independent

nationstates in multinational contexts, have highlighted the inherent contradiction between the international community’s accepted principles of “sanctity of borders” and the “right to national self-determination (Hayden 1992; Sluga 1998).

At the same time, the rhetoric about a borderless Europe (i.e. the retreat of the classic nation state within the European Union) has been, at least partially, translated into reality. Free movement of goods and people was already envisaged in the Treaty of Rome (1957), the founding document of the European (Economic) Community. With the introduction of the Single Market in 1993, based on the 1986 Single European Act, the economic functions (customs, tariffs, etc) of borders inside the EU have been eroded. Since 1995, the 1985 Schengen Agreement and the 1990 Schengen Convention have been progressively implemented, in the process blurring the distinction between international and substate boundaries within the EU (den Boer 1998).

Political frontiers as limits of sovereign states were a European invention and were subsequently exported through colonialism and imperialism. Europe is now facing the biggest challenges to the traditional role of borders. The Schengen Convention, as of 1999 signed by all but two EU member states (the United Kingdom and Ireland) and implemented in ten member states, abolished border controls (passport controls, border police checkpoints) at the internal frontiers and transferred those border controls, standardized and supervised by the Schengen Control Committee, to the external frontiers of “Schengenland.” “The general purpose of frontiers in the sovereign state was to establish absolute physical control over a finite area and to exercise exclusive legal, administrative and social controls over its inhabitants. But the traditional attributes of ‘sovereignty’ are clearly being eroded in Europe and frontiers are losing their hard-edged clarity” (M. Anderson 1996, p. 89). Pooling of sovereignty, the legal prerogative of EU law over national law, and economic and monetary union (with the introduction of the euro in 1999) are often cited as indicators of the demise of the nation-state. This may be exaggerated. Milward (1992) has argued that the EU actually came to the rescue of the nation-state by providing the material benefits that secure its legitimacy. Yet

Milward did not take into account the developments in the 1990s, as expressed in the 1992 Maastricht and 1997 Amsterdam Treaties on European Union, the latter incorporating, for example, the Schengen *acquis* into the institutional framework of the EU.

Will the processes that can be observed in Europe have repercussions elsewhere? Commentators from areas where the European border experience was exported have taken a keen interest (Asiwaju 1996). If borders lose their symbolic and real functions in security and control, will other functions—such as markers of identity and culture—become more salient? Fernand Braudel (1985) observed how the Roman “frontier between the Rhine and the Danube was . . . a cultural frontier *par excellence*,” exercising tangible influence long after its historical demise (p. 66).

The Schengen Convention already entails a transformation of the border-line into a spatial concept of borders, which, in the light of advancing surveillance technology and the need to combat cross-border crime at the locus of its origin (or destination), rather than at the border has been seen as a return of the marches, or *limes* (Foucher 1998).

In addition, and orchestrating this process of erosion, institutionalized cross-border cooperation has become a common feature at nearly all European frontiers, having started along the German–Dutch and German–French frontiers and subsequently expanded with every phase of EU enlargement.

This, against the backdrop of the demise of the Iron Curtain, has also helped to focus attention on the fact that although borders may be barriers, they can also be (or become) points of contact, channels of communication and interaction. Martinez (1994b) describes four types of interaction at borders, arranged on a continuum from closed to open:

1. “Alienated borderlands,” characterized by political and military tensions that allow for very little, if any, exchange across the border. The border is closed; borderlanders on each side perceive of each other as aliens.

2. “Coexistent borderlands,” where contacts are possible and limited exchange takes place but long-term cooperation seems undesirable for political or military reasons.
3. “Interdependent borderlands,” where contacts are frequent, mutual trade and exchange across the frontier has assumed complementary character, and a common borderland mentality is being developed both sides of the border. The border, however, is still closely monitored and only open in so far as the states’ interests are not damaged.
4. “Integrated borderlands,” where all barriers and obstacles to cross-border communication, exchange, and movement of people, goods, services, and capital have been removed and a common cultural cross-border identity is developing.

Although these are “ideal-typical” definitions, it is not difficult to find practical examples to these four stages, which can, as envisaged by Martinez, be seen as stages in an evolution. Number 1 would be the historical example of the bipolar Cold War frontier, the Iron Curtain, as symbolized by the Berlin Wall, or, perhaps, by the “Green Line” separating Turkish and Greek Cypriots. Number 2 could be the borders between former Soviet republics, such as Belarus and Poland. Number 3 is clearly Martinez’s model for the U.S.–Mexican border, where, under the umbrella of NAFTA, goods and capital may flow relatively unhindered across the internal border of the free-trade area, but movement of people is restricted and border control is a high priority. Number 4 would be the internal frontiers of the post-Schengen European Union, classically expressed in the close cross-border relations along the German–Dutch (Euregio) or German–French borders, including the German provision of transferring sovereignty rights to institutions straddling the frontier (Beyerlin 1998).

Yet opening frontiers is not seen solely as a positive process. What is apparent is that people in Europe and the United States seem to harbor an unfocused, general anxiety about frontiers no longer providing the protection they once did. Organized cross-border crime, trafficking of drugs and other smuggled goods, and organized human trafficking seem to indicate that frontier controls are

no longer as effective as they once were. This may be changing as populations become more accustomed to the absence of frontier controls at the internal frontiers. This absence is widely welcomed in frontier regions. In general, the French—normally very sensitive to these matters—seem to have adopted a reasonably relaxed attitude about open frontiers, and those living in the frontier regions seem very pleased with the new situation. Law enforcement agencies seem to have adapted to the new situation without undue difficulty. The nature of frontiers is perceived as changing. New information technology for surveillance and identity control is widely seen as a key factor in securing efficient frontier controls.

The dangers of cross-border crime—drug trafficking, illegal weapons trade, car and cigarette smuggling, money laundering, fraud and corruption, human smuggling, and so on—must not be underestimated. At “their most extreme, substantial rises in the proportion of illegality in international economic activity can destabilize national economies” (Holmes 1999). The rise in internal and cross-border crime in Eastern Europe, particularly in the countries of the former Soviet Union, can be attributed to the difficult transitional situation in these countries: post-communist states attempting, in Claus Offe’s (1996) term, a “triple transition”: the rapid and simultaneous transformation of their political systems, their economic systems, and their boundaries and identities.

The discourse of migration control has become intricately linked with the discourses on crime and security in a process of “securization” (Bigo 1999; Huysmans 1995). Security has become a much broader concept, compared with the focus on military concerns that dominated the discourse until the changes of 1989–1990, encompassing new risks and threats to society, the economy, and the polity itself (Zielonka 1991). This constitution of a security continuum, including the control of frontiers and immigration among police activities in the fight against crime, is, Bigo argues, “not a natural response to the changes in criminality,” but rather a proactive mixing of crime and immigration issues (Bigo 1999, p. 67–68). Buzan has coined the term “societal security” to describe the shift of security concerns from protection of the state to protection against threats, or perceived

threats, against society and identity or against the identity and security of groups within a society (Buzan 1991).

The southern and eastern frontiers of the European Union, as well as the U.S.–Mexican border, demonstrate that the “promotion of borderless economies based on free market principles in many ways contradicts and undermines . . . efforts to keep borders closed to the clandestine movements of drugs and migrant labor.” (Andreas 1996, p. 51). Yet despite these efforts at tightening border controls, even erecting what has euphemistically been dubbed the “tortilla curtain”—a metal wall along the border south of San Diego—and combining military and law enforcement agencies, “many clandestine border crossers are adapting rather than being deterred.” (Andreas 1996, p. 64). Economic factors, “underlying push-pull factors” (Andreas 1996, p. 68), have frustrated repeated attempts at closing the U.S.–Mexican border to illegal migrants. Operation “Wetback” (under Richard Nixon) and, more recently, operation “Gatekeeper,” caused “immediate economic damage, tensions between social groups and [had] almost zero effect on illegal immigration.” (Bigo 1998, p. 159).

Clearly, these functional changes of states will be reflected in the functional changes of their borders, and vice versa. Borders, Foucher (1998) reminds us, “are time inscribed into space or, more appropriately, time written in territories” (p. 249). Thus, “different conceptions of the frontier as an institution existed before the modern sovereign state and other kinds will emerge after its demise” (M. Anderson 1996, p. 5). If we are not witnessing the demise of the nation-state, under the dual pressures of globalization and regional responses, the least we can state is that it is “diversifying, developing,” if “not dying” (Mann 1996).

Or will the new security architecture being created in Europe establish or cement dividing lines that will echo the maintenance of global inequalities? Is the hardening of the external frontier of—perhaps an enlarged—EU part of the Huntingtonian scenario of a “clash of civilizations” (Huntington 1996)? In view of the complexities within what Huntington loosely defines as “civilizations” as well as between them, this is unlikely (Holmes 1998), but frontiers will remain

instruments of politics and instruments for the protection of interests.

RAIMONDO STRASSOLDO
EBERHARD BORT

NATIONALISM

Nationalism has been defined in a variety of ways at different levels of analysis (e.g., Kohn 1955, 1968; Symmons-Symonolewicz 1970; Kamenka 1973; Plamenatz 1973; Smith 1976, 1981; Snyder 1984). The concept combines a sense of identification with a people, an ideology of common history and destiny, and a social movement addressed to shared objectives. This definition raises questions about what differentiates a people or a nation from others, the nature of identification, the conditions under which nationalist ideologies develop, and the course and aims of nationalist movements.

Historically the term *nationalism* was applied to attempts to follow early European models “to make the boundaries of the state and those of the nation coincide” (Minogue 1967, p. 12), that is, to create loyalty to a nation-state (Kohn 1968). It was also applied to struggles, proliferating after World War II, to gain independence from colonial domination and join the community of sovereign states. More recently, however, analysts have found the confusion between the concepts of state and nation to be a hindrance to understanding contemporary nationalism. Only rarely, if at all, do the boundaries of a state coincide with those of a nation. By *nation* we mean an ethnic group that (1) shares one or more identifying characteristics, such as language, religion, racial background, culture, and/or territory; and (2) is politically mobilized or is amenable to such mobilization. Thus, *nationalism* should be distinguished from *patriotism*, in that the identification and loyalty in the former is to an ethnic group or nation, and in the latter to the state.

IDENTIFICATION

Debates centering on the intrinsic nature of collective ethnic identification feature variations on two general themes—primordialism and structuralism. Implied in the primordial perspective is a deemphasis on an instrumental view of ethnic ties. These ties are seen as ends in themselves shaped by forces other than material self-interest; they are persistent and they resist the homogenization predicted by convergence and modernization theorists. The essence of these ties “is a psychological bond that joins a people and differentiates it in the subconscious conviction of its members from all other people in the most vital way” (Connor 1978, quoted in Stack 1986, pp. 3, 4). These bonds stem from “immediate contiguity and kin connection mainly, but beyond them . . . from being born into a particular religious community, speaking a particular language, or even a dialect of a language, and following particular social practice” (Geertz 1963, pp. 14, 15). Thus, there can be multiple identities—for instance, a Moroccan may identify with an ethnic group within Morocco, the Maghrebs of North Africa, the Arabic speaking people, and the Muslim people at large. These identities assume varying significance depending on the context, lending credence to the old saying “My brother and I against my cousin, and my cousin and I against the stranger.” To structuralists, “ethnic identity results instead from objective intergroup differences in the distribution of economic resources and authority” (Hechter 1986, p. 109). Implied here is rational choice and self-interest, that ethnic ties are means to certain ends, and that the boundaries of ethnic groups are changeable.

Neither primordialists nor structuralists would deny the obvious variations in the intensity of identification and in the potential for nationalist movements cross-culturally and over time. Several factors are expected to contribute to these variations. Among the more important of these factors is coterminality of characteristics. In most instances multiple characteristics are involved in distinguishing among ethnic groups—in an overlapping manner at times and coterminously at others. The United States offers an example of overlapping identities where people from different racial backgrounds share the same religious orientation, people with different religious orientation share a common language, and there is no territorial exclusiveness. This overlap in ethnic identification is

credited in part with lowering intergroup tensions (Williams 1947). At the other extreme are peoples in southern Sudan, Eritrea, Tibet, the Tamils and Sinhalese in Sri Lanka, the republics of the former Soviet Union, the republics of former Yugoslavia, and other places where all or a combination of racial, religious, linguistic, cultural, and territorial maps largely coincide. The greater the number of factors that coincide, the greater the gulf or "social fault" among ethnic groups along which nationalist sentiments and tensions are likely to intensify (Nagi 1992).

In addition to differentiating attributes and geographic distributions, a number of features of the social structure contribute heavily to variance in intensity and patterns of nationalism. Hechter (1986) suggests two types of such factors. One is the institutionalization of ethnic differences in legal and normative rules, especially those governing property and civil rights, as was the case in South Africa. The other is differentiation in positions in the division of labor that shape "specialization experiences as well as material interests." Deutsch offers another factor in nationalism, attributing membership in a people essentially to a "wide complementarity of social communication" that "consists in the ability to communicate more effectively, and over a wide range of subjects, with members of one large group than with outsiders" (1953, p. 71). Communication is subject not only to commonality of language and cultural background, but also to available means. These include networks of social relations as well as the ever-advancing technological means of mass communication.

NATIONALISM

In addition to identification and "consciousness of kind," nationalism involves ideology and mobilization for social movement and political action. The ideology stems from identification, the sense of uniqueness of group origin, history, culture, collective authority, and destiny (Smith 1981). Political mobilization and the course of nationalist movements are greatly influenced by a host of internal and external factors. Important among the internal factors are uneven economic conditions and disparities along cultural lines in control of resources, access to goods, and distribution of

positions in the occupational structure. The collective perception of an ethnic group of its deprivation or exploitation may challenge the legitimacy not only of the regime but also of the state itself. The theme of "relative deprivation" has been central to explanations of political violence (e.g., Gurr 1970).

The political system allocates power and authority. An uneven distribution among ethnic groups can be the direct result of exclusionary rules and practices, as in the case of Apartheid in South Africa, or the indirect result of socioeconomic disparities and associated discriminatory practices, as characterized in the relationships between Catholics and Protestants in Northern Ireland. Whatever the reason, a cultural distribution of power is as evocative of a nationalist sense of deprivation as a cultural distribution of resources. The close relationship between power and resources led Lasswell to observe that politics is "Who Gets What, When, How" (1936, p. ii).

Applying a developmental perspective, Huntington (1968) connects political stability or instability to the balance between "institutionalization" and "participation." This line of reasoning suggests to some analysts (e.g., Sanders 1981) a linear relationship between political development and political instability—in this case arising from nationalism, which is credited with having been the most prevalent reason for state-level violence (Said and Simmons 1976). Support for such a pattern of relationships derives also from the expectation that the national integration and political assimilation characteristic of developed societies contribute to a shift from culturally based to functionally based cleavages. The net result is a reduction in the prevalence and intensity of ethnic mobilization in the more politically developed countries. However, clearly implied in Huntington's discussion of relations between demand for participation and institutional capacity is a balance at low levels in the least developed countries and at high levels in the developed ones. Imbalances can be expected at early and middle states of development, which suggests a curvilinear pattern.

There is no unanimity on the relationships between development and nationalism. This is understandable in view of the complexity of both phenomena and the current state of research. An important voice on these relationships is that of

Walker Connor (e.g., 1972), who contends that modernization, the spread of education, and improved means of mass communication are responsible for a resurgence in ethnic nationalism. Juan Linz observes that “in the modern world the aim seems to be to build nations rather than states, a task that is probably beyond the capacity of any state that has not achieved the characteristics of a nation-state before the era of nationalism” (1978, p. 62). The distinction between “level” and “process” of modernization and development is useful in understanding the rise in nationalist sentiments. As Smith has noted, “Perhaps, then, it is not the fact of economic progress or decline that is relevant to ethnic revival, but simply economic change per se. Most change . . . is painful and uprooting” (1981, p. 34). Tensions, strains, and dislocations associated with change in the structure and distribution of power—political change—are no less painful or uprooting. Attempts by central governments to secularize and to shift loyalties from ethnic groups to the state underlie much of contemporary nationalism.

NATIONALIST MOVEMENTS

The literature offers two perspectives in explaining the formation of social movements—collective behavior and resource mobilization. In the former, social movements are viewed as responses to a rise in grievances and the actors are seen as “arational” if not “irrational”; in the latter they are considered as goal-oriented, rational responses dependent on organization and mobilization of resources (Jenkins 1983). Debates concerning the strengths and limitations of these two perspectives are yet to be settled. Important to a discussion of nationalism, however, is that literature on social movements, especially on resource mobilization, is primarily Western in conceptualization and empirical foundations. Significant in this respect are differences in aims that guide social movements. More common to Western societies is “changing some elements of the social structure and/or reward distribution of a society” (McCarthy and Zald 1977, pp. 1217, 1218), as compared to nationalist movements that press for autonomy, if not for secession. The first type of movement seeks change through influencing political institutions, the legitimacy of which is not in question (e.g., civil rights in the United States and labor movements in many countries). Nationalist movements, on the

other hand, often challenge, if not outright reject, the legitimacy of the state (e.g., Croatia, Slovenia, Bangladesh, Eritrea, and others that eventually seceded from larger states, as well as Biafra, Southern Sudan, Quebec, and others where no separation has occurred). This is not to cast doubt on the applicability of theories of social movements to ethnic nationalism but, rather, to point out that the influence of differences among societies in levels of development, political institutions, types of regimes, and movements’ aims has not been adequately explored (see McCarthy and Zald 1977; Tilly 1978; Jenkins 1983).

In the following paragraphs we shall outline some of the important features of nationalist movements and the processes of mobilization. More specifically, we shall consider the role of grievance, resources, repertoires of expression, and aims.

The role of grievances remains unresolved. While traditional analysis places grievances stemming from structural strains associated with social change at the root of movements (e.g., Smelser 1962; Gurr 1970; Gusfield 1970), resource mobilization proponents favor structural “causal” explanations (e.g., Tilly 1978). Some feel discontent is ubiquitous and therefore, by itself, cannot explain the emergence of social movements. McCarthy and Zald go even further: “For some purposes, grievances and discontent may be defined, created and manipulated by issue entrepreneurs and organizations” (1977, p. 1215). In line with this perspective is Smith’s account of “ethnic revival” (1981). Smith maintains that the unique and distinguishing rationale of an ethnic group is the emphasis on group belonging and group uniqueness that links successive generations of the group with specific origins and history. Driving the engines of “historicism” and “nationalism” are discontented intellectuals, educators, and professional intelligentsia. Blocked mobility, opposition and repression by traditional authorities, and frustrated expectations concerning recognition, especially on the part of Third World intellectuals, are factors in the radicalization of these groups, which then turn to historicism and inward to their ethnic communities (Smith 1981).

In explaining the spread of “value-oriented movements,” Smelser (1962) refers to “structural conduciveness.” Two elements of conduciveness

are highly applicable to ethnonationalist movements. One relates to the importance of communication in “disseminating a generalized belief”—a position consistent with that of Deutsch (1953) and Connor (1972), cited earlier. The other is “the availability of means to express grievances” during troubled or uncertain times in order to redress problems.

Attempts to explain nationalist movements must account for the mobilization of resources. McCarthy and Zald outline five central considerations: (1) “aggregation of resources (money and labor)”; (2) the form of organization these resources entail; (3) involvement of individuals and organizations outside the movement; (4) the flow of resources to and from the movement; and (5) “the importance of costs and rewards in explaining individual and organizational involvement” (1977, p. 1216).

The prevailing patterns of social relations are expected to influence the potential for, and forms of, organization and mobilization. Tilly (1978) maintains that combined strength in identification and interpersonal bonds lead to high levels of organization and to greater possibilities for mobilization. In a similar vein Oberschall (1973) offers a classification for patterns of organization. Along one dimension—relations within collectivities—he identifies three types: “communal,” “associational,” and “weakly [organized] or unorganized.” Mobilization, which is facilitated by communal and associational forms, is rendered difficult by the weakly organized and unorganized structures. Along another dimension, Oberschall distinguishes between “vertical” and “horizontal” relations to other collectives and segments of society. Social and political bonds across classes and collectivities can influence mobilization; however, the direction of influence can be expected to vary depending on the type of movement. For example, Oberschall observes: “If in a stratified society there exist [sic] strong vertical social and political bonds between upper and lower classes, mobilization into protest movements among lower classes is not likely to take place” (1973, p. 120). While this may be the case in regard to class conflicts, vertical bonds within an ethnic group can significantly facilitate mobilization.

Strength in family and kinship relations underlies Tilly’s networks of interpersonal bonds

and Oberschall’s communal organization. Houseknecht sees strength here as referring “to the extent to which family/kinship obligations and rights take precedence over their nonkinship counterparts” (1990, p. 1). She outlines important ways in which kinship relates to ethnic identification, nationalism, and the organization of movements. Early socialization builds identification with an ethnic culture and commitment to its values and norms, which continue to be strengthened and enforced through kinship ties. Commonality in cultural background facilitates social communication, and the networks of kinship ties are readily available channels for the mobilization of human and material resources. Furthermore, the traditional authority structure afforded by strong family and kinship systems provides protection in resisting pressures applied by the state’s central authorities.

While informal networks of kinship and interpersonal relations are important to nationalist movements, the role of formal organizations cannot be overstated. As pointed out by McCarthy and Zald (1977), a social movement may include more than one organization; and all organizations in a movement compose a “social movement industry.” Competition over resources can arise between a movement industry and other commitments, as well as among organizations within the same movement industry. The latter form of competition is common to nationalist movements, as in the case of the Kurds. This frequently encourages the involvement of neighboring states or major powers, and often leads to internal conflicts within movements.

These lines of reasoning concerning the role of kinship and interpersonal relations bring up the unresolved debate over the relative effectiveness of bureaucratic centralized movement organizations compared with those of an informal decentralized nature. While some argue that “a formalized structure with a clear division of labor maximizes mobilization by transforming diffuse commitments into clearly defined roles and . . . centralized decision making,” others maintain that “decentralized movements with a minimum division of labor and integrated by informal networks and an overarching ideology are more effective” (Jenkins 1983, p. 539).

Why would individuals and organizations contribute their labor and resources to ethnonationalist

movements? To primordialists, the answer is that they do so in order to preserve cultural integrity and a way of life, to maintain group solidarity and social bonds, and to advance the cause of a community from which a sense of security and pride is derived. These are valued ends in themselves. To collective behavior theorists, the answer is in the collective mood, the social contagion, and the state of mind that are engendered in response to the perception of grievances. To structuralists and resource mobilization proponents, the answer lies in rational collective action and the pursuit of interests.

Opportunities for mobilization are also enhanced by the quality of leadership and its effectiveness in articulating the interests of the group. Smelser explains the significance of charismatic leadership to value-oriented movements. Such forms as “the dreamer prophet of the cult, the nationalist crusader, and the totalitarian demagogue” (1962, p. 355) are compatible with the character of these movements in certain phases of their development. He goes on to point out, however, that “Insofar as a value-oriented movement receives material from outside sources, and insofar as it inherits an organizational structure, the need for charismatic leadership lessens” (p. 356). Useful here are categories identified by Hermann (1986) to analyze political leaders. Particularly important are such contextual factors as to whom the leaders are accountable, forms of interaction with followers, the constraints defined by constituents’ beliefs and norms, the strength and nature of opposition, and available resources.

Repertoires of expression of ethnic nationalist movements vary along a wide spectrum that includes interest articulation, passive resistance, demonstrations and riots, sabotage and terrorist acts, and internal wars. Patterns of expression are shaped by the style of leadership, the level of organization, and resources. They are also influenced by the reactions of the state as well as by external forces. These expressions represent events in the life history of movements. The points at which these movements begin and end are generally difficult, if not impossible, to ascertain. Thus, what might be referred to as beginnings or outcomes may well represent only arbitrarily defined points in a process.

Ethnic movements differ in aims and strategies. Smith identifies six types:

1. Isolation . . . was the most common strategy for smaller ethnic communities in the past. The ethnic community chooses to stay aloof from society as a whole. 2. Accommodation. Here the ethnic community aims to adjust to its host society by encouraging its members to participate in the social and political life of the society and its state. Often, individual members try to assimilate to the host society, or at least become acculturated, for individual advancement. 3. Communalism . . . is simply a more dynamic and active form of accommodation The aim is communal control over communal affairs in those geographical areas where the ethnic community forms a demographic majority. 4. Autonomism. There are . . . various forms and degrees of autonomy Cultural autonomy implies full control by representatives of the ethnic community over every aspect of its cultural life, notably education, the press and mass media, and the courts. Political autonomy or “home rule” extends this to cover every aspect of social, political, and economic life, except for foreign affairs and defense. Ideally, autonomists demand a federal state structure, and this strategy is really only open to communities with a secure regional base. 5. Separatism. This is the classic political goal of ethnonational self-determination In each case, the aim is to secede and form one’s own sovereign state, with little or no connection with former rulers. 6. Irredentism. Here an ethnic community, whose members are divided and fragmented in separate states, seeks reunification and recovery of the “lost” or “unredeemed” territories occupied by its members. In general, this is only possible where the ethnic community has its membership living in adjoining states or areas. (1981, pp. 15–17)

Seeking independent rule, as in secessionist or separatist movements, poses the most serious threat to the state. Such movements challenge not only the legitimacy of the government or regime, but also the integrity of the state itself.

It is reasonable to expect that factors shaping the intensity of nationalist movements will, in turn, influence the formation of secessionist goals.

Territorial coterminality with lines of ethnic identification is a strong contributor, with distance from the ruling center adding to the potential for secessionist claims (Young 1975; Islam 1985; Pankhurst 1988). Timing seems to be important to the rise of such claims as well as to their success. Based on the experiences of several African countries, Young (1975) points out that time is conducive when polity in the parent state falls into disrepute, calling its legitimacy into question because of mismanagement, corruption, and discrimination. He also concludes that times of cataclysmic events in the lives of states offer opportunities for secessionist claims because of the fluidity these events engender, the options they open, and the push for choices to be made. Young cites other antecedents that provide a basis for solidarity and mobilization, such as regional differentials in concentration of wealth and representation in power positions, and at least the minimum political resources to make independent status possible even when economic sacrifice is required. To this list of contributing factors, Islam (1985) adds the magnitude of suffering, the impact of the secession of a region on the rest of the country, whether the seceding region represents a majority or a minority of the population, and the involvement of outside powers.

REGIONAL AND GLOBAL INFLUENCES

The rise of nationalism and the forms and directions it takes are significantly influenced by forces external to the respective states—regional and global socioeconomic and political conditions, and by the spread of ideologies. The power vacuum created by the liquidation of colonialism after World War II tended to be filled by newly created states where borders had been frequently drawn arbitrarily vis-à-vis ethnic distributions. Regional power struggles, territorial disputes, economic competition, and ideological differences have left many regions of the world fraught with turmoil. Since cultural pluralism is characteristic of most, if not all, of the new states, ethnic nationalism often figures prominently in regional conflicts—as a cause at times, and as a consequence at others. The regional dynamics of ethnonationalism can take many forms. It has been a force behind the formation of alliances among independent states, for instance, the Arab League (1945), the Arab Magreb

Union (1989), and the Gulf Co-operation Council (1981). It was also influential in rare cases of voluntary fusion of independent states. Egypt and Syria formed the United Arab Republic (1958) which “was open to other Arab states to join, but only Yemen entered a loose association” (*Encyclopedia of World History* 1998, p. 689). A military coup in Syria ended its union with Egypt in 1961, and Yemen pulled out in 1966. Ethnonationalism was also used as justification for annexation by force as in Germany’s invasion of Austria and the Sudetenland (late 1930s); China’s occupation of Tibet (1950s); and Iraq’s invasion of Kuwait (early 1990s), which was repelled by an international coalition led by the United States and including several Arab countries.

The phenomenal advancements in means of communication and transportation have enormously increased the intensity and scope of global relations. Four features of these relations are particularly relevant to nationalism. First is the spread of ideologies related to human rights and the right to self-determination. Reports of abuses of these rights are communicated in a graphic and rapid, if not an instant, manner. They galvanize global public opinion and prod governments to intercede. The intervention of the North Atlantic Treaty Organization (NATO) countries and others in opposition to “ethnic cleansing” in Bosnia and Kosovo is a case in point. Rapid communication also brings to ethnic communities the successes of others who are engaged in struggles or have succeeded in attaining varying measures of autonomy. Second is the presence of world forums to address these issues and bring to bear the weight of the global community, such as the United Nations General Assembly, the Security Council, the International Court of Justice, and other governmental and nongovernmental organizations. Third is the increasing globalization of the economy, which makes it possible for small sociopolitical units to find multilateral niches, thereby reducing dependency on bilateral economic relations with either former colonial powers or states from which they have seceded. Fourth is the geopolitical relations among major powers. When the world was polarized between the two superpowers—the United States and the former Soviet Union—they frequently supported different sides of conflicts within pluralistic societies, either directly or through proxies. In the past, both countries have taken

positions in support of the doctrine of “self-determination.” President Wilson was a staunch spokesman for the principle during and after World War I. Around the same time, “at the Seventh All Russian Democratic Labor Party Conference of May 12, 1917 . . . in a resolution drafted by Lenin, the conference unequivocally endorsed the right of all of the nations forming part of Russia freely to secede and form independent states” (Connor 1984, p. 45). In contemporary global relations both countries have shown less commitment to the principle. This became clearly evident in the resistance of the former Soviet Union to the independence of the Baltic States, and in the use of military force to keep Chechnya within the fold of the Russian Federation. The approaches of these powers to nationalism have become subject to strategic and economic interests, tempered by the balance of force that can be brought to the situation. The ebb and flow of relations among these powers exerted considerable influence on ethnonationalism for decades.

The vested interests of other states are usually rooted in resources, trade, security, geopolitical advantage, ethnic affinity, or other ideology. More recently, humanitarian considerations have been assuming greater significance in the foreign policy of the West, most notably the United States, progressing “from the call for moral pressure in the 1970s, to economic sanctions in the 1980s, to military intervention in the 1990s” (Kissinger 1999, p. 43), as in the case of Kosovo. While the large states “are likely to intervene for instrumental reasons,” the small ones “are more likely to intervene for affective reasons” (Heraclides 1990, p. 377). Regional and global influences may strengthen or weaken the state’s means of control and repression, contribute to the movement’s resources and sanctuary, and/or raise awareness and help mobilize regional and global public opinion. These interests and their expression, directly or through international organizations, expand or inhibit opportunities for nationalist movements including those with secessionist aims.

The spread of the ideology of minority rights and self-determination plays a special role in secessionist movements. In a comparative analysis, Sigler concludes: “There is historical weight to the charge that minority rights is a guise for separatist sentiment” (1983, p. 188). He maintains that the “concept of minority rights briefly blossomed under

the minorities treaties system” (p.190) that followed from the Treaty of Versailles. The system was to protect the rights of minorities in many countries, mostly in Europe, after World War I. It gave jurisdiction to the Permanent Court of International Justice, but litigations became protracted and difficult to adjudicate, thus severely limiting the court’s role. It gave power to the Council of the League of Nations to intervene but did not guarantee that disciplinary actions would be carried out against states for infractions. Mutual reinforcement of a system of states as a basis for international relations restrained the various states from interfering in each other’s internal affairs. “The collapse of the minorities treaties system . . . has encouraged minority separatist movements In the absence of a strong international system for the protection of minority rights, resort to separatist politics may have become more prevalent” (Sigler 1983, p. 190). This reinforces Smelser’s ideas about structural conduciveness mentioned earlier.

If the odds facing secessionists are great, those facing irredentists are much greater. By definition, irredentism involves multiple secessions, which means contending with forces of more than one state. Consider the difficulties facing the Kurds for whom fulfilling the aim of a unified independent homeland (Kurdistan) is resisted by all the states among which they are divided (Azerbaijan, Iran, Iraq, Syria, and Turkey). An exception was when an ethnic group in one state seeks to attach itself to a neighboring state that includes part of the same group. This tactic is used by some separatists to obtain external support (Young 1975), as in the case of Kashmir that has attracted the backing of Pakistan in its struggle to secede from India. Potential annexation is not necessary for a state to intervene in support of related groups in another state. In the course of extending protection to the Greek and Turkish subpopulations of the island state of Cyprus, war almost erupted between Greece and Turkey.

REACTIONS OF THE STATE

Actions by the authorities and the means of control they employ are largely shaped by the objectives of nationalist movements and greatly affect their course. When perceived as threats to the stability of state and government, they are usually

met with repression. However, nationalist movements that remain clandestine and limited under conditions of severe repression tend to gather momentum and erupt into open expression when a new regime, or change in policy, reduces coercion. Recent events in the former Soviet Union and other countries illustrate the point.

Repression is not the only means used by states in responding to threats of ethnonationalism. Some states, such as the former Soviet Union and the People's Republic of China, adopted population redistribution policies aimed at diluting the coterminality of ethnicity with territory. Language policies in education are also used to increase homogenization. Data and other information about Russia and the former Soviet Union are more readily available than about China. The "russification" of Central Asia involved "several migration waves . . . the most recent of which occurred from the mid-nineteenth century to the 1960's . . . conquest and incorporation of the region was accompanied by Russian in-migration, first of peasants in search of new farmland and later of semiskilled industrial workers who entered with regional economic development under socialism" (Kaiser 1994, p. 238). For example, between 1926 and 1959, the proportion of Russians in the population of Kazakhstan increased from 19.7 to 42.7 percent, and from 11.7 to 30.2 percent in Kurgyzstan (Koslov 1975, quoted in Kaiser 1994). These policies seem to have been counterproductive because of heightening nationalist sentiments among the native populations who did, and continue to, view the Russians as colonialists who enjoy greater power and resources (Kaiser 1994). Migration is not the only means used in population redistribution; native populations may be driven out in a process of "ethnic cleansing" as occurred in Bosnia and Kosovo. Central governments in some pluralist states may adopt redistributive policies in regard to resources to assist economic development in lagging regions. Tito's regime in Yugoslavia introduced such policies which ignited a feeling of being exploited on the part of ethnic groups in the more advanced republics (e.g., Slovenia and Croatia).

Other means in the state's arsenal are arrangements for power sharing in governance and mechanisms for conflict regulation. Nordlinger (1972) outlines six such mechanisms: (1) a stable governing coalition of political parties involving all major conflict groups, (2) proportional distribution of

elective and appointive positions, (3) mutual veto by which government decisions must be acceptable to major conflict organizations, (4) purposive depoliticization in which leaders of conflict groups agree to keep government out of policy areas that impinge upon the various segments' values and interests, (5) regulation by compromise over conflictual issues, and (6) one group granting concessions to another as a way of managing conflicts. He also sees four motives for leaders to engage in conflict regulation: (1) external threats or pressure, (2) negative effects on the economic well-being of the groups involved, (3) aversion to risking violence and human suffering that might result from unregulated conflicts, and (4) the protection of leaders' own power position.

Lijphart places equal emphasis on leaders "whose cooperative attitudes and behavior are needed to counteract the centrifugal tendencies inherent in plural societies" (1977, p. 1). The forms he outlines for "consociational" democracies overlap in many ways with Nordlinger's mechanisms for conflict regulation. One important difference, however, is Lijphart's inclusion of "segmental autonomy," that is, federalism. Nordlinger specifically excluded federalism as a mechanism for regulating conflicts because he saw in it a recipe for a breakup of the state.

Emphasis in the foregoing discussion has been on strategies to prevent the breakup of the state. An alternative, however, is to carry out an orderly and peaceful separation. The division of Czechoslovakia (1993) into two countries (the Czech and the Slovak Republics), although a rare example, renders this alternative real rather than just theoretical.

OUTLOOK ON THE FUTURE

While forecasting is a hazardous endeavor, especially in regard to such complex and volatile phenomena as nationalism, disciplined consideration of important trends and their implications for the future is warranted. Interest here is in long-term change that may span generations and many decades of evolution. As implied earlier, the forces of modernization and development are intricately interrelated to the prevalence, severity, and modes of resolving nationalist tensions. By modernization, we mean the forces of change in institutions, organization, and behavior in adaptation to the

vast and rapid advancement in knowledge and its technological application. In a classic analysis, Black describes the awesome significance of this process:

The change in human affairs now taking place is of the scope and intensity that mankind has experienced on only two previous occasions, and its significance cannot be appreciated except in the context of the entire course of world history. The first revolutionary transformation was the emergence of human beings, about a million years ago, after many thousands of years of evolution from primate life . . .

The second great revolutionary transformation in human affairs was that from primitive to civilized societies, culminating seven thousand years ago. . . . Three [early civilizations]—the Mesopotamian, the Egyptian, and the Cretan—have transmitted their knowledge and institutions to later societies.

The process of change in the modern era is of the same order of magnitude as that from prehuman life and from primitive to civilized societies; it is the most dynamic of the great revolutionary transformations in the conduct of human affairs. What is distinctive about the modern era is the phenomenal growth of knowledge since the scientific revolution and the unprecedented effort at adaptation to this knowledge that has come to be demanded of the whole mankind. (1966, pp. 2–4).

Emerging through this process is change in institutions toward greater capacity for political participation, expanding and more productive economies, and increasing cultural neutrality in the formulation of laws and universality in their application. As has been noted by many analysts of social change, this transformation has been accompanied by change in value orientation toward increasing emphasis on achievement, secularization, individualism, rational choice, the rule of law, and tolerance for differences. Powering this process are mutually reinforcing systems of education, research, and development. Several points are important in explaining the connections between modernization and nationalism.

First, the course of modernization is highly influenced by the ability of leaders “to keep the delicate balance required for survival between the

maintenance of the traditional pattern of values that serves as the basis for cohesion and adaptation to new knowledge that requires a revision of the traditional value system” (Black 1966, p. 4). This “clash of civilizations” is common to developing and transitional societies; it is often seized upon in mobilizing nationalist sentiments. The resulting mixes tend to negate the notion that modernization means turning other societies into clones of those of the West. In fact, there are pronounced differences among the advanced countries in the configurations of institutions, organizations, and values they have evolved.

Second, “the challenge . . . in the societies that modernized earlier was internal, the processes of transformation took place generally over centuries. In the later modernizing societies this challenge has been increasingly external, hence more rapid and even abrupt” (Black 1966, p. 8). As pointed out earlier, rapid and abrupt change in itself can create considerable dislocation in institutions and unpredictability in behavior—conditions of anomie—that are fertile grounds for mobilizing fervor for such emotional causes as nationalism.

Third, with halts at times and set backs at others, modernization is a continual process with different countries, and different peoples within countries, being at varying stages of the process. Certain levels of transformation bring about institutional arrangements, modes of organization, and value orientations favorable to prospects for peaceful and orderly resolution of nationalist tensions. It is no accident that the ethnic sub-populations in Switzerland (French, German, Italian, and others), in former Czechoslovakia (Czechs and Slovaks), in the United Kingdom (English, Scottish, and Welsh), in Belgium (Flemings and Walloons), and in Canada (citizens of Quebec and others), found ways to resolve, or to go about resolving, these issues within peaceful legal frameworks. To be sure, there remain instances of violent conflicts as in the case of Northern Ireland.

The point to be made here is that, in the long run—over an extended span of history—the process of modernization can be expected to lessen ethnic tensions and promote peaceful resolution. At present and in the short run, however, the ubiquity of ethnic conflicts and the escalation in associated violence are to be expected in many

regions and countries of the world. In part, this is because of the abruptness of change in general, the pressure built over decades of ethnic differentiation in the distribution of power and resources, and fluidity in the structure of central authorities that suppressed their expression as happened in Yugoslavia and the former Soviet Union. The influence of fluidity in power structures is illustrated by Naimark in his foreword to a volume aptly entitled *The Revenge of the Past*:

The collapse of the Soviet Union was caused by nationalism, that is, by the demands of the subject nationalities of the USSR for genuine independence and autonomy. Unified in their hostility to the Kremlin's authority, the fifteen constituent Union Republics, including the Russian republic, declared sovereignty and began to build state institutions of their own With the failure of the August 1992 putsch attempt, sovereign republics obtained their independence. Nationalism reigned supreme" (1993, p. ix).

Another major trend expected to have significant dampening effects on violent nationalism is the development of global and regional governmental and nongovernmental organizations addressed, in part or in whole, to investigating, reporting, and intervening with cases of discrimination and abuses of human rights. Precedents, of historic importance, were introduced in 1999 with the military intervention of the NATO countries in attempting to reverse "ethnic cleansing" in Kosovo, and the indictment of a head of state and high officials in a serving government by a United Nations Tribunal for "crimes of war and against humanity." To focus on the United Nations for a moment, among its achievements over the first fifty years, Alger cites the following:

It has invented new tools such as peace-keeping. It has extended its mission to include violent conflicts within states. It has broadened peace-keeping to include an array of supportive humanitarian operations. It has drafted a broad array of human rights conventions covering economic, social, cultural, civil, and political dimensions. (1998, p. 422).

Finally, other trends with potential impacts on nationalism include the *voluntary* formation of

economic and political federations among states such as the European Union, and the globalization of the economy. The growing interdependence among countries brings to bear the weight of regional and global communities in containing the risks of disruptive violence. Furthermore, these trends facilitate greater autonomy for small sociopolitical units by offering multilateral niches that reduce dependence on bilateral economic relations with the countries in which they are part or from which they have seceded. In other words, globalization and regionalization tend to transfer power and authority from the states upward to the larger structures and downward to local levels, thus, increasing local autonomy. As has already been explained, a host of other factors particular to each situation are also at work.

CONCLUSIONS

In conclusion, it can be said that the current pervasiveness of nationalism should be self-evident. The socioeconomic, political, and other human costs are frequently staggering. In the short and intermediate term, the ubiquity of the phenomenon can be expected to continue. In addition to Africa and the Balkans, there remain significant ethnic tensions, if not risks of violence, in many countries of Asia—Russia, China, and India, among others. However, in the long run, major trends of modernization, economic globalization and interdependence, and the development of international organizations and forums to address the problem, all point to conditions less conducive to the mobilization of nationalist sentiments and more tending to peaceful resolutions of such tensions.

As a major feature of social structure, ethnicity is of central theoretical importance. However, many (and often large) gaps in the state of knowledge exist, both in theory and in accumulated data. Basically, three shortcomings in the literature account for this. First, there are conceptual and theoretical limitations, especially at the intermediate levels of abstraction that connect abstract explanatory schemes—of which a notable few exist—with concrete events. Second, the preponderance of empirical work in this area is in the form of case studies that are mostly historical. These case studies offer uniformity neither in concepts nor in

evidence. The third problem with literature on ethnic nationalism is its fragmentation. A coherent picture must draw upon concepts and propositions from a number of traditions, and there are many overriding concepts with which to assemble frameworks to advance theory and to guide the collection of evidence. While they are difficult to plan and execute, there is compelling need for comparative studies to advance understanding of the underlying principles. Clear understanding of nationalism, and of the processes involved, is essential to the evolving of appropriate educational, policy, constitutional, and other legal means for accommodating cultural diversity.

NEGOTIATION OF POWER

In ordinary usage, *negotiation* signifies contracting, bargaining, and attempting to reach an agreement. Many studies of negotiation have been carried out particularly with respect to commercial, diplomatic, political, and trade union relations. Recently, acquisitions from the study of negotiation (modalities, styles, strategies, and so on) have been applied to the analysis of interpersonal and social dynamics, ranging from one-to-one relationships to more complex social situations and the management of organizations. Negotiation has also found a specific field of application in the solution of conflicts (Pruitt and Carnevale 1993).

Negotiation is, briefly, a process in which two or more parties try to reach a satisfactory solution to a shared problem. To be more specific, it is a process in which the actors define their own obligations, costs, and benefits to achieve a common result. It is important to emphasize that negotiation is a process, that is to say, it is a dynamic—and not an instantaneous situation—that may be adopted as a way of regulating relationships. Negotiation is a process of exchange (of information, threats, favors, and so on) that goes on until compromises beneficial for all parties involved begin to become apparent. It is a process that advances cautiously and methodically, so that the interests and the expectations of the parties involved are able to emerge gradually. Only when the parties have succeeded in deciphering the real interests and intentions that lie behind their respective declared positions can possible solutions be identified.

Negotiation processes can be analyzed from various points of view, using various techniques. It is possible, for example, to use macrostructural variables. In this case, the outcome is explained on the basis of variables in the context where the negotiation is carried out. Alternatively, it is possible to use psychological variables, interpreting the result of negotiation in the light of the personal characteristics of the actors and of the psychodynamics that develop between them. A third possibility is the "strategic" approach. A strategic analysis does not ignore context-defined effects and limits on the negotiation process nor the importance of the psychodynamic relationship established by the participants but it assumes that the outcome of negotiation will be primarily the result of strategic actions by the negotiators. According to this approach, a negotiation process can only be reconstructed by starting from the actual choices made from the alternative strategies available by actors in specific situations.

It is in this perspective that the special case of "interpower" negotiation (where the term "power" is used as an abbreviation for "institutional power" or "branch of government") has emerged. The topic has become important because in modern political systems the traditional concept of such powers has been modified; because the opportunities for conflict between them have multiplied; and finally because an increasing number of social and economic issues involving values of fundamental importance for individuals and communities have become the target of decisions, interventions, or actions taken or promoted by the various institutional powers.

During the twentieth century, the state has everywhere become increasingly interventionist, while respecting, in democratic societies, traditional civil and political freedoms. State intervention involves, on one hand, the economy and, on the other, various aspects of everyday life. In the economy, the state regulates private initiative relatively strictly, striving to guarantee the "social rights" of less favored groups without yielding to socialist collectivism. As well as impacting, sometimes significantly, on the lives of individuals, groups, communities, and enterprises, the intervention of the contemporary state upsets the parameters of the classic division of powers (legislative, executive, judicial), threatening its survival.

Indeed, it has led to the gradual rise of a new pattern of division of powers.

State intervention involves a massive increase in the production of regulations and therefore in the opportunities for violating such regulations and promoting legal action. It also exacerbates competition and conflicts among powers, among the various branches of state administration, and between decision-making centers and citizens (Field 1996). Normative activity has expanded so much that it can no longer remain the prerogative of parliament. For practical reasons, it is widely delegated to the executive and to administrative authorities. Moreover, a first decision on many conflicts must be referred to the administrative authorities, so that the classic principle of the exclusive attribution of fundamental functions to separate, corresponding powers is violated. The principle of the clear-cut division of powers has ceased to exist.

On the other hand, the very nature of public administration has changed. It not only carries out normative functions but also possesses wide-ranging discretionary power in defining and safeguarding the public interest. To do this, either official decrees or contractual instruments may be used.

Public administration has become a huge—indeed excessively large, according to many commentators—bureaucratic body. Formally, it continues to be subject to the law (which often leaves the administration a high degree of freedom for discretionary action) and to the directives of the executive. But there are many fields in which the law itself concedes considerable autonomy from the executive to administrative organs.

In addition, the nature of the work of the judiciary has changed. The system of sources for precedent is getting more complex and the number of regulations is mushrooming. Interpretation by judges therefore must involve strongly creative elements. There has also arisen a new area of intervention connected with the increasing number of functions assigned to public administration and the growing role of government. Judges are prompted to set aside their old self-image of being the "voice of the law" and to undertake an independent "political" role, inspired partly by new developments in legal theory, such as the law of interests and values, the sociology of law, and judicial pragmatism.

At the same time, Western states are experiencing two new and extremely important functions that are not comparable to the traditional ones. The first is that of *political orientation*. The intervention of the state must necessarily be organized around a program if it is to have significance and coherence. The program must be one on which the electorate expresses itself at elections and which an organ of the state has the task of translating into concrete provisions for the period of office of the legislature (at the next election, the electorate will decide whether to continue or to change program and governing team).

The body of the state delegated to administer the *political orientation* could only be the former executive. The executive, however, having been charged with its new task, has completely transformed its structures and authority. It has changed from a mainly executive body into a *governing power* that lasts for at least one legislature. Generally, it is the main initiator of the laws necessary to implement the *political orientation* and is followed in such action by both the legislative power and the public administration.

The second new function is that of guaranteeing the principles of the constitution. The United States provided a valid example in this respect, although for many years it was not followed by other countries. The much faster rate of change of the normative system makes it more likely that the laws themselves may violate fundamental values, as well as personal and social rights that the community wants to maintain intact. Parliaments have ceased to be reliable champions of the freedoms and the rights of the citizen. Frequently, they have been transformed into assemblies that merely represent sectarian or corporate interests. For that reason, there has emerged a demand to entrust the defense of those values and freedoms to a body that does not have to face a periodic electoral test. Constitutional courts were therefore created in nearly all political systems of the twentieth century. The interventionist state does not disclaim the division of power as such. The division must remain effective to avoid an excessive or even total concentration of power that would threaten citizens' civil and political freedoms and social rights, or would jeopardize the proper, efficient government of society and the economy. But as we have

noted, the modern state can no longer be considered a harmonic whole made up of separate powers organized around the three functions of legislative, executive, and judicial power.

The division of the powers remains, but it has assumed a different form (O'Toole 1993). It has become a Weberian ideal-type with new features that can be summarily described as follows. There are at least five powers instead of the traditional three:

1. *The governing power* carries out the function of political orientation, defining the main policies. Whether it is embodied in a president, a prime minister, a chancellor, or some other figure, the governing power is an organ that enjoys guaranteed stability, which is indispensable for translating political orientation into action. In general, the governing power will attempt to perform a broader normative function than the one attributed to it, thus entering into conflict or competition with the parliament.
2. *The legislative branch* has taken on the function of confirming the political orientation decided by the governing power when its majority belongs to the same party. Where the majority belongs to a different party, the function is more political and relationships are competitive, because the overriding aim is to win the next election. Nevertheless, obstruction of the policies of the governing power, or its formal removal, must remain absolutely exceptional eventualities. The legislative branch also has other checks and controls over the governing power (formal questioning, inquiries, and so on).
3. *Public administration* has become one of the powers because, although it is subject to law and the directives of the governing power, its sheer size and the growing range of functions assigned to it enable the public administration to pursue objectives in the public interest which it identifies independently with discretionary freedom. The aims of the public administration are achieved by regulation and sanctions.

4. *The judicial power* is the power that guarantees in complete autonomy the proper application of the law to specific cases. The judiciary contributes creatively to the evolution of the normative system. For this reason, it may perform, intentionally or not, an important "political" role.
5. *The supreme court (constitutional court)* has the function of guaranteeing supreme political and social values for all the other powers, especially the governing and legislative powers. These values have to be removed from the cut and thrust of day-to-day politics and constantly defended. In fact, the supreme court identifies these values with wide discretion.

The new model of the division of powers places the governing—and not the legislative—power at the center of the state's organization. It is the governing power that provides the driving force. The other powers act as potential brakes, the legislative branch on the political front and the supreme (constitutional) court on the legal side.

The governing power cannot therefore be compared to a medieval absolute (albeit elective) monarch. Still less can it be compared to the dictators of contemporary authoritarian and totalitarian regimes. It acts in a context of free democracy and in a system of the division of powers that places limits on it and prevents it from taking the place of other powers in the exercise of functions that do not properly belong to it. Realistically, its position within the organization of the state is probably less strong than might appear from the above model.

If we examine what has happened to the former legislative, executive, and judicial functions that today are no longer attributed to or exercised by a specific power, it will become apparent that they are distributed among the new powers without the rigid distinctions that once prevailed. Although every political system has mechanisms for blocking democracy-threatening initiatives (for example, penal norms can be only introduced by acts of parliament), the vagueness and fluidity of the new political situation demands the introduction of new procedures to regulate the relationships of the new powers. New procedures are necessary to

avoid the risk of permanent conflict, the blocking of all political plans, and the struggle to occupy ever-wider areas of influence.

Almost all the major Western nations have, to some extent, adapted to the new model. Of course, each system has chosen its own way of allowing a governing power to emerge and of defining a corresponding series of complementary authorities and checks. Indeed, a surprising variety of solutions has been devised to ensure the optimal functioning of the interventionist state. Since it is impossible to illustrate here the performance and the details of the models established by the major Western nations, we shall merely list some of the most important changes.

Great Britain in the twentieth century has transformed its classic parliamentary government into government by the prime minister, who represents the governing power. This has been possible thanks to the rigid bipartite nature of the British political system, which guarantees the alternation of parties in power; to the adoption of a first-past-the-post voting system that reinforces the two-party system; and to the strict internal discipline in the parties.

France under the Fifth Republic has overcome the disadvantages of its extreme parliamentarism, which were due to the excessive fragmentation and lack of internal discipline of the parties. This has been achieved through the direct election of the president of the republic, the reinforcement of the position of the government with respect to parliament, and the return to a majority electoral law with two ballots. The governing power in France is the president, except when the parliamentary majority is hostile (policies are decided with the prime minister). The Constitutional Council safeguards the ideals of French constitutionalism. In Germany, the governing power is represented by the chancellor. Elected by majority vote in the Bundestag, the chancellor enjoys remarkable stability, partly because of the principle of the constructive vote of no confidence. It is up to the chancellor to dictate the political orientation, which parliament normally backs. The strength of the German political parties, the federal organization of the state, and an effective constitutional court provide an effective counterweight to the power of the chancellor.

In the nineteenth century, Congress was the real center of American political life. During the twentieth century, however, the presidential system of the United States has become actual rather than nominal, and the true driving force of the nation today is the president. Congress has nevertheless kept a significant portion of its former power and is currently the most powerful of all the Western parliaments. The Supreme Court is also rather more than a mere check on the governing power.

Italy is something of an anomaly because its constitution enshrines the model of the social interventionist state, but the country has not succeeded in developing the structures for a new division of powers. The Italian parliament has jealously preserved all its normative functions, but the public administration interprets and applies the regulations with such a high degree of autonomy that it distorts the intentions of the legislator. The strict two-chamber structure slows down parliamentary activity; the government has only weak prerogatives over parliament; and the judiciary, originally conceived as a mere instrument to apply the laws, has actually been performing a largely political role in recent years. These modifications to the institutional order have been fostered by major changes in the political process, especially concerning the demands and behavior of citizens. Two aspects, in particular, deserve attention. First, increasingly frequently, public policy disputes among social or special-interest groups are taken to the legislator, the administrative branch, or the judicial arena for resolution. Second, more and more people request government intervention to solve private problems or to further group interests. The new powers therefore have to tackle new tasks and satisfy additional social demand.

The breakdown of the traditional division of powers, whose roles, functions and relationships are very clearly defined, at least formally, leads to a fluid situation in which the new powers are forced to negotiate with each other.

There are two aspects that coexist in interpower negotiation. The first is negotiation on matters of substance and—albeit generally in less explicit terms—for the attribution of roles. On fundamental issues, it is necessary to make a distinction between topics that involve nonnegotiable values

and interests on which it is possible to reach a compromise or to find some way of compensating the losing party.

Even though the present era is characterized by the spread of secularism and cultural relativism, there are topics on which people—and therefore institutions—are deeply divided. Abortion is one example, for it involves worldviews and values that are not negotiable. In such cases, the majority will impose its position without attempting to mediate an agreement with the minority. The decision adopted, whatever it is, will obviously produce resentment, the undermining of authority, and conflict. The process of developing a common-ground culture and fostering empathy on sensitive topics, such as abortion, is complex, although it may be effective with small groups of participants (LeBaron and Carstarphen 1997). Another such example is the question of worship in schools. Moreover, people are becoming very sensitive about issues such as environment, health, and safety: Divisions and conflicts go through not only interests but values, ideologies, deep-rooted ideas. If the area of decisions imposed by a majority on the minority or the minorities were to extend, the already serious fractures in society would deepen, with consequences that could threaten the very continuance of coexistence.

In addition, negotiation over the attribution of roles can develop at two different levels, the institutional and the political. The subject of negotiation is always the same, concerning the organizational model to be applied to the powers, the levels of government (federal, state, and local), and the sphere in which each power will exercise its influence. All participants claim to be pursuing the public interest but the context in which negotiation is carried out changes. In the first case, constitutional principles, values, and rights are the benchmarks. In political negotiation, however, concrete policy priority decisions are negotiated as well as the allocation of financial and other resources and standards for crucial areas such as health, public safety, and education.

It is also important to bear in mind that other factors apart from those already mentioned play a part in interpower negotiation, including each actor's unique characteristics and awareness of its source of legitimization. The president, or governing power, will be more sensitive to general public

opinion. The legislative power cannot ignore strong pressures exercised both by constituencies and by lobbies. The judiciary is the guardian of the laws, and the public administration bases its position on technical competence and a professed impartiality. The ensuing system looks rather unstable, so the problem then becomes how to combine diverse, conflicting interests, styles, and sensitivities, which all claim to be pursuing a common goal: the public interest and the satisfaction of individual and social needs.

In order to achieve this agreement, it is necessary, first of all, to establish common definitions of what is meant by the "public interest" and by "social and individual needs". Second, negotiating procedures must be agreed upon since the checks-and-balances principle, a feature of political systems with a traditional division of powers and well-defined functions, is no longer adequate. The checks-and-balances principle loses much of its value in a continuously changing situation with different actors. Third, it is necessary to seek the consent of the governed to clear the way for negotiations, enabling citizens to be informed and to exercise some kind of control (Susskind and Cruikshank 1989).

Interpower negotiation should not aim for minimum levels of agreements but should seek to create bargains that improve the working of the political system and produce a genuine gain for citizens. In contrast with normal conditions of negotiation, when powers are involved it is not appropriate to seek the victory of one or other of the parties. Instead, the actors must perceive that they should exploit their differences to achieve benefits jointly.

Taking advantage of differences of interest does not mean helping the other party in order to receive help in turn (*do ut des*) or making a simple exchange. It signifies, above all, learning how to recognize the priorities, responsibilities, and interests of each actor. The first problem to be resolved in interpower negotiation is to identify a limit beyond which it is in no one's interest to go. In the literature on the subject, some analysts propose "best alternatives to nonagreement" (BATNA) as a criterion for verifying the motivation and interests underlying negotiation (Fisher and Ury 1981). Negotiation is thus the key to improvement. If

powers wage battle, each trying to impose its own interests and strengthen its own position, the result may be to block the political system, thus losing the confidence of citizens. Conflict between the courts, the political authorities, and the public administration is not the most effective way to deal with the breakdown of the traditional division of powers.

NONPARAMETRIC STATISTICS

Parameters are characteristics of the population being studied such as a mean (μ), standard deviation (σ) or median (M_d). Statistics describe characteristics of a sample. Sample mean (\bar{x}) and sample median (m) are two examples. In traditional or classical parametric statistics, making inferences from a sample or samples to a population or populations necessitates assumptions about the nature of the population distribution such as a normal population distribution.

Nonparametric statistics may be defined as statistical methods that contribute valid testing and estimation procedures under less stringent assumptions than the classical parametric statistics. However, there is no general agreement in the literature regarding the exact specification of the term “nonparametric statistics.” In the past, nonparametric

statistics and the term “distribution-free methods” were commonly used interchangeably in the literature, although they have different implications. Nonparametric statistics were often referred to as distribution-free statistics because they are not based on a particular type of a distribution in the population such as a normal distribution. It is, however, generally agreed that nonparametric statistics require fewer, or less stringent, assumptions about the nature of the population distribution being studied, compared to classical parametric statistics. It is important to note that nonparametric statistics are not totally assumption-free either, since they must be based on some assumptions applicable to specific tests, such as lack of ties or the independence of two random samples included in the study. They are flexible in their use and are generally quite robust. Nonparametric statistics allow researchers to arrive at conclusions based on exact probability values and the confidence interval.

The major advantages of nonparametric statistics compared to parametric statistics are that: (1) they can be applied to a large number of situations; (2) they can be more easily understood intuitively; (3) they can be used with smaller sample sizes; (4) they can be used with more types of data; (5) they need fewer or less stringent assumptions about the nature of the population distribution; (6) they are generally more robust and not often seriously affected by extreme values in data such as outliers; (7) they have, in many cases, a high level of asymptotic relative efficiency compared to the classical parametric tests; (8) the introduction of jackknife, bootstrap, and other resampling techniques has increased their range of applicability; and (9) they provide a number of supplemental or alternative tests and techniques to currently existing parametric tests.

Many critics of nonparametric tests have pointed out some major drawbacks of the tests: (1) they are usually neither as powerful nor as efficient as the parametric tests; (2) they are not as precise or as accurate as parametric tests in many cases (e.g., ranking tests with a large number of ties); (3) they might lead to erroneous decisions about rejecting or not rejecting the null hypothesis because of lack of precision in the test; (4) many of these tests utilize data inadequately in the analysis because

they transform observed values into ranks and groups; and (5) the sampling distribution and distribution tables for nonparametric statistics are too numerous, are often cumbersome, and are limited to small sample sizes. The critics also claim that new parametric techniques and the availability of computers have reduced the need to use nonparametric statistics. Given these advantages and disadvantages, how does one choose between parametric and nonparametric tests?

Many criteria are available for this purpose. Statistical results are expected to be unbiased, consistent, or robust, or to have a combination of these characteristics. If both tests under consideration are applicable and appropriate, what other criteria may be used in the choice of a preferred test? The power and efficiency of a test are very widely used in comparing parametric and nonparametric tests.

The power of a test is the probability of rejecting the null hypothesis H_0 when it is false. It is defined as $1 - \beta$, where β is the probability of a Type II error, or acceptance of a false null hypothesis. If test A and test B would have the same alpha level of significance and the same sample sizes, and test B has a higher power, then test B is considered a preferred choice. However, calculations of the power of a test are often cumbersome. Another way of addressing the issue of the power of a test is through an asymptotic relative efficiency measure. The relative efficiency of a test in comparison to another test is the ratio of the sample size needed to achieve the same power with similar assumptions about significance levels and population distribution. Asymptotic relative efficiency of a test (sometimes called Pitman efficiency) is measured without a limit on the increase in sample size of that test. Thus, for example, when an asymptotic efficiency of Kendall's τ relative to Personian r is given as .912, it means that the τ with a sample size of 1000 is as efficient as an r with a sample size of 912. The test for asymptotic relative efficiency is now routinely used in the literature to compare two tests.

Based on these criteria, it can be generalized that nonparametric tests and techniques tend to be preferred when: (1) nominal or ordinal data are involved; (2) robust tests are needed because of outliers in the data; (3) probability distribution or

density function of the data is unknown or cannot be assumed, as in the case of small sample sizes; (4) the effects of violations of specific test assumptions are unknown, or only weak assumptions can be made; (5) analogous parametric tests are not available, as in the case of runs tests and goodness-of-fit tests; and (6) preliminary trials, supplemental or alternative techniques for parametric techniques are needed.

NONPARAMETRIC STATISTICAL LITERATURE

The term *nonparametric statistics* was introduced in the statistical literature in the 1940s (Noether 1984). The historical roots of nonparametric statistics are supposed to go as far back as 1710 when John Arbuthnot did a study that included the proportion of male births in London (Daniel 1990; Hettmansperger 1984) using a sign test which is a nonparametric procedure. Spearman's rank correlation coefficient, which is widely used even today, was the forerunner of the chi-square test, which was introduced in 1900.

Initial major developments in the field that introduced and popularized the study of nonparametric methods appeared in the late 1940s and early 1950s, though a few nonparametric tests were published in the late 1920s such as the Fisher-Pitman test, Kendall's coefficient of concordance, and Hotelling and Pabst's paper on rank correlation in the 1930s. Contributions by Wilcoxon and Mann-Whitney were introduced during the 1940s. The term *nonparametric* reportedly appeared for the first time in 1942 in a paper by Wolfowitz (Noether 1984). The 1956 publication of Siegel's text on nonparametric statistics popularized the subject to such an extent that the text was one of the most widely cited textbooks in the field of statistics for a few years. It was during this time that computer software for nonparametric tests was introduced.

The major emphasis in the 1960s and 1970s was on the extension of the field into regression analysis, and analysis of variance to develop tests analogous to the classical parametric tests. It was also discovered during this period that nonparametric tests were more robust and more efficient than previously expected. The basis for the asymptotic

distribution theory was developed during this time period.

A number of texts have been published recently (see, e.g., Conover 1999; Daniel 1990; Hollander and Wolfe 1999; Krauth 1988; Neave and Worthington 1988; Siegel and Castellan 1988; Sprent 1989). Some of these texts can be used without an extensive statistical background; they have excellent bibliographies and provide adequate examples of assumptions, applications, scope, and limitations of the field of nonparametric statistics. In addition, the *Encyclopedia of Statistical Sciences* (Kotz and Johnson 1982–1989) and the *International Encyclopedia of Statistics* (Kruskal and Tanur 1978) should serve as excellent sources of reference material pertaining to nonparametric statistics.

The literature on nonparametric statistics is extensive. The bibliography published in 1962 by Savage had approximately 3,000 entries. More recent bibliographies have made substantial additions to that list.

TESTS AND TECHNIQUES

Nonparametric statistics may be divided into three major categories: (1) noninferential statistical measures; (2) inferential estimation techniques for point and interval estimation of parametric values of the population; and (3) hypothesis testing, which is considered the primary purpose of nonparametric statistics. (Estimation techniques included in the category above are often used as a first step in hypothesis testing.) These three categories include different types of problems dealing with location, dispersion, goodness-of fit, association, runs and randomness, regression, trends, and proportions. They are presented in Table 1 and illustrated briefly in the text.

Table 1, which includes a short list of some commonly used nonparametric statistical methods and techniques, is illustrative in nature. It is not intended to be an exhaustive list. The literature literally consists of scores of nonparametric tests. More exhaustive tables are available in the literature (e.g., Hollander and Wolfe 1999). The six columns in the table describe the nature of the sample, and the eight categories of rows identify the major types of problems addressed in

nonparametric statistics. Types of data used in nonparametric tests are not included in the table, though references to levels of data are made in the text. Tables that relate tests to different types of data levels are presented in some texts (e.g., Conover 1999). A different type of table provided by Bradley (1968) identifies the family to which the nonparametric derivations belong.

The first column in Table 1 consists of tests involving a single sample. The statistics in this category include both inferential and descriptive measurements. They would be used to decide whether a particular sample could have been drawn from a presumed population, or to calculate estimates, or to test the null hypothesis. The next column is for two independent samples. The independent samples may be randomly drawn from two populations, or randomly assigned to two treatments. In the case of two related samples, the statistical tests are intended to examine whether both samples are drawn from the same (or identical) populations. The case of k (three or more) independent samples and k related samples are extensions of the two sample cases.

The eight categories in the table identify the main focus of problems in nonparametric statistics and are briefly described later. Only selected tests and techniques are listed in table 1. Log linear analyses are not included in this table, although they deal with proportions and meet some criteria for nonparametric tests. The argument against their inclusion is that they are rather highly developed specialized techniques with some very specific properties.

It may be noted that: (1) many tests cross over into different types of problems (e.g. the chi-square test is included in three types of problems); (2) the same probability distribution may be used for a variety of tests (e.g., in addition to association, proportion, and goodness-of-fit, the chi-square approximation may also be used in Friedman's two-way analysis of variance and Kruskal-Wallis test); (3) many of the tests listed in the table are extensions or modifications of other tests (e.g., the original median test was later extended to three or more independent samples; e.g., the Jonckheere test); (4) the general assumptions and procedures that underlie some of these tests have been extended beyond their original scope (e.g. Hájek's extension of the Kolmogorov-Smirnov test to regression

NONPARAMETRIC STATISTICS

Selected Nonparametric Tests and Techniques

Table 1

analysis and extension of the two-sample Wilcoxon test for testing the parallelism between two linear regression slopes); (5) many of these tests have corresponding techniques of confidence interval estimates, only a few of which are listed in Table 1; (6) many tests have other equivalent or alternative tests (e.g., when only two samples are used, the Kruskal-Wallis test is equivalent to the Mann-Whitney test); (7) sometimes similar tests are lumped together in spite of differences as in the case of the Mann-Whitney-Wilcoxon test or the Ansari-Bradley type tests or multiple comparison tests; (8) some tests can be used with one or more samples in which case the tests are listed in one or

more categories, depending on common usage; (9) most of these tests have analogous parametric tests; and (10) a very large majority of nonparametric tests and techniques are not included in the table.

Only a few of the commonly used tests and techniques are selected from Table 1 for illustrative purposes in the sections below. The assumptions listed for the tests are not meant to be exhaustive, and hypothetical data are used in order to simplify the computational examples. Discussions about the strengths and weaknesses of these tests is also omitted. Most of the illustrations are either two-tailed or two-sided hypotheses at the

0.05 level. Tables of critical values for the tests illustrated here are included in most statistical texts. Modified formulas for ties are not emphasized, nor are measures of estimates illustrated. Generally, only simplified formulas are presented. A very brief description of the eight major categories of problems follows.

Location. Making inferences about location of parameters has been a major concern in the field of statistics. In addition to the mean, which is a parameter of great importance in the field of inferential statistics, the median is a parameter of great importance in nonparametric statistics because of its robustness. The robust quality of the median can be easily ascertained. If the values in a sample of five observations are 5, 7, 9, 11, 13, both the mean and the median are 9. If two observations are added to the sample, 1 and 94 (an outlier), the median is still 9, but the mean is changed to 20. Typical location problems include estimating the median, determining confidence intervals for the median, and testing whether two samples have equal medians.

Sign Test This is the earliest known nonparametric test used. It is also one of the easiest to understand intuitively because the test statistic is based on the number of positive or negative differences or signs from the hypothesized median. A binomial probability test can be applied to a sign test because of the dichotomous nature of outcomes that are specified by a plus (+) which indicates a difference in one direction or a minus (-) sign which indicates a difference in another direction. Observations with no change or no difference are eliminated from the analysis. The sign test may be a one-tailed or a two-tailed test. A sign test may be used whenever a *t*-test is inappropriate because the actual values may be missing or not known, but the direction of change can be determined, as in the case of a therapist who believes that her client is improving. The sign test only uses the direction of change and not the magnitude of differences in the data.

Wilcoxon Matched-Pairs Signed-Rank Test The sign test analysis includes only the positive or negative direction of difference between two measures; the Wilcoxon matched-pairs signed-rank test will also take into account the magnitude of differences in ordering the data.

Example: A matched sample of students in a school were enrolled in diving classes with different training techniques. Is there a difference? The scores are listed in Table 2.

Illustrative Assumptions: (1) The random sample data consist of pairs; (2) the differences in pair values have an ordered metric or interval scale, are continuous, and independent of one another; and (3) the distribution of differences is symmetric.

Hypotheses: A two-sided test is used in this example.

$$\begin{aligned} H_0: & \text{Sum of positive ranks} = \text{sum of negative} \\ & \text{ranks in population} \\ H_1: & \text{Sum of positive ranks} \neq \text{sum of negative} \\ & \text{ranks in population} \end{aligned} \quad (1)$$

Test statistic or procedures: The differences between the pairs of observations are obtained and ranked by magnitude. *T* is the smaller of the sum of ranks with positive or negative signs. Ties may be either eliminated or the average value of the ranks assigned to them. The decision is based on the value of *T* for a specified *N*. *Z* can be used as an approximation even with a small *N* except in cases with a relatively large number of ties. The formula for *Z* may be substituted when *N* > 25.

$$Z = \frac{T - N(N+1)/4}{\sqrt{N(N+1)(2N+1)/24}} \quad (2)$$

This formula is not applicable to the data in Table 2 because the *N* is < 25 and the calculations in Table 2 will be used in deciding whether to reject or fail to reject (“accept”) the null hypothesis. In this example in Table 2, the *N* is 7 and the value of the smaller *T* is 9.5.

Decision: The researchers fail to reject the null hypothesis (or “accept” the null hypothesis) of no difference between the two groups, with an *N* of 7 at the 0.05 level, for a two-sided test, concluding that there is no statistically significant difference in the two types of training at the 0.05 level.

Efficiency: The asymptomatic related efficiency of the test varies around 95 percent, based on the sample sizes.

Total Scores for Five Diving Trials						
Pairs	X Team A	Y Team B	Y - X Differences	Signed Rank of Differences T_+	Negative Ranks T_-	
1	37	35	-2	-1	1	
2	39	46	7	+4		
3	32	24	-8	-5.5	5.5	
4	21	34	13	+7		
5	20	28	8	+5.5		
6	9	12	3	+2		
7	14	9	-5	-3	3	
				$T_+ = 18.5$	$T_- = 9.5$	

Table 2

Related parametric test: The *t*-test for matched pairs.

Analogous nonparametric tests: Sign test; randomization test for matched pairs; Walsh test for pairs.

Kruskal-Wallis One-Way Analysis of Variance Test This is a location measure with three or more independent samples. It is a one-way analysis of variance that utilizes ranking procedures.

Example: The weight loss in kilograms for 13 randomly assigned patients to one of the three diet programs is listed in Table 3 along with the rankings. Is there a significant difference in the sample medians?

Illustrative Assumptions: (1) Ordinal data; (2) three or more random samples; and (3) independent observations.

Hypotheses: A two-sided test without ties is used in this example.

$$\begin{aligned}
 H_0: & \quad Md_1 = Md_2 = Md_3, \text{ The populations} \\
 & \quad \text{have the same median values.} \\
 H_1: & \quad Md_1 \neq Md_2 \neq Md_3, \text{ All the populations} \\
 & \quad \text{do not have the same median value.}
 \end{aligned}
 \tag{3}$$

Test statistics or procedures: The procedure is to rank the values and compute the sums of those ranks for each group and calculate the *H* statistic. The formula for *H* is as follows:

$$H = \left(\frac{12}{N(N+1)} \sum_{i=1}^k \frac{R_i^2}{N_i} \right) - 3(N+1) \tag{4}$$

where N_i = the case in the *i*th category of rank sums
 R_i = the sum of ranks in the *i*th sample.

$$\begin{aligned}
 H &= \frac{12}{13(13+1)} \left[\frac{(46)^2}{5} + \frac{(16)^2}{4} + \frac{(29)^2}{4} \right] \\
 &\quad - 3(13+1) = 45.9857 - 42 \\
 H &= 3.99
 \end{aligned}
 \tag{5}$$

Decision: Do not reject the null hypothesis, as the chi-square value for 2 df at the 0.05 level is 5.99 and the *H* value of 3.99 is less than the critical value.

Efficiency: Asymptotic relative efficiency of Kruskal-Wallis test to *F* test is 0.955 if the population is normally distributed.

Related parametric test: *F* test. Analogous nonparametric test(s): Jonckheere test for ordered alternatives.

Friedman Two-Way Analysis of Variance This is a nonparametric two-way analysis of variance based on ranks and is a good substitute for the parametric *F* test when the assumptions for the *F* test cannot be met.

Example: Three groups of telephone employees from each of the work shifts were tested for their ability to recall fifteen-digit random numbers, under four conditions or treatments of sleep

Diet Programs and Weight-Loss Rankings					
Group 1	Rank	Group 2	Rank	Group 3	Rank
2.8	3	2.2	1	2.9	4
3.5	7	2.7	2	3.1	6
4.0	11	3.0	5	3.7	9
4.1	12	3.6	8	3.8	10
4.9	13				
$R_1 = 46$		$R_2 = 16$		$R_3 = 29$	

Table 3

deprivation. The observations and rankings are listed in Tables 4 and 5. Is there a difference in the population medians?

$$F_{\tau} = \left[\frac{12}{Nk(k+1)} \sum_{j=1}^k R_j^2 \right] - 3N(k+1)$$

N = number of rows (subjects)

k = number of columns (variables or conditions or treatments)

R_j = sum of ranks in the j th column

$$F_{\tau} = \left[\frac{12}{3(4)(4+1)} \right] [(11)^2 + (6)^2 + (3)^2 + (10)^2] - 3(3)(4+1)$$

$$F_{\tau} = (0.20)(266) - 45 = 8.2$$

Illustrative Assumptions: (1) There is no interaction between blocks and treatment; and (2) ordinal data with observable magnitude or interval data are needed.

Hypotheses:

H_0 : $Md_1 = Md_2 = Md_3 = Md_4$. The different levels of sleep deprivation do not have differential effects.

H_1 : One or more equality is violated. The different levels of sleep deprivation have differential effects.

Test statistic or procedures: The formula and computations are listed above.

Decision: The critical value at the 0.05 level of significance in this case for $N=3$ and $k=4$ is 7.4. Reject the null hypothesis because the F value is higher than the critical value. Conclude that the ability to recall is affected.

Efficiency: The asymptotic relative efficiency of this test depends on the nature of the underlying population distribution. With $k=2$ (number of samples), the asymptotic relative efficiency is reported to be 0.637 relative to the t test and is higher in cases of larger number of samples. In the case of three samples, for example, the asymptotic relative efficiency increases to 0.648 relative to the F test, and in the case of nine samples it is at least 0.777.

Related parametric test: F test.

Analogous nonparametric tests: Page test for ordered alternatives.

Mann-Whitney-Wilcoxon Test A combination of different procedures is used to calculate the probability of two independent samples being drawn from the same population or two populations with equal means. This group of tests is analogous to the t -test, it uses rank sums, and it can be used with fewer assumptions.

Example: Table 6 lists the verbal ability scores for a group of boys and a group of girls who are less than 1 year old. (The scores are arranged in ascending order for each of the groups.) Do the data provide evidence for significant differences in verbal ability of boys and girls?

Scores of Three Groups by Four Levels of Sleep Deprivation

Conditions	I	II	III	IV
Group 1	7	4	2	6
Group 2	6	4	2	9
Group 3	10	3	2	7

Table 4

Illustrative Assumptions: (1) Samples are independent and (2) ordinal data.

Hypotheses: A two-sided test is used in this example.

- H_0 : $Md_1 = Md_2$. There are no significant differences in the verbal ability of boys and girls.
- H_1 : $Md_1 \neq Md_2$. There is a significant difference in the verbal ability of boys and girls. (10)

Test statistic or procedures: Rearrange all the scores in an ascending or descending order (see Table 7). The test statistics are U_1 and U_2 and the calculations are illustrated below.

Mann-Whitney Wilcoxon U Test The following formulas may be used to calculate U .

$$U_1 = N_1N_2 + \frac{N_1(N_1 + 1)}{2} - R_2 \quad (11)$$

$$U_2 = N_1N_2 + \frac{N_2(N_2 + 1)}{2} - R_1 \quad (12)$$

$$R_1 = 1 + 4 + 5 + 9 = 19$$

$$R_2 = 2 + 3 + 6 + 7 + 8 + 10.5 + 10.5 + 12 + 13 = 72$$

R_1 and R_2 refer to the sum of ranks for group 1 and group 2, respectively. (13)

$$U_2 = (4)(9) = [9(9 + 1)/2] - 72 = 9 \text{ and}$$

$$U_1 = 27, \text{ for } U_1 + U_2 = (N_1N_2) = 36$$

Decision: Retain null hypothesis. At the 0.05 level, we fail to reject the null hypotheses of no differences in verbal ability. The rejection region

Rank of Three Groups by Four Levels of Sleep Deprivation

Ranks	I	II	III	IV
Group 1	4	2	1	3
Group 2	3	2	1	4
Group 3	<u>4</u>	<u>2</u>	<u>1</u>	<u>3</u>
R_j	11	6	3	10

Table 5

for U in this case is 4 or smaller, for sample sizes of 4 and 9 respectively.

Efficiency: For large samples, the asymptomatic relative efficiency approaches 95 percent.

Related Parametric Test: F test.

Analogous Nonparametric Tests: Behrens-Fisher problem test, robust rank-order test.

Z can be used as a normal approximation if $N > 12$, or N_1 , or $N_2 > 10$, and the formula is given below.

$$Z = \frac{R_1 - R_2(N_1 - N_2)(N + 1)/2}{\sqrt{N_1N_2(N + 1)/3}} \quad (14)$$

Dispersion. Dispersion refers to spread or variability. Dispersion measures are intended to test for equality of dispersion in two populations.

The two-tailed null hypothesis in the Ansari-Bradley-type tests and Moses-type tests assumes that there are no differences in the dispersion of the populations. The Ansari-Bradley test assumes equal medians in the population. The Moses test has wider applicability because it does not make that assumption.

Dispersion tests are not widely used because of the limitations on the tests imposed by the assumptions and the low asymptotic related efficiency of the tests, or both.

Goodness-of-Fit. A goodness-of-fit test is used to test different types of problems—for example, the likelihood of observed sample data's being drawn from a prespecified population distribution, or comparisons of two independent samples

Verbal Scores for Boys and Girls Less than 1 Year Old

Boys N_1 (sample A):	10	15	18	28					
Girls N_2 (sample B):	12	14	20	22	25	30	30	31	32

Table 6

being drawn from populations with a similar distribution. The first problem mentioned above is illustrated here using the chi-square goodness-of-fit procedures.

X_2 , or the chi-square test, is among the most widely used nonparametric tests in the social sciences. The four major types of analyses conducted through the use of chi-square are: (1) goodness-of-fit tests, (2) tests of homogeneity, (3) tests for differences in probability, and (4) test of independence. Of the four types of tests, the last one is the most widely used. The goodness-of-fit test and the test of independence will be illustrated in this article because the assumptions, formulas, and testing procedures are very similar to one another. The X_2 test for independence is presented in the section on measures of association.

Goodness-of-fit tests would be used in making decisions based on the prior knowledge of the population; for example, sentence length in a new manuscript could be compared with other works of an author to decide whether the manuscript is by the same author; or a manager's observation of a greater number of accidents in the factory on some days of the week as compared to the average figures could be tested for significant differences. The expected frequency of accidents given in table 8 below is based on the assumption of no differences in the number of accidents by days of the week.

Illustrative Assumptions: (1) The data are nominal or of a higher order such as ordinal, categorical, interval or ratio data. (2) The data are collected from a random sample.

Hypothesis:

Test Statistic or Procedures: The formula for calculating this is the same as for the chi-square test of independence. A short-cut formula is also provided and is used in this illustration:

- H_0 : The distribution of accidents during the week is uniform.
- H_1 : The distribution of accidents during the week is not uniform.

$$\chi^2 = \sum \frac{(f_o - f_e)^2}{f_e} \tag{15}$$

$$\chi^2 = \sum \frac{(f_o)^2}{f_e} - N \tag{16}$$

The notation f_o refers to the frequency of actual observations and f_e is the frequency of expected observations.

$$\chi^2 = \frac{225}{30} + \frac{900}{30} + \dots + \frac{1600}{30} + \frac{2025}{30} - N = 230 - 210 = 20 \tag{17}$$

Decision: With seven observations, there are six degrees of freedom. The value for $\chi^2_{v_2}$ is 12.59 at the .05 level of significance. Therefore, the null hypothesis of equal distribution of accidents over the 7 days is rejected at the .05 level of significance.

Asymptotic Relative Efficiency: There is no discussion in the literature about this because nominal data can be used in this analysis and the test is often used when there are no alternatives available. Asymptotic relative efficiency is meaningless with nominal data.

Related Parametric Test. *t* test.

Analogous Nonparametric Tests. The Kolmogrov-Smirnov one-sample test, and the binomial test for dichotomous variables.

The Kolmogrov-Smirnov test is another major goodness-of-fit test. It has two versions, the one-sample and the two-sample tests. It is different from the chi-square goodness-of-fit in that the

Ranked Verbal Scores for Boys and Girls Less than 1 Year Old													
Scores:	10	12	14	15	18	20	22	25	28	30	30	31	32
Rank:	1	2	3	4	5	6	7	8	9	10.5	10.5	12	13
Comp:	A	B	B	A	A	B	B	B	A	B	B	B	B

Table 7

Kolmogrov-Smirnov test, which is based on observed and expected differences in cumulative distribution functions and can be used with individual values instead of having to group them.

Association. There are two major types of measures of association. They consist of: (1) measures to test the existence (relationship) or nonexistence (independence) of association among the variables, and (2) measures of the degree or strength of association among the variables. Different tests of association are utilized in the analysis of nominal and nominal data, nominal and ordinal data, nominal and interval data, ordinal and ordinal data, and ordinal and interval data.

Chi-Square Test of Independence In addition to goodness-of-fit, χ^2 can also be used as a test of independence between two variables. The test can be used with nominal data and may consist of one or more samples.

Example: A large firm employs both married and single women. The manager suspects that there is a difference in the absenteeism rates between the two groups. How would you test for it? Data are included in Table 9.

Illustrative Assumptions: (1) The data are nominal or of a higher order such as ordinal, categorical, interval, or ratio data. (2) The data are collected from a random sample.

Hypothesis:

Test statistic or procedures: The formula for χ^2 is given below. Differences between observed and expected frequencies are calculated, and the resultant value is indicated below.

The expected frequencies are obtained by multiplying the corresponding column marginal totals by row marginal totals for each cell divided by the total number of observations. For example, the expected frequency for the cell with an observed frequency of 40 is $(100 \times 100)/400=25$.

H_0 : The two variables are independent or there is no difference between married and single women with respect to absenteeism.

H_1 : The two variables are not independent (i.e., they are related), or there is no difference between married women and single women with respect to absenteeism. (18)

$$\chi^2 = \sum \frac{(f_o - f_e)^2}{f_e} \tag{19}$$

f_o – observed frequency,
 f_e – expected frequency

Similarly, the expected frequency for the cell with an observed frequency of 170 is $(200 \times 300)/400=150$.

$$\begin{aligned} &(30 - 25)^2/25 + (70 - 75)^2/75 + (40 - 25)^2/ \\ &25 + (60 - 75)^2/75 + (30 - 50)^2/ \\ &50 + (170 - 150)^2/150 \end{aligned} \tag{20}$$

$$\chi^2 = 1 + .33 + 9 + 3 + 8 + 2.67 = 24$$

$$df = (\text{number of rows} - 1) \times (\text{number of columns} - 1) = (3 - 1)(2 - 1) = 2 \tag{21}$$

Decision: As the critical χ^2 value with two df is 5.99, we reject the null hypothesis, at the 0.05 level. We accept the alternate hypothesis of the existence of a statistically significant difference in the ratio of absenteeism per year between the two groups of married and single women.

Efficiency: The asymptotic relative efficiency of a χ^2 test is hard to assess because it is affected by the number of cells in the contingency table and the sample size as well. The asymptotic related efficiency of a 2×2 contingency table is very low,

Frequency of Traffic Accidents for One Week during May

Day	S	M	T	W	T	F	S	Total
Traffic Accidents	15	30	30	25	25	40	45	210
Expected Frequencies	30	30	30	30	30	30	30	210

Table 8

but the power distribution of χ^2 starts approximating closer to 1 as the sample size starts getting larger. However, a large number of cells in a χ^2 table, especially with a combination of large sample sizes, tend to yield large χ^2 values which are statistically significant because of the size of the sample. In the past, Yate's correction for continuity was often used in a 2×2 contingency table if the cell frequencies were small. Because of the criticism of this procedure, this correction procedure is no longer widely used. Other tests such as Fisher's Exact Test can be used in cases of small cell frequencies.

Related Parametric Test: There are no clear-cut related parametric tests because the χ^2 test can be used with nominal data.

Analogous Nonparametric Tests: The Fisher Exact Test (limited to 2×2 tables and small tables) and the median test (limited to central tendencies) can be used as alternatives. In addition, a large number of tests such as phi, gamma, and Cramer's V statistic, can be used as alternatives, provided the data characteristics meet the assumptions of these tests. The χ^2 distribution is used in many other nonparametric tests.

The chi-square tests of contingency tables allow partitioning of tables, combining tables, and using more than two-way tables with control variables.

The second type of association tests measure the actual strength of association. Some of these tests also indicate the direction of the relationship and the test values in most cases extend from -1.00 to $+1.00$ indicating a negative or a positive relationship. The values of some other nondirectional tests fall between 0.00 and 1.00 . Contingency table formats are commonly used to measure this type of association. Among the more widely used tests are the following, arranged by the types of data used: *Nominal by Nominal Data:*

Phi coefficient—limited to a 2×2 contingency table. A square of these test values is used to interpret a proportional reduction error.

Contingency coefficient based on the chi-square values. The lowest limit for this test is 0.00 , but the upper limit does not attain unity (value of 1.00).

Cramer's V statistic—not affected by an increase in the size of cells as long as it is related to similar changes in the other cells.

Lambda—the range of lambda is from 0.00 to 1.00 , and thus it has only positive values.

Ordinal by Ordinal Data:

Gamma—uses ordinal data for two or more variables. Test values are between -1.00 and $+1.00$.

Somer's D—used for predicting a dependent variable from the independent variable.

Kendall's tau—described in more detail below.

Spearman's rho—described in more detail below.

Categorical by Interval Data

Kappa—The table for this test needs to have the same categories in the columns and the rows. Kappa is a measure of agreement, for example, between two judges.

The tests described above are intended for two-dimensional contingency tables. Tests for three-dimensional tables have been developed recently in both parametric and nonparametric statistics.

Two other major measures of association referenced above are presented below. They are Kendall's τ (the forerunner of this test is also one

Annual Absences for Single and Married Women

Days Absent		Married Women		Single Women		Row Totals
		f_o	(f_e)	f_o	(f_e)	
Low	(0–5)	30	(25)	70	(75)	100
Medium	(6–10)	40	(25)	60	(75)	100
High	(11+)	30	(50)	170	(150)	200
Column Totals		100		300		400

Table 9

of the oldest test statistics) and Spearman’s ρ (one of the oldest nonparametric techniques). They are measures of association based on ordinal data.

τ is a measure of rank-order correlation. It also tests for independence of the two variables observed. It assumes at least ordinal data. The test scores of τ range between -1.00 and $+1.0$ by convention. A score of $+1.00$ indicates a perfect agreement between rankings of the two sets of observations. A score of -1.00 indicates a perfect negative correlation which means the ranking in one observation is in the reverse order of the other set of observations. All other scores fall between these two values. The test statistics for data with no ties is given below.

The test statistic:

$$\tau = \frac{S}{n(n-1)/2} \tag{22}$$

S measures the difference between the pairs of observations in natural order. A number of students are ranked according to their mathematical and verbal test scores. The six students are identified by letters A to F. There is no need to know the actual scores, and if actual scores are known, they will be converted to ranks as in Table 10.

What is being measured here with τ is the degree of correspondence between the two rankings based on mathematical and verbal scores. The calculations can be simplified if one of the values is arranged in the natural ascending order from the lowest value to the highest value. The lack of correspondence between the two rankings can be measured by just using the second set of rankings which, in this case, is verbal ability.

Illustrative Assumptions: (1) The data are at least ordinal. (2) Variables in the study are continuous.

Hypothesis:

- H_0 : Mathematical and verbal test scores are independent.
- H_1 : Mathematical and verbal test scores are related positively or negatively. (23)

The number of concordant pairs is measured by the agreement between the two pairs based on their corresponding standing in their own ranking, and discordant pairs are calculated on the basis of the disagreement between them. The example given below in Table 11 consists of no tied ranks.

$$S = 8 - 7 = 1$$

$$\tau = \frac{S}{n(n-1)/2} = \frac{8-7}{6(5)/2} = \frac{1}{15} = 0.067 \tag{24}$$

Decision: With $n = 6$, the researcher fails to reject the null hypothesis H_0 at 0.05 level since $\tau = 0.067$ is smaller than $\tau = 0.600$, which is the critical value for a two-tailed test.

Efficiency: The asymptotic relative efficiency: Both Kendall’s τ and Spearman’s ρ have an asymptotic relative efficiency of .912 compared to the Personian r (correlation coefficient) which is a parametric test and can go up to 1.12 in exponential type of distribution data.

Related Parametric Test: Personian correlation coefficient (in case of interval or ratio data).

Analogous Nonparametric Tests: Spearman’s ρ (rho).

Mathematical (X) and Verbal (Y) Test Scores for Six Students						
	A	B	C	D	E	F
X Math	9	15	8	10	12	7
Y Verbal	10	13	9	11	4	12

Table 10

In many studies, however, the same values may occur more than once within X observations, within Y observations, or within both observations—in which case there will be a tie. In the case of tied ranks, different formulas for τ_a , τ_b , τ_c are used. There is, however, no general agreement in the literature about the usage of subscripts. More detailed treatment of this topic is provided in Kendall and Gibbons (1990). Kendall's τ measures the association between two variables, and when there are more than two variables, Kendall's coefficient of concordance can be used to measure the association among multiple variables.

Spearman's ρ (rho) is another popular measure of a rank-correlation technique. The technique is based on using the ranks of the observations, and a Personian correlation is computed for the ranks. Spearman's rank correlation coefficient is used to test independence between two rank-ordered variables. It resembles Kendall's tau in that regard, and the two tests tend to be similar in their results of hypothesis testing.

Runs and Randomness. A run is a gambling term that in statistics refers to a sequence or an order of occurrence of event. For example, if a coin were tossed ten times, it could result in the following sequence of heads and tails: H T H H H T T H H T. The purpose of runs test is to determine whether the run or sequence of events occurs in a random order.

Another type of runs test would be to test whether the run scores are higher or lower than the median scores. A runs up-and-down test compares each observation with the one immediately preceding it in the sequence. Runs tests are not very robust, as they are very sensitive to variations in the data.

As there are no direct parallel parametric tests for testing the random order or sequence of a

series of events, the concept of power or efficiency is not really relevant in the case of runs tests.

Regression. The purpose of regression tests and techniques is to predict one variable based on its relationship with one or more other variables. The procedure most often used is to try to fit a regression line based on observed data. Though only a few simple regression techniques are included in Table 1, this is one of the more active areas in the field of nonparametric statistics.

The problems relating to regression analysis are similar to those in parametric statistics such as finding a slope, finding confidence intervals for slope coefficients, finding confidence intervals for median differences, curve fitting, interpolation, and smoothing. For example, the Brown-Mood method for finding a slope consists of graphing the observations on a scatter diagram; then a vertical line is drawn representing the median value, and points on both sides of the vertical line are joined. This gives the initial slope, which is later modified through iterative procedures if necessary. Some other tests are based on an extension of the rank order of correlation techniques discussed earlier.

Trends and Changes. Comparisons between, before, and after experiment scores are among the most commonly used procedures of research designs. The obvious question in such cases is whether there is a pattern of change and, if so, whether the trends can be detected. Demographers, economists, executives in business and industry, and federal and state departments of commerce are always interested in trends—whether downward, upward, or existing at all. The Cox-Stuart change test, or test for trend, is a procedure intended to answer these kinds of questions. It is a modification of the sign test. The procedures are very similar to the sign test.

**Mathematical (X) and Verbal (Y)
Test Scores in Rank Order**

Values (X, Y)	Rankings (X, Y)	(Y is similar in natural order to X)	Y is reverse of natural order of X)
(7, 12)	(1, 5)	1	4
(8, 9)	(2, 2)	3	1
(9, 10)	(3, 3)	2	1
(10, 11)	(4, 4)	1	1
(12, 4)	(5, 1)	1	0
(15, 13)	(6, 6)	<u>0</u>	<u>0</u>
		8	7

Table 11

Example: We want to test a statement in the newspaper that there is no changing trend in snowfall in Seattle between the last twenty years and the twenty years before that. The assumptions, procedures, and test procedures are similar to the sign test. These data constitute twenty sets of paired observations. If the data are not chronological, then values below the median and above the median would be matched in order. The value in the second observation in the set is compared to the first and would be coded as either positive or plus, negative or minus, and no change. A large number of positive or negative signs would indicate a trend, and the same number of positive and negative signs would indicate no trend. The distribution here is dichotomous, and, hence, a binomial test would be used. If there are seven positive signs and thirteen negative signs, it can be concluded that there is no statistically significant upward or downward trend in snowfall at the 0.05 level as $p(k = 7/20/0.50)$ is greater, k being the number of positive signs. The asymptotic relative efficiency of the test compared to rank correlation is 0.79. Spearman's coefficient of rank correlation and Kendall's Tau may also be used to test for trends.

Proportion. The term "portion" or the term "share" may be used to convey the same idea as "proportion" in day-to-day usage. A sociologist might be interested in the proportion of working and nonworking mothers in the labor force, or in comparing the differences in the proportion of people who voted in a local election and the voter

turnout in a national election. In case of a dichotomous situation, a binomial test can be used as a test of proportion; but there are many other situations where more than two categories and two or more independent samples are involved. In such cases, the chi-square distribution may also be viewed as a test of differences in proportion between two or more samples.

Cochran's Q test is another test of proportions that is applicable to situations with dichotomous choices or outcomes for three or more related samples. For example, in the context of an experimental situation, the null hypothesis would be that there is no difference in the effectiveness of treatments. Restated, it is a statement of equal proportions of success or failures in the treatments.

NEW DEVELOPMENTS

The field of nonparametric statistics has matured, and the growth of the field has slowed down compared to the fast pace in the 1940s and 1950s. Among the reasons for some of these changes are the development of new techniques in parametric statistics and log linear probability models, such as logit analysis for categorical data analysis, and the widespread availability of computers that perform lengthy calculations. Log linear analysis has occasionally been treated in nonparametric statistics literature because it allows the analysis of dichotomous or ordered categorical data and allows the application of nonparametric tests. As indicated earlier, it was not included in the tests discussed in this article because it is a categorical response analog to regression or variance models.

There is further research being conducted in the field of nonparametric robust statistics. The field of robust statistics is also in the process of developing into a new subspecialty of its own. At the same time, development of new tools—jackknife, bootstrapping, and other resampling techniques that are used both in parametric and nonparametric statistics—has positively impacted the use of nonparametric techniques. Based on the contents of popular computer software, the field of nonparametric statistics cannot yet be considered part of the mainstream of statistics, although some individual nonparametric tests are widely used.

There are many new developments taking place in the field of nonparametric statistics. Only three major trends are referenced here. The scope of application of nonparametric tests is gradually expanding. Often, more than one nonparametric test may be available to test the same or similar hypotheses. Again, many new, appropriate, and powerful nonparametric tests are being developed to replace or supplement the original parametric tests. Last, new techniques such as bootstrapping are making nonparametric tests more versatile.

As in the case of bootstrapping, many other topics and subtopics in nonparametric statistics, have developed into full-fledged specialties or subspecialties—for example, extreme value statistics, which is used in studying floods and air pollution. Similarly, a large number of new techniques and concepts—such as (1) the influence curve for comparing different robust estimators, (2) *M*-estimators for generalizations that extend the scope of traditional location tests, and (3) adaptive estimation procedures for dealing with unknown distribution—are being developed in the field of inferential statistics. Attention is also being directed to the developments of measures and tests with nonlinear data. In addition, attempts are being made by nonparametric statisticians to incorporate techniques from other branches of statistics, such as Bayesian statistics.

Parallel Trends in Development. There are two parallel developments in nonparametric and parametric statistics. First, the field of nonparametric statistics is being extended to develop more tests analogous to parametric tests. Recent developments in computer software include many of the new nonparametric tests and alternatives to parametric tests. Second, the field of parametric statistics is being extended to develop and incorporate more robust tests to increase the stability of parametric tests. The study of outliers, for example, is now gaining significant attention in the field of parametric statistics as well.

Recent advancements have accelerated developments in nonparametric and parametric statistics, narrowing many distinctions and bridging some of the differences between the two types, bringing the two fields conceptually closer.

OBSERVATION SYSTEMS

The most sensitive, sophisticated, and flexible instrument of observation available today is the human being. All the recent advances in technology have not changed this central fact; we can monitor communications, transcribe conversations using language processing software, and conduct computer-assisted content analysis of the results. Still, at some point a person who understands the social context must infer the meaning of the communications. Systematic methods of observation may vary the unit of analysis, shift the boundaries of categories, and adjust the level of judgment allowed, but sociologists are ultimately left with the basic reality of human beings watching other human beings. The role of the methodologist is to make this process more systematic.

Most sociological data are filtered through the perceptions of informants in an idiosyncratic manner. Retrospective accounts of events, opinion polls, and surveys measure the output of the social perception process. Only systematic observation, with valid and reliable instruments, provides a record of the events themselves rather than the retrospective reconstruction of the events. The more rigorously defined the categories, the more confident the researcher can be that the data

reflect the events and not just the biases and preconceptions of the informants.

While some of the systems that are described below were developed for specific purposes such as the observation of business case-study groups or the diagnosis of psychiatric patients, most attempt to capture the full range of social behavior and may thus be applied to a wide range of settings. Not included here are specialized systems that have been developed for single contexts, such as the classroom behavior of small children, the responses of subjects in tightly controlled laboratory experiments, and the evaluation of employees. One fast-food restaurant, for example, has developed a thirty-one-category observation system that managers can use to observe and evaluate counter staff. Items include "There is a smile," "The bag is double folded," and "Change is counted efficiently."

Observation systems have been used for a wide variety of purposes over the years. Early uses included psychiatric diagnosis, job placement, and basic research into group process and development. As corporate assessment centers came into widespread use for the selection of executives, early observation systems reappeared for the analysis of leaderless-group exercises. More recent applications have included research and consulting on team building and training, the evaluation of social workers, the prediction of success and failure of military cadets, the study of leadership networks in large corporations, the evaluation and treatment of problem children in the classroom, the evaluation of psychiatric interventions, the analysis of delinquent behavior, and resocialization,

and consultation on mergers and consolidations (Polley et al. 1988). In the past ten years, direct observation has been in decline. As a result of the high costs in terms of time and money, systematic observation has often given way to retrospective rating systems (Bales 1998). Such methods are, however, a poor substitute for direct observation.

SINGLE-CATEGORY SYSTEMS

Elliot D. Chapple introduced the *interaction chronograph* in 1940. It was a simple device that consisted of two telegraph keys. Observers were instructed to press key A when person A spoke and key B when person B spoke. A record of the conversation was kept on a moving paper tape. Not surprisingly, inter-rater reliabilities were nearly perfect. Twenty-five years later, the human observers were replaced by voice-activated microphones attached to analog-digital converters (Wiens et al. 1965). That such a simple device could replace the human observer suggests that the systems were not taking full advantage of the observers' capabilities. In reality, the decision to record such objective and basic information simply shifted the burden of interpretation from the observer to the researcher. Elliot Chapple (1940) and his successors developed elaborate schemes for interpreting the patterns of lines and blanks that appeared on their paper tapes. At the peak of its popularity, the interaction chronograph was used for everything from psychiatric diagnosis to employee placement.

MULTIPLE CATEGORY SYSTEMS

Chapple's work serves as an important benchmark. The near-perfect reliability is achieved at the cost of validity. The observation systems that followed it generally traded off a measure of reliability for greater validity. More meaningful sets of categories will almost certainly be harder to employ with any degree of inter-rater reliability.

Interaction Process Analysis (IPA) was one of the earliest attempts to devise more meaningful categories. Bales (1950) began with an encyclopedic list of behaviors and gradually consolidated them into an elegant set of twelve basic categories. Fifty years later, his original system is still one of the most widely applied observation methods.

The IPA category list was evolving at the same time that Parsons and Bales (1955) were developing a model of family socialization. They saw family leadership in the 1940s and 1950s as divided between the father and the mother. IPA perpetuates this somewhat dated division through its primary dimension; six categories are provided for coding task-oriented behaviors and six are for coding socioemotional behaviors (Table 1). When Slater (1955) suggested that this role differentiation could be extended to a general model of effective leadership in groups, he sparked a continuing controversy. But it must be remembered that this conceptualization preceded any serious consideration of either androgyny or flexibility in sex roles.

Additional symmetries are built into IPA. Three of the six socioemotional categories carry positive affect, and each has a direct counterpart on the negative side. Task-oriented behavior is seen as the process of asking questions and offering answers, though the answers—in the form of suggestions, opinions, and orientation (or information)—may be in response to questions asked or implied. Finally, the functionalist orientation of Parsons and Bales (1955) appears in the identification of six problems faced by groups: communication, evaluation, control, decision, tension reduction, and reintegration.

Following Chapple's lead, Bales developed and marketed a moving paper-tape recording device. The interaction recorder allowed for observation of groups rather than just dyads; the tape was divided into twelve rows and moved past a window at a constant speed so that the observer could write a code, indicating who was speaking to whom, within a category-by-time sector on the tape. This added complexity and enlarged the unit of analysis. The interaction recorder provided a continuous on-off record while IPA recorded discrete acts. The coding unity was, however, kept small. IPA coders often record two or three acts for a single sentence and are expected to record *all* acts. The first serious challenge to Bales's IPA system was Borgatta's Interaction Process Scores (IPS) system (1963). Borgatta argued that the twelve categories failed to make some crucial distinctions. His redefinition of the boundaries resulted in an eighteen-category system that had the advantage of greater precision and the disadvantages of greater

Interaction Process Analysis			
Category	Emotion	Task	Problem
1. Shows solidarity	Positive		Reintegration
2. Shows tension release	Positive		Tension reduction
3. Agrees	Positive		Decision
4. Gives suggestion		Answer	Control
5. Gives opinion		Answer	Evaluation
6. Gives orientation		Answer	Communication
7. Asks for orientation		Question	Communication
8. Asks for opinion		Question	Evaluation
9. Asks for suggestion		Question	Control
10. Disagrees	Negative		Decision
11. Shows tension	Negative		Tension reduction
12. Shows antagonism	Negative		Reintegration

Table 1

SOURCE: Adapted from Bales (1950) p. 14.

complexity and a lack of symmetry. The former problem was largely solved by the availability of a self-training workbook (Borgatta and Crowther 1965). Such a manual has never been widely available for IPA.

The next logical step after categorization is the organization of categories. IPA had an implicit organization that was lacking in IPS. This, and the fact that IPA had twelve rather than eighteen categories, made IPA the easier system to learn and use. As Weick (1985) points out, however, there is a problem of "requisite variety." A system for understanding a phenomenon must be at least as complex as the phenomenon itself. Weick uses the metaphor of a camera with variable focal length. In order to photograph objects at twenty different distances, the camera must have at least twenty focal settings or the pictures will not all be of equal clarity. This creates real problems for the interaction chronograph. Clearly, social behavior is more complex than Chapple's on-off category system. Unfortunately for researchers, it is also more complex than IPA's twelve-category system. This creates a dilemma. The mind can hold only so many categories at once; even with twelve categories, most observers tend to forget the rarer ones in an attempt to simplify their task.

MULTIDIMENSIONAL SYSTEMS

Timothy Leary (1957) proposed one of the first observation systems based primarily on dimensions rather than categories. His interpersonal diagnosis system placed sixteen categories at the compass points of a two-dimensional circumplex. The dimensions, dominance-submission and love-hate, would prove to be the two most common dimensions among the systems that followed. While intended primarily for the diagnosis of psychiatric disorders, the system also identified the "normal," or less intense, variant of each behavior as well as the likely response that each behavior would generate in other people. For example, the general behavior in the direction of dominance is "manage, direct, lead"; this behavior is likely to "obedience" in others. The extreme version of the category is "dominate, boss, order." This falls into the larger category of behavior that is described as "managerial" when in the normal range and "autocratic" when in the abnormal range. More than a method of observation, the interpersonal diagnosis system was a remarkably well-articulated theory of interpersonal relations. Were it not for Leary's well-publicized advocacy of lysergic acid diethylamide (LSD), the system might very well be in common

use today. While the research was briefly resurrected by McLemore and Benjamin (1979), it never had a major impact on either social psychology or psychiatry. Leary claimed that the system worked so well for psychiatric diagnosis that a receptionist trained in its use could provide diagnoses based on observations in the waiting room that rivaled those obtained by psychiatrists after conducting a diagnostic interview.

Leary's two dimensions were theoretically derived. In a 1960 doctoral dissertation, Arthur Couch pioneered the application of factor analysis to interpersonal behavior, thus offering an empirical alternative for the derivation of dimensions. Couch's six dimensions of interpersonal behavior were derived from the factor analysis of a vast amount of data on twelve groups of five undergraduates each. The individuals were given a large battery of personality tests and the twelve groups were observed participating in a wide variety of tasks across five meetings each. While the factor analysis is not independent of the original categories of measurement and observation, Couch's data set was so exhaustive as to deserve credence.

MULTILEVEL SYSTEMS

The three dimensions of Bales and colleagues' SYMLOG (System for the Multiple Level Observation of Groups) (1979) owe much both to IPA and to Couch's empirical work. They also reflect the legacy of Leary's circumplex. Dominant-submissive (up-down, or U-D) was the first factor from Couch's analysis; in IPA it corresponds to total amount of talking rather than to interaction in any specific set of categories; Leary's interpersonal diagnosis system had already identified the primary dimension as dominant-submissive. In essence, this was also the dimension that Chapple's interaction chronograph measured. Friendly-unfriendly (Positive-negative, or P-N), Couch's second factor, was represented in IPA by the three positive and three negative socioemotional categories, and it corresponds to love-hate in Leary's system. Task-oriented-emotional expressive (forward-backward, or F-B), the controversial distinction from IPA, was a compromise that created one bipolar dimension out of two of Couch's remaining factors. These three dimensions, generally referred to by the code letters shown above, define a three-dimensional conceptual space. Following Leary, Bales

and his colleagues then defined the compass points of the space. In this case, definitions were produced for all twenty-six vectors in the three-dimensional space. Thus, a dominant, unfriendly, task-oriented act (UNF) is defined as "authoritarian and controlling," and a submissive, unfriendly, emotional act (DNB) is described as "withdrawn and alienated." This was a creative solution to the dilemma of providing requisite variety while keeping the number of categories reasonable. While there are twenty-six categories, they are organized into three dimensions, so coders can hold the three-dimensional space rather than the twenty-six categories in mind. The twenty-six category descriptions then become a reference to be used when first learning the system and trying to understand where specific behaviors fit.

In addition to the basic level of behavior described above, SYMLOG also provides definitions for the twenty-six vectors on the level of nonverbal behavior. This level is coded when unintentional messages are sent through nonverbal behaviors or when the nonverbal—or paralinguistic—cues are at variance with the overt verbal cues. In developing his descriptions of facial expression and nonverbal cues, Bales drew on the work of the eighteenth-century French Encyclopedists. He found that Diderot and his colleagues had developed a more sophisticated understanding of facial expression and nonverbal nuance than have modern social scientists.

SYMLOG also allows for the coding of verbal content. Theoretically, the two levels of behavior—overt and nonverbal—could be coded without reference to the content of the message. Conversely, the content of messages could be coded from written transcripts without reference to the behaviors of the speakers. The content coding level attends only to evaluative statements. Each statement is first coded PRO (for statements in favor of something) or CON (statements against something). The content of the value statement is then coded in the same three-dimensional space that was used for behavior. Finally, the level of the value statement is recorded. Levels begin with the self and move outward: self, other, group, situation, society, and fantasy.

When the full SYMLOG system is used for coding a conversation, the result is a set of simple

sentences written in code. For example, Figure 1 records a brief exchange that took place from 1:23 to 1:24. Joe ordered Bill to stop contradicting him. The behavior was authoritarian (UNF) and the value statement was against negativity in Bill (CON N BIL). Bill responded in a rebellious manner (UNB) and made a value statement against Joe's authoritarianism (CON UNF JOE). Ron intervened in a "purposeful and considerate" manner (UPF) and made a value statement in favor of reducing the level of conflict (PRO DP GRP). If we see contradictions between the overt and nonverbal behavior, we could add lines such as 123 JOE GRP N DN. This would indicate that underneath Joe's authoritarianism is a note of insecurity and nervousness. (The first "N" in the message stands for "nonverbal," the "A" in each of the messages in Figure 1 stands for "act.") Clearly, the system requires fairly extensive training of coders. Most SYMLOG coders went through a fifteen-week course that was run as a self-analytic group. During this time, they alternated between serving as group participants and retreating behind a mirror to serve as coders. While there remain some universities in which such courses are still taught, the use of this method peaked in the late 1970s and early 1980s. Most work being done with SYMLOG at this time uses a parallel system of retrospective rating which requires no special training. This has resulted in time and cost savings, but at the expense of sacrificing the dynamic moment-to-moment process measurement that the original SYMLOG observation system made possible.

SYMLOG adds depth and sophistication to the coding of social interaction but again enlarges the unit of measurement. While IPA is an act-by-act coding system, SYMLOG is a "salient-act" coding scheme. Since it takes longer to record a SYMLOG observation, the coder must select the most important acts for recording. Clearly, this results in a loss of reliability as disagreements may result not only from two observers interpreting the same act differently but also from two observers selecting different acts for recording. Because of this, two observers are generally sufficient for IPA, but five or more are recommended for SYMLOG. Alternatively, interaction can be coded from video recordings. By going over the record repeatedly and picking up different acts with each pass, a higher percentage of acts can be picked up

by each coder, thus increasing the inter-rater reliability and decreasing the number of coders required. The only problem with this alternative is that SYMLOG does not record intensity. When multiple coders are used, more intense acts are likely to be selected as salient by more coders and will thus be weighted more heavily than the less intense acts that may be picked up by only one or two coders. Using only two coders and allowing them multiple passes in order to pick up a higher percentage of acts eliminates this implicit weighting effect.

The issue of reduced reliability is directly related to the problem of subjectivity. Moreno (1953) was an early critic of IPA; he argued that the observations of nonparticipants were meaningless because they could not possibly comprehend the life of a group to which they did not belong. While his position was extreme, it raised a difficult problem for any system that relies on the observations of outsiders. By standing outside the group, the outsider gains distance and "objectivity." Unfortunately, it is not clear that objectivity has any real meaning when speaking of interpersonal interaction. IPA sidestepped the problem by providing very clear specifications of categories. SYMLOG confronts the problem directly since observers are required to make fairly strong inferences as to the meaning of behavior. The coder is instructed to take the role of the "generalized other," or the "average" group member. When a group is polarized, this may be impossible. Half the group is likely to interpret an act in one way and the other half in a different way. This is another reason for having multiple observers. It is hoped that the various biases of the observers will cancel one another out if five or more people observe. Polley (1979) goes a step further by providing "descriptive reliabilities." Instead of simply reporting a reliability figure, descriptive reliabilities allow for a systematic analysis of observer bias. It is argued that observations tell us as much about the observer as about the observed. This is particularly true when group members are trained to serve as observers, as is the case in the self-analytic groups that are often the subject of SYMLOG observations.

Both IPA and SYMLOG have been repeatedly criticized for their use of a bipolar model of the relationship between "task-oriented" and "emotional" behavior. Two of these critiques have proposed adding a fourth dimension. Hare (1976)

Time	Who	To Whom	Act/Non	Direction	Description	Pro/Con	Direction	Level
123	JOE	BIL	A	UNF	Stop contradicting me!	C	N	BIL
123	BIL	JOE	A	UNB	Don't give me orders.	C	UNF	JOE
124	RON	GRP	A	UPF	I think we should all calm down.	P	DP	GRP

Figure 1. Sample SYMLOG Coding

went back to Parsons' original Adaptation, Goal Attainment, Integration, Latent Pattern Maintenance (AGIL) system and concluded that the task dimension should be divided into two dimensions: serious versus expressive and conforming versus nonconforming. Wish and colleagues (1976) proposed leaving the task-emotion dimension intact, even though it did not seem to be quite bipolar, and adding a fourth dimension: intensity. Polley (1987) has argued that emotionality is already captured in the friendly-unfriendly dimension and that the third dimension should be reserved for recording conventional versus unconventional behavior. This solution contends that the polarization of task and emotion is an artifact from the 1950s and has largely lost its meaning since then. If work is defined as devoid of emotional satisfaction, then task and emotion are bipolar. As soon as we recognize the possibility of having an emotional reaction—positive or negative—to work, the two dimensions become orthogonal. As Stone points out, the task-emotion polarity “implies that most work involves sublimation of the libido, and demands impulse control. Moreover, it becomes difficult to imagine management’s orientation . . . fostering individual creativity as some so-called excellent companies have been able to do” (1988, p. 18). It is becoming increasingly apparent that no “universal” scheme for coding interpersonal interaction exists totally independent of cultural and temporal context.

SPECIALIZED SYSTEMS

While Leary's system was intended primarily for psychiatric diagnosis, and IPA was originally designed for the coding of case discussion groups at Harvard Business School, the methods described above represent attempts to develop comprehensive and general coding schemes. In addition to these all-purpose methods, observation systems

have been devised for somewhat more specific relationships or channels of communication.

Richard Mann's (1967) sixteen-category system codes only one-way relationships from members to leaders. By narrowly defining the relationships to be observed, Mann was able to provide a much more detailed picture. Coding categories are provided for four types of impulse, four different expressions of affect, three variations of dependency, and five ego states. The additional sophistication is achieved by drastically reducing the number of observed relationships. If we observe a ten-person group using Mann's leader-member relationship scheme, we are looking at nine one-way relationships. If we use one of the all-purpose methods, we are coding forty-five two-way relationships.

The most thoroughly studies channel of communication is probably the nonverbal. While this is a small part of the SYMLOG system, proxemic behavior has been exhaustively categorized by Hall (1963) in terms of posture, orientation of bodies, kinesthetic factors, touch code, visual code, thermal code, olfaction code, and voice loudness. The potential complexity of this mode of communication is further illustrated by the fact that Birdwhistell (1970) developed an equally elaborate system for the coding of movement. While Hall's system codes states, Birdwhistell's codes state-to-state transitions. Each of these coding schemes concentrates on the physical nature of nonverbal behavior. In contrast, Mehrabian's system (1970) attempts to directly record the meaning of the behavior via a three-dimensional model that closely parallels SYMLOG. Again, the difference is in whether meaning is inferred by the observer or deferred to the researcher.

The other channel of communication that has been studied in depth is content. Again, this is a small part of SYMLOG; all content that does not carry a positive or negative evaluation is ignored.

In 1977, Philip Stone and his colleagues published *The General Inquirer*, a computerized content analysis system. While many of the applications involve the coding of written text, it has also been used for the coding of transcribed conversations. In one of the first applications of the method, Dexter Dunphy used *The General Inquirer* to code descriptions that group members had written of recent sessions. The great advantage of the methods is that it allows the user to define a dictionary. Three of the earliest dictionaries were the *Harvard III Psychosocial Dictionary*, the *Stanford Political Dictionary*, and the *Need-Achievement Dictionary*. It would also be possible to develop a SYMLOG value-level dictionary. In the case of a computerized content analysis system, the dictionary designer infers meaning *before* the behavior is coded.

RECENT DEVELOPMENTS

Observation systems only flourish when supported by a substantial research group. Because of the expense and the need for multiple coders, it is difficult to use observation systems as an isolated researcher. For three decades (the 1950s through the 1970s) such a group existed at Harvard. Bales and his colleagues had a well-equipped observation room and plenty of graduate student labor available. When Bales retired in 1985, the observation laboratory ceased to function as a research center. For most of the 1980s there were really no major research centers conducting observation work.

In the 1990s Joseph McGrath and his colleagues at the University of Illinois established a major research agenda around McGrath's theory of time, interaction, and performance (TIP) (1991). While much less method-driven than Bales's IPA and SYMLOG research groups, McGrath's group uses an observation method known as "time-by-event-by-member pattern observation" (TEMPO) (Futoran et al. 1989).

TEMPO was designed as a general observation method for the analysis of a wide range of group performance settings. It is divided into two sets of categories. The first codes on four performance functions:

1. Propose content—solutions, ideas.
2. Propose process—goals, strategies, acts.

3. Evaluate content—agreement, disagreement, clarification.
4. Evaluate process—agree, modify, disagree.

The two "proposal categories" are further classified as: (1) new—a new proposal; (2) prior—previously proposed; or (3) dictate—repeat content for clarification or emphasis. The two evaluation categories are further classified as: (1) agree, (2) clarify or modify, (3) disagree, or (4) reject/veto.

The second set of categories codes seven nonproduction function categories:

- T. Task digression
- P. Personal comments
 - I. Interpersonal comments
- R. React to experiment
- D. Digressions
- U. Uninterpretable
- S. Silence

McGrath's group devised their own methodology rather than relying on IPA or SYMLOG because they were concerned with both process and activity. They felt that the existing systems did not allow for the level of temporal pattern recognition that they were looking for. Their primary criteria for the system were that it: (1) be time-based, (2) identify individual member behavior, (3) recognize multiple acts within a single speech, (4) allow for multiple simultaneous acts and periods of inactivity, and (5) relate act to task products. Virtually all their observation studies are based on the analysis of videotaped records of interacting groups. The TIP theory and the TEMPO method are central to the line of research that McGrath and his colleagues conducted in the 1990s. *Small Group Research* devoted a special issue to six articles that resulted from a single large research project known as "The JEMCO Workshop Study" (McGrath 1993), but additional work from this research team has resulted in numerous journal articles and books.

Another major research effort that has produced its own observation system is led by Susan Wheelan. The work of Wheelan and her colleagues focused on group development. The Group Development Observation System (GDOS) is based in Wilfred Bion's concept of basic assumption and

work groups (1959). It consists of seven categories (Wheelan et al. 1993):

1. Dependency statement
2. Counterdependency statement
3. Fight statement
4. Flight statement
5. Pairing statement
6. Counter-pairing statement
7. Work statement

Like McGrath's group, Wheelan's group is primarily concerned with temporal patterns in group development. The conceptual underpinnings of the two lines of research are, however, very different. Again, GDOS has resulted in numerous journal articles and books. A special issue of *Small Group Research* was also devoted to this line of research (Wheelan 1999).

While there have been a number of other observation systems to emerge in the past decade, these two represent extended lines of research. Most of the publications that have used observation systems since 1980 have used either modifications of existing systems or idiosyncratic systems that were used once or twice and so did not generate a comparative body of work.

A DECADE OF SMALL GROUP RESEARCH

In 1990, *International Journal of Small Group Research* and *Small Group Behavior* merged to form a new international and interdisciplinary journal known as *Small Group Research*. This journal publishes research on small groups that ranges across sociology, psychology, organizational behavior, social work, group psychotherapy, communications, and management information systems. As the only interdisciplinary journal in the field of small groups, it is a good indicator of the popularity of the observation systems in general and also of specific systems. Table 2 presents the results of an inventory of the past decade of research published in *Small Group Research*. In addition to tabulating the total number of articles using observation systems each year, it also indicates whether the articles used direct observation, videotapes, or transcriptions and whether they used one of the

four most popular general-purpose methods (IPA, SYMLOG, TEMPO, and GDOS) or some other method.

Of the 270 articles published in *Small Group Research* over the past decade, 41 used observation methods. IPA and SYMLOG are still in use; the other most common methods were TEMPO and GDOS, described above. However, the majority of articles (28) used idiosyncratic observation methods. While many represent real contributions to the literature, the lack of a common method makes comparisons across studies difficult. The other trend that is evident from Table 1 is that relatively few studies (9) used live observation. The remaining studies were almost equally split between the coding of videotapes and the coding of transcriptions. Perhaps the real loss in this shift of methodology is that so many rely on transcripts. One of the strengths of observation methods is that they capture paralinguistic cues; these data are lost to systems that rely on transcriptions.

THE FUTURE OF OBSERVATION SYSTEMS

Observation systems have been used less and less in recent years for a mundane reason: cost. Training observers is time consuming, as is the actual process of observing and coding behavior. At this point, serious research using direct SYMLOG observation is being done at only two or three institutions. In contrast, the much less time-consuming method of SYMLOG retrospective rating (using either the Bales items or the Polley revisions) is currently in use in at least fifty institutions around the world. While there is some indication of a resurgence of interest in direct observation, as evidenced by the studies cited in the preceding sections, it is clear that the method requires a substantial commitment of time and money on the part of the researcher.

While the costs of direct observation are high, it is clear that there are a great many aspects of social behavior that simply cannot be understood without it. Basic research still needs to be done on group development, particularly as it relates to team building in organizations. The effects of various leadership styles and decision-making processes on group functioning are still not thoroughly understood. A wide range of styles is currently

used by group therapists, but these styles are more often backed by rival schools of thought than empirical evidence.

As with content analysis, the future of observation systems may well lie with computerization. Johansen (1989) coined the term *groupware* to refer to computer systems for the support of groups or teams. To date, most of the systems have provided little more than an "electronic flipchart" for nominal group technique sessions. With advances in artificial intelligence, more sophisticated examples of groupware have been gradually emerging. Speech-recognition programs for the automatic transcription of meetings could greatly reduce the cost of using content analysis. Programs have been developed for recognizing emotional content in speech. If these were to be combined with voice-activated, some automatic scoring of behavior—at least at the paralinguistic level—should be possible. Until technology substantially reduces the costs, a return to the widespread use of observation systems seems unlikely.

RICHARD B. KETTNER-POLLEY

OCCUPATIONAL AND CAREER MOBILITY

Occupational and career mobility in adulthood is often referred to as intragenerational social mobility. It involves change in an individual's position in the labor market over the adult life course. Change is studied with respect to both type of work and the rewards derived from work. The term *career* refers to an individual's job history. Empirical *regularity* in the careers of individuals in the labor force defines what we call a "career line" or "job trajectory," since a work history common to a portion of the labor force reflects the existence of structurally determined linkages among jobs in the economy. Jobs are located in particular firms, whereas occupations and industries encompass jobs in many firms. An individual may remain in the same occupation or industry but change firms (and jobs within the same firm) any number of times. Since the process of job change does not necessarily involve a change of occupation or industry, but a change of occupation or industry always involves a job change, the process of job change provides a more detailed account of career movement. Changes in the rewards derived from work usually accompany job changes but can also occur during the course of tenure in a job.

Research on intragenerational mobility has focused on the labor force as a whole and on employees in particular occupations and firms. Research on the labor force as a whole has usually considered change in occupation and industry, as measured for detailed categories or more aggregated groupings that define broad occupational

and industrial groups. It has also considered change in the rewards derived from work, focusing primarily on occupational prestige and earnings. Research on particular occupations and firms has usually focused on job status and authority changes within organizational hierarchies and on changes in work rewards.

Early work on intragenerational mobility involved the mathematical modeling of transition probabilities, usually among a few, highly aggregated categories (see Mayer 1972 for a review). This work used Markov models and semi-Markov models to analyze transition probabilities in a sequence under the assumption that the job category an individual will occupy in the future depends only on the job category occupied in the present and not on job categories occupied previously. Although there was empirical support for this assumption in some studies, it was not found to be broadly applicable. In semi-Markov models, transition probabilities are permitted to vary with time and for subgroups of the population. These models capture declines in mobility with age or duration of stay and allow for the fact that some individuals are more likely to move than others. There is evidence that mobility is an exponentially declining function of time (Mayer 1972) and that some individuals become "movers" while others become "stayers" (Blumen et al. 1955).

Later analyses have considered more refined models of job change, focusing on job shifts as elementary acts in the mobility process. Job shifts may be either voluntary or involuntary, and may occur at a decreasing rate with time in the labor market. They are also more likely to occur within a firm than between firms as labor market experience increases (Rosenfeld 1992; DiPrete and Nonnemaker 1997). As time spent in a firm increases, both rates of promotion and rates of leaving the firm also decline (Petersen and Spilerman 1990; DiPrete and Nonnemaker 1997). When the effect of labor market experience is considered simultaneously, firm tenure may have a positive effect on within-firm job mobility, but this effect indicates that the rate of within-firm job mobility declines with labor market experience more slowly for each year of tenure with an employer than for each year of pre-employer labor market experience. Job shifts (both voluntary and involuntary) are strongly and negatively related to job tenure. As the duration of a job increases, the probability

of leaving it declines. Most of this decline occurs in the first year of a job, after which there is a leveling off (Topel and Ward 1992). Within firms, however, job tenure has a positive effect on the probability of promotion, in some instances increasing up to a point and then decreasing (Felmlee 1982; Althausser and Kalleberg 1990; Petersen and Spilerman 1990). The rate of mobility varies with characteristics of the individual, the job, the occupation, the employing organization, and the economic environment.

Change in the rewards derived from work usually accompanies a job shift (Sørensen 1974; Rosenbaum 1984; Topel and Ward 1992). Voluntary job shifts are associated with increases in prestige and wages; involuntary job shifts, with losses. Job shifts *within* firms and occupations are more often associated with gains in prestige and wages than those *between* firms and occupations (DiPrete and Kreckler 1991; DiPrete and McManus 1996; Cheng and Kalleberg 1996). In general, the rewards of changing jobs decline with labor market experience and job tenure. Wages, as well as the opportunity for wage growth and promotion, bear a negative relationship to the probability of a job shift (Petersen and Spilerman 1990; Topel and Ward 1992). Change in wages also occurs during the course of a job (Topel 1991), declining with labor market experience and, at a decreasing rate, with job tenure (Topel and Ward 1992). For the labor force as a whole, occupational prestige and earnings increase over the adult working life. The shape of these trajectories tends to be concave downward—with a rise early in the career, a plateau during the middle years, and a slight decline as the end of the work career approaches. Status and earnings trajectories have the same form, but the former is flatter (Mincer 1974; Rosenfeld 1980). There is also variation in the shape of these trajectories for those in different career lines (Spilerman 1986).

Given the heterogeneity of career lines and the important role that age, or duration since career entry, plays in shaping career lines, there have been attempts to study the path of careers in recent years. Not only does mobility decline sharply with age, and therefore with the proximity of a job to the end of a career line, but job changes that occur later in an individual's work life tend to involve jobs requiring skills that are more similar than those that occur earlier in the work life

(Spenner et al. 1982; Althauser and Kalleberg 1990). There is also evidence that early career experiences have an important effect on later career outcomes. This evidence indicates not only that those entering *different* career lines, who receive different rewards at career entry, can expect different career outcomes (Marini 1980; Spenner et al. 1982), but also that early experiences *within* a career line can condition subsequent progression and the level of reward attained relative to others who enter the same career line (Stewman and Konda 1983; Rosenbaum 1984). The career lines most often studied have been trajectories within institutional structures, but there have also been attempts to describe career lines that cross institutional boundaries (Spilerman 1977; Spenner et al. 1982; Althauser and Kalleberg 1990).

LABOR MARKET STRUCTURE

The concept of "career line" or "job trajectory" derives from the view that the labor market is structured in a way that makes some types of job changes more likely than others. Early work on career mobility ignored this structural differentiation, estimating the overall (linear) relationship between the status and earnings of an individual's first job and the status and earnings of a job held later in the career (Blau and Duncan 1967; Coleman et al. 1972; Marini 1980). Jobs resembling each other in status, pay, and working conditions, however, are sometimes part of a career line and sometimes not, even if part of a career line can be attached to different career lines. Jobs providing similar current rewards may therefore not offer the same prospects for future mobility.

Since career lines are rooted in labor-market structure, their existence demonstrates that intragenerational mobility is influenced by the structure of the labor market and changes in that structure, as well as by the demography of the labor force and individual characteristics that affect movement within segments of the labor market. If jobs have entry requirements and confer rewards, the structure of jobs plays a critical role in establishing the link between the attributes of individuals and work rewards. Recognition that the labor market is structured in a way that produces segmentation among career lines has led to attempts not only to describe career lines but to identify the forces shaping them.

Pioneering work by White (1970) directed attention to the importance of social structure in shaping careers by modeling the way in which vacancies in a structured labor market trigger career movement. More recent models of vacancy-based movement have further delineated the ways in which vacancy chains, job distributions, and managerial staffing and hiring practice structure the relative career chances of individuals (Sørensen 1977; Skvoretz 1984; Stewman and Konda 1983; Stewman 1986). In these models the availability of job openings determines career advancement possibilities, and the shape of organizational hierarchies affects the probability of advancement. Since most organizational hierarchies are pyramidal, with many more low-level than high-level positions, the average employee's advancement must slow down over time. Aggregate age-promotion curves appear to be described empirically by an exponential-decline function where the highest promotion chances occur at the outset, declines are a fixed proportion of an individual's current chances, and promotion chances become increasingly rare but not impossible. In short, promotion favors youth, declines gradually, but does not disappear for older workers. There may also be chances for an increase in promotion during the initial career years when most on-the-job training occurs.

Although career advancement often occurs as a result of job change to fill a vacant position, not all career movement depends on or is affected by a job opening. New jobs in organizations are sometimes created for particular individuals, and jobs that are vacated may be eliminated rather than filled. New jobs can also be created by individual moves to become self-employed, and the termination of self-employment does not necessarily create a vacancy. Within organizations, career advancement occurs through upgrading as well as vacancy filling. An employee receives an upgrade promotion when a certain level of seniority or a certain performance marker is reached. Such promotions involve reclassification to a higher rank and do not depend on a vacancy's being present (Stewman and Yeh 1991; Barnett and Miner 1992). Both upgrade promotions and vacancy promotions may occur during the course of an individual's career. These alternative advancement mechanisms, however, are not necessarily found equally throughout an organizational hierarchy. In several occupational categories studied

in one organization, most lower-level promotions were vacancy based, and a higher proportion of upper-level promotions occurred through upgrading (Barnett and Miner 1992). The mechanisms available for promotion affect an individual's promotion chances. It has been found that if promotion occurs through upgrading based on performance rather than vacancy filling, salary grade level is not necessarily associated with a lower probability of promotion (Petersen and Spilerman 1990). Similarly, the effect of hiring temporary workers on the promotion chances of permanent workers depends on the extent to which promotion occurs through vacancy filling rather than upgrading (Barnett and Miner 1992).

Because the structure of the labor market affects career movement, there have been attempts to understand the structural bases of segmentation among career lines. During the 1940s and 1950s, institutional economists called for an understanding of well-defined systems of jobs and firms, drawing a distinction between internal and external labor markets. For example, Dunlop (1957) argued that within a firm there are groups of jobs, or "job clusters," each of which is linked together by technology, the administrative organization of the production process, and the social customs of the work community. A job cluster usually contains one or more key jobs and a group of associated jobs, and the wage rates for the key jobs mediate the effects of labor market influences, including union and government wage policies, and forces in the market for products on the wage structure of the firm. The distinction between internal and external labor markets was later reintroduced by Doeringer and Piore (1971), who discussed what they called a "mobility cluster." The central idea was that administrative rules and procedures tend to set up separate markets for those already hired (an internal labor market) and those seeking employment (an external labor market). A firm hires workers from the outside labor market into "entry jobs," and other jobs are filled internally as workers progress on well-defined career ladders by acquiring job-related skills, many of which are firm-specific. Thus, firms make investments in individuals, and these investments segment the workforce with respect to advancement opportunity.

The concept of the internal labor market was developed further in what was first called *dual* and

then *segmented* labor market theory (Gordon 1972; Kalleberg and Sørensen 1979). This theory draws a distinction between primary and secondary jobs, arguing that the internal labor market is only one kind of work setting. *Primary* jobs emphasize long-term attachment between workers and firms and offer built-in career ladders and promotion opportunities, whereas *secondary* jobs do not offer these advantages. The distinction between primary and secondary jobs may occur within the same firm or between firms, since primary jobs are considered more likely to be found in oligopolistic, unionized industries, and secondary jobs in competitive industries.

Dual and other segmented labor-market theories have come under attack as being too crude to meaningfully characterize the multiple dimensions on which labor markets vary. Attempts to measure labor-market segmentation by crude topologies, including industrial and occupational categories, have also been criticized. Because there is extensive heterogeneity within industrial and occupational categories, and because there is no way to link them to the kinds of job clusters hypothesized to exist, it has been argued that more disaggregated analyses of jobs and firms are needed. Many subsequent analyses have focused on particular bureaucracies or firms, and those examining larger segments of the labor market have sought to measure the characteristics on which employing organizations and occupations vary.

Attempting to develop a systematic conceptual scheme for studying labor market segmentation, Althausser and Kalleberg argued that "the concept of an internal labor market should include any cluster of jobs, regardless of occupational titles or employing organizations, that have three basic structural features: (a) a job ladder, with (b) entry only at the bottom, and (c) movement up this ladder, which is associated with a progressive development of knowledge and skill" (1981, p. 130). Based on four possible pairings of type of control and prospects for advancement, they differentiated four types of labor market structures: (1) firm internal labor markets, which are internal labor markets controlled by firms; (2) occupational internal labor markets, which are internal labor markets controlled by occupational incumbents; (3) firm labor markets, which provide

firm-specific security without advancement prospects; and (4) occupational labor markets, which provide occupational security without advancement prospects.

Within a firm or an occupation, there may be multiple job ladders that vary in length and shape, and there are structured relationships among job ladders. Job mobility occurs not only along formal organizational and occupational ladders but across them (Baron et al. 1986; Stewman 1986; DiPrete 1989). For example, job ladders often cross detailed and even aggregated occupational boundaries. DiPrete (1987) described the permeability of these boundaries as depending on several types of contingencies: (1) skill-based contingencies, (2) information-based contingencies, (3) contingencies due to the configuration of positions in an organization, and (4) contingencies that emerge from the institutionalization of formal structure. Internal labor markets limit competition from outsiders by offering a combination of closed and restricted mobility contests that involve movement on and across job ladders (DiPrete and Krecker 1991; Stewman and Yeh 1991).

Because employing organizations vary in the kinds of jobs they offer, the occupational groupings in which those jobs fall, and the wages they pay, there has been some attempt to examine the effect of organizational characteristics on job mobility. Large organizations offer better pay, have more job ladders offering opportunities for promotion and wage growth, and offer better employee benefits. Organization size is therefore positively related to mobility within an organization and negatively related to voluntary movement out of an organization (Hachen 1992; DiPrete 1993; Cheng and Kalleberg 1996). Organizations in concentrated industries and industries dominated by conglomerates experience both lower rates of within-firm mobility and lower rates of voluntary exit because they have higher average wage levels, and there is a negative relationship between the average wage level of an industry and the probability of both within-firm mobility and voluntary firm exit. High-wage industries have lower rates of within-firm mobility than low-wage industries because, net of organizational size, internal labor markets are less prevalent in firms in high-wage industries. Capital-intensive industries have higher rates of

both within-firm mobility and voluntary firm exit but lower rates of involuntary exit. These differences are linked to the greater prevalence of internal labor markets in firms in capital-intensive industries (Hachen 1992).

Although there is general agreement that the technical character of work influences organizational development, existing variation in institutional and personnel structures, especially cross-nationally, indicates that the technical character of work alone does not determine job ladders and career lines. These are affected by the historical circumstances surrounding an organization's founding, including the gender, racial, and ethnic composition of the workforce; by market and other social conditions that affect organizational change and employment growth; and by the negotiating strength of various bargaining units.

A number of explanations have been advanced for the emergence of internal labor markets. One focuses on the development of specialized knowledge and skill relevant to employment in particular occupations, jobs, and firms. Becker (1964) noted that when a worker receives training specific to the needs of an employer, the worker's value to the employer increases since a new employee would have to receive similar training before being able to perform at the same level. It is therefore in the interest of the employer to retain workers with such specific training by providing them with opportunities for promotion, salary growth, and employment security. When firm-specific skills are rewarded, workers also have an interest in remaining with the employer because the wages and other benefits they could obtain from another employer are lower. Based on this reasoning, Williamson (1975) argued that internal labor markets emerged because they were preferable to long-term contracts for maintaining the employment relationship. Thus, internal labor markets are seen as resulting from employers' needs for renewable supplies of otherwise scarce, highly skilled workers. Substantial empirical evidence is consistent with this view. Another explanation, offered by Bulow and Summers (1986), is that job hierarchies offering promotion prospects and wage increases are an important means of motivating workers when individual performance is not easily monitored.

The emergence and spread of internal labor markets is also seen as related to the development

of personnel departments, formalized rules, and the rise of bureaucratic control. Although there is some empirical support for this view, at least some internal labor markets preceded the emergence of bureaucratic control systems and rules (Althauser 1989; Stovel et al. 1996). Spilerman (1986) has noted that workers have an interest in barring lateral entry and in having high-level positions filled through promotion. Workers may also wish to limit employer discretion by having decisions about promotion and layoff tied to seniority. These worker interests cause labor unions to work to create more widespread job hierarchies and promotion. Although internal labor markets have been argued to be a result of unionization, evidence suggests that they are to some degree an alternative to unionization (Pfeffer and Cohen 1984). In manufacturing establishments, the technology of production helps to manage the workforce, binding workers to a specific organization with specific machines and production technology, and providing necessary skills and training. Unionization reduces turnover by providing workers with a voice, skewing compensation toward deferred benefits over current wages and bonuses, and paying a larger proportion of total compensation as fringe benefits valued particularly by senior workers. In the presence of a governance system under unionization, the internal labor market and other forms of bureaucratic control are redundant if not in competition with union mechanisms.

Because the prevalence of internal labor markets varies across organizations, there has been some attempt to explain why they are found more often in some organizations than others. It was initially argued that firms characterized by high profit levels, oligopolistic pricing, and large organization size were more likely to create internal labor markets because they could better afford to. However, there is evidence that internal labor markets are not merely a derivative feature of core-economy organization (Althauser 1989). Hachen (1992) has suggested that they are affected by three characteristics of employer personnel policy: the need to retain workers, the availability of alternative mechanisms for retention, and the ability to use specific mechanisms. In labor-intensive industries where labor costs are substantial and worker replacement is used as a strategy to maintain or even lower wage levels, retaining workers is less important. As a result, within-firm mobility rates

are low, and involuntary exit rates are high. When an organization desires to retain workers, offering higher wages and increasing internal opportunities are two means of retention, but organizations vary in their ability to use these mechanisms. A large organization will be better able to offer internal opportunities. An organization that can offer high wages may have less need to offer advancement opportunities.

Career lines not only involve substantial movement between job ladders within firms but often cross firm and industry boundaries rather than remaining within them. In the U.S. economy, most job change involves a change of employer (DiPrete and Krecker 1991). It has been estimated that only somewhat over a quarter of U.S. workers are continuously employed by the same employer for twenty years or more (Hall 1982). In some careers, such as the salaried professions, crafts, and "secondary" labor-market positions, firm and industry are not a locus of career line structure. Nevertheless, moves between firms and industries often occur between related positions, so that labor-market segmentation emerges even without institutional barriers.

Aspects of the structure of labor markets, other than internal labor markets, that have implications for occupational and career mobility have been documented in cross-national research. One type of cross-national variation is in the relationship between the educational system and the labor market, which varies according to the structure of the educational system. In countries with more stratified and standardized educational systems, such as Germany, Austria, France, and Norway, there is a tighter linkage between educational preparation and labor-market position than in the United States. In these countries, reliance on educational degrees and other credentials as screening devices is greater, and rates of occupational and job mobility are lower (Haller et al. 1985; Allmendinger 1989; DiPrete and McManus 1996). In the United States, where schooling is more open and comprehensive, the number of years of education attained matters more, and career mobility is higher because a larger proportion of employees are allocated to low-level entry positions in organizations. In Great Britain, which has a stratified educational system, similar to those of the other European countries, occupational mobility is higher than in the United States because

the linkage between education and training prior to labor-market entry and job placement is weaker. Workers are also more likely to attain part-time education after labor-market entry that leads to occupational change (Winfield et al. 1989).

Another aspect of labor market structure that varies cross-nationally is the degree of institutional separation between manual and white-collar work, which affects mobility across this boundary. Existing throughout Europe, but strongest in the German-speaking middle-European countries, is the institution of apprenticeship for manual work, which restricts access to jobs for skilled workers to those who complete an apprenticeship after elementary schooling. In countries where the institution of apprenticeship is less strong, as in France and the United States, access to a job as a skilled worker is more dependent on affiliation with a specific enterprise and is open to those moving up from unskilled jobs. The greater stratification of the educational system in countries where the institution of apprenticeship is strong also restricts upward mobility from manual to nonmanual jobs.

Another variation observed cross-nationally is in the degree of separation between hierarchically ranked white-collar positions. In Austria and France, there is greater separation among hierarchical layers of white-collar work than in the United States, where the higher levels of white-collar work are more open to entry from below (Haller et al. 1985). In the United States, both the highest and lowest categories in the occupational structure are less separated from the middle layers than they are in Austria and France. As a result, mobility over relatively long distances is more common in the United States. This difference may be due in part to the less stratified educational system in the United States.

Another type of variation in labor market structure found across countries is in the links of the labor market to other national institutions such as the state and centralized employer and labor associations. In some countries, such as China, the state remains the major employer (Zhou et al. 1997); in others, such as Austria and France, large enterprises and whole industrial sectors are nationalized (Haller et al. 1985). Labor markets in Europe have also been described as less flexible than those in the United States because "corporatist"

institutional arrangements of various types coordinate and regulate the labor markets. Countries described as corporatist have relatively centralized wage-setting institutions that result in less volatility in wages and smaller wage differences (DiPrete and McManus 1996; Gottschalk and Smeeding 1997). They may also have greater employment security that reduces involuntary job mobility, but restrictions on wages may result in relatively high unemployment as well.

Because the availability of vacancies in organizational hierarchies affects career advancement, and the supply of labor affects both the probability of advancement and wages, career progress in all countries is affected by demographic factors such as the size and distribution of education and skills in various age cohorts and the rate of exit from positions (Stewman and Konda 1983). It is also affected by organizational growth and contraction that result in the creation and termination of jobs. Change in the actual structure of jobs occurs in response to social and economic influences, including technological development. At the level of the firm, expansion increases the rate of promotion, and contraction decreases it (Stewman and Konda 1983; Barnett and Miner 1992). Expansion of an industry, as measured by growth in the average size of firms or the establishment of new firms, increases the rate of job shifts within and between firms in the industry and decreases the rate of involuntary exit (Hachen 1992; DiPrete 1993; Haveman and Cohen 1994; DiPrete and Nonnemaker 1997). Contraction of an industry, as measured by decline in the average size of firms or the closing of firms, decreases the rate of job shifts between firms in the industry and increases the rate of movement out of the industry, including movement to unemployment. Contraction of an industry may either decrease or increase the rate of within-firm mobility, since contraction may lead to the internal redeployment of labor as a substitute for new hiring. Internal mobility that reflects reorganization occurs primarily among lower white-collar, service, and blue-collar workers. Movement out of the industry and to unemployment occurs primarily among service and blue-collar workers (DiPrete 1993). Change that involves merger and acquisition within an industry has fewer effects, but they tend to be similar to the effects of industry contraction (DiPrete 1993; Haveman and Cohen 1994). The effects of *occupational* expansion and

contraction differ somewhat from those of *industrial* expansion and contraction. Expansion of an occupation increases the rate of mobility between firms in an industry but not within firms. Contraction of an occupation increases the rate of mobility within firms (due to the redeployment of labor) and increases the rate of movement to unemployment but does not increase the rate of movement out of the industry (DiPrete and Nonnemaker 1997). The adverse effects of economic turbulence in either an industry or occupation are dampened by employer tenure.

Since the structure of the labor market affects both job mobility and wage growth, aspects of labor market structure account for the aggregate declines in job mobility and wage gain observed over the course of workers' careers. One aspect of labor-market structure that plays a role in explaining the declining change in career rewards is the pyramidal shape of organizational and occupational hierarchies, which contain many more lower-level than higher-level positions. Given this structure and the role of vacancy filling in promotion, the chances of promotion and wage growth linked to promotion decline with labor-market experience. To the extent that upward mobility is possible, workers entering a career line are in competition with others at the same level for advancement to the next highest level. Because jobs at the next level are filled from those occupying positions in the level below, entry to a job ladder and performance at each step on the ladder affect ultimate career attainments. Rosenbaum (1984) has described the process by which employees in a cohort are progressively differentiated throughout their careers in a series of implicit competitions as being like a tournament. Selections among the members of a cohort occur continually as careers unfold, and each selection affects the opportunity to advance further. As a result, individuals are distributed more and more to "winner" and "loser" paths, and interpersonal variance in wages rises with labor-market experience and firm tenure. Those who are not promoted are more likely to leave the firm, but their gain from doing so is less than the gain of those who are promoted internally.

According to human capital theory, the shape of wage trajectories over the career course is a function of the changing productivity of workers. Wage growth through labor-market experience

results from learning on the job that increases a worker's productivity and value to the employer. On-the-job training occurs in formal training programs provided by employers or as a result of informal instruction by supervisors and coworkers and simply by doing the job. Time away from the job, in contrast, can lead to skill depreciation. Because investments in training are costly, these are concentrated in the early part of careers, leading to greater wage growth at early rather than later career stages. Formal and informal training in a particular firm and on particular jobs can provide knowledge and skills that are general or specific. General knowledge and skills are applicable in other firms and other jobs, whereas specific knowledge and skills are applicable only in the firm or job where they are acquired. As workers develop firm- and job-specific human capital, they are less likely to leave that firm or job because their productivity and resulting wages are higher than they would be in another firm or job. Although productivity may be greater in the firm or job where specific human capital is acquired, increments in productivity decline over time. As a result of this decline and biological aging, productivity may be lower at the end of a career than it was earlier.

One problem with human capital theory is that the relationship between labor market experience and worker productivity has not been adequately tested. Labor-market experience may affect wages because it is a proxy for seniority if wages rise with seniority and job tenure regardless of productivity. For women, labor-market experience may be an outcome rather than a determinant of career mobility if entry into career lines offering little opportunity for advancement affects labor-force participation (Marini 1980; Marini and Fan 1995). Evidence on the relationship between labor market experience and productivity within occupations suggests that, although labor market experience has some bearing on productivity, its effect on career advancement is largely independent of productivity (Horowitz and Sherman 1980; Medoff and Abraham 1980, 1981; Maranto and Rodgers 1984). Much variability is also seen across occupations and work contexts in the extent to which work experience affects either productivity or earnings (Horowitz and Sherman 1980; Spilerman 1986). Evidence also contradicts the "tradeoff hypothesis"—that individuals sacrifice earnings at

the beginning of their careers for better long-term career prospects. Individuals with lower earnings early in their careers actually have lower rather than higher job status and earnings later.

More recent economic explanations of the relationship between labor-market experience and wage growth have focused on new arguments about the role of productivity in shaping the desire of employers, especially those who make large investments in screening and training employees, to retain workers and motivate high performance over time (Lazear 1981; Lazear and Rosen 1981; Malcomson 1984; Bulow and Summers 1986). Promotions and wage increases are seen as a means of eliciting effort from workers when the monitoring of their efforts and outputs is prohibitively expensive. These explanations deviate from the view that labor is paid its marginal product in each short period, assuming that workers are paid their marginal product over the life cycle or in some cases in excess of their marginal product. So far, none of these explanations has an empirical basis, and, as single-factor explanations, they are unlikely to account for the diverse compensation schemes observed across occupations and work settings (Talbert and Bose 1977; Spilerman 1986). A further problem is that they ignore the role of nonmonetary incentives in retaining workers and motivating high performance.

Other economic explanations of career mobility have combined human capital theory and information theory to consider the role of imperfect information and the acquiring of additional information as influences on career decision making (e.g., Jovanovic 1979). As in human capital theory, voluntary job mobility is assumed to result from a comparison of the benefits derived from one's current job with those that could be obtained from another job. The decision to search for or accept another job is argued to be affected by new information about either the current job or a possible alternative. Because certain aspects of a job cannot be assessed prior to employment, new information is argued to be acquired through actually working on the job, and this information affects assessment of the quality of the person-job match. Jobs that survive are those evaluated as a good match, or at least as a better match than could be obtained elsewhere. With increases in labor-market experience, workers acquire more information about the labor market and are better

able to demonstrate their performance, which in turn provides more information to employers. As a result, matches improve over the course of a career, and, because it becomes increasingly less likely that a better match can be found, job mobility declines. Although the role of information is implicit, a related argument is linked to the vacancy-based model of career advancement (Sørensen 1977). According to this argument, as time in the labor market increases, people who enter the labor market in a position below their optimum level because a better vacancy is unavailable have more time to take advantage of vacancies and to close the gap between their current and potential rewards. What these models do not consider is the path dependency of careers, whereby there are long-term effects of early job placements on later career outcomes. Job placement early in a career not only shapes worker experience and training but is used as a basis for screening by employers that affects later career opportunities.

Information about the labor market and specific alternative jobs may also change with labor-market experience in ways that affect assessments of the likelihood that a better alternative is available. At labor-market entry and during the early career, both occupational aspirations and the importance attached to a variety of job attributes decline. These changes suggest a diminished view of the labor market, which makes it less likely that a better alternative to one's current job will be perceived to be available. As firm and job tenure increase, it is also likely that knowledge of specific alternative job opportunities declines, since the time since the worker's last involvement in job search is longer and contacts with others who would be sources of information are fewer.

If opportunities for career advancement and wage growth are used by employers to retain workers who have firm- and job-specific knowledge and skill, career advancement and wage growth may also decline over the course of individual careers because they become less necessary means of retaining workers. They become less necessary because increases in firm- and job-specific knowledge and skills increase the extent to which a worker will be more valuable to the current employer than to an alternative employer and because the value of accrued employee benefits, including retirement benefits, makes it increasingly costly for a worker to change employers. As firm

and job tenure increase, personal relationships and familiarity with the work environment also increase, reducing the likelihood that a worker will change employers or jobs. There is also less time left as a career advances to recover the costs of a change of employer or job and achieve the same level of functioning as was attained with the current employer or a higher level (Groot and Verberne 1997).

WORKER CHARACTERISTICS

Given the structure of the labor market, particularly the local labor market where most job search occurs, entry into a career line is affected by worker characteristics, such as job-related credentials (e.g., education, intelligence, physical attributes), job preferences, and access to resources (e.g., information, material support, sponsorship by influential others). In some career lines, worker characteristics at entry may also influence career progression, whereas in others such characteristics may have little effect after access to a career line is obtained. If worker characteristics at entry continue to have an effect, they may do so in part because they influence subsequent on-the-job training and performance.

Most theoretical attempts to explain individual differences in career mobility have focused on individual differences in worker performance. In human capital theory, workers are seen as rational actors who make investments in their productive capacities to maximize lifetime income (Becker 1964; Mincer 1974). The investments usually studied are education and on-the-job training, although the theory applies to other investments, such as effort, job search, geographic mobility, and health. It is assumed that labor markets offer open opportunity and that earnings growth is a function of change in productivity due to how hard individuals work and to the ability, education, and training they possess. Individuals can increase their productivity not only through formal education but by learning on the job. Because investments in education and training are costly, workers concentrate their investments in the early part of their careers, sacrificing immediate earnings for better long-term career prospects. Although worker qualifications that may affect productivity have been found to be associated with advancement, these

associations are consistent with explanations other than that afforded by human capital theory. In the theory of vacancy-based competition, workers' performance-related resources are also assumed to affect career advancement, but the mechanism by which they affect advancement is left unspecified (e.g., Sørensen 1977).

Sociologists generally view the relationships between education and experience, on the one hand, and career advancement on the other, as influenced primarily by the organizational, and even the broader societal, context in which the administrative arrangements that govern promotions and salary advancement arise. Spilerman (1986) has suggested that education and experience bear weaker relationships to promotion and earnings when organizational rules rigidly prescribe the temporal paths of occupational and earnings advancement. These rigid schedules are usually found in workplaces where the majority of workers are engaged in a very few career lines, or where multiple career lines exist, but there is little opportunity for transferring among them. Such schedules often result from unionization, since labor unions seek to standardize work arrangements. Even the effects of education and experience that exist under this type of personnel system vary across cities in ways suggesting an influence of general societal beliefs that educated and experienced workers should be paid more. Because such beliefs do not specify how much more, compensation schedules vary widely. Education and experience appear to bear stronger relationships to earnings in large nonunionized organizations that encompass many occupational specialties. However, even in these organizations, societal notions of equity and custom may affect wage structures. In Japan, for example, both seniority and family size are major determinants of salary in large companies (Dore 1973).

Sociological accounts differ from economic explanations in recognizing that the rewards of work derive from job occupancy and that a relatively enduring structure of jobs determines the relationships of individual effort, ability, and performance to work rewards. In the sociological view, jobs are assigned wage rates via processes operating at the societal and organizational levels; and the mechanisms that match individuals to jobs produce associations between individual effort, ability, and training, on the one hand, and work

rewards, on the other. Jobs differ in the routes by which they are entered and in the extent to which performance can affect work rewards.

What influences advancement is not the attributes of individuals per se, but their attributes in relation to organizational positions. Organizations define the criteria by which ability is identified. To the extent that ability is not tied to those criteria, it will not be recognized and rewarded. If individuals of limited ability are able by chance or other more calculated means to meet the criteria by which ability is identified, they will be assumed to have ability by an inference process in which the direction of causality is reversed. An important consequence of this system is that factors affecting access to positions, of which ability is only one, and factors affecting performance in accordance with organizationally recognized criteria, including the willingness to conform to organizational goals and practices, have an important influence on long-term career outcomes.

Given the importance of the structure of jobs in mediating the relationship between individual attributes such as education and experience and job rewards, it is not surprising that unchanging attributes have little direct effect on rewards within job status categories. However, they have an important effect on careers via their influence on access to positions in the structure of jobs. Education is a major determinant of access to job ladders and career lines, and movement within these produces relationships between education and experience and work rewards. The organizational hierarchies to which college graduates, especially those from preferred colleges, have access increase the effects of college on career attainments over time. These hierarchies are moved through via experience. Within at least some career lines, education increases rates of promotion and wage gain (Rosenbaum 1984; Petersen and Spilerman 1990; Sicherman and Galor 1990). Education bears a positive relationship to within-firm and within-occupation mobility and a negative relationship to mobility between occupations, firms, and industries, as well as a negative relationship to moves to unemployment (Sicherman and Galor 1990; Cheng and Kalleberg 1996; DiPrete and Nonnemaker 1997). When mobility does occur between occupations and firms, education increases the likelihood that these moves are voluntary and in an upward direction. Education also helps to buffer workers

from economic turbulence. Young, educated workers are both helped less by organizational expansion and hurt less by organizational contraction (Rosenbaum 1984; DiPrete 1993; DiPrete and Nonnemaker 1997).

Over time, career histories become differentiated in the timing and occurrence of advancement. Early recognition and achievement relative to members of the same entry cohort have long-term effects on career mobility. Those receiving early promotions have more rapidly advancing subsequent careers and ultimately attain higher-level positions and higher earnings than those not receiving early recognition (Stewman and Konda 1983; Rosenbaum 1984). The age when a person enters a position bears a negative relationship at career advancement (Petersen and Spilerman 1990; Rosenfeld 1992). The early recognition of "stars" and its cumulative effect on subsequent career movement has been argued to occur as a result of labeling processes that identify such individuals as especially able—as high achievers who are likely to achieve more.

One problem in research on career mobility has been the limited availability of actual measures of worker ability and performance. Most research has studied the effects of education; formal on-the-job training; and informal training acquired through experience in the labor market, in a firm, or on a job. This set of influences is not only limited, but measures of these influences have tended to be crude and indirect. Informal training through experience has usually been inferred from the durations of time spent in the labor market, in a firm, or on a job. Since direct measures of ability and performance have rarely been obtained, knowledge of the effects of ability and performance on career mobility remains limited.

In both theory and research, there has been relatively little attention paid to the influence of worker characteristics other than ability and performance. There is evidence that individual differences in work and job values affect entry into career lines and that these change over the career course, in part as a result of experiences in the labor market (Lindsay and Knox 1984; Judge and Bretz 1992). However, the effect of workers' values, normative beliefs, preferences, and personality characteristics on career mobility has not been

studied, and individual variation in these characteristics has often been assumed to be either unimportant or nonexistent. Similarly, little attention has been paid to the influence of noncareer events and activities on career advancement. There has been some limited study of the effects of family roles, which indicates that marriage and children have different effects on the career advancement of women and men, but relatively little is known about the effects of family and other noncareer events and activities on career mobility.

Apart from ability and performance, the worker characteristics receiving the most attention in research on career mobility have been ascriptive characteristics such as gender, race, and ethnicity. The structure of the labor market mediates the relationship of these characteristics to job rewards, since these characteristics become a basis for the differentiation of job ladders and career lines, as well as a basis for access to the jobs within them (Spilerman 1977; DiPrete 1989; Marini and Fan 1995; Yamagata et al. 1997). Because other measures of worker characteristics and the process of employer evaluation and selection have received little research attention, however, understanding of the multiple factors that produce differences in career mobility among groups defined by ascriptive characteristics remains limited.

Another type of worker characteristic that has received some research attention is the social ties of workers, particularly as used in the process of job change. It has been argued that social networks provide a kind of capital—social capital—that is useful to workers in career advancement. Social ties of high status are seen as furthering career advancement more than those of low status, and it has also been argued that weak social ties are more helpful than strong social ties because weak ties provide a less redundant source of information and influence (Granovetter 1974; Lin 1990). There is evidence that workers do rely on others whom they know in the process of job change, but the extent to which social ties are a source of information and influence varies with the structure of the labor market and a worker's place in it. In China's largely state-controlled economy, a worker's social ties are not used as a source of information but are a source of influence on state authorities with decision-making power over jobs. In market economies, social ties are used as a source of both

information and influence, although the extent to which they are used varies across countries and for different types of career lines (Wegener 1991; Bian and Ang 1997). In at least some countries, workers in lower-status positions are more likely to use social ties when changing jobs than workers in higher-status positions. Evidence has been inconsistent on whether the use of social ties in obtaining jobs produces better outcomes, but when social ties are used and have an effect, obtaining help from those of high status rather than low status increases job rewards. Empirical evidence on the influence of the strength of social ties has been inconsistent, in part because the strength of social ties has been defined and operationalized in a variety of ways. In some countries strong social ties have been shown to be more helpful than weak ones. In other countries weak social ties are more helpful for workers in jobs of high status, whereas strong social ties are more helpful for workers in jobs of lower status (Wegener 1991; Bian and Ang 1997).

SELECTION BY EMPLOYERS

Movement within a career line is affected not only by the characteristics of workers but by the characteristics and actions of those empowered by employers to make hiring and promotion decisions. Evaluation of performance and ability is usually based on incomplete information. In many jobs, performance is difficult to assess. Ability is even harder to assess, because it is inferred from performance. In addition, human perceptive capabilities are limited and variable. As a result, employers tend to rely on readily available information, or "signals," such as the amount of education attained, where it was attained, the amount and types of prior job experience, observable personal attributes, and evidence of past performance such as the rate of career advancement and prior job status and earnings (Spence 1974). The use of such signals is particularly likely when job shifts are made between organizations and between job ladders within an organization rather than within an organization or a job ladder (Rosenfeld 1992). The criteria on which individuals are evaluated are therefore often superficial, and having the resources (i.e., money, knowledge, and skill) to identify the way the evaluation process works and acquire an appropriate set of signals plays an

important role in career advancement. Because of the difficulty of obtaining information, employers are susceptible to employees' attempts to supply and manipulate information about themselves as well as others.

Another influence on the evaluation of ability and performance is attitudes and beliefs previously acquired by those with decision-making authority. Information is unconsciously filtered and interpreted through that cognitive lens. The effect of prior attitudes and beliefs is evident in the prejudice and stereotyping triggered by ascriptive characteristics such as gender, race, and ethnicity (Hamilton 1981; Marini 1989), which have been a focus of theories of discrimination in the labor market (see, e.g., Blau 1984).

In addition to the difficulties that arise in assessing performance and ability, personal relationships and political coalitions influence mobility. As noted, there is growing evidence that personal contacts and relationships can constitute important sources of information and influence in gaining access to jobs. For workers seeking advancement, they can provide information about available positions and how to apply or present oneself favorably as a candidate. They can also result in preferential treatment based on personal liking and trust, shared interests, or expected gain on the part of those making hiring and promotion decisions. For employees responsible for hiring and promotion, personal contacts and relationships can provide information about candidates that reduces the risk of error in the selection process and increases the likelihood that individuals with similar interests and a sense of loyalty or indebtedness to them will be advanced. Personal contacts and relationships can also affect decisions if they lead to a desire to gain favor with others supportive of a candidate. Because those making hiring and promotion decisions can act to advance their own interests and the interests of others, a candidate's position in workplace political coalitions can affect advancement prospects.

MARGARET MOONEY MARINI

OCCUPATIONAL PRESTIGE

Individuals have repeatedly demonstrated an ability to rank occupations according to their prestige, a relative social standing in a society. Occupational prestige is one of the most empirically studied aspects of stratification structure in modern societies. Social stratification theories, however, differ

in their views of the concept of prestige. Wegener points out that theories vary primarily in their suppositions of the foundation on which prestige is based, that is, achievement, esteem, honor, or charisma. Wegener also distinguishes two types of stratification theories, one that views prestige as a hierarchy of positions and the other as an attribute of socially closed groups.

By and large, stratification theories that emphasize order in society (e.g., functionalist theories) conceive prestige as an attribute of individuals or of individual social positions that form a hierarchy. Stratification theories that emphasize conflict (e.g., Weber) think of prestige as designating social aggregates, or individuals within social aggregates, influenced by social closure processes. (Wegener 1992, p. 255)

Despite such variation in theoretical views, most empirical studies share the notion that occupational positions are hierarchically ordered along a single dimension as judged by the individuals in the society. Efforts to measure such a concept involve a reputational approach in which respondents are asked to evaluate occupations.

The modern study of occupational prestige dates to a landmark survey fielded in 1947 by the National Opinion Research Center under the direction of Cecil C. North and Paul K. Hatt (Reiss 1961). Although others had conducted earlier investigations in the United States, NORC's national sample and broad coverage of the occupational hierarchy became the model for later inquiries. Perhaps the best known product of the North-Hatt study was Duncan's Socioeconomic Index (SEI) (1961), which assigned to each detailed occupational category a predicted prestige score based on the age-standardized education and income characteristics of occupational incumbents reported by the 1950 Census of Population. Although this index proved to have somewhat different properties than prestige, it exploited the limited occupational titles evaluated by the North-Hatt study to construct the first metric scale of socioeconomic status for all occupations.

In the 1960s, a second generation of studies was carried out by NORC (Hodge et al. 1964). Piecing together surveys from 1963, 1964, and 1965, Siegel (1971) generated the first prestige

scale for all Census occupations. This scale served for twenty years as the foundation of socioeconomic status scores, and it became the backbone of Treiman's International Prestige Scale (1977). In 1980, however, a major change in the occupational classification system employed by the U.S. Bureau of the Census called into question scores based on earlier classifications of occupational titles, since there was no sensible way to match old and new categories. In 1989, the NORC General Social Survey undertook another periodic sounding of Americans' evaluations of the general social standing of occupations (Nakao and Treas 1994). In the 1989 survey, a total of 740 occupational titles were selected to ensure reasonable coverage of the 503 detailed occupational categories of the 1980 census classification system. These titles were rated by a sample of 1,166 respondents, each of whom rated 110 occupations. The evaluation involved sorting cards, each bearing one occupational title, onto a sheet displaying a nine-rung ladder of social standing (from "1" for the lowest possible social standing to "9" for the highest possible). Based on their ratings, a score was calculated for each occupation and was converted to a scale so as to have a logical range from 0 (lowest) to 100 (highest) of prestige scores. For use in data analyses of most social surveys, in which occupations are coded according to occupational categories, scores assigned to categories, not titles, become necessary. Thus, using the scores for occupational titles in respective categories, a score was computed for each of the 503 detailed occupational categories of the 1980 census. The 1989 survey, which was the first to collect evaluations for all occupational categories at one time, yielded new prestige scores. These scores became the basis for updating the Socioeconomic Index (Hauser and Warren 1997).

Five generalizations may be drawn from the empirical research on occupational prestige.

First, very different methods for soliciting occupational evaluations yield very similar prestige hierarchies. Presenting respondents with an occupational title (e.g., electrician), the North-Hatt study asked them to "pick out the statement that best gives your personal opinion of the general standing that such a job has." Five response categories, ranging from "excellent standing" to "poor standing," were presented, along with a "don't know" option. One might readily fault the ambiguous

instructions calling for both a “personal” opinion and a reading of “general” standing. Nonetheless, the results proved virtually identical to those of the 1964 and 1989 surveys, which asked respondents to sort cards bearing occupational titles onto a “ladder of social standing,” the method that became the primary standard against which all other inquiries are evaluated (Nakao et al. 1990). The 1964 study went on to ask respondents to sort occupations onto a horizontal ruler according to another specific dimension (e.g., freedom and independence, perceived income, how interesting the work). However different the tasks, the correlation with social standing evaluations was over .90 for eight of nine dimensions.

Even when respondents are instructed to cluster occupations according to their similarity (rather than to rank them by social standing), multidimensional scaling methods reveal that one of the organizing principles behind judged similarity is a prestige hierarchy. Burton (1972) first demonstrated this with a nonrandom subsample of volunteers solicited from an advertisement in the Harvard student newspaper. Kraus et al. (1978) achieved similar results with a representative sample of 463 urban Israelis. To confirm that people view occupations in terms of an up/down classification scheme, Schwartz (1981) showed that ranking occupations according to “vertical” paired adjectives (e.g., top/bottom) yields results highly correlated with prestige scores, while rankings based on evaluative (e.g., kind/cruel), potency (e.g., big/little), and activity (e.g., slow/fast) dimensions fail to replicate prestige orderings. Studies that directly asked the respondents on what basis they rated occupations, or that asked them to rate occupations on selected dimensions such as “value to the society” or “power,” did not culminate in conclusive results. Individuals’ evaluations seem to be based on their judgments of the “overall desirability” of occupations (Goldthorpe and Hope 1974; Hauser and Featherman 1977). In short, the prestige hierarchy is so central to how we evaluate occupations that it emerges from virtually any reasonable effort to elicit it.

Second, overall prestige rankings are very stable over time. Hodge et al. (1964) reported a correlation of .99 between the 1947 North-Hatt study and their own in the mid-1960s. Nakao and Treas (1994) found a correlation of .96 between

the mid-1960s and 1989. This stability is not surprising. First, the relative income and education levels associated with various occupations are quite stable over time (Treiman and Terrell 1975). Second, to the extent that prestige is fixed by the division of labor and workplace authority, we do not expect the prestige of flight attendants to soar above that of pilots.

This is not to say that prestige never changes. Hodge et al. (1964) noted modest gains for blue-collar occupations, an upswing in scientific occupations and the “free” professions (e.g., “physician”), and a downturn in artistic, cultural, and communication occupations. Nakao and Treas (1994) compared the scores for 160 occupational titles evaluated in both 1964 and 1989 and found that the mean score moved up from 45.2 to 47.5 while the standard deviation declined from 17.3 to 15.8. They noted especially that the bottom of the American occupational prestige distribution shifted upward between 1964 and 1989. Low-status service and farming occupations especially came to be more favorably evaluated (see Table 1). This may be, in part, due to changes in the occupation itself. Farmers, for example, have undergone changes and have come to be seen as “agribusiness” owners. Thus, change in prestige may occur not only because of the succession of new generations who hold different views, but also because all age groups change their thinking about the relative standing of occupations. Changes in the general public’s familiarity with an occupation can also affect its rating, as demonstrated for “nuclear physicist” between 1947 and 1963 (Hodge et al. 1964). Thus, individual occupations change even though the overall ranking of occupations remains quite stable over time. The growing prestige of low-status occupational titles warrants further study, especially because it is inconsistent with socioeconomic trends observed in the workforce and in the workplace—the growing inequality in earnings, the decline of unionized blue-collar employment, the influx of traditionally devalued workers like women and immigrants, and the absence of systematic skill upgrading for blue-collar workers (Nakao and Treas 1994).

Third, prestige evaluations are surprisingly comparable from one society to another. Arguing that industrialization everywhere demands a similar organization and reward of work, Treiman

OCCUPATIONAL PRESTIGE

**Prestige Scores for Selected Occupations in the United States, 1964 and 1989
(1980 Census Major Occupational Categories)**

Occupational Title	1964	1989
Managerial and Professional Specialty Occupations		
Department head in a state government	80	76
Banker	72	63
General manager of a manufacturing plant	64	62
Lunchroom operator	31	27
Accountant	57	65
Chemist	69	73
Public grade school teacher	60	64
Clergyman	69	67
Lawyer	76	75
Musician in a symphony orchestra	59	59
Technical, Sales, and Administrative Support Occupations		
Medical technician	61	68
Manager of a supermarket	47	48
Insurance agent	47	46
Travel agent	43	41
Cashier in a supermarket	31	33
Telephone solicitor	26	22
Secretary	46	46
Post office clerk	43	42
Shipping clerk	29	33
Bill collector	26	24
Bank teller	50	43
Service Occupations		
Housekeeper in a private home	25	34
Policeman	48	59
Bartender	20	25
Cook in a restaurant	26	34
Janitor	16	22
Barber	38	36
Farming, Forestry, and Fishing Occupations		
Farm owner and operator	44	53
Gardener	23	29
Logger	26	31
Precision Production, Craft, and Repair Occupations		
Airplane mechanic	48	53
Superintendent of a construction job	51	57
House painter	30	34
Baker	34	35
Operators, Fabricators, and Laborers		
Saw sharpener	19	23
Welder	40	42
Assembly line worker	27	35
Bus driver	32	32
Locomotive engineer	48	48
Filling station attendant	22	21

Table 1

SOURCE: Nakoa and Treas (1994); Siegel (1971).

(1977) assembled eighty-five prestige studies of sixty nations, tribal societies, and territories. Comparing the United States with fifty-nine other societies yielded an average intercorrelation of .837; in other words, about 70 percent of the variation in U.S. prestige evaluations is shared in common

with the “average” society available to Treiman. To be sure, the correlations ranged from .98 for Canada to .54 for Zaire. Prestige hierarchies are similar, but not identical. Notable differences relate to level of economic development (Treiman 1977) and the greater appreciation of manual

labor in socialist societies (Penn 1975; for a Chinese exception, see Lin and Xie 1988).

Fourth, subgroups within a society also tend to agree about the relative ranking of occupations. Efforts to discern differences between blacks and whites, between those employed in more versus less prestigious jobs, have typically found little effect of the respondent's social location on his or her view of the occupational hierarchy (e.g., Goldthorpe and Hope, 1972; Kraus et al. 1978). To be sure, higher-status groups assign somewhat higher absolute rankings to high-status jobs than do lower-status groups, who tend to boost lower-status jobs somewhat (Hodge and Rossi 1978). Apparently, this phenomenon does not arise because groups hold self-serving views of the social order. Instead, high-status individuals agree more among themselves and, thus, avoid random ranking errors that move both high- and low-status occupations toward the middle of the distribution. In comparison to the differences among individuals in their ratings (i.e., reported interrater correlations range from .42 to .745), the variation between groups is smaller than the variation within groups (Hodge et al. 1982). Since location in the social structure has been shown to influence so many other attitudes, it is surprising that groups agree so closely on the order of occupations. The mechanisms leading to this consensus are not well understood. By early adolescence, however, children can agree on how jobs rank (Gunn 1964).

Fifth, the main factors associated with an occupation's prestige are its education and income levels, the basic logic behind the original construction of the Socioeconomic Index (Duncan 1961). Socioeconomic scores based on these two factors account for about 80 percent of the variation in prestige attributed to different occupations (Hodge 1981). Based on the 1989 prestige scores and the occupational data from the 1990 U.S. Census, Hauser and Warren (1997) also reported that in several models they used, between 70 and 80 percent of the variance in occupational prestige was accounted for by occupational education and earnings.

In the studies of status attainment models, socioeconomic status scores were demonstrated to be superior to prestige scores in accounting for a son's occupational achievement using his father's status (Featherman et al. 1975; Featherman

and Hauser 1976; Treas and Tyree 1979). It would be a mistake, however, to dismiss occupational prestige. Subgroups of raters agree not only on the prestige of an occupation, but also on how prestige differs from the occupation's socioeconomic location (Hodge 1981). Furthermore, a more recent study by Kerckhoff et al. (1989) showed in a comparative study of status attainment in the United States and Great Britain, that differences between the two countries were illuminated in the models using prestige scores, but not in the models using the Socioeconomic Index. The British data yielded stronger intergenerational effect on the respondents' occupations than did the United States data when prestige scores were used. This implies that the prestige scale captures different aspects of the status attainment process than the Socioeconomic Index does.

However important the educational requirements and economic rewards of occupations, they are not alone in determining the prestige accorded occupations. The racial or age composition of jobs may also figure in their public evaluation. Even controlling for education and occupation, a higher proportion of nonwhites in an occupation is associated with a lower prestige rating (Siegel 1971). Occupations dominated by the very young or the very old are similarly disadvantaged (Siegel 1971). However, the proportion of women in an occupation was shown to have no or little effect on prestige (England 1979; Bose and Rossi 1983; Fox and Suschnigg 1989).

There is no conclusive evidence that American respondents consistently downgrade the status of female-gendered occupational titles (e.g., policewoman) as compared with male titles (e.g., policeman). However, male (but not female) respondents do downgrade the standing of occupations in which women find employment—a relation that holds after the income and education levels of workers are taken into account (Meyer 1978). Further studies are warranted investigating systematic associations between gender and occupational evaluation.

Empirical studies of occupational prestige are based on the notion that prestige represents a hierarchy of social standing of individuals or aggregates based on their occupations. This notion is widely used in analyses of social survey data as a

variable indicating an individual's social status. While it is a useful index, the assumption behind its application as a measure of social status is that individuals' social positions are manifested by the occupations they hold. This assumption is rooted in the fact that occupation is a means through which social and economic resources are distributed. Furthermore, occupation is salient in one's life, providing not only economic needs, but also social relations that establish one's role in a society. This assumption may hold true in most industrialized countries, yet it perhaps deserves a further consideration in future research. As to what measure is appropriate as an index of social status in what context (for example, socioeconomic scale versus prestige scale), further research is called for that would lead us to a more thorough understanding of the stratification system and the process of individuals' attainment of social positions within it.

ORGANIZATIONAL EFFECTIVENESS

See Bureaucracy; Complex Organizations; Industrial Sociology; Organizational Structure; Social Organization.

ORGANIZATIONAL STRUCTURE

Organizations are composed of a variety of elements. Perhaps the fundamental component is *organizational structure*, the set of interrelationships (social bonds) between positions. Even organizations of globe-encircling proportions, such as multinational corporations, demonstrate "the consciously coordinated activities of two or more people" (Barnard 1938, p. 73). Similarly, it may be argued that relationships between and among sets of such organizations form the social structure of whole societies.

Within an organizational structure, groups or sets of social relationships can be differentiated by task specialization, known as the *division of labor*. People are assigned to specific positions within an organizational structure to increase the specificity of tasks and the reliability with which they are performed. Organizational structure is both (1) an outcome resulting from interactive processes between elements within the organization, as well as between the environment and the organization, and (2) a determinant of those interactive processes. Organizational structure calls forth or inhibits particular behaviors by organizational participants.

Interaction among parties to a relationship results in shared understandings that become part of an organization's culture. Focusing as it does on relationships constituting organizational structure, the social systems perspective for organizational analysis has been criticized as having a static cast. By contrast, organizational theorists contend that studying social processes among constituent parties is dynamic because it examines how social change occurs as participants grant or withhold their consent for collective actions. When the volitional and cognitive exigencies among constituents change, their behavior toward each is altered. Negotiation among organizational participants leads to the creation of new relationships, fluidity in existing relationships, and the potential for breaking off longstanding relationships. Processes influencing expectation and negotiation are complicated by the structural advantages enjoyed by dominant constituent parties. Whether change in agreed-upon relations is viewed as desirable often depends on whether a given constituent party perceives change to be disproportionately beneficial to itself when compared with the benefits to other specific constituent groups or to the overall organization. Moreover, more powerful constituents can, to their own benefit, cloud less powerful constituents' perceptions of what is actually in the latter's self-interest.

Much traditional theory and research on organizations, almost always implicitly (sometimes explicitly), assumes that decisions by upper participants benefit the entire collectivity. Most analyses do not differentiate benefit to the collectivity from benefit to upper-, middle-, or lower-level participants. Most researchers simply proceed on the implicit assumption that owners and managers are prime, if not sole, legitimate participants in and *entitled* beneficiaries of organizational structure. It is assumed, moreover, that lower-level employees in particular, and lower level participants generally, are incidental to the social construction of the organization, and are thus passive contributors to and beneficiaries of organizational structure. By contrast, modern sociological theory (as expressed throughout the present discussion of organizational structure and its correlates) increasingly differentiates among upper-, middle-, and lower-level participants as well as, separately, the organization as a whole. Thus, in this view, a much broader array of constituents contributes directly

or indirectly to organizational survival and therefore merit an appropriate share of rewards. Researchers need explicitly to identify and differentiate all participants and constituents that contribute directly or indirectly to an organization. Allocation of resources to an organization's tasks, defined through the division of labor, critically affects the power balance between participants, thus raising important and politically disturbing questions. Organizational structure, composed of collectively endorsed and enacted resource allocation agreements, can be usefully understood from an "organizational justice" perspective.

Organizational justice research seeks to understand how resources are allocated in ways believed to be "fair" by various interactants. The perceived fairness of resource allocations by organizational participants is distributive justice; the perceived fairness of the process through which resource allocation decisions are made is procedural justice. Both distributive justice and procedural justice interact to influence organizational participants' perceptions of fairness. Distributive justice may follow underlying norms of allocation, including an assessment of both the quantity and the quality of participants' contribution to a given effort (thus, their earned equity in the organization), as well as the extent to which resources are evenly allocated among participants (thus, their right to equal treatment) and, moreover, how much participants *need* the resources they receive (thus, their right to basic means for survival) (Linkey and Alexander 1998). These norms underlying the allocation of resources may affect the satisfaction of organizational participants through the outcomes of allocation decisions. Procedural justice has two components: the structure and form of procedures through which resources are allocated, and the social and emotional relations between parties in an exchange relationship (interactive justice). As Brockner and Siegel (1995) point out, the difference between these two components may signal the difference between how much control participants have over the process of allocative decisions, and their intent toward others in making such decisions.

Researchers have proposed two different viewpoints to explain variations in organizational participants' satisfaction with procedural and distributive justice. The self-interest explanation is that individuals wish to maximize their resources and

are more satisfied when their rewards are greater. The group-values explanation is that individuals evaluate themselves in the context of group membership; the perception of an individual as fair is colored by perceptions of the fairness of his or her group, and how resources are allocated to an individual indicates his or her worth relative to other members of the group. Both the self-interest and the group-values explanations have helped to explain organizational participants' satisfaction with the allocation of resources. These two approaches are reflected in the focus of allocation rules based on the *attributes* and *contributions* of recipients (Cook and Yamagishi 1983). *Attributes* are personal characteristics such as gender, age, and ethnicity that are used to determine social status. *Contributions* refer to valued inputs made by participants in an exchange relationship; among these valued inputs are performance and effort. Classification is not always clear-cut; for example, *ability* might be classified as an attribute in some circumstances but as a contribution otherwise.

While most of the organizational justice literature focuses on the contributions of organizational participants, a growing number of studies focus on their attributes. Evidence suggests that the degree to which organizational participants endorse norms for resource allocation to individuals is associated with their own placement within an organizational structure. Moreover, endorsement of these norms may also vary according to demographic characteristics such as age, gender, and income, as well as cultural factors such as political affiliation and religious affiliation (Jason S. Lee and Stolte 1994; Linkey and Alexander 1998). An important question for further research is whether individuals with given attributes alter their endorsement of allocative norms as their own placement within the organization's structure varies over the course of their own tenure in the organization. Further, *satisfaction* with resource allocation outcomes is associated with structural, demographic, and cultural factors (Huo et al. 1996; Irwin 1996); although the evidence for a consistent association between gender and satisfaction is mixed (e.g., Sweeney and McFarlin 1997; Lee and Fahr 1999). Given the level of ethnic and gender segregation within the workforce, particular tasks appear to be associated with certain attributes as workers are distributed into organizational positions. Additionally, institutional factors, such as

state legislation, and cultural values may affect allocators' distribution norms. In some cases, distribution norms for external constituents related to a given organization through its impact on their culture, economy, or community may differ from distribution rules for those participating directly in an organization. These factors contribute to differential allocation of resources to participants within organizational structures, and their different perceptions of, and satisfaction with, allocation outcomes.

Blau and Scott's *cui bono* criterion (1962) explicitly raises the question of who benefits from particular policies and characteristics of organizational structure. Blau and Scott suggest a fourfold topology of organizations: (1) mutual benefit organizations, such as clubs, where presumably egalitarian *members* are prime beneficiaries; (2) business or industrial organizations, where *owners* are prime beneficiaries; (3) service organizations, such as hospitals, where *clients* are prime beneficiaries; (4) commonweal organizations, such as the State Department, in which the *public-at-large* is prime beneficiary. For each type of organization, researchers should systematically examine patterns of benefit by virtue of a constituency's location either (1) externally in an input-output exchange relationship to the organization or (2) internally as upper-, middle-, or lower-level participants in its organizational structure (Etzioni 1961). A fully developed distributive justice perspective would evaluate the benefit a constituency derives from the organization relative to its contribution to the organization's *sustained* existence (Alvarez 1979).

Not only does the allocation of resources impact organizational structure, it also affects assessments of organizational structure in terms of effectiveness and efficiency. *Organizational effectiveness* may be defined as the capacity of an organization to produce intended and unintended outcomes. An organization may unknowingly, unintendedly, or inadvertently serve the interest of a given constituency. Such "latent" functional consequences are seldom explored and documented in advance by social scientists. More usually, latent functions are discovered when they become manifest because organizational activities are dramatically altered or the organization ceases to exist, with the consequence that former latent beneficiaries are severely affected. Indeed, previously unrecognized support from such latent beneficiaries may have

been critical to organizational well-being (perhaps survival), and the disaffection of such beneficiaries might threaten future organizational survival. But the concept of "latent" functions has not yet produced a research literature.

Notwithstanding vexing conceptual problems raised by the issue of "latency," research on organizational effectiveness has traditionally overemphasized manifest purposive action, by reference to the organization's *intended* outcomes (or formal goals). It is obvious, but critical to note, that if the organization goes out of existence, it can no longer accomplish anything. Hence, perhaps the most important task (latent or manifest) for any organization is its continued survival. While some organizations are designed, and are prepared from the outset, to go out of existence upon completion of the task for which they were initially created, many, perhaps most, organizations are quick to acquire new purposes so as to maintain themselves in existence. Indeed, some organizations such as political parties and governments have been known to kill their own people in attempts to remain in existence. Thus, the "cost" per se of getting things done is, at least theoretically, of no consequence in assessing organizational effectiveness. Traditionally, assessing effectiveness requires the comparison of organizational activities to an optimal standard outlined in organizational goals. Since different organizational constituencies (or stakeholders) may have different and sometimes conflicting expectations, this traditional approach has serious limitations.

By contrast, the "cost" of getting things done is paramount in any assessment of *organizational efficiency*. "Costs" of accomplishing any given task can be of various kinds; and each type of cost may be assessed by various techniques, with varying degrees of efficacy. Unfortunately, social science has not reached any consensus on what types of costs and benefits are worth measuring. Thus, in its broadest sense, *efficiency* may be viewed as the assessment of an organization's inputs (either in kind or in the distribution of those inputs) relative to its output, in a more narrow view it is simply cost per unit of production. Traditionally, efficiency is reflected in economic analyses and cost-accounting techniques (e.g., Rossi and Freeman 1993). However, it may reflect other kinds of resources, such as opportunity costs; risk; and political, social, and social benefits. Like effectiveness, the

attributes and positions of organizational stakeholders influence how efficiency is perceived and assessed.

This review is categorized into four functional requirements for social system survival, as posited by Parsons (1960): (1) adaptation to the environment, (2) goal attainment, (3) integration of its members into a “whole,” and (4) creation of cultural understandings (often latent) among members by which the meaning of collective action can be judged. We do not suggest Parsons’s AGIL scheme is the only or the definitive way to classify organizational structures or attendant activities. Rather, AGIL focuses on the totality of a particular organization (as a social system) and raises questions of how its organizational structures come into being, change, and persist; within each category we question “who benefits” from consensual, consciously coordinated activities.

ADAPTATION TO THE ENVIRONMENT

“Environment” refers to a broad array of elements that are “outside” organizational boundaries but are relevant to organizational functioning. Organizational boundaries are the set of agreed-upon relationships that constitute organizational structure. Dill defines the task, or technical, environment as all features of the environment “potentially relevant to goal setting and goal attainment” (1958, p. 410). Established beliefs and practices embedded within the organization may systematically affect the shape and operation of the focal organization’s structure. Scott (1998) terms these influences the *institutional environment* of organizations; others refer to it as *organizational culture*. An organization may seek to control or reshape all or some elements in its environment as a means to lessen uncertainty about its capacity to endure. An organization might reshape its own organizational structures if it is unable to reshape the environment (e.g., Aldrich 1979). Dess and Beard (1984) suggest that Aldrich’s topology of environmental characteristics (1979) may be classified into three categories: (1) munificence, or the environmental availability of resources needed by organizations; (2) complexity, or the similarity or dissimilarity of environmental entities and their distribution across the environment; and (3) dynamism, or the degree of change in the environment.

Organizations are embedded within larger societies. The societal culture (relatively integrated sets of values and value-based orientations) of a given society directly affects the kinds of organizational structures that can be sustained by organizations. Nevertheless, organizational structures and their internal organizational cultures might be a stronger determinative force than the outer societal culture. Hence, some organizations are often viewed as determinative importers of social change into some societies (e.g., technology transfers by multinational corporations). Organizational culture and the external societal culture inevitably affect one another; exploring specific nuances at the interface between these two cultural arenas is still a matter for future research. Blau (1994) notes that differential mobility among social groups may alter organizational structures, either increasing or constraining opportunities. Gains in social equity made by groups characterized by gender, ethnicity, age, or socioeconomic status may result in the alteration of organizational structures. The ability of workers to form coalitions both within and outside organizations may alter organizational hiring, promotion, and retention practices. Such restructuring may increase the mobility of groups in gaining more equitable organizational positions, or it may retain inequalities through the eventual resegregation of occupations (Cohen et al. 1998).

Neither effectiveness nor efficiency is an unalloyed universal good. As given constituencies gain stature and power, they are able to reform, reconstitute, or create relationships accordingly; but what makes one constituency more effective and/or more efficient may impact negatively on either the effectiveness or the efficiency of another. Hence, while not its sole determinant, the *net balance of power* between constituencies is an important variable in the formation and maintenance of organizational structure. When environmental conditions remain relatively constant, the stratification of organizational structure may also remain relatively constant as it is being reified, recreated, and reenacted, given that those already well placed are advantaged within each new round of structured interactions. However, when environmental conditions are visited by strong or rapid changes for example, in political culture, technology, or rapid changes (for example, in political culture, technology, or demographic characteristics), these may precipitate renegotiation and

recalibration of social structures within the organization. Because modern organizations seldom resemble a zero-sum model, not all gains by one constituency constitute a loss for another. However, unless the organization continues to grow, prosper, and reward formerly well-rewarded constituencies, a sense of relative deprivation due to perceived loss of effectiveness and efficiency in obtaining organizational rewards may lead to intergroup conflict.

Thus, organizations are affected by the exchange of resources between organizations and various constituencies, including those providing resource inputs to an organization, the exchange of labor for wages, and those between organizations and consumers of outputs. Environmental pressures, including competition for resources, may influence organizations to change structure, including strategic alliances, mergers, joint ventures, downsizing, and divestitures. Organizations may choose to maintain or change relationships on the basis of competition, power to create stable market relations, and institutional attachments through interpersonal and interorganizational relationships (Baker et al. 1998). Such changes presumably allow organizations more flexibility in responding to turbulent and uncertain environments, and each changes the stance of an organization in relation to others that compete for related resources in a market. This is accomplished by increased organizational efficiency, in which decreased labor force size, or hierarchy, and increased organizational interdependence results in fewer costs in producing outputs. The impacts of such strategies have been consequential for workers' expectations of long-term connections to workplaces, and expectations about their careers. Workers increasingly expect duties to be assigned on the basis of experience and training rather than organizational structure (Powell 1996). Pugh and Hickson (1996) argue that as organizational environments become more turbulent and uncertain, organizations require a "redundancy of function" in which individuals are called on to have a wide variety of skills and fill multiple functions in a highly interdependent environment. Thus, workers develop flexible organizational "roles" rather than fulfilling a function based on a hierarchical position (Powell 1996). Older and younger workers may experience a sense of relative deprivation as a result of changes in organizational structure

and as their own expectations of future employment opportunities decrease (Lerner 1996). Lerner concludes that procedural justice in organizational restructuring has not led to distributive justice in terms of employment opportunities and expectations.

The *state* (the system of governance in a society) is another global element with pervasive repercussions for organizational functioning. The state may regulate the organizations directly by instituting programs within them or indirectly by state regulation of what an organization may produce or how it may transact with other organizations such as suppliers or consumers. Organizations may attempt to influence governmental actions so that public policy does not constrain them or so that it will actively benefit them. Organizations frequently influence legislation directly, as by activities of lobbyists on retainer. Organizations often mount campaigns either to achieve or to prevent the enactment of specific legislation by directly influencing general public opinion and particular voters. Even if legislation is passed over their opposition, organizations can achieve their purposes by subsequently influencing the allocation of resources for its enforcement. Fligstein and Mara-Drita (1996) note that market relations between buyers, sellers, and the state are characterized by a power struggle in which each participant mobilizes resources to enact its own interests in maintaining (or altering) current relationships.

Communities are attentive to organizations located in their midst since changes in organizational structure can have considerable repercussions for the community at large. As Scott (1998) points out, not all organizations are strongly tied to the communities in which they are located. Locally based firms have a greater vested interest in community prosperity than do geographically dispersed firms, and they may act to assure continued community prosperity. Organizations may strongly affect the allocation of public goods and services as well as specifications in local policies, such as zoning and tax laws. Organizations may affect communities in which they are located through either implicit or explicit threats of "exit" as well as by directly impacting regulatory and economic conditions. The number, size, and type of organizations located in a community also have widespread consequences for individual local residents. South and Xu (1990) compared industries

that dominate their local metropolitan economy with those that do not, finding that employees in dominant industries earn higher wages. Thus, organizations have important political, economic, and normative effects on individuals with or without organizational membership and on their community's organized power structures.

We now explore how organizations respond to and create their own environments, "Gatekeepers" are organizational participants at various levels who "selectively" permit information and people to traverse boundaries into and out of an organization. They "legitimate" particular environmental constituencies, with whom the organization then establishes institutional relations. Relations with constituencies not so "selected" become invisible, neutralized, or illegitimate. The breadth of the environmental domain that an organization claims in this manner has consequences for its stability. Narrow domains are associated with greater stability, while broad, inconsistently defined domains are associated with loss of function (Meyer 1975). At the same time, normative and regulatory forces outside organizations may exert pressures on gate-keepers to allow or disallow certain pieces of information or particular people.

"Loose coupling," or a seemingly weak relationship between parts of an organization (Pfeffer and Salancik 1978), is one of many ways in which organizations learn to deal with a broad environmental domain. This weak relationship allows change in one part of an organization to precipitate minimal or no change in other parts. Relationships between subunits or individuals in organizations, and relationships between the organization and other environmental entities, may be loosely coupled. Organizations may respond to potentially disruptive threats by very limited conformity in a specific sector, and yet this limited conformity projects an aura of complete organizational compliance. In reality, components of organizational structure affected by a given threat may be effectively uncoupled from many other components and processes, resulting merely in the appearance of compliance (DiMaggio and Powell 1983). Loose coupling can also lead to structural "inertia" in an organization's response to environmental changes, causing "lags" between environmental changes and adaptations to them on the part of various organizational structures. However, the degree to

which loose coupling is useful as a strategy depends on the particular situation and linkages involved. Loose coupling in terms of outsourcing labor, autonomous work teams, organizational networking, and increasingly separated divisional organizational forms have all been adopted in the last decade as a response to increased market competition and technical complexity. Such modifications of organizational structure are most often justified by upper-level participants as attempts to increase either or both the organization's efficiency and *responsiveness* (effectiveness) to environmental challenges perceived to threaten organizational survival. What is left unsaid, however, is that a narrow economic conception of what constitutes efficiency or effectiveness by upper-level participants, such as executives and stockholders, may have devastating consequences for middle- and lower-level participants as well as for the surrounding community. Indeed, the very fact that they are essentially disenfranchised from organizational decision making may engender a confrontational relationship with upper-level participants that may render all parties inefficient and ineffective for the process of inventing alternative problem-solving solutions that contribute to the organization's holistic and long-term well-being.

Assessing the effectiveness of an organization's capacity to adapt may be less focused on outcomes than on the processes of organizational change. Organizational theorists have suggested that organizational effectiveness is reflected in how well an organization acquires and processes information and with what flexibility and adaptability (Weick 1977). Galbraith (1977) contends that organizations reduce environmental complexity by changing communication structures within organizations. Other researchers suggest that organizations are effective when their subunits are congruent with the specific environment with which they interact, and when organizations overall are congruent with their environments (Lawrence and Lorsch 1967). Such perspectives of organizational effectiveness may not be linked to the achievement of goals but, from a managerial perspective, may rest in the survival, or profitability of organizations. As Lerner (and maybe others) demonstrate, such goals may not be satisfactory to middle- and lower-level participants whose employment opportunities and expectations may be adversely affected by a particular organizational adaptation.

Further, since organizational participation is affected by the demographic characteristics of participants, the specific demographic consequences (whether intended or unintended) of environmental adaptation must be examined.

Who benefits in the adaptation of organizations to the environment? Elites (fiduciaries, executives, and high-level managers) are only one kind of constituency vying for potential benefits derived from organizational structure. Middle- and lower-level organizational participants are often neglected in the research literature on organizational structure. Often, when research findings indicate that either an "organization" or a "community" benefits from a particular activity, what is really meant is that *upper*-level participants benefit. Certain populations (women and ethnic minorities, for example) participate differentially at upper, middle, and lower levels of organizational structure; thus, a focus on upper-level participants is insufficient to fully describe patterns of benefit.

GOAL ATTAINMENT

"Goal" refers to a desirable future state of affairs. *Official* goals are the formal statements put forth by organizations to state their general purposes (Perrow 1961). *Operative* goals, on the other hand, refer to "what the organization is actually trying to do" (Perrow 1961, p. 855). The degree of congruency between official and operative goals is variable. It is important to distinguish organizational goals from the motives of individual organizational participants (Simon 1964). However, researchers need to clarify how particular goal activity differentially benefits specific internal or external constituencies. Goals limit and direct organizational decision making and suggest criteria by which organizational performance can be measured.

Over time, organizations establish multiple, often disparate, and sometimes conflicting goals. Kochan and colleagues (1976) argue that goal multiplicity and conflict are associated with both horizontal (number of tasks at the same level of structure) and vertical (number of levels between the "highest" and "lowest" units) differentiation of organizational structure. In the pursuit of multiple goals, coordination of effort is necessary, leading to vertical differentiation of organizational

structure. Organizations change their goals over time, for both external and internal reasons. Thompson and McEwen (1958) contend that goals vary because interaction with elements *external* to the organization can be of two kinds: competitive or cooperative. The only competitive option in their discussion we call *bounded competition*, referring to the fact that the interaction takes place within the bounds of the normative structure (institutional environment) of the larger social system. By contrast, we conceive of *raw* or *unbounded competition* as taking place outside any normative order common to the contending parties and is not accounted for by Thompson and McEwen's discussion. In the extreme absence of common normative understandings, hostility between contending parties can rise to a level wherein one party believes itself justified in attempts to annihilate another. Accordingly, Thompson and McEwen define competition as rivalry between two or more organizations mediated by a third party. Organizations compete for resources viewed as desirable for organizational functioning. Thompson and McEwen discuss three cooperative styles of interaction between organizations and external elements, each underscored by a decreasing level of hostility: co-optation, bargaining, and coalition. Co-optation is the absorption of an external element into the organization, neutralizing its potential hostility by incorporating it within the organization's structure. Bargaining is direct interaction with environmental entities in which some kind of exchange takes place so that the organization can get what it desires. Coalition is an agreement, usually of specific duration for specific collective purposes, combining the efforts of two or more organizations, and restricting the right of each to set goals unilaterally. Notice that coalition requires very low levels of hostility between an organization and its partners; indeed, a potential outcome may be loss of separate identity and structural unification. These strategies can increase or decrease the size and complexity of organizational structure and the allocation of resources within it.

Organizational goals also change for *internal* reasons. Constituencies within the organization frequently form *coalitions*, initially for self-protection against real or imagined threats to the pursuit of their own interests. Each unable to impose its will on others, but fearing imposition, makes alliances with other constituencies perceived to be

friendly. Some such alliances capture key positions of the organizational structure, thus giving greater access to the allocation of organizational resources. This dominance can be maintained over time by securing the cooperation of other elements and coalitions within the organization through the selective distribution of resources. How central a given goal is to an organization may depend on the composition of the dominant coalition and the relative balance of power within it.

This discussion has emphasized the complexity of goals and goal setting, given a variety of internal and external factors. The processes by which groups or members of organizations gain power, and the loose coupling between goals and motivations, have a large impact on goal setting. It is useful to discuss the processes of power in organizations in more depth. Many theorists have proposed definitions of power, but it was Emerson who proposed one of the most useful: *Power* resides in the dependency of one on the resources of another (1962). Resource control theorists believe that individuals or organizational subunits exercise power because they allocate resources needed by others to reduce uncertainty or because their resources are specialized or are central to the workflow of the organization (Lachman 1989). Researchers have paid much attention to structural conditions associated with power in organizations. Spaeth (1985) found that resource allocation is central to task performance since lower-level employees are assigned to produce given outputs and are provided with the necessary resources to do so. The higher the level of the worker, the more discretionary resources she or he will have to allocate. Recently, researchers have explored the relationship between technological innovation and shifts of power among organizational members. Burkhardt and Brass (1990) found that early adopters of a computerized information system in a federal agency increased their centrality and power in organizational networks. These shifts did not completely alter the power structure since those in power were not completely displaced by early technology adopters. Barley (1986) makes clear that technology provides organizational members an occasion for structuring.” The same technological system may have different implications and may cause different social changes in different organizational structures. Thus, Barley disputes the claims by some researchers that

technology has objective material consequences regardless of the social contexts within which it exists.

Scott (1998) writes that organizations attempt to build structures not only to accomplish a division of labor, but also to create a structure of authority. As organizations become more formalized—that is, as procedures and rules are explicitly formulated—power differentials are built into the system and institutionalized. The distributive advantage of upper participants is not obvious since hierarchy is presumably built on specific task competence and power is vested for specific task achievement. Those with institutionalized power need not mobilize to have their interests served, since they control the flow of resources and information. The institutionalization of power contradicts resource control theory, which asserts that those who control the contingencies for change in organizations gain power. Lachman (1989) emphasizes that when the relative power of subunits changes, the previous power structure significantly affects the new one. He found that the greatest predictor of subunit power after organizational change was its degree of power before the change, regardless of its control over organizational contingencies or changes.

The complexity of goals within organizations creates a number of difficulties in assessing effectiveness. The use of *goals* as virtually the sole criterion for effectiveness places excessive focus on the outcomes, rather than the processes, of organizational activities. While some goals may be universally held within an organization, these are usually held with varying degrees of intensity by various constituencies. Moreover, multiple, and sometimes conflicting, goals are held by various organizational constituencies; notably those at different hierarchical levels, but also those defined by a variety of other factors. Goals may be difficult to operationalize for organizations such as human service agencies, and “fuzzy goals” may be adaptive in avoiding conflict or in concealing operative goals (Weiss 1972). Often, the evaluation of organizational effectiveness is skewed toward one or another constituency’s view of what constitute legitimate organizational goals or the priority assigned to given goals. Also, goal displacement may occur when compliance with indicators of good job performance (such as the number of calls taken per hour at a computer help desk) supplants

the intended outcome of job performance (solving computer users' technical problems).

Accordingly, evaluation researchers have suggested a number of strategies for resolving some of the conflicts in determining and measuring goals. Stake (1975) suggests "responsive" evaluation that takes into account multiple and conflicting constituencies' goals, treating each as a separate and valid view of organizational functioning. One of the goals of responsive evaluation is to inform each group of the others' perspectives. Patton (1997) suggests a shift from goals to outcomes, focusing on expected changes, maintenance, or prevention that are the intended focus of organizational activity. Scriven (1975) suggests "goal-free" evaluation that focuses on only the actual, measurable outcomes of organizational activities compared to a profile of the demonstrated needs of participants. "Goal-free" evaluation does not include a formal elicitation of goals nor a review of formal organizational documents, but focuses instead on the needs of organizational participants, whether these are formally stated or not. The success that these alternative perspectives have in circumventing goals as the focus of effectiveness evaluation is variable, but they do constitute an acknowledgement of the difficulties in assessing organizational effectiveness solely through goal attainment.

Organizational *efficiency*, like *effectiveness*, is also tied to the attainment of organizational goals, but measures attainment against its costs. Cost-effectiveness analysis measures the monetary benefits of a program against the financial costs of implementing it. Cost-benefit analysis can estimate the broadly conceived benefits of a program versus its various costs, but usually also monetizes the benefits and compares them. Not only do these types of analyses face the same challenges described above in determining how the effectiveness of organizational activity is to be determined, they must choose a cost-accounting perspective that also reflects a particular "interest group" perspective. Freeman and Rossi (1993) describe three cost-accounting perspectives: (1) The individual level weighs costs, benefits, and effectiveness from the perspective of the unit targeted by an organization (people, groups, or organizations). (2) The program sponsor level takes the perspective of the sponsor in valuing benefits and accounting for costs, and examines the profitability of a

given organizational activity. 3) The communal (or societal) perspective assesses both the direct and the indirect effects of organizational activity in a broad context and for a wide variety of participants. Both upper-level organizational participants and researchers have overemphasized the program-sponsor perspective, emphasizing short-term impacts and economic outcomes and short-changing factors that are integral to self-perceived well-being of often less powerful constituencies, such as the impact on their psychic, social, cultural, or political condition. Recent developments in "socioeconomics" seek to develop theoretical approaches that may bring these considerations under systematic analysis (Etzioni 1990, 1996, 1998; Granovetter 1985, 1992; Granovetter and Swedberg 1992). Monetizing such factors is difficult and controversial, but the costs and benefits of broader social and cultural factors both in monetary and other forms is included in efficiency studies using the communal perspective.

Economic analyses, however, frame their results in a monetary context for use by managers or policy makers, framing outcomes in ways that are less relevant to mid- and low-level workers, who do not control the allocation of resources. Additionally, it is difficult (and controversial) to monetize benefits, especially those involving complex social contexts, such as cultural and political changes. It may be difficult to combine multiple and/or conflicting goals in economic analyses, including the unintended consequences of organizational action. Finally, by definition, economic analysis takes an incremental approach to change, assuming that benefit is achieved if the benefits outweigh the costs. For some kinds of organizational activities, an incremental approach toward cost-effectiveness or cost-benefit analysis may not be appropriate if a partial change in outcomes is not desirable. For example, many programs designed to prevent drug use do not measure outcomes in terms of decreased drug use among participants, but in the extent to which total nonuse of drugs may be effectuated.

Setting and attainment of goals are complex processes affected by factors internal and external to organizations and by processes for power distribution. The *cui bono* criterion alerts the researcher not to take formal goals at face value but to identify how key actors and groups in coalitions

differentially benefit from goal activity. In spite of its tendency to persist, organizational structure can be and is altered to reflect the power of new alliances among internal and external constituencies who benefit from new institutional arrangements. Organizations survive because powerful constituent alliances continue to derive benefit from them.

THE INTERNAL INTEGRATION OF ORGANIZATIONAL STRUCTURE

Organizations cohere in part because some elements of organizational structure are designated to coordinate other organizational elements into a collective “whole” in the pursuit of goals. This discussion of integration will examine (1) how some organizational variables affect composition of organizational structure; (2) structure’s differential outcomes for stratified groups; and (3) who benefits from integration.

One factor important to integrating organizational members is technology, knowledge about how to get things done. Organizations often must increase coordination to achieve technically complicated tasks. Galbraith (1977) notes four mechanisms for increasing task coordination: (1) Rules standardize both acceptable actions and agreed-upon ends. (2) Schedules coordinate interdependent activities or multiple activities occurring at the same time. (3) Departmentalization routinizes the division of labor by grouping homogeneous tasks together. (4) Organizational hierarchy helps to coordinate tasks that are interrelated among departments. Organizational size can be an important factor affecting internal structure. Several measures have been used for size, including the physical plant, number of clients, or number of employees (Kimberly 1976). Most researchers have treated size as a determinant of organizational structure. It can be an indicator of demand for organizational services or products, providing constraints or opportunities for structural change.

These two variables are related to a number of structural outcomes, the most important of which are complexity or differentiation, formalization, and centralization. Complexity is the diversity of factors that must be simultaneously coordinated to get a task done. Horizontal differentiation is the

specification of component elements of tasks performed at the same level of organizational structure. Vertical differentiation is the number of levels of importance, power, and control among units. Multiple and complex technologies are associated with increased structural differentiation (Dewar and Hage 1978). Increased size (number of participants) is necessary to achieve high degrees of structural differentiation, although a large organization may be minimally differentiated and simply coordinated. Nevertheless, larger organizations are generally more structurally differentiated and more complexly coordinated (cf. Blau and Schoenherr 1971).

Formalization is the extent to which rules for behaviors and relations in organizations are explicitly specified for participants directly or indirectly associated with particular tasks. This means that formalized positions have standardized powers and duties, regardless of the particular individual incumbent. Organizations with routine technology have a greater degree of formalization (Dornbusch and Scott 1975) at a more minute level of detail. Glisson (1978) contends that routinized technology may produce greater formalization. Formalization, however, is only moderately associated with organizational size (e.g., Blau and Schoenherr 1971).

Centralization refers to the extent to which decision making in an organization is concentrated or dispersed. Dornbusch and Scott (1975) point out that organizations may engage multiple technologies that vary in terms of clarity, predictability, and efficacy. Tasks high on these dimensions are more likely to be centralized, but tasks low on the dimensions are likely to be allocated to specialists, decentralizing organizational authority. Centralization through rules is associated with use of routine technology (Hage and Aiken 1967). There is an inverse relationship between size and centralization: Larger organizations tend to decentralize decision making.

Recent organizational restructuring in the United States has resulted in some organizations becoming “smaller” in size than they were three decades ago. The adoption of new technologies including computer-assisted production and just-in-time inventory systems have resulted in a decrease in vertical hierarchy, and a flattened lateral

hierarchy. At the same time, the complexity of the technology and the need for increased coordination has increased interdependence of organizational subunits or “teams,” while centralization has decreased (Galbraith and Lawler 1993). Reengineering technologies has often resulted in changing the processes of work, rather than directly changing organizational structures, but has contributed to the increasingly interdependent relations among organizational subunits (Keidel 1994). Such reengineering has led to flexibility in team function, resulting in “semistuctures” in which some aspects of performance are prescribed, but the processes through which teams operate are not (Brown and Eisenhardt 1995). Scott (1998) notes, however, that the resources needed to successfully alter structure to function in a more lateral, independent fashion are considerable, and many organizations do not have the resources to make this kind of structural transformation.

Consistently with generalized values in the host society, organizational structure has differential outcomes for people of diverse identities. Labor theorists offer various explanations for *occupational segregation*, the organizational practice of reserving specific kinds of jobs for people of given ethnicity or gender. Occupational segregation results in lower earnings in jobs traditionally held by relatively powerless groups—minority men and white and minority women. Kaufman (1986) found that black men were more likely than white men to be employed in highly routinized, less skilled jobs and were less likely to be in job ladders involving increasing levels of status dominance over other workers. Tienda and colleagues (1987) found that, although women’s earnings increase as they move into jobs traditionally held by males, male incumbents experience a greater increase in earnings than their female counterparts. Some researchers contend that market forces have created an occupationally segregated labor force, while others believe that organizational practices are responsible. Bridges and Nelson (1989) argue that although market forces produce gender-related inequalities (as expected), these are exacerbated by intraorganizational decisions resulting in preservation of occupational segregation.

Although hierarchy appears to be determined rationally by high-level managers and by owners, labor theorists reveal that organizational structure

has differential outcomes for people based on ethnicity and gender. Further, the structural inequalities between wages and perquisites for workers at various levels of the organization may be quite large and not necessary to maintain a task-oriented division of labor on which an organization’s survival might depend. Marxists, work redesign theorists, and researchers exploring organizational “structuring” explicitly address how organizations benefit, or fail to benefit, worker categories. These perspectives challenge the presumption of rationality for organizational structures imbalanced in favor of a given constituency. Problems in assessing benefit are due to the assumption that managers or the environment determine what middle and lower participants do without exploring resistance to more generally beneficial institutional policies by upper participants. Researchers examining the impact of variables such as size on formalization frequently exclude human agents, and thereby reify organizational structure. Such research fails to give due consideration to how organizational structuring might account for these phenomena. To the extent that workers successfully and persistently subvert, modify, or resist organizational structuring of their activities, researchers cannot justify the assumption that structure is the sole result of owner, managerial, or environmental influences.

LATENT FACTORS IN STRATEGIC PLANNING

Values guide and give meaning to activities. A set of activities, however, may be variously interpreted from alternative value perspectives. Activities that are rational and meaningfully appropriate for an organizational task (in a bank, for example) may also be in substantial congruity with prescriptions and proscriptions of, say, an ostensibly unrelated religious organization serving the same client population. This hidden or latent positive affinity might make a bank clerk appear particularly productive as new customers are attracted to the bank and give favorable reactions for service received from the bank in spite of, rather than because of, role performance as bank clerk. The latent import could be negative, in which case the bank clerk might look particularly unproductive.

Although there is no assurance an organizational structure staffed with a demographically

diverse population has a higher probability of survival, rational theorists believe its chances are increased. As an organization takes in participants with demographic characteristics different from those of previous participants, modalities of personal values at different participant levels will change. This creates a latent potential for future pressure to change goals and procedures. For effective long-term strategic planning, decision makers are well advised to consider implications of alternative demographic concentrations among actual or potential external constituencies and among each internal participant level. Cultivation of new markets to absorb organizational output may require recruitment from populations with new attributes as much as recruitment from new populations to reduce labor costs may require acceptance of new types of participant contributions. Such changes inherently precipitate structural change. An organization that sets narrow limits to organizational culture may as a latent consequence inadvertently limit its capacity to adapt to altered environmental conditions and thus decrease its capacity to survive.

Research examining the link between organizational culture and effectiveness has reflected managerial interest in improving organizational performance through the control and directed change of organizational culture. Research examining the link has been mixed, finding a direct relationship between the two (e.g., Petty et al. 1995), examining culture as a set of mediating variables in organizational performance (e.g., Saffold 1988), and finding no relationship between the two (e.g., Reynolds 1986). While most studies have examined factors internal to organizations in the construction of culture, some have examined the links between culture and organizational markets, networks, and environmental factors (e.g., Burt et al. 1994). One reason for the mixed findings in the association between organizational culture and effectiveness is a difficulty in defining and measuring culture. Culture has been variously defined as underlying shared values and beliefs among participants (Schein 1991); meanings of actions among individual participants (Golden 1992), and means of governing transactions among individual participants (Ouchi 1980). Culture has therefore been measured in terms of strength, meaning the congruence of managerial beliefs to managerial practices (Denison 1990);

individual practices, affect, and cognitions (Silvester et al. 1999); and organizational types governing transactions among participants, which exhibit traits such as the degree of hierarchy or flexibility (Ouchi 1980). These differences in the definitions of culture and in its measurement account for some of the variability of findings in the organizational culture literature. Additionally, differences in organization types and criteria of effectiveness may also account for differential findings of the link between culture and organizational performance. A struggle between proponents of qualitative and quantitative methods has led to a bifurcated literature and a lack of multimethod studies examining the complexities of organizational culture (Martin and Frost 1996). Most studies on organizational culture and effectiveness focus on overall performance, profit, and productivity from the perspectives of the organizational elite, upper management, and administrators while purporting to describe a “whole” organization’s culture and outcomes.

While organizational culture is both an important *result* and a *determinant* of organizational structure, it appears to have been given both narrow and exaggerated importance by writers whose focus is on profit-making organizations. In the mid-1980s researchers contended that centralized control of corporate culture by managers was correlated with organizational success (e.g., Deal and Kennedy 1982). Meyerson and Martin (1987) call this the integrationist perspective, but argue that organizational theory has encompassed at least two other perspectives, the differentiation perspective and the fragmentation perspective. The differentiation perspective acknowledges that there may be “nested” cultures and subcultures within organizations that may embrace different forms, ideologies, and rituals. The fragmentation perspective observes that clearly conflicting cultural understandings and practices in organizations may exist, and may shift as coalitions form around specific tasks and as organization members deal with the ambiguity of their tasks.

Martin (1992) notes that one or all of these cultural characteristics may be present within organizations, but that participants’ positions throughout the organizational structure may affect how they perceive an organization’s culture. Management may take an integrationist view of culture,

seeing it as a way of controlling and coordinating organizational activity. Rank-and-file workers may be more likely to adopt a differentiation perspective instead, and those whose jobs are characterized by a high degree of ambiguity and environmental uncertainty may be more likely to adopt a fragmentation perspective. The issue here is how much of values essential to its own well-being each constituency will surrender in return for real or imagined benefits derived from continued organizational participation. Upper participants are only one constituency potentially benefiting from organizational culture. Other constituencies may use it as a vehicle to express resistance to, or interest in, a wide array of organizational and environmental conditions. If upper participants seek effectiveness in goal achievement and efficient productivity for increased profits, lower participants might seek security of employment and quality of working conditions. Participants may see the organization as a forum within which each subgroup expresses its own array of self-interests for potential incorporation into organizational culture in the context of collective, perhaps universal, concern for organizational survival. Depending on their relative power (location) within the organization's structure, constituents may be limited in the degree to which they can enact and establish understandings about the distribution of rewards (of various kinds including but not limited to economic rewards) relative to their own structural positions and to their self-perceived contributions to organizational survival.

If participants decide the distribution of rewards is unsatisfactory or inequitable relative to some other comparison group or individual, relative deprivation theorists argue that participants will then attempt systemic or individual remedies. Indeed, lower participants may choose to treat "official" cultural accounts with disbelief or to subvert them (Smircich 1983). The form that perceived unfairness takes influences the actions that people are likely to take; Skarlicki and Folger (1997) found that if participants perceive organizations as having low procedural justice and low distributive justice, they are more likely to take retributive action against an organization for perceived injustices than those who believe that only procedural or distributive justice is low. However, researchers have failed to demonstrate how unfavorable comparisons cause behavioral outcomes.

Historically, groups of workers have understood existence of ethnicity and gender inequality in the work place, but not all groups have taken steps to remedy the problems. The organizational justice perspective may allow exploration of organizational structuring as a process in which agency exists on the parts of participants and constituents of organizations at both aggregate and individual levels in accord with their cultural orientation.

CONCLUDING REMARKS

Current theory and research on organizational structure have been characterized by both managerial determinism and by a vague environmental determinism used to exonerate owners and managers from detrimental consequences of their structural designs upon middle and lower participants within the organization. Owners and higher-level managers often overemphasize short-term gains achieved by production and managerial techniques undermining relative empowerment of lower participants. On their behalf, organizational theorists and researchers contribute unwittingly to intensification of unnecessary control over workers, consumers, community residents, and other types of participants (Clegg 1981). Research guided by an organizational justice perspective may reduce an overemphasis on the competitive advantage of upper participants (disguised as advantage by the *organization* against external adversaries) and open new vistas on cooperative actions beneficial to all participants and related to the perceived value of their contributions to organizational survival. In the final analysis, perhaps the only justification for rewards received by a category of organizational participants is the contribution it makes to the essential task of organizational survival (Alvarez 1979).

ORGANIZED CRIME

NOTE: Although the following article has not been revised for this edition of the Encyclopedia, the substantive coverage is currently appropriate. The editors have provided a list of recent works at the end of the article to facilitate research and exploration of the topic.

Organized crime is considered one of the most serious forms of crime for two reasons: (1) It is so often lucrative and successful; and (2) it is so difficult to counteract. In the broadest terms, organized crime can be viewed as any form of group conduct designed to take advantage of criminal opportunities, whether on a one-time or a recurring basis. More commonly, the label *organized crime* has more restricted usage.

It should not be a surprise to find criminals associating for the purpose of committing crime. The achievement of goals through cooperative efforts is a common element of contemporary life. Association with other criminals creates an interesting dilemma for the individual criminal. Having coconspirators increases the visibility of criminal conduct, the risks of apprehension, and, upon apprehension, the risk of betrayal. On the other hand, some types of criminal opportunities can be exploited only through group behavior. Offenders who fail to join with others may thereby limit their rewards from criminal conduct. For organized crime to persist, it must function both to overcome the risks of associating with others and result in positive benefits and increased rewards for those who participate.

No one knows how much organized crime is committed every year. Rather than being measured in numbers of events, the significance of organized crime is generally recorded in the dollar volume of activities. Some have argued that revenue estimates for organized crime are advanced more in the interest of drama than of accuracy, but the estimates are nonetheless staggering. For example, annual revenue from the sale of drugs is placed in the \$40 to \$60 billion range, and annual revenue from illicit gambling operations, at \$20 to \$40 billion.

Organized crime is unlikely to be reflected in official crime statistics for three reasons: first, crime statistics record information about individual criminal events rather than about the individuals or groups committing them; second, many of

the activities of organized crime groups involve so-called victimless crimes where no report of a crime is made; and third, persons who are victimized by organized crime groups may be unlikely or unwilling to come forward and report their victimization.

Organized crime is best understood by examining the nature of ongoing criminal organizations, their activities, and societal response to the behavior of these organizations. A secondary use of the term, referring to criminal support systems that aid all offenders, is also briefly noted.

ONGOING CRIMINAL ORGANIZATIONS

Organized crime usually refers to the activities of stable groups or gangs that commit crimes on an ongoing basis. While not all group crime is properly labeled “organized crime,” there exists no standard definition of the term. Instead, the phenomenon has been variously described as “a cancerous growth on American society” (Andreoli 1976, p. 21); “one of the queer ladders of social mobility” (Bell 1970, p. 166); “a society that seeks to operate outside the control of the American people and its governments” (President’s Commission 1967, p. 1); and “the product of a self-perpetuating criminal conspiracy to wring exorbitant profits from our society by any means” (Salerno and Tompkins 1969, p. 303).

Scholars have identified the following as elements that characterize all groups labeled as organized crime: a hierarchical organizational structure, dominated by a strong leader; a territorial imperative, exhibited in attempts to monopolize all lucrative criminal opportunities within a geographic area; a predilection to violence both to enforce internal norms and to advance economic objectives; and a desire to influence the social response to criminal conduct, as demonstrated in significant investments in public corruption. Cressey (1969) identified these latter two characteristics—the “element of enforcement” and the “element of corruption”—as the essential features of organized crime.

In the United States, organized crime has been personified in ethnically based criminal organizations and, in particular, the twenty-four fictive “families” believed to make up the American Mafia. Joseph Valachi, in testimony before the United States Senate in 1963, revealed a sordid

and secret world in which he claimed these criminal organizations operated and prospered.

While some scholars pointed to inconsistencies in Valachi’s statements, and other criminals would later question the depth of his experience and knowledge, his testimony spawned a series of books and movies that placed Italian criminal organizations in the forefront of the public’s consciousness with respect to organized crime.

The term *mafia* (with either upper- or lowercase letters) is used variously to apply to a secret criminal organization or to a life-style and philosophy that developed in sixteenth- and seventeenth-century southern Italy and Sicily in opposition to a series of foreign rulers who dominated the area. The life-style combines the idea of manliness in the face of adversity with an antagonism to authority and a closeness and reliance on family and clan.

Smith (1975) argues that applying the “mafia” label to Italian criminal organizations in the United States was both fateful and calculated. It was fateful because it imbued these organizations with international connections that there was little evidence they had. This may in turn have helped these organizations consolidate and solidify their power, in competition with other ethnic (primarily Irish) criminal organizations that were actually more prevalent in the early decades of the twentieth century. Use of the label was calculated in that it gave Italian criminal organizations a subversive and sinister character designed to ensure public support for extraordinary law enforcement efforts to eradicate these groups.

Overlooked in much of the attention paid to Mafia “families” was the fact that bands of brigands and smugglers, displaying many of the same organizational attributes as “mafia,” were well established in Elizabethan England; that criminal organizations linked to a life-style based on the primacy of male-dominated families and the concept of dignity and manliness are common in Central and Latin America; and that criminal societies and associations have been successful vehicles for social mobility in many cultures, for example, the Chinese Triads or the Japanese Yakuza.

Also overlooked were some significant changes occurring during the late 1960s and early 1970s in the major cities in which the Mafia “families” were

believed to operate. These changes signaled what Ianni (1974) called “ethnic succession” in organized crime: That is, as the populations of inner cities came to be dominated by racial minorities, so too were the ranks of those running criminal organizations. This gave rise to law enforcement characterizations of such groups as the “Mexican Mafia” or the “Black Mafia,” not because of their associations with Mafia “families” but as a short-hand way of communicating their organizational style and methods of operating.

By the 1980s, the term *organized crime* had lost its ethnic distinction. Instead, the label started being applied to many more criminal associations, from motorcycle and prison gangs to terrorist groups to some juvenile gangs. Observed in all these groups were the organizational characteristics that had first been identified as distinctive of Mafia “families.”

ACTIVITIES OF ORGANIZED CRIME GROUPS

The activities in which organized crime groups are involved constitute another distinctive hallmark. Broadly defined, the term *organized crime* can be used to describe the activities of a band of pickpockets, a gang of train robbers, or a cartel of drug smugglers. Practically speaking, however, use of the term is somewhat more restrictive.

Commentators, scholars, and lawmakers generally use the term when referring to criminal conspiracies of an entrepreneurial nature—in particular, enterprises focused in black-market goods and services. Black markets are those in which contraband or illegal goods and services are exchanged. In this more restrictive use of the term, the activities of drug smugglers would be included while the conduct of pickpockets or train robbers would not.

These latter groups, and others involved in various forms of theft and extortion, commit what are best termed *predatory crimes*. As such, they are generally regarded as social pariahs. Society and the forces of social control will actively seek to root out such groups and bring them to justice. This is despite the fact that such groups may display a highly evolved organizational structure, a strong sense of territory, and a tendency toward violence.

Contrast this with groups engaged in entrepreneurial conduct. These groups supply the society with goods and services that are illegal but in demand. While some in society may still view these criminals as social pariahs, many in society will not. Instead, the criminal group establishes patron–business relationships with criminal and noncriminal clients alike. The forces of social control are not so bent on eradicating these groups because of the widespread social support they garner. This support, when added to the profits reaped as criminal entrepreneurs, creates both the means and the conditions for corruption.

If any one activity can be considered the incubator for organized crime in the United States, it would be the distribution and sale of illegal alcohol during Prohibition. The period of Prohibition (1920–1933) took a widely used and highly desired commodity and made it illegal; it also created the opportunity for a number of predatory criminal gangs to evolve as entrepreneurs. These entrepreneurs then developed important client and business relationships and emerged from Prohibition as wealthy and somewhat more respectable members of their communities.

Gambling and other vices have similar social support profiles. Purveyors of these services are widely perceived as engaged in victimless crimes, that is, black-market transactions involving willing buyers and sellers. Their activities, while morally unacceptable to many, arouse little social concern.

Societal ambivalence becomes even more pronounced where gray-market goods and services are involved. These are situations where legal goods or services are being provided in an illicit manner or to persons ineligible to receive them. Abuses of wartime rations is a good example of a gray-market situation, as is the negotiation of so-called sweetheart labor contracts or the illegal disposal of hazardous waste.

Criminal groups involved in gray-market activities are very tightly meshed in the economic and social fabric of the legitimate community. The persona of such groups is more likely to be legal than illegal, and the capacity of their members to become closely affiliated with persons of power and authority is likely to be great. Public corruption becomes not only likely but inevitable.

Combined with the characteristics that groups of criminals exhibit, the activities in which they engage are also likely to define such groups as organized crime. Some commentators feel it is impossible to separate a group's character from the nature of the crimes it commits. To this way of thinking, selling drugs requires a certain level of organization, but it is impossible to tell whether a group has evolved an organizational style in order to sell drugs or began to sell drugs as a consequence of its organizational capacity.

What is clear is that the capacity to exploit one type of criminal opportunity can be parlayed into other legal and illegal endeavors. Similarly, profits from organized crime activities can permit individual criminals to climb that "queer ladder of social mobility" that wealth creates.

SOCIETY AND ORGANIZED CRIME GROUPS

The final aspect of organized crime that distinguishes it from other forms of crime is its relationship with the society in which it operates. Organized crime is the one form of crime that assesses criminal opportunities in light of the probable social response as well as the possible economic and social rewards.

Cressey (1969) identified this capacity of organized crime as a "strategic planning" capability. Using this capability, organized crime groups choose "safe crime": where there is high social tolerance or at least ambivalence toward the conduct; where the chances of apprehension are therefore not great; where, even if apprehended, the chances of conviction are small; and where, even if convicted, the likelihood of serious consequences is also small.

In this assessment, society's attitudes toward various criminal activities become a key determinant in the nature of organized crime activities that will be displayed. Society's attitudes, as embodied in the criminal law, become even more significant.

Packer (1969) argued that in black- and gray-market situations, the criminal law may actually serve as a protective tariff. As such, the law limits the entry of entrepreneurs into the proscribed marketplace while guaranteeing, for those who do

enter the market, exorbitant profits. The theory of deterrence does not work in such markets because as the sanction increases so do the likely rewards.

A similar analysis by Smith (1978) suggests that the law operates in many marketplaces to segment genetic demand, labeling some legal and some illegal. By so doing, the law does not reduce demand; what it does is change the dynamics of the market, creating the "domain" or market share of organized crime. In this sense, it is society—through its legislative enactments—that generates and structures the dynamics of organized crime opportunities.

Social institutions also play a role in structuring the nature and success of organized crime. The nature of government and the underpinnings of justice systems loom large in determining how organized crime groups will operate and succeed. Anglo-American legal systems, founded on the principle of individual responsibility for criminal acts, deal at best ineptly with group crime. When faced with more sophisticated criminal conspiracies, they appear to falter.

Where criminal organizations are armed with investments in public corruption, justice systems will not operate properly. Where government operates ineffectively or unfairly, the black market will flourish. Where there is the tendency to proscribe what cannot be controlled, criminal organizations will reap social support and financial rewards.

CRIMINAL SUPPORT SYSTEMS

A secondary use of the term *organized crime* refers to support systems that aid the criminal activities of all offenders. The typical list of support systems includes the tipster, the fix, the fence, and the corrupt public official. Each of these mechanisms serves to reduce the risks of criminal conduct or to lessen its consequences.

For example, tipsters function to provide criminals with information critical to committing a crime, such as the internal security schedule for a building or the timing of valuable cargo shipments. By doing so, they reduce the uncertainties the offenders face and enhance the chances for success. As a reward, tipsters receive a percentage of the "take," or proceeds of the crime.

The fix arranges for special disposition of a criminal's case, once it is in the justice system. This might mean seeing that paperwork is lost, or that a light sentence is imposed. Usually, the fix operates with the aid of corrupt public officials who are in a position to accomplish the required improper acts.

The fence serves as the market for stolen property, transforming it into cash or drugs for thieves. In the role of middleman, the fence determines what thieves steal, how much they are paid to do so, and, consequently, how often they steal. Fences provide structure and stability to a wide range of offenders. Like other criminal support systems, they impose organization on the activities of criminal groups and individual criminals.

Not all criminals can access the services of criminal support systems. These mechanisms will not act to serve the notorious or the psychotic. In this way, criminal elites are established and preserved. For those who use these support systems, crime is organized, the justice system is predictable, and success is likely.

There was a time when the "criminal underworld" was a physical place, a true sanctuary to hide and protect criminals. Now the underworld exists as a communication system, an important dimension of which involves support systems that can aid and protect offenders. The manner in which these systems function provides stability and organization to the underworld.

SUMMARY

Organized crime refers primarily to the broad range of activities undertaken by permanent criminal organizations having the following characteristics: a hierarchical organizational structure; a territorial imperative; a predilection for violence; and the capacity and funds to corrupt public officials.

These groups tend to locate in gray or black markets where they establish patron-client relationships with much of society. The funds they earn as entrepreneurs, combined with social support for their activities, permit them to influence the social response to their acts. They may become upwardly mobile as a result of investing their profits in both legal and illegal endeavors.

Organized crime also refers to criminal support systems such as the tipster, the fix, the fence,

and the corrupt official, who impose organization and stability in the underworld.

P

PARADIGMS AND MODELS

The terms “paradigm” and “model” have enjoyed considerable popularity in sociology, in part because the terms have a range of meanings. In everyday language, *model* has two senses: (1) a replica of an object being modeled, for example, a “model of a building,” and (2) an exemplar to be emulated, as in “role model.” “Paradigm” is somewhat more esoteric in everyday usage, but has become quite important in academic disciplines including sociology, largely due to Thomas S. Kuhn’s 1962 book, *The Structure of Scientific Revolutions*.

The original meaning of *paradigm* overlaps that of “model” in the sense of exemplar. The term comes from the study of grammar where a paradigm provides a model of, for example, the way to conjugate all the regular verbs of a particular type (I love, you love, he or she loves, etc.). Its appearance in sociology predates Kuhn, but since Kuhn, it has become a much grander idea. Merton used the device of analytical paradigms for presenting codified materials, by which he means a technique for exposing the “complete array of assumptions, concepts and basic propositions employed in a sociological analysis” (1949, p. 13). Parsons treated “paradigm” in a similar way when he presented paradigms for social interaction and social change and emphasized that these are distinct from theories (1951, p. 485).

It is quite clear, however, that Kuhn’s work has brought “paradigm” from relative obscurity to a central place in the discourses of the humanities, the social sciences, and the history and philosophy

of science. Kuhn’s paradigm and his model of change in science are highly controversial; yet, they have had considerable influence in these academic fields. Some of the effects Kuhn intended; many effects, however, were unintended, causing Kuhn to disavow explicitly some of the interpretations of his work (Kuhn 1970, 1974). Crews (1986) comments that a loose reading of Kuhn’s book—which he calls the most frequently cited academic book of modern times—even justifies the rejection of science as empirical.

WORKING DEFINITIONS

A useful definition of *model* draws on Kaplan:

Any system A is a model of a system B if the elements and relationships of A aid in the understanding of B without regard to any direct or indirect causal connection between A and B. (1964, p. 263)

For example, one could use ideas about political change (system A)—stable government, crisis, revolution, new government attains stability—to model change in science (system B). Models range from informal analogies or metaphors (e.g., society as an organism) to highly formal equation systems.

A model contains elements that have (or are given) properties—that is, are characterized by descriptive terms, and connections among some or all of these elements. One could construct a physical model of a social network using balls with holes in them and rods that fit into the holes. The rods would connect some but not all of the balls;

the balls (elements of the model) would represent individuals in the network and the rods (connections) would link those individuals who communicate with one another.

The critical property of a model is an isomorphism with its object, the thing being modeled. Strictly speaking, *isomorphism* is a one-to-one correspondence between the elements and relationships in the model and the elements and relationships in its object. Needless to say, strict isomorphism is not satisfied by many metaphors and analogies even though these can aid understanding; the lack of strict isomorphism, however, should serve as a caution in taking analogies too literally. Similar caution applies to models in general since it is all too easy to reify the model, that is, confuse the model with its object. Models do not capture all the properties of their objects, so that even with strict isomorphism, a model inevitably omits significant aspects of the object. As long as those concerned with a model recognize this limitation, they can employ the model fruitfully and unproblematically.

A loose usage of “model” treats it as synonymous with “theory” or as theory expressed in mathematical symbols. While it is possible to have a model of a theory, the working definition given above rules out synonymous usage because a model of x must resemble x in terms of pattern or structure, whereas a theory about x , that predicts or explains x , need not, and generally does not, resemble x . In short, theories of x do not have to be isomorphic with x ; models do.

In formulating a working definition of *paradigm*, it would seem reasonable to follow Kuhn since he is largely responsible for the contemporary significance of the idea. This presents serious difficulties, however, for as Laudan observes, “Kuhn’s notion of paradigm has been shown to be systematically ambiguous . . . and thus difficult to characterize accurately” (1977, p. 73). While constructing a definition of “paradigm” is a formidable task, it is an essential one because the paradigm is critical to an understanding of Kuhn, and Kuhn’s work plays an important role in many of the current controversies in sociology. Some of the ambiguity disappears if one distinguishes between what a paradigm *is* and what a paradigm *does*; still, it would be presumptuous to believe that one could fully capture Kuhn’s concept with all its

nuances. The following working definition has the more modest goal of representing many of his key ideas:

A paradigm is a significant scientific achievement recognized by a particular community of scientists that provides a model from which springs a coherent tradition of scientific research and also a general way of looking at the world.

The principal functions of a paradigm include: (1) determining what kinds of problems are appropriate objects of study, (2) specifying appropriate ways to study these problems, and (3) delimiting the types of theories and explanations that are acceptable. For example, one could consider Durkheim’s *Suicide* ([1897] 1951) as a paradigm for many sociologists that provides a model for research and a way to look at phenomena. For Durkheimians, *Suicide* is an exemplar that specifies ways to look for and at social facts, and that limits explanations of given social facts to other social facts, rather than, for example, explaining social facts with psychological ideas like motives.

It is important to distinguish “paradigm” from “theory.” While a well-developed paradigm may contain a number of specific theories, a paradigm is “metatheoretical.” A theory makes statements about the world, whereas a paradigm involves statements about the nature of acceptable theory, the appropriate entities to investigate, and the correct approaches to these investigations. As an exemplar, a paradigm serves as a normative standard; hence, it is a special type of model, a model of what the given scientific community considers to be exemplary work.

KUHN’S MODEL OF SCIENTIFIC CHANGE

Kuhn developed a model of change in science built around his concept of paradigm. The model employs several concepts related to “paradigm” that extend its meaning: normal science, anomaly, crisis, revolution, paradigm shift, and incommensurability. Brief explications of these ideas follow. (Page references below are to Kuhn 1970.)

Normal Science. When a paradigm gains acceptance in a scientific community, it is largely in terms of a promise of success if researchers in the community follow the exemplar. “Normal science

consists in the actualization of that promise, an actualization achieved by extending the knowledge of those facts that the paradigm displays as particularly revealing, by increasing the extent of the match between those facts and the paradigm's predictions, and by further articulation of the paradigm itself" (p. 24). To Kuhn, normal science involves "mopping-up operations [that] engage most scientists throughout their careers" (p. 24), and is primarily devoted to puzzle solving: "Perhaps, the most striking feature of the normal research problems . . . is how little they aim to produce major novelties, conceptual or phenomenal" (p. 35).

Anomaly. The term *anomaly* refers to "the recognition that nature has somehow violated the paradigm-induced expectations that govern normal science" (p. 52).

Crisis. A *crisis*, a period of "pronounced professional insecurity" (p. 68–69), occurs when enough anomalies accumulate so that scientists question the appropriateness of the paradigm.

Revolution. Kuhn takes scientific *revolutions* to be "those non-cumulative developmental episodes in which an older paradigm is replaced in whole or in part by an incompatible new one" (p. 92).

Paradigm shift. Kuhn argues that scientists with a new paradigm do not merely have new interpretations for what they observe, but rather "see" things differently. This difference in perception, or paradigm shift, is in a sense similar to the Gestalt switch studied by psychologists, in which the same figure can yield a right-hand face or a left-hand face depending on how it is viewed.

Incommensurability. During crisis periods, rival paradigms coexist and advocates of rival paradigms cannot understand one another because they have different ways of seeing the world, different standards for appraisal, and different objectives for their scientific community; that is, there is *incommensurability*. Consequently, paradigm conflicts are not resolvable by appeal to a set of shared criteria.

These concepts allow a sketch of Kuhn's model:

Paradigm I → Normal Science → Anomalies → Crisis → Revolution → Paradigm II

When the members of a scientific community accept a paradigm, that acceptance generates a set

of shared commitments to objectives, methods for achieving those objectives and criteria for appraising theories and research. These commitments are the foundation for a period of normal science, since what to study, how to study it, and what constitutes adequate explanations are not problematic. During normal science, the community regards the paradigm itself as unalterable and immune to challenge. Scientists work to solve the puzzles that the paradigm presents and for which the paradigm guarantees solutions; in this process of puzzle solving, refutations for theories contained in the paradigm arise and empirical studies come up with unexpected findings. The more serious refutations and the more surprising findings come to be regarded as anomalies, and as these anomalies accumulate, scientists are at a loss as to how to deal with them. In the crisis period, rival paradigms arise, but because paradigms are incommensurable, scientists adhering to rivals have no common basis for choosing among the competitors. Paradigm II wins out because some scientists undergo the conversion experience of a paradigm shift where they see the world in a new way, because the adherents of Paradigm II are especially persuasive, or because the adherents of Paradigm I die off.

Kuhn's model questions ideas of cumulation and progress in science. While normal science is cumulative, revolutions do not preserve all, or even the most important, achievements of previous paradigms. "There are losses as well as gains in scientific revolutions" (p. 167). Furthermore, the incommensurability thesis argues that Paradigm II does not win out because it is better or more progressive; the lack of shared standards precludes definitive judgments.

CRITIQUE

Kuhn's work has raised important questions for scholars in the history, philosophy, and sociology of science and has generated a large literature in these areas. Interestingly enough, it has also had broad appeal to intellectuals outside of these specialized fields. Although Kuhn presented his basic model in 1962, his ideas continue to command attention and engender controversy, both within relevant technical fields and in broader academic circles. His work seems to have had less impact in

the natural sciences, although it attacks the conventional views of many natural scientists.

Kuhn's emphasis on scientific communities and on noncognitive factors in the development of science clearly appeals to sociologists, especially sociologists of science—for instance, those who study social networks among scientists or the effects of reward systems. His model provides an antidote to the mythology of cumulative, linear growth of knowledge, the view that characterizes science as building one discovery on another and, with each increment, coming closer to total truth about nature. Nearly forty years after his initial publication, it is difficult to appreciate how dominant such mythology was when Kuhn challenged it.

If prior views overemphasized cognitive and rational factors and held to a naive and simplistic view of progress in science, many post-Kuhnians underemphasize the cognitive and the rational or overemphasize the social and the political; moreover, some totally deny the possibility of scientific progress. For many, Kuhn provides the license to remove science from its pedestal, to deny that science has any distinctive character or special claim on society's attention or support, and to demand that social sciences cease their attempts to be scientific. Close examination of a few of Kuhn's key ideas indicates how Kuhn came to be used in ways he, himself, disavowed.

The first problem is the ambiguity of the term "paradigm." Masterman (1970), a sympathetic critic, has pointed to twenty-one different senses of "paradigm" in the 1962 book, and Kuhn has added to the problem with later modifications of his ideas (1970, 1974). Laudan notes, "Since 1962 most of Kuhn's philosophical writings have been devoted to clearing up some of the ambiguities and confusions generated [by the 1962 book] . . . to such an extent that . . . [m]ore than one commentator has accused the later Kuhn of taking back much of what made his message interesting and provocative in the first place" (1984, pp. 67–68).

The metaphorical language in Kuhn's model poses a second serious problem. As Laudan puts it:

Notoriously, he speaks of the acceptance of a new paradigm as a "conversion experience," conjuring up a picture of the scientific revolutionary as a born-again Christian, long on zeal and short on argument. At other times

he likens paradigm change to an "irreversible Gestalt-shift." . . . Such language does not encourage one to imagine that paradigm change is exactly the result of a careful and deliberate weighing-up of the respective strengths of rival contenders. (1984, p. 70)

Although Laudan believes that problems of misinterpretation can be "rectified by cleaning up some of the vocabulary," and although Kuhn has assumed some responsibility for the misunderstandings due to his own rhetoric (1970, pp. 259–260), it should be noted that Kuhn's ambiguity and his vivid metaphors are important reasons for much of the enthusiastic embracing of his model. The possibility of reading into the meaning of "paradigm" and "paradigm shift" enables the model to serve a variety of agendas.

Kuhn's incommensurability thesis is both the most frequently criticized and the most frequently misused element of his model. It has provided ammunition for a radical subjectivism that denies all standards (Scheffler 1967). In attacking those who use Kuhn to justify any sweeping paradigm of their own, Crews writes, "By incommensurability Kuhn never meant that competing theories are incomparable but only that the choice between them cannot be *entirely* consigned to the verdict of theory-neutral rules and data" (1986, p. 39; emphasis added). Since Kuhn never clearly specified how rules and evidence entered into paradigm change and since he understated the degree to which different scientific communities can share rules and objectives, it is not surprising that this thesis became a rallying point for attacks on scientific rationality.

Another major criticism—and one that goes to the heart of Kuhn's model—involves the indivisible character of paradigms. Paradigm shift is an all-or-nothing process; a paradigm is accepted or rejected as a whole. Treating the parts of a paradigm as inseparable almost requires the transition from one paradigm to another to be a conversion experience; moreover, such a holistic view does not provide an accurate picture of how large-scale changes of scientific allegiance occur (Laudan 1984, pp. 71–72).

Many of these criticisms are widely held. Nevertheless, Kuhn's model remains important to many disciplines including sociology. Some scholars remain adherents to the basic features of the

model; others believe they must respond to the model's challenges to contemporary philosophy and methodology of science.

USE OF "PARADIGM" IN SOCIOLOGY

While several leading British sociologists of science who focus on the sociology of knowledge reflect the intellectual mood of Kuhnian analysis (Collins 1983), the main applications of "paradigm" have occurred in either descriptive or normative efforts in the sociology of sociology.

Analysts have employed versions of Kuhn's concept to classify sociological activities as belonging to one or another paradigm; for example, Ritzer (1975) distinguishes three paradigms for the field at large: social facts, social definition, and social behavior. Bottomore (1975) identifies four paradigms of macrosociology: structural-functionalist, evolutionist, phenomenologist, and structuralist. Other sociologists discriminate varying numbers of paradigms from as few as two to as many as eight for a single subfield. Some writers classify theories into different paradigms; others categorize research strategies; still others codify more general philosophical orientations. In addition to disputing the number of paradigms, sociologists also disagree about whether paradigm applies to the field in general or only to subfields and whether there are any paradigms at all in sociology, that is, whether the field is preparadigmatic.

A few studies have applied Kuhn to examine historical development of a paradigm. Colclough and Horan (1983), for example, use content analysis of status attainment studies to illustrate Kuhn's model. Their analysis finds evidence for a stage of normal science and a stage in which anomalies arise, and they suggest the onset of a crisis for status attainment research.

Sociologists who use Kuhn focus on different properties of paradigms and debate the utility of their approaches or their faithfulness to Kuhn (cf. Ritzer 1975, 1981a, 1981b; Eckberg and Hill 1979; Hill and Eckberg 1981; Harvey 1982). Compounding the confusion are the many interpreters who read their own meanings into Kuhn. One critic argues:

[F]or the most part the use of the term paradigm in sociology fails to reflect the

analytic elements of Kuhn's concept . . . Arbitrary pigeon-holing schemes of varying degrees of sophistication, are constructed and theories of, ideas about, and approaches to, sociology are dropped in. The result is a personalized schematic device that . . . plays little part in providing . . . any explanation or understanding of the growth of knowledge. The labeling of such pigeon-holes as paradigms legitimizes the scheme and implies an authority it does not possess. (Harvey 1982, p. 86)

The disarray led Bell to ask "Does the term 'paradigm' carry too many possible meanings for rigorous thinking? Has it become quasi-mystical? Is it time to review its many usages and to consider discarding it in favor of more precise terms that convey to others more accurately what we mean to say?" (1990, p. 17) Bell went on to answer yes to all three questions.

MODELS IN SOCIOLOGY

The first basic distinction necessary to characterize the use of models in sociology is among substantive, measurement, and statistical models. The substantive modeler's objective is to model a specific theory, phenomenon, or process in order to learn (or teach) something about the specific object of the model. For example, Pfeffer and Salancik (1978) use a theory of interpersonal power and dependence (Emerson 1962) to model interorganizational relations, or Gamson (1969) creates an elaborate game that simulates the operation of key features of a society. In both examples, the model focuses on a particular problem—to learn about organizational relations in the first, or to teach students about major aspects of society in the second.

The objective of a measurement model is to create and justify a measuring instrument that has a wide range of applicability. One measurement area to which sociologists were early contributors is attitude measurement; sociologists were among the first to develop models for scaling attitudes. These scaling models provide the rationale for assigning numbers to represent different expressions of the attitude. For example, Bogardus (1925), in a classic work, created a measure of social distance on the analogy of physical distance, in which allowing a member of some ethnic group

into your family represented less social distance than only allowing that person to live in your neighborhood. Guttman (1950) developed one of the most frequently used attitude scaling models, which defines and justifies procedures for ordering a set of attitude questions.

Statistical models are the basis for the systematic quantitative analysis of sociological data, and most empirical research in the field employs one or more statistical models. These models are general tools, broadly applicable to diverse problems; the nature of the subject matter that the data reflect is largely irrelevant to the model as long as the data have certain properties (e.g., as long as they are drawn randomly from some population). A large number of different statistical models appear in the sociological literature. Some are simple, for example, using the analogy of coin tossing to evaluate the likelihood that a given event occurred by chance; others are highly complex, using systems of equations to represent the structure of relationships in a set of variables. Models for multivariate analysis have become extremely important to sociology, including, for example, structural equation models, also known as path or causal models (Bielby and Hauser 1977), and log-linear models (Goodman 1984).

In recent years, models have become a central feature of the sociological literature. Researchers have constructed verbal, mathematical, and computer models to deal with a range of substantive phenomena and measurement issues. The application of statistical models to sociological data has increased dramatically in both the diversity of models employed and their mathematical sophistication. The most significant developments, however, have occurred in the creation, elaboration, and testing of formalized models of substantive phenomena, that is, models involving mathematics or logic.

In the early years of model building, substantive sociologists did not regard formal models as central to their concerns. Many mainline researchers were dubious about the utility of formal models in advancing knowledge about a substantive problem and often considered model construction as primarily an intellectual exercise, stimulating to the creator but of little relevance to anyone else. Articles presenting models appeared mainly

in esoteric journals read by small audiences of the initiated.

A striking feature of recent sociological work is the emergence of formal models as a central feature of several research traditions. Papers presenting formal models, extensions of these models, critiques of them, and empirical studies testing the models have appeared regularly in journals such as the *American Sociological Review*. While specialized journals such as the *Journal of Mathematical Sociology* still publish many articles dealing with substantive models, the fact that general sociological journals also publish reports dealing with formal models indicates that formal modeling has become much more integrated with substantive research in several problem areas of the discipline.

Recent research involving formal models has dealt with a diversity of substantive problems, employed a variety of mathematical tools, and used many different types of data to evaluate the empirical predictions of the models. Sociologists have constructed models for collective behavior (Heckathorn 1996; Kim and Bearman 1997), demographic processes (Yamaguchi and Ferguson 1995), exchange processes (Lawler and Yoon 1996; Yamaguchi 1996; Molm 1997; Burke 1997), geographic mobility (Herting et al. 1997), organization ecology (Gábor et al. 1994; Hannan et al. 1995) performance expectations and power-prestige orders (Troyer and Younts 1997; Berger et al. 1998), and social differentiation-inequality (Rickson and Palange 1994; Nielsen 1995; Orbell et al. 1996; Mark 1998). What has changed from the past is that highly developed models in each of these lines of research have become part of the core of theory building rather than merely interesting adjuncts.

FUNCTIONS OF MODELS

A model, first of all, is an abstract representation of what the modeler regards as important aspects of the object being modeled. It involves assumptions, explicit or tacit, about that object, its elements, and the relationships among these elements. The definition given above requires that modeling lead to increased understanding; examining the relationships assumed in the model and ascertaining those that fit the object well, those

that fit the object somewhat, and those that do not fit at all serves this most important function. In other words, scrutinizing ways the model resembles the object and ways it does not can uncover previously unrecognized features of the object. Formal models, as noted earlier, employ logical or mathematical tools to derive conclusions from the model's assumptions, and researchers then test whether these conclusions represent hitherto unknown properties of the object. A model, in general, provides the means to ask new questions about the phenomenon it represents and thus functions to generate new ideas.

A model provides a vehicle for communication. Since a model is more abstract than its object and since it omits many properties of the object, it is easier for writer and audience to share understanding of the model than of the object. Caution, however, is necessary, particularly when the model is a vague analogy (e.g., society as a living organism). The possibility of reading into analogies and metaphors can defeat shared understanding when the audience focuses on aspects that are unintended. A model may display the complexities of the object. Attempting to represent the ties among members of a social group, for example, may require the elaboration of a simple model that represents only the presence or absence of a relationship to one that distinguishes types of relationships—attraction, task interdependence, relative status, and so on. Even if a model inadequately represents its object, it can enhance the understanding of that object by exposing issues that need to be addressed. One important class of models—those known as “baseline models”—are developed in order to study how the object deviates from the model's minimal representation. Investigating discrepancies between a baseline representation and the object can direct the construction of a more complex model (Cohen 1963).

The last general function to be noted is that a model can serve to relate what appear to be different phenomena. An abstract model can apply to a variety of different objects, thus calling attention to their common aspects; sometimes, particularly with metaphors and analogies, the features of one phenomenon serve as the model for another. Using drama as a model for everyday interaction calls attention to some common elements (e.g., what it means to play a role).

Berger and colleagues (1980) present a typology of models based upon more specific functions. Although their concern is mathematical models, their typology has more general application; they distinguish: (1) explicational models, (2) representational models, and (3) theoretical construct models. Explicational models are those for which the primary goal is to explicate or render precise one or more concepts. Many social network models are explicational models in that they provide an explication of the concept of social structure (Marsden and Lin 1982). While all models are representational, in this typology the term refers to those models that attempt to represent a particular observed social phenomenon. The majority of models developed in sociology are representational in this sense as long as one has some latitude in interpreting “observed,” in many cases, the object of the model is a generalization from observed phenomena. Coleman (1964, 1973) has formulated a number of representational models dealing with social change and with collective action.

Theoretical construct models are those which formalize an explanatory theory. In sociology, these models have focused on a variety of substantive topics as the following examples illustrate: Fararo and Skvoretz (1989) have devised a model drawing on social structural theories of Blau (1977) and Granovetter (1973); Hannan and Freeman (1989) have constructed models of organizational birth and death processes based on bioecological theories; Berger and colleagues (1977) have formulated a model of status characteristic theory (Berger et al. 1966, 1972).

Sociological models are models in a sense that is close to the everyday meaning of model as a replica or representation. It is even reasonable to think of many of them in the other everyday sense, as exemplars, since we can point to sociological research traditions devoted to their development and test. Only with the benefit of more hindsight than is presently available, however, will it be possible to judge whether any of these models are paradigmatic.

BERNARD P. COHEN

PARENTAL ROLES

In the opening years of the twenty-first century, most adults are or will become parents. The ages at which they start having children, as well as the number of children they have, differ significantly from earlier generations and from culture to culture, as do the social and economic conditions of parenthood. In this article, several major aspects of parenthood in the contemporary United States—and other industrialized nations—are discussed. First, several *demographic patterns* associated with parenting are reviewed. Second, the *rewards and costs* associated with parenting are examined. Third, *changes in the responsibilities of parents*, as defined by social perceptions of the nature of childhood, are discussed. In this section, special attention is given to gender differences in parenting styles. The fourth section examines *the impact of the first child's birth* on the parents. The paper closes with a discussion of *parent-child relations in middle and later life*.

DEMOGRAPHIC TRENDS IN PARENTING

Average Number of Births per Woman. One of the most dramatic changes in the nature of parenthood in industrialized nations has been the *decline*

in the average number of births to each woman. In the United States, this number has decreased from seven births per woman to two, over the past 200 years. This downward trend has not been steady or consistent, however. During some periods, such as the Great Depression of the 1930s, the rate of decline was much more pronounced, while at other times, most notably during the post-World War II baby boom (1946–1962), the number of births per woman actually increased. In 1936, the middle of the Depression, American women were giving birth to two children, on the average. At the peak of the baby boom, in 1957, the number reached 3.6 births per woman. For nearly twenty years following this peak, the birth rate dropped dramatically. Since the mid-1970s, the birth rate has been fairly stable. There are, however, racial and socioeconomic differences in fertility. In the United States, white women have the fewest births, followed by black and Hispanic women. White women aged 40 to 44 have given birth to an average of 1.9 children, while African-American and Hispanic women have had 2.1 and 2.6 children, respectively (U.S. Bureau of the Census 1999).

Reasons for the Declining Birth Rate. Why has the average number of births per woman decreased over the past 200 years? One major reason is that in the past women had little control over their childbearing. Through the eighteenth and nineteenth centuries, married women gave birth to as many children as they were biologically capable of having. This pattern persisted into the twentieth century for many women, although by the end of the nineteenth century many middle-class women were beginning to use birth control. Childbearing in the United States is now largely controlled through the use of various contraceptive methods and, to a lesser extent, through medically induced abortion. Most people have the number of children they want to have, and generally, they want no more than two children. Only a small percentage of couples want, and actually have, more than two children (Shehan and Kammeyer 1997, pp. 183–184).

A second reason for the historical decline in childbearing is that children are no longer economic assets for their families. Through much of the nineteenth century, the labor of children helped families survive. Most Americans lived on farms, where children could help out in many ways. Even

the children who lived in small towns and cities often worked at young ages to help support their families. When laws pertaining to child labor and mandatory education were passed in the late nineteenth and early twentieth centuries, children became less valuable to their parents in economic terms. Today, children require large economic expenditures from their parents, as discussed later in this article. Most people have the number of children they think can afford, and thus, the number they have is much lower than in the past (Shehan and Kammeyer 1997, p. 184).

A third reason for today's low fertility rate is the high number of women who are in the paid labor force. Economic need has led to a dramatic increase in the employment of mothers, married as well as divorced. In 1960, fewer than one in every five mothers of preschool children was employed. Today, over 60 percent are employed. The increased demand for substitute child care has become one of the most pressing social problems in industrial nations. Child-rearing duties decrease the amount of time and energy women can devote to their jobs; therefore, those who are career oriented may choose to forego childbearing altogether or to limit the number of children they have (Shehan and Kammeyer 1997).

Changes in the Characteristics of Parents.

Social change in the twentieth century has not only reduced the average number of children born per woman in industrialized nations but has also seen a change in the marital status and age at which women begin to have children. The childbearing period seems to be expanding, as some women continue to become mothers in their teen years while others wait until they are in their late twenties, thirties, or early forties. Developments in reproductive biology have even made it possible for women who have gone through menopause (which typically occurs in the early fifties) to have babies. Teenage childbearing was fairly common in the post-World War II baby boom, but most of the teenagers who had babies during that era were married. Teen birth rates fell from the mid-1950s to the mid-1980s then increased in the early 1990s. Today, the rate of teen childbearing is lower than it was at the beginning of the 1990s, but most teen births (71 percent) occur outside of marriage (Shehan and Kammeyer 1997, p. 186).

Another significant change in fertility is the increase in births to unmarried women. Today, American women spend fewer years in marriage because they are marrying at older ages and are more likely to get divorced. As a result, there is less time available to them to have children within the context of marriage. One-third of all births in the United States today are to unwed mothers. The rate is higher among blacks than it is among whites. Childbearing outside marriage actually varies widely among industrialized nations, from Japan, where only 1 percent of all babies are born to unmarried women, to Sweden, where the comparable figure is 53 percent.

As a consequence of the high out-of-wedlock birth rate and the high divorce rate, an increasing number of adults are engaging in solo parenting. In 1995, about twelve million American families—or about one-fourth of all families with children—had only one parent (U.S. Bureau of the Census 1995). While the majority of single parents are women, men are also raising children alone. Today, about one-sixth of all single-parent homes are headed by men.

THE CHANGING SOCIAL CIRCUMSTANCES OF PARENTING

The demographic shifts that have occurred in industrial nations since World War II—particularly the increases in divorce and out-of-wedlock births—have increased the likelihood that children will have little or no contact with one of their biological parents during some period of their childhood. Only one in every four children of divorced parents who live with their mothers sees his or her father once a week; and close to half have little or no personal contact of any type with their fathers after divorce. Men's contact with their biological children from previous marriages is reduced when they remarry and become involved in the lives of stepchildren or have children with their new partner. Other adults, however, may step in to fill the gap in children's access to their biological parents. For instance, three-fourths of the children who live with their fathers share their homes with other adults. About one-third live in multigenerational households (with grandparents and other relatives), and another third

live with their father and his intimate partner. Children in these homes may or may not benefit from the added financial and emotional resources that nonrelated adults can offer (Shehan and Seccombe 1996).

Single-parent families headed by women often have financial problems. Many live below the poverty level. A major contributing factor to this "feminization of poverty" is the fact that not all noncustodial fathers are ordered by the courts to pay child support after divorce, and, of those who are, fewer than half actually pay the full amount.

GOVERNMENT SUPPORT FOR PARENTS

The major changes in family patterns that have occurred over the past twenty-five years have made government leaders from around the world very aware of family problems. Concerns about declining birthrates and the aging of the population have been widespread throughout industrial nations. Many governments have adopted "pro-family" attitudes and attempted to create more supportive environments for families. But industrial nations have differed significantly in the extent to which they have provided support for families. The U.S. government has been reluctant to assume public responsibility for care of children, instead passing laws that reinforce the private nature of child support obligations. According to one indicator of "family friendliness," the United States, along with Portugal, Italy, Ireland, Spain, and Greece, is among the least generous of the industrialized nations in terms of its benefits packages for families with children (Gauthier 1999, p. 7).

As women's labor-force participation increased in industrialized nations in the 1970s, renewed attention was given to the provision of maternity leave plans. In most countries, these plans were upgraded, at least in terms of their duration, increasing by six weeks, on average across eighteen industrialized nations. Major increases in maternity pay also occurred in most countries. But in the United States, where only thirty states had provisions for maternity leave, no pay was mandated. In 1992, the Family and Medical Leave Act was passed by the U.S. Congress and signed into law by President Bill Clinton. The legislation provides public and private employees in companies with fifty or

more workers the right to take up to twelve weeks leave each year to care for a newborn or newly adopted child; or for a seriously ill child, spouse, or parent; or for their own serious health conditions (Gauthier 1999).

THE CHILDBEARING DECISION: THE REWARDS AND COSTS OF PARENTING

Since individuals are now better able to control their reproductive functions due to advances in contraceptive technology and access to legal abortion, it is important to examine why the majority of adults still choose to become parents. For most people, becoming a parent involves a decision-making process in which the anticipated rewards and costs of parenting are weighed. One major influence on this choice is societal pressure. While most societies encourage fertility among their members, the United States is considered to be particularly *pronatalist*, which means its dominant values and attitudes promote and encourage childbearing (Schoen 1997).

Rewards of Parenting. In earlier historical periods, children were valued in large part because their labor could greatly enhance a family's economic survival. Today, children may continue to have economic value for parents who view them as a type of old age insurance. A small minority of parents, typically those from rural areas, also see children's ability to participate in household labor as a valuable asset. Having children may also enable a family to maintain control over property or a family-owned or family-operated farm or business. For most families, though, children may be more of an economic liability than a benefit. Their primary value to their parents is emotional and symbolic. Understanding the noneconomic benefits of child rearing helps in understanding why most people choose to become parents when they are no longer forced to do so by biological necessity.

Studies of the value of children to their parents have identified many major rewards that child rearing provides. One reward is *family continuity or personal immortality*. The birth of children ensures that the father's family name will continue into the future, at least for one more generation, and may give the parents a sense of immortality, a feeling that part of them will survive after death.

Becoming a parent can also lead to a *change in social identity*. It bestows adult status, which carries with it implications of maturity and stability. In fact, for many people, parenthood is *the* event that gives them a sense of feeling like an adult. Having children may also produce a sense of achievement, not only for the physical fact of conception but also for the challenges of raising a child. Moreover, many parents also feel a sense of accomplishment through their children's achievements. Finally, during the child-rearing years, the legitimate authority that is attached to the parent role, as well as the resulting power and influence parents have over their children's lives, may increase parents' self-esteem, especially for those who have little control over other aspects of their lives.

The most frequently mentioned reward of child rearing involves primary group ties and affection. Children help their parents establish new relationships with their own parents, grandparents, aunts and uncles, siblings, and friends; such relationships can provide emotional support and practical assistance. Children are also expected to help prevent loneliness and to provide love and companionship for their parents. Many people regard childbearing as a sacred duty and may feel that by becoming parents they are fulfilling a divine commandment. Moreover, the physical and symbolic sacrifices involved in child rearing are perceived by some as a sign that parents are more virtuous and altruistic than childless adults (Shehan and Kammeyer 1997, pp. 187-189).

The Costs of Parenting. There are also numerous costs associated with parenting. These costs are economic as well as social and emotional. Over the years, economists have estimated the *direct economic costs* (e.g., food, clothing, shelter, medical and dental care, toys, recreation, leisure, and education) and the *indirect economic costs* (e.g., foregone savings and investments, lower standards of living, and loss of potential income for parents who leave the labor market to care for the child) of child rearing. The direct costs of raising a child to age 18 have risen by more than 20 percent in recent decades, after adjustments for inflation and for changes in family size have been made. In 1998, raising a child to adulthood, which includes sending her or him to a state university for four years, costs middle-income parents an average of

\$459,014; that's \$301,183 in direct costs and \$157,831 in costs associated with college education (Longman 1998).

Another important economic cost of parenthood that must be considered is the current or future family income that is given up when parents leave the labor force—or reduce their hours in employment—to care for children. Virtually all parents face some opportunity costs in having children. Using estimates and procedures developed by the U.S. Department of Agriculture—which provides reports on the costs of child rearing annually—the following example of the opportunity costs encountered by parents is offered. A married woman with an annual salary of \$23,600 who stays home to care for a child from birth until kindergarten age (at which point she reenters the labor force on a half-time basis) can expect to sacrifice nearly \$1 million in lost income by the time that child reaches age 21 (Longman 1998). When opportunity costs are added to the direct costs of child rearing that were listed above, a middle-income couple can expect to spend slightly more than \$1.45 million on one child by the time she or he completes college.

In the United States and other industrialized nations, however, parents receive some governmental subsidies for raising children. In the United States in 1998, each dependent child was worth a \$2,650 deduction on his or her parents' federal income taxes. Parents are also able to take a tax credit for child care expenses—a maximum of \$720 for one child in a low-income family to a maximum of \$1,440 for two or more children (Longman 1998).

The presence of children may also be costly to adults through the restriction of their activities and the resulting loss of freedom. Parents are responsible for the mental, emotional, physical, spiritual, and social development of their offspring. Obviously, such responsibility may consume much of the parents' time and attention and may require a readjustment of lifestyle to take the children's needs and activities into account. Consequently, parenting may have negative effects on marriage. Studies have shown that the birth of children may hurt a couple's affectional and sexual relationship, due largely to frequent interruptions, a loss of privacy, and increased demands on time and energy. The birth of children often results in role

segregation, which means that spouses engage in fewer joint activities as they attempt to fulfill their parental responsibilities (Walzer 1998).

When the Costs Outweigh the Rewards. For a small minority of adults in industrialized nations, the anticipated costs of having children outweigh the anticipated rewards, and they decide to have no children. Throughout most of the twentieth century, the proportion of childless marriages in the United States was only 5 to 10 percent. The rates of childlessness increased in the last decades of the century, however. In the late 1990s, nearly one in every five American women aged 40 to 44 (considered the final years of the childbearing period in women) was childless (U.S. Bureau of the Census 1995, 1999).

The individuals with the highest education in our society are the ones least likely to have children, because they experience the highest opportunity costs associated with childbearing and child rearing. In the United States, middle-aged women with graduate degrees are three times more likely than those who drop out of high school to be childless. Two-income couples who earn more than \$75,000 are much more likely than those who make less than \$20,000 to be childless (Longman 1998).

Adults who choose to remain childless may believe that having children would interfere with their ability to achieve in their careers or in other types of public service. They may feel that caring for children would drain away the time and energy that could be devoted to other highly valued pursuits. Another important consideration for such adults is the expectation that the commitment to parenthood would reduce the time available to devote to their marriage. To voluntarily childless couples, marriage rather than children may be the primary source of affection and sense of belonging.

THE CHANGING RESPONSIBILITIES OF PARENTS

Views of children and childhood, and of parental responsibilities, have changed over the centuries. For most of human history, simple physical survival of children was the dominant issue in child rearing. Prior to the seventeenth century, parental

love was rarely identified by child-rearing experts as a critical factor in the development of a child. In medieval societies, there was no recognition of any characteristics that distinguished children from adults; children merged naturally into adult society from about the age of 7. There were no boundaries separating the adult world from the world of children (Cunningham 1995). It wasn't until the sixteenth century that childhood was viewed as a period of innocence. Children were idolized and valued as a source of amusement or escape for adults. Later in the sixteenth century, and carrying over into the seventeenth and eighteenth centuries, childhood began to be seen as a time of immaturity and children were believed to need discipline and guidance as they prepared for adulthood. Parents were expected to provide physical care, consistent discipline, and a model for proper behavior.

At the close of the nineteenth century, during the Victorian age, awareness of the vulnerability of children and a belief in the sacredness of childhood emerged. Compulsory schooling, which removed children from the labor force, was introduced and drew a sharp line between childhood and adulthood. Once children were regarded as different from—and inferior to—adults, they became dependent on older persons for survival (Shehan 1999). In some segments of American society today, there is a belief that parents alone can—and should—meet all their children's needs. Parents are responsible not only for their children's physical well-being but also for their psychological adjustment. Often, flaws in a person's adjustment are traced to a lack of parental love or some other parental shortcoming.

The Mother Role. To many people, parenting is synonymous with mothering, and mothering is believed by many to be an instinct found in all women. While scientists have yet to find an instinctual motive for motherhood among humans, they have demonstrated a strong learned need among women to have children. Most women, given the choice to become mothers, would choose to do so, and most women who are already mothers would choose the role again (Genevieve and Margolies 1987).

The belief that motherhood is necessary for women's fulfillment and for the normal healthy development of children has waxed and waned

throughout our history, largely in response to economic conditions. When women's labor is not needed outside the home, the mother role is glorified and exalted; when women's labor is essential to the economy, the importance of the mother-child bond is downplayed (Margolis 1984). Earlier in our history, when our economy was agrarian, parenting was more of a joint venture. Child rearing was shared among a larger number of adults and the mother-child bond was not regarded as primary. Only after industrialization and urbanization changed the nature of work and family life did the role of mother in child development become preeminent. As will be discussed below, similar changes are under way in regard to the father role.

The Father Role. While the verb *to mother* is used to refer to the nurturance and care given to children, usually by women, the verb *to father* has a much more restricted meaning. To many, this simply refers to the male role in procreation. The responsibilities attached to the father role have traditionally been economic. To be a good father, a man had to be a good provider. Participation in the daily custodial care of the child was not expected, nor was companionship or nurturance. In recent decades, with the entrance of large numbers of mothers into the labor force, the expectations attached to the father role have begun to change. Men can no longer be good fathers simply by being good providers. They must also participate more fully in the daily care of their children and in the socialization process (Griswold 1993).

It appears that these expectations are being reflected in changed behavior. More fathers are attending childbirth education classes with their wives and are present at the births of their children, and the average amount of time men spend with their children has increased since the early 1970s. These changes support the argument that men are psychologically capable of participating in all parenting behaviors. Perhaps the most telling evidence of the extent to which Americans' ideas about the father role have changed since the 1940s can be found in the expert advice on parenting. In the first edition of his classic book about child care, which was published in 1945, Dr. Benjamin Spock reminded fathers that they need not be as involved in child care as mothers, at most preparing a bottle for the baby on Sundays. By the

1980s, Dr. Spock was admonishing fathers to take on half of all child care and housework tasks.

TRANSITION TO PARENTHOOD

Some sociological studies have found that many couples experience the birth of their first child as a crisis. The changes brought about by the addition of a baby to a household are indeed extensive. Occupational commitments, particularly of the mother, may be reduced, and family economics must be reorganized as spending increases and earnings are reduced. Household space must be reallocated to accommodate the infant's lifestyle. The parents' time and attention must be redirected toward the infant. Relationships with kin, neighbors, and friends must be redefined to include the baby's schedule. The marital relationship itself may be disrupted due to the enormous demands for time, energy, and attention made by the baby. As a result, new mothers frequently report unexpected fatigue, confinement to the home and a sharp reduction in social contacts, and the loss of the satisfaction that accompanied outside employment. New fathers may feel added economic pressure (Walzer 1998).

The severity of the crisis experienced by new parents does not seem to be related to the quality of the marital relationship before the birth of the child or to the degree to which the child was planned and wanted. Instead, it may be the degree to which the parents had romanticized parenthood in conjunction with their lack of preparation for the role that leads to a feeling of crisis. As a result of the tremendous changes brought about by the presence of children and the burdens associated with child rearing, marital satisfaction appears to decline sharply around the time of the first child's birth and to remain low until children leave the home (Shehan and Kammeyer 1997, pp. 213-214).

PARENTING IN THE MIDDLE YEARS

During the twentieth century, there was a steady increase in the number of young adults who returned to their parents' homes to live. When children return home to live with their parents, there are both advantages and disadvantages. Many of

the problems are caused by the ambiguity of the situation. Parents may wonder whether they should establish and enforce rules governing their children's behavior (e.g., curfews, financial obligations, use of drugs and alcohol, and guests). Both parents and their young adult children are likely to revert to the roles they played when the children were adolescents. Young adults may revert to being emotionally, physically, and financially dependent on their parents but may find it stressful being "adult teenagers." Parents, too, are likely to feel stress when their young adult children return home to live. They are often forced to make major changes in their daily routines, and to take on unwanted burdens such as extra cooking, cleaning, and laundry when children return home. There can also be financial strains for the parents, associated with larger food bills and greater utilities costs. Conflicts between parents and their adult children may arise simply because of crowded household conditions. When adult children bring their furniture, sports equipment, pets, and clothing back home, the "empty nest" can become a "cluttered nest." But in spite of the problems that can arise when young adults live with their parents, both groups typically feel that the situation has many benefits (Shehan and Kammeyer 1997, pp. 260-265).

PARENTING IN THE LATER YEARS OF LIFE

The rewards of parenting can persist throughout life. Continued attachment to their children helps to minimize elderly parents' sense of isolation and loneliness. Children's readiness to take care of parents' needs helps to build a sense of security in old age and is important in day-to-day survival. However, elderly parents also want to continue to help their children. Their contributions to their adult children occur in many forms, from providing financial assistance to help with housework and care of grandchildren. Elderly persons derive a great sense of pride and satisfaction from their parental role, even when their sons and daughters are middle-aged adults with children of their own. Being recognized by their children for their value and competence as parents helps them to maintain high levels of self-esteem. When adult children provide aid and assistance to their elderly

parents—especially if they take a condescending attitude toward their parents and make all decisions for them—the latter may find it demoralizing. The ideal situation is one where elderly parents and their adult children help each other and make decisions together. All things considered, the relationships between elderly parents and their adult children are very positive (Shehan and Kammeyer 1997, pp. 273–275).

PARTICIPATORY RESEARCH

Participatory research integrates scientific investigation with education and political action. Researchers work with members of a community to understand and resolve community problems, to empower community members, and to democratize research. The methods of participatory research include group discussions of personal experience, interviews, surveys, and analysis of public documents. Topics that have been investigated with this approach include community issues such as polluted water supplies and the school curriculum, employment issues such as working conditions and unionization, and theoretical issues about consent and resistance to domination. For social scientists who question the traditions of being detached and value-free, and who seek an approach that is less hierarchical and that serves the interests of those with little power, participatory research is a valuable alternative.

Participatory research can be identified by five characteristics: (1) participation by the people being studied; (2) inclusion of popular knowledge; (3) a focus on power and empowerment; (4) consciousness raising and education of the participants; and (5) political action. A precise definition should be avoided so that each group that does participatory research can be free to develop some of its own methods.

Participation in the research process by the people being studied is best viewed as a continuum that includes low levels of participation, such as asking people who are interviewed to read and comment on the transcripts of their interviews, as well as high levels of participation. Ideally, community members have a significant degree of participation *and control*, and help to determine the major questions and overall design of the study.

Second, participatory research validates popular knowledge, personal experience and feelings, and artistic and spiritual expressions as useful ways of knowing. If researchers are to work with community members as co-investigators, they must respect people's knowledge. Moreover, one of the rationales for community participation in research is the assumption that people understand many aspects of their situation better than outsiders do. Practitioners have used group discussions, photography, theater, and traditional tales to draw on popular knowledge (Barndt 1980; Luttrell 1988).

A focus on power and empowerment also distinguishes most participatory research. "The core issue in participatory research is power. . . the transformation of power structures and relationships as well as the empowerment of oppressed people," states Patricia Maguire in her excellent analysis of the field (1987, p. 37). Participatory researchers differ widely in their positions on empowerment, and include radicals who try to transform the power structure by mobilizing peasants to wrest land from the ruling class, as well as conservatives who ignore power relations and focus on limited improvements such as building a clinic or a collective irrigation system.

The fourth characteristic of participatory research—consciousness raising and education—is closely related to power. Group discussions and projects typically attempt to reduce participants' feelings of self-blame and incompetence, and try to relate personal problems to unequal distributions of power in the community and the society. Participants often become visibly more confident and effective as they speak out in discussions, learn that others share some of their experiences, and learn research skills and relevant technical information.

Finally, participatory research includes political action, especially action that cultivates "critical consciousness" and is oriented toward structural change, not toward adjusting people to oppressive environments (Brown and Tandon 1983). Some scholars argue that "real" participatory research must include actions that radically reduce inequality and produce "social transformation." Research and action, from this perspective, should be guided by a general theory like Marxism to help identify the underlying causes of inequality and the best strategies for changing society. Others

caution against expecting to achieve radical changes because "social transformation requires . . . organizing, mobilizing, struggle" as well as knowledge (Tandon 1988, p. 12). These researchers point to the value of small collective actions in educating people about the local power structure, creating greater solidarity and feelings of power, and providing new knowledge about how power is maintained and challenged. Many projects include little or no collective action and are limited to changing the behavior of individual participants, strengthening or "creating a community network" and "fostering critical knowledge" (Park 1978, p. 20).

In some cases, participatory research produces major changes, as exemplified by a project with residents of a small town in the state of Washington. The town was going to be destroyed by the expansion of a dam, and the U.S. Army Corps of Engineers was planning to disperse the community. But with the assistance of Professor Russell Fox and numerous undergraduates from Evergreen State College, residents clarified their own goals for a new community, learned about the planning process, and produced a town-sponsored plan for a new town. Their plan was accepted by the Corps of Engineers after prolonged struggle involving the courts and the U.S. Congress. The new town thrived and continued to involve the entire community in planning decisions (Comstock and Fox 1982).

A study of the working conditions of bus drivers in Leeds, England, illustrates the mixed results that are more typical of participatory research. As a result of greater pressure at work accompanying Prime Minister Margaret Thatcher's program of deregulation, bus drivers were experiencing increasing stress, accidents, and conflicts at home (Forrester and Ward 1989). With the help of professors from the University of Leeds who were running an adult education program for workers, a group of eight bus drivers, selected by their local union, decided to do research that would investigate stress at work and motivate the drivers' union to take action. They designed and carried out a survey of a sample of drivers and their families, studied accident records, and measured physical signs of stress. Although the report presenting their findings failed to produce the desired action by the union, the project was successful in many other ways—workers' stress became part of the

agenda for the union and the national government, and the report was used by workers in other countries to document the need for improved working conditions. The participants in the research gained research skills and knowledge about work stress, and the professors produced academic papers on work stress and participatory research. The professors had a dual accountability (as they put it) both to the bus workers and to the university; their projects produced results that were valuable to both groups.

THE HISTORY OF THE FIELD AND RELATIONS TO OTHER FIELDS

Participatory research was developed primarily by Third World researchers, and most projects have been in Third World communities. In the 1970s it became clear that mainstream economic development projects were failing to reduce poverty and inequality. In response, researchers began to develop alternative approaches that increased the participation of the poor in development programs and aimed at empowering poor rural and urban communities as well as improving their standard of living (Huizer 1979; Tandon 1981, 1988). For example, in the Jipemoyo Project in Tanzania, researchers and villagers investigated traditional music and dance practices and developed cooperative, small-scale industries based on these traditions, such as the production of “selo drums” for sale in urban areas (Kassam and Mustafa 1982). In other projects, peasants and farmers participated with agricultural and social scientists to determine the most appropriate and productive farming methods. Several projects in Latin America, led by Orlando Fals Borda and labeled “participatory action research,” integrated the knowledge of peasant activists and academics to build rural organizations and social movements.

Participatory researchers in the Third World are closely associated with Paulo Freire, an exiled Brazilian educator with roots in Marxism and critical theory. His book *Pedagogy of the Oppressed* is the most influential work in participatory research. Freire argues that teaching and research should not be dominated by experts but should be based on dialogue with a community of oppressed people. Through dialogue and collective action, people can develop critical consciousness, learn the

skills they need to improve their situation, and liberate themselves. A similar approach has been developed by the influential Highlander Research and Education Center in the southern United States. Organized by Myles Horton and others in the 1930s, Highlander has inspired many participatory researchers with its success in educating and empowering poor rural people (Gaventa and Horton 1981; Gaventa et al. 1990). Another important center of participatory research has been the Participatory Research Network in Toronto, focusing on adult education (Hall 1975, 1981).

The development of participatory research in the 1970s was also fostered by challenges to positivist social science by feminists, Marxists, critical theorists, and others (Bernstein 1983; Harding 1986). The critics emphasized the links between knowledge and power. They argued that the positivists’ emphasis on objectivity, detachment, and valuefree inquiry often masked a hidden conservative political agenda, and encouraged research that justified domination by experts and elites and devalued oppressed people. The critics proposed alternative paradigms that integrated research and theory with political action, and gave the people being studied more power over the research (Carr and Kemmis 1986; Lather 1986; Rose 1983).

The development of alternative paradigms, together with the emergence of participatory research in the Third World and the political activism accompanying social movements of the 1960s and 1970s, sparked a variety of participatory research projects by North American social scientists. John Gaventa investigated political and economic oppression in Appalachian communities, and grass-roots efforts to challenge the status quo, and Peter Park criticized mainstream sociology from the perspective of participatory research and critical theory. Health-related issues such as wife-battering, health collectives, and toxic wastes were studied by Patricia Maguire and others, while researchers in education examined community efforts to improve public schools and participatory methods of teaching (Luttrell 1988). Issues at the workplace such as struggles for unionization have been investigated by many participatory researchers; they have documented the impact of factors such as ethnic divisions and women’s work culture on the success of unionization (Bookman and Morgen 1988).

Participatory research is closely related to several other fields. Feminist approaches to research and teaching often closely resemble participatory research and emphasize nonhierarchical relations between researcher and researched, raising consciousness, taking action against sexism and other forms of domination, and valuing expressive forms of knowledge (see Smith 1987; Stanley and Wise 1983). Feminists have done the majority of the participatory research projects in North America, but they do not use the label, and feminists and participatory researchers rarely consult each other's work.

A similar approach has been developed by William F. Whyte, who works with representatives of management and workers to study organizational problems such as reducing production costs, or redesigning training programs. His approach differs from participatory research in that it gives little attention to power and empowerment, or to consciousness raising and education, and the action component of the projects is coordinated with management and does not directly challenge the existing power structure. Whyte labels his approach "participatory action research," which will cause confusion since the same term is used to describe Orlando Fals Borda's very different, more radical approach.

Participatory research also overlaps with several traditional social science methods, especially participant observation, ethnography, and intensive interviews, all of which rely on empathic interpretation of popular knowledge and everyday experience and that lead researchers to be engaged with the people being studied, not detached from them. Applied research also focuses on social action, but usually for the privileged—those with the money and sophistication to employ researchers or consultants.

ISSUES IN PARTICIPATORY RESEARCH

Two issues underlie many of the problems confronted by academic participatory researchers: the relations between researchers and the researched; and the tensions between being politically active and producing objective, academic studies.

Relations between researchers and researched are problematic at each stage of a participatory

research project (on stages, see Maguire 1987; Vio Grossi 1981; Hall 1981). At the beginning of the project the researchers must consider what segments of the community will participate. Although some participatory researchers talk about "the oppressed" people in a community or "the poor" as if they were a homogeneous group, most communities are complex and internally stratified, and the more powerless people usually are more difficult to include.

The power of the researcher versus the researched also is problematic in the next stage of a project, when participants identify and discuss community problems. Researchers have specific skills in facilitating the group and obtaining information, and typically have more time, money, and other resources. Therefore, they can take more responsibility (and power) in the project, and community members often want a researcher to take charge in some areas. There are also conflicts during group discussions between validating participants' knowledge and power versus educating for critical consciousness and validating the researchers' power (Vio Grossi 1981).

When the project moves to the stage of designing research on community problems, researchers are especially likely to have a power advantage, since community members typically lack the skills and the interest to carry out this task. If community members are to be equal participants in designing a complex research project, they first need an extended educational program like the adult education classes for the Leeds bus drivers. Otherwise, the research probably will have to be fairly limited, or the researchers will control the research design, while community members participate as consultants and trained research assistants. In this case it becomes especially important that community members have substantial power in setting the research agenda (e.g., Merrifield 1989).

Conflicts between activism and involvement versus academic objectivity and detachment are another source of problems. However, many of the problems can be resolved by questioning the assumed incompatibility between being involved with the people one is studying and producing objective or valid evidence. On the one hand, involved researchers often produce valid knowledge. Sociology and anthropology include many

examples of systematic, highly regarded ethnographies and interview studies by researchers who were very involved with the community. Moreover, participating as an activist probably yields just as valid an account as being a traditional participant observer. On the other hand, research methods associated with being detached, such as surveys and quantitative analysis, often contribute to effective political action. For example, a research group in Bombay organized a participatory census of pavement dwellers in a large slum. Their results documented that slum dwellers had been underenumerated by the official census and had been unjustly denied census-dependent services. Participants also created strong community organizations and learned how to use existing services (Patel 1988). In this project, community involvement and academic standards were compatible. In other projects, participatory researchers have experienced many conflicts between serving the interests of the community being researched, and producing knowledge that is valuable to the academic community.

RECENT DEVELOPMENTS

Participatory research methods have gradually spread through the social sciences and related fields in recent years. Researchers in health (Cornwall and Jewkes 1995; Mishra et al. 1998), family sociology (Small 1995), community psychology (Stoecker and Beckwith 1992; Yeich and Levine 1992), and other fields are using participatory research methods. Several journals have devoted special issues to participatory research, including *American Sociologist* (Stoecker and Bonacich 1992, 1993), *The Journal of Social Issues* (Bryden-Miller 1997) and *Human Relations* (Chisholm and Elden 1993). New books on participatory research also have appeared (De Koning and Martin 1996; Fals-Borda and Roshman 1991; Park et al. 1993).

The growing numbers of studies using participatory research methods vary widely in the degree to which they depart from traditional social science methods. In most studies, control over the research design remains with the researcher, although the researched may have power over a limited component of the project. In addition, many studies do not include social action as part of the project. As participatory research continues to

develop, researchers will continue to struggle with balancing the power of the researcher and the researched, and with the conflicting demands of activism and academic standards.

FRANCESCA M. CANCIAN
CATHLEEN ARMSTEAD

PEACE

Humans have always prized and sought peace. The conditions believed to foster peace and the very conception of peace, however, have varied in different periods and cultures. In this article, we examine contemporary scholarly understandings of peace and how to achieve and maintain peace (Barash 1991; Galtung 1996; Stephenson 1994). In particular, we discuss the views of American sociologists and other social scientists who regard themselves as engaged in peace studies, peace research, conflict resolution, and related fields.

The concept of peace is contested. Some analysts use the term “peace” in opposition to war; this is *negative peace*, defined as the absence of direct physical violence. Other analysts stress *positive peace*, defined as social relations marked by considerable equality in life chances, by justice, or even by harmony. Some writers use the term “peace” to refer only to relations among global actors in a world system, while others include relations among persons and groups as well as among countries. Finally, some observers regard peace as a stable condition and others think of it as many never-ending processes.

In this article, we discuss certain aspects of positive peace, while focusing on negative peace. Furthermore, we emphasize international peace, but also consider large-scale relations within societies. With these focuses, we examine three categories of peace processes: (1) *building peace*, developing processes that prevent the emergence of destructive conflicts; (2) *making peace*, developing processes that contribute to deescalation and settlement of conflicts; and (3) *keeping and restoring*

peace, fostering processes that help maintain peace and construct equitable relations.

BUILDING PEACE

The analysts providing the research and theorizing examined here and in the next sections vary in the relative importance they give to variables and conditions from different sources: from within one or more of the contending parties, from the relationship among them, and from their social context. Each is discussed in turn.

Internal Factors. Considerable work has been done about the processes and the conditions within countries that contribute to international peace or war and within large-scale groups that contribute to societal peace or destructive conflict. One such body of work stresses the role of self-serving elites in arousing, sustaining, and exacerbating antagonisms against other countries or groups. For example, during the years of the Cold War, many observers analyzed the existence and effects of a political–military–industrial complex in promoting the arms buildup in the United States and in the Soviet Union (Mills 1956; Sanders 1983).

More recently, peace workers have been directing their attention to political and intellectual elites who develop and promote ethno-nationalist ideologies. The way such ideologies are based on a socially constructed history and shared community is the subject of considerable analyses (Anderson 1991). In addition, many analysts stress the contribution that such ideologies make to the emergence and exacerbation of bitter fights and of genocide (Anthony Smith 1991). Finally, observers often examine how military, political, and intellectual leaders promote such ideologies for their personal benefit.

Peace workers believe that analyzing such processes demystifies them and their products. Furthermore, they believe that such unmasking undermines the effectiveness of those seeking to mobilize followers to wage struggles that deny legitimacy to their opponents. This kind of critical analysis is a major form of peace research.

Another large body of writing about building peace examines the education and socialization of members of a society or group in ways that promote peace. This includes research and theorizing about the ways this has been done and about the

ways that it might be done. The feminist scholarly perspective is an influential source for important contributions to this body of work. For example, using this perspective, the invisibility of women in studies of conflicts and peace processes becomes apparent, and feminist scholars provide new insights into international and domestic conflicts by paying attention to the roles women play in such conflicts (Enloe 1989). Furthermore, considerable research demonstrates consistent differences between women and men regarding support for the use of military means in international conflicts. The popular expectations, however, tend to exaggerate the degree to which men and women differ in their conduct in conflicts and negotiations (Stephenson 1996; Taylor and Miller 1994).

Feminist work tends to emphasize that the gender differences that do exist result significantly from past socialization of males and females into gender roles and from patriarchal social structures. Men learn to be relatively competitive and hierarchical, while women emphasize integrative relations. The feminist perspective fosters a vision that social relationships could be less patriarchal and therefore less unjust and less prone to destructive conflict than they generally have been.

How language and imagery are used to give meaning to conflicts helps frame conflicts and thus affects how they are waged. For example, analysts examine how the mass media and films contribute to an overreliance on violence and the threat of violence to wage conflicts (Gibson 1995). Such work also illuminates the processes of dehumanization of opponents in social conflicts, as well as revealing how such dehumanization contributes to the destructive escalation of struggles.

Since conflicts are inherent in social life, the role of social structure and culture in shaping how conflicts are waged is highly significant for building peace. Analysts are giving increasing attention to variations in the repertoire of methods used to conduct conflicts, including constructive ones, that are available for different people in different historical periods (Tilly 1978). Efforts to study and to train people in the methods of nonviolent action and problem-solving conflict resolution methods therefore contribute to building peace internationally and domestically (Kriesberg 1998).

Relational Factors. Several aspects of the relations among global and among societal actors

affect the likelihood that those actors will interact peacefully. One long-standing area of peace studies has been the effect of integration between societies and of sectors within societies. Integration is indicated by the high rate of exchange of goods, peoples, and ideas across societal and group lines, relative to exchanges within. Research findings support the generalization that such integration enhances mutual security and reduces the probability of countries' waging wars or threatening each other's security. Increased integration not only creates greater bonds of mutual interest and identity, but also improves communication and exchanges that parties regard as equitable. Furthermore, research on ethnic and other cleavages within societies also indicates the importance of integration, cross-cutting ties, and shared identities in preventing such cleavages from manifesting themselves in destructive conflicts (Dahrendorf 1959; Kriesberg 1998).

Considerable evidence has been reported indicating that democratic countries do not make war against each other (Gleditsch and Heegre 1997). Although the finding and particularly its interpretation are contested, the finding seems robust, given particular definitions of democracy and war. The finding may be explained by the tendency of governments in democratic societies to accord legitimacy to each other and credibility to each other's claims. Furthermore, negotiating differences may tend to be regarded as more acceptable and more skillfully practiced in democratic than in nondemocratic societies.

Contextual Factors. The social context within which possible adversaries interact certainly affects their relations. The context includes the social system within which adversaries interact, including the overall level of integration, the nature of institutional structures, the likelihood of external intervention in conflicts, and the kind of norms that are shared. The concepts of positive peace and structural violence help in understanding the relationship between social context and peace. Unlike personal violence, structural violence is indirect. It refers to the "avoidable denial of what is needed to satisfy fundamental needs" (Galtung 1980, p. 67). Thus, structural conditions may damage and cut short people's lives by restrictions of human rights or by malnutrition and illness, while other people using available knowledge and resources do not suffer the same deprivations. Such

inequities are built into the global order and constitute negative peace. This influential idea has stimulated various studies, particularly regarding conditions in peripheral or underdeveloped regions. The literature about the development of the world system and of colonialism obviously bears on this matter (Chase-Dunn and Hall 1997).

The expansion in the number, scope, and size of international nongovernmental organizations (INGOs) is a subject of growing sociological attention, reflecting INGOs' increasing global importance. Many kinds of transnational organizations perform activities and are arenas for interactions that supplement or even compete with states and with international governmental organizations. INGOs include multinational corporations, religious and ideological organizations, professional and trade associations, trade union federations, and ethnic associations. These groupings provide important bases of transnational identity and action (Smith et al. 1997).

Critical analysts view these developments as part of a new global order in which a transnational elite exercises hegemonic domination. Their work stresses the increasing global inequality and the development of a transnational elite that fosters globalization and profits from it. From this perspective, the U.S. government's promotion of democracy throughout the world is a method of maintaining order while promoting free markets and capitalism. Democracy, in this context, means *polyarchy*, a system in which a small group rules and mass participation is limited to choosing leaders in managed elections (Robinson 1996, p. 49).

International and supranational governmental organizations are also taking on increasing importance; witness the peacekeeping activities of the United Nations after the Cold War. Social scientists, including sociologists, have examined the conditions in which such institutions emerge and survive, how they serve to improve the quality of life, and how they may help to prevent conflicts from erupting and escalating destructively (Etzioni 1965).

The people of the world are already highly interdependent and are becoming increasingly so. This is true at the societal and at the global level. The flow of goods, capital, labor, ideas, and information is ever faster, ever less expensive, and ever more extensive. Consequently, the people of the

world share problems relating to environmental threats, governmental abuse and brutal conflicts spurring large-scale refugee flows, dislocations resulting from rapid social change, and challenging social relations among groups that are culturally different.

These phenomena contribute to the growing homogenization of the world. More and more people share images, ideas, and norms relating to consumer preferences, forms of entertainment, the protection of human rights, and economic development. But these phenomena also generate particularistic reactions and threaten destructive conflicts within and between societies. Experiences with these phenomena around the world and within each society are not the same for everyone. Some people reject the spreading secularism and the dominance of Western, particularly American, ideas and power. The empirical contradictions and the moral dilemmas arising from these developments are increasingly matters of inquiry among peace workers (Boulding 1990).

MAKING PEACE

Recent peace work has focused on limiting the destructive escalation of conflicts, fostering transitions toward deescalation, and conducting negotiations that help end conflicts constructively. Internal, relational, and contextual factors contribute to these ways of making peace.

Internal Factors. Among internal factors, sociological work attends particularly to popular forces that pressure governments to move toward accommodations with external adversaries. This interest combines with the growth in theory and research about social movements to generate many studies of peace movements (Lofland 1993; Marullo and Lofland 1990). Analyses of campaigns against nuclear weapons and other evidence indicate that, at least within the United States and western Europe, public opinion and organized public pressure have influenced governments, often in the direction of peacemaking (Joseph 1993; Klandermans 1991).

In addition, certain internal structural factors can help leaders to recognize the needs of the other side and to communicate responsiveness. Such factors may include leaders who are accorded legitimacy, openness to considering alternative

courses of action, sources of good information about outside groups, and norms limiting intolerance. Such factors and specific policy-making procedures can help limit escalation, manage crises, and negotiate settlements (Wilensky 1967).

Relational Factors. Most work on peacemaking focuses on the relations between adversaries, including analyses of tacit bargaining, formal and informal negotiations, and providing mutual reassurance about security. The relationship between the United States and the Soviet Union, and their alliances during the Cold War, has been the subject of considerable study. Contributions have been made about the extent to which that conflict and the proxy wars associated with it were based on misunderstandings and on processes of dehumanization that fostered conflict escalation (Gamson and Modigliani 1971).

Other writing has drawn from and contributes to studies of problem-solving conflict resolution and conflict transformation. This work includes the analysis of ways of waging struggles constructively so that escalation is limited, and so that possibilities of reaching mutually acceptable accommodations are not foreclosed. This is an argument examined in studies of the use of nonviolent action, as in the American civil rights struggle and in many other conflicts (Powers and Vogeley 1997; Wehr et al. 1994; Sharp 1973).

Work on relational aspects of peacemaking also includes analyses of conciliatory gestures and other initiatives to deescalate conflicts, of the management of crises, of the transformation of intractable conflicts into tractable ones, and of strategies and techniques for negotiating mutually acceptable agreements (Patchen 1988). It also includes the efforts by persons in one camp to exchange information and possible options for peacemaking with their counterparts in the opposing camp, through conferences, dialogue groups, and ongoing workshops.

The ending of the Cold War illustrates the success of some of these methods (Kriesberg 1992). Specifically, such methods include negotiating mutual assurances that vital interests would not be threatened, as was done in the Conference for Security and Cooperation in Europe, resulting in the Helsinki Accords, signed in 1975. Included in the Accords was a shared commitment to norms, for example, about protecting human rights, which

fostered increased mutual exchanges. In addition, the American and Soviet military alliances established confidence-building measures and later restructured their military forces to be less provocative. Nonofficial channels such as the Pugwash meetings and the Dartmouth conference assisted in reaching agreements that helped to transform the Cold War. These developments have served as inspirations for efforts to limit or transform other regional conflicts.

The transformation of the conflict in South Africa about apartheid is another important illustration of the effectiveness of some of these methods (Kriesberg 1998). For example, the African National Congress (ANC), with the leadership of Nelson Mandela, consistently pursued nonracist goals, thus offering assurance that whites were and would remain recognized as South Africans. The means used in the struggle to end apartheid were considered in that light; they were initially nonviolent, and even when the decision to wage armed struggle was undertaken, terrorism was excluded. Informal and unofficial communications prepared the adversaries for working out an agreement that was acceptable to all the major adversaries in the seemingly intractable conflict in South Africa (van der Merwe 1989).

Of course, in some cases when challengers initiated nonviolent struggles, they were repressed or the conflicts escalated destructively. Such cases, as in China and in Northern Ireland, deserve and have received attention. However, there are many case studies and quantitative analyses indicating that reliance on violence and threat of violence is frequently counterproductive and often mutually destructive (Vasquez 1993).

Contextual Relations. One important aspect of a conflict's context, affecting its transformation and its peaceful settlement, is the involvement of intermediaries. Analysts using a sociological approach give attention to the role of nonofficial persons and groups as well as official intermediaries. Such intermediaries often provide a variety of mediating services, including helping bring adversaries to the negotiating table, facilitating meetings, aiding in developing new options, building support for an agreement, and helping to implement and to sustain an agreement that is reached (Burton 1990; Laue 1973). Persons and groups providing such services vary greatly in the way

adversaries understand their role and in the resources they bring with them. For example, unofficial mediators with relatively few material resources may be able to provide exploratory services relatively well, since their engagement generally involves low risks for the antagonists. Mediators with a major stake in the fight and with great resources can provide compensations and assurances that are relatively important in closing negotiations and implementing them.

The U.S. government and U.S. private citizens have played important mediating roles in many international and even internal conflicts in other countries (Kriesberg 1992). American mediation in Israeli-Arab conflicts has been particularly extensive and often crucially effective. U.S. secretaries of state and U.S. presidents have conducted major mediating efforts, often using considerable resources to induce the negotiating parties to conclude an agreement and to implement it. Among the notable agreements reached are those mediated by Secretary of State Henry Kissinger in 1974 between Israel and Egypt and between Israel and Syria, and the 1978 Camp David agreements between Israel and Egypt, mediated by President Jimmy Carter and leading to the two countries' signing a peace treaty.

Nonofficial persons and groups from the United States have also provided mediation services, for example in the conflict between Israeli Jews and Palestinians. Nonofficial channels have been particularly important due to the long-standing refusal of the Israeli government to recognize the Palestine Liberation Organization (PLO) as the representative of the Palestinians. Jewish and Palestinian Americans have often had the knowledge, interest, and contacts to provide useful channels for exploring possible options and ways of taking steps toward official mediation and negotiation.

Mediation efforts, obviously, do not always succeed. Many efforts never result in agreements. In some cases, agreements are reached but not ratified or not implemented. On occasion, agreements are followed by disastrous breakdowns, as happened in Rwanda in 1994. Of course, failing to mediate probably would not have yielded better results. Nevertheless, this indicates that we need to know much more about the type of mediation that tends to be effective at each stage of various kinds of conflicts.

Among the many other relevant contextual factors, we note only a few. First, changes in prevailing norms and understandings sometimes embolden one party in a conflict and undermine the faith of its opponent. The result is that a conflict that has long persisted can move toward resolution. For example, changing views about human rights and democracy contributed to ending the civil wars in Central America and apartheid in South Africa.

The context also includes a wide range of international governmental and nongovernmental organizations, with varying capabilities of contributing to peacemaking. The mass media are also increasing the global attention to especially terrible events at particular times. Finally, the increasing availability of weapons of all kinds enables more and more people to challenge existing conditions, as well as enabling those in authority to resort to violent means of control.

KEEPING AND RESTORING PEACE

The recent transformation and settlement of protracted international and societal conflicts and the radical transformation of previously authoritarian and repressive societies have heightened attention to the challenges of building postconflict relations that are enduring and just (Lederach 1997). Changes within one or more antagonist camps and between former antagonists are crucial in meeting these challenges. In recent years, analysts have given particular attention to the role of intermediaries, standards of human rights, and other elements of the antagonists' social context.

Internal Factors. A fundamental change in ways of thinking among members of one or more antagonistic sides can be a powerful factor in producing an enduring peace between them. This does sometimes happen. For example, most Germans after the defeat of Nazism repudiated what they themselves had believed and done; instead, they welcomed beliefs, values, and institutions shared with the victors. To some extent, a similar transformation occurred among Russians as the Cold War ended. As a result of the American civil rights struggle of the 1950s and 1960s, most southern American whites became convinced that they were wrong to resist ending the Jim Crow system of discrimination. Similarly, most South African

whites would now concur that the ending of apartheid was right and just.

Changes in internal social structure also are frequently crucial. Countries that have had internal conditions engendering overreliance on military means and goals that threatened vital interests of other countries may reduce their external threat only after undergoing a fundamental internal restructuring. The restructuring may entail civilian control of the military and the development of a civil society and democratic institutions. Peaceful accommodations in postconflict relations within a country may also depend upon fundamental changes in one or more sides of the past conflict. This occurs as governments change or as the leadership of an ethnic, a religious, or a class movement undergoes change.

Relational Factors. Traditionally, efforts to restore peace after a conflict ends include policies to redress the grievances that were viewed as the conflict's source. For communal differences within a country, this may entail more autonomy for citizens with different languages or religions and provisions for popular participation in determining the form and degree of autonomy. For example, during the early 1950s, the status of Puerto Rico in relationship to the rest of the United States was being reconstituted. A Puerto Rican nationalist group resorted to violence in seeking independence. The suppression of violent attacks while avoiding general repression, the availability of a legitimate electoral political process, social and economic improvements, and programs of integration and autonomy, including cultural nationalism, combined to produce a generally peaceful relationship in which alternative arrangements are contested within the established political system.

In the United States, a wide variety of methods and strategies are employed to redress grievances and increase equity; they include programs of affirmative action for women and minorities. Such programs, however, have become subject to challenge and have been reduced. This demonstrates the ongoing nature of conflicts related to socially constructed differences between citizens.

In recent years, peace workers have been giving considerable attention to fostering mutual understanding and tolerance among peoples with different cultural backgrounds living in the same society (Weiner 1998). This attention extends to

reconciliation between peoples who perpetrated gross human rights violations and peoples who suffered profound losses during periods of repression or of violent struggle. Reconciliation is complex, variously combining several processes: (1) acknowledging the truth of what happened; (2) administering justice for past misdeeds, and ensuring future justice and security; (3) extending forgiveness to members of the group that committed wrongs (sometimes in response to expressions of remorse); and (4) accepting responsibility by those who committed wrongs or failed to oppose them. In postapartheid South Africa, for example, the work of the Truth and Reconciliation Commission represents one way to deal with these postconflict issues.

A variety of recent developments contribute to reconciliation among the different peoples making up the United States. The truth about discrimination, violent repression, and other injustices regarding Native Americans, African Americans, and other groups has been more frequently acknowledged; this is evident in the mass media, in scholarly work, and in governmental statements. In addition, religious and other community organizations, corporations, and local governments have promoted or provided education programs, workshops, training, and dialogue groups to help persons of different communities learn about each other's experiences and perspectives.

Furthermore, long-standing policies have been instituted to strengthen a shared identity as Americans. The conception of Americans as belonging to a single ethnic group or an assortment of people melting into a single ethnicity, however, is changing. Instead, the multicultural character of America is increasingly accepted and even celebrated.

Contextual Factors. International organizations are increasingly expected to play critical roles in keeping and restoring the peace. United Nations and other peacekeeping forces have undertaken many more such tasks since the Cold War ended. Regional organizations and individual countries, particularly the United States, have intervened to restore and sustain peace (Moskos 1976; Segal and Segal 1993). Even after an agreement ending civil strife has been reached, the continuing engagement of external governments is crucial for the survival of the agreement and its implementation (Hampson 1996).

International nongovernmental humanitarian and advocacy organizations have grown greatly and are often helpful in restoring and maintaining peace (Lederach 1997). They may support the development of civil organizations that sustain peace. Even in the postconflict reconstruction of what was Yugoslavia, some success may be found. For example, many governmental and nongovernmental activities have helped the people in Macedonia manage external threats and the dangers of internal strife.

CONCLUSIONS

Peace work and the ways of thinking about peace have greatly expanded in recent decades. Peace is increasingly understood to be multidimensional and dynamic. Consequently, the ways of promoting peace are also manifold, and they vary in different settings for different actors. Theory and research about aspects of peace and their promotion draws from and contributes to social theory and social practice.

Recent applied and scholarly peace work is based on past experience, but the realities of the current world necessitate fresh thinking and innovative practices. New approaches and ideas are developing, combining knowledge and experience from many new interdisciplinary fields, including conflict resolution, feminist studies, security studies, and international relations.

Much more work needs to be done to understand the nature of peace and how its various aspects can be promoted. Peace is not easily advanced, is never total, and is never wholly secure. Whatever peaceful gains may be made must be energetically defended against the inevitable threats arising from new challenges.

LOUIS KRIESBERG

PENOLOGY

Penology, an applied field of sociology, is the theoretical study of prison policy, prison management, and the resulting prison culture. The sociological contributions to prison issues are applicable worldwide and offer practical solutions to problems relating to overcrowding, prison violence, and prison culture. While there is a rich European and American history of prison (e.g., Howard 1777; Beccaria 1819; Bentham 1843; Foucault 1977; Hirsh 1992), the focus here is on American prisons from the 1940s to the commencement of the twenty-first century. The following discussion begins with major sociological analyses of prison and concludes with changes in American prison policy over the past fifty years.

With a few exceptions (e.g., Goffman 1966), prison sociology has traditionally followed some variety of structural analysis. This theoretical perspective is concerned with a societal member's values, attitudes, roles, activities, and relationships that are assumed to be significantly influenced by the organization and structure of the member's environment. There are two broad types of this perspective that have been utilized in prison analysis; both focus on the structural components of prison and the members of that system. The first type, structural functionalism, focuses on how these components affect order in prison. The second type, conflict theory, focuses on how the structural components of prison and the larger society create conflict in prison.

THEORETICAL ANALYSIS

Structural Functionalism. Clemmer's *The Prison Community* (1940) is an early form of structural functional analysis. Based on interviews with staff and inmates, Clemmer's exploratory study is an ethnography of prison. This pioneering work set forth the argument that administrative policy (i.e., authoritative control over inmates, or the lack of control over inmates) influenced inmate subculture. This subculture included behavior, rules, and

attitudes. Inmates could be unruly, and could prey on each other and staff if control was lacking.

This behavior would disrupt prison order and inmate adjustment to prison life. The prison administration would attempt to reestablish order by increasing control efforts, and inmates would counter these efforts through a process of "prisonization." "Prisonization" was a socialization process through which seasoned inmates inducted new inmates into the inmate subculture. The content of this socialization for new inmates included the learning of negative attitudes toward work, government, family, and inmate groups other than their own. Inmate behavior would become resistant, obstructive, and subterfugal. Clemmer saw this "prisonization" and the resultant inmate subculture as unfortunate and unintended consequences of the administrative controls. He believed the negativism and hostility perpetuated by the inmate subculture was disruptive to the inmates' reform and was "a stronger force for evil than the programs are for good" (Clemmer 1940, p. xiii).

Sykes's *The Society of Captives* (1958) was a qualitative, exploratory, and ex post facto study that also applied a structural functional analysis. Attempting to determine the cause of a series of prison riots, Sykes studied institutional records and interviewed correctional officers, civilian work supervisors, and inmates. Sykes found the cause of the prison disequilibrium to be rooted in the prison structure and values that followed from a policy of control. He argued that management's major task was to control the inmates, but the prison's system of power was flawed with structural weaknesses that left administrators serious difficulties in imposing their control regime on the inmates. These structural weaknesses involved the inmates' lack of a sense of duty to obey correctional officers, and the correctional officers' lack of legitimate rewards and punishments, with which they could encourage inmate submission.

Power based on authority, Sykes claimed, has two essential elements: the legitimacy of control efforts and a sense of duty to obey by those who are controlled (1958, pp. 46-47). He found the latter to be present down to the correctional officer level at the New Jersey State Prison, which operated under a traditional organizational hierarchy. The sense of duty to obey disappeared,

however, when the control efforts were applied to inmates. The correctional officers had to make deals (i.e., giving correctional officer duties to trusted inmates in exchange for their help in preventing trouble) and compromises (i.e., overlooking rule violations) with inmates to achieve compliance and order. Sykes argues that correctional officer corruption (i.e., reciprocity) could not be eliminated by replacing the correctional officers. New correctional officers were aggressively pressured by the inmates (i.e., threats of riots, blackmailing staff) until they, too, compromised the rules and regulations.

The problem was a weakness of the prison system. "The effort of the custodians to 'tighten up' the prison undermines the cohesive forces at work in the inmate population and it is these forces which play a critical part in keeping the society of the prison on an even keel" (Sykes 1958, p. 124). The cohesive forces are the less violent and more stable inmates who are given illicit privileges in exchange for their help in encouraging inmate cohesiveness and prison equilibrium. If the prison officials strip these inmates of their power (tighten up), the more violent and less stable inmates rise to power.

In addition to providing the structural functional analysis described above, Sykes argued that the result of imprisonment on inmate values, attitudes, and behaviors is a product of the patterns of interaction the inmate experiences on a daily basis (1958, p. 134). For example, inmates feel helpless and frustrated when staff refuse to explain bureaucratic decisions. Sykes described the hardships of imprisonment (i.e., rejection, degradation, deprivation, alienation, and lack of safety) felt by the inmates, and he acknowledged that "Somehow the imprisoned criminal must find a device for rejecting his rejectors, if he is to endure psychologically" (1958, p. 67). Sykes also depicted the correctional officers' work environment as dangerous and tense. He reported that the correctional officers were heavily outnumbered in a potentially violent setting, and were often frustrated by the administrative pressure to maintain order while they lacked unconditional compliance from the inmates.

The Prison: Studies in Institutional Organization and Change by Cressey (1961) and *Theoretical Studies in Social Organization of the Prison*, by Cloward

and colleagues (1960) were also structural functional analyses. Both studies depicted prisons as authoritarian systems governed by bureaucratic hierarchy and empowered to control inmates. They described how the control policy in prison affects the power structure which, in turn, influences communication and values (i.e., staff pursuit of power over inmates, inmate restraint from talking to staff). Cressey (1961) found that two different prison policies, one emphasizing custody and the other treatment, had different hierarchies with contradictory purposes. The two hierarchies, with different models of decision making, one authoritative and the other participatory, had to increase their efforts to communicate with each other to facilitate the security desired by the custody branch and the programming desired by the treatment branch. It was also reported in the Cressey study (1961) that inmates and staff can work together effectively when the role expectations of their respective groups are not involved. Effective communication deteriorates when inmates and staff allow their respective group pressures to interfere with their relationships (1961, pp. 229–259).

Webb and Morris's *Prison Guards* (1978) focused on the organization of prison structure, which Clemmer (1940) had felt contributed to the maintenance of prison order (or disorder) and determined the inmates' prison experience. They focused on the correctional officers' subculture, and concluded that the officers saw maintaining security as their main function. While discipline was expressed as the means for carrying out the policy, poor prison facilities and inexperienced administrators were seen as barriers to prison order and safety.

Webb and Morris (1978) reported that the officers' major complaints about administrators were lack of communication and failure to consult the officers when decisions had to be made. This suggests that those making the decisions were distrustful of the officers' ability to participate in decision making, and preferred to monopolize power at the top. It also means that information that the officers would know best (i.e., security issues relating to certain inmates) was not being considered by those making the decisions. The correctional officers saw their safety compromised. The frustration caused by this poor communication process led to correctional officers being

openly critical of the administration, and to their finding ways of undermining the administration's authority (i.e., doing no more than they were told).

Webb and Morris (1978) described how the officers developed their own protective society. The veteran correctional officers pressured the new to become "hardened" and "con-wise," and if, after six months to a year, the officers were not seen as "con-wise," then they were given the derogatory label "pro inmate." This pressure to be estranged and nonsympathetic in their attitudes toward inmates was the correctional officers' way of protecting themselves from "getting conned" or "being burned" by the inmates.

Kauffman's *Prison Officers and Their World* (1988) was another structural functional analysis of the correctional officer subculture. Correctional officers had been blamed by the central administration for the riots and inmate violence that had plagued the Massachusetts prison system in the 1970s. Based on interviews with sixty correctional officers, Kauffman describes the rite of passage that many new correctional officers went through: how the recruits were assigned the high-inmate-contact positions in cellblocks, abandoned by the administration and veteran officers, and aggressively tested by the inmates. The general result of this treatment was an emotional hardening toward the inmates, and the acceptance of violence by staff as a means of controlling inmates. Kauffman concludes that the power veteran officers had over staff recruits was an unintended consequence of the lack of a clear administrative policy for bringing order to the prison system. She found that the administration was determined to find someone to blame for the rite of passage many recruits went through, rather than adopting a policy "to counter the continuing legacy of chaos and violence" (1988, p. 199).

The influence of prison policy on the structure, process, behavior, and attitudes in the prison (a focus typical of both structural perspectives) is also represented in DiIulio's *Governing Prisons* (1987). He shows how prison management problems have been addressed in Texas, California, and Michigan through the development and use of different management policies. He refers to the Texas policy as one of "control," where authority is centralized and where the use of administrative-controlled inmates to control other inmates

("building tendering") prevailed until the decision in *Ruiz v. Estelle* (1980) ruled the system illegal. DiIulio claims that California has a "consensus" policy, in which each warden works to get inmate "consensus" on classification systems, there are elaborate in-service training programs for correctional officers, and there are community-related educational/vocational programs for inmates. DiIulio (1987) found that Michigan has a third alternative, which emphasizes a bureaucratic system of measuring and dispensing different levels of inmate "responsibility" and accountability. DiIulio found the quality of life for inmates inside the Michigan prisons better than what he had found in other state prisons. Staff had a difficult time accepting the responsibility model, however.

Conflict Theory. The second theoretical strand of prison sociology, conflict theory, saw tight controls on inmates as unjust and called for the sharing of power with them. Wright's *The Politics of Punishment* (1973) is the first of three works representing this second branch of structural analysis that will be reviewed here. Wright is more critical of prison operations than the structural functionalists. He thought rehabilitation was manipulative in the way that it attempted "to coerce the prisoner to conform to established authority" (1973, p. 325), and then use this conformity as the basic criterion for parole. Wright believed inmates were almost totally helpless to protect themselves against the dehumanization of "liberal" totalitarian rule he found in most prisons.

The prison administration's focus on rehabilitation was an individualistic solution that avoided and disguised the real causes of criminality. Wright claimed that it was the structural flaws in the capitalist system (i.e., unemployment and the lack of opportunities outside the prison), not individual failings, that were the problem. Wright believed that crime could be reduced, and prisons reformed, by moving the American capitalist society toward socialism. Within this context, prisons could be decentralized and not controlled by a "self-perpetuating, unrestrained bureaucracy" (1973, p. 342). The administration of punishment could be placed under public surveillance. The prison under this system would "serve the interests of the people rather than of the elite" (1973, p. 337). Wright suggests that prison management has typically held to the position that prison order can be

obtained only with traditional control strategies (i.e., correctional officer power over inmates), and that the effect of these strategies has been oppressive and inhumane prison conditions.

Hawkins's *The Prison: Policy and Practice* (1976) is another critical analysis of prisons and prison management. Although Hawkins's prison experience was gained in the United Kingdom, his message was relevant to American prison practitioners and researchers. Among his claims was that correctional officers had only been superficially studied by the functional branch of sociologists, who presented them as stereotypes acting out assigned roles (1976, p. 81). Hawkins saw the correctional officers in a situation of role conflict (security versus treatment) that was due to the absence of clear job descriptions and training. The results of this conflict for the correctional officers were negative attitudes toward the administration and obstructive behavior. These results, along with the conflicting goals of imprisonment (punishment versus rehabilitation), were seen by Hawkins as impediments to prison reform. Hawkins also urged that prison evaluations should be more than just "eulogistic and imprecise descriptions of success stories" (1976, p. 178).

In his assessment of the Attica prison in New York, Hawkins also found that the relationship between correctional officers and inmates was a crucial factor in the 1971 riot. The problem was mostly structural. The officers were assigned to large blocks of inmates, rather than to small units where they could have established rapport with the inmates. In the large units the officers worked with different inmates each day, thus reducing the opportunities and motivations for staff and inmates to develop mutual respect and understanding. The structural problem went further, however. Hawkins, citing a New York State Special Commission's report on Attica, reported that there were unnecessary priorities in the correctional officer recruitment policies (i.e., age, physical size, and strength were more important than skills in persuasion, leadership, and interpersonal relations).

Irwin's *Prisons in Turmoil* (1980) also represents this "conflict" branch of sociological theorizing. Irwin, an ex-felon and past leader in the prison reform movement of the 1970s, shows how American penal policy has followed changes in the economic and political conditions in the United States.

His thinking ran against the usual functionalist sociology, which explained prison policy and activity largely in terms of internal events. Irwin believed that sociologists (e.g., Clemmer 1940; Sykes 1958) who studied prison cultures were blinded by their focus on prison structure, and therefore failed to recognize the fact that when inmates enter prison, they bring their outside values with them. He also believed that if prisons are to be safe and free from malicious authoritarianism, staff and inmates should have more formal input into policy and grievance decisions.

These sociological analyses of prison were written in different phases of the development of penal policy. It is very difficult to determine whether the literature influenced the policy, or vice versa. Most likely, they shaped each other. The point of the following brief history of the development of American penal policy over the past fifty years is not to make the causal argument, but to help the reader get a sense of the changing ideologies leading to the current management model.

CHANGES IN AMERICAN PENAL POLICY

Retribution to Rehabilitation. Prisons in the United States have traditionally been centralized hierarchical organizations with authoritarian and coercive management. Policies and procedures have been formulated at the central administrative offices and passed down in military fashion to prison administrations for implementation. This is assuredly true of the management style that administered the penal philosophies of the 1950s. The decade began with a "Big House" warehousing of inmates that implemented a classical penal philosophy embracing retribution, "care," and the notion that punishment should fit the crime. The decade ended with a changed perspective on crime and punishment, emphasizing that punishment should fit the individual and the inmate should be rehabilitated. By 1958, a noncustodial treatment branch of prison management shared an uneasy coexistence with the custody branch. Three types of treatment programs (psychological, educational, and economic) were centrally administered under the rubric of the rehabilitative ideal (Irwin 1980). The idea was to treat the individual problem that "caused" the individual to commit the crime. By the end of this decade, most prison

administrators had implemented this rehabilitative model without any interference from federal and state governments.

Rehabilitation to Reintegration. The early 1960s saw variations of the rehabilitative or treatment model of the late 1950s sharing an uneasy coexistence with an authoritative management style that had traditionally maintained order and control in large prison bureaucracies. Public and prison administrative acceptance of the "rehabilitative ideal" as a penal policy was partly rooted in its advocates' view that the new scientifically based treatment model could provide a remedy for crime.

By the middle 1960s, the call for community involvement in rehabilitation was signaled in a report by the President's Commission on Law Enforcement and Administration of Justice. Advocating a shift to a policy of reintegration, the report advised that rehabilitation might be best done outside prison, and that community programs should be designed that could change both the inmate and society (U.S. President's Commission 1967, pp. 27-37). It took a few years to catch on, but in the late 1960s a number of community alternatives to prison were developed and heavily underwritten by federal revenues.

Reintegration to Retribution. This reintegration policy continued into the 1970s. Prison administrators were pressed to design reentry programs such as work and educational release, and home furloughs. But public support waned in the mid-1970s, when the "get-tough-with-criminals" and antirehabilitative mood became dominant. The second theoretical strand of prison sociology, conflict structuralism, began around this time. This orientation was influenced by the 1960s societal reaction and critical theories that denounced the 1950s conservative structural functionalism. Riots and litigation forced federal courts to scrutinize the repressive management of correctional facilities and community-based treatment programs to ensure compliance with the Eighth Amendment right to protection from cruel and unusual punishment.

If prisons were being unfair in their partiality toward manipulative rehabilitation (e.g., Wright 1973; Hawkins 1976: the liberal critique), then retribution ought to replace it as a penal goal. The mid- to late 1970s saw a readoption of the early

classical policy—"let the punishment fit the crime"—rather than the rehabilitative or positivist policy of "letting the punishment fit the criminal." A different argument was that rehabilitation rarely worked (e.g., Martinson 1974: the conservative critique). Prison technologies had not successfully rehabilitated inmates despite prison administrators' repeated claims of success. The Martinson survey (1974) of 231 treatment reports in New York concluded that treatment had not worked. The publication of this survey ended any lingering hope for serious rehabilitative programming.

The "new" word in penal policy was "retribution." Though it had been criticized by many social scientists and judges since the early 1900s, in 1972 the U.S. Supreme Court offered retribution as an appropriate reason for capital punishment (*Furman v. Georgia*, 408 U.S. 238, 1972). The neoclassical doctrine generally implies deterrence as a function of punishment. Wilson and Herrnstein (1985) are among those who take this position. There are others, however, who argue that retribution is the main function, and that there does not have to be any further utilitarian purpose such as deterrence. The argument these penologists make for retribution is that inmates are incarcerated because they deserve to be, not because they should be treated and not because their punishment should serve as a deterrent. Many penologists credit the retributive model with encouraging prison management to create an environment where inmates can serve their time safely and productively, rather than a harsh environment designed to deter crime. The deprivation of freedom was a harsh enough punishment: Prisons did not have to be punishing beyond that.

As the 1980s commenced, national policy emphasized broad reductions in domestic welfare programs. The criminal justice system warmed to the reacceptance of the classical notion that punishment should fit the crime rather than the criminal. The widespread adoption of determinate sentencing continued throughout the 1980s and 1990s, as it became increasingly difficult for social theorists to agree on definitive causes of crime. By 1999, most states had determinate sentencing, action supportive of the classical model. This, along with the conservative "get even tougher" response to violent crimes and drug offenses, was why the U.S. prison population more than tripled from 1980 to 1998. With 1,277,866 inmates in state and federal

prisons (U.S. Department of Justice 1999), the United States ranks with Russia as having the highest-known incarceration rates of any industrialized nation in the world.

The Penal Debate. One contemporary justification for prison is its crime deterrence function, for which there is considerable public support. Many sociologists take the neoclassical position that an appropriate and updated crime control policy should include an increase in the swiftness and certainty of punishment for street offenders, and that control efforts should focus on both the before-sentencing work of police and prosecution, and the after-sentencing work of corrections. The deterrence advocates' penal policy is based on the theory of criminality that proposes that the frequency of an individual's criminal behavior is a matter of the individual's choice, and a consequence of that behavior's reinforcement or punishment in the past. The individual's choice is based on the expectation of subsequent reward or punishment.

Despite the general public's belief that prison is a deterrent to crime, there is considerable research evidence to the contrary, leaning some sociologists against deterrence. They argue that crimes of passion are less apt to be deterred by prison sentences than crimes committed for monetary gain. The threat of prison is less likely to deter someone of lower socioeconomic status, who has less "good life" and status to lose, than someone of wealth and higher status. Additionally, the courts are so overcrowded that the possibility of swift and certain punishment is diminished.

Entering the twenty-first century, the prevailing model of sentencing is still grounded in the neoclassical deterrence ideology. When it comes to the serving of the sentence, however, the neoclassical retributive, nondeterrence doctrine prevails. This retribution policy requires a correctional system that does not abuse individual treatment, but instead makes rehabilitation programs voluntary, restricts autonomy of movement, specifies the length of sentence in advance (determinate), and implements it in a fair and safe environment. Since about 1973, prison administrators have addressed these fairness and safety issues, specified in the retribution policy, by attempting to minimize the potential violence associated with overcrowding, gang membership, and racism. They

have tried to do this by separating the inmate populations into small functional housing units (Levinson and Gerard 1973) that are supervised by a decentralized “unit management” team. Current research (i.e., Farmer 1994) has shown that, if implemented properly, this method of managing inmates can facilitate increased communication, safer conditions, a more satisfying work environment for staff, and more personal programming for inmates.

Sociologists and penologists generally expect the twenty-first-century prison situation to continue its current trends. Incarceration rates will continue to climb as sentences become longer, and as good-time awards and parole options decrease. Acquired immune deficiency syndrome (AIDS) and racism in prison will be more closely watched and more rigorously dealt with. Inmates will become more violent as confinement, with less programming, becomes more Spartan and harsher. Gang membership in prison will increase, along with management efforts to combat the membership. Prison “privatization” in areas of prison construction and management, inmate work, and services (i.e., food, health, counseling, education) will become a more widely accepted solution to increasing prison costs and decreasing prison budgets.

PERSONAL AUTONOMY

Personal autonomy refers to a person's sense of self-determination, of being able to make choices regarding the direction of her or his own actions, including the freedom to pursue those choices. With personal autonomy, an individual is able to engage in effective self-regulation—successfully monitoring needs and values; responding adaptively to the environment, and initiating, organizing, and directing actions toward the achievement of needs. For some theorists, the psychological experience of autonomy has its origin in the organism's natural tendency to organize both itself and its environment in the pursuit of goals. In this view, a sense of autonomy requires the absence of restraining forces that can limit this natural tendency. Importantly, feelings of autonomy are not only crucial for adequate intrapersonal functioning—competent action and adequate psychological health—but are also essential for the adequate functioning of a healthy society.

CONCEPTIONS OF PERSONAL AUTONOMY

Early personality theorists viewed autonomy as one element of a dialectical process in the developing self. Angyal (1941), for example, proposed that personality develops in the context of two conflicting pressures, autonomy and surrender (or homonomy). A pull toward autonomy leads toward differentiation from other people and the physical environment, connoting individuation, separation, independence, freedom, and the like. The tendency toward autonomy, however, is met by a countervailing pull toward surrender, felt by the individual as a desire to become part of something greater than oneself, uniting with others and with the physical environment. Surrender is reflected in concepts such as community, union, interdependence, and obligation. A similar dialectic can be seen in the theorizing of Otto Rank (1929) and David Bakan (1966). For instance, in Bakan's approach, a concept comparable to autonomy is agency, a tendency toward manipulation that results in aloofness and differentiation of the personality. Agency is viewed as occurring in conflict with communion, a tendency that pushes a person toward connectedness and personality coherence.

The dialectical view of autonomy is interesting, suggesting as it does that autonomy has little meaning outside some notion of wholeness or integration against which the individuating, segregating pressure of autonomy can push. More recent theorists also seem to understand that the concept of autonomy implies the question "Autonomy from what?" But rather than viewing autonomy as one element in an intrapsychic union of opposites, current conceptualizations focus on conflicts between an individual's need for self-determination and potential external constraints encountered in the social environment (Deci and Ryan 1985; Ryan et al. 1997). In this view, autonomy is conceptualized as reflecting the organism's natural developmental trajectory toward increasing complexity and the concomitant press toward greater organization of its environment in the process of self-development (Ryan et al. 1997). But, of course this natural development is not guaranteed. Insufficient resources—such as insecure attachment in infancy, emotional detachment in adolescence, inadequate social support in adulthood, or even neurobiological deficits in the individual—represent potential oppositional forces to the expression of autonomy. Desires for interpersonal relatedness do not stand in conflict with autonomy needs from such a perspective, but rather play a supportive role (Ryan 1991). Thus, the development of autonomy requires responsive parental nurturing, including recognition of and support for the child's expression of autonomy. In adulthood, the sense of autonomy is facilitated by an interpersonal environment that allows the individual to view his or her intentions to act as being caused by internal, personal motivations rather than being caused by external sources.

THEORIES OF AUTONOMY

Theories relevant to an understanding of autonomy all share the assumption that individuals are motivated in some way to have the freedom to determine their own fate. For instance, deCharms (1968) proposed a general motivational tendency to strive to be an agent of causality. Individuals who initiate an intentional behavior experience themselves as the causal origin of the action and as intrinsically motivated. Individuals who do not experience personal causation, but rather view themselves as pawns being impelled by external

causes will experience action as being extrinsically motivated.

Causality Orientations Theory. Intrinsic motivation is viewed as a basic ongoing motivational propensity of all individuals that directs activity unless it is blocked in some way (Deci and Ryan 1985). Major constraints on experiencing intrinsic motivation can include stable or transient individual differences in the ways that individuals make sense of events. The most important causal orientations for understanding autonomy are the autonomy orientation and the control orientation. Individuals experiencing an autonomy orientation do not feel their behavior to be controlled by external contingencies. Instead, the individuals' experiences are ones of choice, flexibility, awareness of needs, effective accommodation to the environment, and responsiveness to available information. Such individuals are able to effectively seek out situations that allow them to experience autonomy, to use information in initiating action, and to be resilient in the face of difficulties. Only in an individual experiencing a "control orientation" does the tension between desired autonomy and controlling forces become salient and intrinsic motivation become reduced. In situations requiring action, such individuals experience feelings of pressure and anxiety, and action comes to be viewed as controlled by either internal factors not of their making (e.g., perceived obligations) or external forces (Deci and Ryan 1985). An individual's causal orientation is important because failure to experience autonomy is associated with reduced functioning, poorer health, and increased psychopathology (Deci and Ryan 1987; Ryan et al. 1995).

Undermining Effects of Reward on Intrinsic Motivation. Intrinsic and extrinsic motivation are affected not only by individuals' orientations toward explaining the causes of their actions, but also by the presence of external rewards or punishments for engaging in certain actions. Engaging in an intrinsically motivated activity means that it is the feelings of enjoyment and excitement that result from the activity that are rewarding. Presence of other rewards is unnecessary to such experiences (Deci and Ryan 1985). In fact, an important finding is that receiving rewards can be detrimental for behavior that is normally intrinsically motivated. Children or adults who begin receiving rewards for engaging in such behavior

may find motivation for that activity to become extrinsic in nature (Lepper and Greene 1978). Paradigmatic demonstrations of this phenomenon involve paying college students for performing enjoyable tasks such as solving puzzles and giving children a ribbon and gold star as a good-player award for playing with magic markers (Deci 1971; Lepper et al. 1973). Subsequent to receiving rewards, interest in the activity can be decreased once rewards are again absent. This decrease in task interest is thought to indicate a shift toward extrinsic motivation for performance of the task. Moreover, rewards can have similarly deleterious effects on tasks that require an individual to be creative.

Both the pervasiveness and the interpretation of these negative effects on task interest and creativity remain matters of heated debate (Eisenberger and Cameron 1996, 1998; Hennessey and Amabile 1998; Lepper 1998; Sansone and Harackiewicz 1998). There do, however, appear to be some reliable conditions under which tangible rewards such as money, candy, or gold stars decrease intrinsic motivation. Receiving expected rewards regardless of the quality of one's performance leads participants to subsequently spend less time engaging in a task once the reward is removed.

Cognitive Evaluation Theory. The primary autonomy-based interpretation for reduced task interest comes from cognitive evaluation theory (Deci and Ryan 1985). Cognitive evaluation theory suggests that, to the extent that rewards are controlling, intrinsic motivation will be decreased. Controlling events are ones that make individuals feel pressured to behave in a certain way. The presence of controlling events decreases feelings of self-determination by leading perceivers to believe that they are acting in order to receive a desired outcome. For example, tangible rewards like money or physical awards that are given regardless of the quality of the work can lead an individual to view actions as being instrumental for getting a desired outcome, and thus as controlled by those rewards. But receiving rewards can also be informative, conveying that one is competent. Such feedback about performance increases intrinsic motivation. Thus, in some contexts the informational function of a reward may override the decrease in intrinsic motivation that results from its controlling function. This is particularly the case,

according to cognitive evaluation theory, for unexpected or intangible rewards such as praise. In addition, when receipt of a reward is contingent on performance, a tangible cue highly symbolic of one's achievement can also be intrinsically motivating (Harackiewicz et al. 1984; Sansone and Harackiewicz 1998). Related research on creativity has been explained in terms of how rewards can orient the individual toward goal-relevant stimuli. For creativity tasks where one's thinking needs to be divergent and less stimulus-bound, such a goal-related focus can be counterproductive, reducing the cognitive flexibility and intense involvement in a task needed for producing novel solutions (Amabile 1983).

The findings regarding intrinsic and extrinsic motivation have important implications for the ideal socialization of members of a society (Ryan et al. 1997). One task of a society is appropriate socialization of its members, directing their behavior in productive avenues. In a sense, a major task of culture is to provide individuals with appropriate means of determining how their lives can contribute to a fuller development of humankind, offering as it were, an appropriate avenue for "heroism" (Becker 1971). Ryan and colleagues (1991, 1997) argue that creating individuals who are cooperative and not alienated from society requires that socializing agents provide opportunities for autonomy within a supportive context of belongingness. Behavior that is experienced as occurring either under social pressures or from internal forces of incompletely integrated, or introjected, societal values will not be experienced as autonomous. Successful internalization of societal values such that they result in intrinsically motivated behavior is thus ideal for effective functioning of a society.

Reactance Theory. A second theory that has implications for understanding decreased interest in a task after receiving controlling rewards is reactance theory. From this perspective, loss of autonomy, of ability to choose to engage in some action, means loss of freedom. Thus, when individuals begin to anticipate a reward for behavior that was previously driven solely by intrinsic motives, they may in some contexts come to see that reward as an attempt to impose on them some type of action-outcome contingency. They may feel a sense that the attempt is intended to restrict their

ability to freely engage or not engage in the activity at will. This loss of expected freedom induces a state of psychological tension known as reactance (Brehm 1993; Brehm and Brehm 1981). Reactance involves the experience of active, negative emotional states such as frustration and anger, and results in an individual's engaging in active attempts to regain the lost freedoms. From this perspective, reduced interest in a task is not a result of declining intrinsic motivation per se, but is merely an expression of a general motivation to regain lost freedom of choice. It is important to note that defiant rebellion against controlling influences does not necessarily mean regaining freedom. Automatically withdrawing effort from activities that were previously pleasing means that one's choices are being controlled in an oppositional way by those external influences (Deci and Ryan 1985).

AUTONOMY IN THE CONTEXT OF CONTROL NEEDS

The recent conception of autonomy proposed by Deci and Ryan (1985) is similar in many ways to an earlier notion of the motivation to have effective interaction with one's environment, effectance motivation (White 1959). White proposed that a variety of behaviors of the active organism, such as play, exploration, and active curiosity, can best be explained by proposing a need to engage in activities that lead to feelings of efficacy, and that allow the developing organism to become competent. Thus the notion of an effectance or mastery motive is closely related to a motive for autonomy in that both reflect a force that directs the organism toward increasing competence in managing the self and personal goals, or in managing one's environment. Indeed, the need for autonomy, mastery, and a third motive, power (Winter 1973) can all be viewed as reflections of an organism's need for personal control over various domains of their life (Marsh et al. 1998). Personal control involves a contingency between actions and outcomes, a sense of having in one's repertoire actions that can increase the likelihood of getting desired outcomes. Thus needs for power reflect a need for control over the social environment, and needs for mastery reflect a need for control over the physical and nonsocial environment; autonomy reflects intrapersonal control needs.

From such a control motivation perspective, autonomy is reflected in controlling the self, regulating emotional responses, and making decisions regarding one's actions. A key assumption of such an approach is that autonomy involves beliefs about contingency— notions about oneself as a causal force, consistent with deCharms's (1968) notion of origins versus pawns. A particularly distinguishing feature of need for autonomy as a control motive is that it becomes defined in large part as reflecting a need to resist others' controlling influence. From Deci and Ryan's (1985) perspective, however, autonomy is about the choice over what action-outcome contingencies to explore, *not* about control per se. From their perspective, need for self-determination is quite independent of control needs; it is in a sense prior to control. Thus, if control needs are about whether the individual can have a shot at winning a game through his or her actions, autonomy is about having the choice of whether to enter the game—to decide whether to try to explore the contingencies, regardless of whether or not there are contingencies once the choice is made. Such need for autonomy is a proactive, ever-present force, not a reactive force that emerges in response to *loss* of intrapersonal control. In this way autonomy has an element much like early notions of mastery needs; effectance motivation was explicitly hypothesized to not be a deficit-based need and thus was viewed as dissimilar to tissue-deficit drives like hunger (White 1959).

However, the research on the effects of reward on intrinsic motivation makes it clear how sensitive the experience of autonomy is to deficits of autonomy. Autonomy is uniquely about freedom from control, in that having the freedom to explore contingencies in the world, to attend to intrinsic experiences of action rather than having to attend to the controlling features of a situation, is, in a real sense, about the ability to have control over oneself. In fact, individuals who have greater needs for autonomy show somewhat greater ability to detect another's nonverbal displays in which affect and expression of dominance versus passivity are expressed; needs for power, in contrast, are uncorrelated with such skill (Marsh et al. 1999). Perhaps the nonverbal behavior of others is more informative to an individual with greater need for autonomy because the intentions of others might offer some threat to one's own freedom. Thus,

considering autonomy within a context of control needs, and as potentially involving homeostatic processes (Pittman and Heller 1987), seems to have utility.

In general, though, understanding autonomy and its relationship to different domains of control needs, and understanding the effects of loss of autonomy, seem to be important factors not yet fully explored by social scientists. In particular, many of the cognitive processes that have been explored with loss of control in mastery domains have been less frequently explored in the domain of autonomy. Control motivation research demonstrates that individuals have strong tendencies toward biased perceptions that events are under their personal control, and that cognitive processes function to help maintain such biases. The extent to which autonomy-based action is similarly mediated by biased cognitive processes suggests important questions for future study.

Perhaps the most fundamental question not addressed in current research on autonomy harkens back to personality theorists' beliefs that autonomy motives should be understood as standing in perpetual intrapsychic conflict with the need of the individual for surrender and communion with others. If such forces operate independently of one another, separate theories for autonomy and control and for belongingness processes are reasonable. On the other hand, early theorists may be correct in the belief that the desire for autonomy, control, and independence act in a continual creative conflict with the individual's desire for social acceptance, integration, and union. From such a perspective, the tension may result in emergent phenomena not otherwise predicted by considering the needs independently of one another. Reexamining this dynamic tension may provide a useful next direction for developing a more complete picture of the impact of autonomy needs on the individual and on his or her connection with other individuals, important social groups, and society.

KERRY L. MARSH

PERSONAL DEPENDENCY

Personal dependency is the tendency to seek support, security, reassurance, and guidance from outside the self. The object of dependency may be another person, a social unit (e.g., family, a religious group), or a symbolic belief system from which people receive positive outcomes, such as assistance, love, and/or the attainment of personal goals. The support requested can be physical (dependency on a caregiver by infants and persons who are very old, sick, or disabled), cognitive (a student's reliance on his or her teacher), and/or emotional (reliance on another person for reassurance and love). A dependent relationship implies the existence of interpersonal bonding, commitment, involvement, obligation, and trust.

An analysis of social science literature clearly reveals that personal dependency has been conceptualized in either negative or positive terms. On the one hand, personal dependency has been equated with weakness, immaturity, and passivity, and it has been viewed as an obstacle to the development of an autonomous and mature person. On the other hand, personal dependency has been viewed as a basic human motivation, which accomplishes important adaptive functions. It seems to contribute to the process of coping with life adversities and to set the basis for the

formation of close relationships and social ties as well as for social cooperation and hierarchical social structures. In this article, I first present negative and positive conceptualizations of personal dependency. I then attempt to provide a more integrative conceptualization of dependency, in which its positive and negative aspects can coexist.

NEGATIVE VIEWS OF PERSONAL DEPENDENCY

During the last century, several social science professionals have viewed personal dependency in adulthood as a sign of weakness and immaturity. For example, Bornstein (1993) defines personal dependency in terms of negatively valued beliefs and emotions. Dependency-related beliefs refer to mental representations of the self and the social world that justify the tendency to seek support from other persons in times of need. Specifically, they include the perception of the self as weak, helpless, and ineffectual, as well as the beliefs that other persons are powerful and have the ability and skills to solve life problems and to control the course and outcomes of environmental events. Dependency-related emotions include the arousal of anxiety and worry upon external demands to deal with life tasks in an independent manner as well as fears of criticism, rejection, and separation. According to Bornstein (1993), these beliefs and emotions detract from independence, reinforce dependency over the life span, and facilitate its generalization across different interpersonal situations and social settings.

The emphasis on the negative aspects of personal dependency seems to reflect Western societies' values of independence, autonomy, and mastery. It also seems to reflect the view that mature, well-adjusted persons should attempt to cope with life tasks in an autonomous and self-directed way. As a result, the tendency to turn to others for support, assistance, and reassurance in times of need can be equated with immaturity, helplessness, and powerlessness, as well as with the failure to meet cultural expectations and standards. Moreover, it can be viewed as a risk factor for psychological problems, such as depression, anxiety, alcoholism, and eating disorders, as well as for negative social phenomena, such as loss of personal identity

and blind obedience to totalitarian leaders. In extreme cases, when people suffer from persistent and severe interpersonal or occupational problems, personal dependency is considered to be a specific type of diagnosable psychological disorder.

The negative view of dependency can be traced to early writings of Freud, who argued that dependency in adulthood consists of immature and infantile forms of behaviors. In his view, a dependent orientation toward life is related to gratifying and frustrating breast-feeding experiences during the first year of life, when infants' survival completely depends on their mother's goodwill. Abrupt weaning, frustrations related to rigid and insensitive feeding schedules, and/or the failure to end the nursing period are hypothesized to result in a failure to adequately deal with conflicts regarding dependency and autonomy. This failure is reflected in the arousal of anxiety every time one is required to act in an independent manner; the experience of serious doubts about one's own ability to be an autonomous person; and the longing for the infantile, dependent relationship with the feeding mother. Problematic breast-feeding experiences are also hypothesized to lead people to believe that the solution for their problems is outside and that others can take care of them in the same way that their mothers fed them.

The problem with Freud's ideas is that they are not supported by empirical findings (see Bornstein 1993, for a review). First, studies have failed to find a coherent and meaningful pattern of association between feeding experiences in infancy and self-reports of personal dependency in adulthood. Second, there is no strong evidence that personal dependency in adulthood is associated with mouth- and food-related activities as well as with oral behaviors (e.g., thumbsucking). Third, mixed results have been found in studies assessing the association between personal dependency and psychological disorders that have an oral component, such as eating disorders, alcoholism, and tobacco addiction. However, although findings do not support Freud's premise that dependency equals immaturity and infantilism, it still continues to exert a major influence in psychological writings.

A related approach to personal dependency can be found in object relation theories, which

emphasize the crucial role that the early child-parent relationship plays in social and emotional development (Greenberg and Mitchell 1983). Like Freudian theory, these theories view events occurring during the first one or two years of life as critical for the development of personal dependency. However, unlike Freud, the proponents of object relations theories do not emphasize feeding experiences. Rather, they focus on the child's relationship with his or her parents and the failure to resolve conflicts around nurture and closeness, on the one hand, and separation and autonomy, on the other. In these terms, personal dependency reflects an infantile desire to merge with other persons and to be cared for by them. Furthermore, it is related to the search for absolute love and enmeshed relationships, the use of psychotropic drugs, and the identification with strong leaders and highly cohesive groups.

One basic hypothesis derived from object relation theories is that parenting style during infancy and childhood may be critical for an understanding of the development of offspring's personal dependency. Bornstein (1993) follows this idea and contends that overprotective and/or authoritarian parenting may create a vicious circle that increases the likelihood of offspring's dependency. Specifically, overprotective and/or authoritarian parents may prevent their children from engaging in exploratory and trial-and-error activities that promote a sense of mastery and autonomy. As a result, these children may perceive themselves as weak and may tend to seek others' help when confronted with life tasks. This support-seeking tendency may elicit others' helping behaviors, which, in turn, may further reinforce personal dependency. Along this reasoning, personal dependency would be overtly expressed mainly when the other (e.g., a parent, a teacher) is perceived as a powerful authority, and may underlie the blind pursuit of strong and authoritarian leaders who can offer protection and help.

The contribution of parenting style to personal dependency has also been acknowledged in social learning theories, which focus on the type of behaviors that parents reinforce throughout childhood and adolescence (Rotter 1982). Specifically, children whose parents positively reinforce passive and dependent behaviors are hypothesized to become dependent adult persons. These children

may learn that dependent behaviors are adequate instrumental means for obtaining positive outcomes (e.g., love, esteem) from parents and that active and autonomous behaviors should be inhibited if they want to maintain a good relationship with parents. Social learning theories also hypothesize that this learning would be generalized across situations, leading people to behave in a dependent manner in a wide variety of social contexts. Like object relation theories, social learning theories suggest that overprotective and/or authoritarian parenting would lead to offspring's dependency, because such parents may reinforce passive and dependent behaviors. However, social learning theories differ from object relation theories in that they view personal dependency as an active instrumental means for obtaining positive outcomes from authority figures.

In emphasizing parental reinforcement and learning processes, social learning theories also highlight the role that the learning of gender roles—the learning of cultural norms and expectations regarding feminine and masculine traits and behaviors—may play in the development of personal dependency (Mischell 1970). This is particularly noted in Western cultures, where the equation between dependency and femininity may lead parents to reinforce dependent behaviors among girls and to punish these behaviors in boys. In this way, parents may provide differential reinforcement for boys and girls, leading children to meet cultural expectations concerning the expression of dependency. However, one should recall that the “dependency = femininity” equation reflects Western societies' norms and that other cultural contexts can produce different gender-role expectations and different patterns of parental reinforcement.

The negative aspects of dependency have been also emphasized by interpersonal theories of personality (e.g., Leary 1957). In these theories, dependency has been equated with personal characteristics of weaknesses, passivity, and helplessness. Moreover, it has been associated with suggestibility, compliance, and the adherence to others' beliefs and interests as a means for obtaining love, approval, and support. Interpersonal theories also emphasize that dependency is associated with fear of negative evaluation and test anxiety, which, in turn, may further exacerbate dependency. These

worries may divert cognitive resources away from active, self-directed behaviors and may lead people to escape or avoid any situation that demands autonomy and independence.

Like psychoanalytic theories, interpersonal theories also suggest that personal dependency in adulthood increases the risk for psychological problems. In this context, studies have examined the association between self-reports of dependency, on the one hand, and depression, anxiety, substance abuse, and eating disorders, on the other. However, results are mixed. Whereas some studies have indeed found a positive association between self-reports of dependency and psychological disorders, other studies have failed to find such an association. Moreover, there is evidence that dependency may be an outcome rather than a cause of psychological disorders (Bornstein 1993). For examples, there are studies showing that the onset of depression and the resulting increase in helplessness and powerlessness feelings promote passive and dependent behavior. Accordingly, longitudinal studies have shown that the onset of alcoholism is followed by an increase in dependent behavior.

The above findings put into question the view that dependency is a negative personal characteristic. Rather, they may imply that dependent behavior reflects a cry for help, reassurance, and support in dealing with emotional and social problems. As such, dependent behavior may be an adaptive means for overcoming life difficulties with the help of others. In these cases, avoiding support seeking and maintaining a facade of autonomy and self-reliance may have detrimental consequences for people who really need help and support to overcome their predicaments.

POSITIVE VIEWS OF PERSONAL DEPENDENCY

The positive sides of personal dependency have been emphasized by psychological and sociological theories that focus on the development and stability of social relations, contracts, and organizations. In terms of Kelley's interdependence theory (1979)—the most influential theory on interpersonal relationships—the reliance of person on a partner for the satisfaction of his or her own needs is a basic requirement for the development and

stability of close and positive relationships. In fact, Kelley suggests that there can be no stable relationship when a person is unable or unwilling to rely on his or her partner. Dependency is the psychological glue that maintains a close relationship over time. Moreover, it seems to prevent people from moving toward alternative relationships.

Along the above reasoning, personal dependency is considered to be one core component of the experience of love and to be associated with other components of this phenomenon, such as commitment, intimacy, and trust. For example, theory and research have emphasized that a person's dependency on a romantic partner precedes commitment to the relationship—precedes the intention to maintain the relationship in the future. Accordingly, dependency seems to play a critical role in the development of closeness and intimacy within love relationships. People who can rely on their partners for need satisfaction have been found to develop a sense of trust and confidence in their partner's goodwill, which, in turn, may facilitate the taking of risks in the relationship and the sharing of intimate feelings and thoughts with the partner. As a result, people may strengthen their willingness to initiate and maintain intimate patterns of communication while developing a sense of togetherness with the partner.

Personal dependency has been also viewed to play a positive role in group dynamics as well as in the stability of hierarchical relationships within social organizations. In this context, personal dependency seems to precede a person's willingness to participate in group activities and to collaborate with others in teamwork, mainly when others are at a higher rank in the organizational hierarchy. People who are unable or unwilling to rely on others for goal achievement and task completion may be reluctant to participate in teamwork, may prefer to work alone, and may react negatively to authority figures who threaten their independence. Only when people feel that they need support and guidance from others may they be positively oriented toward teamwork and authority figures. In fact, there is evidence that the level of dependency members of a group feel toward each other is a sign of group cohesion and a positive predictor of group effectiveness. In a broader perspective, personal dependency seems to be a prerequisite for the phylogenetic development of social ties and structures.

Theory and research have also highlighted the association between dependency and positive personal characteristics. First, research has shown that the equation between dependency and passivity is not always true. In fact, there are many situations in which dependency leads to active forms of behavior, such as attempts to outperform others in order to attract the attention of an authority figure. Second, positive associations have been found between dependency and sensitivity to interpersonal cues—the ability to decode and understand others’ messages. Third, there is evidence that personal dependency is related to health-promotion behaviors, such as seeking of medical treatments and compliance with them, as well as to relationship-enhancing traits, such as sociability, self-disclosure, and cooperative orientation in social interactions.

Studies in the field of stress and coping have shown that people who seek support and guidance from others in times of need possess positive mental representations of the self and the social world. In these studies, the tendency to rely on support seeking as a coping strategy has been found to be related to the perception of the self as capable of coping with stressful events and environmental demands. This tendency has been also found to be associated with optimistic beliefs about distress management as well as about others’ ability and willingness to provide support and guidance.

Personal dependency has also been found to result in adaptive behavior. The tendency to seek support from others has been conceptualized as a basic behavioral strategy that people use in coping with life adversities. In Lazarus and Folkman’s model (1984), the most influential theory in the field of stress and coping, support seeking is considered to be one of the most frequently used coping strategies. More important, research has consistently found that reliance on this coping strategy leads to positive psychological and social outcomes. Specifically, people who cope with life problems by seeking support from others tend to feel better, to experience less distress, and to show fewer problems in social functioning than people who rely only on themselves. Moreover, the belief that one can depend on others in times of need has been found to facilitate social adjustment.

Studies in the field of stress and coping have also shown that a reluctance to seek support in

times of need has negative health and adjustment outcomes. People who rely exclusively on themselves in dealing with intense and persistent stressful events have been found to experience, in the long run, high levels of distress and serious problems in physical health and social functioning. These findings may reflect the fragile nature of the “pseudo-safe” world of a person who believes that he or she can deal alone with all life problems and does not need the help of others. It seems that the lack of others to depend upon leaves this person vulnerable and helpless in face of stressful events.

The adaptive advantage of personal dependency has been particularly emphasized in Bowlby’s attachment theory (1969). In his terms, human infants are born with a prewired repertoire of behaviors aimed at maintaining proximity to other persons and seeking their support in times of need. These behaviors seem to reflect a basic human motivation and to accomplish a crucial adaptive function—to guarantee the survival of the helpless infant by eliciting helping behaviors in parents. According to Bowlby, this motivation persists over the entire life span, even among mature and autonomous adults. In fact, Bowlby does not view dependency as a sign of immaturity and infantilism, but as a healthy motivation that facilitates the process of coping with life problems and the development of positive social ties.

According to Bowlby, the tendency to rely on others in times of need is an inborn affect regulation device, which is automatically activated upon the experience of distress. In these cases, other persons function as a “haven of safety” to which people can retreat for comfort and reassurance and as a “secure base” from which they can develop their unique personalities in a loving and approving atmosphere. As a result, the overt expression of dependency needs and behaviors may have beneficial effects on the process of distress management as well as on the individual’s psychological wellbeing.

Bowlby also proposes that actual experiences related to the expression of dependency needs exert tremendous influence on social and emotional development. On the one hand, interactions with significant others who are responsive to one’s dependency needs may lead to the experience of more and longer episodes of positive affect and the development of positive feelings

toward the world and the self. On the other hand, interactions with rejecting others may elicit chronic distress, serious doubts about others' intentions, and problems around dependency-autonomy themes.

Along the above reasoning, actual experiences related to the expression of dependency needs may shape the way people cope with life adversities. Specifically, interactions with significant others who are responsive to one's dependency needs set the basis for the construction of effective distress management strategies. People may find out that acknowledgment and display of distress elicits positive responses from significant others. They may also learn that they are capable of eliciting helping responses from others and that support seeking is an effective way of coping. In this way, the satisfaction of dependency needs would lead people to regulate affect by overtly expressing distress and engaging in active seeking of support.

Interestingly, Bowlby does not conceptualize dependency and autonomy as antagonistic motivations. Rather, he suggests that the satisfaction of dependency needs might facilitate the development of an autonomous person. In his terms, autonomous activities in infancy are activated when a caregiver satisfies infants' dependency needs and when he or she is perceived as a "secure base" to which infants can retreat in case of danger. Thus, infants who can use the caregiver as a "secure base" can show a balance between dependency and autonomy. They can move away from the caregiver without being anxious about his or her availability, can return to him or her when danger arises, and can recommence autonomous activities (e.g., play, exploration) as the proximity to the caregiver is reestablished. Overall, the expression of dependency needs does not necessarily mean that the person cannot engage in autonomous behavior. Rather, the expression and satisfaction of these needs seems to set the basis for a confident and pleasurable development of autonomy.

AN INTEGRATIVE VIEW OF PERSONAL DEPENDENCY

The above-reviewed literature clearly indicates that personal dependency may have both negative and positive implications for the individual and the society. The main question here is whether and how the negative and positive aspects of personal dependency can coexist. In other words, one should

attempt to present a more integrative view of personal dependency, which can explain how this phenomenon may be an adaptive device and at the same time may lead to maladjustment and social problems.

As noted earlier, Bowlby argues that personal dependency is a healthy human behavior and that the tendency to seek support from others has positive psychological and social effects. However, this healthy pattern of behavior can become dysfunctional upon the recurrent frustration of one's cry for help. According to Bowlby, when people perceive significant others as nonresponsive to their dependency needs, they may learn that support seeking fails to bring the expected relief and that other defensive strategies should be developed. One of these strategies is a "fight" response, by which people attempt to compulsively elicit others' love and support through controlling and clinging responses. That is, these persons seem to develop an overly dependent pattern of behavior. The problem with this strategy is that it may create an anxious focus around social relationships; doubts about one's autonomy; anxious demands for proximity; fears of separation, rejection, and criticism; and inability to leave frustrating social interactions. As can be seen, this defensive strategy seems to result in all the negative consequences that psychoanalytic and social learning theories have linked to personal dependency.

Along the above reasoning, personal dependency per se is not a pathological sign of weakness and immaturity. Only when healthy dependency needs are frustrated and a person adopts an overly dependent defensive strategy is he or she caught in a vicious circle of anxiety, helplessness, maladjustment, and increasing dependency. In this view, psychoanalytic and social learning theories have in fact dealt with overdependency rather than with the normal expression of dependency needs. Moreover, most of the findings relating dependency to emotional and social problems have been obtained from self-report questionnaires that tap overdependency rather than the tendency to seek support from others in times of need. These questionnaires include items about fears of rejection, separation, and criticism; need for approval; and doubts about autonomy.

The above reasoning receives strong support in studies that focus on the interpersonal and

intrapersonal correlates of adult attachment styles. Shaver and Hazan (1993) define attachment styles as stable patterns of beliefs, emotions, and behaviors in social relationships, and divide them into three types: secure, avoidant, and preoccupied. The "secure" style is defined by feelings of comfort with dependent relationships as well as by the tendency to seek support from others. The "avoidant" style is defined by reluctance to depend on others, avoidance of close relationships, and an overemphasis on autonomy and self-reliance. The "preoccupied" style is defined by compulsive attempts to minimize distance from others via clinging behaviors and fears of rejection, separation, and criticism. Overall, these three styles can be organized along a dependency continuum, with the "avoidant" style reflecting underdependency, the "secure" style the normal expression of these needs, and the "preoccupied" style overdependency.

Studies in adult attachment styles have consistently documented the adaptive advantage of the normal expression of dependency needs, as manifested in the secure style. First, securely attached persons have been found to report on more positive interactions with parents than avoidant and preoccupied persons. Second, persons addressing the secure style have been found to show less distress in times of stress than persons who address either an avoidant or a preoccupied style. Third, secure persons have been found to have more positive and stable close relationships and to be more positively involved in social activities than avoidant and preoccupied persons. That is, the overt expression of dependency needs is related to positive personal and social outcomes. In contrast, either the inhibition of these needs or the adoption of an overly dependent pattern of behavior seems to have detrimental effects on psychological and social functioning.

In conclusion, the above line of thinking and findings emphasize the balance between dependency and autonomy needs. The overt expression of dependency needs in adulthood does not necessarily compete with or inhibit autonomy needs. Rather, as Bowlby suggests, the satisfaction of dependency needs may facilitate the expression of autonomy needs. In these cases, people can freely move back and forth between dependency and autonomy, can flexibly accommodate to social demands, and then can maintain an adequate level

of social adjustment and functioning. Only when this balance is disrupted, either among persons who overemphasize autonomy or among those who behave in an overly dependent manner, is adjustment at risk. In these cases, people may be unable and/or unwilling to flexibly adjust to the social world, in which they should act autonomously at same times and rely on others at other times.

Of course, a person's balance between dependency and autonomy needs depends not only on psychological factors. Rather, it also results from cultural and societal norms, values, and expectations. In fact, this balance would be different in societies that emphasize collectivist values (e.g., acceptance of social roles, family maintenance, and security) and in societies that emphasize individualistic values (e.g., personal achievement, mastery, freedom, and autonomy). Theory and research should attempt to provide a better understanding of the interface between cultural norms and values, a person's history of social interactions, and his or her expression of personal dependency. Moreover, they should throw away anachronistic and simplistic views of personal dependency and adopt a more integrative view of this basic human motivation.

PERSONALITY AND SOCIAL STRUCTURE

Three questions underlie the study of social structure and personality: What is social structure? What is personality? And, what is the relationship between the two? The history of this area and the current state of knowledge contain tremendous variability in the answers to these questions.

For example, social structure includes whole cultural configurations, social institutions such as family and the state, social stratification and class, the nature of roles, organizational structures, group dynamics, and micro-features of day-to-day interactions. Social structure also includes process and change at the group level, such as economic depression-recession, modernization, revolution, war, organizational growth and decline, human development and aging, and life-course transitions (school-to-work, retirement).

Concepts and approaches to personality also have a rich history in this area, with many variations. These include attitudes, abilities, affective and attributional styles, values, beliefs, cognitive schema, identities, aspirations, views of the self and others, and individual behaviors. The concept of personality, too, connotes both structure and process or change. Most contemporary observers would agree with a definition of personality as “regularities and consistencies in the behavior of individuals in their lives” (Snyder and Ickes 1985, p. 883). In some approaches, attitude and the self precede and determine behavior; in other approaches, people observe behavior and infer their own mental states and features of self.

Neither a simple answer nor close consensus exists among scholars on the nature of the relationship between social structure and personality, although most would agree that the relationship is

reciprocal rather than asymmetric, and modest rather than extremely strong or extremely weak (House and Mortimer 1990; Miller-Loessi 1995; Mortimer and Lorence 1995). That is, multiple areas of research provide clear evidence that variations in social structures shape components of personality, *and* that variations in personality in turn affect social structure. Humans are not completely pawns in the face of social forces, nor are they entirely independent, autonomous agents, unfettered by social influences. The study of human lives shows clear evidence of both forms.

The study of social structure and personality has its roots in the disciplines of sociology, psychology, and anthropology. Scholars whose ideas and research offer inspiration include Marx (1963), Freud (1928), Mead (1934), Lewin (1951), Gerth and Mills (1953), Inkeles and Levinson (1954), Smelser and Smelser (1963), and Turner (1956).

The focus of scholarship in the 1930s, 1940s, and early 1950s was to define the basic concepts and processes for personality, for social structure, and for the relationship between the two. This era produced and elaborated developments such as field theory, role theory, and interactionist perspectives on the self, along with concepts such as self, significant other, role taking, socialization, the authoritarian personality, modal personality, and national character.

In the 1950s, the sociological research on social structure and personality focused on macroscopic empirical studies of national character: What was national character? How did it vary? Could it be defined in terms of modal personality types? A long tradition of comparative anthropological studies of culture and personality informed these studies. For example, some of these studies considered the relationship between social class and personality, with *social class* defined as white-collar–blue-collar. *Personality* referred to some underlying continuum of “adjustment,” and the link between social class and personality occurred in socialization, in particular in child-rearing practices.

The 1960s produced major changes in the study of personality and social structure. First, the quantity of research increased significantly, concurrently with the massive growth of sociology and psychology as disciplines and with the growth of higher education. Second, research in the area

became more diffuse and more differentiated. What had been a fairly identifiable area of research scattered to subareas of scientific disciplines, such as the sociology of medicine, social stratification, small group dynamics, or attitude-behavior research. The research problems multiplied; research methods and strategies multiplied; theories and explanations multiplied; and journal outlets and books multiplied. At the same time, communication, integration, and cross-fertilization across the research fragments declined, although in recent years this may be changing. In short, during this era “social structure and personality” became an umbrella description for many different lines of investigation that were only loosely connected.

The third major change in the 1960s was a refocusing of research on social structure and personality, one that continues into the 1990s. The empirical macroscopic studies of national character, and the emphasis on holistic conceptions of culture and national character, declined. On the sociological side, the emphasis shifted to studying “*aspects* of societies in relation to *aspects* of individuals” (House 1981, p. 526). On the psychological side, a looser, multidimensional approach to personality replaced the earlier Freudian approach, which was based on a coherent dynamic system and on personality types and structures (DiRenzo 1977).

House (1981) describes this major refocusing of research in terms of three principles, which also define ideals for the investigation of personality and social structure. First, the *components* principle suggests that social structures such as roles, positions, and systems are multidimensional, and theory should specify which dimensions are important for which personality phenomena (such as stress, self-esteem, and locus of control). Second, the *proximity* principle suggests focusing first on understanding the more proximate stimuli that affect people and then mapping the causal patterns across broader levels of social structure in time and space. Third, the *psychological* principle identifies the importance of specifying the psychological processes involved when social structures and processes affect the self, personality, and attitudes. House’s three principles nicely summarize many of the recent advances in the study of social structure and personality. They also define the nature

of limitations in current knowledge, and identify research frontiers.

The contemporary landscape of research on social structure and personality in sociology is a patchwork of problems and areas. These include social stratification, work, and personality (Kohn et al. 1983); social structure and health, both physical and psychological (Mirowsky and Ross 1986); disjunctive social changes (war, economic depression) and individual adjustment (Elder 1974); role transitions and psychological changes (O’Brien 1986); variations in self-concept by structural position (Gecas and Burke 1995); human development, aging, and social change (Featherman and Lerner 1985; Alwin et al. 1991); and political and discriminatory attitudes, social institutions, and change (Kiecolt 1988), to mention just a few.

One of the most substantial and important areas of research involves the study of social stratification, work and personality, and the program of research of Kohn, Schooler, and colleagues (1983; Kohn and Slomczynski 1990; Kohn et al. 1997). The Kohn-Schooler model reflects the dominant approach in this particular area, and illustrates the major sociological approach to the study of social structure and personality. Spenner (1988a, 1988b, 1998) provides detailed review of this research. In comparison, approaches in psychology are more microscopic—in focusing on shorter intervals of time and smaller arenas of social space—and more likely to rely on experiments and lab studies, or field research versus large-scale survey research of people’s work lives and personality histories.

The Kohn-Schooler model begins with dimensions of jobs that are defined and measured as objectively as possible (versus subjective dimensions and measures of individual’s jobs). These structural imperatives of jobs include: occupational self-direction (substantive complexity of work, closeness of supervision, and routinization); job pressures (time pressure, heaviness, dirtiness, and hours worked per week); extrinsic risks and rewards (the probability of being held responsible for things outside one’s control, the risk of losing one’s job or business, job protections, and job income); and organizational location (ownership, bureaucratization, and hierarchical position). The three basic dimensions of personality in this research include intellectual flexibility, self-directedness of orientation, and sense of well-being or distress.

Among the subdimensions of these organizing dimensions are authoritarian conservatism, personally responsible standards of morality, trustfulness, self-confidence, self-deprecation, fatalism, anxiety, and idea conformity.

The type of analysis used in the Kohn-Schooler research estimates the lagged and contemporaneous reciprocal relationships between conditions of work and dimensions of personality in nonexperimental, panel, survey data. The major data come from a national sample of over 3,000 persons, representative of the male, full-time labor force, age 16 and over in 1974. About one-third of these men were reinterviewed about ten years later, with measures being taken of work conditions and personality at both points in time. Most of the studies of women in this tradition refer to wives of men in the sample. In a series of structural equation model analyses that adjust for measurement error in dimensions of jobs and personality, the authors document an intricate pattern of lagged (over time) and contemporaneous selection and socialization effects. *Selection effects* refers to the effects of personality on work and social structure; *socialization effects* refers to the effects of work (social structure) on self and personality. Most of the effects of personality on work are lagged, as workers appear to select jobs of a given type depending on measured aspects of their personality, or to slowly mold jobs to match their personalities. Conversely, the effects of jobs on personalities appear to be somewhat larger and to involve both contemporaneous and lagged effects. The largest relationships center on components of occupational self-direction, in particular, on substantive complexity of work. For example, substantive complexity of work environments increases intellectual flexibility for men by an amount that is one-fourth as great as the effect of intellectual flexibility a decade earlier, net of controls for other variables and confounding influences.

Kohn, Schooler, and colleagues interpret their findings with a "learning-generalization" explanation. In it, people learn from their jobs and generalize the lessons to spheres of their lives away from the job. Rather than using alternate psychological mechanisms such as displacement or compensation, the structural imperatives of jobs affect a worker's values; orientations to self, children, and society; and cognitive functioning. They do this

primarily through a direct process of learning from the job and generalization of what has been learned to off-job realities. The collected research shows that these generalizations appear to hold under a broad range of controls for spuriousness, alternate explanations, and extensions. The extensions include men's and women's work lives, self-direction in leisure activities, housework, and educational domains, as well as a number of replications of the basic model including careful comparisons with samples from Poland and Japan, and more recently from the Ukraine (Kohn et al. 1997).

Similar summaries exist for many other areas of research in social structure and personality, but this line of research has been one of the most important. The limitations of the Kohn-Schooler program of research illustrate some of the frontiers facing research on work and personality. First, are these conditions of work the most important dimensions of social structure? Do they combine and exert their effects in a more complicated recipe? Are there other features of context that should be considered? Second, are these the appropriate dimensions and combinations or personality? Are there left-out dimensions or other larger meta- or organizing dimensions of personality, such as flexibility-rigidity or general affectivity (Spencer 1988a) or processual dimensions of personality, that might be more important?

Third, there are many alternate explanations that replace or extend the learning-generalization explanation for how jobs and personality reciprocally relate (for review, see O'Brien 1986). They include: (1) fit hypotheses, in which the quality of the match between dimensions of personality and dimensions of social structure determines the effects of the person on the job and vice versa; (2) needs and expectancy explanations, in which additional layers of cognitive weighting, interpretation, and processing mediate the relationships among job attributes, personality dimensions, and work attitude outcomes; (3) buffering and mediational hypotheses, in which the effects of social structure on personality (or vice versa) are accentuated or damped for certain extreme combinations of work conditions, or outside influences such as social support buffer the effects of social structure on personality; and (4) social information processing and attributional explanations, which posit additional perceptual or judgmental, evaluational or

choice, or attributional processes that affect job-attitude and attitude-behavior linkages.

At more microscopic levels (shorter time intervals such as seconds or minutes, and smaller domains of social space, such as intrapsychic, or face-to-face interactions) the challenge for research on social structure and personality is to discover the meanings and processes that underlie longer-term, larger-scale correlations between the two. This challenge applies not only to how job or social structure affects personality, but also to how a domain of personality selects a worker into an occupational or another role, or serves as a catalyst for human agency and leads to attempts by people to modify their roles and circumstances. For example, if learning generalization operates as hypothesized, what does that mean? Is the learning part of the process as straightforward as textbook images of reinforcement psychology and social learning theory imply it is? Survey research designs, the dominant methodology, typically assume and rarely observe, specify, or test the social-psychological and psychological concomitants of learning generalization. What are the associated perceptual, affective, cognitive, and behavioral concomitants of learning generalization? What are the supporting and disconfirming attribution patterns and mediations? Or is the learning process below the level of cognitive operations and attributional web of inferences that people use to make sense of their world? Experimental and observational design may be more informative than the typical survey research approach. The field understands many of the ingredients but not the specific recipe.

At a mezzoscopic level—careers, the human life span, organizations, and other institutional settings and mechanisms—the challenge to research on social structure and personality is to put the snapshots of relationships in motion and understand the dynamics over longer periods of time. For example, in the Kohn-Schooler model, how are its findings nested in adult development, and how is adult development affected by the dynamics implied in this model? Age and developmental variations have received only limited attention in the Kohn-Schooler approach. Further, much of our knowledge about relationships between various social structures and personality assumes a system in equilibrium (for example, a single coefficient capturing an effect over five or ten years). We know much less about the dynamics of social

structure–personality relationships, including estimation of trajectories, threshold effects, and rates of change. Here too, different types of research and data designs will be required to advance the state of knowledge.

Finally, at a larger, macroscopic level—encompassing decades and centuries, and whole institutional spheres and societies—the challenges confronting research in social structure and personality are multiple. They include discovering the larger sociohistorical, psychological, and biological contexts and processes in which social structure–personality relationships are embedded, and then mapping and tracing the lines of influence across levels. For example, many research streams are exclusively national or subnational, in terms of generalizations. The Kohn-Schooler approach, with systematic studies in the United States, Poland, Japan, and the Ukraine, is a notable exception, but even here we are still early on in understanding how the models vary in comparative studies of national and subnational contexts. Further, the state of knowledge is young in our understanding of how historical variations in the content and composition of work, the labor process, and the family, or in organizational form and practice altered relationships between social structure and personality. This larger challenge also includes discovering how long-term variations in human personality feed back on long-term variations in social structures, shaping history and defining what is possible for the evolution of social forms and processes.

KENNETH I. SPENNER

PERSONALITY MEASUREMENT

WHAT IS PERSONALITY?

"Personality" is an ambiguous term derived from the natural language, and not necessarily a scientific concept. Consensus among interested scientists as to its precise meaning has been fairly modest. One major cleavage is between views of personality as core dynamic processes inherent in all people

and views that emphasize characteristics on which individuals differ. Because the second sort of view defines personality in a way as to make it far more conducive to measurement, this article focuses on personality as certain potentially measurable characteristics of individuals.

Which measurable characteristics? There are many kinds of characteristics, and useful ways of categorizing characteristics have been developed (Norman 1967; Angleitner et al. 1990). Characteristics that fall into many of the categories do not fit common definitions of personality. Descriptors of physical characteristics (e.g., short, muscular) lack sufficient reference to psychological (behavioral, affective, cognitive) features. Descriptors invoking social roles (e.g., motherly, professional) and social effects (e.g., famous, neglected) involve social-contextualization and relativization too heavily to give inferences about an individual's personality attributes. Descriptors of emotions (e.g., elated, afraid) and many motivational and intentional states (e.g., hungry, reluctant, inspired) are too prone to reference relatively transient characteristics. And some descriptors (e.g., awful, impressive) are so purely evaluative that they provide insufficient specificity with respect to psychological features.

Among descriptors that refer to presumably more internal and enduring psychological attributes, three categories stand out. Abilities or talents (e.g., skillful, creative, athletic) refer to maximum rather than typical levels of performance on tasks. Beliefs and attitudes (e.g., religious, racist, environmentalist) concern affectively tinged habits of mind pertaining to specific objects and concepts. Although personality models have frequently contained some ability- and attitude-related content, at their core are traits (e.g., daring, patient) that are more directly related to typical behavioral patterns. Because they are expressed behaviorally, enduring motivational patterns (e.g., need for achievement) might also be easily fit within definitions of personality that emphasize typical behavior patterns. "Temperament" usually denotes the more clearly inborn and genetically derived aspects of personality, whereas "character" is often used to denote acquired moral qualities. But these terms are otherwise synonymous with personality, which can be defined as consistencies in patterns of behavior—where behavior is

defined broadly to include affect, cognition, and motivation—on which individuals differ. Overall, personality is a lay concept of sufficient importance and usefulness to have been taken up and refined by scientists.

In natural languages, personality descriptors are alternately represented as adjectives (e.g., adventurous), attribute nouns (e.g., adventurousness), or type nouns (e.g., adventurer). Because adjectives differentiate properties, personality adjectives are inherently central to personality description, although some languages lack an adjective class and carry on this adjective function in other ways (Dixon 1977). Psychologists move easily between adjectives and attribute-noun characterizations of the same trait (as with extraverted and extraversion): Either form suggests properties that exist in varying degrees. Type-noun characterizations, in contrast, imply a categorization—one either is an extravert or one is not—which in turn suggests the assumption of a bimodal frequency distribution of individuals on the trait. Such bimodal distributions appear to be rare. Although type-noun characterizations of personality traits have great popular appeal, their use by academic psychologists has become quite limited. There has been a search for categorical taxons underlying the traits related to certain mental disorders (e.g., Meehl 1995), but this task is not easy. Recent correlational studies indicate that symptoms of mental disorders, and of personality disorders in particular, are continuously distributed in the population, and have substantial overlap with measures of various personality traits (Costa and Widiger 1994).

In the last three decades, many psychologists have addressed the fundamental issue of whether personality traits are real, or whether they exist only in the eye of the beholder. Mischel's early review (1968) suggested that personality measures were at best modest predictors of relevant actual behaviors. However, a consensus has emerged that when criterion behaviors are aggregated, across time or across situations, personality measures can become quite highly predictive (Kenrick and Funder 1988). This follows, of course, from definitions of personality offered above: Personality does not denote single behaviors but rather consistent patterns in multiple behaviors. Moreover, studies involving twins and adoptees have repeatedly indicated that personality-trait scores are partially (as much as 50 percent) heritable, implying biological

underpinnings. Such behavior-genetic findings have stimulated the development of models that set forth biological explanations for personality variation, attempting to delineate phenotypic constructs so that they correspond directly to known biological mechanisms (e.g., Gray 1987; Rothbart et al. 1994; Zuckerman 1995). Nonetheless, studies with twins and adoptees also indicate that differences in experience, mainly of the type *not* shared by family members, have a profound effect on personality characteristics (Plomin 1990). There are also some indications of important effects of culture.

Although personality traits reflect behavioral consistencies across situations, a variety of research findings indicate that some situations facilitate expression of personality traits more than do other situations (Caspi and Moffitt 1993). Highly structured or ritualized social settings (e.g., a funeral home, a lecture hall) tend to attenuate the expression of personality differences, whereas relatively unstructured settings (e.g., a nightclub, a playground) bring out personality differences. This pattern has three important consequences for personality measurement. First, to the extent that a society's social milieu are age-stratified, one might expect across-time continuity in apparent traits to be somewhat "heterotypic"—leading to different surface characteristics at different ages. Second, personality characteristics are best assessed by placing the individual in a relatively unstructured situation in which responses are relatively unconstrained by social norms; therefore, the stimuli on personality measures should not have correct responses. Third, to the extent that a cultural milieu is highly structured and ritualized, one might expect to see less emphasis on personality differences than would be found in relatively individualistic cultural milieus (Miller 1984).

PERSONALITY MEASUREMENT CAPTURES CONSISTENCIES

Measurement can be defined as a set of rules for assigning numbers to entities (such as individuals) in such a way that attributes of the entities are faithfully represented. Measurement procedures typically set up, or specify, regularized administration conditions. Thus, measurement generally involves consistency of procedure; but personality measurement has an even deeper relation to consistency.

As noted above, a consensual definition of personality would emphasize characteristics that are internally rather than externally caused, psychological rather than overtly physical, and stable and enduring rather than transient. Because of the emphasis on stable and enduring qualities, reliability—relative absence of measurement error—is of first importance in personality measurement. A reliable measure by definition registers characteristics that are consistent across time, as indicated by test-retest reliability coefficients or across situations. Internal consistency, or inter-item reliability, is an analogue of cross-situational stability. Each item represents a unique situation in either of two ways: (1) its referent content may refer to a distinct situation (e.g., "I talk a lot at parties"), or (2) simply being presented with this item as distinguished from another item (e.g., "I talk very little at parties") is a unique immediate situation for the respondent. Reliability is most often measured either by a stability coefficient, indicating the correlation between scores at one time and those at another, or by an internal consistency coefficient (e.g., coefficient alpha) that represents the average correlation between pairs of all possible split halves of the test items, although a variety of alternative reliability models are available. Until cross-time stability is established, a trait's stability is only presumed and it might be better termed an attribute, since the latter term has fewer implications as to stability.

Another criterion for the reliability of personality judgments is the extent to which different observers agree in rating a target. This is a more demanding criterion; ideally, to the degree an individual has a characteristic it will be obvious to both self and observers. However, a number of influences tend to attenuate agreement between observers. Some characteristics (e.g., sociability) are highly observable, whereas others (e.g., anxiety level) are less so. Interobserver agreement is typically reduced by having observed the target at different times or in different situations. Generally, we might expect the self to be the most privileged observer, but in certain ways the self-viewpoint can be misleading. Personality characterizations have social functions and, understandably, self-observer agreement is prone to be affected by conscious impression management and unconscious self-enhancement tendencies (Paulhus and

Reid 1991). Finally, quite independently of content, observers differ in their use of measurement scales (e.g., differential tendencies to agree or disagree, respond extremely, or use the middle option if available). Given this minefield of potential difficulties, the moderate level of interobserver agreement documented in the research literature may be quite remarkable. It makes sense to capitalize on the conjoint perspective of multiple judges: the best arbiter of the degree to which an individual can be characterized with a certain trait may be the pooled judgments of several observers well acquainted with the subject (Hofstee 1994; Kolar et al. 1996), perhaps conjoined with self-ratings. Though greater acquaintance clearly increases judges' accuracy, there is, particularly for the more observable traits, surprisingly good consensus among near strangers for the traits of a target (Borkenau and Liebler 1993).

Another important, but demanding, index of consistency is across-time stability: within a sample of individuals, the extent to which one's relative standing at time 1 correlates with that at time 2. Across-time stabilities tend to be very high for short intervals (e.g., a day or a week) but diminish with greater intervals to a more moderate level. Even across long intervals, cross-time stabilities in adulthood—particularly after age 30—for most personality traits are impressively high (Costa and McCrae 1997). It appears, however, that the further the measurement intervals reach into childhood and especially infancy, the lower the stabilities become; judgments of infant temperament may not do much better than chance in predicting judgments of later adult personality. Stabilities may be held down by the incommensurability of the contexts within which infant and adult temperaments function: It is difficult to apply many adult traits (e.g., industrious, artistic, unselfish) to infants, so that any forms of continuity would have to be heterotypic. It seems likely, however, that levels of traits often do change from childhood to adulthood. Part of this change could be genetically programmed, as a different set of genes comes on-line with greater maturity, and an initial set goes off-line; on the other hand, much may change under the influence of experience. To Wordsworth's assertion that "the child is father of the man," psychometricians offer an assent beset with caveats: "usually," "in many ways," "with definite exceptions."

PERSONALITY DATA HAS MULTIPLE SOURCES

Data on behavior patterns are most commonly elicited from self and observers or acquaintances using standardized measures of personality traits. Scores on these structured measures are compared within a sample in a "nomothetic" manner, that is, seeking generalizations that can be applied to all individuals. Historically, the dominant position of this structured, nomothetic approach stems from the success of well-known inventories like (1) the Minnesota Multiphasic Personality Inventory (MMPI), which is actually more of a psychiatric symptom inventory than a personality inventory; (2) the California Psychological Inventory (CPI), which resembles the MMPI in numerous respects but taps rather different content, with scales labeled so as to stress the presence (or absence) of adaptive traits; and (3) the Myers-Briggs Type Indicator (MBTI), a measure based on parts of C. G. Jung's typology. The MBTI has been criticized by psychometricians, ignored by academic researchers, yet bought up by the millions in other circles. Today, these older inventories have competition from numerous new inventories that in some cases are shorter and more efficient.

Nonetheless, there are potentially useful alternatives to the questionnaire. Some embody an idiographic approach—seeking individually unique constructs that are not generalized to all people—rather than a nomothetic one. For example, in George Kelly's Role-Construct Repertory Test, each testee nominates a set of personally significant acquaintances, then derives idiographic constructs by comparing subsets of them. Such idiographic measures undoubtedly have a unique contribution: They may generate results that are more meaningful to the individual measured. But knowledge of general laws illuminates understanding of the individual case; it is possible to adapt many nomothetic measures to serve idiographic ends. Thus, improved nomothetic understanding lays the groundwork for improved idiographic understandings.

Questionnaires, whether used nomothetically or idiographically, are essentially overt and direct in their measurement approach. A trait is assessed with reference to a person's behaviors, emotions, and cognitions. Descriptions, which may be at a

rather broad level, are collected. This overt method can be highly efficient, but has a significant disadvantage: Because the descriptive content provides clues to what is being measured, respondents completing the measure could, if motivated, intentionally present an inaccurate picture. Moreover, responses can be provided thoughtlessly. Some of those who are dissimulating or not paying attention can be identified using so-called validity indexes. These indexes are computed by scouring the response pattern for various signs of less than honest and accurate responding: unusual levels of agreement with unfavorable items, disagreement with favorable items, denying common vices, claiming rare virtues, responding dissimilarly to items with similar content, or responding similarly to items with contradictory content.

Projective measures, in contrast, are covert measures of personality that are more resistant to dissimulating or inattentive responding. These measures assume a “projective hypothesis” first defined by Rorschach, Jung, and others early in this century: If an individual is presented with a vague or ambiguous stimulus, that individual’s response will be determined by habitual internal tendencies, preoccupations, and cognitive styles, rather than being affected by features of the stimulus. In a word, respondents “project” their proclivities onto the stimulus. Projective measures are potentially very sensitive receptors for personality variation. As noted above, personality differences are clearest when individuals are confronted with unstructured situations; vague and ambiguous stimuli are unstructured situations. One might simply place the individual in an unstructured situation and observe which behaviors, emotions, and thoughts ensue.

The most popular unstructured stimuli for these purposes have been inkblots (e.g., the Rorschach and Holtzman stimulus sets), sets of pictures—selected for their ambiguity—about which stories are elicited (e.g., the Thematic Apperception Test [TAT] and its derivatives), and figure drawings; in the last case the individual is presented with blank paper and asked to draw a certain object (e.g., person, house, tree). Other commonly used unstructured stimuli include incomplete sentences (e.g., “Most people __.”) and single words for which an association is elicited. The raw material provided by the respondent must then be

coded and interpreted with reference to response patterns of aggregate respondents. These measures capture aspects of personality covertly and indirectly; due to the ambiguity of the test materials, respondents are unlikely to guess what is being measured.

Though attractive in theory, projective measures have been problematic in practice. The rock upon which they are prone to founder is the crucial one of reliability. A first problem is that individuals’ responses to projective stimuli are affected by social context and environment, and to a considerable degree they change from one day to another. This problem may be partially solved by gathering responses to many stimuli, preferably on multiple occasions, and looking for consistent patterns across time and across stimuli. A second problem is that observers often have low levels of agreement with regard to coding and interpreting the stimuli; that is, there is often a great deal of interobserver noise obscuring any underlying signal. There have been recent attempts to create interpretive coding schemes with better reliability. The best example is Exner’s comprehensive system for the Rorschach (1986), which integrates features of several previous Rorschach scoring systems.

The Rorschach and the TAT remain fairly popular measures in clinical settings, and continue to generate a stream of research. Presently, however, many psychologists are skeptical about the usefulness of these measures, given the laborious, complex procedures for collecting and scoring data. One problem may be the sheer volume and range of the data that such free-response methods bring in; perhaps only a fraction of these data are of any importance, and we are not yet sure which fraction deserves the most attention. Projective measures might in the future become increasingly important, to the extent that they can be made more reliable, parsimonious, and efficient.

Other forms of data can be coded using the interpretive schemes developed for projective measures. For example, politician’s speeches, reports of early memories, and virtually any autobiographical material can be analyzed in much the same way as stories elicited from the TAT. Most often, such material has been analyzed in terms of implicit motivational features (e.g., achievement, power,

intimacy), and evidence suggests that such covertly measured motivation is not substantially correlated with indexes of similar content derived from structured measures of self-attributed motivation (McClelland et al. 1989). In general, autobiographical data seems to provide information outside that provided by personality questionnaires, given that individuals seem to store schematic beliefs about traits separately from autobiographical memories (Klein and Loftus 1993). Therefore, autobiographical data could become an important part of the comprehensive assessment of individuals.

WHICH TRAITS ARE WORTH MEASURING?

Whether the measurement method is overt or covert, another crucial issue concerns the particular traits that one ought to measure. Most commonly, this issue has been handled within a scale-construction strategy that might be called “rational”: A researcher decides which trait (i.e., construct) he or she wants to measure, creates a pool of potential items, tries them out on a sample of respondents, and perhaps iterates between data and preconceived theory to create a relatively efficient measure of the construct. A second, “empirical” strategy is in some ways a variant of the first. The researcher includes in the sample of respondents one or more criterion groups (e.g., introverts, psychopaths, artists) and determines the set of items that best differentiates each criterion group from a control sample, thus leading to a “criterion-keyed” scale for the construct (e.g., introversion, psychopathy, creative temperament). In either strategy, the researcher begins with an a priori conception of what ought to be measured, but in the empirical strategy this conception is identified with a criterion group. It is not difficult to combine rational and empirical strategies, as was done in the only major revision of the original MMPI.

Unfortunately, a field that accumulates a great host of a priori conceptions can become quite chaotic, and this was the predominant state of affairs in personality measurement until at least the 1970s, when expert compendiums on personality traits could still be organized alphabetically by trait (e.g., London and Exner 1978), as if there were no other way to order them. There were

many constructs, and it was clear that some of them were related to others, but the structure underlying the whole set of constructs was unclear. From the early decades of the twentieth century, investigators seeking an ordering framework turned to a statistical technique called “factor analysis.” *Factor analysis* is a method for reducing a large number of observed variables to a smaller number of hypothetical variables (factors), by analyzing the covariances among the observed variables and identifying redundancies in the set of variables. Factor analysis can be used to identify parsimonious sets of variables within sets of items built by any scale-construction strategy. Historically, reviews of factor analyses of various collections of personality scales (e.g., French, 1953) have not led to a consensus on a common framework (Goldberg 1972).

Significant progress on the structural problem came largely by temporarily averting attention from the a priori constructs of experts in order to study those personality conceptions of laypersons that are embedded in the natural language. As noted at the outset, personality traits are socially meaningful phenomena about which laypersons comment and generalize, and the lexicon of any language is a repository of descriptors referencing a wide variety of human characteristics. The lexical hypothesis formalizes this state of affairs into a strategy for identifying necessary features for an organizing framework, or taxonomy, of personality attributes (Goldberg 1981). This hypothesis essentially states that the more important the attribute, the more likely people are to develop a word for it. The most important attributes will then be those represented by numerous terms (often representing specific aspects of broader concepts) within one language, and by recurrence across many languages. Once descriptors are gathered, for example from a dictionary, they can be used by individuals to describe themselves or others. Factor analysis of this data, in any language, can be used to search for a few dimensions underlying numerous descriptors.

Expert personality constructs are typically based on certain aspects of the lay descriptive vocabulary, but scientists may refine and extend lay distinctions in useful ways. Therefore, one cannot obtain a *sufficient* model of personality traits by

studying lexical descriptors, but one can find *necessary* features for such a model, aspects that—based on their salience to lay observers—are too important to leave out. In this respect, lexical models of personality dimensions offer minimum-content criteria for other personality models, pointing clearly to some (but not all) of the trait concepts important enough to measure. In practice, lexical models have helped focus attention on important variables previously omitted from expert-derived models.

Lexical studies involve (1) culling descriptors from a dictionary; (2) omitting descriptors that are infrequently used or, by the consensus of multiple judges, refer to categories less relevant to personality (e.g., physical traits, temporary states); (3) aggregating the remaining descriptors (typically 300 to 400) into a questionnaire format with a multipoint (e.g., 1 to 5) rating scale; (4) administering the forms so constructed to a large (usually >400) sample of respondents for description of self, a well-acquainted peer, or sometimes both; and (5) factor-analyzing the descriptors to derive an indigenous or “emic” personality structure for that language. Such studies have been conducted in over a dozen languages, including English, German, Dutch, Italian, Spanish, Hungarian, Czech, Polish, Filipino, Korean, Turkish, and Hebrew.

Findings of these lexical studies (reviewed by Saucier 1997) show some variations, probably due to differences in sampling of subjects and variables as much as to actual differences between languages. But the most common result has been a robust structure of five independent (uncorrelated) factors, with apparent cross-language universality for the three largest of these factors: extraversion (which includes sociability, activity, and assertiveness), agreeableness (which includes warmth, generosity, humility, patience, and nonaggressiveness), and conscientiousness (which includes dependability, orderliness, and consistency). The remaining two factors (one referencing aspects of emotional stability, the other aspects of intellect, imagination, and unconventionality) are generally smaller and more variant from one study to another. Despite these partial inconsistencies between one emic structure and another, the five-factor structure, often labeled the “Big Five,” has been shown to be easily translatable into a large number of languages (McCrae et al. 1998). Moreover, the

Big Five appears to capture the structure of trait judgments about children as well as adults (Digman and Shmelyov 1996).

The Big Five has had considerable influence on personality questionnaires. For example, one prominent three-factor inventory (the NEO Personality Inventory) was revised to add the two missing factors from the Big Five, in this case agreeableness and conscientiousness (McCrae and Costa 1985). Moreover, the five factors have strong relations to the constructs measured by other prominent inventories, including the Myers-Briggs Type Indicator, the 16PF inventory, and the Personality Research Form. Four of the five factors (excluding intellect/imagination) are substantially correlated with measures of personality disorder symptoms and some mood, anxiety, and impulse control disorders cataloged in current psychiatric nosologies; a safe generalization seems to be that disorders tend to co-occur with extreme scores on personality dimensions (like the Big Five) on which there is wide variation in the general population (Costa and Widiger 1994). However, psychotic syndromes map rather poorly onto the Big Five, as do a few other clearly important individual-differences constructs, like religiousness and attractiveness (Saucier and Goldberg 1998)

Although the Big Five have obtained some degree of consensus as an organizing framework for personality characteristics, there are at least five remaining issues whose resolution might lead to a different consensual structure: (1) The generalizability of the Big Five factors to languages spoken in non-Western, nonindustrialized nations, and indeed in less complex societies, is as yet uncertain. (2) The Big Five represent very broad, global trait constructs, and groups of more specific constructs are typically more useful in prediction contexts; however, there is as yet little consensus about the particular specific subcomponents that make up each of the broad factors. (3) There may be factors in related domains, such as abilities or attitudes, that could arguably be added to the model. (4) The organization of personality variables into factors based on lexical representation might be reasonably superseded by a set of factors based on a superior rationale, for example, correspondence to main lines of biological or environmental influence. And (5) there may be constructs

well represented among natural-language descriptors that will prove to be of great importance. Personality-relevant constructs with apparently meager representation in natural language descriptors, but attracting much current research interest, include those having to do with (1) defense mechanisms (Paulhus et al. 1997), (2) coping styles (Suls et al. 1996), and (3) personal goals and strivings (Pervin 1989).

One important criterion by which personality constructs might be added to, or eliminated from, a basic descriptive model is validity. Validity should be clearly distinguished from reliability: *Reliability* concerns whether a scale is measuring anything at all, and is a prerequisite to any form of validity. *Validity* concerns the meaning of a scale score, that is, the accuracy of the inferences one can make from the scale. For a construct that demonstrates validity, there is a good argument for meaningfulness and usefulness with respect to other phenomena. Validity evidence is gathered in an ongoing process, rather than in any single study.

A prior question, of course, is whether personality measures have a substantial enough degree of validity to make them worthwhile. Mischel's early critique (1968) suggested they did not. An increasingly large volume of studies documents the many ways in which they do. For example, conscientiousness is a valuable predictor of effective job-related performance (even after the predictive value of intelligence is accounted for and removed), and has also been associated with increased longevity. Low scores on emotional stability (i.e., high scores on neuroticism) are predictive of higher rates of divorce, of male midlife crises, and of health-related complaints (though not actually greater illness). Agreeableness has associations with aspects of conflict (or absence of conflict) in close relationships, and extraversion predicts variation in a wide range of social-interaction variables.

PROSPECTS AND FURTHER APPLICATIONS

As the foregoing review indicates, the science of personality measurement is no longer at the primitive stage represented by early taxonomies of virtues (such as those of Plato or Confucius), of physiological humors (such as that of Galen), or by

the pseudoscience of astrological signs which beckons from magazine racks. Unlike these approaches, current personality measurement is far more explicit about (1) defining personality, (2) measuring attributes in a standardized, reliable manner, (3) attending to multiple sources of data, (4) checking the validity of hypothesized models, and (5) placing the plethora of possible constructs within a parsimonious and empirically justifiable organizing framework. Nonetheless, current scientific practices are inevitably based on assumptions that are subject to being overturned. Rorer (1990) provides a conceptual review of personality assessment with attention to differences between the assumptions of mainstream and alternative paradigms.

Personality as a discipline has come to be located mainly within the larger umbrella of psychology. This is reasonable, given that personality deals with the behavior, affect, and cognitions of individuals, and with individual differences. But certain aspects of personality seem to be equally relevant to other sciences. Many of the more in-born, dispositional aspects of personality are clearly rooted in biology and genetics, and personality change may well be associated with physiological changes—as cause or effect. Moreover, humans are social as well as biological beings, and personality functions within a social context. The sociological aspects of personality need more attention: Although Goffman (1972) proposed aspects of one useful sociological theory of personality, and Bellah et al. (1985) described certain social-structural contexts that may foster narcissism, generally the relation of personality variation to its broader social context is but dimly understood.

In anthropology, one finds a rich tradition of studies of "culture and personality." Past work in this area has been hindered by use of less than adequate personality measurement models. For example, many studies used projective personality measures with insufficiently developed reliability. If improvements are made in analysis of projective data, it may be possible to take a new look at old data. Moreover, linguists and anthropologists may be uniquely well equipped to gather and judge evidence pertinent to the cross-cultural universality of basic personality dimensions, and help answer several important questions: Which dimensions of interindividual variation are not only

measurable in any culture, but derivable from the indigenous language of any culture? What is the meaning of between-culture variation in the classification of personality characteristics? To what extent is "modal personality" a viable way of differentiating societies, or of mapping cultural change, and how do temperament and social structure interact? Do cultures differ in how they organize the heterogeneity that personality variation introduces?

The fascinating generalizations offered by Mead, Benedict, and others must be considered provisional, given the probably limited range and value of data upon which they are based. If waves of advancement in personality measurement were joined to waves of advancement in other social sciences, a powerful current might ensue, which would yield a far better understanding of societies in terms of the diverse range of humans within each of these societies.

GERARD SAUCIER

PERSONALITY THEORY

WHAT IS PERSONALITY?

A definition of *personality*, and there are many such definitions, must precede a treatment of personality theory. One must note at the start that personality is not an entity or a thing. It is a mentalistic construct that serves as an abstract cognitive device for understanding (1) the characteristic ways human beings behave or are inclined to behave; (2) their perceptions of their defining characteristics; and in the view of many, (3) the common (in some cases measured) perception that others have of them. This view of “personality” overlaps to a great extent with William James’s view of self ([1890]1952), both psychological and social. Though personologists may at times refer to personality as if it had been reified, this stems less from their intention than from a limitation of the language used. Given this condition, one can only strive to assure as close a correspondence as is possible of the definition of this word with the complex reality it is intended to reflect and capture.

Definitions of personality vary depending on the standpoint—scientific, philosophical, humanistic, or strictly psychological—that one adopts. Personality for our purposes is one or another heuristic enabling social scientists to understand and predict human behavior, both overt and tacit, and individuals’ complex responses to the events that sweep over them daily. To speak of individuals’ personalities is to allude to all their longstanding, characterological properties that dispose them, given any set of circumstances, to respond in a predictable way. In popular parlance “to really know someone” is to understand that person’s self-concept and the idiosyncratic manner in which he or she deals with problems of daily life, whether social, political, or purely intrapsychic. In short, to know someone is to have a knowledge of their personality; but the personality of an individual is not a simple matter to assess. To realize this, one has only to consider that there is a shifting presentation of self as a function of the multifarious

situations in which one can find oneself. The same person with a single personality has a number of personae at his or her disposal for (generally) adaptive use.

It is useful to quote in this context a classic statement by William James:

Properly speaking, a man has as many social selves as there are individuals who recognize him and carry an image of him in their mind. To wound any one of these images is to wound him. But as the individuals who carry the images fall naturally into classes, we may practically say that he has as many different social selves as there are distinct groups of persons about whose opinion he cares. He generally shows a different side of himself to each of these different groups. Many a youth who is demure enough before his teachers and parents, swears and swaggers like a pirate among his "tough" young friends. We do not show ourselves to our children as to our club-companions, to our customers as to the laborers we employ, to our own masters and employers as to our intimate friends. ([1890] 1952, chap. X, "The Consciousness of Self," pp. 189–190)

This statement, written in the 1880s, has a modern ring, and clearly presages the later work of, say, Hartshorne and May (1928) and Walter Mischel (1968). Clearly it represents a theory of personality that is relativistic and relational. Relative to the former aspect, it invokes a double perspective. The first is the perspective of individuals as they present themselves very differently and even inconsistently in various contexts to different classes of people. The second is the perception of observers who make judgments about individuals' personalities (or characters) based on the limited sampling of behavior they have witnessed either directly or indirectly. As such, it also presents the notion of self and of personality, though these two terms do not have identical meanings, as much more complex when viewed from within by the individual than when viewed from without by society. Relative to the relational aspect, personality appears to be shaped by the demand characteristics of the social group within which the individual performs. In this Jamesian perspective, personality is the flip side of self, that

is, observers' characterizations of others as distinguished from the views that those latter individuals have of themselves. Indeed the everyday language that individuals use to describe themselves (as well as others) has provided the vocabulary (e.g., altruistic, aggressive, nurturant, inquisitive, venturesome) for defining the components of the construct, personality (e.g., Cattell 1964, 1965). Further, the equivalents of these terms, used to personologically distinguish individuals, can be found in most of the world's languages. (This notion has been labeled the "fundamental lexical hypothesis," and is addressed below.)

An individual's identity—understanding of his or her character and typical patterns of behavioral responses to social and other environmental stimuli—is the result not simply of their personal history, but of his or her construal of that history and of the either vivid or tacit memories that form the warp and weft of their self-understanding. It is generally accepted that memories are never absolutely veridical. The fact that false memories are more or less richly interlarded with relatively true memories suggests that personality as viewed from its owner's standpoint is partially self-constructed. William James stated that "False memories are by no means rare occurrences in most of us, and, whenever they occur, they distort the consciousness of the me . . . The most frequent source of false memory is the accounts we give to others of our experiences" ([1890]1952, p. 241). He asserts that this is a source of the errors in testimony that the individual has every intention of making honest. This is confirmed in more recent analyses (e.g., Laurence et al. 1998) that demonstrate that people's characterizations of themselves or others can be compellingly shaped by the situational as well as by intrapsychic demands that subjects experience when they must make judgments about personality. That these dynamics may be at work when individuals are completing even the best-validated and most reliable of personality inventories is reason to draw conclusions from such inventories with caution.

THEORIES IN GENERAL

Theories that have been developed to explain the dimensions of personality and the way personality develops are too numerous to describe (see Table

PERSONALITY THEORY

Selected Personality and Related Theories, and Their Originators

Adler, Alfred	Developed a holistic theory, individual psychology, characterized by teleological, sociobiological, and self-actualizing dynamics. Utilized notion of unconscious, but used a rational, commonsense approach to remediating problems.
Allport, Gordon	Theorized that structural elements of personality comprised traits disposing individuals to respond to stimulus fields in predictable patterns. Traits are viewed as both individualizing and nomothetic.
Angyll, Andreas	Developed a partial theory that stressed the human's need to serve superordinate group goals, while striving for self-individualization.
Bandura, Albert	Developed a social cognitive theory of human development in which the modeling of behavior by important others shapes each person's behavior and character. This theory has a strong teleological emphasis meshed with sense of self-efficacy.
Berne, Eric	Posited a phenomenological theory of human personality, <i>transactional analysis</i> , comprising three distinct ego states: parent, adult, and child.
Binswanger, Ludwig	An existential psychologist, a disciple of Heidegger, who elaborated a phenomenological approach to the understanding of human behavior, especially in the face of the most difficult aspects of life.
Burrow, Trigant	Pioneered view of humans as profoundly social, interactive, personologically shaped by group activity. An early group therapist.
Boss, Medard	A Heideggerian whose antitheoretical approach nevertheless limns a view of human nature that is constructivist, but with traces of the psychoanalytic and the phenomenological.
Cattell, Raymond	Developed a complex trait theory and psychometric measure (16 PF) through factor-analysis of vernacular trait expressions.
Corsini, Raymond	Formulated a developmental theory of personality of Adlerian and Rogerian inspiration, involving a strong genetic component; emphasized formative influence of parental values, educational experiences, and critical stochastological events.
Digman, John	(See McDougall, W.)
Dollard, John	Developed (with Neal Miller) a theory of personality of behavioral inspiration, constituted largely of evolving habits; drives and stimulus-response connections account for dynamics of changing personality structures.
Erikson, Erik	Elaborated a stage-based, life-span model of human development that was psychosocial and psychoanalytic in inspiration. A major focus is on personal identity development.
Eysenck, Hans	Fashioned a psychometrically supported model of human personality that is biologically trait-based and hierarchically organized.
Frankl, Viktor	Developed a life-span, noninstinctual, teleological model of human development in which the dominant motivational force is the will to meaning, underpinned by values and ideals.
Freud, Sigmund	Developed a state-based, conflict theory of personality that is pansexual and deterministic. The central construct is the Oedipal conflict, the resolution of which enables, especially for the male, the full expansion of the psyche.
Horney, Karen	Developed a revisionist psychoanalysis that shed its androcentric features; her sociopsychological theory later evolved along Adlerian lines and generated a cogent feminine psychology.
Jackson, Don	With J. Haley, P. Watzlawick, J. Beavin, and others at the Mental Research Institute in Palo Alto, California, formulated a humanistic, systems-oriented approach to understanding human character and behavior.
Janet, Pierre	Founder of <i>psychological analysis</i> . Formulated a holistic psychology of the person, including a theory of rapport, the unconscious, and the complexes that drive human behavior. A nineteenth-century empiricist, he developed, inter alia, notions of transference and suggestibility.
Jung, Carl	Founder of <i>analytic psychotherapy</i> . Posited a holistic psychology of the person, including a theory of the unconscious and the complexes that drive human behavior.
Kelly, George	Developed <i>personal construct theory</i> , a constructivist system of human personality development, predicated on the assumption that individuals construe reality in light of their life history. These construals govern anticipation and realization of events.

(continued)

Selected Personality and Related Theories, and Their Originators (continued)

Lewin, Kurt	Developed a topological psychology predicated on Gestalt psychological principles; this is a psychophysical model for human behavior utilizing geometric constructs to conceptualize personality determinants.
Lowen, Alexander	Reichian in inspiration, Lowen developed <i>bioenergetic analysis</i> , predicated on a multifactorial model of human personality, heavily organicist in character. Therapy involves body work.
Maslow, Abraham	Fashioned the <i>psychology of being</i> , a model of human nature as self-actualizing, holistic, creative, and joyful. This nomothetic model postulates a hierarchy of psychophysical needs that will sequentially assert themselves, if not impeded.
May, Rollo	Developed an existential personology that accents the dynamic. This <i>continental existentialism</i> provided the elements and "givens" for conflicts at the core of personality development.
McDougall, W.	The <i>five-factor model</i> of personality has a distinguished lineage: Formulated by W. McDougall and developed by L. Klages, F. Baumgartner, G. Allport, E. Borgatta, D. Fiske, E. Tupes and R. Christal, and J. Digman, among other more recent investigators, it involves a strong heritability component; this model is cross-cultural and statistically and psychometrically generated.
Mead, George	Developed <i>social interaction theory</i> , a system of social behaviorism in which individuals symbolically interiorize their roles and status as a function of the interactive perceptions of others.
Miller, Neal	(See Dollard, John)
Meyer, Adolf	Developed a psychobiological theory of personality, stressing the unity of mind and body, the former a function of the latter. The theory has a strong orientation to the organismic in the genesis of psychopathology.
Murray, Henry	Elaborated a comprehensive, holistic theory that stressed motivation, environment, the psychodynamic, the idiographic-nomothetic spectrum, the personal, the life-span history, and specifically the cerebral determinants of one's ever-in-flux personality.
Piaget, Jean	Developed a partial theory of personality comprising a seminal model of cognitive development that deliberately made abstraction of emotions and social matrices. The model is characterized by an ineluctably sequenced, linear series of cognitive stages.
Rank, Otto	A polymath, he developed a humanistic personology based on minimizing primordial fears (of life and death) and developing one's will, which integrates a person's sense of who he or she is. Influenced Carl Rogers.
Rogers, Carl	Developed a theory of human nature characterized by self-actualization and holism; an innate organismic valuing process, if left unimpeded, leads individuals to live fully effloresced, authentic, and healthful lives.
Skinner, Burrhus	Developed an operant conditioning theory, which serves as a scientific heuristic for understanding the development of behavioral habits and capabilities of any organism; mistakenly thought by some to deny existence of intrapsychic realities.
Sullivan, Harry	Developed an interpersonal theory of personality that focuses on the social situation rather than the person; this theory postulates that individuals' personalities are a reflection of the assessment others make, or are imagined to make, of them.
Wolpe, Joseph	Rejecting psychodynamic methodologies, he evolved a theory of personality development that was of Pavlovian inspiration. His theory is of interest principally to psychotherapists.

Table 1

l for a partial list). They each have been zealously defended and propagated by their adherents. In spite of the paucity of empirical validation for most of them, this has not assured their demise. Though most of the large-scale, molar theories that are still studied have been developed in the twentieth century, the study of human personality has veered in the second half of the century toward the manageably molecular. The trend to fine, multivariate analyses of human behavior in the

established experimentalism of academia has created its own tension with the countervailing movement to holistic conceptualizations of personality. The synthesizing of psychosociological findings with those that are cognitive, affective, and psychoneuro-endocrinological is a work in progress. At the end of the day, this scientific project has eventuated in scholarly specialization in numerous subdisciplines, which can only, with great difficulty and some contortions, be articulated

into a unified and coherent theoretical system. The task still needs to be addressed.

HISTORICAL PRECURSORS

It needs to be noted that theorizing about the determinants of human behavior in individuals as well as their social groups has its origins in antiquity and has progressed throughout history. There is a rich vein of philosophical speculation on this subject in the Greco-Roman civilization that was the seedbed of Western culture. Hellenistic thinkers and playwrights bequeathed a rich assortment of treatises and ideas to what would become Euro-American concepts of the nature of personality and its development. The ideas that are most salient for us and that have had the greatest impact on modern Western thought have come from the great Hellenistic thinkers that preceded the era of Roman cultural and military hegemony. Among the pre-Socratics, physiological theories of the development of personality can be traced at least to Empedocles. Later Hippocrates (fourth century B.C.E.) and still later Galen (second century C.E.) (Kagan 1994) postulated that the physical humors of the body are related to temperament. Blood, black bile, yellow bile, and phlegm were linked, as these nouns suggest, to sanguine, melancholic, choleric, and phlegmatic temperaments, respectively. The specifics of this theory are given no credence today, but the principle that personality has physiological determinants (or at least correlates) is very much alive.

Plato and Aristotle proposed powerful models of human psychological development. In *Laws*, for example, Plato proposed an environmental perspective relative to the problems that are occasioned by parents' overreactions to children's spontaneous and immature behaviors.

The privacy of home life screens from general observation many little incidents, too readily occasioned by a child's pains, pleasures, and passions which are not in keeping with a legislator's recommendations, and tend to bring a medley of incongruities into the characters of our citizens. (Book 7, sec. 788)

He does not exclude a genetic perspective as the following passage from the same work attests.

Now of all wild young things a boy is the most difficult to handle. Just because he more than

any other has a fount of intelligence in him that has not yet "run clear," he is the craftiest, most mischievous, and most unruly of brutes. So the creature must be held in check, as we may say, by more than one bridle—in the first place, when once he is out of the mother's and the nurse's hand, by attendants to care for his childish helplessness, and then further, by all the masters who teach him anything. (Book 7, sec. 808)

Plato's student, Aristotle, was a more entrenched environmentalist than Plato. He affirmed the principle of *tabula rasa* in his treatise "On the Human Mind."

Mind is in a sense potentially whatever is thinkable, although actually it is nothing until it has thought. What it thinks must be in it just as characters may be said to be on a writing-tablet on which as yet nothing stands written. This is exactly what happens with the mind. (Book 3, chap. 4, sec. 430)

That the human personality evolves as a function of the myriad contingencies that befall a person during the course of life has been entrenched since classical times. Plato asserted that

While spoiling of children makes their tempers fretful, peevish and easily upset by mere trifles, severe and unconditional tyranny makes its victims spiritless, servile, and sullen, rendering them unfit for the intercourse of domestic and civic life. (Book 7, sec. 791)

RELIGION AND THE PATHOGNOMONIC

That the human character has dysfunctional and even evil propensities is a nomothetic principle that was propagated in Western thought as a salient dogma of the Christian church. Although widely rejected, it pervaded much of political and social theorizing up to and even beyond the seventeenth century. Its most radical expression was in the homilies of such divines as Jonathan Edwards. The biblical dictum "I was shapen in iniquity and in sin did my mother conceive me" (Psalm 51) founded in part the traditional Christian view that human nature is fundamentally flawed by "original sin." It found expression in various vehicles of social thought and intellectual discussion of that time. The philosophers of the Enlightenment in

Europe repudiated this doctrine, although it continued to be propagated in religious circles and adumbrated in secular writings. The notion that human nature was essentially corrupt persisted in many of the systems of philosophy that flourished in the nineteenth century.

The dominant personality theorists of that period were clinicians with medical training. This professional background reinforced the pathological slant they gave to their descriptions of the human personality. Their theories of human psychological development gave prominence to the causes of deviant behavior rather than to the conditions for normal growth. Models of human personality were larded with dispositions to aggressive and narcissistic behavior. Freud in his more mature writings designated the aggressive instinct as one of the two pillars of his drive theory; the other, of course, was the erotic, a notion conceived in variously narrow and broad terms. His expansive pleasure principle was anticipated in the eighteenth century in the philosophy of Utilitarianism. Jeremy Bentham, a member of that school, stated that humans routinely engage in a “felicific calculus” ordained to maximize pleasure and minimize pain.

Twentieth-century theoreticians, principally university-based experimentalists, have striven to develop personological models focusing on wellness rather than on the pathognomonic. Gordon Allport is one of the outstanding representatives of this movement. Nevertheless the vocabulary, grammar, and notions of dysfunction and pathology continue to be woven into modern trait psychology. For example, Eysenck’s three-factor model of personality contains a psychoticism factor and a neuroticism factor, and neuroticism is one of the factors in the influential five-factor model of human personality postulated by William McDougall and most recently associated with the work of Paul T. Costa and Robert R. McCrae.

SELF-ACTUALIZATION

A contrary movement, often termed “humanistic,” is based on the self-actualizing and growth-oriented models of Kurt Goldstein, Otto Rank, Carl Rogers, Abraham Maslow, the cognitive psychologist Jean Piaget, and many others in which

pathology is conceptualized as a departure from normality rather than a component of it. Rogers, for example, asserted that just as plants are shaped by the directions they must take in seeking sources of light, human beings evolve throughout their life spans by reaching for the emotional and social sustenance that will allow the “organismic valuing process” to shape them into fully effloresced and functioning persons. Intrinsic wickedness and pathology have no place in these models of human nature. And although human nature can be thought of in terms of fundamental human needs, as in Maslow’s *Psychology of Being*, the needs are not directed to destruction of self and others but to the fullest expression of a creative, generous, and joyful life expression. This is clearly in conflict with the psychodynamic models of nineteenth-century psychiatry, among them the Freudian system, which explained the engine of human development in terms of libidinal drives and tension reduction.

Self-disclosure and social transparency is one of the more healthful aspects of this model of the normal personality. O. Hobart Mowrer stated that psychological health depends on conditions that ensure transparency, and he traced its historical roots as far back as the ancient practice of *exomologesis*, in which a community of believers periodically engaged in collective confession of their violations of community mores, as in the monastic communities of the (Semitic) Essenes. This principle finds its most celebrated expressions in the psychotherapeutic literature. Moritz Benedikt, in the last third of the nineteenth century, and Carl Gustav Jung, in the twentieth, made it central to their therapeutic systems. They emphasized the critical importance for patients of divulging the “pathogenic secrets” that are woven into the fabric of their lives. A modern expression of this burgeoned in the 1960s in the therapeutic community (TC) movement, in locations such as Daytop Village and Phoenix House, where each day began with a morning meeting in which each member of the “family” publicly recounted his or her failures of the preceding day.

That we know more than we can tell and that we know more than we are aware that we know has been postulated since the pre-Socratics of Hellenistic Greece. Johann Christian Reil’s seminal work, “Rhapsodien,” published in 1803, describes the phenomenon of multiple personalities, and a complex topographical model of the human psyche. It

is rarely questioned as we approach the twenty-first century that our behavior is influenced and our personality shaped by information that is sedimented in the organism, to paraphrase Merleau-Ponty, but which exists at a subsymbolic level and cannot in every instance be consciously accessed. The somatic-marker hypothesis of Antonio Damasio (1994; see chap. 8, pp. 165–201) is a recent expression of this position, which has profound implications for our conceptualization of what “personality” is and how it is shaped.

DEVELOPMENTAL PSYCHOLOGY AND PERSONALITY THEORY

It is self-evident to the psychologist that one cannot treat the construct of personality without grounding it in a scientific developmental psychology. This is true even of those theories that are simply descriptive rather than causal-explanatory. Persons are not born with personalities, although Thomas and Chess (1980), for example, have demonstrated in their widely cited New York Longitudinal Study that temperamental traits, constituents of some models of personality, are strongly influenced by hereditary factors. Personalities develop from infancy to adulthood and, indeed, across the life span. If the developmental psychology on which a personality theory is based is seriously flawed, then it is highly probable that that personality theory, itself, is also flawed. Ausubel et al. (1980) have reviewed a large number of developmental theories and their derivative personality theories. These theories range from the preformationist and quaintly theological to the most social and educationist systems that have flourished in the humanist climate of late-twentieth-century Western thought. They are, it must be emphasized, of unequal value. It flows from this that as the prevailing models of developmental psychology have evolved in the light of empirical research, personality theories have also had to evolve. For example, in the measure that the psychosexual stage theory of human development proposed by Freud a hundred years ago has been superseded and, arguably, discredited, to that extent has Freudian personality theory become superannuated. This can be stated of a number of personality theories whose value to scholars is now largely of a historical character. It is useful to add at this point that a theory of developmental psychology *is* a theory of personality as long as it

provides an integrative and broad-scale view of the way human beings develop socially, psychically, and characterologically.

THE MOVEMENT TO HOLISM

Holism, a much-used term of Greek etymology, characterizes an approach to understanding human personality that integrates all aspects of the person and, more recently, the social matrix in which it has been shaped and finds expression. Human psychology that attempts to explain behavior by appeal to only one “faculty” or one dimension of the human organism, that restricts itself to, say, simply rationalist or neuroendocrinological processes without understanding the systemic character of personality, has largely fallen into disfavor. Jan Christian Smuts, Alfred Adler, and Kurt Goldstein were early proponents of an integrative and holistic approach to the study of human beings, integrating organicist as well as social dimensions in a comprehensive view of personality and its determinants. Abandonment of fragmentary models has increased the appeal of Maturana and Varela’s work (1980). Situated in a constructivist tradition, this work is not only biological but also profoundly social-psychological in its conceptualization of the human person. For example, these researchers’ concept of “autopoiesis” is that the integrity and unity of the organism is generated from within, even as it interacts with and accommodates its surroundings. Every person is a self-organizing entity. The feed-forward mechanisms of which modern constructivists speak indicate that knowledge is to a great extent the construction of schemas involving the total organism. In this respect even the human’s immunological system is part of a larger knowing system. The congruence between this vision and the self-actualizing models of Goldstein, Maslow, and Rogers is obvious. Unidimensional systems have evolved toward multidimensionality. Personologists have increasingly pursued the goal of formulating integrative models of human experience.

“Holism,” as an approach to understanding human personality, can now be characterized more broadly as biopsychosocial. The knowledge that individuals have of themselves, whether tacit or conscious, is not simply intrapsychically determined. That knowledge is a function of what they

have been told they are by those who are most meaningful to them. The principle of Harry Stack Sullivan that our self-concept is the image that we see reflected in the eyes of those who are making appraisals of us had its antecedents in the concept of the "looking-glass" self, developed by Charles Horton Cooley, George Herbert Mead, and James Mark Baldwin at the beginning of the twentieth century. A broadly systemic view of the development of the human person has come into focus, and it is profoundly sociologized.

THE FEMINIST DYNAMIC

It is a commonplace notion of modern psychology that nomothetic models of the person have in the past been formulated by Caucasian males who unreflectively based them on male psychological norms. If, as Nietzsche said, all theory is autobiographical, it would follow that theories of personality developed by males reflect in part their personal and culturally circumscribed experiences. Sigmund Freud's, Lawrence Kohlberg's, and Erik Erikson's theories of moral development and evolution of human identity have been identified, among others, as based on male norms. Deviations from this male template have been considered abnormal. Karen Horney was among the first to repudiate psychoanalytic assertions that women were endowed with a moral sense inferior to that of males because they could not as children resolve the "Oedipal conflict" in the univocal sense that boys could. Feminists, including Inge K. Broverman, Pat Chesler, Carol Gilligan, and Carolyn Z. Enns have detailed the distortions implicit in characterizations of the typical female personality as submissive, conformist, masochistic, depression-prone, and so forth. The internalization of social roles by both men and women inevitably results in personality profiles that reflect those roles. The argument is made that establishing a template for normality that derives from a culture-circumscribed social role for men necessarily casts the typical feminine personality in the realm of the deficient, at least to the extent that it is laden with the deficits of the roles in which women have been socialized.

Whether there are universal, that is, nomothetic psychological differences between men and women arising from genetic determinants of gender-related behavior is an empirical question that is

still being studied by behavioral geneticists. If indeed there is no significant difference in the psychological development of the two sexes independent of fluid, relativistic cultural variables, it would not seem to matter which sex one used as the nomothetic template for healthy human development. The focus of analysis would necessarily shift to the socially constructed roles that are imposed on females. Assessing women as inferior by virtue of their possession of personality traits they have internalized in a society that has prescribed them would seem patently unjust.

NEUROPSYCHOLOGICAL INFLUENCES IN PERSONOLOGY

Just as there are no two Coke bottles and no two newly minted pennies that are perfectly identical, a fortiori there are no two human beings who are truly identical. Reminded that the preponderance of the human genome endows each of us with characteristics that are universal, we must also acknowledge that there are at least 20,000 genes, called "polymorphic genes," that come in many varieties, that get randomly assorted at conception, and that endow us in part with our individuality. The genes that define us as human are called "monomorphic genes." They account for the fact that we all look recognizably human and normally act so. Whatever nomothetic principles have been truly (or purportedly) established relative to the psychobiological and behavioral properties of the human, they derive, by definition, from these genes.

Behavioral geneticists such as Robert Plomin and Thomas Bouchard (among other researchers in this field) have established the contribution of heredity to personality. For example, Bouchard has done well-regarded studies on twins reared apart that have shed light on the heritability of personality traits. Although his findings and those of other behavioral geneticists have excited controversy and negative comment, there is a convergence of evidence to show that indeed some of the variance one finds in certain personality traits is of genetic origin. But one needs to recognize that the controversy is fraught as much with ideological and political concerns as with strictly scientific ones, and the values embedded in these conflicting opinions can tilt arguments in one direction as well as another. The flashpoint, par excellence, for

this controversy is the position taken on the personality trait “intelligence,” a construct referring to certain adaptive and creative human capabilities. That these capabilities are still imperfectly understood ensures that the various constructs purported to define them are even more imperfectly formulated. Psychometricians are placed at an even further remove from these nebulous realities when they attempt to measure them, often by paper-and-pencil instruments.

The power of environment to shape or misshape personality is incontestable. Attachment Theory, associated with the work of John Bowlby, among others, offers a cogent explanation of the conditions for healthful psychological development. This theory has an affinity with the principles evolved by such ethologists as Tinbergen, Lorenz, Hinde, and other students of the social life of animals. Failure to develop a strong infant–primary caregiver bond during the period of primary socialization (that is, between the appearance of the first social smile at several weeks of age and the appearance of stranger anxiety at, say, six to eight months of age) is thought to lay the groundwork for developmental psychopathy—and the rupture of this bond in the first years of life, is thought to lay the groundwork for later affective disorders. A related perspective is that of Object-Relations theorists, whose views on “mothering” and its influence on development are more (human) relational and less instinct- or drive-based than the classical psychoanalytic model.

Although the influence of childhood experiences, both positive and negative, on adult personality is not in dispute, the partial reversibility of these effects is asserted by Michael Rutter, Jerome Kagan, and others. The variables at issue, for example, bonding in infancy to a primary caregiver and stimulus deprivation in toddlerhood are, after all, continuous and complex. The strength and duration of the variables, and their interaction with genetic variables of an idiographic and often unknown character, produce personality effects that are not predictable with any accuracy. The principle of *neoteny*, that is, the slowing of developmental rates and the retention of plasticity and developmental capabilities well into adulthood, is at issue here. Humans enjoy a relatively long period of growth from infancy to adulthood, a period in which earlier psychological deformity can be mitigated, if not entirely undone. In the wake of a

traumatic infancy and childhood, prolonged immaturity provides humans with the affordances of redemption.

HOMUNCULARISM

Theories of personality development range on a continuum from the most rigidly preformationist at one end to the most malleable and environmentally sensitive at the other. Historically, Western psychology has been shifting toward the latter. In his remarkable work, *Centuries of Childhood* (1962), Philippe Ariès has demonstrated the long tradition of viewing children as miniature adults, *homunculi*, so to speak. The homuncular theory in its most primitive form postulated that the human organism, a little man (i.e., homunculus), contained in the semen of the male, is deposited in the uterus of the mother. It is presumed organically and morphologically complete. It merely needs to be nurtured to a mature status. The term has been extended as we know to embrace the postulate that not only the organic features of the mature human reside in the neonate but also the psychological features.

Children are, in this view, born with preformed characters and the cognitive structures of adults. To quote Ausubel et al.,

The basic human properties and behavioral capacities—personality, values, and motives; perceptual, cognitive, emotional, and social reaction tendencies—are not conceived as undergoing qualitative differentiation and transformation over the life-span but are presumed to exist preformed at birth. (1980 p. 15).

Vestiges of homuncularism remain in the work of twentieth-century personality theorists who attribute to infants and older children cognitions and emotions that, in a univocal sense, can only be the product of adult mentation. Confusing infantile sexuality with adult sexuality, as in classical psychoanalysis, is an example of this (cf., e.g., Thomas and Chess 1980, chap. IV, for a broader look at this issue). Among the more important of these innate schemas are the “racial unconscious” of Carl Gustav Jung and the “phylogenetic unconscious” of Sigmund Freud. They both have important implications for personological features and specific behaviors that are predicated on them.

It is widely recognized that the younger the organism, the more plastic it is in terms of acquiring and altering the learnings and adaptations it needs in order to thrive. Early-twentieth-century theories of human development postulated rigid and clearly delineated stages. These stages are no longer considered to have the rigid boundaries they were once supposed to have. In the earlier stage models it was presumed, but never demonstrated, that personality structure was established and firmly set by the age of, say, six or seven. In this view, the principal features of the personality did not change; they were only elaborated. This prescientific homuncularism has yielded to life-span developmental models.

There exists a countervailing point of view. Research has revealed the profound and subtle possibilities for change in the human personality that exist throughout the maturational process. Critical to this process of differentiation are education and other environmental factors, not excluding the benign and nurturant conditions that need to prevail during infancy in the home. Relevant to this orientation to human development is, again, the principle of neoteny. The slowing of humans' development from infancy to adulthood, has afforded humans the opportunity for evolving the complex and diverse personalities that, in the view of these theorists, is the hallmark of this species.

THE NOMOTHEIC AND THE IDIOGRAPHIC

That the psychologist as scientist has, in the past, inclined to a nomothetic and deterministic understanding of human beings is understandable. After all, it is difficult to build a science on the idiographic. Nevertheless, the concern of rank-and-file persons not to see themselves simply as one of billions of "knock-off's" from a universal template is also understandable. This may underlie some of the concern about cloning. "If there are clones about, how will you know who people really are?" ask some. Though there is a misconception about the phenomenon of cloning that underlies that question (after all, identical twins meet the definition of clones, and we come to know *who they are*), it indicates the concern about personal identity found in Western society. More specifically, the need to be an individual and to be

different (but not too different) from everyone else is evident in many Western and Westernized cultures. This plays out in the theorizing of personologists who have developed personality theories that give emphasis to the environmental factors that impinge on individuals in all phases of their lives, and that individuate them. It is this diversity in personal histories that accounts to a large extent for the uniqueness of each person. That members of the same family who have similar histories still mature to adulthood with very different personality profiles attests to the interaction of genetic factors with education, not excluding stochastic events that may have powerful formative impact on development.

THEORIES: DICHOTOMIES AND STAGES

The study of personality has addressed the question of what dynamics operate in all human beings to shape their behavior throughout the life span. This question assumes that there are some species-wide principles governing the development of human traits from conception to demise. It also addresses the question of what factors effect the individuation of human beings such that no one person is like any other person though they all share the same monomorphic genic substrate. Social scientists will recognize the ancient dichotomy for conceptualizing the relative contributions of nature as distinguished from life experiences. The code for this derives from Shakespeare's characterization of Caliban in *The Tempest*. Prospero refers to him as "a born devil, on whose nature Nurture can never stick." The expressions "nomothetic" and "idiographic" also refer to this dual factor—to wit, the universal principles governing the set "human beings" vis-à-vis relative principles governing the development of individuals within the set. In reality these are not true dichotomies except insofar as we wish to logically make them so. As in other conceptual polarities, explaining the emergence of a human being into adulthood admits of varying theoretical frameworks. A comparable perspective is reflected in the anthropological and linguistic distinctions between the *etic* (that is, the most general, often universal, frame for analyzing cultural behavior) and the *emic* frame (which examines social subsets of the species). An example of the former is Francis Galton's hypothesis, recently labeled "fundamental lexical hypothesis" (cf. Goldberg 1990, p.

1216), which affirms that the world's languages all contain terms describing similar personality traits, albeit traits that, although they have the same meaning, are valued differently, and present themselves with varying intensity and frequencies. An example of the latter is the principle (inherent in most multicultural perspectives on personality development) that the geohistorical background of any distinct society profoundly shapes the ideals of human behavior, morals, and social conduct, which get incarnated as "personality" in the majority of its members. The Sapir-Whorf hypothesis goes even further and states that the very structure of the language that a cultural subset of the human race speaks affects the character of their ideation and the consequent conduct of the group's affairs. But earlier, Nietzsche affirmed that "philosophers within the domain of the Ural-Altai languages" look into the world differently and take different paths than "Indo-Germans and Moslems: the spell of grammatical functions is in the last resort the spell of physiological value judgments and racial conditions" ([1885]1952, p. 472)

There have been zealous partisans of theories explaining human behavior that have, for reasons ideological as much as scientific, conceptualized personality into sets of dichotomies, in which they have emphasized one polarity rather than another. This antipodal schema has been with us since antiquity. The motifs of heroism and cowardice, of altruism and selfishness, of loyalty and betrayal, of candor and duplicity, of anguish and ecstatic joy, among other descriptors of the human experience that can play out in all human lives, received their finest expression in the works of such tragedians as Sophocles and Shakespeare. On the other hand, the uniqueness of each person and the passion for establishing one's personal identity is no less prominent in the great literature of the West. One has only to review, for example, the plays of Tennessee Williams, the great oeuvre of Cervantes, the vast range of characters in the novels of Balzac or Dickens, or in, say, Thomas Mann's *Magic Mountain*, to grasp the diversity that artists have displayed in limning the contours of these distinct personalities, to which readers have been able to resonate.

That human personality evolves and becomes different as an individual proceeds through a series of life stages would seem to be self-evident.

This view presumes, of course, that the construct "stage" is grounded in something real in human development. There are a number of complications to this view. First, the scope for change gets narrowed in the measure that variance in personality factors is explained by genetic factors. Conversely, the scope for change gets broadened in the measure that it is explained by education and other experience. Obviously, stage theory is less plausible, or less coercive in its implications, in the measure that personality development is fluidly malleable and educationally structured. The opposite seems true if biologically prestructured. But there is a second-order level for explaining personality change in a genetic perspective. One can accept a measure of predetermination in the psychoneurological substrate for personality, but it is not illogical to allow room in this model for a series of hardwired developmental periods. The model of Arnold Gesell, for example, though predeterministic, allows for qualitative stage-based shifts in the cognitive, psycho-motoric, interpersonal, and affective preferences and capabilities of the person.

As Piaget noted, whether or not one "sees" human development progressing from infancy to adulthood in stages is a function of how fine-grained and molecular one makes one's analysis. It is a question of scale. Standing inches from a *pointillist* painting, say, by Seurat, one sees only a multitude of tiny dots of pigment. It is only in distancing oneself so that the entire painting or large sections of it come into focus that the transitions from beach to sea to boats to trees to bathers become apparent. The phases of the panorama stand out as one macroscopically scans the canvas. It is difficult (but not impossible) to discern the shape of a galaxy when one is part of it.

As the analysis of personality development has assumed a more scientific, microscopic focus, there has been a tendency for the stage-based theories to fall into disrepute. This may account for the decline in popularity of the schemas developed by Freud, Erikson, Piaget, Sullivan, and Kohlberg, for example. Though these conceptualizations of human personality development continue to enjoy widespread support in part, if not in whole, they are partially in eclipse by virtue of advances in the newer human sciences. Cognitive science, psychoneurology, endocrinology, and social and

developmental psychology, among other disciplines, have inevitably superannuated all these grand systems to a greater or lesser degree.

SUMMARY

On entering the twenty-first century, the Zeitgeist will favor, it appears, theories of personality that are life-span developmental, less instinct-driven but more persons-relational, constructivist, process-oriented and dynamic, that is, Heraclitean, holistic, teleonomic, evolutionary, genetics-based, gender-equal, emic, sociological, and idiographic. Clearly, personality theories that predate World War II are not, by and large, consistent with these descriptors. It appears that the era of the grand systems is past. Personology will reconcile itself to more modest paradigms for describing, explaining, and predicting human behavior.

Students who wish to follow the development of this discipline are urged to regularly consult the *Annual Review of Psychology*, the *Journal of Personality and Social Psychology*, the *European Journal of Personality*, *Developmental Psychology*, and other respected periodicals that publish articles in this domain. An excellent and more detailed analysis of many of the issues raised above can be found in *Theories of Personality* by Hall, et al. (1998, chap.1, 15).

FRANK DUMONT

PERSUASION

The average number of hours the television set is on in American households is 6.8 hours a day (Peterson 1981). When not watching their 6.8 hours of television, most people spend the bulk of their time in talk with others. Much of this talk is geared not just to making oneself understood but to convincing someone else of the value and correctness of one's viewpoint. The average adult spends the majority of his or her waking hours at work, where, depending on the job, much activity involves efforts to get others to do one's bidding or being the object of such efforts. All this television watching, conversation, and work takes place in a social and political climate that, in theory if not in practice, encourages the exchange and dissemination of ideas among large numbers of people.

These facts have led some to conclude that this is an era of persuasion in which understanding who says what to whom in what way and with what effect is of critical importance (Lasswell 1948). In fact, some argue that the current era of persuasion is one of the few periods in the four millennia of

Western history characterized by such a degree of openness to argument (McGuire 1985).

Whether or not the present era is unique in this manner, more and more people are becoming conscious of the persuasive contexts in which they spend most of their time. Indeed, if the increasingly ingenious efforts of advertisers to pique interest and shape tastes and habits are any indication, people are becoming increasingly savvy about others' efforts at persuasion. This means that we have a very practical interest in understanding just how persuasion works. It also means that social scientists, and social psychologists in particular, have an interest in understanding and explaining a pervasive social phenomenon.

As one aspect of understanding persuasion, social psychologists have long studied attitude formation and change. During the 1920s and 1930s psychologists focused on describing the attitudes people hold. This led to the development of techniques for measuring attitudes, primarily scales such as the Likert scale, which continue to be used today by persuasion researchers. The second period of interest in attitude research occurred during the 1950s and 1960s, with the main focus moving from description to the study of attitude change and the effects of attitudes on behavior. (For a review of the research on attitude-behavior consistency, see Ajzen and Fishbein 1977.) This interest waned considerably during the next two decades as social psychologists became increasingly interested in social perception, or how people selectively interpret and respond to their social environments. The resurgence of interest in attitudes, and particularly in persuasion, that followed is thus largely informed by social psychology's more general emphasis on how people process the information they take in from their environment.

One might speculate that the interest in explaining persuasion and attitude change over mere attitude description reflects the increasing influence of mass media. However, this coincidence of research interest and social change is belied by the lack of communication between those studying the effects of mass media on attitudes and those studying persuasion in more immediately interpersonal contexts (Roberts and Maccoby 1985). The discussion here reflects this split in research focuses, concentrating solely on persuasion research in face-to-face, interpersonal contexts and

dealing only peripherally with research on the effects of mass media on attitudes. (See Roberts and Maccoby 1985 for a review of this literature.) The issue of brainwashing, an extreme form and method of persuasion, is considered only when it has direct relevance to less extreme persuasion contests and processes.

Of relevance to research on persuasion is the study of normative compliance occurring in settings where no active attempt is made to influence, but people change their opinions or judgments nonetheless. Asch's (1951) research on conformity demonstrated that subjects involved in a simple task of judging the length of a line were highly influenced by the judgments of others present, even when no overt influence attempts were made. In these studies people working with the experimenter gave incorrect assessments of the relative lengths of lines viewed. Even in cases of obviously incorrect judgments, most subjects conformed to the majority's assessment. Normative compliance is found to be greater the closer to unanimity the majority view, the larger the number holding it, and the more the conforming subject is attracted to and invested in group membership.

The persistence of findings of normative compliance, even in the absence of overt influence attempts, raises an obvious question: What happens when such overt attempts at persuasion are made? This and related questions are the focus of persuasion research. The focus in persuasion research is on attitude change "occurring in people exposed to relatively complex messages consisting of a position advocated by a communicator and usually one or more arguments designed to support that position" (Eagly and Chaiken 1984, p. 256). More simply defined, *persuasion* is an effort to change people's attitudes, these being the emotional and cognitive responses they have to objects, people, experiences, and so on.

FACTORS AFFECTING THE LIKELIHOOD OF PERSUASION

The guiding question of who says what to whom in what way with what effect has largely determined what factors researchers look to in explaining and predicting persuasion. These factors fall into four general classes: source or communicator variables, message variables, channel variables, and receiver variables. Reflecting two decades of research on

social cognition, studies of the effects of these variables on persuasion investigate how these factors affect persuasion by shaping the way in which people process information in the persuasion context. Indeed, the term *process* reflects the computer analogy often used to capture the manner in which people perceive, interpret, and respond to their environment.

For example, in studying the effects of source characteristics (the characteristics of the person communicating the persuasive message) researchers might examine how the likability of the source leads the receiver (the object of persuasion) either to attend to or to ignore the quality of the arguments accompanying the message. Similarly, researchers examine other aspects of cognition (e.g., attention, comprehension, receptivity, retention) for the manner in which they mediate the effects on persuasion of source, message, channel, and receiver variables.

Source Variables. The source variable of greatest interest is the credibility of the person communicating the persuasive message, including the communicator's apparent knowledge, social class, attractiveness, and likability. Consistently with common sense, the more credible the source, the more persuasive the source and the more likely that the receiver will change his or her attitude in the direction of the persuasive message. More interesting, however, is the combination of source credibility with other factors, and their combined effect on persuasion. For example, if the target person is not personally involved with the issue at hand, source credibility is more likely to enhance persuasion than if the person is highly involved in the issue. This is because personal involvement is likely to be associated with greater argument scrutiny by the target person, reducing the likelihood of immediate acceptance of even a credible source's position (Chaiken 1980).

The effects of source credibility on persuasion are thus mediated by the extent to which the target is motivated to thoughtfully scrutinize the supporting arguments presented by the source. Personal involvement in the issue is one such motivation, but specific knowledge of the topic (without any particularly emotionally charged investment in it) and being educated in general are also factors that mediate the effect of source credibility because of their impact on the manner in which the

target processes information at his or her disposal. Level of involvement, knowledge, and education are all characteristics of the receiver. The above example thus reveals the complex relationships between the factors that affect persuasion and their joint effects on information processing.

Message Variables. Many aspects of the persuasive message itself have been examined by research on persuasion. These include message style, ordering of arguments presented, speed of delivery, and message repetition. The effects of message repetition on persuasion are particularly interesting because they reveal the often unexpected combined effects of variables. For example, a study by Cacioppo and Petty (1979) revealed that only if supporting arguments are strong does repetition enhance persuasion, since repetition leads to greater argument scrutiny by the receiver, which enhances persuasion only to the extent that arguments are convincing.

Common sense might tell us that the use of humor in a message will enhance its persuasiveness by increasing the attractiveness of the source or, in the case of weak supporting arguments, distracting the target's attention from the content. Researchers have hypothesized that humor should enhance persuasion with a highly credible source, but not with a less credible source, since humor is likely to further reduce credibility in the latter case. However, there is little evidence to support the expected effects of humor on persuasion. The observed effects are rarely significant, and are as often negative as positive. Furthermore, the combined effects of humor with source credibility, or humor's impact on interest, retention, or source evaluation, are not found (McGuire 1985).

Channel Variables. Channel variables refer to the medium in which the message is communicated. For example, message persuasiveness varies depending on whether the message is given in person or in verbal, written, audio, or video form. In addition, channel variables include factors such as distraction—either direct distraction created by the behavior of the source or indirect distraction such as repeated external noise during the communication.

Petty and Cacioppo (1981) studied the effects of distraction on persuasion and found that its effects are mediated by cognitive factors such as the target's ability or motivation to scrutinize the

arguments. If the message is accompanied by a distracting noise, for example, this will enhance persuasion if accompanying arguments are weak, since it decreases the receiver's ability or motivation to pay close attention to the supporting arguments. Conversely, if the supporting arguments are strong, distraction decreases the likelihood of persuasion, especially with knowledgeable targets, since it makes it unlikely they will pay attention to the strong arguments designed to persuade them.

Similarly, other channel variables, such as the use of catchy music in television ads, affect persuasion to the extent that they motivate the receiver to generate positive rather than negative thoughts in response to the message. Generating thoughts is distinguished from argument scrutiny because it refers to the additional arguments or ideas the receiver brings to bear in evaluating a message, not to the supporting arguments provided by the communicator. Channel or other variables enhance persuasion to the extent that they generate positive thoughts or supporting arguments in the target (Greenwald 1968). Like other factors affecting persuasion then, the impact of channel variables on persuasion is mediated by the resulting cognitive processes engaged in by the target of the persuasive message.

Receiver Variables. Since persuasion is oriented toward convincing someone to adopt a particular viewpoint or opinion, it makes sense that the person himself or herself has some impact on the persuasion process. Interest in the personality correlates of persuasion was high during the 1950s but waned in the following decades as individual-level explanations of social phenomena became less popular among social psychologists. However, more recent work has revived interest in the effect of receiver variables on persuasion.

A variety of receiver variables relating to personality characteristics have been studied to determine receiver susceptibility and resistance to persuasion. With respect to self-esteem, researchers predict that greater self-esteem will decrease the likelihood of persuasion to the extent that it increases the likelihood that the receiver will carefully scrutinize the arguments, and decreases the likelihood of the receiver's being swayed by a credible source in the absence of strong supporting arguments. Therefore, like the other factors

affecting persuasion, self-esteem exerts its effects on persuasion through the variables related to the manner in which the receiver processes the information available in the persuasion context.

Results of studies of self-esteem and persuasion offer mixed results, some indicating negligible effects (Barber 1964) and others suggesting that the lower the self-esteem, the greater the tendency to conform, especially when the aspect of self-esteem involved is closely related to the issue at hand (Endler et al. 1972). The effects of self-esteem are complex, especially when combined with other variables. For example, greater influenceability is associated with higher, not lower, self-esteem as the complexity of the persuasive message increases.

More consistent findings have been produced on the effects of receiver's mood on responses to persuasive attempts. Interestingly, research has shown that neutral or bad moods decrease susceptibility to persuasive attempts, largely because targets are more likely to scrutinize messages when in a neutral or bad mood than when in a good mood (Wegener et al. 1995; Rosseli et al. 1995).

The effects of authoritarianism or dogmatism have also received considerable research attention. *Dogmatism* is defined as a general inclination to be closed-minded, intolerant, and deferential to authority. Research has shown that receivers low in dogmatism are persuaded by strong, but not by weak, arguments. Dogmatic receivers, in contrast, are persuaded by strong arguments only when the source is nonexpert. With expert sources, dogmatic individuals are equally persuaded by strong and weak arguments (DeBono and Klein 1993).

Aside from personality characteristics, persuasion researchers, like other social researchers, have shown a longstanding interest in the issue of gender differences. A summary of 148 studies of the effects of gender on persuasion (Eagly and Carli 1981) indicates that women are more easily influenced than men. However, as consistent as these findings are, the magnitude of gender differences in influenceability is small enough to raise doubts about its practical significance for people's everyday lives (McGuire 1985).

However trivial these differences may be, they have inspired persuasion researchers to search for

an explanation. One plausible account is that “greater female susceptibility and greater male predictability might derive from socialization differences such that conforming pressures are exerted more strongly and uniformly on women, compressing them into a narrow band of high influenceability” (McGuire 1985, p. 288). Thus, the effects of gender on influenceability result from the different social experiences of men and women (for example, the greater likelihood that women will hold jobs in which they will receive more persuasion attempts than they themselves perform).

METHODOLOGICAL AND THEORETICAL ISSUES IN THE STUDY OF PERSUASION

While all studies of persuasion tend to focus on some combination of the variables discussed above, more general research orientations have not been uniform. One way of dividing research approaches to persuasion is to distinguish between the descriptive and the mathematical models. The former may focus on any combination of variables affecting persuasion, but their predictions tend to be stated in the form of verbal argument or a set of hypotheses. Mathematical or probabilistic models, on the other hand, cast their predictions about persuasion in the form of equations, with variables and their relationships represented in algebraic terms. While the choice of research approach does not dictate which variables the researcher focuses on, some argue that the greater precision of probabilistic models makes for a more exact understanding of the conditions likely to produce persuasion (McGuire 1985). Others (e.g., Eagly and Chaiken 1984) refer to these models as “normative,” meaning that they describe how persuasion ought to work, not necessarily how it works in reality.

Whatever the relative merits of descriptive and probabilistic approaches, there is some consensus among persuasion researchers that a more general theory of persuasion is necessary if the vast research findings in the area are to be integrated in a meaningful manner (Eagly and Chaiken 1984). As this discussion shows, the research on persuasion is blessed with a large number of well-conceptualized variables, most of which are easy to operationalize, that is, to create in a laboratory setting. The discussion also shows, however, that even when a small portion of all the possible combinations of these variables are matched with

one or two of the mediating cognitive processes, the resulting insights into persuasion are far from some of the commonsense notions alluded to throughout this discussion. This fact lends support for the call for a more unifying theory of persuasion to integrate the somewhat fragmented picture that emerges from a combining-of-variables approach.

SUSCEPTIBILITY AND RESISTANCE TO PERSUASION

This discussion raises important questions about issues of susceptibility and resistance to persuasion. When is being easily persuaded good? When is resistance good, and how can it be taught? If Americans are spending between six and seven hours a day in front of their television sets, and the rest of their waking hours in persuasive communications with others on the job or at leisure, teaching resistance to all this persuasion might become a top priority. For example, when research reveals that motivating people to generate reasons for their attitudes toward a product ultimately causes them to change their initial attitude, and even to purchase a product on the basis of their changed attitude (only to regret it later) attention is called to the conditions under which enhancing resistance might be warranted (Wilson et al. 1989). On the other hand, when research shows that two years of viewing *Sesame Street* caused both black and white children to manifest more positive attitudes towards black and Hispanics, something is learned about the conditions under which enhancing attitude change and persuasion is desirable (Bogatz and Ball 1971).

Whether one values resistance or openness to persuasion, our understanding of resistance to persuasion is enhanced by our understanding of what increases the likelihood of persuasion. As this discussion has shown, source variables (e.g., credibility), channel variables (e.g., distractions), message variables (e.g., argument strength), and receiver variables (e.g. personality characteristics) can all affect the receiver’s susceptibility or resistance to persuasion. In addition, research has shown that when people perceive persuasive messages as threats to their freedom, they resist persuasion and maintain their original position or, in some cases, adopt a position opposite to the one advocated in the message (Brehm 1966).

More recent research on values reveals another factor involved in susceptibility and resistance to persuasion. In general, people are more susceptible to messages which are consistent with their own values, and more resistant to those that are not. For example, Han and Shavitt (1994) have shown that receivers with individualistic values (e.g., Americans) are more persuaded by advertising messages emphasizing individualistic themes (e.g., "Take care of number one!"). In contrast, receivers with collectivistic values (e.g., Koreans) are more persuaded by advertising messages emphasizing collectivistic themes (e.g., "For you and your family!"). Thus, whether we are interested in enhancing persuasion or increasing resistance to it, understanding the role of values in the persuasion process is crucial.

Ultimately, resistance to the potential loss of autonomy involved in persuasion is not surprising in a culture that places a premium on such individuality and freedom. In addition, such concerns are not unwarranted, given the fact that many of the attempts at persuasion people face in natural settings are specifically designed to minimize the threatening aspects of such attempts and thus to reduce resistance (hence the use of the word "seductive" to refer to arguments, advertisements, etc.). Are people continually at risk, then, of potentially harmful persuasion?

One could argue that in people's ability to be persuaded lies the possibility of autonomy. If people are easily persuaded, then they are in similar measure unlikely to be overwhelmingly persuaded by a particular viewpoint over all others. They may be likely to resist total indoctrination, if only because they are susceptible to some other credible source sending a convincing message in a captivating medium.

SUSAN McWILLIAMS

PHENOMENOLOGY

Phenomenology is a movement in philosophy that has been adapted by certain sociologists to promote an understanding of the relationship between states of individual consciousness and social life. As an approach within sociology, *phenomenology* seeks to reveal how human awareness is implicated in the production of social action, social situations and social worlds (Natanson 1970).

Phenomenology was initially developed by Edmund Husserl (1859–1938), a German mathematician who felt that the objectivism of science precluded an adequate apprehension of the world (Husserl 1931, 1954). He presented various philosophical conceptualizations and techniques designed to locate the sources or essences of reality in the human consciousness. It was not until Alfred Schutz (1899–1959) came upon some problems in Max Weber's theory of action that phenomenology entered the domain of sociology (Schutz 1967). Schutz distilled from Husserl's rather dense writings a sociologically relevant approach. Schutz set about describing how subjective meanings give rise to an apparently objective social world (Schutz 1954, 1962, 1964, 1966, 1996; Schutz and Luckmann 1973; Wagner 1983).

Schutz's migration to the United States prior to World War II, along with that of other phenomenologically inclined scholars, resulted in the transmission of this approach to American academic circles and to its ultimate transformation into interpretive sociology. Two expressions of this approach have been called *reality constructionism* and *ethnomethodology*. Reality constructionism synthesizes Schutz's distillation of phenomenology and the corpus of classical sociological thought to account for the possibility of social reality (Berger 1963, 1967; Berger and Berger 1972; Berger and Kellner 1981; Berger and Luckmann 1966; Potter 1996). Ethnomethodology integrates the Parsonian concern for social order into phenomenology and examines the means by which actors make ordinary life possible (Garfinkel 1967; Garfinkel and Sacks 1970). Reality constructionism and ethnomethodology are recognized to be among the most fertile orientations in the field of sociology (Ritzer 1996).

Phenomenology is used in two basic ways in sociology: (1) to theorize about substantive sociological problems and (2) to enhance the adequacy of sociological research methods. Since phenomenology insists that society is a human construction, sociology itself and its theories and methods are also constructions (Cicourel 1964, 1973). Thus, phenomenology seeks to offer a corrective to the field's emphasis on positivist conceptualizations and research methods that may take for granted the very issues that phenomenologists find of interest. Phenomenology presents theoretical techniques and qualitative methods that illuminate the human meanings of social life.

Phenomenology has until recently been viewed as at most a challenger of the more conventional styles of sociological work and at the least an irritant. Increasingly, phenomenology is coming to be viewed as an adjunctive or even integral part of the discipline, contributing useful analytic tools to balance objectivist approaches (Aho 1998; Levesque-Lopman 1988; Luckmann 1978; Psathas 1973; Rogers 1983).

TECHNIQUES

Phenomenology operates rather differently from conventional social science (Darroch and Silvers 1982). Phenomenology is a theoretical orientation, but it does not generate deductions from

propositions that can be empirically tested. It operates more on a metasociological level, demonstrating its premises through descriptive analyses of the procedures of self-, situational, and social constitution. Through its demonstrations, audiences apprehend the means by which phenomena, originating in human consciousness, come to be experienced as features of the world.

Current phenomenological techniques in sociology include the method of “bracketing” (Bentz 1995; Ihde 1977). This approach lifts an item under investigation from its meaning context in the commonsense world, with all judgments suspended. For example, the item “alcoholism as a disease” (Peele 1985; Truan 1993) is not evaluated within phenomenological brackets as being either true or false. Rather, a *reduction* is performed in which the item is assessed in terms of how it operates in consciousness: What does the disease notion do for those who define themselves within its domain? A phenomenological reduction both plummets to the essentials of the notion and ascertains its meanings independent of all particular occasions of its use. The reduction of a bracketed phenomenon is thus a technique to gain theoretical insight into the meaning of elements of consciousness.

Phenomenological tools include the use of introspective and *Verstehen* methods to offer a detailed description of how consciousness itself operates (Hitzler and Keller 1989). Introspection requires the phenomenologist to use his or her own subjective process as a resource for study, while *Verstehen* requires an empathic effort to move into the mind of the other (Helle 1991; Truzzi 1974). Not only are introspection and *Verstehen* tools of phenomenological analysis, but they are procedures used by ordinary individuals to carry out their projects. Thus, the phenomenologist as analyst might study himself or herself as an ordinary subject dissecting his or her own self-consciousness and action schemes (Bleicher 1982). In this technique, an analytic attitude toward the role of consciousness in designing everyday life is developed.

Since cognition is a crucial element of phenomenology, some theorists focus on social knowledge as the cornerstone of their technique (Berger and Luckmann 1966). They are concerned with how commonsense knowledge is produced,

disseminated, and internalized. The technique relies on theoretical discourse and historical excavation of the usually taken for granted foundations of knowledge. Frequently, religious thought is given primacy in the study of the sources and legitimations of mundane knowledge (Berger 1967).

Phenomenological concerns are frequently researched using qualitative methods (Bogdan and Taylor 1975; Denzin and Lincoln 1994, 1998). Phenomenological researchers frequently undertake analyses of small groups, social situations, and organizations using face-to-face techniques of participant observation (Bruyn 1966; Psathas and Ten Have 1994; Turner 1974). Ethnographic research frequently utilizes phenomenological tools (Fielding 1988). Intensive interviewing to uncover the subject’s orientations or his or her “life world” is also widely practiced (Costelloe 1996; Grekova, 1996; Porter 1995). Qualitative tools are used in phenomenological research either to yield insight into the microdynamics of particular spheres of human life for its own sake or to exhibit the constitutive activity of human consciousness (Langsdorf 1995).

Techniques particular to the ethnomethodological branch of phenomenology have been developed to unveil the practices used by people to produce a sense of social order and thereby accomplish everyday life (Cuff 1993; Leiter 1980; Mehan and Wood 1975). At one time, “breaching demonstrations” were conducted to reveal the essentiality of taken-for-granted routines and the means by which threats to these routines were handled. Since breaching these routines sometimes resulted in serious disruptions of relationships, this technique has been virtually abandoned. Social situations are video- and audiotaped to permit the painstaking demonstration of the means by which participants construct their identities, their interpretations of the meanings of acts, and their sense of the structure of the situation (Blum-Kulka 1994; Jordan and Henderson 1995). Conversational analysis is a technique that is frequently used to describe how people make sense of each other through talk and how they make sense of their talk through their common background knowledge (Psathas 1994; Schegloff and Sacks 1974; Silverman, 1998). The interrelations between mundane reasoning and abstract reasoning are also examined in great depth as researchers expose, for example, the socially constituted bases of scientific

and mathematical practice in commonsense thinking (Knorr-Cetina and Mulkay 1983; Livingston, 1995; Lynch, 1993).

THEORY

The central task in social phenomenology is to demonstrate the reciprocal interactions among the processes of human action, situational structuring, and reality construction. Rather than contending that any aspect is a causal factor, phenomenology views all dimensions as constitutive of all others. Phenomenologists use the term *reflexivity* to characterize the way in which constituent dimensions serve as both foundation and consequence of all human projects. The task of phenomenology, then, is to make manifest the incessant tangle or reflexivity of action, situation, and reality in the various modes of *being in the world*.

Phenomenology commences with an analysis of the *natural attitude*. This is understood as the way ordinary individuals participate in the world, taking its existence for granted, assuming its objectivity, and undertaking action projects as if they were predetermined. Language, culture, and common sense are experienced in the natural attitude as objective features of an external world that are learned by actors in the course of their lives.

Human beings are open to patterned social experience and strive toward meaningful involvement in a knowable world. They are characterized by a typifying mode of consciousness tending to classify sense data. In phenomenological terms humans experience the world in terms of *typifications*: Children are exposed to the common sounds and sights of their environments, including their own bodies, people, animals, and vehicles. They come to apprehend the categorical identity and *typified* meanings of each in terms of conventional linguistic forms. In a similar manner, children learn the formulas for doing common activities. These practical means of doing are called *recipes for action*. Typifications and recipes, once internalized, tend to settle beneath the level of full awareness, that is, to become *sedimented*, as do layers of rock. Thus, in the natural attitude, the foundations of actors' knowledge of meaning and action are obscured to the actors themselves.

Actors assume that knowledge is objective and that all people reason in a like manner. Each actor assumes that every other actor knows what he or she knows of this world: All believe that they share common sense. However, each person's biography is unique, and each person develops a relatively distinct stock of typifications and recipes. Therefore, interpretations may diverge. Everyday social interaction is replete with ways in which actors create feelings that common sense is shared, that mutual understanding is occurring, and that everything is all right. Phenomenology emphasizes that humans live within an intersubjective world, yet they at best approximate shared realities. While a *paramount reality* is commonly experienced in this manner, particular realities or *finite provinces of meaning* are also constructed and experienced by diverse cultural, social, or occupational groupings.

For phenomenology, all human consciousness is practical—it is always consciousness of something. Actors intend to introduce projects into the world; they act in order to implement goals based on their typifications and recipes, their *stock of knowledge* at hand. Consciousness as an *intentional process* is composed of thinking, perceiving, feeling, remembering, imagining, and anticipating directed toward the world. The objects of consciousness, these intentional acts, are the sources of all social realities, which are, in turn, the materials of commonsense.

Thus, typifications derived from common sense are internalized, becoming the tools that individual consciousness uses to constitute a *lifeworld*, the unified arena of human awareness and action. Common sense serves as an ever-present resource to assure actors that the reality that is projected from human subjectivity is an objective reality. Since all actors are involved in this intentional work, they sustain the collaborative effort to reify their projections and thereby reinforce the very frameworks that provide the construction tools.

Social interaction is viewed phenomenologically as a process of reciprocal interpretive constructions of actors applying their stock of knowledge at hand to the occasion. Interactors orient themselves to others by taking into account typified meanings of actors in typified situations known to them through common sense. Action schemes are geared by each to the presumed projects of

others. The conduct resulting from the intersection of intentional acts indicates to members of the collectivity that communication or coordination or something of the like is occurring among them. For these members, conduct and utterances serve as *indexical* expressions of the properties of the situation, enabling each to proceed with the interaction while interpreting others, context, and self. Through the use of certain interpretive practices, members order the situation for themselves in sensical and coherent terms: In their talk they gloss over apparent irrelevancies, fill in innumerable gaps, ignore inconsistencies, and assume a continuity of meaning, thereby formulating the occasion itself.

Ongoing social situations manifest patterned routine conduct that appears to positivist investigators to be normative or rule guided. Phenomenologically, rules are indexical expressions of the interpretive processes applied by members in the course of their interactions. Rules are enacted in and through their applications. In order to play by the book, an interpreter endeavors to use a rule as an apparent guide. However, he or she must use all sorts of background expectancies to manage the fit somehow between the particular and the general under the contexted conditions of the interaction, and in so doing is acting creatively. Rules, policies, hierarchy, and organization are accomplished through the interpretive acts or negotiations of members in their concerted efforts to formulate a sense of operating in accord with a rational, accountable system. This work of doing structure to the situation further sustains its commonsensical foundations as well as its facticity.

Phenomenologists analyze the ordering of social reality and how the usage of certain forms of knowledge contributes to that ordering. It is posited that typified action and interaction become *habitualized*. Through sedimentation in layered consciousness, human authorship of habitualized conduct is obscured and the product is externalized. As meaning-striving beings, humans create theoretical explanations and moral justifications in order to legitimate the habitualized conduct. Located in higher contexts of meaning, the conduct becomes objectivated. When internalized by succeeding generations, the conduct is fully institutionalized and exerts compelling constraints over individual volition. Periodically, the institutions

might be repaired in response to threats, or individuals might be realigned if they cognitively or affectively migrate.

The reality that ordinary people inhabit is constituted by these legitimations of habitualized conduct. Ranging from commonsense typifications of ordinary language to theological constructions to sophisticated philosophical, cosmological, and scientific conceptualizations, these legitimations compose the paramount reality of everyday life. Moreover, segmented modern life, with its proliferation of meaning-generating sectors, produces multiple realities, some in competition with each other for adherents. In the current marketplace of realities, consumers, to varying degrees, may select their legitimations, as they select their occupations and, increasingly, their religions (Berger 1967).

PRACTICE

Doing phenomenological sociology involves using procedures that are distinct from positivist research. Phenomenological practice is increasingly evident in the discipline as more subjectivist work is published. The phenomenological analysis of mass media culture content, for example, applies the elements of the approach to yield an understanding of the reflexive interplay of audience lifeworlds and program material (Wilson 1996). Thus, TV talk show discourses may be described as social texts that are refracted by programmers from commonsense identity constructs. The visual realization yields narrative images that audiences are seduced into processing using their own experiences. The viewers' lifeworlds and the TV representations are blended into reality proxies that provide viewers with schemata to use in configuring their personal orientations. Subsequently, programmers draw upon these orientations as additional identity material for new content development.

Phenomenological work with young children examines how both family interactions and the practices of everyday life are related to the construction of childhood (Davila and Pearson 1994). It reveals how the children's elemental typifications of family life and common sense are actualized through ordinary interaction. Penetrating the inner world of children requires that the phenomenological practitioner view the subjects in children's own terms, from their levels and viewpoints

(Waksler 1991; Shehan 1999). Such investigation shuns adult authoritative and particularly scientific perspectives, and seeks to give voice to the children's experience of their own worlds. Infants' and children's communicative and interactive competencies are respected and are not diminished by the drive toward higher-level functioning (Sheets-Johnstone 1996).

At the other end of the lifecycle, phenomenologists investigate how aging and its associated traumas are constituted in the consciousness of members and helpers. The struggle for meaning during aging accompanied by chronic pain may be facilitated or impaired by the availability of constructs that permit the smoother processing of the experiences. Members of cultures that stock typifications and recipes for managing aging and pain skillfully may well be more likely than others to construct beneficial interpretations in the face of these challenges (Encandela 1997). Phenomenological work encourages the helpers of the elderly to gain empathic appreciation of their clients' lifeworlds and enhanced affiliation with them through the use of biographical narratives that highlight their individuality and humanity (Heliker 1997).

The healing professions, particularly nursing, seem to be deeply imbued with a phenomenological focus on the provision of care based on a rigorous emphasis on the patient's subjective experience (Benner 1995). Substantial attention has been devoted to the ethical implications of various disease definitions, to how language shapes the response to illness, and to how disease definitions and paradigmatic models impact communication between health professionals and patients (Rosenberg and Golden 1992). Significant work on the phenomenology of disability has demonstrated how the *lived body* is experienced in altered form and how taken-for-granted routines are disrupted by invoking new action recipes (Toombs 1995). Nonconventional healing practices have also been examined, revealing how embodiment and the actor's subjective orientation reflexively interrelate with cultural imagery and discourse to transfigure the self (Csordas 1997). Further, phenomenological work has suggested that emotions are best analyzed as interpreted processes embedded within experiential contexts (Blum 1996; Solomon 1997).

IMPLICATIONS

For phenomenology, society, social reality, social order, institutions, organizations, situations, interactions, and individual actions are constructions that appear as suprahuman entities. What does this suggest regarding humanity and sociology? Phenomenology advances the notion that humans are creative agents in the construction of social worlds (Ainlay 1986). It is from their consciousness that all being emerges. The alternative to their creative work is meaninglessness, solipsism, and chaos: a world of dumb puppets, in which each is disconnected from the other and life is formless (Abercrombie 1980). This is the nightmare of phenomenology. Its practitioners fear that positivist sociologists actually theorize about such a world (Phillipson 1972).

Phenomenologists ask sociologists to note the misleading substantiality of social products and to avoid the pitfalls of reification. For the sociologist to view social phenomena within the natural attitude as objects is to legitimate rather than to analyze. Phenomenological sociologists investigate social products as humanly meaningful acts, whether these products are termed attitudes, behaviors, families, aging, ethnic groups, classes, societies, or otherwise (Armstrong 1979; Gubrium and Holstein 1987; Herek 1986; Petersen 1987; Starr 1982). The sociological production of these fictive entities is understood within the context of their accomplishment, that is, the interview setting, the observational location, the data collection situation, the field, the research instrument, and so forth (Schwartz and Jacobs 1979). The meaning contexts applied by the analyst correlates with those of the subjects under investigation and explicates the points of view of the actors as well as expressing their lifeworlds. Phenomenological sociology strives to reveal how actors construe themselves, all the while recognizing that they themselves are actors construing their subjects and themselves.

Phenomenologically understood, society is a fragile human construction, thinly veneered by abstract ideas. Phenomenology itself is evaluatively and politically neutral. Inherently, it promotes neither transformative projects nor stabilization. In the work of a conservatively inclined practitioner, the legitimation process might be supported,

while the liberative practitioner might seek to puncture or debunk the legitimations (Morris 1975). Phenomenology can be used to reveal and endorse the great constructions of humankind or to uncover the theoretical grounds of oppression and repression (Smart 1976). Phenomenologists insist upon the human requirements for meaning, subjective connectedness, and a sense of order. These requirements may be fulfilled within existent or emancipative realities (Murphy 1986).

The phenomenological influence upon contemporary sociology can be seen in the increased humanization of theoretical works, research methods, educational assessment procedures, and instructional modes (Aho 1998; Darroch and Silvers 1982; O'Neill 1985; Potter 1996). Phenomenological thought has influenced the work of postmodernist, poststructuralist, critical, and neofunctional theory (Ritzer 1996). Notions such as constructionism, situationalism, and reflexivity that are at the core of phenomenology also provide the grounds for these recent formulations. For example, the premise of poststructuralism that language is socially constituted denying the possibility of objective meaning is clearly rooted in phenomenology. The procedure known as *deconstruction* essentially reverses the reification process highlighted in phenomenology (Dickens and Fontana 1994). The postmodernist argument that knowledge and reality do not exist apart from discourse is also clearly rooted in phenomenology. Postmodernism's emphasis on the representational world as reality constructor further exemplifies the phenomenological bent toward reflexivity (Bourdieu 1992). On the other hand, phenomenology has been used to reverse nihilistic excesses of postmodernism and poststructuralism (O'Neil 1994). The emphases of the critical school on the constitution of the liberative lifeworld by the autonomous, creative agent via the transcendence of linguistic constraint echoes a theme of phenomenological thought (Bowring 1996). Neofunctionalism, a looser and more inclusive version of its predecessor, finds room for a microsocial foundation focusing on the actor as a constructive agent (Layder 1997).

Phenomenology, while remaining an identifiable movement within the discipline of sociology, has influenced mainstream research. Inclusion of qualitative research approaches in conventional research generally expresses this accommodation

(Bentz and Shapiro 1998). The greater acceptance of intensive interviewing, participant observation, and focus groups reflect the willingness of nonphenomenological sociologists to integrate subjectivist approaches into their work. The study of constructive consciousness as a method of research has broadened and strengthened the standing of sociology in the community of scholars (Aho 1998).

Phenomenology has made a particular mark in the area of educational policy on a number of levels. The flaws of objective testing have been addressed using phenomenological tools. The issue of construct validity, the link between observation and measurement, has been studied ethnographically as a discursive activity to clarify the practices employed by education researchers to establish validity (Cherryholmes 1988). Testing of children has increasingly respected the subjectivity of the test taker (Gilliatt and Hayward 1996; Hwang 1996). Educators are more alert to the need for understanding the learner's social and cognitive processes, for taking into account the constraining parameters of consciousness, and for encouraging self-conscious reflection. Instructional practices that emphasize constructivist approaches have gained great support among professionals and have been broadly implemented to the benefit of learners (Marlowe and Page 1997).

The future impact of phenomenology will depend on its resonance with the needs and aspirations of the rising generations of sociologists. The drive of some among this emerging generation is to examine the obvious with the infinite patience and endurance that is required to come up with penetrating insight. The arena of discourse analysis perhaps holds the greatest promise of this achievement and will likely elicit substantial effort. The phenomenology of emotions also appears to entice young scholars. The reflexive analyses of popular and mediated culture in relation to identity formation will likely draw further interest, as will the study of virtuality, cyberspace, and computer simulcra. The study of children, the family, and education will increasingly be informed by an emphasis on constructive consciousness. Due to its lack of presumption and openness, the phenomenological movement in sociology has proved hardy during the closing decades of the twentieth century and is well situated to encounter the new millennium.

POLICE

For modern sociology the core problem of police has been, and continues to be, the extrication of the concept *police* from the forms and institutions in which it has been realized and the symbols and concealments in which it has been wrapped. Doing so is essential to the interpretive understanding of the idea of police and is prerequisite to mature answers to the question of what policing means, has meant, and can mean. In one form or another it is the project that has occupied sociologists of police since the early 1960s, and although there is occasional overlap and interchange, attention to it is primarily what distinguishes contributions to the sociology of police from scholarly efforts in the study of police administration, jurisprudence, criminalistics, and police science.

THE POLICE: A SOCIOLOGICAL DEFINITION

By the end of the 1960s a small number of now-classic empirical studies of police had made it apparent that conventional understandings of the idea of police were fundamentally and irreparably flawed. In the face of large-scale studies by Reiss (1971) and Black (1971) which showed that the model tour of duty of a patrol officer in the high-crime areas of the nation's largest cities did not involve the arrest of a single person, it became impossible for sociologists to continue to speak of police as "law enforcers" or of their work as "law enforcement." Likewise, both Skolnick's *Justice without Trial* (1966) and Wilson's *Varieties of Police Behavior* (1968) illustrated dramatic differences in the way police were organized and the relationships they elected to enjoy with courts and law. Similarly, early studies of both the exercise of patrol officer discretion (Bittner 1967a, 1967b) and requests for police service (Cumming et al. 1965; Bercal 1970) cast substantial doubt on the notion that a substantial, much less a defining, activity of police was "fighting crime."

Police Role and Functions. The task of extricating the concept of police from these common misconceptions was assumed by Egon Bittner in *The Functions of Police in Modern Society* (1970). A fundamental theme of Bittner's work was that to define police as "law enforcers," "peacekeepers," "agents of social control," "officers of the court," or, indeed, in any terms that suppose what police should do, confuses police role and function. Throughout history, in this country and in others, police have performed all sorts of functions. In fact, the functions, both manifest and latent, that police have performed are so numerous and so contradictory that any attempt to define police in terms of the functions they are supposed to perform or the ends they are supposed to achieve is doomed to failure.

Force as the Core of the Police Role. Sociologically, policing cannot be defined in terms of its ends; it must be defined in terms of its means. In *Functions* Bittner advanced an approach to understanding the role of the police that was based on the single means that was common to all police, irrespective of the ends to which they aspired or were employed. The means Bittner found to define police was a right to use coercive force. Police,

said Bittner, are "a mechanism for the distribution of non-negotiably coercive force" (1971). No police had ever existed, nor is it possible to conceive of an entity that could be called police ever existing, that did not claim the right to use coercive force.

Sociologically, Bittner's formulation had three major virtues. First, it was universal. It was applicable to police everywhere and at all times, police as diverse as the sheriff's posse of the old West, the London bobby, the FBI, or the police of Hitler's Third Reich or Castro's Cuba. Second, it was politically and morally neutral. It could be used to refer to police whose behavior was exemplary as readily as it could be applied to police whose behavior was appalling. Third, it made it possible to make explicit and to probe in systematic ways a host of questions about the role of police that could not previously be explored because they had been concealed in the confusion between role and function: Why do all modern societies, from the most totalitarian and most tyrannical to the most open and democratic, have police? What does having police make available to society that no other institution can supply? What functions are appropriate to assign to police and what are best left to other institutions?

These questions are of such enormous consequence and so fundamental to an understanding of the role of the police that it is difficult to conceive of a sociology of police existing prior to their recognition.

Why Police? If police are a "mechanism for the distribution of non-negotiably coercive force," why should all modern societies find it necessary to create and sustain such a mechanism? What does having such a mechanism make available to modern societies that no other institution can provide?

Bittner's answer is that no other institution has the special competence required to attend to "situations which ought not to be happening and about which something ought to be done NOW!" (1974, p. 30). The critical word in Bittner's careful formulation of the role of the police is "now." What the right to distribute coercive force gives to police is the ability to resolve situations that cannot await a later resolution. The crucial element is time. Turning off a fire hydrant against the wishes of inner-city street bathers, preventing the escape

of a serial murderer, halting the escalation of a domestic dispute, or moving back the curious at the scene of a fire so that emergency equipment can pass—these and hundreds of other tasks fall to police because their capacity to use force may be required to achieve them “now.”

This view of police radically inverts some conventional conceptions. While popular opinion holds that police acquire their right to use coercive force from their duty to enforce the law, the sociology of police holds that police acquire the duty to enforce the law because doing so may require them to invoke their right to use coercive force. Similarly, focus by police on the crimes and misdemeanors of the poor and humble, and their relative lack of attention to white-collar and corporate offenders, is often promoted as reflecting a class or race bias in institutions of social control. While not denying that such biases can exist and do sometimes influence the direction of police attention, if such biases were eliminated entirely, the distribution of police effort and attention would undoubtedly remain unchanged. It would remain unchanged because the special competence of police, their right to use coercive force, is essential in enforcement efforts in which offenders are likely to physically resist or to flee. In white-collar and corporate crime investigations, the special competence of lawyers and accountants is essential, while the special competence of police is largely unnecessary.

INSTITUTIONAL FORMS

Although all modern societies have found it necessary to create and maintain some form of police, it is obvious that any institution that bears the right to use coercive force is extraordinarily dangerous and highly subject to abuse and corruption. The danger of the institution of police would appear to be magnified when it gains a monopoly, or a near-monopoly, on the right to use coercive force, and when those who exercise that monopoly are almost exclusively direct and full-time employees of the state. Appearances and dangers notwithstanding, these are nevertheless the major terms of the institutional arrangement of police in every modern democracy. Some comment on the sociology of this institutional uniformity may be helpful.

Avocational Policing. For most of human history most policing has been done by individuals,

groups, associations, and organizations in the private sector. This type of private-sector policing, done by citizens not as a job but as an avocation, may be classified into at least three types, each of which offered a somewhat different kind of motivation to private citizens for doing it (Klockars 1985). Historically, the most common type is *obligatory avocational policing*. Under its terms private citizens are compelled to police by the threat of some kind of punishment if they fail to do so. In American police history the sheriff's posse is perhaps the most familiar variety of this type of policing. The English systems of frankpledge (Morris 1910) and parish constable (Webb and Webb 1906) were also of this type.

A second type of private-sector policing, *voluntary avocational policing*, is done by private citizens not because they are obliged by a threat of punishment but because they, for their own reasons, want to do it. The most familiar American example of this type of policing is vigilante groups, over three hundred of which are known to have operated throughout the United States up to the end of the nineteenth century (Brown 1975).

A third type, *entrepreneurial avocational policing*, includes private citizens who as English thief takers, American bounty hunters, French agents provocateurs, and miscellaneous paid informants police on a per-head, per-crime basis for money.

The institutional history of these avocational forms of policing is thoroughly disappointing, and modern societies have largely abandoned these ways of getting police work done. The central flaw in all systems of obligatory avocational policing is that as the work of policing becomes more difficult or demanding, obligatory avocational policing takes on the character of forced labor. Motivated only by the threat of punishment, those who do it become unwilling and resistant, a situation offering no one any reason to learn or cultivate the skill to do it well. All forms of voluntary avocational policing suffer from the exact opposite problem. Voluntary avocational police, vigilantes and the like, typically approach their work with passion. The problem is that because the passionate motives of voluntary avocational police are their own, it is almost impossible to control who and where and what form of police work they do and on whom they do it. Finally, the experience with

entrepreneurial forms of avocational policing—thief takers, bounty hunters, and paid informants—has been the most disappointing of all. The abuse and corruption of entrepreneurial avocational police has demonstrated unequivocally that greed is too narrow a basis on which to build a police system.

Sociologically, the shortcoming of all forms of avocational policing is that none of them offers adequate means of controlling the police. This observation leads directly to the question of why one might have reason to suspect that a full-time, paid police should be easier to control than its avocational precedents. What new means of control is created by establishing a full-time, paid, police vocation?

The answer to this problem is that only when policing becomes a full-time, paid occupation is it possible to dismiss, to *fire*, any particular person who makes his or her living doing it. The state can only hire entrepreneurial avocational police, bounty hunters, paid informants, and thief takers; it cannot fire them. Vigilantes are driven by their own motives and cannot be discharged from them. Obligatory avocational police are threatened with punishment if they don't work; most would love to be sacked. Because the option to fire, to take police officers' jobs away from them, is the only essential means of controlling police work that separates the police vocation from all avocational arrangements for policing, how that option is used will, more than anything else, determine the shape and substance of the police vocation.

The Police Vocation. The English, who in 1829 created the first modern police, were intimately familiar with the shortcomings of all forms of avocational policing. They had, in fact, resisted the creation of a paid, full-time police for more than a century, out of fear that such an institution would be used as a weapon of political oppression by the administrative branch of government. To allay the fears that the "New Police" would become such a weapon, the architects of the first modern police, Home Secretary Robert Peel and the first commissioners of the New Police, Richard Mayne and Charles Rowan, imposed three major political controls on them. Peel, Mayne, and Rowan insisted that the New Police of London would be unarmed, uniformed, and confined to preventive patrol. Each of these features shaped in profound

ways the institution of the New Police and, in turn, the police of the United States and other Western democracies that explicitly copied the English model.

Unarmed. Politically, the virtue of an unarmed police is that its strength can be gauged as a rough equivalent of its numbers. Weapons serve as multipliers of the strength of individuals and can increase the coercive capacity of individuals to levels that are incalculable. One person with a rifle can dominate a dozen citizens; with a machine gun, hundreds; with a nuclear missile, thousands. One person with a police truncheon is only slightly stronger than another, and that advantage can be quickly eliminated by the other's picking up a stick or a stone. In 1829 the individual strength of the 3,000 constable, unarmed New Police offered little to fear to London's 1.3 million citizens.

While this political virtue of an unarmed police helped overcome resistance to the establishment of the institution, the long-run sociological virtue of an unarmed police proved far more important. Policing is, by definition, a coercive enterprise. Police must, on occasion, compel compliance from persons who would do otherwise. Force is, however, not the only means to compel compliance. Sociologically, at least three other bases for control are possible: authority, power, and persuasion.

Unarmed and outnumbered, the New Police "bobby" could not hope to police effectively on the basis of force. Peel, Mayne, and Rowan knew that if the New Police were to coerce successfully, they would have to do so on the basis of popular respect for the authority and power of the institution of which they were a part. The respect owed each constable was not owed to an individual but to a single, uniform temperament, code of conduct, style of work, and standard of behavior that every constable was expected to embody.

In order to achieve this uniformity of temperament, style, conduct, and behavior, the architects of the New Police employed the option to dismiss with a passion. "Between 1830 and 1838, to hold the ranks of the New Police of London at a level of 3300 men required nearly 5,000 dismissals and 6,000 resignations, most of the latter not being altogether voluntary" (Lee 1971; p. 240). During the first eight years of its organization, every position on the entire force was fired or forced to resign more than three times over!

Unlike their earlier London counterparts, the new American police were undisciplined by the firing option. What prevented the effective use of the firing option by early American police administrators was that police positions were, by and large, patronage appointments of municipal politicians. In New York, for example, the first chief of police did not have the right to fire any officer under his command. So while London bobbies were being dismissed for showing up late to work or behaving discourteously toward citizens, American police were assaulting superior officers, taking bribes, refusing to go on patrol, extorting money from prisoners, and releasing prisoners from the custody of other officers.

In New York, Boston, Chicago, and other American cities the modern police began, in imitation of London's bobbies, as unarmed forces; but, being corrupt, undisciplined, and disobedient, they could not inspire respect for either their power or their authority. In controlling citizens they had no option but to rely on their capacity to use force. The difficulty with doing so unarmed is that someone armed with a multiplier of strength can always prove to be stronger. Gradually, against orders, American police armed themselves, at first with the quiet complicity of superior officers and later, as the practice became widespread, in open defiance of departmental regulations. Eventually, in an effort to control the types of weapons their officers carried, the first municipal police agencies began issuing standard service revolvers.

The long-run sociological consequence of arming the American police can be understood only by appreciating how it shaped American police officers' sense of the source of their capacity to control the citizens with whom they dealt. While the London bobbies drew their capacity for control from the profoundly social power and authority of the institution of which they were a part, American police officers understood their capacities for control to spring largely from their own personal, individual strength, multiplied if necessary by the weapon they carried on their hips. This understanding of the source of their capacity for control led American police officers to see the work they did and the choices they made in everyday policing to be largely matters of their individual discretion. Thus, the truly long-run sociological

effect of the arming of the American police has been to drive discretionary decision making to the lowest and least public levels of American police agencies. Today how an American police officer handles a drunk, a domestic disturbance, an unruly juvenile, a marijuana smoker, or a belligerent motorist is largely a reflection not of law or agency policy but of that particular officer's personal style. This is not to say that law or agency policy cannot have influence over how officers handle these types of incidents. However, one of the major lessons of recent attempts by sociologists to measure the impact of changes in law or police policy in both domestic violence and drunken driving enforcement is that officers can resist those changes vigorously when the new law or policy goes against their views of proper police response (see Dunford et al. 1990; Mastroski et al. 1988).

Uniformed. Politically, the requirement that police be uniformed is a guarantee that they will not be used as spies; that they will be given information only when their identity as police is known; that those who give them information, at least when they do so in public, are likely to be noticed doing so; and that they can be held accountable, as agents of the state, for their behavior. The English, who had long experience with uniformed employees of many types, understood these political virtues of the uniform completely. In fact, an incident in 1833 in which a police sergeant assumed an ununiformed undercover role resulted in such a scandal that it nearly forced the abolition of the New Police.

By contrast, the early American understanding of the uniform was totally different. Initially it was seen to be a sign of undemocratic superiority. Later it was criticized by officers themselves as a demeaning costume and resisted on those grounds. For twelve years, despite regulations that required them to do so, early New York policemen successfully refused to wear uniforms. In 1856 a compromise was reached by allowing officers in each political ward to decide on the color and style they liked best.

Despite the early resistance to the uniform and the lack of appreciation for its political virtues, American police eventually became a uniformed force. While the London bobby's uniform was explicitly designed to have a certain "homey"

quality and to reflect restraint, the modern American police officer's uniform is festooned with the forceful tools of the police trade. The gun, ammunition, nightstick, blackjack, handcuffs, and Mace, all tightly holstered in shiny black leather and set off with chromium buckles, snaps, badges, stars, flags, ribbons, patches, and insignia, suggest a decidedly military bearing. The impression intended is clearly one not of restraint but of the capacity to overcome the most fearsome of enemies by force.

The Military Analogy and the War on Crime.

To understand the sociology of the American police uniform, it is necessary to see in it a reflection of a major reform movement in the history of the American police. Around 1890 American police administrators began to speak about the agencies they administered as if they were domestic armies engaged in a war on crime (Fogelson 1977).

The analogy was powerful and simple. It drew upon three compelling sources. First, it sought to connect police with the victories and heroes of the military and to dissociate them from the corruption and incompetence of municipal politics. Second, it evoked a sense of urgency and emergency in calls for additional resources. From the turn of the century to the present day, the war on crime has proved a useful device for getting municipal governments and taxpayers to part with money for police salaries and equipment. Third and most important, the war on crime and the military analogy sought to create a relationship between police administrators and politicians at the municipal level that was similar to the relationship enjoyed by military generals and politicians at the national level. At the national level Americans have always conceded that the decision on whether to fight a war was a politicians' decision, but how that war was to be fought and the day-to-day discipline of the troops was best left to the generals. By getting the public and the politicians to accept these terms of the police-politics relationship, the early police administrators found a way to wrest from the hands of politicians the tool they needed to discipline their troops: the option to fire disobedient officers.

The uniform of the war-ready American police officer is testimony to the fact that since the 1940s, American police administrators have won the battle to conceive of police as engaged in a war

on crime. In doing so they have gained control of the option to fire for administrative purposes. However, the cost of that victory has been enormous.

A major problem is the idea of a war on crime and the expectation police have promoted that they can, in some sense, fight or win it. In point of fact, a war on crime is something police can neither fight nor win for some fundamental sociological reasons. It is simply not within the capacity of police to change those things—unemployment, the age distribution of the population, moral education, civil liberties, ambition and the social and economic opportunities to realize it—that influence the amount and type of crime in any society. These are the major social correlates of crime, and despite presentments to the contrary, police are but a small tail on a gigantic social kite. Moreover, any kind of real “war on crime” is something that no democratic society would be prepared to let its police fight. No democratic society would be able to tolerate the kinds of abuses to the civil liberties of innocent citizens that fighting any real “war” on crime would necessarily involve. It is a major contribution of the sociology of police since the 1960s to demonstrate that almost nothing police do can be shown to have any substantial effect on reducing crime.

The problems of policing in the name of crime when one cannot do much of anything about it are enormous. It is not uncommon for patrol officers to see their employers as hypocritical promoters of a crime-fighting image that is far removed from what they know to be the reality of everyday police work. They may seek to explain what they know to be their failure to do much about crime in terms of the lack of courage of their chief, the incompetence of police administration, or sinister political forces seeking to “handcuff” the police. They often close off what they regard as the disappointing reality of what they do in cynicism, secrecy, and silence—the “blue curtain,” the occupational culture of policing.

Equally problematic as a spoil of the early chiefs' victory in their war on crime is the quasi-military police administrative structure. Once heralded as a model of efficiency, it is now regarded as an organizationally primitive mode of management. It works, to the extent that it works, by creating hundreds and sometimes even thousands

of rules and by punishing departures from those rules severely. The central failing of such an administrative model is that it rests on the unwarranted assumption that employees will not discover that the best way to avoid punishment for doing something wrong is to do as little as possible. The administration can, in turn, respond by setting quotas for the minimum amount of work it will tolerate from employees before it moves to punish them, but if it does so, that minimal amount of work is, by and large, all it will get.

Preventive Patrol. The third major mechanism with which architects of the New Police sought to neutralize their political uses was to confine police to preventive patrol. This restriction was understood to have the effect of limiting the uniformed, patrolling constable to two relatively apolitical types of interventions: situations in which constables would be called upon for help by persons who approached them on the street and situations that, from the street, constables could see required their attention. These political virtues of patrol impressed the architects of the New Police, particularly Sir Richard Mayne. Mayne postponed the formation of any detective unit in the New Police until 1842, and during his forty years as commissioner held its ranks to fewer than 15 detectives in a force of more than 3,500.

In the early American experience, uniformed patrol served the principal purpose of imposing some semblance of order on unruly officers. Patrol offered some semblance of assurance that officers could be found at least somewhere near the area to which they were assigned. And while American police created detective forces almost immediately after they were organized, patrol has become in the United States, as in Britain and other modern democracies, the major means of getting police work done.

Sociologically, patrol has had tremendous consequences for the form and substance of policing. It has, for example, been extraordinarily amenable to the three most profound technological developments of the past century: the automobile, the telephone, and the wireless radio. And while there is no evidence that increasing or decreasing the amount of patrol has any influence whatsoever on the crime rate, each of these technological developments has made police patrol more convenient

and more attractive to citizens who wish to call for police service. It is not an exaggeration to say that the vast majority of the activity of most modern police agencies is driven by a need to manage citizen demand for patrol service.

In recent years, attempts to manage this demand have taken many forms. Among the most common are the creation of computer-aided dispatch systems that prioritize the order in which patrol officers are assigned to complaints and increasingly stringent policies governing the types of problems for which police will provide assistance. Also increasingly common are attempts to handle complaints that merely require a written report, by taking that report over the telephone or having the complainant complete a mail-in form. In no small part, such efforts at eliminating unnecessary police response and making necessary police response efficient have produced some of the increasing cost for police labor.

REORIENTING POLICING

Despite efforts at prioritization, limitation of direct police response, and development of alternative ways of registering citizen complaints, demand for police service continues to grow. Despite the fact that individual citizens appear to want this form of police service more than any other, some contemporary approaches suggest that the entire idea of “dial-a-cop,” “incident-driven” policing requires reconsideration. Two such approaches, “community-oriented policing” (Skolnick and Bayley 1986) and “problem-oriented policing” (Goldstein 1979, 1990), have been advanced as the next generation of “reform” movements in American policing (Greene and Mastrofski 1988).

As theories of police reform, both “problem-oriented” and “community-oriented” policing are grounded in the suspicion that the traditional police response of dispatching patrol officers in quick response to citizen complaints does little to correct the underlying problem that produced the complaint. To some degree at least, this suspicion is confirmed by studies that tend to show that a fairly small number of addresses tend to generate disproportionate numbers of calls for police service, and that patrol officers commonly return to such “hot spots” again and again to attend to similar problems (Sherman et al. 1989).

Both problem-oriented and community-oriented policing offer strategies to deal with such problems that go beyond merely dispatching an officer to the scene. Problem-oriented policing offers a generic, four-step, problem-solving strategy—scanning, analysis, response, and assessment—that police can use to identify problems and experiment with solutions. Community-oriented policing, by contrast, does not offer a mechanism for problem analysis and solution. It is, however, committed to a general strategy that calls for cooperative, police-community efforts in problem solving. In such efforts it encourages the employment of a variety of police tactics—foot patrol, storefront police stations, neighborhood watch programs—that tend to involve citizens directly in the police mission.

While both approaches to reorienting policing have been heralded as revolutionary in their implications for the future of policing, both confront some major obstacles to their realization. The first is that neither problem-oriented nor community-oriented police efforts have been able to reduce the demand for traditional patrol response. Unless that demand is reduced or police resources are increased to allow it to be satisfied along with nontraditional approaches, the community- and problem-oriented policing approaches will most likely be relegated, at best, to a secondary, peripheral role.

The second problem confronting both community- and problem-oriented policing stems from the definition of police and the role appropriate to it in a modern democratic society. The special competence of police is their capacity to use force, and for that reason all modern societies find it necessary and appropriate to have them attend to situations that cannot await a later resolution. Reactive, incident-driven, dial-a-cop patrol is a highly popular, extremely efficient, and (as nearly as possible) politically neutral means of delivering that special competence. To expand the police role to include responsibility for solving the root problems of neighborhoods and communities is an admirable aspiration; but it is a responsibility that seems to go beyond the special competence of police and to require, more appropriately, the special competence of other institutions.

In the past quarter of a century, the scholarly literature on police has grown so dramatically that

a guide is quite helpful if not essential for the reader who seeks to explore the sociology of police. There are seven classic works in the sociology of police that continue to frame most modern dialogues: Michael Banton's *The Policeman in the Community* (1968), Egon Bittner's *Functions of Police in Modern Society* (1970), Herbert Packer's *The Limits of the Criminal Sanction* (1968), Jerome Skolnick's *Justice without Trial* (1966), William Westley's *Violence and the Police* (1970), and James Q. Wilson's *Varieties of Police Behavior* (1968). These classic works are informed, dramatized, broadened, and otherwise enhanced by a second generation consisting of five extraordinary empirical and theoretical works: Donald Black's *Manners and Customs of the Police* (1980), David Bayley's *Forces of Order: Police Behavior in Japan and the United States* (1976), William Ker Muir, Jr.'s *Police: Streetcorner Politicians* (1977), Peter Manning's *Police Work: The Social Organization of Policing* (1977), and Jonathan Rubinstein's *City Police* (1973).

Beginning in the 1980s, the literature on the sociology of police may be thought of as dividing into three tracks. One track continues the general reflections on the nature of the police institution and its enterprise and includes Richard Ericson's *Making Crime* (1982), Carl Klockars's *The Idea of Police* (1983), Robert Reiner's *The Politics of the Police* (1985), and most recently Richard Ericson and Kevin Haggarty's *Policing the Risk Society* (1997). A second track includes a collection of studies that focus on particular types of or particular problems in policing. Among them are Geoffrey Alpert and Laurie Fridell's *Police Vehicles and Firearms: Instruments of Deadly Force* (1992), Gary Marx's *Undercover* (1988), Maurice Punch's *Conduct Unbecoming: The Social Construction of Police Deviance and Control* (1985), and Lawrence W. Sherman's *Policing Domestic Violence* (1992), as well as two collections, *Modern Policing*, edited by Michael Tonrey and Norval Morris (1992), *Police Violence: Understanding and Controlling Police Abuse of Force*, edited by William A. Geller and Hans Toch (1996). The third track is, of course, the enormous literature on community policing. The collection edited by Jack Greene and Stephen Mastrofski and entitled *Community Policing: Rhetoric or Reality* (1988) is a good guide to the early literature. Herman Goldstein's *Problem-Oriented Policing* (1990) is, of course, essential. Malcolm Sparrow, Mark Moore, and David

Kennedy's *Beyond 911* (1995), and George Kelling and C. Coles's *Fixing Broken Windows* (1996) are two works of some influence in contemporary discussions of the promise of community policing.

CARL B. KLOCKARS

POLISH AND EASTERN EUROPEAN SOCIOLOGY

CENTRAL AND EASTERN EUROPEAN SOCIOLOGY

There is no doubt that central and eastern European sociologies have similar intellectual, historical, and political roots and can be treated as one block, in contrast to western European sociologies, which are not characterized by uniformity (Nedelmann and Sztompka 1993). This holds true especially for the postwar period in the development of eastern European sociologies. The only exception to this pattern is Polish sociology, which is why we analyze the history and current state of Polish sociology separately. In this brief analysis of central and eastern European sociology we focus on Russian, Hungarian, Czech, Bulgarian, and Rumanian sociologies (see Kolaja and Das 1988; Genov 1989; Keen and Mucha 1994).

Overall, we do not evaluate these sociologies as very impressive, especially in comparison to western European sociologies, on the one hand, and American sociology, on the other. Central and eastern European sociologies have not produced important contributions either to classical tradition or to contemporary sociology. The only contribution to classical world sociology that should be mentioned here comes from Russian tradition and belongs to Pitrim Sorokin (1959, 1962).

The postwar period in the development of eastern and central European sociology is marked

by the imposition of the communist system on the societies in that region. This historical development had overwhelming impact on the development of sociology in these societies. In Russia we witness further expansion of orthodox Marxism—the development that began right after the Bolshevik revolution in 1917, when sociology was removed from universities along with “bourgeois” professors. Historical materialism was proclaimed the only true scientific sociology, whereas the critique of “bourgeois sociology” was the only way of dealing with Western social thought and adopting Western sociological ideas. In the 1950s and 1960s in Russia, a kind of “empirical” Marxist sociology was established. Because of this development, survey research on the conditions of the working class on a large scale was launched and has continued up to this day. This continuing research is atheoretical and purely descriptive.

The so-called Stalinist period, which began right after World War II and lasted until the late fifties, or in some countries even the early sixties, was marked by the almost complete defeat of academic sociology. Sociology was labeled a “bourgeois pseudo-science” (Kolosi and Szelenyi 1993, p. 146), and was abolished as an academic and autonomous discipline. It is hard to overestimate the negative outcomes of this period and the entire period of the communist system in the eastern and central European countries. The development of sociology has been substantially slowed down if not, in some cases, completely stopped. This is why it was only in the 1960s that debates about the scientific character of sociology reemerged in Hungarian and other sociologies in this region. During most of the time after the Stalinist period and until the 1990s, sociologies of this region were trying to free themselves from Marxist ideology, which was not easy since communist regimes always treated sociology as dangerous discipline. These factors are basically responsible for the retardation of these sociologies, as compared to the rest of European sociology. Another important factor that should be mentioned here is the intellectual tradition. As opposed to such countries as Germany, France, Great Britain, and even Poland, the central and eastern European countries have had no tradition of sociological thought.

In this context it is easy to see why, during the communist period and even after the collapse of

the communist system, there was little significant achievement in sociological theory and research in eastern and central European countries.

For example, in Bulgaria it was only in 1985 that sociology began as an academic discipline at few universities. The factor that ignited this development was the fact that Bulgarian Sociological Association organized the VII World Congress of International Sociological Association (ISA) in Varna in 1970. However, the organization of the World Congress of ISA was possible due to purely political decision made by Bulgarian communist government and ISA authorities, but not as the result of advancement of Bulgarian sociology itself.

In Rumania and Czechoslovakia the condition of sociology was very bad, and practically until 1989 the discipline of sociology in these countries was subjected to special controls by the communist regimes. For example, in Czechoslovakia, to have any sort of academic career, communist party membership was required. In East Germany it was only after 1980 that earning a Ph.D. in sociology was allowed for East German academics. Even in the former Yugoslavia, sociology was strictly controlled by the government; this control, in conjunction with the lack of a sociological research tradition, created a situation in which substantial development of the discipline of sociology was very difficult (Keen and Mucha 1994).

Only in Hungary were there important contributions to sociology. These were made by Gyorgy Konrad and Ivan Szelenyi in urban sociology and especially in the sociology of inequalities, classes, and intelligentsia. Their book, *The Intellectuals on the Road to Class Power*, is probably the most famous contribution of Hungarian sociology to world sociological literature (Konrad and Szelenyi 1979). Research on economical sociology by Istvan Gabor, Janos Kornai, and Elmer Hankiss, and on social structure and stratification by Tamas Kolosi, was also significant, not only for our understanding of Hungarian society but also for a general understanding of the phenomena studied.

As mentioned previously, Polish sociology is a special and different case, which is why we treat it separately. There is a rich tradition of sociological thought in Poland. Important contributions to sociology that have significance for this discipline were made by Polish sociologists. Even during the communist period, sociology in Poland remained

relatively free in terms of research, the process of institutionalization of academic life, and contact with Western sociology.

THE ORIGINS OF SOCIOLOGY IN POLAND

To understand the past and present status of Polish sociology, one should take into account its peculiarity, namely, its particularly tight, intrinsic link with the course of Polish national history, overabundant with uprisings, wars, revivals and transformations. The nineteenth century and the period up to World War II were characterized by the reception of the dominant European trends of social thought. The organicism of Herbert Spencer is reflected in the works of Jozef Supinski (1804–1893), called the founder of Polish sociology. He formulated, for the first time, the problem of the interplay between the nation and the state, which became persistent later on in Polish sociology. Ludwik Gumplowicz (1838–1909) was one of the classic exponents of the conflict tradition and probably the only Polish sociologist of that period who entered the standard textbooks of the history of sociology. He published several works, mainly in German: *Der Rassenkampf* (1883), *Grundriss der Soziologie* (1885), *Die soziologische Staatsidee* (1892), and *Soziologie und Politik* (1892). Gumplowicz's peculiarity consisted in his being an advocate of sociologism before Émile Durkheim. His approach to social life was that the emergence and functioning of social organizations are marked by enduring conflict between social groups, for example, ethnic groups. This is why in some textbooks he is also called a social Darwinist.

The psychologism of Gabriel Tarde and Gustave Le Bon influenced the ideas of Leon Petrazycki (1867–1931), whose three fundamental works were originally published in Russian: *The Introduction to the Study of Politics and Law* (1892), *An Introduction to the Study of Law and Morality* (1905), and *The Theory of Law and State* (1907). His *Die Lehre vom Einkommen* (two volumes, 1893–1895) was published in Berlin. For Petrazycki, observation is a basic method of investigating and studying objects and phenomena. As regards psychic phenomena, the observation consists in self-observation, or introspection. The task of sociology is to detect objective tendencies of social phenomena. Unconscious adaptation processes might be replaced by deliberate steering of man's destiny with the help

of law. The ideal pursued by Petrazycki consisted in the human psyche's being so fitted to the requirements of social life that normative systems (e.g., morality) would prove unnecessary.

Another advocate of psychologism was Edward Abramowski (1868–1918). His main writings include *Individual Elements in Sociology* (1899), and *Theory of Psychological Units* (1899), in which he sketched his theory of sociological phenomenalism. Its main thesis was that the development of societies is based on the constant interaction between objective phenomena and human consciousness, which are causes and effects alternately. In three works—*Problems of Socialism, Ethics and Revolution*, and *Socialism and the State*, all written before 1899 and published in *Social Philosophy: Selected Writings* (1965)—he applied sociological phenomenalism to the analysis of the strategy of class struggle and to the realization of the socialist system. Social revolution should be preceded by “moral revolution”—a deep transformation of conscience. A cooperative is a germ of a socialist society, while the state is its enemy. A cooperative can be transformed into a real republic—a cooperative *res publica*.

Ludwik Krzywicki (1859–1941) was the foremost representative of the first Polish Marxists' generation. Among his works are: *Modern Social Issue* (1888), *Political Economy* (1899), *Sociological Studies* (1923), and *Idea and Life* (1957). Krzywicki was under substantial influence from Darwin and Comte, which led him to the idea of society as a section of natural phenomena and social evolution as a part of universal evolution. The merging of historical materialism with positivistic scientific criteria produced a natural-evolutionistic branch of Marxism comprising the canon of “iron historical laws,” of which Krzywicki himself was the representative. His conception of “historical background” allowed him to invent the original typology of social systems. Also, he was the author of original conception of “industrial feudalism,” being the precursor of the “welfare state” theory.

Another follower of Marx's ideas, Kazimierz Kelles-Krauz (1872–1906), published, among other works, *The Law of Revolutionary Retrospection* (1895), *Sociological Law of Retrospection* (1898), *Economic Basis of Primitive Forms of the Family* (1900), *A Glimpse of XIX Century Sociology* (1901), and *Economic Materialism* (1908). Kelles-Krauz defined the

sociological theory of Marxism as monoeconomism, according to which the whole of social life is determined by the mode of production. However, the central point of his sociological conception was the law of revolutionary retrospection. It referred exclusively to the sphere of social consciousness and was supposed to explain the origins of the revolutionary ideal in a way parallel to monoeconomism: The ideals by which the whole reformatory movement wishes to substitute the existing social norms are always similar to norms from the more or less distant past.

Stefan Czarnowski (1879–1937), in his *Leading Ideas of Humanity* (1928), *Culture* (1938), and *Works*, (2 vols., 1956), continued Durkheim's ideas. *Culture* is Czarnowski's top achievement, in which he claims that culture is the whole of objective elements of social heritage, common for several groups and because of its generality able to expand in space. Czarnowski overcame the dualism of Durkheim's conception, granting both society and culture the character of reality *sui generis*. Characteristic of all these conceptions was the overt impact of the actual sociopolitical conditions on the content of social theory.

The soliology of Florian Znaniecki (1882–1958) and the social (or cultural) anthropology of Bronislaw Malinowski (1884–1942) were different from the above-mentioned bodies of work in at least two respects. First, the works of both Znaniecki and Malinowski gained worldwide recognition; second, both consisted of general conceptions not restricted in scope by particular conditions of time, place, and culture. Znaniecki was coauthor (with W. I. Thomas) of *The Polish Peasant in Europe and America* (1918–1920) and author of numerous books, such as *Cultural Reality* (1919), *Introduction to Sociology* (1922), *The Laws of Social Psychology* (1925), *Sociology of Education* (2 vols., 1928–1930), *The Method of Sociology* (1934), *Social Actions* (1936), *The Social Role of the Man of Knowledge* (1940), *Cultural Sciences* (1952), and the posthumous volume *Social Relations and Social Roles*. He is well known as the author of the concept of “humanistic coefficient,” and of a theoretical system unfolding the postulate of universal cultural order and axionormatively ordered social actions. Bronislaw Malinowski, author of *Argonauts of Western Pacific* (1922), *The Sexual Life of Savages in North-Western Melanesia* (1929), *Coral Gardens and Their Magic* (1935), *A Scientific Theory of Culture and Other Essays* (1944),

and *Freedom and Civilization* (1947), among other works, found world esteem as one of the most influential scholars in establishing the functional approach in cultural anthropology.

BETWEEN POST-WAR YEARS AND THE COLLAPSE OF COMMUNISM, 1949–1989

The history of Polish sociology in this period has yet to be written. Among the best attempts to characterize Polish sociology under communism are Wladyslaw Kwasniewicz's articles: "Dialectics of Systemic Constraint and Academic Freedom: Polish Sociology under Socialist Regime," and "Between Universal and Native: The Case of Polish Sociology" (Kwasniewicz 1993, 1994). It was a time when sociology underwent severe criticism (including condemnation in the period 1949–1956), a time of a great shift toward Marxist orientation, but also a time of continuation of traditional lines of theorizing and of implementing in Polish sociology several novelties emerging in Western sociology (especially after 1956, when Polish sociology was brought back to life). The revival and development of Polish sociology was possible at that time thanks to the following outstanding intellectuals of the older generation: Jozef Chalasiniski (1904–1979), who wrote *Young Generation of Peasants* (1938), *Society and Education* (1948), *Young Generation of the Villagers in People's Poland* (a series of volumes, 1964–69), and *Culture and Nation* (1968). He was a prominent student of Polish intelligentsia, peasantry, and youth. Stanislaw Ossowski (1897–1963), who wrote *On the Peculiarities of Social Sciences* (1962) and *Class Structure in the Social Consciousness* (1963, English ed.). The latter contained fresh, stimulating, and critical overviews of theories of both class and social stratification. Maria Ossowska (1896–1974), who wrote *Foundations of the Study of Morality* (1947) and *Social Determinants of Moral Ideas* (1970). Andrzej Malewski (1929–1963), whose work will be mentioned in the next section. Stefan Nowak (1925–1990), whose work will also be mentioned in the next section.

While Ossowski studied class structure and stratification theoretically, Jan Szczepanski initiated empirical research around the problems of the emergence of a socialist-grown working class and an intelligentsia. His book *Polish Society* (1970) summarizes about thirty monographs that emerged from this research project between 1956 and 1965.

The period from 1956 up to the 1970s was certainly the time of a strong group of Marxist sociologists, including among others Zygmunt Bauman, Julian Hochfeld, Wladyslaw Markiewicz, and Jerzy Wiatr.

MAJOR CONTEMPORARY CONTRIBUTIONS

The major group of Polish sociologists consequently avoided pure theorizing. However, a large number of works present novel interpretations of contemporary sociological theories. Functionalistic orientation was extensively studied by several sociologists, among them Piotr Sztompka (*System and Function: Toward a Theory of Society*, 1974), and by social anthropologists like Andrzej Paluch (*Conflict, Modernization and Social Change: An Analysis and Critique of the Functional Theory*, 1976). Another extensively studied orientation is interactionist theory by such theoreticians as Marek Czyzewski (*The Sociologist and Everyday Life: A Study in Ethnomethodology and Modern Sociology of Interaction*, 1984), Elzbieta Halas (*The Social Context of Meanings in the Theory of Symbolic Interactionism*, 1987), Zdzislaw Krasnodebski (*Understanding Human Behavior: On Philosophical Foundations of Humanistic and Social Sciences*, 1986), Ireneusz Krzeminski (*Symbolic Interactionism and Sociology*, 1986), and Marek Ziolkowski (*Meaning, Interaction, Understanding: A Study of Symbolic Interactionism and Phenomenological Sociology as a Current of Humanistic Sociology*, 1981).

There are also good examples of innovative works within the domain of conflict theory by Janusz Mucha (*Conflict and Society*, 1978), Marxist theory by Andrzej Flis (*Antinomies of the Great Vision*, 1990), social exchange theory by Marian Kempny (*Exchange and Society: An Image of Social Reality in Sociological and Anthropological Theories of Exchange*, 1988), and "sociological theory of an individual's identity" by Zbigniew Boksanski (*Identity–Interaction–Group: Individual's Identity in Perspective of Sociological Theory*, 1989). Since social anthropology used to be treated in Poland as closely related to sociology, I should mention Piotr Chmielewski's work, *Culture and Evolution* (1988), in which he gives penetrating theoretic insight into evolutionistic theory from Darwin through his own contemporaries, and Zdzislaw Mach's book, *The Culture and Personality Approach in American*

Anthropology (1989), which presents a critical evaluation of this influential theoretical paradigm.

Original, creative efforts at the level of history of social thought, metatheory, and sociological theory have been quite substantial in the postwar period. In the domain of history of sociology an important achievement is the monumental, two-volume *History of Sociological Thought* by Jerzy Szacki (1979). The work is not just a simple presentation of theories of significant social thinkers from social philosophy of antiquity to contemporary sociological controversies of the 1970s. Critical analysis of each conception is accompanied by a penetrating account of its place in intellectual history, its relation to other orientations, and its role in the development of the social sciences. It can be said that this work presents the "true history of social thought." The work does not have its equivalent in world literature.

We should also mention another original, creative work in the domain of history of sociology. Edited by Piotr Sztompka, *Masters of Polish Sociology* (1984) presents a comprehensive account of Polish sociology from its beginnings up to martial law in 1981 and after—a period that has been described as initiating a search for a new perspective for Polish sociology.

The greatest achievements in the fields of metatheory and/or philosophy of social sciences include two books by Stefan Nowak and Edmund Mokrzycki. Nowak's book, *Understanding and Prediction: Essays in Methodology of Social and Behavioral Sciences* (1976), can be considered the vehicle by which Polish sociology entered metatheoretical debates of contemporary social sciences as a fully mature partner. Nowak discusses several issues crucial for sociological metatheory, such as the usefulness of the "humanistic coefficient," laws of science versus historical generalizations, inductionism versus deductionism, the time dimension, causal explanations, reduction of one theory to another, and axiomatized theories. The solutions he proposes are novel and enlightening. The same can be said about Edmund Mokrzycki's book, *Philosophy and Sociology: From the Methodological Doctrine to Research Practice* (1983). Mokrzycki argues that since early positivism began circulating in the 1950s as the methodological foundation of sociology, the result has been that empirical sociology

has lost the character of a humanistic discipline without acquiring the status of a true scientific discipline. As a way out, Mokrzycki proposes to put sociology within the framework of a broadly understood theory of culture.

In the field of sociological theory, the following achievements should be pointed out. First, we should mention the theoretical group dealing with class, social structure, and stratification. This group is headed by Włodzimierz Wesolowski, whose *Classes, Strata, and Power* (Wesolowski 1979) serves as their leading theoretical achievement. The crux of the argument is that while, theoretically, relationship to the means of production determines attributes of social position (such as income, work, and prestige), the uniformity of that relationship created under socialism makes the means of production lose their determining properties. In this circumstance, status becomes disengaged from class and tends to "decompose" so that we encounter the phenomenon of "leapfrogging" by groups along certain dimensions. This statement was the point of departure for further studies on meritocratic justice, educational meritocracy, and stratification and structure in comparative perspective (Słomczynski et al. 1981; Słomczynski 1989; Kohn and Słomczynski 1990), social mobility (Wesolowski and Mach 1986), as well as for other studies.

A second group of works deals with problems in the field of sociology but bordering on microsociology and social philosophy. Paweł Rybicki's *The Structure of the Social World* (1979) introduces to sociological debates in Poland, for the first time in a very comprehensive way, problems of micro-macro link, the problematics of a small group, and ontological dilemmas especially related to individualism versus holism controversy. On the other hand, Andrzej Malewski's work (1975), aimed primarily at modification and experimental testing of the social-psychological theories of L. Festinger, M. Rokeach, and N. E. Miller, also undertakes fundamental methodological and theoretical problems of the integration of social sciences, which Malewski tries to solve through the procedure of theoretical reduction. Jacek Szmatka's work *Small Social Structures: An Introduction to Structural Microsociology* (1989), tries to reach virtually all the same goals that his predecessors, mentioned above, tried to reach. The final result of these endeavors

is his structural microsociology, based on assumptions of emergent sociological structuralism, the structural conception of the small group, and specific conception of short- and long-range social structures.

Still another type of theorizing is present in the next two important theoretical works, Sztompka's *Theory of Social Becoming* (1990) and Jadwiga Staniszkis's *The Ontology of Socialism* (1989). The two works are very different in terms of style of theorizing and level of abstraction, but they have one goal in common: to produce theoretical conceptions that would account for tensions, problems, and processes of Polish society. Sztompka, who develops his conception around such categories as human agency and social movements, is highly abstract and stays within the Marxian tradition. Staniszkis engages in her analysis categories such as power, politics, legitimization, and ideology. She is less abstract and refers frequently to concrete societies. However, she too stays within the Marxian tradition.

Sociology of Culture, by Antonina Kloskowska (1983), continues vital traditions of this field in Polish sociology and also provides several theoretical innovations. The term *sociology of culture* is understood here to refer to a branch of sociological theory that is culture oriented and that operates with various types of cultural data. Basic subject matter for this theory is symbolic culture, while basic factors are conditions and functions of symbolic culture in the domain of societal culture. Kloskowska develops, among other theories, communication theory of symbolic culture and theory of symbolic culture development; one of her statements is that symbolic culture can perform its functions only when it preserves its original character, and its values remain intrinsic and autotelic, and are sought for their own sake.

The most vital and extensively cultivated, however, is empirical sociology of Polish society. Its standards of research procedures do not differ from western European ones. Polish sociology owes many important methodological and technical improvements to two prominent and in some sense classical methodologists: Stefan Nowak and Jan Lutyński. The empirical branch of Polish sociology is very diversified and multifaceted. Especially extensive are studies on several aspects of

social consciousness of Polish society (continuing Ossowski's 1963 work); its changes in time perspective (Koralewicz 1987), value system, attitudes, aspirations (Nowak 1980, 1982, 1989), class consciousness, and political participation (Ziolkowski 1988); and collective subconsciousness and the concept of collective sense (Marody 1987, 1988). Another important and vital field of research are studies on political and legal system of Polish society (Staniszki 1987), legitimization of the social order (Rychard 1987), repressive tolerance of the political system (Gorlach 1989), local power elite (Wasilewski 1989), and deviance and social control (Kwasniewski 1987). The third domain of research consists of different aspects of social and economic organization of the Polish society, namely self-management and current economical crisis (Morawski 1987), determinants of economical interests (Kolarska-Bobinska 1988), and conditions of social dimorphism (Wnuk-Lipinski 1987). There are also interesting studies on the life values of youth in Poland (Sulek 1985), the role of the army in the Polish political and social scene (Wiatr 1988), and the birth and the role of the Solidarity movement (Staniszki 1984). We should also mention the Polish attempt to develop the framework of sociotechnics by Adam Podgorecki (1966), which convinced many academics to switch to the study of practical applications of sociology.

CURRENT TRENDS AND PERSPECTIVES IN POLISH SOCIOLOGY

The events of 1989, which marked the beginning of an economical, political, and social transformation in Poland, gave Polish sociologists rich empirical material to study. The great interest in research on Polish transition provoked even the suppositions of overpoliticization of Polish sociology. Nevertheless, new perspectives appeared in the field of social structure, stratification, and mobility (Wnuk-Lipinski 1989, 1996; Domanski 1994). Attempts to construct a model of the middle class in postcommunist societies have been made by H. Domanski and J. Kurczewski. There is a special focus on the consolidation of young central and eastern European democracies and political and party systems in studies by Ewa Nalewajko (1997). Another well-developed field is the study of power and business elites, their roots and integration by Jacek Wasilewski (Wasilewski 1997, 1998) and

Włodzimierz Wesolowski (1995, 1996). The mainstream of current Polish sociology is focused on society in transition, but this does not mean that there are no pure theoretical studies being in process. The basic science type endeavor is being pursued in the tradition of structural social psychology (i.e., group processes). The theoretical research program in network exchange theory developed by Szmataka, Mazur, and Sozanski is one of the most methodologically advanced in sociology, and their new studies on network conflict theory gained some recognition in world sociology (Szmataka et al. 1997, 1998; Szmataka and Mazur 1998).

KINGA WYSIENSKA
JACEK SZMATKA

POLITICAL AND GOVERNMENTAL CORRUPTION

Everyone knows what political corruption is, but it is notoriously hard to define. Different cultures

have different conceptions of corruption: what would be considered corrupt in Denmark might be seen as simply polite in Indonesia. This understanding also varies across time: buying office was standard procedure in eighteenth-century Britain but would be inexcusable today. Arnold Heidenheimer has divided corruption into three categories (Heidenheimer et al. 1978). “*White*” corruption includes acts that a majority of people would not consider worthy of punishment. “*Gray*” corruption includes acts that “some elements” would want to see punished, but others would not. “*Black*” corruption includes acts that a “majority consensus . . . would condemn and would want to see punished on the grounds of principle.” Heidenheimer suggests that as societies modernize, behavior that was once seen as “white” becomes “gray,” and may eventually turn “black.” Others have suggested that the concept of “corruption” develops as societies move from seeing governmental offices as private property to believing them to be public trusts.

The American political scientist V. O. Key Jr. (1936) defines *graft* as “an abuse of power for personal or party profit.” Joseph Nye, another American political scientist, calls corruption:

[B]ehavior which deviates from the formal duties of a public role because of private-regarding (family, close family, private clique) pecuniary or status gains; or violates rules against the exercise of certain types of private-regarding influence. This includes such behavior as bribery (use of a reward to pervert the judgment of a person in a position of trust); nepotism (bestowal of patronage by reason of ascriptive relationship rather than merit); and misappropriation (illegal appropriation of public resources for private-regarding uses) (Nye 1967).

One long-running controversy in political science is whether corruption can serve a useful purpose for society. The most traditional school of thought, the “moralist” school, insists that corruption is always a breach of the public trust and must never be tolerated. Foremost in the ranks of this school were the “muckrakers,” American journalists who wrote books, during the early twentieth century, denouncing big business and public corruption. But in a review of a muckraking classic,

Lincoln Steffens’s *The Shame of the Cities*, the American political scientist Henry Jones Ford (1904, p. 678) argued that corruption was better than “slackness and decay.” If businessmen had to corrupt politicians in order to get things done, that was an acceptable cost of progress. Ford’s heirs, the so-called revisionists, became important in social science during the 1960s. Such revisionists as Nye and Samuel Huntington argued that corruption could serve useful social purposes. Corruption could bridge gaps between otherwise antagonistic groups. It could ease the path to modernization by overcoming bureaucratic inertia. It could foster social integration by binding people closer to the state.

More recently, scholars have returned to emphasizing the ill effects of corruption. It can increase the costs of administration, bloating national budgets. Rather than cutting bureaucracy, corruption tends to expand it, as officials seek more opportunities to shake down citizens. If businessmen must bribe in order to function in a particular country, they may take their investments elsewhere. Corruption can weaken the private sector into dependence and degrade the public sector into banditry. The economic collapse of Indonesia, a country previously seen as an example of the coexistence of corruption and prosperity, has fueled this school of thought. Recent research by Paolo Mauro (1997), an economist at the International Monetary Fund, has shown that highly corrupt countries tend to invest less of their gross domestic product, spend less on education, and have lower economic growth rates than their cleaner counterparts.

CORRUPTION IN THE UNITED STATES

The United States is less corrupt than almost all Third World countries. Its capitalist economy and democratic government offer fewer opportunities for massive political graft than the socialist kleptocracies of Africa. American government’s dispersal of power prevents the sort of presidential corruption that has characterized Latin America. The American press, its freedom constitutionally guaranteed, is quick to jump on accusations of malfeasance, often blowing them out of proportion. The American legal system has inherited the English tradition of protecting private property and respecting individual rights.

But for most of its history, the United States has had a reputation of being more corrupt than most western European countries. British observers such as Lord Bryce expressed this sentiment most often, contrasting the probity of the Victorian era to the iniquity of the Gilded Age. The exuberant democracy of the nineteenth century spawned extensive patronage, widespread vote fraud, and a venal political class. Indeed, Bryce and Alexis de Tocqueville noted that the most able Americans went into business rather than government; when they needed political favors, they bought them from those lesser talents who had won office. Civil servants continue to have a lower status in the United States than in Europe. In addition, the American system is much more permeable than its European counterparts. Its numerous state and local governments encourage popular participation. They also give citizens more chances to corrupt bureaucrats.

As a general rule, corruption in the United States has been greater at the state and local levels than in the federal government. While no president has ever been imprisoned, many mayors and governors have. Fixated on Washington, the media often ignores what happens in city halls or, especially, state capitols. This gives boodlers more confidence that their misdeeds will go unpunished. Since city governments conduct most law enforcement, more scandals take place in local police departments than in the Federal Bureau of Investigation (FBI). Since state and local governments conduct most construction, contractors develop more shady relationships with governors or mayors than with presidents. Many defense firms, however, have cozy ties with Congress members and Pentagon officials.

While there was corruption in colonial America (even George Washington used liquor to buy votes during his candidacy for the Virginia legislature), municipal graft did not truly take off until the nineteenth century. Powered by the Industrial Revolution, and fed by waves of immigration, American cities boomed during this period. While governmental institutions were weak, a new form of organization filled this gap: the political machine. Michael Johnston defines a political machine as a “party organization within which power is highly centralized, and whose members are motivated and rewarded by divisible material incentives rather than by considerations of ideology or

long-term goals of public policy” (1982, p. 38). While they would sometimes advocate social reform if they believed it would win votes, machine politicians were primarily interested in the spoils of office: jobs and favors for their supporters and graft for themselves. Machines developed close ties to business interests seeking contracts or other concessions: construction contractors, real estate developers, insurance agencies, law firms, organized crime. Ward leaders mobilized machine supporters, often the immigrant poor, through small favors such as Christmas baskets; the fixing of minor crimes; or, for the most loyal, undemanding government jobs.

While the stereotypical machine was Democratic, there were many Republican machines until the New Deal made urban workers loyal Democrats. City machines were the most common, but there were rural machines (most notably in southern Texas), suburban machines, and even statewide machines. While one normally associates machine politics with the inner-city poor, one of the strongest remaining machines in the country is the Republican organization of Nassau County, New York—a New York City suburb that is one of the wealthiest counties in the United States. (It is probably best known as the political base of former U.S. Senator Alfonse D’Amato.)

Probably the most famous machine was Tammany Hall, which dominated Manhattan’s Democratic organization from the early nineteenth century until the early 1960s. Descended from the Sons of Liberty of the Revolutionary era, it rose to supremacy after the Civil War under the leadership of William “Boss” Tweed and Richard Croker, and reached its zenith of power around World War I under the guidance of the unusually shrewd Charles F. Murphy. In the 1930s, Murphy’s successors made a series of miscalculations that crippled Tammany. They alienated both President Franklin D. Roosevelt and Governor Herbert Lehman, and they supported John O’Brien, an inept hack, as the successor to the discredited Mayor James J. Walker. O’Brien lost the 1933 mayoral race to Fiorello LaGuardia, a nominal Republican, staunch New Dealer, and sworn Tammany foe. LaGuardia’s three terms in office helped pound the nails into Tammany’s coffin. Other Democratic organizations in New York City, particularly those in the Bronx and Brooklyn, became more important.

While Tammany enjoyed a brief comeback in the 1950s under Carmine DeSapio, its fate was sealed when DeSapio lost his race for Democratic district leader in 1961. Manhattan had become gentrified, and its new, wealthier residents had no interest in Tammany-style politics.

Many cities had machines. Until the New Deal, Chicago had rival Democratic and Republican organizations whose battles for power occasionally turned violent. After the New Deal, the Democratic organization dominated Chicago and some of its leaders, especially Mayor Richard J. Daley (1955–1976), became national figures. Philadelphia had a Republican machine of legendary rapaciousness that managed to hold onto City Hall until 1951. Once it became clear that the GOP would not return to power, many longtime Republican ward bosses switched parties and built a powerful Democratic machine. Kansas City had its Pendergast organization, which produced President Harry Truman. Jersey City's two machine mayors, Frank "I Am the Law" Hague and John V. Kenny, dominated its politics from 1917 to 1971. Machines were not confined to the North: Edward "Boss" Crump ruled Memphis for many years, while San Antonio became notorious for its vote buying and graft.

Political machines have declined throughout the twentieth century. Prompted by Lincoln Steffens's *The Shame of the Cities* (1904), Progressive reformers strengthened the civil service and reduced machine influence in city government, sometimes by making elections nonpartisan or by replacing elected mayors with the council-manager system. While Franklin D. Roosevelt rewarded those machine Democrats who backed him (most notably Chicago Mayor Edward Kelly and Edward Flynn, "the Boss of the Bronx"), some observers have argued that his New Deal eventually undermined machines by replacing their handouts with bureaucratic programs (although Richard J. Daley could show them how those could be turned to a machine's advantage).

The postwar years brought many changes to American cities that hurt machines. Television gave candidates a means to reach voters without the help of local bosses. Court decisions greatly restricted the amount of patronage leaders could bestow upon their followers. The rise of public

sector unions further restricted bosses' ability to hand out jobs, and in some cities, unions replaced party bosses as the main support for politicians. Inquiries such as the 1951 Kefauver hearings exposed the links between many urban politicians and organized crime.

Political scientists and journalists have offered varying assessments of political machines. Some praise them for integrating immigrants into American politics. Many of the newcomers had little experience with democracy and little understanding of the Anglo-American tradition. Machine politicians gave them something concrete for their vote, whether that was a small gift, help with the law, or a job. Machines have also been praised for making government function; Richard J. Daley boasted that Chicago was "the city that works." Others have criticized machines for corrupting government, enriching political hacks, and providing poor public services.

While few machines still operate, American cities still see plenty of graft. Periodic scandals rock urban police departments, most recently in New Orleans and Washington. Frequently, there are revelations about the scandalous relations between construction firms and politicians. In the mid-1980s, a scandal concerning the Parking Violations Bureau ended the careers of many New York City politicians. Marion Barry, the four-term mayor of Washington, made himself a synonym for graft and misgovernment.

There have also been many scandals concerning state government. During the late nineteenth century, businessmen, especially railroad magnates, bribed state legislators en masse. From Arizona to South Carolina, recent sting operations have found state legislators pathetically eager to accept pay-offs. The cozy relationships between state officials and the construction industry have had national implications. In 1973, Vice President Spiro Agnew resigned as part of a plea bargain stemming from bribes he accepted as governor of Maryland.

There are large regional differences in attitudes toward corruption. What is considered scandalous in Minnesota may be seen as merely inappropriate in New York and harmless in Louisiana. Daniel Elazar argues for a theory of political culture that explains these differences. Puritan New England developed a "moralistic" conception of

governance that emphasized the common good. When New Englanders settled the states of the northern tier, from Michigan to the Pacific Northwest, they brought this culture with them. These states continue to be intolerant of corruption. The Middle Colonies attracted a diverse ethnic mix that made it difficult to agree on a common good. Instead, they developed an “individualistic” political culture that saw politics as a business and tolerated politicians’ pursuit of self-interest. States in a belt running west from New York and New Jersey to Illinois and Missouri continue to accept petty graft as part of the normal way of conducting politics. The South developed politics dominated by elite factions and low public participation. Elazar calls this culture “traditionalistic.” Particular states have developed their own cultures tolerant of or antagonistic to corruption. The Scandinavians who settled the upper Midwest brought their squeaky-clean politics with them. Louisiana’s French heritage bestowed upon it the Napoleonic Code, with its emphasis on state power and a certain lassitude about graft.

CORRUPTION AT THE FEDERAL LEVEL

While there were scandals during the Republic’s early years, corruption did not become a major problem until the Jacksonian era of the 1820s and 1830s. Mass political parties brought with them the “spoils system” through which the president bestowed government jobs upon his supporters. The “spoils system” came to dominate government to the extent that some presidents spent most of their time fulfilling the demands of state party leaders for rewards for their followers. After a disappointed office seeker assassinated President James Garfield in 1881, demands for reform led Congress to pass the Pendleton Act two years later, which created the modern civil service; but it was not until the early twentieth century that merit came to predominate in government employment.

The Industrial Revolution increased business influence in government. The Civil War saw a series of military procurement scandals, beginning a long tradition in American life. During the years after the war, there were several scandals concerning the relationships between politicians and railroads (many of which received government subsidies). In addition, during this period,

many prominent officials were found to have taken bribes, most notably William Belknap, Ulysses Grant’s secretary of war.

While the Progressive era saw a general reform of American politics, the United States experienced several scandals during the 1920s. The sale and production of alcoholic beverages was forbidden during the Prohibition era (1920–1933), but the public’s continuing thirst spawned a vast underground liquor trade that fueled the rise of organized crime and corrupted many public officials. The administration of President Warren Harding (1921–1923) is usually considered the most corrupt in American history. Charles Forbes, head of the Veterans’ Bureau, was convicted of fraud, conspiracy, and bribery. In the “Teapot Dome” scandal, Interior Secretary Albert Fall secretly leased federal oil reserves to two businessmen in return for cash gifts and no-interest loans; Fall was eventually imprisoned for bribery.

The succeeding decades saw few high-level scandals. There were many congressional peccadilloes, but the worst that could be discovered about any high officials was influence peddling by some of Harry Truman’s cronies and acceptance of small gifts by Dwight Eisenhower’s chief of staff. The Watergate scandal (1972–1974) made up for lost time, bringing down President Richard Nixon and sending many of his closest allies to jail. While it is beyond the scope of this article to explain the details of this affair—there are entire books that do that—we should note that little about Watergate concerned financial corruption, primarily Nixon’s tax evasion and massive illegal contributions to his 1972 reelection campaign. Watergate was mostly a matter of abuse of power, especially Nixon’s use of the government to harass his political enemies and his cover-up thereof.

Watergate led to a flood of legislation. The 1971 Federal Election Campaign Act was extensively amended in 1974. The Ethics in Government Act of 1978 created the institution of the independent counsel to investigate official malfeasance. The Foreign Corrupt Practices Act of 1977 forbade American companies to bribe overseas officials. Prosecutors and journalists became more aggressive in their investigations of corruption. Two major scandals rocked Congress: the revelation of corrupt links between a South Korean lobbyist and several congressmen (“Koreagate”)

and the willingness of some senators and representatives to take bribes in a sting investigation (“Abscam”).

The 1980s saw their share of scandals. The Iran-Contra affair, which involved the covert sale of arms to Iran and the illegal diversion of the profits to Nicaraguan anti-communist rebels (the “contras”), tarnished the last years of the Reagan Administration. A long investigation found favoritism and influence peddling to be rife within the Department of Housing and Urban Development (HUD). The collapse of many savings and loans (S&Ls), which cost the government \$500 billion to pay back depositors, revealed suspicious relationships between some thrift operators and prominent politicians, most notably House Speaker Jim Wright. The so-called Keating Five senators lobbied for easier treatment for S&L owner Charles Keating; revelations about their activities ended the careers of three of the five.

While Bill Clinton promised to run the “most ethical administration in history,” he has instead presided over an era as sleazy as those of his predecessors. Scandals forced out HUD Secretary Henry Cisneros and Agriculture Secretary Mike Espy. There were charges that foreigners made large illegal donations to the Democratic National Committee during the 1996 election. The most explosive charges surrounded Clinton himself. Allegations of corrupt real estate deals by Clinton when he was governor of Arkansas led to an independent counsel investigation that began in 1993 and continues as of this writing. This investigation eventually produced the charge that Clinton had perjured himself and had obstructed an inquiry into his affair with a White House intern. Clinton was questioned about this affair as part of a sexual harassment lawsuit. Clinton was eventually impeached, but the Senate failed to convict him.

CORRUPTION IN WESTERN EUROPE

Italy is probably considered the most corrupt country in western Europe. Southern Italy has a long history of patron-client relationships that take precedence over written law. In this highly stratified society, landowners and professionals serve as natural patrons to their clientele of laborers and peasants. The Mafia, of course, is part of this system of

patronage. Italy’s complex administrative law undermines efficiency, and so requires mediation in order to function. Politicians and local notables help citizens, especially businessmen, navigate the maze of red tape—for a price.

After World War II, Italy developed a strong party system that permeated all of society. While Italy had many small parties, three dominated politics until 1993: the Christian Democrats, the Socialists, and the Communists. In order to keep the Communists out of power, the Christian Democrats dominated every government from 1947 to 1993; after 1962, they usually governed with the support of the Socialists. Both the Christian Democrats and the Socialists were deeply factionalized, with politicians commanding their own followings. As such, the parties could only be held together through bargaining—which often included graft. The Christian Democrats, in particular, were dependent upon the support of local leaders in the South and in Sicily (which were both far behind the rest of country economically), many of them with ties to the Mafia. Southern politicians used the national government’s resources to support their local economies. Often this meant public works boondoggles, which enriched politically connected (and Mafia-owned) construction firms and which only increased the contempt held by northern Italians for their southern countrymen.

Because many Italians feared that a communist government would bring their country into the Soviet bloc, the Christian Democrats were essentially a perpetual governing party. Proportional representation meant that no party would ever gain a majority, so coalition governed Italy. While squabbling among factions meant that particular governments usually lasted a year or less, the same parties always came out on top. The Christian Democrats and the Socialists used their power to create a vast web of patronage, which enmeshed Italy’s many state-owned firms, the national broadcasting system, executive agencies, and public banks. The lack of turnover loosened what few inhibitions Italian politicians had about exploiting their positions for financial gain. While the Communists remained out of power, they cut backroom deals with the ruling parties to enrich themselves, especially after the 1970s, when they distanced themselves from the Soviet Union and when regional autonomy gave Communists more chances to govern.

These arrangements collapsed in 1992–1993. There were a number of reasons for this change. Under the pressure of global competition, Italian business owners grew weary of the high taxes and inefficient government produced by widespread corruption. The drive for European monetary union required Italy to reduce its huge budget deficit. The end of the Cold War made communist control less unthinkable (especially when the party renounced communism and renamed itself the Democratic Party of the Left).

It was a team of prosecutors investigating corruption in Milan's construction industry who really rocked Italy's political world. Led by Antonio Di Pietro (who now sits in Italy's Senate and may be the next president), the so-called clean hands brigade demolished the Italian establishment during 1992–1994. Prosecutors exposed massive patronage, political awarding of contracts, and bribery. It became clear that organized crime had friends at the highest levels. Former Prime Minister Bettino Craxi, a Socialist, was convicted of corruption after he fled to Tunisia. Giulio Andreotti, a Christian Democrat who had served as prime minister seven times, is, as of this writing, on trial for being a member of the Mafia.

The corruption investigations touched even those who benefited from them. After the Italian party system collapsed in 1993, the media tycoon Silvio Berlusconi led a conservative coalition to victory in the March 1994 elections. Berlusconi's government collapsed when prosecutors announced that they were investigating him. In 1998, Berlusconi was convicted of bribing tax inspectors (although he was later acquitted of other charges), but he remains leader of his Forza Italia party.

Spain also has a long history of corruption and patronage. Governments have long relied on local notables to administer the law. While Francisco Franco strengthened the state during his long rule (1939–1975), he made appointments more on the basis of loyalty than competence. The return of democracy brought greater professionalism, but local patrons remain important. It was corruption on a national scale that grabbed the headlines in the 1990s. A series of scandals embarrassed the socialist government of Prime Minister Felipe Gonzalez, who led Spain from 1982 to 1996. Many observers attributed the corruption to the socialists' arrogance after so many years in power. In

1991, Deputy Prime Minister Alfonso Guerra resigned after his brother Juan was accused of using party facilities for private gain. A series of scandals surrounded Socialist party finances. The heads of the Bank of Spain and the Civil Guard were besmirched by corruption. This wave of "sleaze" helped lead to the socialists' defeat in 1996.

France has had many scandals throughout its history. Some have even threatened the stability of the regime. Conservatives opposed to the Republic used the Panama Canal scandal (1892–1993) and the Stavisky affair (1934) to attack the legitimacy of democratic government. Others have simply been embarrassing, as when it was revealed that President Valéry Giscard d'Estaing had accepted diamonds from the infamous tyrant Jean-Bedel Bokassa, president of the Central African Republic and a longtime French client. Overall, the French tend to have a cynical view of government, accepting corruption and the abuse of power as the way the world works.

The "long presidency" of François Mitterand (1981–1995) included a series of scandals, many of them concerning the finances of Mitterand's Socialist Party. Rising campaign costs forced socialists, who lacked conservatives' constituency among business, to raise money in irregular ways. Contractors who sought business with socialist-governed municipalities were told to contribute to party-controlled consultancies, which funneled the money to the national party. The exposure of this practice embarrassed the socialists, but they could plausibly claim that other parties engaged in similar schemes. The businessman Roger-Patrice Pelat, who was indicted for insider trading before his death in 1989, had questionable relationships with many politicians, including his close friend Mitterand and Prime Minister Pierre Bérégovoy, who committed suicide in 1993 after it was revealed that Pelat had given him an interestfree loan.

Two other leading French politicians have come under fire in recent years. Alan Juppé, a conservative former prime minister, has been charged with obtaining fraudulent jobs for Gaullist party activists when he worked for then-Paris Mayor Jacques Chirac, who is now president. Roland Dumas, a former foreign minister and chief of the Constitutional Court, is under investigation for his ties to a defense contractor, which hired his mistress and paid her a \$9 million commission.

Greece is another southern European country notorious for corruption and clientelistic politics. The governments of Andreas Papandreu (1981–1989, 1993–1996), longtime leader of the Pan-Hellenic Socialist Movement (PASOK), were widely perceived as crooked and patronage ridden, but Papandreu himself was acquitted of embezzlement charges in 1992. Tax evasion is common, and the economy remains dependent upon state patronage and contracts.

Many of the countries of northern Europe have become bywords for clean government. The governments of Scandinavia, the Netherlands, and Switzerland, in particular, are known for their honesty. A typical “scandal” in these countries would be a politician using party funds to pay for diapers for her baby. One major exception is Belgium, which is known as the “Italy of the North” for its corruption and cronyism. The government was shaken by a case of the pedophile murderer Marc Dutroux, who had conducted his activities in such a way that it appeared he had official protection. The 1991 murder of a Socialist Party boss remains unsolved, and many suspect the involvement of leading politicians and the Mafia. Willy Claes, former North Atlantic Treaty Organization (NATO) secretary general, was convicted in December 1998 of accepting a bribe from a defense contractor when he was economic affairs minister. Two other prominent Belgian politicians were also convicted.

Corruption was widespread in British politics during the eighteenth and early nineteenth centuries, but the Northcote-Trevelyan reforms of 1854 established the modern British civil service, which is world renowned for its honesty. Indeed, many former British colonies, such as Singapore, have benefited from their reputation for sound administration. The conservative governments of Margaret Thatcher (1979–1990) and John Major (1990–1997) saw their share of scandals, notably some involving large donations to the Conservative Party by questionable characters. (The United Kingdom does not limit donations to parties, nor does it require them to be disclosed.) Years of one-party rule led to a certain degree of arrogance and self-satisfaction, but little real corruption. While many observers attributed Major’s defeat in 1997 to “sleaze,” it appears that is just another way of saying, “The Tories had been in power for too long and it was time to give someone else a chance.”

Germany is also known as a relatively corruption-free country, although, contrary to popular belief, the Nazi regime was filled with petty graft and party patronage. In the 1980s, it was revealed that the Flick industrial group had made illegal donations to the major political parties, while this embarrassed the government of Chancellor Helmut Kohl (1982–1998), it never threatened its stability. More recently, there have been scandals about bribery in the construction industry and about the involvement of big-city police with the drug trade and prostitution. Probably the most serious threat is the large network of ex-communists in the former East Germany, which has become known for favoritism and intimidation.

The most conspicuous European scandal of the late 1990s has concerned the European Commission, the governing body of the European Union. An internal audit, leaked to members of the European Parliament, revealed waste, corruption, and cronyism in many Euro-programs. It revealed that Edith Cresson, commissioner for research policy and a former French prime minister, had appointed her dentist to coordinate acquired immune deficiency syndrome (AIDS) research and had presided over a fraud-ridden job training program. In order to stem a parliamentary drive to censure or remove the commissioners, commission president Jacques Santer appointed the Committee of Independent Experts to investigate the audit’s charges. The panel produced a report that essentially found the allegations to be true. Faced with a parliamentary revolt, and with Cresson unwilling to quit alone, all twenty European Commissioners resigned in March 1999.

CORRUPTION IN EAST ASIA

During the last quarter of the twentieth century, East Asia has had the fastest-growing economy in the world, but the economic crisis of 1997–1998 exposed the vast corruption of some countries. Indonesia was the most conspicuous case. During his 1966–1998 reign, Suharto amassed a fortune that may reach into the tens of billions of dollars. His children enriched themselves by acting as middlemen between state-owned firms and contractors; serving as the Indonesian partners of many foreign investors; and acquiring interests in aviation, broadcasting, automobiles and many other industries. Businessmen close to Suharto, such

as industrialist Liem Sioe Liong and timber magnate Mohammed "Bob" Hasan, came to dominate the economy. As long as Indonesia kept growing, most citizens and businessmen accepted Suharto's banditry. Indonesia's economic and political collapse in 1998 led to demonstrations against his rule and to bloody riots in Jakarta, the capital. Suharto quit in May 1998; B. J. Habibie, his successor, found his associates implicated in a multi-million-dollar banking scandal. Abdurrahman Wahid, elected president in October 1999, announced that he would pardon Suharto should he ever be convicted of corruption.

The Philippines has a long history of corruption. A small group of families has long dominated Philippine politics, buying off their supporters through graft and patronage. Filipino culture emphasizes personal relationships, rather than formal institutions. As such, written law has little connection with the workings of the Philippine government. The Philippine civil service, police, and congress have particularly corrupt reputations. After independence in 1946, several Philippine presidents were known to be corrupt, especially Elpidio Quirino (1948–1953) and Carlos García (1957–1961). Ferdinand Marcos (1965–1986) put them all to shame, especially after he declared martial law in 1972. Philippine Airlines became a private commuter line for the Marcos family. Marcos bullied wealthy families into giving up their holdings to his family and friends. The Central Intelligence Agency (CIA) estimated that Marcos himself was worth \$10 billion, but after Marcos fell from power, investigators were able to track down only a fraction of that sum. Despite her promises of a new era, the administration of Corazon Aquino (1986–1992) was also wracked with corruption. Fidel Ramos (1992–1996), however, built a reputation for honesty and presided over a period of prosperity.

Thailand is world renowned for its tolerance for drug trafficking and prostitution, and it is widely alleged that these businesses have allies in the government. The country also has a political culture dominated by patronage, bribery, vote buying, and crony capitalism. Prime Minister Banharn Silpa-Archa (1995–1996) was particularly identified with these practices, but the crisis of 1997–1998 disrupted many of Thailand's arrangements. The country has now adopted a more

democratic constitution and has banned vote buying and insider deals.

South Korea has a political system that concentrates power in the presidency. It is not surprising that corruption has been concentrated there, too. Park Chung-hee seized power in 1961, vowing to end the sleaze of South Korea's early years. Park amassed enormous power over South Korea's economy and government. While most observers agree that he mostly used that power to his country's betterment, his dominance convinced many businessmen that they needed to donate to Park's party if they wanted to win his favor. After Park was assassinated in 1979, Chun Doo Hwan assumed the presidency. There were rumors of corruption surrounding Chun, which were confirmed in 1996 when he and his successor, Roh Tae Woo, were convicted of corruption and sedition. Chun was sentenced to life in prison; Roh received seventeen years. Kim Young Sam, who succeeded Roh in 1993, had a clean image that was soiled when his son Kim Hyun Chul was convicted in 1997 of receiving bribes. The collapse of one of the nation's leading conglomerates sparked charges that it had corrupt ties with Kim's government.

The Liberal Democratic Party (LDP) dominated Japanese politics from 1955 to 1993; it still leads most governing coalitions. On the international stage, it projected an image of serene competence. Behind the scenes, Japanese back rooms saw wheeling and dealing that would put any Chicago pol to shame. Kakuei Tanaka, prime minister from 1972 to 1974, ran a pork-barrel-fueled machine that dominated the LDP. Tanaka forced the government to extend the bullet train line into his mountainous home base, nearly bankrupting the national railroad in the process. In 1983, Tanaka was finally convicted of accepting bribes from the American aircraft manufacturer Lockheed, which had spread around \$22 million among Japanese politicians in the 1970s. While the LDP's rule was broken in 1993, it regained control in 1994, and by 1996 an old Tanaka ally, Ryutaro Hashimoto, was serving as prime minister. In recent years, scandals have rocked the Ministry of Finance, which wields great power over the Japanese economy. Finance officials have been accused of covering up banks' financial troubles and of leaking sensitive information to bank executives.

CORRUPTION IN SOUTH ASIA

The nations of South Asia (India, Pakistan, Bangladesh, and Sri Lanka) are all former British colonies that benefited from the United Kingdom's common law tradition and bureaucratic honesty; but all have sunk into a morass of corruption. Pakistan is now considered one of the most corrupt countries in the world. Tax evasion is ubiquitous: only about half of assessed taxes are actually collected. Businessmen believe that they must pay government officials if they seek a public contract. Civil servants are poorly paid, and believe they must take bribes in order to survive. The two most recent prime ministers, Benazir Bhutto (1988–1990, 1993–1996) and Nawaz Sharif (1990–1995, 1997–present), have presided over administrations rife with corruption. In April 1999, Bhutto and her husband were convicted of taking kickbacks on government contracts. They were each sentenced to five years in prison.

A recent book on India and Pakistan calls corruption in India “pervasive, systematic, structured, and graded . . . running from the bottom to the top of the political order.” The British gave India an honest civil service, but Indira Gandhi's state of emergency (1975–1977) destroyed its integrity and morale by forcing bureaucrats to break the law. Now India's estimated fifteen million civil servants shake down citizens for every service imaginable, from installing phone lines to permitting people to enter the country. Corrupt politicians hold power on a national scale. Jayalitha Jayaram, the notorious boss of Tamil Nadu state, brought down the government of Prime Minister Atal Bihari Vajpayee through her defection in April 1999. A 1996 corruption investigation discovered that Jayaram owned 10,000 saris and 350 pairs of shoes.

CORRUPTION IN THE MIDDLE EAST

The Middle East is a nation bereft of functioning democracies, save Israel and Turkey. The predominance of authoritarian regimes has created a situation ripe for corruption. The Saudi royal family has a reputation for corruption on a massive scale. It treats the national income as royal revenue and distributes it at whim. There are 7,000 royal princes, whom the *Economist* described as “lawless and hedonistic.” Not content with their

generous allowances, they collect huge commissions on foreign contracts and muscle in on private business. Public anger at royal corruption, particularly that of King Saud, fueled an Islamic fundamentalist movement for a time. Crown Prince Abdullah assumed management of the government in January 1996, and his honesty and ruthlessness have defused the threat from the opposition.

Egypt is world renowned for its bureaucratic corruption. Its one million civil servants are notoriously indolent and graft hungry. Bribes are necessary to engage in any government transaction. The government is unable to provide most public services, opening the door for Islamist groups to fill the void. Morocco, Tunisia, and Algeria are also known for their corruption. In Algeria, years of corrupt rule by the military and the National Liberation Front fueled an Islamist revolt that has led to a savage civil war.

Turkey's fragile democracy has been besieged by corruption. Its parties are far more concerned with seeking patronage and state contracts than with promoting ideological agendas. Former Prime Minister Tansu Ciller (1993–1996) has become vastly wealthy while in politics, and allegations of graft and cronyism have swirled about her. A staunch secularist, she nevertheless formed a coalition government with Islamic leader Necmettin Erbakan in 1996, because he promised to prevent an investigation of Ciller's finances. She made a similar deal with Erbakan's successor, Mesut Yilmaz, who had his own skeletons to hide. Yilmaz's government finally fell in November 1998 because of continuing allegations about corruption. There have also been charges that the police are in league with gangsters, right-wing hit squads, and drug traffickers.

CORRUPTION IN SUB-SAHARAN AFRICA

With the possible exception of the former Soviet Union, sub-Saharan Africa is the most corrupt region in the world. Colonial rule left weak governments and few educated administrators. Socialist-minded leaders created state-dominated economies that failed disastrously and offered numerous opportunities for graft. With arbitrary boundaries left over from colonial times, few states have developed a sense of “nationhood,” and political actors' first loyalty is usually to their ethnic group.

“Personal rulership” is perhaps the most common political system in Africa. The ruler has almost unlimited legal competence. He is not concerned with building a following among the general public; instead he attends to the needs of his more powerful supporters, usually in the military or in state-owned firms. But state power is too limited to implement any policy except pillage. Personal rulership tends to be corrupt and arbitrary, but also weak and unstable.

The most extreme form of personal rulership is what Max Weber called a “sultanistic” regime. Such a state has no claim to legitimacy, whether based on tradition, ideology, charisma, or social order. The ruler runs the state to benefit him and his allies. He treats the public treasury as an extension of his personal fortune. He sells import and export licenses to the highest bidders, and appoints his cronies to run state-owned firms where they can exploit their nation’s resources. Because the ruler’s whims (and those of his supporters) supersede the written law, there is no predictability to the state’s actions. This discourages private enterprise, since businessmen cannot know whether their property will be confiscated. The only path to success is through winning the ruler’s fickle favors. While sultanistic states rarely function well enough to collect taxes, that did not bother many African leaders, who had their own streams of revenue: exporting natural resources through state-owned firms (especially during the high-commodity-price 1970s) and collecting foreign aid from the Cold War rivals. The French have remained active in their former colonies and have propped up many an unsavory dictator.

Mobutu Sese Seko, who ruled Zaire (now the Democratic Republic of Congo) from 1965 to 1997, was a perfect example of a sultanistic ruler who treated the state as his personal property. The *Economist* (1997, p.21) described his rule as the “systematic theft of the state from top to bottom.” Mobutu accumulated a fortune that amounted between \$4 and \$9 billion. Bribes, kickbacks, the public treasury, the returns from Zaire’s mineral wealth, French and American aid—all went into Mobutu’s Swiss bank accounts. By the end of his reign, he owned nine villas in Belgium; a Brazilian coffee plantation; a mansion in Spain; property in several African cities; and estates in Portugal, Switzerland, and the French Riviera. He also owned

tens of thousands of bottles of wine bottled in the year of his birth.

Mobutu found Zaire a poor country—and left it destitute. In the name of Zairean nationalism, he seized expatriate-owned businesses in 1973 and gave them to his cronies, who promptly ran them into the ground. (Uganda’s Idi Amin did much the same thing at the same time with Asian-owned businesses, with the same results.) Zaire is world-renowned for its mineral resources, including cobalt, diamonds and copper. Mobutu nationalized the mining industry—and wrecked it. Rather than paying them, Mobutu let his soldiers work for their money by robbing ordinary citizens. Pity the poor businessman trying to import goods into Zaire, for he had to pass a gauntlet of nine state agencies, all of them demanding bribes. The end of the Cold War meant that Mobutu’s Western allies would no longer subsidize his regime. By the mid-1990s, Mobutu’s government had stopped functioning, and a guerrilla uprising took root. With his army more interested in looting than in fighting, Mobutu fled the country in May 1997 and died soon after. By that point, Zaireans’ purchasing power was only one-fourth what it had been in the 1950s, when they still lived under Belgian rule. The Belgians left behind an excellent system of roads. By the 1990s, it had deteriorated to the point where it was no longer possible to drive across Zaire.

While Mobutu set an impressive standard for banditry, other African rulers did their best to keep up. Mali’s Moussa Traoré, Niger’s Gnassingbe Eyadema, Cameroon’s Paul Biya, and Gabon’s Omar Bongo are some of the more noteworthy kleptocrats who have misgoverned Africa over the past generation. Few have had the panache of Jean-Bedel Bokassa of the Central African Republic (1965–1979). Like Mobutu, Bokassa treated his land as his private domain. Unlike Mobutu, Bokassa went so far as to crown himself emperor in a ceremony modeled after Napoleon’s coronation. Through his control of the diamond trade, Bokassa accumulated a truly imperial fortune. His antics became an embarrassment to his French masters, who overthrew him after he personally led a massacre of children who were protesting the cost of school uniforms. The French spread a rumor that Bokassa ate his political opponents; distraught by this charge, Bokassa revealed that he had given

diamonds to leading French politicians, including then-President Valéry Giscard d'Estaing.

Of all African countries, Nigeria is probably the most notorious for corruption. Bribery is universal and scamming seems to be the national pastime. With its vast reserves of petroleum, Nigeria experienced an economic boom during the 1970s oil crisis. The returns from that wealth mostly went to the military and to corrupt politicians. The nation's schools, hospitals and roads are in dreadful condition. President Shehu Shagari's administration (1979–1983) was so corrupt that the army overthrew him so they could get in on the action. More recently, Sani Abacha stole billions of dollars from the national treasury during his 1993–1998 dictatorship. Abacha realized that distributing import licenses for fuel was a good way to reward his cronies. He allowed the nation's oil refineries to deteriorate, forcing this oil-producing nation to import gasoline, and thereby enriched his pals. Alas, poor Abacha did not get to enjoy his wealth for long: He died suddenly in June 1998, allegedly in the company of prostitutes. (Some have suggested that Abacha's rivals poisoned his Viagra.)

CORRUPTION IN LATIN AMERICA

While Latin America has not been pillaged as thoroughly as Africa, corruption is a serious problem in most countries in the region. Only Chile, Costa Rica, and Uruguay have reputations for being relatively clean. Latin America's corruption is rooted in its Spanish and Portuguese colonial past. Far from home, colonial bureaucrats were able to exploit their positions for profit, often treating their offices as their private possessions. Mercantilistic regulation meant that merchants and landowners often had to bribe officials in order to do business. Independence changed little. Hispanic traditions of paternalism meant extensive involvement by the state in the economy, which created great opportunities for bribery and smuggling. A foreign investment boom in the late nineteenth century strengthened local economies, but often primarily enriched a few leaders at the top. Nationalists attacked foreign investment, especially in the oil industry, and replaced it with state-owned firms, which frequently became deeply corrupt. The domestic private sector remained underdeveloped and dependent on the state.

Much of Latin America's corruption has swirled about the various strongmen who have held power over the years. Alfredo Stroessner, who dominated Paraguay from 1954 to 1989, turned his country into a gangster's paradise. Nazi war criminals and international drug traffickers flocked to live under Stroessner's protection. Stroessner treated Paraguay's government as his personal fiefdom, distributing patronage to his supporters and providing few services to ordinary citizens. Stroessner ensured his longevity by spreading the graft around. High tariffs in neighboring Argentina and Brazil spawned a thriving smuggling trade. Many military officers became millionaires through this trade, buying Rolls-Royces and building mansions. Eventually, the armed forces were wholly funded by the smuggling of cigarettes, whiskey, cocaine, and heroin. The costs of the vast Itaipú hydroelectric project mushroomed from a 1973 estimate of \$2 billion to a final figure of \$21 billion in 1991. Much of the overrun appears to have gone into officials' pockets through kickbacks and bribery.

Venezuela saw a series of *caudillos* who made huge fortunes off the nation's oil wealth. General Juan Vicente Gomez (1910–1935) accumulated \$200 million and became the nation's largest landowner. Major Marcos Pérez Jiménez did even better during his short reign (1951–1957), building a fortune of more than \$250 million. The Somoza clan ruled Nicaragua from 1936 to 1979, dominating the economy and stashing away tens of millions of dollars. Haiti has had scarcely one uncorrupt leader in its entire history, but the Duvaliers (François 1957–1971; Jean-Claude 1971–1986) stand out even in that wretched lot. When Jean-Claude fled Haiti in 1986, he was said to be worth \$800 million. Fulgencio Batista, president of Cuba from 1940 to 1944 and from 1952 to 1958, accumulated a fortune of between \$100 and \$300 million. Rafael Trujillo treated the Dominican Republic as his personal fiefdom during his 1930–1961 reign. At one point, Trujillo acquired the country's only shoe factory and then forbade Dominicans to go barefoot. Visitors to Santo Domingo noted that the country's poverty must be exaggerated: After all, everyone wore shoes! Trujillo's practice of requiring a 10 percent bribe on every governmental transaction helped him fill his bank accounts with up to \$500 million.

While presidential corruption is a long tradition in Latin America, a newer plague is infecting

states from the Rio Grande to the Andes: drug trafficking. *Norteamericanos*' insatiable appetite for cocaine, marijuana, and heroin (and their government's insistence on maintaining the ban on such substances) is undermining political stability in several Latin American countries. Cocaine cartels have been a fixture in Colombia since the 1970s. In the 1980s, the Medellín cartel threatened the stability of the Colombian government. More recently, it was revealed that the Cali cartel had partially funded the presidential campaign of Ernesto Samper (1994–1998). The Revolutionary Armed Forces of Colombia (FARC), guerrillas funded by the drug trade, now control much of the country. Many observers fear that Colombia will become the hemisphere's first "narco-state."

However, Mexico may get there first. Because of the extensive border it shares with the United States, Mexico has long been an ideal location for smugglers. When the Drug Enforcement Administration (DEA) increased surveillance in South Florida and the Caribbean during the late 1980s, the cocaine trade moved into Mexico. Since then the drug trade has boomed in Mexico, corrupting nearly every area of the Mexican government. Even General Jesús Gutiérrez Rebollo, who was leading Mexico's war on drugs, was arrested for accepting bribes from a major drug trafficker. The Mexican police are universally believed to be corrupt. State governors, army officers, party leaders—the drug traffickers have ties to them all.

Several leaders have made their countries havens for the drug trade. The most famous, of course, is Manuel Antonio Noriega, who dominated Panama from 1983 to 1989. An American invasion brought him to the United States, where he now serves a sentence for drug trafficking and racketeering. Vinicio Cerezo, president of Guatemala from 1985 to 1990, was widely suspected of being friendly to the drug trade. For a time during the 1980s, Bolivia was run by a group of military officers known as the "cocaine colonels."

Some of the larger nations in Latin America have developed large, clientelistic political party machines. Probably the most famous is Mexico's Institutional Revolutionary Party (PRI), which has (under different names) dominated Mexican politics since 1929. Since then, the PRI has won every presidential elections and most state ones, often

fraudulently. Since the 1980s, however, the National Action Party (PAN) and the Democratic Revolutionary Party (PRD) have become serious competitors for power. The PRI's influence permeates Mexican society through corporatist labor and business organizations. PRI patronage dominates many institutions. Mexico's state-owned oil company, Petroleos Mexicanos, is notoriously corrupt. Mexico has a long history of presidents who retired wealthy. José López Portillo, president from 1976 to 1982, parlayed the oil boom of those years into a fortune of at least \$5 billion. Carlos Salinas de Gortari (president, 1988–1994) moved to Ireland under widespread suspicion of massive corruption. His brother, Raul, was later convicted of arranging the murder of a prominent PRI politician. While Salinas privatized many of Mexico's state-owned firms, thereby opening up its economy, some of these companies went to PRI allies under suspicious circumstances.

From 1958 to 1998, two political parties dominated Venezuela in close cooperation. Vast oil wealth provided the necessary resources for patronage (a country of 22 million has 1.3 million government employees) and subsidies. The state nationalized many industries, providing more opportunities for patronage and graft, but also leaving the private sector weak and dependent. During the boom of the 1970s, politicians could indulge their penchant for cronyism and corruption. The decline in oil prices in the 1980s diminished the parties' ability to mollify dissent. Jaime Lusinchi, president from 1983 to 1988, had to remain in exile for several years to avoid prosecution for misuse of state property. Carlos Andrés Pérez, a fixture in Venezuelan politics since the 1950s and twice president (1974–1979, 1988–1993), was impeached in 1993 for abuse of public funds. Hugo Chávez, who had led an attempted coup d'état against Pérez, was elected president in 1998 without the support of the major parties.

Brazil lacks strong political parties, but it does not lack for patronage. Especially in rural areas, there is a tradition of machine politics dominated by local elites who use public resources to win mass support. President Fernando Collor de Mello (1990–1992) emerged from this background. While other Brazilian presidents had corrupt reputations, such as Juscelino Kubitschek de Oliveira (1956–1962) and José Sarney (1985–1990), Collor

became the first president to be impeached by Congress. He resigned before he could be removed from office. Corruption under the Collor regime included overpricing on government contracts, rigging public bidding, insider deals, and illegal fundraising. Collor's campaign treasurer, Paulo César Farias, collected \$2 billion in kickbacks from leading contractors. Collor himself spent \$2.5 million on a garden at his home. One corrupt Collor ally in the Brazilian Congress claimed his wealth came from winning the lottery 333 times; he used the lottery as a means of laundering his corrupt wealth. Some observers argued the Collor era's corruption stemmed from changes in Brazil's electoral law that made it more difficult for the president to form stable coalitions in Congress. Brazil's economic crisis reduced the public resources available for bargaining, forcing Collor to turn to private sources.

CORRUPTION IN COMMUNIST AND POST-COMMUNIST STATES

Nowhere in the world does corruption pervade society more thoroughly than in communist and post-communist states. The absolute command of resources that characterizes communist states, and many post-communist states, makes them perfect loci for massive corruption. Under Joseph Stalin and Mao Zedong, terror kept corruption from getting out of line. As communist states aged, corruption became more flagrant. In the USSR, the regime of Leonid Brezhnev (1964–1982) became a synonym for graft and inefficiency. Almost all Communist Party officials took bribes; most exploited their offices for all the privileges they were worth. Organized crime, which has a centuries-old history in Russia, established close ties with party leaders. Indeed, the black market often was all that kept the USSR from collapsing. Managers of state factories and farms had to be corrupt to survive. They lacked the material necessary to meet their goals, so they bribed officials to approve their production. Ordinary citizens had to bribe, too, in order to get consumer goods, medical care, and housing.

Other communist countries featured extensive corruption that came to light after the revolution of 1989–1991. Exposure of the lavish lifestyles

of the East German elite—who had always preached Marxist simplicity—led to massive demonstrations and helped trigger the end of the communist regime. The leaders of Bulgaria and Romania have also been revealed to be corrupt.

The communist era bequeathed a legacy that made massive corruption inevitable in most post-communist countries: a contempt for written law, a complete lack of protections for private property, a cynical public, an arrogant officialdom, a state-dominated economy, an absence of any institutions independent of the state. Some post-communist states made the transition relatively easily and with relatively little corruption: Poland, Hungary, the Czech Republic, Slovenia, and the Baltic states. But the states of the former USSR (with the exception of the Baltics) have traveled a rockier path that has mostly led in to a swamp of corruption.

When Russia privatized many of its state firms in 1992, the bulk of them went to former communist apparatchiks, ex-KGB agents, *mafia* leaders, and a few well-connected businessmen. These “oligarchs” generally paid bargain-basement prices. They have dominated Russian politics in the post-communist era and have supplied crucial support for President Boris Yeltsin. The crash of the ruble in the summer of 1998 damaged both their political credibility and their economic clout. Former Prime Minister Viktor Chernomyrdin is widely believed to have made a multi-billion-dollar fortune from the privatization of the state natural gas monopoly, Gazprom—one of the few Soviet-era companies that makes something that anybody wants. Allegations of massive corruption have swirled about former Finance Minister Anatoly Chubais, once the great hope of reform.

Paid poorly or not at all, military officers have turned to selling their own equipment. During the conflict in Chechnya, some Russian soldiers actually sold weapons to the Chechen separatists. Officers often would rather smuggle than perform their military duties. Some even sell nuclear material or chemical weaponry to rogue states. Customs officials are so corrupt and obstreperous that the U.S. government actually trains Russian businessmen in techniques for avoiding them.

Despite all the talk of Russian capitalism, the state still dominates the economy. Most Russians

still work for state firms. Businessmen must obtain licenses for most activities, which creates great opportunity for extortion. More important, Russia has not created the kind of legal system necessary for private enterprise to flourish. With few laws to govern the emerging capitalist economy, bureaucrats can take away a company's assets at a whim. With their property at the mercy of corrupt officials, even honest businessmen must bribe to stay afloat. There is little tradition of respecting private property in Russia. Even under the czars, all land belonged to the sovereign; even the wealthiest landowner was legally a tenant.

Taking advantage of this time of troubles, organized crime has taken over much of the Russian economy, with the help of their old communist and Komitet Gosudarstvennoy Bezopasnosti (Committee for State Security) (KGB) allies. The police and other law enforcement agencies are underpaid, undermanned, and demoralized. With domination of their home territory assured, Russian gangsters are now spreading their activities worldwide.

Other post-communist states have their own patterns of massive corruption. Foreign investors have shied away from Ukraine, despite its rich farmland and modern factories, because its all-encompassing graft and labyrinthine bureaucracy makes doing business almost impossible. As in Russia, former communist officials and *mafia* gangsters dominate the economy. Ex-communists made Bulgaria and Romania bywords for corruption until the voters booted them out.

China has moved toward a market economy while retaining the Communist Party's monopoly on political power. This has created many opportunities for corruption. Party leaders have plundered state firms, received state loans, and embezzled state funds. The People's Liberation Army has entered a variety of businesses, some legal, some not. The children of communist leaders—the so-called “princelings”—have used their positions to build fortunes. Some observers have argued that corruption has smoothed the transition to capitalism by circumventing bureaucratic rules. It is true that corruption has been most visible in the fastest-growing parts of China, especially in the southern province of Guangdong, where it may well have opened doors that strict legality would have kept shut. Corruption may now be harming commerce.

Like Russia, China lacks a system of property law, so businessmen remain at the mercy of officialdom and cannot settle their disputes in court. They must instead rely on bribery and *guangxi* (connections), which often translates into giving local bosses a cut of their profits. Foreign investors are losing patience. There are also signs that corruption is impairing governance. During the Yangtze River floods of the summer of 1998, water washed away many “bean-curd” dams and bridges. Officials had embezzled the money that would have strengthened these structures. Premier Zhu Rongji has used these disasters to justify his current anticorruption campaign.

North Korea has not moved away from communism one bit, so there is no private sector to shake down. Instead, the state itself has become a criminal enterprise. With its economy in ruins, North Korea has become a “gangster state” that sells narcotics and counterfeit money around the world. It can no longer pay its diplomats, so they support themselves by smuggling. North Korea's fake \$100 bills are so convincing that they led the United States to redesign its currency. To fuel its drug trade, the state runs its own methamphetamine factories and opium poppy farms.

THE OUTLOOK FOR THE FUTURE

The global trend toward democracy and capitalism may decrease corruption in the long term, but in the short term it may increase the perception of corruption. The openness brought by democracy allows for greater disclosures of official malfeasance. Graft that would have remained secret under an authoritarian regime instead comes out, perhaps damaging the public's opinion of politicians. While capitalism reduces the state's role in the economy, thereby decreasing the opportunity for officials to enrich themselves, the privatization schemes necessary for the transition to free markets often become a bonanza for those in power.

There are several attempts to fight corruption on an international level. Transparency International, founded in 1993, organizes anticorruption efforts across the world. Its annual survey of perceptions of corruption has embarrassed many graft-ridden countries. Transparency International now has chapters in seventy countries. In 1997, twenty-nine members of the Organization for Economic Cooperation and Development (OECD) signed

the Convention on Combating Bribery of Foreign Public Officials. This accord, which went into effect in February 1999, forbids the bribery of foreign executive, legislative, and judicial officials. Countries that signed the accord had to agree to punish offenders severely, to help each other prosecute offenders, and to encourage the wider use of sound accounting and auditing practices. The International Monetary Fund (IMF) and the World Bank now often condition their loans on steps to reduce corruption and “crony capitalism.” In 1997, the World Bank established a comprehensive anticorruption program.

RICHARD McGRATH SKINNER

POLITICAL CORRECTNESS

THE HISTORY OF POLITICAL CORRECTNESS

While the term *political correctness* (hereafter, PC) entered common parlance only in the mid-1990s and may soon lose its popularity, the phenomenon to which it refers, namely ideological conformity with the views of those in power or in fashion, is millenia old. To have PC, there must be ideology, and ideology developed with the formation of states. To the extent that all states use violence or the threat thereof to serve the interests of the few who control the state by extracting resources from the many who do not, states always face a problem of legitimacy. If they are to minimize their use of coercive violence to extract surplus production, states must try to convince their subjects that the state serves the interests not only of the ruling class but of the society as a whole. Such is the role of ideology, whether religious or secular.

Until the French Revolution, most states tried to legitimate themselves by identifying themselves with a religion, for instance, Confucianism in China, various branches of Christianity in Europe, and Islam from Morocco to Indonesia. In these “premodern” states, PC was virtually synonymous with religious orthodoxy, as defined by the political and religious elites in control. It was enforced by sanctions ranging from execution, torture, and expulsion to expropriation, ostracism, disfranchisement, discrimination, and segregation. In the late eighteenth century, the American and French revolutions abruptly shifted the onus of state legitimation from religious orthodoxy to a secular ideology of “liberty, equality, fraternity.” This ideology was, however, widely at variance with the structure of highly stratified societies (such as the United States, a slave society) and the practice of coercive states that were often democratic in name only. The bourgeois liberal ideology of the French Revolution gradually spread to much of the world in the nineteenth and twentieth centuries, briefly challenged by two large counter-movements, one reactionary (fascism), one radical (Marxism). Both challenges collapsed, fascism after a quarter-century, in mid-twentieth century, and Marxism in three-quarters of a century, some forty years later.

All these political movements thrived on the elaboration of ideology that served not only to legitimate state power, but to obscure the enormous discrepancy between the democratic, egalitarian ideals and the oppressive, exploitative reality. What the priesthood had been to religiously based PC, the intelligentsia and the bureaucracy became to secular PC. The actual term “political correctness” began to be used principally in the Marxist tradition, which claimed the ability to perform scientific analysis of social and political events, and thus allowed for the possibility of being correct or incorrect in one’s analysis. The “party line,” as defined by the ruling elite in communist regimes, invariably claimed correctness, of course, and invented elaborate *ex post facto* rationalizations for even the most radical policy changes (e.g., the 1939–1941 Soviet-Nazi alliance to gobble up Poland). Soon, however, the concept of PC was adopted by opponents of Marxism to ridicule the dogmatism and obvious opportunism of communist regimes, as, for instance, in George Orwell’s brilliant satire *Animal Farm*.

More recently, in the 1990s, the term PC was revived in the English-speaking world, and rapidly gained currency as a description of the self-imposed ideological conformity and censorship practiced by intellectual, business, and governmental elites in the United States, Canada, Britain, and elsewhere. While the term is principally a weapon used by conservatives to ridicule liberals, it is used across the ideological spectrum, sometimes in healthy, self-deprecatory criticism of fellow liberals or radicals.

CONTEMPORARY POLITICAL CORRECTNESS

In the current context, PC has several interesting features, as follows:

1. While PC is often supported by state regulations, legislation, and a wide range of legal and extralegal measures (covering such things as “hate speech,” sexual harassment, homosexuality, and affirmative action), its principal focus of conformity enforcement is situated in the intellectual, bureaucratic, and business elites that “voluntarily” adhere to the PC

ideology, exercise extensive self-censorship, and practice more or less subtle forms of ostracism against mavericks.

2. PC ideology is widely at variance with what the majority of the population regards as commonsensical, and it conflicts with the interests and beliefs of many large groups (e.g. males, whites, religious fundamentalists, the poorly educated). It thus pits the liberal ruling elites against the populist masses. The colleges and universities, especially the elite institutions among them, are the most vocal and articulate proponents of PC, as are, of course, the graduates of such institutions when they accede to the command posts of government and business.
3. PC is not a coherent political movement aimed at changing the fundamental structure of society, as were Marxism and fascism, for example. Rather, it is an inchoate cultural movement aimed at imposing on a supposedly benighted populous the values, lifestyles, and speech patterns of the elites. It attacks almost exclusively the symbolic aspects of popular culture, rather than the fundamental features of social inequality and injustice. One of its principal cultural products is a rich crop of rapidly changing euphemistic neologisms, the use or nonuse of which serves as evidence of whether one is PC or not.

The central tenets of this elite PC ideology in the United States include the elements discussed below.

1. *PC is a theoretical celebration of “diversity” on many fronts: religious, ethnic, racial, linguistic, and sexual.* The corollary of this celebration of diversity is the rejection of the older ideology of the melting pot, of cultural assimilation, of English-language dominance, and an alternative vision of American society as a mosaic of racial, ethnic, linguistic, religious, and “lifestyle” groups clamoring for recognition of special status, and competing for scarce resources.

This diversity tenet has led in practice not so much to *tolerance* of “otherness,” a

widely accepted value, but to institutionalized, officialized recognition of group affiliation, rights and quota in employment, education, contracts, and so on. These “affirmative action” programs have often been “voluntary” and flexible, but they have faced massive resentment because they violated many values held dear by masses of Americans. They flew in the face of the principle that *individuals* have legal rights, not groups, and that these rights are *equal*. They also squarely violated universalistic norms, such as that merit, competence, or seniority should govern allocation of resources, rather than ethnic or racial membership. A massive backlash against affirmative action, bilingual education, and other “special group rights” programs resulted, because PC is seen, not only as creating division and dissension in American society, but as imposing a double standard of tolerance. For instance, black students are allowed to autosegregate on campuses in a way that white students are not. Hate speech codes are also asymmetrically enforced for blacks and whites, men and women, heterosexuals and homosexuals. Indeed, the very same “hate” words, such as “queer” and “nigger,” are differently evaluated depending on who uses them!

2. *PC embraces a libertarian ideology holding that individual freedom is, in principle, only limited by respect for the rights of others.* Again, if PC libertarianism were evenhandedly applied, it would meet little opposition. This, however, is not the case. Take two examples: drug use and hate speech. The PC position on drug use is one of unequivocal condemnation of tobacco use (increasingly a lower-class habit), even those forms of it that do not pollute the air (such as chewing tobacco). Alcohol use, on the other hand, is widely tolerated, even though its lethality is second only to that of tobacco. As for the illegal drugs, there is no clear PC line, although many self-styled libertarians are amazingly tolerant of heavy state repression and suspension of civil rights involved in the “war against drugs.”

Attempts to control hate speech on campuses and elsewhere is another glaring example of PC double standards. First, many PC proponents have little trouble reconciling their self-styled libertarianism and defense of free speech with attempts to restrict the latter for those with whom they disagree. Second, there is blatant lack of evenhandedness in ostracizing certain kinds of hate speech but not others. Thus, college professors may with impunity refer to their opponents as “male chauvinist pigs,” “racist honkies,” or “fascist cops,” but not as “dumb broads,” “ignorant niggers,” or “flaming faggots.” “Afrocentrist” teachers are allowed to spread anti-Semitic venom by alleging that African slavery was dominated by Jews, but psychometricians and psychologists like Arthur Jensen, Philippe Rushton, and Richard Herrnstein are virulently attacked for suggesting that part of the persistent difference in performance of whites and blacks on intelligence quotient (IQ) and other standardized tests may be genetic in origin. Examples of this double standard of PC enforcement in academia are legion, as documented in Dinesh D’Souza’s *Illiberal Education*.

The offence, it seems, lies as much in the gender, skin pigmentation, or sexual preference of the offender as in the hate speech itself. Only certain combinations are taboo. Others are tolerated, or even found amusing. (Stand-up comedy is an excellent barometer of PC, for instance, and most stand-up comics are acutely attuned to PC. Women may, with impunity, insult men; gays may insult straights; and blacks may insult whites—but not vice versa.)

3. *PC embraces conservationist, environmentalist causes; these, again, would receive wider acceptance if PC were not so elitist, selective, and sentimentalist.* PC ecologism is usually cast as a morality play between good guys (Native Americans, Aborigines, Greenpeace, the Sierra Club) and bad guys (loggers, oil companies, maquiladoras). The reality, of course, is much more nuanced. Native peoples, for

example, began to show as great a proclivity to overfish, overhunt, overgraze, overlog, and otherwise degrade their environment as that of more “advanced” peoples, as soon as they gained access to the destructive technology (steel axes, nylon nets, firearms, chain saws) that make these activities possible. There is also now a powerful backlash against ecologism among Third World intellectuals who argue, rather persuasively, that the ecological movement in the West is highly elitist. The “Green” movement is spearheaded, they say, by leisured romantics, intellectuals, biologists, and other educated members of affluent societies who, after despoiling their own countries, want to convince the poor countries to stop development in order to preserve unspoiled playgrounds for the scientists and eco-tourists of the rich countries.

4. *PC shows a concern for equality, which, once more, would be widely shared in the general population, if it had not been extended by PC proponents in two radically new directions.* The first extension concerns the transformation of the notion of *individual* equality of *opportunity* into *group* equality of *results*. The latter is as controversial as the former is almost universally accepted. The PC model of the ideal society is no longer one in which social rewards are fairly distributed to individuals according to their abilities, efforts, and ethics, but one in which socially defined racial and ethnic groups achieve proportional representation in every sphere of activity. Such a model of a quota society is not only absurd and unrealizable; it is also a prescription for perpetual conflict. The definition of groups is arbitrary and manipulable for gain. Millions of people are of mixed descent, a disallowed category in contemporary America. The population base for establishing proportionality is elastic. (For instance, should blacks be 2 percent of the students at the University of Washington, their percentage in the population of the State of Washington, which it serves, or 12 percent, the percentage of blacks in the United States?) Why should some

groups (e.g., Hispanics) be represented, but not others (e.g., Arabs)? Why is an overrepresentation of whites among physics professors objectionable, but not an overrepresentation of blacks on basketball teams, or of Hassidic Jews in the diamond trade? Why do PC liberals, who proclaim that race does not matter, defend, in the same breath, race-based affirmative action? (Even a formerly sensible Nathan Glazer reversed himself recently on this score and now believes in the necessity for a proportional black presence at elite universities. If blacks, why not poor rural whites, surely another oppressed minority?) In short, the quota society is a bad idea that deserves a quick burial. South Africa just abolished racial apartheid. Why should the United States perpetuate it?

The second controversial extension of the concept of equality by the PC proponents is on the gender front. Few Americans would contest the ideas that women’s worth is equal to that of men, that women should have equal rights with men, that they should be able to compete with men on equal terms, and that they should receive equal pay and benefits for equal work. But the PC agenda goes well beyond that consensual definition of gender equality. PC feminists are generally quite ambivalent about accepting the obvious differences between men and women; if they do accept these differences, they generally ascribe them more to nurture than to nature, and they seek either to ignore or to minimize them; and, quite inconsistently, they want to preserve gender segregation where it favors women (e.g., in sports). PC feminists, in short, want a unisex society, except where it suits them. Finally, PC feminists want the right to be protected against “sexual harassment” whenever they *feel* they have been harassed. Many, in addition, would want to subject sexual relations to a code of conduct involving repeated, explicit verbal assent (unilaterally imposed on men) for every sexual act. Some colleges have gone as far as institutionalizing this nonsense.

Needless to say, the common sense of most Americans, women as well as men,

refuses to accept an ideology that flies in the face of experience, and there is a substantial backlash against radical feminism. Yet PC feminist dogma still rules supreme in many policy domains—for instance, in the military, which tries not only to achieve full gender integration but to rule sex out of existence in its ranks. Any officer bold enough to suggest that this is impossible immediately jeopardizes his or her career.

5. *PC takes a secular outlook that has its roots in eighteenth-century Enlightenment and has dominated Western intellectual life ever since, but that arouses deep antagonism in the half or more of the American population that considers itself religious, and, even more so, in the quarter or so who are fundamentalist Christians.* PC secularism is more than Jeffersonian separation of church and state in that it also frontally attacks the “religious right” on moral issues such as contraception, divorce, and marriage, as well as most controversially—abortion and homosexuality. PC secularism is also at variance with its classical Enlightenment expression in that it does not automatically align itself with the scientific mainstream. For example, many PC secularists reject the mounting evidence supporting the partially genetic underpinning of human behavior, of gender differences, and of basic abilities and character traits. While they may ridicule biblical creationism, they espouse an extreme “social constructionist” view of human behavior and human relations, which is, in fact, a form of secular creationism.

THE EFFECTS OF POLITICAL CORRECTNESS

Because the current form of American PC is such an elite phenomenon, its effect has been limited to the relatively small class of literate bureaucrats and academics who take it seriously. It did stifle intellectual discourse on American campuses and did promote the teaching of a good deal of nonsense masquerading as scholarship. But there is little evidence that it makes many converts, and considerable evidence that it brings out a conservative

backlash. Indeed, PC ideology already seems on the defensive, vulnerable as it is to ridicule. American cultural products always have some resonance in other countries, especially English-speaking and Western European ones: the United Kingdom, Canada, Australia, Scandinavia, the Netherlands, and Germany in particular. But in those countries as well, its influence has been limited to the intellectual elite. In much of the rest of the world, American-style PC has had even less resonance, either because the issues it addresses have little relevance there (e.g., race relations), or because other political and economic problems (such as human rights violations or poverty) give such issues as feminism or conservation much lower priority. Indeed, many PC tenets may even clash more openly with the values of non-Western cultures than they do with the common sense of Westerners.

The probability is, thus, high that the current wave of American-style PC has already crested and that it will be ephemeral. But then, a new brand will crop up, probably no more sane than the current one. Intellectuals, alas, often prove themselves to be much more the sycophants of power than the guardians of reason.

PIERRE L. VAN DEN BERGHE

POLITICAL CRIME

Political crime has been more often an object of partisan assertion than of independent research.

Passions are easily aroused, facts are difficult to establish. Nevertheless, a growing number of studies have contributed to (1) articulating the issues in defining political criminality, (2) describing instances and patterns of resistance to political-legal authority, (3) cataloging and analyzing governmental efforts to prevent and counter such challenges, and (4) proposing research agendas.

THE PROBLEM OF DEFINITION

Political criminality may be narrowly or broadly defined, with greater or lesser regard for definitions offered by laws and interpretations by authorities. Moreover, the values and politics of observers frequently influence their conceptions of what and who is politically criminal. The resulting *mélange* of definitions has led Kittrie and Wedlock to conclude pessimistically, "It may be that an objective and neutral definition of political crime is impossible, because the term seems to involve relativistic relationships between the motives and acts of individuals and the perspectives of government toward their conduct and allegiances" (1998, p. xxxvi). However, an alternative view is implicit in their understanding of political criminality as perceptual and relational, defined in interaction between opposing parties.

Whose perceptions decide what is to be called political crime? Apart from partisan and subjective answers, the empirical reality of political criminality is that it is defined by those with enough power to impose their perceptions. Insofar as a political authority structure has been established, one may argue that the dominant parties within it by definition have the power to define criminality (Turk 1982a, pp. 11–68, 1984; pp. 119–121; for more restrictive legalistic definitions, see Ingraham 1979, pp. 13, 19; Frank Hagan 1997, p. 2). However, this view leaves unsettled the question of how authorities themselves may be defined as political criminals.

The most common resolution is to expand the definition to include anyone who commits extralegal acts defending or attacking an authority structure. For example, Roebuck and Weeber consider political crime to be any illegal or disapproved act committed by "government or capitalistic agents" or by "the people against the government" (1978, pp. 16–17). This very subjective definition (disapproved by whom?) leaves one unable to distinguish either between acts against and on behalf of

authority or between legal and nonlegal behavior. A more promising approach is to recognize that criminality may be defined at different levels of political organization—international as well as national.

International conventions, treaties, and judicial decisions have gone far toward formally defining war crimes, genocide, terrorism, violations of human rights, and environmental depredations. Such international standards may be invoked as criteria for labeling not only individuals but also agencies and regimes as political criminals guilty of "state crimes" (Barak 1991; Ross 1995). Even when formal legal criteria have not been articulated, evidence of harmful consequences of governmental policies and corporate practices may be used to define as political crimes "acts of commission and omission that result in grave social harm" (Tunnell 1993, p. xiv).

Formal pronouncements and unofficial assertions, however, may not have much significance. Accusations against governmental and corporate regimes are unlikely to impact on them unless there is a significant likelihood that they will be penalized for their actions. Within nations, acts by subnational authorities have sometimes been effectively treated as political crimes by national authorities who saw them as endangering societal or elite interests. An example is the American federal government's historic crackdown on state and local violations of constitutionally guaranteed civil rights in the South.

At the international level, it is still rare for even gross violations of human rights to result in sanctioning. Though often accompanied by rhetorical accusations of criminality, expeditions such as the Kosovo intervention by the North Atlantic Treaty Organization (NATO) have typically been launched more out of geopolitical concerns than legal or moral ones, and tend to end in new political and economic accommodations rather than criminal trials. For the present, the lack or weakness of international policing and judicial institutions leaves powerful nations such as the United States free to reject or ignore such charges as practicing genocidal policies toward Native Americans, holding political prisoners, torturing detainees and convicts, and illegally authorizing operations in other countries by the Federal Bureau of Investigation (FBI), the Drug Enforcement

Agency (DEA), and the Central Intelligence Agency (CIA). With little or no chance of their enforcement, invoking international or national laws to define political crimes will continue to amount to little more than largely subjective and partisan ideological tactics.

Another question is whether political criminality is to be defined only as behavior. While one may agree that only specified harmful acts *should* be punishable, the historical fact is that, in addition to offending behavior, nonbehavioral attributes such as ethnicity and class background have frequently been used by antagonists as criteria of intolerable political deviance. Moreover, imputed as well as observed deviations or threats have been used. Anticipation as well as reaction are involved in the identification of political criminality. At the beginning of World War II, Japanese immigrants and their descendants in the United States were officially defined as security risks and forcibly relocated to prison camps, and during both world wars many German nationals and immigrants were subjected to surveillance and orders restricting their freedom to travel outside the areas where they lived.

In sum, political criminality is most realistically defined as whatever is treated as such by specified actors (usually governments, dominant groups, or their agents) who have the power to impose their conceptions in particular historical situations.

RESISTING AUTHORITY

Resistance to political authority may be more or less deliberate, organized, or planned. As noted above, even the appearance or potential of resistance may be sufficient for authorities to act against perceived challengers. Actual resisters may be engaged in activities ranging from merely disrespectful comments to the most violent assaults, from spontaneous eruptions to carefully orchestrated attacks, from individually motivated acts to organized strategies of rebellion. Acts of resistance may be categorized as evasion, dissent, disobedience, or violence.

Resisters may simply evade the orders and demands of the powerful. Avoiding masters, bosses, tax collectors, and military conscription has generally been safer than explicit defiance—because open defiance tends to force authorities to

respond, while tacit evasion is more easily ignored or minimized. Russian serfs learned in such instances as the St. Petersburg massacre how ruthless the Cossacks could be in suppressing dissenters and petitioners—the kind of lesson that has been taught to peasants and workers over the centuries in many lands. As Karl Marx complained, peasants and industrial workers tend to settle for mere survival and small gains instead of becoming revolutionaries. Fear of brutal repression is not groundless, and those with little social power are realistically skeptical even in democratic societies (as regularly shown in legal and political attitude polls) of notions that they can expect protection because they have legal rights.

The right to speak out against authority is enshrined in many legal traditions but in practice is limited by the varying tolerance of authorities and people—decidedly lower in wartime and economic hard times. After centuries of attempting to deter such offenses as seditious libel and treasonous utterances, more democratic governments have de facto concluded that the effort is incompatible with the concept of free speech (Law Commission 1977; Stone 1983; Hurst 1983; cf. Franks 1989). However, other labels may be invoked to authorize punishing those whose dissent is especially galling, especially when authorities feel particularly threatened. U.S. Senator Joseph McCarthy, for instance, achieved the lasting notoriety of “McCarthyism” by making freewheeling accusations of “subversion” against a wide spectrum of targets—from known communists to President Dwight Eisenhower. Though McCarthy’s failure to refrain from smearing the president and the army, both icons in 1950s America, resulted in his downfall, the political climate remained one in which public objections to capitalism, American foreign policies, and even racial segregation carried the risk of being labeled a “communist” or at least a “fellow traveler.”

Dissenting is one thing, but actually disobeying rules and commands is another. Lower-class people have historically suffered many demonstrations of their vulnerability, and so have characteristically been less likely than higher-class people either to dissent or to disobey overtly (Turk 1982a, pp. 69–114). On the other hand, dissenting or disobedient higher-class, especially youthful, resisters have typically been subjected to less punitive treatment. For instance, sentences of Vietnam

draft resisters decreased in response to the political repercussions of imprisoning growing numbers of higher-class young men (Hagan and Bernstein 1979). Not surprisingly, civil disobedience has been more likely to be a higher-class than a lower-class mode of resistance—that is, a tactic of those whose backgrounds encourage them to believe, perhaps erroneously, in their own significance and efficacy and in legal rights and protections. Certainly in the 1960s, in the early stages of the civil rights movement, marchers against southern segregation were far more likely to be students, intellectuals, and “bourgeois” than laborers, farmers, and “proletarians.”

Violent resistance by individuals and small organizations seldom threatens authority structures directly, but does indirectly weaken them in that authorities facing or fearing violence typically adopt extralegal and repressive control measures—which contradict beliefs in legal restraints on governmental power. The more actually and ideologically democratic the political order, the greater the contradiction—which is associated with the greater vulnerability of democratic than despotic regimes to terrorism (Turk 1982b, p. 127).

Political violence tends to escalate from coercive to injurious to destructive forms, in an interaction spiral generated by decreasing hope on the side of one or both parties of an acceptable accommodation and/or by perceived advantages in escalation (Turk 1996). Coercive violence, which may complement or succeed verbal or legal appeals and arguments, is intended to pressure opponents to change their policies or practices—typical acts being telephoned threats, disruption of communications, and rioting. Injurious violence is aimed at causing limited damage to property or persons, with little or no risk of lethal damage, when opponents do not respond satisfactorily to coercion—as when Quebec separatists blew up mailboxes and American student radicals firebombed Reserve Officers Training Corps (ROTC) buildings on university campuses. Torture and execution mark the transition from injurious to destructive violence. Destructive violence seeks to terrify active and potential opponents and to eliminate the enemy’s resources of personnel, supplies, and facilities; examples include the assassinations of governmental (or revolutionary) leaders, as well as acts of terrorism (e.g., the Oklahoma City bombing).

Political offenders have commonly been viewed as morally or mentally defective. However, even the most violent assassins and terrorists appear unlikely to exhibit psychopathology (Turk 1983, 1984, p. 123; cf. Schafer 1974; also Robins and Post 1997). The effort to understand political resisters begins in recognizing that they may vary enormously in political consciousness and motivation, organizational involvement, and readiness to commit violent acts, in addition to other characteristics, such as class origins. Distinctions must be made among deliberate political actors, emotional reactors to climates of political instability and violence, and apolitical opportunists such as ordinary criminals who merely seek to profit from their contacts with resistance figures and movements.

ASSERTING AUTHORITY

Political dominance is defended legally and often extralegally at all institutional levels. The highest and broadest level is typified by national (and increasingly international) policies of insulation (regulating access and mobility, e.g., through immigration and licensing laws), sanctioning (defining and enforcing behavioral rules, e.g., through criminal laws), and persuasion (disseminating favored communications, e.g., through education and censorship)—that is, through *statecraft*, governing strategies designed to ensure that potential resisters lack the opportunities, resources, and will to challenge authority (Gamson 1968). More specifically focused on controlling resistance is political policing—the organized effort to gather relevant intelligence, manipulate channels of communication, neutralize opposition, and deter challenges.

Because the value of information can never be fully anticipated, intelligence gathering is inherently limitless. Advancing technologies of surveillance and analysis enable ever more extensive and intensive monitoring of human behavior and relationships. The distinction between public and private is increasingly dubious in both law and practice. Recurring legislative and judicial efforts to impose legal restraints have occasionally slowed but never stopped the trend (Marx 1988). One of the most celebrated efforts—to end surveillance of civilians by U.S. Army intelligence officers—failed when the highest court ruled in 1972 “that it was not the business of the Supreme Court but of

Congress to monitor executive practices like surveillance” (Jensen 1991, p. 255).

Authorities have never been entirely comfortable with the ideal of free and open communications. Even where that ideal has been most firmly asserted in law, in practice the right to disseminate critical information and ideas has been limited (Kittrie and Wedlock 1998, *passim*). Openly or subtly, communications favoring the status quo have been facilitated, while dissent has been inhibited to a greater or lesser degree. For example, Eugene Debs (leader of the Socialist Party) was convicted and imprisoned not explicitly for his outspoken opposition to American involvement in World War I, but instead for “conspiracy” to obstruct military conscription and war production—a charge under the Espionage Act of 1917, which required no direct evidence of either conspiracy or obstructive actions.

When resistance is encountered, some blend of enclosure and terror tactics is used—that is, a combination of methods designed not only to suppress resistance but also to convince offenders that apprehension is inevitable and punishment unbearably severe. Psychological as well as physical coercion is accomplished by subjecting targets to sanctions varying from character assassination to torture and extermination. An example of the first is the FBI’s effort to discredit Martin Luther King, Jr., as a subversive agitator, a communist sympathizer or dupe, and an immoral womanizer. As for the second, South African apartheid forces provided many instances, including the beating death under interrogation of Steve Biko, leading voice of the “black consciousness” movement.

International covenants notwithstanding, torture and other violations of human rights continue throughout the world (regularly documented by Amnesty International and other organizations). Extreme human rights abuses are reported not only in dictatorships such as Iraq and authoritarian regimes such as Sri Lanka but also in democracies such as Britain, India, Israel, and the United States. Clearly, authorities facing serious challenges are unlikely to be restrained by legal or other norms.

The ultimate goal of political policing is general deterrence. Insofar as the subject population does not knowingly and willingly accept the political order, fear and ignorance may still ensure

acquiescence. Surveillance, censorship, and neutralization are designed not only to repress political deviance but also to discourage any inclination to question the social order. But intimidation must be supplemented by persuasion if superior power is to be legitimated—transformed into authority. A classic technique is the political trial, in which legal formalities are used to portray the accused as a threat to society, to convey the impression that political policing is legally restrained, and to reinforce the sense that political dominance is both right and irresistible. Such trials have not been limited to totalitarian states such as Nazi Germany and the Soviet Union (Kirchheimer 1961), but have also occurred with some regularity in democratic nations such as the United States. Historically, examples have occurred from the Puritans’ legalistic suppression of Anne Hutchinson to the Chicago trial for “conspiracy” of eight assorted radicals with varied causes, whose only link was that they “represented the spectrum of leftist dissidents” (Belknap 1994, p. 240; see also Christenson 1986).

RESEARCH AGENDAS

Studies of political criminality have raised far more questions than they have answered. In the future, it will be not isolated, small-scale investigations but ongoing research programs, that will be essential if the quest for systematic explanations of political criminality is to be successful. Such programs will necessarily be multilevel, integrating research on the political socialization of individuals, the radicalization of defenders as well as challengers of authority, the interaction of resistance and policing strategies, and the conditions under which the political organization of social life is relatively visible (low rates of both resistance and repression).

The viability of a political authority structure can in principle be objectively defined: The probability of its survival increases or decreases. Accordingly, research can identify progressive actions (which increase viability) and destructive actions (which decrease viability) by anyone involved in political conflict. Turk (1982a, pp. 181–191) hypothesizes that random violence, economic exploitation, and weakening social bonds are destructive, while nonviolent actions increasing the life chances of everyone instead of only some people are likely to be progressive.

AUSTIN T. TURK

POLITICAL ORGANIZATIONS

Investigations of the behaviors of political organizations occur at an intersection of sociology, political science, and organizations studies. This interdisciplinary perspective offers great potential for richly informed understanding and comprehensive theoretical explanation of numerous facets of these crucial social actors and their relationships with the larger society and polity in which they are embedded. Four fundamental questions have dominated research and theorizing in this field over the past several decades: (1) What sociopolitical conditions encourage the creation of political organizations? (2) How are participants recruited and induced to provide crucial resources for political action? (3) What mobilization processes enable political organizations to work together most effectively toward collective ends? (4) What strategies and tactics exert the greatest impact on public policy makers' decisions? This article attempts to provide brief answers to these questions. Although most of the empirical research on political organizations concentrates on the United States, some recent evidence from European nations is examined.

The least restrictive definition of a political organization is any formally organized, named group that tries to influence the policy decisions of public officials. Most political organizations take the form of a voluntary association of persons or

organizations that pools its members' and constituents' financial and other resources, and engages in conventional political actions to affect policy-making outcomes. Common synonyms for this type of organization are "interest groups," "pressure groups," and "collective action organizations." Ironically, political parties are not political organizations, because their primary purpose is to elect candidates to public office and only incidentally to press for specific policy agendas. Most public bureaucracies should be excluded, unless they act regularly to promote their own policy preferences within a government. Another questionable type is the social movement organization whose primary political tactics involve rallies, demonstrations, and violent forms of protest (including revolutionary actions intended to overthrow the government) rather than working within routine channels of the political system. Some social movement organizations eventually transform into conventional political interest groups, if they survive their turbulent youths as outside challengers. However, certain profit-making corporations might be considered quasi-political organizations, in instances where their government affairs officers lobby for preferential treatment from legislators and regulators (Salisbury 1994).

Political organizations—including such types as labor unions, professional societies, business and trade associations, churches, neighborhood and community organizations, fraternities and sororities, nationality and racial-ethnic federations, civic service, philanthropic, and cooperative groups, medical and legal societies, conservation leagues, and even recreational and hobby clubs—encompass a broad range of formal goals. Political purposes need not be their primary goal nor compose the majority of their activities, but the critical requirement is that they go beyond merely providing direct services to their members by seeking to change or preserve the social, economic, cultural, or legal conditions faced by their members or those on whose behalf they operate. One interesting type is the so-called citizens' group or public interest group (PIG), which purports not to benefit narrow sectarian or economic self-interests but to promote the broader collective values of the society (Berry 1977). For example, civil rights, civil liberties, environmental protection, feminist, and consumer advocacy associations frequently proclaim a disinterested agenda. A close examination

of their supporters and activities suggests that they do not differ fundamentally from other political organizations in methods of operation (Schlozman and Tierney 1986, pp. 30–35). Based on listings compiled by various American directories, perhaps as many as 23,000 voluntary associations operate at the U.S. national level (many with dozens or hundreds of chapters and branches in state and local communities). Of these, perhaps half qualify as political organizations based on their efforts to communicate their positions on national policy issues to the federal government (Knoke 1990, p. 208). They range in size from the American Association of Retired Persons (AARP), with more than twenty-five million members, to small staff organizations with fewer than a dozen operatives bankrolled by foundations or public donations.

The creation, growth, and expansion of U.S. political organizations seem to occur in cycles corresponding to national political and economic events, including shifts in the legislative, regulatory, and judicial climate (Berry 1977, p. 13; Schlozman and Tierney 1986, pp. 74–82; Gray and Lowery 1996). American labor unions established a national policy presence during the New Deal, and public interest groups blossomed during the civil rights, antiwar, and feminist social movements of the 1960s. Business advocacy associations flocked to Washington in the 1970s and 1980s in reaction to restrictions imposed by newly established federal regulatory agencies for environment, occupational safety and health, consumer protection, and equal employment opportunity (Vogel 1996). Increasingly, mass membership associations have yielded ground to institutionally based organizations, including corporations; universities; foreign firms and governments; and confederations of U.S. state and local governments, such as the National League of Cities.

Interest groups rarely form spontaneously but require leadership and resources. Interest group foundings and expansions may be best understood as involving exchanges between entrepreneurial organizers, who invest capital in a set of benefits offered to potential members as the price of membership, and members who pay dues in order to receive these benefits. Intergroup subsidies may occur; for example, the American Federation of Labor–Congress of Industrial Organization (AFL-CIO) founded the National Council of

Senior Citizens, helped to recruit its early members from unions, and continued to underwrite its activities. Although committed citizen activists, such as Ralph Nader or John Gardner, occasionally provide an energizing impetus for launching new organizations, many public interest groups rely on patronage from wealthy individuals or foundation sponsors to get launched (Walker 1983), as well as on favorable mass media treatment to bolster their legitimacy. Once an organization is formed, its survival, growth, and effectiveness depend on its ability to attract and hold new members and other organizational sponsors. Labor unions and business associations can acquire substantial war chests through dues and assessments on their members, but PIGs have more limited capacities to tap potential diffuse constituents' money. The virtual collapse of Greenpeace in the 1990s underscores the vulnerability of many activist organizations to quickly dwindling support.

For more than three decades, a central paradigm to explain member contributions has been the economic or rational choice model developed in Mancur Olson Jr.'s *Logic of Collective Action* (1965). Olson considered the conditions under which people would voluntarily contribute their resources to an organized group seeking a public good (such as a governmental farm crop subsidy) from which no eligible recipients could be excluded. Olson argued that utility-maximizing actors would refuse to pay for public goods that will be produced regardless of their contributions, and thus would take a "free ride" on the efforts of other members. As a result, the model predicts that most political organizations should fail to mobilize their potential supporters if they were to rely solely on public goods to obtain sustenance. Olson concluded that such entities are viable only if they offer "selective incentives" to prospective members in exchange for their contributions toward the organization's public-good lobbying efforts. These inducements might include magazine subscriptions, group insurance, social gatherings, certification and training programs, and similar benefits from which the organization could effectively exclude noncontributors unless they pay dues and assessments. In Olson's formulation, a political organization's policy objectives are reduced to a secondary "by-product" of its members' and supporters' interests in obtaining personal material

benefits. Despite his appealing analytical arguments, Olson's propositions were repeatedly challenged by empirical investigations of the incentive systems of real voluntary organizations. Members often respond to diverse inducements apart from personal material gains, including normative and purposive appeals and organizational lobbying for public goods (Moe 1980, pp. 201-231; Knoke 1988, 1990, pp. 123-140). For example, right-to-life organizations appeal to their supporters' religious, ideological, and emotional convictions about the illegitimacy of abortion and the necessity to take direct action to shut down clinics as well as to campaign on behalf of prolife politicians. The availability of picnics or T-shirts could hardly provide a compelling motivation for most participants in these groups. The internal economies of political organizations turn out to be more complex than originally believed. Organizational leaders have an important role in defining the conditions and prospects for their members and in persuading them to contribute to collective efforts that may run counter to the members' short-term personal interests.

The governance of political organizations is often posed as a choice between oligarchic or democratic alternatives. Persistent leadership and staff cliques in labor unions, trade associations, fraternal organizations, professional societies, and other types of associations are frequently interpreted as evidence of an inevitable "iron law of oligarchy." However, apart from labor unions (with their legal monopolies on occupational representation within certain industries), most voluntary groups are too dependent on their members for critical resources to enable officials to flout the memberships' interests in the long run. Consequently, most political organizations' constitutions provide for an array of democratic institutions, including competitive elections, membership meetings, referenda, and committee systems (Berry 1984, pp. 92-113; Knoke 1990, pp. 143-161). But actual practices of consulting members to formulate collective actions vary widely, and researchers have only begun to examine how the democratic control of political organizations shapes their capacities to mobilize their members for collective actions. The analytic task is further complicated by the complex interactions of formal governance processes with executive and leadership actions,

bureaucratic administration, environmental conditions, and the internal economy of member incentives.

Political organizations serve a dual function for a political system. First, they aggregate the interests of citizens holding similar preferences, enabling them to press their demands on government officials more effectively. By articulating member demands and pooling the scarce resources of weak individuals, interest groups fashion a louder voice that is not readily dismissed by those in positions charged with public policy making. However, not all interests are created equal. Because higher-socioeconomic-status groups are more likely to join and participate in political organizations, the pressure-group system is biased against representing the views of less organized class, race, gender, and ethnic interests (Verba et al. 1995; Van Deth 1997). Second, political organizations provide public authorities with channels to communicate policy information and provide benefits to their electoral constituencies. Adroit politicians can manipulate public opinion to some degree by selectively targeting which interest groups will receive coveted access to present a case for modifications to pending policy decisions. Public officials and political organizations have a mutual interest in delivering policy successes that permit them both to survive to play the influence game again and again (Browne 1998, pp. 226–228). The fragmentation of political power among numerous policy arenas in the American federal system offers many aggrieved groups several institutional pressure points—legislatures; executive agencies; regulatory bodies; and courts at the local, state, and national levels—through which to raise their demands and promote their preferred solutions onto the public policy agenda for debate and resolution. This duality of political organizations at the interface between the state and its citizenry assures that the interest-group system exerts a crucial, if constitutionally ambiguous, impact on shaping many outcomes of collective political action.

Researchers have made substantial progress in uncovering the evolving techniques deployed by political organizations in lobbying public policy makers on specific issues (Schlozman and Tierney 1986, pp. 261–385; Knoke 1990, pp. 187–213; Baumgartner and Leech 1998, pp. 147–167). Campaign contributions and litigation are relatively

rare methods, while contacting governmental officials (legislative, executive, regulatory), testifying at hearings, presenting research findings, and mobilizing their mass memberships are the most prevalent tactics. But mustering the appearance of grassroots support by hiring consultant firms and lobbying specialists to generate calls and letters may be quickly discredited as phony “astroturf” (Kollman 1998, pp. 157–160). The Internet and the World Wide Web are only the most recent technological innovations to be pressed into the interest-group battle. The impact of political money, primarily unlimited political action committee (PAC) “soft money” election campaign contributions, is a highly emotional topic. Some researchers conclude that a corrupt campaign financing system allows large corporations to enjoy disproportionate political access and influence (Clawson et al. 1998), while others see the corporate capacity to act in unison on political affairs as more problematic and conditional (Mizruhi 1992; Grier et al. 1994). All lobbying methods aim at gaining organizational access to policy makers by winning their attention, communicating with contacts about mutual information needs, and reinforcing for those targets the importance of continuing to pay attention to the organization’s issues (Browne 1998, pp. 68–82). However, the precise conditions under which diverse lobbying tactics exert demonstrable impacts on policy decisions remain elusive.

One increasingly important strategy is collective action by a coalition of political organizations, often competing against an opposing coalition that advocates the contrary policy position. The organizational-state conceptualization of national policy domains emphasizes the shifting nature of short-term networks among organized interest groups mobilizing and coordinating their collective resources in campaigns to pass or defeat particular legislative proposals. The processes by which interorganizational communication networks generate collective action were examined in empirical studies of the U.S. national energy, health, agriculture, and labor policy domains (Laumann and Knoke 1987; Heinz et al. 1993), and in a comparison of U.S., German, and Japanese labor policy making (Knoke et al. 1996). European political scientists have been especially energetic in applying a policy network perspective to understanding how informal bargaining between interest groups

and officials shapes policy outcomes in complex institutional settings (Peterson 1992; Verdier 1995).

Debates among European scholars about the organized representation of societal interests initially concentrated on corporatism as a distinctive form of interest intermediation. Although many definitions of corporatism and neocorporatism abound (Cox and O'Sullivan 1988), the dominant theme concerns how interest groups become incorporated into public policy-making processes through institutionalized access to the levers of state power rather than as seekers of intermittent influence and access that characterize fragmented, pluralist systems such as the United States (Baumgartner and Walker 1989). A corporatist arrangement involves explicit policy negotiations between state agencies and interest groups, followed by implementation of policy agreements through these political organizations, which enforce compliance by their members. The corporatist state takes a highly interventionist role by forming private sector "peak" (encompassing, nonvoluntary, monopolistic) interests groups; delegating to them quasi-public authority to determine binding public policy decisions; and brokering solutions to conflicts (Hirst 1995). In return for a stable share of power, privileged corporatist organizations are expected to discipline their members to accept the imposed policy decisions. Within national labor and other policy domains a closed tripartite network of state agencies, business, and labor organizations collaborates on solutions to such problems as workplace regulation and income distribution, and imposes these compromises on the society. Although much corporatist bargaining occurs primarily within the executive and regulatory sectors, the social partnership aspect of negotiated class conflicts should carry over into the parliamentary arena. The corporatist organizations representing capital, labor, and state interests jointly sponsor legislative proposals originated by agreement with the executive branch. Other interest groups are effectively excluded from participating in these corporatist agreements, resulting in a pattern of cumulative cleavages between them and the corporatist core. These disgruntled, excluded status groups are sources of new social movements against the corporatist monopolies; ecological, antinuclear, feminist, homeless, and immigrant groups are examples of these deprived segments.

This well-ordered corporatist framework seems to be breaking down as a result of the 1986 Single European Act that leads inexorably to an integrated internal market (Mazey and Richardson 1993; Fligstein and Mara-Drita 1996). Simultaneously, a "Europe of regions" is developing, with such areas as Scotland, Brittany, and the Basque country of Spain attaining formal representation and integration into European Union (EU) affairs. The Union is not yet a state, because it still lacks full sovereign power to make and enforce many types of decisions, particularly taxation. Rather, EU policy making is nonhierarchical, open, complex, conflictful, and unpredictable. With Brussels emerging as a supranational forum for resolving social, environmental, producer, and consumer conflicts, new forms of interest representation and lobbying are arising to tackle the expanding EU policy agenda. To varying degrees across different policy domains, the member states are steadily losing control over intergovernmental bargains, while "networks of actors . . . have become guardians of the policy agenda at the subsystemic level of EU governance, over which political controls are often weak or attenuated" (Peterson 1997, p. 7). In sum, the European Union is embarked on a huge, unforeseeable natural experiment that seems likely to transform traditional corporatist state-society relations into a system more closely resembling the "disjointed pluralism" of United States (Mazey and Richardson 1993, p. 24). The situation offers unbounded theoretical and research opportunities.

Despite occasional pessimistic appraisals that "interest-group studies have defined themselves into a position of elegant irrelevance" (Baumgartner and Leech 1998, p. xvii), research on political organizations is thriving at several levels of analysis, from the individual members to organizational political economies to the integration of societal interests into national and supranational polities. Analysts must exert greater effort to link these diverse focuses into a comprehensive explanation of interest organization behaviors situated within their sociopolitical environments. Especially promising avenues include developing formal models of rational social choice at the micro and macro levels; developing models of intra- and interorganizational exchange network; accounting for historical and institutional differences in interest representation processes across diverse national settings; and the functions of nongovernmental agencies

(such as the World Health Organization) and pressure groups (such as Amnesty International) in the world system. Given the vastly expanded sociopolitical functions of modern states in all their permutations, a better understanding of the roles that political organizations play as developers, mediators, expresser, and manipulators of societal interests is indispensable.

POLITICAL PARTY SYSTEMS

DEFINITIONS

Political parties have been defined both normatively, with respect to the preferences of the analyst, and descriptively, with respect to the activities in which parties actually engage. Normative definitions tend to focus on the representative or educational functions of parties. Parties translate citizens' preferences into policy and also shape citizens' preferences. Parties are characterized as "policy seeking." Thus, Lawson (1980) defines parties in terms of their role in linking levels of government to levels of society. She states, "Parties are seen, both by their members and by others, as agencies for forging links between citizens and policy-makers." Von Beyme (1985, p. 13) lists four "functions" that political parties generally fulfill: (1) the identification of goals (ideology and program); (2) the articulation and aggregation of social interests; (3) the mobilization and socialization of the general public within the system, particularly at elections; and (4) elite recruitment and government formation.

Descriptive definitions usually stay closer to Max Weber's observation that parties are organizations that attempt to gain power for their members, regardless of constituent wishes or policy considerations. Parties are characterized as "office seeking." "Parties reside in the sphere of power. Their action is oriented toward the acquisition of social power . . . no matter what its content may be" (Weber 1968, p. 938). Schumpeter ([1950] 1975) applies this type of definition to a democratic setting. He argues that parties are organizations

of elites who compete in elections for the right to rule for a period. Or as Sartori (1976, p. 63) puts it, "a party is any political group identified by an official label that presents at elections, and is capable of placing through elections (free or nonfree), candidates for public office."

The present article employs a descriptive definition but also investigates how well parties perform functions described in the normative definitions. Thus, a party system may be characterized as the array or configuration of parties competing for power in a given polity. The focus here will be almost exclusively on Western-style democracies.

ORIGINS

Von Beyme (1985) suggests three main theoretical approaches to explain the emergence of political parties: institutional theories, historical crisis situation theories, and modernization theories. (Also see LaPalombara and Weiner 1966.)

Institutional Theories. Institutional theories explain the emergence of parties as largely due to the way representative institutions function. Parties first emerge from opposing factions in parliaments. Continuity, according to such theories, gives rise to stable party constellations based on structured cleavages. These theories seem most relevant to countries with continuously functioning representative bodies, such as the United States, Britain, Scandinavia, Belgium, and the Netherlands. However, institutional theories do not explain developments well in some countries, such as France, because continuity of parliament has been absent, and the parliament's strength and independence has come repeatedly into question. The timing of the franchise is also relevant, but its effect is indeterminate because a party system has often been partly established before the franchise was fully extended. Moreover, liberal bourgeois parties that have helped establish parliamentary government have often been opposed to extending the franchise to the lower classes, while leaders such as Bismarck or Napoleon III have sometimes extended the franchise in nonparliamentary systems for tactical political reasons (von Beyme 1985, p. 16). Likewise, Lipset (1985, chap. 6) argues that a late and sudden extension of the franchise has sometimes contributed to working-class radicalism because the lower classes were not slowly

integrated into an existing party system. Voting laws can also affect the structure of the party system. Single-member districts, with a first-past-the-post plurality winner, as in the United States and in Britain, are said to encourage a small number of parties and ideological moderation (competition for the center). National lists, with proportional representation (PR), are said to encourage multipartism (fractionalization) and ideological polarization. However, PR may have this effect only if it is implemented concurrently with the extension of the franchise, because already-established parties may otherwise be well entrenched and leave little room for the generation of new parties. Lijphart (1985) notes that voting laws may also affect other features of political life, such as voter turnout and efficacy or system legitimation, but that these effects have not been extensively investigated.

Crisis Theories. Critical junctures in a polity's history may generate new political tendencies or parties. Crisis theories are especially associated with the Social Science Research Council's (SSRC's) project on Political Development (e.g., LaPalombara and Weiner 1966; Grew 1978). According to SSRC scholars, five such crises can be identified in political development: the crises of national identity, state legitimacy, political participation, distribution of resources, and state penetration of society. The sequence in which these crises are resolved (if only temporarily) and the extent to which they may coincide can affect the emerging party system. Thus, Britain's well-spaced sequence contributed to the moderation of its party system. The recurrent piling up of crises in Germany from the mid-nineteenth century to the mid-twentieth century, and the attempt to solve problems with penetration (strong-state measures) contributed to the fragmentation, polarization, and instability of its party system. The piling up of all five crises in mid-nineteenth century America contributed to the emergence of the Republican Party—and the second party system. From a slightly different perspective, von Beyme (1985) notes three historical crisis points that have generated parties. First, the forces of nationalism and of integration during the nation-building process have often taken on roles as political parties. Second, party systems have been effected by breaks in legitimacy as a result of dynastic rivalries, as between Legitimists, Orleanists, and Bonapartists in mid-nineteenth

century France. Third, the collapse of parliamentary democracy to fascism has produced characteristic features in the party systems of post-authoritarian democracies: "a deep distrust of the traditional right; an attempt to unify the centre right; [and] a split on the left between the socialists and the Communists" (p. 19).

Modernization Theories. Some theories, following the tenets of structural functionalism, argue that "parties will not in fact materialize unless a measure of modernization has occurred" (LaPalombara and Weiner 1966). Modernization includes such factors as a market economy and an entrepreneurial class, acceleration of communications and transportation, increases in social and geographic mobility, increased education and urbanization, an increase in societal trust, and secularization. LaPalombara and Weiner argue that the emergence of parties requires one, or both, of two circumstances: citizens' attitudes may change, so that they come to perceive a "right to influence the exercise of power," or some group of elites or potential elites may aspire to gain or maintain power through public support. Clearly, not all elements of modernization are necessary, since the first party systems (in the United States and Britain) emerged in premodern, agrarian, and religious societies. Also, not all modernization theories are functionalist. Thus, Moore (1966) and others have suggested the emergence of a bourgeoisie increases the probability of the emergence of democracy.

Probably the most influential theory of the origins of party systems is by Lipset and Rokkan (1966) and Lipset (1983). While ostensibly anchored in Parsonsian functionalism, theirs is a comparative-historical approach that borrows from each of the categories listed here. According to Lipset and Rokkan, the contours of the party systems for western European states can be understood in the context of the specific outcomes of three historical episodes. The three crucial junctures are (1) the Reformation, "the struggle for the control of the ecclesiastical organizations within the national territory"; (2) the "Democratic Revolution," related to a conflict over clerical/secular control of education beginning with the French Revolution; and (3) the opposition between landed and the rising commercial interests in the towns early in the "Industrial Revolution." A significant fourth struggle between owners and workers

emerges in the later stages of the Industrial Revolution. Lipset and Rokkan suggest that the shape of current party systems was largely determined during the stages of mass mobilization in the pre-World War I West.

Following Lipset and Rokkan, von Beyme (1985, pp. 23–24) lists ten types of parties that have emerged from this historical development: (1) liberals in conflict with the old regime, that is, in conflict with: (2) conservatives; (3) workers' parties against the bourgeois system (after c. 1848) and against left-wing socialist parties (after 1916); (4) agrarian parties against the industrial system; (5) regional parties against the centralist system; (6) Christian parties against the secular system; (7) communist parties against the social democrats (after 1916–1917) and anti-revisionist parties against "real Socialism"; (8) fascist parties against democratic systems; (9) protest parties in the petty bourgeoisie against the bureaucratic welfare state system (e.g., Poujadisme in France); (10) ecological parties against a growth-oriented society. No one country contains all ten sorts of parties, unless one includes splinter groups and small movements.

PARTY SYSTEMS AND SOCIETY

Even under a purely office-seeking definition, parties in a democracy must have some connection to society since they have to appeal to voters' material or ideal interests. Yet the connection between the party system and social structure or social values is rather weak in most countries—and much weaker than would be expected under a theory that sees parties as mediating between society and the state. In many cases, organizational or institutional factors may be much more important than social factors in determining party strength.

Social Cleavages. The party types listed above clearly have some connection to divisions or cleavages in society. Parties may seek to represent social classes, religious denominations, linguistic communities, or other particular interests. Three types of politically relevant social cleavages may be identified:

1. Positional cleavages correspond to a party supporter's place in the social structure. This may be an ascriptive position into which one is born, such as race, ethnicity, or gender, or it may be a social structural

position, such as social class or religious denomination, which one might be able to change in the course of a lifetime. Of course, the distinction between ascriptive and social structural position is not absolute, but may itself be partly determined by social norms. Also, against Marxist expectations, class determinants of party support are generally overshadowed by racial, ethnic, religious, regional, or linguistic determinants, when these are also present. One explanation for this finding is that, while one can split differences on class (especially monetary) policies, similar compromises are much more difficult where social "identity" is concerned.

2. "Behavioral" cleavages, especially membership, generally have a greater impact on party support than positional cleavages. Studies have shown that while working-class status is mildly correlated to support for leftist parties, union membership is quite strongly correlated. And while religious denomination is correlated to support for religious parties (e.g., Catholics and Christian Democrats in Germany), strength of belief or church attendance is much more strongly correlated.
3. Ideological cleavages are preferences, values, worldviews, and the like, which may not correspond entirely to one's position in society. Indeed, ideological orientations may overshadow positional cleavages as a determinant of partisan preferences. For instance, several of the ostensibly working-class communist parties of western Europe have traditionally drawn large percentages of their support from middle-class leftists.

Not all cleavages or issues that exist in a society are politically relevant at any given time, or if they are, they may not correspond to party support. One can distinguish between latent and actual cleavages around which politics are mobilized. Some cleavages may remain latent for a very long time before becoming politicized. For instance, women's issues had been relevant for decades before the "gender gap" emerged in the elections of the 1980s. One can also consider the process of politicization as a continuum that begins when a new social division or issue emerges, develops into

a (protest) movement, then a politicized movement, and ends—at an extreme—with the creation of a new political party or the capture of an existing party. Of course, this process may be halted or redirected at any stage.

Party Loyalty and Party System Change: Alignment, Realignment, Dealignment. Parties may persist over time, and the party system alignment may be stable. There are several possible reasons for this:

1. The social cleavages around which a party was built may persist.
2. Voters may grow up in a stable party system and be socialized to support one or another party. Studies show that when a new cleavage line emerges in party alignment, it begins with the youngest generations. These generations then carry their new party loyalties with them throughout their lives, though perhaps to a decreasing extent if the events that originally motivated them fade over time. Likewise, older generations tend to resist alignments along newly emerging cleavage lines because they remain loyal to the parties they began to support in their own youth.
3. Parties may become organizationally entrenched and difficult to dislodge. Even if cleavages or issues emerge that cause voter dissatisfaction with existing parties, these parties may have the organizational resources to outmaneuver new movements or parties. They may be able to “steal” the new parties’ issues and absorb or coopt their constituencies, or they may be able to stress other issues that distract voters from the new issues.

However, newly emerging cleavage structures may overwhelm these inertial tendencies. The party system may respond in three ways to new social cleavages. The first two are processes of party “realignment”:

1. New parties may be formed to appeal to the new constituencies. A classical example is the emergence of the British Labour Party in the late nineteenth and early twentieth centuries when the Liberals and Conservatives did not pay sufficient attention to the concerns of the growing

working classes. The more recent emergence of Green parties in some European countries is another example. The creation of the American Republican Party in the 1850s shows the explosive impact a new party can have: Lincoln’s election precipitated the South’s secession.

2. Existing parties may change their policies to appeal to new constituencies. For instance, existing parties seem now to be in the process of killing the European Greens by adopting their issues. Perhaps the best example of this process is found in American history. Bryan’s Democrats moved to absorb the Populist Party, and Al Smith’s and Franklin Roosevelt’s Democrats moved to absorb the growing urban ethnic constituencies (Burnham 1970; Chambers and Burnham 1975).
3. If neither of these changes occurs, there may be a period of “dealignment” in which much of the population—especially new constituencies—is alienated from all parties, and turnout or political participation declines. New constituencies may organize themselves into pressure groups or social movements that fail either to form new parties or to capture existing parties. Existing parties may become internally more heterogeneous and polarized, single-issue actions may proliferate, referenda may increase, and citizen action groups may simply bypass parties. Scholars since the mid-1960s have debated whether Western politics are going through a period of realignment or dealignment (Dalton et al. 1984). Of course, both processes may be occurring: dealignment may be a way-station on the road to party realignment.

STRUCTURAL FEATURES

Certain structural features of the party system may be important independently of parties’ connections to society.

Representativeness. The electoral system determines how votes are translated into seats in the legislature. The results can vary widely. At one extreme, a system of proportional representation

(PR) with a single national list enables even tiny parties to get representatives into the legislature. Thus, if 100 parties each received 1 percent of the vote, each would receive 1 seat in a 100-seat legislature. Such systems put no obstacles in the way of party system fragmentation. At the other extreme, first-past-the-post plurality voting with single-member constituencies tends to overrepresent larger parties and underrepresent smaller parties. Thus, if party A won 40 percent of the vote in every district, and parties B and C each won 30 percent of the vote in every district, party A would get all the seats in the legislature, and parties B and C would get none at all. Such systems discourage party system fragmentation. Still, regionally concentrated minority parties tend to be less underrepresented than minority parties whose support is spread across all districts. If 100 parties were completely concentrated in each of 100 districts, the electoral system could not prevent fragmentation. Some election systems combine features. German voters have two votes, one for a district candidate and one for a party list. If any candidate receives a majority in his or her district, that candidate gets a seat. The remaining seats are allocated proportionately according to the list votes. Furthermore, a party must receive at least 5 percent of the national vote to get any seats from the list portion. This system attempts to reduce party system fragmentation and at the same time to reduce overrepresentation and underrepresentation. It was once thought that PR reduces government stability and endangers democracy. However, recent research gives little support for this proposition: “electoral systems are not of overriding importance in times of crisis and even less in ordinary times” (Taagepera and Shugart 1989, p. 236).

Volatility. Party system volatility, or fluctuations in electoral strength, encompasses several different processes (Dalton et al. 1984; Crewe and Denver 1985). It includes the gross and net flow of voters between parties, as well as into and out of the electorate because of maturity, migration, death, and abstention. It also includes realignment and dealignment: changes in the electoral alignment of various constituencies, and the overall weakening of party attachments. Scholars have long debated whether electoral volatility contributed to the collapse of democracies in the 1930s, especially the mobilization of first-time or previously alienated voters. Recently, Zimmermann and Saalfeld

(1988) concluded that volatility encouraged democratic collapse in some, but not all, countries. Studies also show that most postwar antidemocratic “surge” parties draw support disproportionately from voters who are weakly attached to parties or weakly integrated in politically mobilized subcultures such as labor, religious, or ethnic organizations. Yet volatility and protest do not always flow in an antidemocratic direction. On the contrary, they are also normal components of democratic politics. Few would argue that the New Deal realignment harmed American democracy or that most new-left or ecology movements are antidemocratic. In order for volatility to cause trouble for democracy, it must be accompanied by antidemocratic sentiments. Indeed, massive vote switching among *democratic* parties may be the best hope for *saving* democracy during a crisis. Everything depends on the propensity of voters to support antidemocratic parties.

Fragmentation. In the wake of World War II, some scholars argued that the fragmentation of party systems, partly caused by proportional representation, contributed to the collapse of European democracies. In a fragmented party system, they argued, there are too many small parties for democratic representation and effective government. Citizens are confused and alienated by the large array of choices. Because parties have to form coalitions to govern, voters’ influence over policy is limited, and they become further disenchanted with democracy. With so many small parties, governing coalitions can be held hostage to the wishes of very minor parties. Empirical studies show some support for these theses. Fragmentation is associated with reduced confidence in government and satisfaction with democracy. Governments in fragmented party systems tend to be unstable, weak, and ineffective in addressing major problems. However, other scholars argue that party-system fragmentation is not the main culprit. Fragmentation contributes to problems, but other factors are more important. Since fragmented party systems are often composed of blocs of parties (as in, e.g., the Netherlands and Italy), voters have less difficulty reading the terrain than alleged. Besides, party system polarization may contribute to governmental instability and ineffectiveness more than to fragmentation. Scholars have looked at this possibility in both the interwar period and the

postwar period. While the evidence is not overwhelming, it tends to support the thesis.

Polarization. Sartori's model of "polarized pluralism" (1966, 1976) is the most influential account of party system polarization. In a polarized party system, according to Sartori, a large (but not majority) party governs more or less permanently in unstable coalitions with various other parties. At least one extremist (antisystem) party is in quasi-permanent opposition. Extremist parties are sufficiently unacceptable to others that they cannot form alternative coalitions, but they are strong enough to block alternative coalitions that do not include themselves. Sartori argues that this leads to stagnation and corruption at the center, frustration and radicalization at the periphery, and instability among governing coalitions. He cites Weimar Germany, Fourth Republic France, and contemporary Italy as examples. Much empirical evidence supports Sartori's model. Polarization is associated with illiberal values in postauthoritarian democracies such as West Germany, Austria, Italy, and Spain.

The dynamic may also work in reverse. When intolerant and distrustful relations among political actors were institutionalized by constitutional guarantees in some postauthoritarian countries, they became crystallized in a polarized party system. Cross-national research shows that polarization harms other aspects of democracy, as well. Polarization is negatively related to democratic legitimation and trust in government, and is positively associated with cabinet instability. However, other elements of Sartori's model have been disputed. In particular, studies in the early 1980s of Italy—the model's current exemplar—called into question Sartori's claim that polarized pluralism generates extremism and thus harms democracy. These studies claimed that the Italian Communists had moderated and that the centrist Christian Democrats had become less intolerant of them. However, the studies' own evidence were not entirely persuasive, and subsequent developments—while not reversing course—do not present a decisive break with earlier patterns.

COALITIONS

Single-party government in Western democracies is relatively rare (Laver and Schofield 1990). The multiparty systems of most countries necessitates

coalition government. Even in two-party America, a president and Congress of different parties produce a kind of coalition government. (Indeed, internal party discipline is so weak in America, as well as in some parties in Italy, Japan, and other countries, that one can characterize parties themselves as coalitions of political actors.) Most work on coalition government attempts to predict which parties get into office. One of the most influential theories predicts that "minimum connected winning" (MCW) will form most often. This theory combines office-seeking and policy-seeking approaches, predicting that parties will form bare-majority coalitions (so that the spoils can be divided among the smallest number of winners) among contiguous parties on the ideological dimension (so that there is not too much disagreement about policy). MCW theory succeeds fairly well in predicting coalitions in unidimensional party systems, but less well in multidimensional systems, which are often fragmented, polarized, and/or based on rather heterogeneous societies. Likewise, research suggests that in unidimensional systems, offices are most often allocated among the winning parties proportionately to their electoral strength. In multidimensional systems, however, offices are allocated less according to parties' electoral strength than according to their "bargaining" strength, that is, how much they are needed to complete the majority. Thus, if three parties won 45 percent, 10 percent, and 45 percent of the vote, the small party would have just as much bargaining strength as either of the larger parties.

Research also shows that party-system fragmentation and polarization and the presence of antisystem parties all contribute to cabinet instability. Theorists have sometimes posited that cabinet instability leads to instability of democracy—that it may reduce governments' capacity to solve problems effectively, and that this may reduce the regime's legitimacy. Yet research gives only mixed support for this conjecture. Investigators have found that cabinet instability tends to depress the electorate's evaluation of "the way democracy works," but its effects on other measures of democratic legitimation and confidence in government are inconsistent. Research on contemporary democracies shows that cabinet instability is related to civil disorder and governmental ineffectiveness. But research on the period between the world wars indicates that cabinet instability cannot be

definitely tied to the collapse of democracy. Cabinets in France and Belgium were as unstable as those in Germany and Austria, but only the latter democracies collapsed (British and Dutch cabinets were more stable). Why is cabinet instability not more clearly tied to problems for democracy? One possibility is that cabinet instability simply reflects the severity of problems. Just as electoral volatility may reflect citizens' desire for change, cabinet instability may reflect elites' flexible response to the problems. Neither of these need reflect a desire for a regime change, simply for a policy change. Indeed, cabinet *immobility* might be more damaging to effectiveness and democratic legitimation if problems are severe enough. In this respect, cabinet instability, like electoral volatility, probably has an indeterminate effect on democratic survival.

Oversized grand-coalition governments also have ambiguous effects on liberal democracy. The most important theory is Lijphart's (1977, 1984) model of "consociational democracies," plural societies with high levels of intercommunal conflict. In such polities, parties are unwilling to go into opposition because they risk losing too much and because party strength—closely tied to the size of the ascriptive communities—changes too slowly to make their return to office likely. Thus, formal opposition could lead to more extreme conflict. The alternative is a grand coalition government of all major parties, combined with a degree of federalism and proportional allocation of state services according to party or community size. Since potential conflict is too dangerous, open opposition is delegitimated and suppressed. In this respect, consociational procedures are intended to be a method for *reducing* extreme underlying intercommunal conflict through contact among opponents (at the elite level), which promotes trust. If these measures succeed, the "game among players" can move to one in which moderate conflict and tolerance of opponents becomes legitimated. This appears to have succeeded in the Netherlands and Austria, and failed most miserably in Lebanon. On the other hand, if grand coalitions are formed in societies *without* extreme underlying conflict, they may *initiate* a vicious circle of intolerance and delegitimation. To form a grand coalition, prosystem parties generally move closer to the center of the policy spectrum than

they would otherwise do. This move may leave their more militant (but still prosystem) constituents politically homeless, and they may seek harder positions in a more extremist party or movement. These constituents do not so much abandon their party as the party abandons them. Thus, if a grand coalition submerges a moderate competitive structure, it can generate polarization. The grand coalition government of 1966–1969 in West Germany, a country with little intercommunal conflict, was probably largely responsible for the rise of antisystem voting at the time. If the grand coalition government had not ended fairly quickly, it might have caused serious problems for West German democracy.

RESEARCH DEVELOPMENTS IN THE 1990s

Research on political parties and party systems has continued to stream unabated in the 1990s, yet many of the basic principles outlined above continue to hold true. Three important research areas may be mentioned. First, scholars have sought to understand the role of party systems in democratization, especially in central and eastern Europe, but in other regions as well. Second, the study of political extremism has been knit more closely with the study of party systems. Third, recent stock taking in the field of political legitimation has highlighted the importance of party systems.

The "third wave" of democratization, beginning with transitions in southern Europe in the mid-1970s, and continuing with transitions in Latin America, East Asia, and central and eastern Europe, is one of the most important social and political developments of the last quarter of the twentieth century. Scholars seeking explanations for the relative success or failure of democratic transition and, especially, consolidation have generally highlighted the importance of well-functioning party systems. Thus, Huntington (1991, chap. 6) argues that party-system polarization is one of the greatest hazards to democratization (also see Di Palma 1990; Lipset 1994). Theorists of democratic transitions have pointed to the importance of "pacting" between authoritarian-regime soft-liners and democratic-opposition moderates, and to the exclusion of regime hard-liners and antiregime extremists (O'Donnell and Schmitter 1986; Karl

and Schmitter 1991). The importance of moderation during the transition period, prior to the legalization of a party system, parallels the importance of moderation of a party system within an existing democracy (Weil 1989). Empirical studies of democratization in Latin America (Remmer 1991), Central and Eastern Europe (Fuchs and Roller 1994; Toka 1996; Wessels and Klingemann 1994), and East Asia (Shin 1995) tend to support this thesis—as do general, comparative treatments of democratization (Linz and Stepan 1996).

The study of political extremism has taken party systems into account more fully in the 1990s than had perhaps previously been the case. Earlier studies often characterized extremism in terms of psychological predispositions, socialization, or economic dislocations. These accounts tended to focus on personal distress—sometimes in absolute terms, but sometimes in terms of reference groups and relative deprivation—and were often couched in functionalist theories of social dislocation in the course of social modernization. A later wave of extremism research focused more on resource mobilization within social movements. It was not deprivation (absolute or relative) that created extremism, according to this view, but the ability to organize. A third wave of extremism research has emphasized political “opportunity space,” gaps or niches in the opposition structure, which political entrepreneurs can fill if they are skillful. Extremism often arises not so much because conditions have worsened, nor because groups have newly organized, as because existing parties within the party system have vacated certain ideological positions and opened competitive opportunities or niches for extremists. Mainstream parties may vacate these niches because they enter or leave office, or because they feel they need to compete more effectively with another party. The reader will notice that it is not so much that these three accounts contradict each other as that they are nested, with the first most specific and the last most general. Perhaps the most important recent study of right-wing extremism in Western polities is Kitschelt and McGann (1995). Other useful recent collections of essays include Weil (1996) and McAdam and colleagues (1996).

Studies of legitimation, confidence, and trust continue to attend to the effects of parties and

party systems. Recent surveys of the literature show that party systems do not always or uniformly have an influence, but when they do, a moderate opposition structure is most conducive to these forms of political support. Polarization, grand coalitions, and “cohabitation” (“divided government” in America) do not tend to promote legitimation, confidence, and trust (see Fuchs et al. 1995; Listhaug 1995; Listhaug and Wiberg 1995).

Finally, a few recent general contributions to the literature may be listed. Important recent books that bring the field up to date include Ware (1996) and Mair (1997). Also, a new journal devoted to political parties and party systems, *Party Politics*, from Sage Publications, began publication in 1995 and has become a major outlet for scholarship in this field.

FREDERICK D. WEIL

POLITICAL SOCIOLOGY

Two distinct but converging intellectual traditions have defined the field of political sociology: the social stratification tradition pioneered by Karl Marx and Frederick Engels; and the organizational tradition originated by Max Weber and Robert Michels (Lipset 1981). In the first, political sociology is defined broadly as the study of social power in all institutional sectors of society with a primary emphasis on the state and its structural roots in the class system. This tradition takes a holistic view of social structure and change, arguing that the class system determines the organization of the state and political action. The state is conceived as the institutional structure whose central function is maintaining the social order and is thus examined in terms of its functions. The second tradition defines political sociology more narrowly in terms of the organization of political groups and political leadership with primary emphasis on the structure of the state and the groups that compete for control over the state. The state is conceived as the legitimate monopoly on the means of violence. This approach emphasizes the informal and formal organization of political parties, interest groups and social movements, their links to the governmental bureaucracy and formal centers of policy making, the legitimating myths that are used to justify the system of rule, the organization of the legal system, and the sources and impact of public opinion, including the organization of the mass media and electoral politics.

As societies modernize and become more complex, it becomes increasingly difficult to distinguish these two traditions. Institutions become more complex and differentiated, thus developing their own distinctive autonomy while at the same time being shaped by the larger system of power. In response, analysts have blended these approaches together, synthesizing arguments drawn from the competing perspectives. We begin with a brief

summary of the classic ideas and their bearing on contemporary work and then examine attempts to integrate these approaches.

KARL MARX AND THE THEORY OF THE STATE

Karl Marx and Frederick Engels developed two distinct theories of the state: an instrumental theory; and a structuralist argument (Carnoy 1979). In the first, the state is a tool or instrument of the dominant class, used to protect the property system and impose order through force and ideological manipulation. The dominant class is a ruling class, meaning that it simultaneously dominates the economy and the political system. This class is socially cohesive and politically unified, which gives it direct control over the state. The state is the institutionalization of power or, to draw on Max Weber's conception (1947), the legitimate monopoly on the means for force in society and, as a tool of the upper class, consolidates upper-class power by force and fraud.

In the contemporary period, this argument inspired Mills's theory of the "power elite" (1956), defined in terms of the cohesive leadership group that unifies the corporate rich, the political directorate, and the military elite, as well as Domhoff's theory of business dominance (1979, 1990, 1998) and Useem's inner-circle thesis (1984). In these arguments, the capitalist class is seen as socially cohesive—integrated through exclusive private clubs, prep schools and universities, debutante balls, and interlocking corporate directorships. These networks create an inner-circle leadership group that controls the largest multinational corporations and is central to these various networks. Domhoff (1998) argues that this upper class rules through four processes: (1) policy planning in which leading inner-circle-controlled policy organizations, such as the Business Roundtable, the U.S. Chamber of Commerce, and the Brookings Institution, develop the major policy proposals that are eventually adopted; (2) campaign contributions that select the candidates for electoral office (Clawson et al. 1992); (3) special-interest lobbying for specific firms and industries; and (4) ideological control through publicity campaigns that control the political agenda and mold public opinion so as to minimize opposition. Thus the ruling class

constitutes an organized leadership group with considerable cohesion and political unity.

Marx and Engels also advanced a structural theory of state, treating it as the autonomous product of class struggles. Thus, in his essay *The Eighteenth Brumaire of Louis Bonaparte* ([1852] 1964), Marx argued that the political development of the working-class movement combined with disorganization and internal conflicts within the ruling class led to a military dictatorship. The capitalist class was too divided to rule directly and thus had to be protected by a military dictator. Extending this argument, Neumann (1942) explained the rise of fascist dictatorship in Germany during the 1930s in terms of a combination of working-class mobilization, a disorganized bourgeoisie and strong autocratic political traditions. Drawing on Gramsci's ideas about the "modern prince" of modern bourgeois civil society (1957), Poulantzas (1973) advanced a structuralist theory of the state, arguing that market competition disorganizes the capitalist class, requiring that the state operate as a "relatively autonomous" institution that organizes the capitalist class into a hegemonic bloc while disorganizing the working class. Critics have pointed out that this functionalist argument lacks a specific mechanism for class rule (Skocpol 1981). In response, Offe (1984) and Block (1987) argued that in capitalism the state is barred from entering profit-making enterprise, which makes state managers structurally dependent on capitalists to make investments and thereby create employment, taxes, and economic growth. State managers are thus structurally pressured to create capital accumulation and act autonomously to promote reforms that rationalize and stabilize the capitalist system.

Thus the stratification tradition has gradually incorporated arguments from the organizational tradition, focusing on leadership groups and the autonomy of political institutions. By conceiving political institutions as independent but structurally dependent on the capitalist economy, these analysts have synthesized Marxian arguments with organizational arguments. Still this position has been subjected to several criticisms. First is that social stratification is not primarily a question of class but one of prestige and exclusionary social practices (Weber 1947; Parkin 1979). As Weber (1947) argued, classes are defined by their market position, which rarely provides sufficient cohesion for successful political mobilization. Status groups,

in contrast, are based on shared values and a code of honor, thus readily mobilizing for political action. Thus the political struggle over the state is typically not about class but about the lifestyles and prestige of status communities. Second, political institutions have their own autonomous logic and interests, operating independent of the interests and action of classes and other organized groups. Thus Michels ([1911] 1962) argued that formal organization creates oligarchic leadership which is able to divert political organizations from their official goals to promoting the interests of the permanent staff. Similarly, Weber (1947) argued that rational-legal authority and bureaucratic organization tend to replace traditional and charismatic rule, thus creating the "iron cage" of the modern bureaucratic state. Both arguments underscore the independent importance of political organizations, to which we now turn.

MAX WEBER, ROBERT MICHELS, AND THE ORGANIZATIONAL APPROACH

The second major approach is rooted in the work of Weber and Michels as well as the classic elite theorists Gaetano Mosca ([1896] 1939) and Vilfredo Pareto ([1935] 1963). Their core argument is that rule by the few (or the elite) is inevitable. This is due to the scarcity of leadership talent, the psychological need of masses for leadership, and the imperatives of complex organization. The central political question, then, is not the elimination of a ruling class or the creation of a classless society but the institutional mechanisms that regulate elite recruitment and the effectiveness of various formulas for legitimating elite rule. Thus Michels's thesis about the "iron law of oligarchy" ([1911] 1961) took as its primary target the German Social Democratic Party (SPD), contending that, despite its formal goal of promoting working-class democracy and internationalism, the SPD was in fact controlled by the permanent staff who used it to promote their own careers and positions. This proved prescient when, a few years later, the SPD rallied to the autocratic German Kaiser to support World War I against the French working class. Similarly, Weber's arguments about the "iron cage" of bureaucracy (1947) were borne out by the creation of the Soviet Union which created a highly rationalized political economy more oppressive than any in western Europe. It thus came to dominate human conduct independent of its formal

goals. In a similar vein, Mosca ([1896] 1939) and Pareto ([1935] 1963) argued that participatory or "direct" democracy is not feasible and that, at its core, modern democracy is a system for institutionalizing elite turnover by requiring that elites peacefully compete for popular support in competitive elections. Thus democracy is really a system for selecting among competing elites and thus reducing the risks of incompetent hereditary leaders and violent struggles for power. It also legitimizes the system by encouraging mass to assume that they have a say in their rulers and thus contributes to political stability.

Schumpeter (1942) developed this further into the pluralist theory of democracy, arguing that by forcing candidates to compete for popular votes in elections with multiple political parties, providing adult suffrage, and protecting rights to speech and assembly, modern representative democracy also disperses power and creates a degree of popular accountability. Electoral competition means that elites have to mobilize popular support and thus respond to public concerns. Dahl (1957, 1982) and Rose (1968) argued that this creates a countervailing power system that ensures that all significant groups have a voice and a vehicle for countering more powerful groups. In this vein, Duverger (1962) shows that electoral rules determine the number and type of political parties. Majoritarian systems with single-member districts and "winner-take-all" elections (e.g., the United States and Britain) create two-party systems with nonideological parties because voters are unwilling to throw away their ballots to support third parties. Proportional systems that allocate legislative seats based on their proportion to the popular vote create multiple ideological parties. This, in turn, creates different opportunities for political expression with majoritarian systems experiencing more protest and conflict because they are less responsive while proportional systems have greater governmental instability due to the number and contentiousness of political parties (Powell 1982).

This pluralist thesis has come under several criticisms. First, competitive elections and rules protecting freedom of association and speech do not counteract the institutional bias of politics. Thus Schattschneider (1960) argued that the interest groups and parties in the United States overwhelmingly represent the upper class. Business and the professions are well represented, while

workers, consumers, and disadvantaged groups are weakly represented (Schlozman and Tierney 1986; Berry 1997; Form 1995). Second, pluralist institutions provide no guarantee that disadvantaged groups will be able to mobilize and secure access to the system (Gamson 1975; Piven and Cloward 1979). Thus McAdam (1982) and Jenkins (1985) show that movements on behalf of African-Americans and farm workers were politically blocked by their upper-class opponents until the 1960s, when electoral realignments and increased resources for these groups allowed them to successfully mobilize. Thus political opportunities for the excluded and disorganized are historically variable and by no means institutionally guaranteed. Third is the organizational argument that oligarchy undermines the responsiveness of political parties and interest groups to their supporters (Schattschneider 1960; McConnell 1966). Thus, despite a plurality of organizations, these are internally autocratic and largely unresponsive to member interests.

Arguing that pluralists and stratification theorists share a similar "society-centered" approach, "state-centered" analysts have analyzed the role of state managers as autonomous agents of political change (Nordlinger 1981; Evans et al. 1985; Skocpol and Amenta 1986). Thus, instead of being the tools of special-interest groups (pluralism) or of the upper class and class struggles (neo-Marxism), these state managers independently develop policies that promote their ideological visions and politico-administrative interests. This ability is rooted in the growing autonomy and resources of the state, which is becoming more rationalized and more central to contemporary political economies. Bureaucracy and professionalization insulate government agencies from outside control, thus making them more independent. Because many policies are responses to problems that have previously been addressed, policy precedents have a strong positive feedback effect on the development of new policies. Thus the greater the policy development and administrative capacities of governmental bodies, the greater the ability of state managers to initiate rationalizing reforms (Finegold and Skocpol 1995; Amenta 1998).

This perspective (also called "historical institutionalism" [Skocpol and Campbell 1995]) is a useful corrective to society-centered theories. It shares with classic elite theory the idea that policy

making can be independent of societal constraint, and it develops the idea of state capacities. It has been criticized, however, for overemphasizing the autonomy of state managers and failing to specify the conditions under which political institutions are autonomous (Domhoff 1996). In response, Amenta (1998) has synthesized state-centered arguments with resource mobilization theory (Tilly 1978; McAdam 1982; Jenkins 1983) to explain how political institutions mediate the impact of social movements on policy change. Likewise, Finegold and Skocpol (1995) show how political leaders during the New Deal mobilized business support for their policies but also became dependent on business leaders. Some contend that this perspective applies better to the more rationalized stronger states in western Europe and Japan, where state managers and coordinated corporatist bargaining have been central to post-World War II economic policy (Schmitter 1981; Katzenstein 1985). The United States is a strong case for capitalist dominance, thus supporting the stratification approach, while other states display stronger state institutions and thus support the organizational approach.

POSSIBILITIES FOR SYNTHESIS

Since both traditions have proved useful, several have attempted to synthesize them. One approach has been treating these theories contextually, arguing that each theory bears in particular settings or with specific aspects of political change. Thus Laumann and Knoke (1987) argue that some policy arenas are organized pluralistically with multiple competing groups and considerable fluidity, while others are more centralized with a smaller number of actors and a more hierarchical relationship among them. Thus they compare the more pluralistic health care arena with the more centralized field of energy policy. Similarly, Dye (1995) argues that pluralism better explains patterns of elite recruitment while a hierarchical "power elite" model better explains decision making. The challenge for such a contextual synthesis is to develop a rationale for the conditions under which neo-Marxist, pluralist, and state-centered arguments are relevant.

A second approach is to integrate these arguments into a more comprehensive theoretical framework. Lukes (1974) and Alford and Friedland (1985) have advanced a multidimensional theory

of political power that conceptually integrates these perspectives. The starting point is Weber's classic conception of power as the ability to secure one's will against that of others even if against their resistance (1947). Thus power is always relational, involving interactions among at least two or more parties. It is also hierarchical, in the sense that one party or group is stronger or controls the other. It is also a potential or capacity. History shows that power is often based on force—whether physical or psychological coercion—but that such force is inherently unstable. No society can be organized solely on the basis of force because, at the first opportunity, people will break the rules. Terror is not only unstable but also inefficient. Thus power holders attempt to institutionalize their power; that is, they try to make it more stable by being seen by subordinates as legitimate. Authority is power that is widely perceived by subordinates as fair and just, and thus is more likely to be stable. Manipulated authority is power that power holders have attempted to legitimize by controlling information and creating false images among subordinates. Authentic authority is freely accepted by subordinates as fair and just (Habermas 1976).

Lukes (1974) distinguishes three dimensions of power: decision-making power, agenda control, and systemic power. *Decision-making power* exists when subordinates are aware of an underlying conflict of interest with power holders but are induced to act in the power holder's interest. Resources, such as wealth, charismatic claims, or the threat of violence, allow power holders to control subjects against their will. Even if compliance is not total, claimants with superior resources will typically control the behavior of subordinates. This is the aspect of power on which pluralists and state-centered analysts focus.

In *agenda control*, power holders prevail because they control what issues will be decided and what potential issues are removed from the political agenda. Such processes constitute "nondecisions" (Bachrach and Baratz 1970) in that power holders decide not to decide. Agenda control is more subtle than decision-making power, and is difficult to study but is nonetheless central to the political system. Thus, in a community power study of Gary, Indiana, Crenson (1971) found that powerful industrialists pressured local government to ignore local pollution problems created by the

steel plants. Similarly, Perrucci (1994) found that state and local officials mounted joint publicity campaigns with Japanese auto corporations that convinced local voters that the large tax breaks granted to these foreign auto companies would create jobs and tax revenues despite unequal tax burdens. Because the mass media are central to creating public issues, they are typically key. Domhoff (1998) argues that upper-class control over the mass media, the leading universities, and the major policy organizations prevents issues such as unemployment and redistributive tax reform from becoming topics of decision making. News stories are largely created by press releases and interviews with government officials, which gives government officials considerable say over what issues will be aired in the mass media. Subordinates may be aware that power is being wielded, but they cannot force their own perspectives onto the political agenda. Thus this second dimension strongly controls the decision-making process by determining what issues and views get included or ignored. Elite theorists are the key architects of this type of work.

In *systemic power*, power holders benefit by structural arrangements, such as the distribution of wealth or superior political organization. Subordinates may not be aware of their conflicting interests with power holders and may, in fact, be ideologically indoctrinated to accept the authority of power holders. This may stem from several processes. One is the inability of subordinates to mobilize and press their interests. Disorganized and resource-poor groups are often unable to mobilize (Gaventa 1985; Jenkins 1985). Second are ideologies that legitimize power. Under slavery, slave owners successfully promoted the idea that they were paternalistic "father figures" who cared for and protected their childlike slaves. Insofar as slaves accepted this ideology, they were reluctant to rebel and resisted in ways that were controllable (Genovese 1974). Neo-Marxists advance this type of analysis.

Alford and Friedland (1985) contend that different theories of power have different objects of explanation and different time scales, with systemic arguments focusing on long-term structural change, agenda setting about moderate-term institutional changes, and decision making about short-term behavior. These are hierarchically organized

with systemic power-setting limits on the agenda-setting process, which in turn sets limits on decision making. Thus studies that focus solely on first- or second-dimensional power without including the systemic context are limited and potentially flawed. Seemingly conflicting theories of political power can be synthesized once we specify their objects of explanation and integrate them into a larger theoretical framework.

Hicks and Misra (1993) advance an alternative synthetic "political resource" theory, arguing that institutional contexts define the infrastructures or facilitative conditions that enable specific groups to mobilize and secure their interests (called "instrumental resources"). Thus neo-Marxian and pluralist arguments about the political actions of specific groups need to be combined with state-centered and elite arguments about institutional capacities and policy precedents. They show that factors identified by all these theories affect the amount of social welfare spending in Western democracies. Similarly, in a study of the adoption of public venture capital firms by state governments in the United States, Leicht and Jenkins (1998) show that corporatist bargaining between big capital and labor combine with strong administrative capacities of state governments to create new entrepreneurial economic development policies. Thus, instead of specifying a causal hierarchy among theories, this approach identifies interactive combinations of factors identified by these various power theories.

At this point, it is unclear which approach will eventually prevail. The contextual approach has considerable flexibility but needs to explain the conditions under which different power theories hold. The multidimensional power argument has conceptual breadth but lacks clear empirical relevance. Unless competing theories can be tested simultaneously in empirical analyses, it is difficult to evaluate how useful a purely conceptual synthesis is. In effect, Alford and Friedland (1985) have simply demonstrated that structural, institutional, and behavioral explanations refer to different objects. The political resource theory has strong empirical promise but needs greater specification as to the interactive combinations that integrate these power theories. Single-factor theories clearly need to be surpassed so that a broader theory of power and the state can be developed that will account for a variety of contexts as well as different

power processes within an inclusive theoretical framework.

J. CRAIG JENKINS

POPULAR CULTURE

Since the 1960s, studies of popular culture in the United States have proliferated and a range of novel arguments have been proposed, linking patterns of popular culture production and consumption to systems of stratification and power. Before the 1960s in Europe, Roland Barthes ([1957] 1972) and Fernand Braudel ([1949] 1966) championed (for quite different reasons) increased attention to everyday culture and its social significance, and members of the Frankfurt school emigrating to the United States brought new theories of mass

culture to American academics (Rosenberg and White 1957; Lowenthal 1961), but American scholars still did not generally see any value in studying popular culture.

Beginning in the mid-1960s, as the American middle class began to be targeted by the mass media as the desired audience, more American educators started to show more interest in media-based popular culture, even though in much of academia, studying popular culture was either declassé or taboo (Ross 1989). A few hardy souls from sociology and literary criticism looked at popular culture as a realm of interesting fads and fashions, ephemeral cultural forms that plummeted though modern urban life with regularity, gave rise to much cultural entrepreneurship, and left ordinary citizens running to keep up with what was "happening." Sociologists found it a bit easier to justify ongoing attention to these social ephemera because of the established tradition in sociology of examining urban and suburban communities and their cultures (Park 1955; Lynd and Lynd 1929). By the mid-1960s a quite active community of scholars around Bowling Green University proliferated empirical and descriptive accounts of everything from fast-food restaurants to rock and roll (Keil 1966; Nye 1972; Cawelti 1972; Browne 1982). At roughly the same time, a small group of literary scholars drew on longstanding literary interest in the voices of the people in literature (Shiach 1989, chap. 2, 4), and argued that to understand contemporary uses of language, one had to study commercial language in popular culture (McQuade and Atwan 1974). This work did not have much success in changing either sociology or literature. In sociology, it was eclipsed conceptually by sociological work that linked patterns of popular culture to systems of institutional control (Cantor 1971; Denisoff 1974; Hirsh 1972). This work had greater legitimacy because it addressed the organizations' literature, but it also reinforced the sense that the study of popular culture was not really important enough to stand on its own.

By the end of the 1960s, as the political climate shifted, radical scholars began to champion studies of popular culture either to understand the world of "the people" (disregarded by elites) or to account for the political passivity of the working class and poor. They tried to resuscitate questions about elite distaste for popular culture itself and its relation to systems of social control. These

questions gave popular culture new importance, not as an aesthetic or commercial system but as a political actor in systems of stratification and power (Schiller 1969; Guback 1969; Aronowitz 1973; Gans 1974).

This legacy has been carried into present-day popular culture research as it has spread through sociology, literature, anthropology, history, and cultural studies. Ongoing fascination with “politics from below” has made this subfield a conceptually complex and politically “left” branch of cultural studies, not concerned so much with the moral fabric of society or the ideational sources of its integration (subjects derived from the Weberian tradition of cultural studies), but rather with the use of culture to exert or avoid systematic domination from above.

Many contemporary attempts to explain patterns of cultural domination through popular culture are indebted to (and in different ways critical of) the work on mass culture and consciousness begun by the Frankfurt school. Members of the Frankfurt Institute of Social Research originally organized themselves to examine the philosophical underpinnings of Marxism, but when Hitler came to power, since most of the leading members of the group were Jewish, this project was disrupted and many figures came to the United States. The work on mass culture that developed from this group was (not surprisingly) devoted to understanding the success of Nazism by dissecting and analyzing the psychological and political effects of mass society (Jay 1973). Members of the Frankfurt school perceived mass culture as aesthetically and politically debilitating, reducing the capacities of audiences to think critically and functioning as an ideological tool to manipulate the political sentiments of the mass public. They argued that in modern industrial societies, the pursuit of economic and scientific rationality provided an impoverished environment for human life. The realm of culture, which might have provided respite from the drudgery of everyday life, was itself being industrialized, yielding a commercial mass culture that atomized audiences and lulled them with emotionally unsatisfactory conventionality. This world of commodities only added to the dissatisfactions that deflected people from their desires. The dulling of their senses made them politically passive, and their emotional discontent made them easy targets for propaganda that addressed their

powerful inner feelings. This combination, according to theory, was what made the propaganda in Nazi Germany so effective (Horkheimer and Adorno 1972).

During the 1960s, critical theory, as the work of the Frankfurt school came to be known, continued in U.S. intellectual circles to be used to explain the political conservatism of the working class, but it was also taken up in the student movement as a critique of commercial mass culture that justified the efforts by “flower children” to create radical social change through cultural experimentation. The problem was that, for the latter purpose, critical theory was too deterministic to have much room for human agency, including cultural strategies for change. Constructivist models from the sociology of culture could be and were used to explain how ordinary people could break the hold of political institutions over their imaginations (Blumer 1969; Goffman 1959; Berger and Luckmann 1966; Schutz 1967; Becker 1963), but they did not explain how ideological control of populations by elites could work. The insights of the Italian communist political writer Antonio Gramsci (1971) about hegemony seemed a better scheme for explaining both the role of ideology in systems of power and the constructed nature of social reality. According to Gramsci, elites maintained their power and legitimacy by creating hegemonic definitions of reality that were accepted as common sense by the population. By subscribing to these views, nonelites collaborated in their own oppression. Gramsci’s work, available in English translations and popularized in the academic community in the 1970s, gave the study of culture and power in the English-speaking world new direction.

By the 1970s, much innovative work on popular culture was coming out of Great Britain. The British school of cultural studies drew attention to the role of nonelites in systems of power, but it focused more on working-class culture—particularly its role as a crucible for cultural resistance, innovation, and change. This school had its roots in the work of E. P. Thompson (1963) and Raymond Williams (1961; 1977; 1980). These authors began from the premise that the working class is not defined just by relations of production, but also by a self-consciousness bred in a class-based way of life. The working class has its own history and traditions that give its members distinct values and a complex relation to societal level systems of

power. In their own cultural enclaves, class members are active producers of their own political institutions and popular entertainments (and through them defined social realities). So while the public culture of Western industrialized societies may be dominated by elites who control the mass media and who try to use cultural systems for exerting power, their hegemonic control is circumscribed by the cultures of subordinated groups. The realm of popular culture, in this tradition, is an arena of conflict in which cultural identity, authority, and autonomy are contested. Social rifts are made manifest in the multiplicity of points of view that enter into the public sphere along with the hegemonic messages of much mass culture (Curran, Gurevitch, and Woolcott 1979; Hall and Whannel 1965).

While early British cultural studies paid greatest attention to working-class culture, the ideas about cultural resistance were easily transferred to the analysis of other subordinated groups such as women, youth, and minorities. This broader approach to cultures of resistance gave birth to the kind of subcultural analysis conducted, for example, by Dick Hebdige (1979). He argues that innovations in youth culture come from marginalized working-class youths rebelling against both their parents and hegemonic culture. New developments in music and dress are culled from the cultural possibilities made available in mass society, both in commercial commodities and local cultures. These cultural resources are mixed and reassembled to create new subcultural styles. Much innovation of this sort comes from minority communities and is picked up by middle-class kids in part because it is so offensive to their parents. The irony, of course, is that if they make these styles popular, they end up making them part of the world of mass culture, economic mainstays of the entertainment industry.

One of the most interesting literatures spawned in America by this British school comes from historians looking to the realm of popular culture to try to understand class, gender, and ethnic relations in the United States. Roy Rosenzweig (1983), Kathy Peiss (1985), and George Lipsitz (1990) look at how class, gender, and ethnic culture are sustained and dissolved over time in patterns of resistance, co-optation, mutual influence, and change. They identify ways that residues of older cultural traditions both resist and are incorporated into the cultural mainstream, and

ways that different groups have absorbed and used elements of both traditional and mass culture to fashion distinct identities and ways of life.

Rosenzweig (1983), studying the white working class in nineteenth-century America, treats popular culture as a site of resistance to work discipline in the factory. The division of life into periods of work and leisure for workers in this period was not, to Rosenzweig, the articulation of two spheres of activity, but a political division that was part of a struggle over control of time by workers.

Peiss (1985) looks at women workers in nineteenth-century cities. She demonstrates that young working women used their new economic independence to resist the constraints of the family as well as of the factory. They were able to develop new styles of dress, dancing, and play, but could not free themselves from their highly structured gender relations.

Lipsitz (1990) looks at how ethnic and class cultures have been sustained and dissolved in the late twentieth century in the United States. He sees popular culture forming a kind of popular memory, obscuring and yet reviving the U.S. working class's immigrant past and ethnic complexity. Centralized mass media such as television have helped to create and record the decline of immigrant identity under the force of consumerism. In contrast, more participatory cultural forms like street dancing and parading during Mardi Gras and some popular music forms have allowed ethnic groups to play their identities and create an urban mixed culture that simultaneously embraces and rejects traditional ethnic identity.

Another direction in the analysis of class and culture has been developed by Pierre Bourdieu (1984) and his colleagues in France. They have been looking for the mechanisms by which domination has been sustained across generations. If social constructivists are right and social life must necessarily be "created" by each new generation, then social *stability* over time needs theoretical explanation. To Bourdieu, culture is a main source of class stability. He argues that each rank has its own kind of cultural tastes, some systems of taste constituting cultural capital that can be exchanged for economic capital. People at the top of the hierarchy have a class culture with a high amount of cultural capital. They teach this culture to their

children and thereby give them an economic edge. This kind of elite culture is also taught in school, but kids from less affluent backgrounds often resist learning it. This cultural resistance by the working class is not a victory, according to Bourdieu; rather, it is a trap for reproducing the class system.

Bourdieu's theory of cultural and social stratification is interestingly unlike most models found in the United States and Britain because it has no special place for a homogenizing mass culture. Bourdieu argues that members of different social ranks may see the same films (or other forms of mass culture), but they see them in different ways and they like or dislike them for different reasons. Elite culture is more abstract and formal than working-class culture, so elite filmgoers pay more attention to film language while nonelites care more about plots and stars. These differences in cultural consumption are more significant to Bourdieu than differences of cultural production (mass versus handmade culture) because elites identify with formal approaches to culture and prefer to associate with (and hire) those who share their views.

Scholars in both Britain and the United States have been profoundly influenced by Bourdieu. Paul DiMaggio (1982), in a study of the Boston Symphony and its development in the nineteenth century, paid attention to the differentiation of tastes and social ranks at issue when concerts for elite audiences were purged of popular songs and were used to define a special repertoire of classical music. This happened when the symphony was established as an elite musical institution and drove out competing musical organizations that had more "democratic" tastes. DiMaggio argues that this cultural differentiation took place when immigrant groups grew dramatically in Boston and took over local politics there. The superiority of traditional elites was no longer visible in the public sphere, but it remained central to the economy. The creation of cultural institutions identifying this elite with elevated tastes helped to make class power visible and to sustain it over time by giving upper-class Bostonians a distinctive culture.

In Britain, Paul Willis (1977) has confirmed Bourdieu's perceptions about class reproduction through his study of the education of working-class youths. He argues that distaste for the "elevated" values of the school among working-class

youths is expressed in school by resistance to lessons. This resistance does not have the optimistic possibilities found in the theories of Williams (1977) or Hebdige (1979), but results in class reproduction. Working-class youths, in eschewing elite cultural values, end up reproducing their own domination within the class system. MacLeod (1987) in the United States finds much the same thing, although he focuses on differences between blacks and whites. Members of gangs from both ethnic communities who lived in the same housing project found difficulty escaping their social rank because of difficulties at school. The blacks believed that by going to school they could achieve mobility, while the white kids did not. Still, both groups were kept in their "places" by a lack of cultural capital.

Since the end of the 1970s, there has been a growing literature, stimulated by the women's movement, on gender stratification and popular culture. The bulk of it addresses two media—novels and film—because of the centrality of women to the economic development of these two areas of popular entertainment. As Ann Douglas (1977) pointed out in her seminal and controversial book, *Feminization of American Culture*, women readers and women writers helped to establish this form of popular novel writing in the United States during the nineteenth century. Sentimental novels were tailored to the domesticated women in the period, who had to stay home and devote their attention to familial relations and child rearing. The novels focused on interpersonal relations and problems of individuals' morals (as opposed to large issues of morality)—just the kind of thing that both fit and justified middle-class women's highly circumscribed lives. Douglas decries the role of women writers in shaping this disempowering literature for women and praises in contrast more "masculine" and male writings from the period (hence generating much controversy about her easy acceptance of the literary canon). Most important for students of popular culture, she argues that the sentimental novels were models of mass culture that have been used ever since in romance novels and soap operas.

Janice Radway (1984) questioned this easy dismissal of romance novels, and went out to study in a quasi-ethnographic fashion the readers of contemporary romance novels to see how they were affected by their reading. She found that the

novels had more mixed effects than Douglas supposed. While they taught traditional gender relations (including male violence toward women), they also celebrated the gentler side of men and (more important) were used by women readers as a reason to deflect demands on their time by husbands and children. Women claimed their reading time as their own, and used it to withdraw temporarily from the uninterrupted flow of demands on their attention.

Gaye Tuchman's book (1989) provides some interesting history that serves as a vantage point from which to view the controversy between Douglas and Radway. She shows that, around the turn of the century, publishing houses began to reject the women novelists and their sentimental novels and to favor male novelists. Publishers were central to the switch to the canons of modernism, and the "expulsion" of women from the profession of novel writing. Women readers still constituted the major market for novels, but their market had become so lucrative that high-status male poets, who had eschewed the novel before, began to be interested in it. Once this occurred, their tastes were taken as authoritative and the novel was quickly placed in their hands. Tuchman makes clear that changes in taste like this were neither arbitrary nor grounded purely in aesthetics; they were the result of economic changes in the literary market, institutional decisions about how to address them, and institutional trivialization of women and their culture.

The attention to gender and film has been inspired not by the importance of the female audience or the centrality of women to the film industry (the opposite is the case), but rather by the importance of actresses, of the faces and bodies of film stars, to the commercial and cultural success of the industry. When feminist studies of film began in the 1970s, most of the work was on the exploitation of the female body in films by male filmmakers and for a male audience. This kind of analysis stressed how commercial films used male-centered notions of sexuality and power, presenting women in films as objects of desire and/or violence (Weibel 1977; Tuchman et al. 1978). In the 1980s, researchers turned away from the study of film production and toward analyses of film language and film consumption to construct a psychology of film watching (Modleski

1982; Mulvey 1989). Much of this literature focuses on the voyeuristic pleasure film watching provides men by allowing them to gaze at women's bodies while sitting in a dark theater where the female objects of the gaze cannot look back. Scholars in this tradition examine in shot-by-shot detail how men and women are differentially presented on film: men are generally in medium shots, carrying the action of films, while women stand in the background (or are dissected in close-ups to appear as faces or other body parts, available to the male gaze).

Because this type of analysis seemed to prove so decisively that films are constructed for a male audience, feminists wondered why women seem to find so much pleasure in going to the movies. One answer is that some films contain strong and interesting female characters who address issues of concern to female audiences. Another is that interpretations of films are not so controlled by authorial intentions, and are much more a matter of audiences' active readings of messages. Drawing on Nancy Chodorow's ideas about female psychology (1978), Carol Gilligan's ideas about female reasoning (1982), Lacanian psychology, and poststructuralist views of the politics of interpretation (Eagleton 1983), a psychology of film emerged around how audiences (particularly women) construct meaning from film texts (Mulvey 1985, 1989; Erens 1979). The most recent works of media analysis have rejected altogether such a dualistic approach to gender. Learning from studies of sexuality itself, they have considered how gender categories are at stake in popular culture. They examine how gender dualism is enforced and contested in the mass media (Gamson 1998).

In the 1980s, two opposite developments in culture theory have emerged from renewed attention (in poststructuralism in general and in the film theory described above) to the multivocality of texts and the proliferation of meanings through multiple readings. The upbeat one emphasizes the liberatory nature of culture, and is related to: (1) the poststructuralist argument that asserting alternative interpretations undermines the authority of canonical readings; (2) feminist versions of reader response theory that contend that how you use culture is central to what it is; and (3) the idea from the British school of cultural studies that competing social voices enter into the public sphere and are available for readers or audiences to find.

Advocates of this position claim that efforts at social control through culture do not work very well because, in their own life worlds, people use the cultural resources around them in their own ways. These new constructivists—for example, Robert Bellah (Bellah et al. 1985) Ann Swidler (1986), Joseph Gusfield (1989), and Michael Schudson (1989)—are much like Goffman (1959) and earlier symbolic interactionists who presented everyday life as a cultural achievement, but they see the construction of meaning in everyday life (in an optimistic reversal of Foucault and other poststructuralists) as a healthy exercise of power as well as symbolic manipulation (Foucault 1970, 1975, 1979; Jameson 1984; Zukin 1988).

This optimistic view of the proliferation of meanings in everyday life is countered by students of postmodernism who derive from structuralism and poststructuralism an interest in the languages of culture and see in modern urban society a loss of meaning resulting from the multiplication of signs and their decontextualization or reappropriation. They argue that commercial culture has such a need to assign meaning to objects (in order to make sense of their consumption and use) that signs are proliferated, reappropriated, mixed, and reused until they lose their meaning. For example, as famous paintings are used to sell cosmetics, images of the Old West are used to signify the solidity of banks, and bits and pieces of past architecture are mixed to construct a new built environment, history is made meaningless. The play with signs goes on without serious thought to what this does to human life. The result is (to postmodernists) a politically debilitating alienation. Cultural production and counterproduction, the argument goes, may reduce hegemony by undermining attempts to define “common sense,” and may give people pleasure through the free play of signs, but they provide only an illusion of freedom, and breed a loss of meaning in life. This view of modern urban life contains some of the unremitting pessimism of the Frankfurt school, but it is tied to a view of cultural decentralization that is at odds with traditional critical theory.

The diverse approaches to popular culture that have developed since the 1960s seem to have produced a proliferation of meanings for popular culture itself, but the result has not been alienation. Popular culture research has gained an analytic richness that it lacked when few scholars

dared or cared to approach it. Conflicting theoretical views about what makes popular culture significant may make it more difficult to define and characterize (much less understand) the field. But all the debates consider how groups come to understand the world they live in, and how those understandings subordinate or alienate them (on the one hand) or liberate them to make meaningful lives, in spite of efforts by others to control them (Long 1997). This heritage is clear, and gives both meaning and direction to popular culture studies.

CHANDRA MUKERJI

POPULATION

As a topic, *population* refers to the size and composition of social groupings and the dynamics of change in these characteristics. It extends to the determinants and consequences of levels, differentials, and changes in fertility, mortality, and spatial distribution. Within the social sciences, population study has a broad concern with the cultural, social, economic, and psychological causes and consequences of these characteristics (see Hauser and Duncan 1959; Coleman and Schofield 1986; Stycos 1987; Namboodiri 1988). Within sociology, the main concern is with linkages between social institutions and the dynamics of population change and equilibrium (see Taeuber, Bumpass, and Sweet 1978; Nam 1994; Greenhalgh 1996). *Demography* is an important component of population study that focuses on data collection, measurement, and description. (Though it would be impossible to cite all articles relevant to the general topic of population, a number of useful articles are cross-referenced at the end of this article.)

OVERVIEW OF POPULATION HISTORY

A brief overview of major changes in the characteristics of human populations will suggest some of

the linkages between social life and these characteristics. (For a more detailed discussion see, for example, Wrigley 1969; Petersen 1975.)

During Neolithic times, hunting and gathering groups probably consisted of only a few dozen individuals. Based on the technology and the area believed to have been populated, it is estimated that in about 8000–6000 B.C. the population of the world was only five million to ten million (Yaukey 1985, p. 38). Probably about half of all children died before age 5. Mainly because of the high mortality of infants and children, life expectancy was probably only about 20 years, although some adults would have survived to advanced ages. Maternal mortality was also high, probably resulting in considerably shorter life expectancy for females than for males (United Nations 1973, p. 115). In such a setting, the social consequences of these fundamental demographic facts would have been enormous. Many of our current social values and institutions have their roots in this harsh environment.

Death was sudden, random, and frequent—at least five times as common, in a population of a given size, as in a developed country today. A major function of religion was to enable people to interpret death as a part of the life course and to surround it with rituals. New births to offset these deaths were essential for the survival of a group. There can be no doubt that many groups, of various sizes, failed in this effort, but the survivors were our ancestors. Children were important to the economy of the household and community from an early age, and young adults were crucial to the welfare of older adults. Practices and institutions to encourage fertility—of humans, as well as of the environment of plants and animals—were essential. Marital unions of some type would have been virtually universal and would have begun at an early age. It is likely that unions would have been arranged by the parents, partly because they occurred at such early ages, as well as because of the social advantages of arranged marriages for strengthening an intergenerational network of social obligations. Thus the social institutions of religion, marriage, and the extended family, among others, had some of their original impetus in the extremely high mortality of human prehistory and the consequent imperative for high fertility and child survivorship.

One of the most remarkable functions of social institutions is that they provide valves or mechanisms by which population size can be regulated to be compatible with the prevailing environmental circumstances and the level of technology (Davis 1963). As just mentioned, high mortality must be accompanied by comparably high fertility if a population is to sustain itself. For the most part, it is the level of mortality that drives the level of fertility, through various intervening mechanisms, although mortality (infanticide) has sometimes served as a means of population control. The social regulation of population size usually takes the form of increasing or decreasing the average number of births per woman, to compensate for uncontrollable influences on mortality.

Humans have a much greater capacity to reproduce than is often recognized, and even in situations of very high mortality and fertility there is usually an untapped potential for even higher fertility. There are well-documented "natural fertility" populations in which the *average* woman who survives the childbearing ages has 10 to 11 children after age 20, and it is estimated that the average after age 15 could be as high as 16 children under some circumstances. (Of course, if maternal mortality is high, many women will not survive the childbearing years.) The potential supply of births is adequate to balance even the most severe conditions; if it were not, the species would not have survived.

Over the long run, there has been a pattern of increased life expectancy with two major transitions. The transition from hunting and gathering to settled agriculture and larger human settlements produced a net increase in life expectancy, although with some shifts in causes of death. Larger settlements have a higher incidence of infectious diseases because of inadequate sanitation and sources of clean drinking water. The second major transition began in the seventeenth century with industrialization and the progressive reduction of deaths from infectious diseases. Fluctuations in mortality due to transitory influences have been superimposed on these two main transitions (Tilly 1978; Wrigley and Schofield 1981). Some of the short-term increases in mortality, due to wars, famines, and epidemics, have been devastating. For example, the Black Death in fourteenth-century Europe eliminated more than one-third of the population in several areas.

During the transition to agriculture and larger settlements, mortality fell and population size increased. It is believed that, starting in roughly 5000 B.C., world population approximately doubled every 1,000 years, reaching 100 million around 500 B.C. It doubled again in the next 1,000 years, reaching 200 million around 500 A.D., and again in the next 1,000 years, reaching 425 million in 1500 A.D. (McEvedy and Jones 1978). Most of the growth was in Europe and the Middle East. This is obviously an extremely low rate of growth by modern standards, around 0.07 percent per year, but it was a marked increase from the hunting and gathering era.

The increase in carrying capacity with a new technology and social organization probably had its principal effect on reproduction at the household level (Laslett and Wall 1972; Goody 1976, 1983). If territory for new settlements is absent or inaccessible, having too many children will lead to excessive division of land and property. Some kind of limitation on reproduction will result.

The most important social mechanism or lever for regulating fertility has probably been limitation of exposure to the risk of conception—in short, regulation of sexual activity. Thus, in preindustrial Europe, the age at marriage was high—on average, in the mid-twenties. The motivation for delaying marriage and the formation of new households probably arose because the parental generation had limited land to pass to their children. Marriage and childbearing were deferred until a viable household could be established. These household-level motives led to a general consensus that marriage at later ages was preferable. Associated with late age at marriage were voluntary rather than arranged marriages, and apprenticeships or domestic service for many young people. Alternatives to married life developed—for example, celibate religious communities. These behaviors can be viewed as mechanisms for fertility limitation, even though they certainly had more direct functions as well. Within marriage there was probably very little use, or even knowledge, of contraception.

When short-term increases in mortality occurred, as with a famine, war, or epidemic, the social response was an increase in the prevalence of marriage and/or a reduction in the mean age at

marriage. Again, these motivations operated primarily at the household level, in the sense that when mortality rose, there were increased opportunities for land division and settlement, and new households could be formed more quickly.

The attempt here is to characterize population growth and homeostasis in the broadest terms, up to the beginning of the industrial era in the West. Because of limited space, this description glosses over enormous differences worldwide in the patterns of reproduction and social structure and their linkages. There have several ethnographic and historical analyses of these variations (see, e.g., Hanley and Wolf 1985).

The growth of population that accompanied industrialization is indicated by the following estimates. World population was about 545 million in 1600; 610 million in 1700; 900 million in 1800; 1,625 million in 1900. It is expected to be about 6,100 million in 2000 (McEvedy and Jones 1978; United Nations 1998). The period saw an acceleration in the rate of growth, as well as enormous increases in sheer numbers of people. Prior to 1900, Europe increased most rapidly. In other parts of the world, most of the increase was concentrated in the twentieth century. This period of rapid growth is described as the *demographic transition*. It is discussed briefly below. (See the end of this article for relevant cross-references.)

MORTALITY DECLINE

The transformation of mortality from a common event, occurring most often to children, to a relatively rare event, occurring most often to the elderly, arose from a confluence of technological and social developments. Most important among these was the control of infectious diseases spread by microorganisms in the air and water. An improved understanding of the etiology of these diseases, together with technical capacity and political support for public health measures, led to childhood vaccinations, clean drinking water, and improved sanitation (McKeown 1976). Standards of personal hygiene and cleanliness of clothing improved. There is little evidence that improvements in diet were important, and curative (as contrasted to preventive) medicine played a relatively small role in the main part of the transformation.

In developed countries, the infant mortality rate has steadily fallen from about 250 deaths (in the first year of life) per 1,000 births to a present level of fewer than 10 per 1,000 births (Mosley and Chen 1984). One consequence of a decline in the risk of infant and child deaths is to increase the sense of parental control over reproduction. It is more rational to develop notions of desired numbers of children when the survivorship of children is less random. Similarly, as survivorship improves, it is more rational to invest in children's future by providing them with formal education. The cost of children, to their parents and to the larger society, increases as child mortality falls and life expectancy improves (see, e.g., Easterlin 1976).

The increase in life expectancy, currently about 73 years in the developed countries, has also resulted in a rise in the mean age of the population, in a substantial increase in the proportion who are elderly or retired, and in a shift to causes of death associated with old age. These trends have broad social implications—for the employment of and advancement in opportunities for young people, the resilience of political structures, and the cost of retirement programs and medical care for the elderly, for example.

Fewer births per woman, together with the now negligible rates of maternal mortality in developed countries, have resulted in a substantially greater life expectancy for women than for men. Although at birth there are about 104 males for every 100 females, there are progressively more females, per male, for every age after about age 30 in the United States. The elderly population consists disproportionately of women. Also, because women tend to be younger than their husbands, they typically experience much longer periods of widowhood than men do.

In today's developing countries, mortality decline has been much more rapid than it was in the developed countries, because an accumulation of Western public health measures could be introduced nearly simultaneously. Most of the decline has occurred since World War II and the ensuing independence of most of these countries from colonial powers, although some of it can be traced back to earlier decades of the twentieth century. The rapidity of the mortality decline and its largely exogenous nature have been factors in the delay of a subsequent fertility decline in many cases (see

Preston 1978). (See the end of this article for relevant cross-references.)

FERTILITY DECLINE

Within Europe, the onset of substantial reductions in fertility occurred first in France early in the nineteenth century, and last in Ireland early in the twentieth century. In the earliest cases, the onset of fertility control coincided with mortality decline rather than following it. In general, a lag between the decline in mortality and the decline in fertility resulted in substantial population growth. In the United States and Britain, 1880 is regarded as a watershed year for the widespread initiation of contraception.

With no exceptions, from the cases of France through Ireland, the initiation and the bulk of the modern fertility declines occurred mainly as a result of contraception rather than delayed marriage, and in contexts in which contraception was publicly regarded as immoral, supplies and information were illegal, and methods were primitive by today's standards. As a generalization, births were not intentionally spaced or postponed; rather, attempts were made to terminate childbearing at some earlier parity than would have been the case without intervention. Some married couples appear even to have chosen to have no children or only one child. The main contraceptive method was withdrawal (*coitus interruptus*). Abstinence was probably not infrequently used as a last resort. Rhythm may have been used, but probably incorrectly; douching was common but was probably ineffective. Sterilization was not available, although it is likely that a high proportion of hysterectomies served the same function. Condoms were not widely available until the twentieth century.

It is clear that the motivation to control fertility was both powerful and personal. It is unfortunate that it is so difficult at this distance to reconstruct the specific strategies that were employed, patterns of communication between couples, and sources of information. However, at least two generalizations can be made. One is that the practice of contraception required an ideational justification, to the effect that individual couples have a personal right to control their family size. From a modern perspective it is easy to overlook the fundamental importance of this concept. It is not just a coincidence that France was the first country

to experience contraception on a wide scale, that it was the home of the Enlightenment, and that it was also the first European country to experience a fundamental political revolution. Intervention to prevent a birth rests on the premise that it is legitimate for an individual—or a couple—to make critical choices affecting personal welfare. Contraception can be viewed as a manifestation of a value for personal freedom, even in the face of strong pronatalist pressures from both church and state.

A secondary condition for contraceptive use in the West appears to have been some degree of local development, as evidenced by higher literacy and a higher standard of living. Historical research continues into the importance of specific factors such as the relative status of women, the transition to a wage-earning class, local industrialization, improvements in social security and public welfare, and so on. (For more details on specific countries, see, e.g., Ryder [1969]; Livi Bacci [1977]; Teitelbaum [1984]. For a general discussion of these factors in Europe, see van de Walle and Knodel [1980]. For theoretical discussions, see Caldwell [1976, 1978]. See also Nam [1994].)

Turning to the transition in economically less developed countries, one to two generations of reduced mortality, combined with a traditional high level of fertility, resulted in annual growth rates of 3 percent or more. However, beginning in the late 1960s, some Asian countries, particularly Taiwan and South Korea, began to experience rapid declines in fertility. At present these countries have reached approximate equilibrium between fertility and mortality rates, although they continue to grow because of their youthful age distributions. About a decade later, Thailand, Indonesia, and several Latin American countries such as Colombia and Mexico showed rapid reductions in their fertility rates. By the late 1990s, dramatic fertility declines were under way in nearly all countries outside of sub-Saharan Africa and Pakistan, and even these countries have shown clear declines among better-educated urban couples. The declines are due in small part to delayed marriage, but for the most part to use of contraception—primarily sterilization, and secondarily reversible methods such as intrauterine devices and the pill (see Bulatao and Lee [1983]; Cleland and Hobcraft [1985]; see also the country reports published on the Demographic and Health Surveys Project by Macro International [1985–2000]).

The conditions for these fertility declines show both similarities to and differences from the Western declines. It appears critical for couples to accept the idea that it is appropriate to intervene in the procreative process. In Pakistan, for example, it is commonly held that the number of births, as well as their gender and survivorship, is in the hands of Allah, and it would be wrong to interfere with his will. (It must be noted that a stated religious rationale for high fertility often masks other factors, such as a subordinate role for women. In other Islamic countries, such as Indonesia, Bangladesh, and even Iran, family planning is considered to be consistent with Islam.) Contraception tends to be found where the concepts of political and economic self-determination are better established, particularly among women. Female education is the single strongest correlate of fertility change.

In contrast with the Western experience, however, it also appears critical to have institutional support for contraception. The countries that have shown the clearest declines in fertility had national family planning programs with visible support from the highest levels of the government. The most effective programs have integrated family planning services into a general program of maternal and child health, and provide couples with easy access to a range of alternative methods (see Lapham and Mauldin 1987). Many countries are actually passing beyond this phase of the contraceptive transition, beginning in the 1990s, so that government-subsidized programs are being replaced by privatized services, at least for the middle class.

The consequences of population growth for economic development have been much debated (Simon 1977; Birdsall 1980). There have been some cases, such as Japan and South Korea, in which rapid economic expansion occurred simultaneously with rapid increases in population. Virtually all such cases were transitional, and the fertility of those countries is currently at replacement level, so the debate is now of mainly historical interest. There is a general consensus that low growth facilitates development. A growing population has a young age distribution, with many new entrants to the labor force and relatively few old people in need of pensions and health care. These factors may stimulate economic growth, but they must be balanced against the costs of supporting

and educating large numbers of children. In several countries, such as the Philippines, the economy is unable to employ large cohorts of young people satisfactorily, especially those who are better educated, and they emigrate in large numbers. In addition, household welfare can be adversely affected by large numbers of children, even in situations of economic expansion at the macro level. The negative consequences of rapid growth extend beyond the economy and into the areas of health, social welfare, political stability, and the environment. (See the end of this article for relevant cross-references.)

CHANGES IN POPULATION DISTRIBUTION

Enormous changes in geographical distribution have been superimposed on the major trends in population size described above. Many of the social problems attributed to rapid population growth are more accurately diagnosed as consequences of increasing concentration. Urban areas, in particular the megalopolises of developing countries such as Mexico City, Buenos Aires, and New Delhi, have been growing during the twentieth century at more than twice the rate of the countries in which they are located. Cities are centers of concentration of economic, intellectual, and political life (see Hawley 1981), but rapid growth has exacerbated the problems of inadequate housing, sanitation, transportation, schooling, unemployment, and the crime associated with urban life. It is estimated that, in the year 2000, 76 percent of the population of developed countries is urban (compared to 26 percent in 1900 and 55 percent in 1950). In the developing countries, 41 percent is urban in 2000 (compared to 7 percent in 1900 and 18 percent in 1950).

The growth of cities has resulted in part from the excess of births over deaths in rural areas. With out-migration serving as one of the household-level valves for population regulation, individuals have been displaced from areas that cannot absorb them and have moved to cities, which are perceived to have better economic opportunities. Often that perception is incorrect. With a few exceptions, fertility is lower in cities than in rural areas.

A second major type of population redistribution in recent centuries has, of course, been across

national borders. Movement to the Americas was greatest during the half-century between 1880 and 1930, and continues to the present. There are many streams of both short-term and long-term international migration, for example out of South and Southeast Asia and into the Middle East, Europe, and North America, and from Africa into Europe and North America, and the economies of several sending countries are strengthened by monthly remittances from their emigrants (United Nations 1979, 1997). (See the end of this article for relevant cross-references.)

POPULATION OF THE UNITED STATES

The United States has a population of approximately 278 million in the year 2000 and a growth rate of somewhat less than 1 percent annually, roughly one-third of which is due to immigration and two-thirds to natural increase. Fertility is slightly below replacement level, but there are more births than deaths because of the large size of the baby boom cohort, born from the late 1940s through the early 1960s. Age-specific fertility rates are increasing gradually for women in their thirties and forties, mainly because of postponed first and second births rather than later births. Otherwise, rates have been remarkably stable since the early 1970s. Rates below age 20 were dropping in the late 1990s but are still higher than in most other developed countries. For several excellent articles on fertility levels, differentials, and trends in the United States, see Casterline and colleagues (1996). See also National Center for Health Statistics (1999) and more recent annual reports in the same series.

Perhaps the most serious issues related to fertility are the large numbers of unplanned births to young women and the high numbers of abortions—about 2 for every 5 births—that could have been averted by contraception. Few developed countries have a range of contraceptive methods as limited as that of the United States. For example, intrauterine devices (IUDs) and progesterone-based pills are the two main nonsurgical methods in the rest of the world, but IUDs are not available in the United States. As mentioned earlier, most of the fertility decline in the West occurred while contraception was considered immoral and was explicitly illegal. Although contraception and even abortion are now legal, deep cultural ambiguities

remain in the linkage between sexuality and procreation. A litigious environment has inhibited both the development of new contraceptives by American pharmaceutical companies and the marketing of new contraceptives developed elsewhere, and the U.S. government plays a minimal role in such development.

Life expectancy in the late 1990s was 73 years for males and 79 years for females (PRB 1998). Although life expectancy is increasing for both males and females, the female advantage is also gradually increasing. The female advantage was nearly 3 years at the beginning of the twentieth century, nearly 4 years at the middle, and nearly 7 years at the end of the century (Gelbard et al. 1999). The greatest improvements in mortality are in the highest age groups, especially after age 85. Because of increases in the number of elderly and projected changes in the age distribution of the labor force, the age at receipt of full Social Security benefits is scheduled to increase gradually, from 65 to 66 by the year 2009 and to 67 by the year 2027 (Binstock and George 1990).

Among males, whites have approximately a 5-year advantage over nonwhites, and among females, whites have approximately a 4-year advantage (National Center for Health Statistics 1989; and more recent annual reports in the same series). Life expectancy for black males is falling, due mainly to deaths by homicides to black males in their twenties and a greater prevalence of cardiovascular disease among blacks (Keith and Smith 1988). Infant mortality rates for nonwhite babies are increasing, due to low birth weights and inadequate prenatal care. These reversals of earlier long-term improvements are indicators of worsening conditions among poorer Americans. (For more description of the population of the United States, see Bogue [1985]; Lieberman and Waters [1988]; Sweet and Bumpass [1988]; Nam [1994].) (See the end of this article for cross-references to articles containing more discussions of the population of the United States.)

FUTURE POPULATION

The overriding concern of world population policy in recent years has been the achievement of a new equilibrium between fertility and mortality,

so that growth will be slowed or stopped. Sometimes this policy is stated in terms of enabling couples to have the number of children they want to have, and no more, because surveys in most developing countries indicate that couples desire smaller families than they actually have (see the country reports published by Macro International [1985–2000]).

The concept of *replacement fertility* is important for understanding population projections. Normally stated in terms of the female population, the reproductive value of a woman of a given age is equal to the number of daughters she will have who will survive to (at least) this same age. If the average reproductive value is exactly 1, then fertility is at replacement level. This occurs when the average woman has about 2.1 births in her lifetime (a little above 2.0, to compensate for children who do not survive). If there has been a history of higher fertility, then the population has been growing and is relatively young, with many women in the peak ages of childbearing. As a result, there can continue to be more births than deaths (i.e., population growth) for a very long time after the net reproduction rate has reached or even fallen below the replacement value of 1.0. However, in the long term, replacement fertility will lead to a no-growth population, and below-replacement fertility will lead to population decline.

Strictly speaking, reproduction is intergenerational, but it is estimated with the net reproduction rate, a synthetic measure calculated from age-specific fertility and survival rates within an interval of time such as one year. If an artificial cohort of women is subjected to these rates and does not replace itself, then current fertility is interpreted to be below replacement.

Projected improvements in mortality would have a relatively low impact on population growth. For reproduction, it is survivorship up to and through the childbearing ages that matters. Improvements in survivorship after age 45 or so have little impact. Projections do require some assumptions about the future of the human immunodeficiency virus (HIV) and acquired immune deficiency syndrome (AIDS) epidemic, primarily in sub-Saharan Africa and also in South and Southeast Asia.

In the year 2000, world population is estimated to be 6.1 billion, with a growth rate of about 1.8

percent annually. If the current rate were to continue, world population would reach 9.2 billion by the year 2025. Even if reproduction immediately came into balance with mortality, as just described, world population would continue to increase. Population momentum, due to the youthful age distribution, would produce an excess of births over deaths (i.e., growth) for more than a century. World population would reach 7.5 billion by 2025, eventually stabilizing at nearly 10 billion. Substantial future growth is inevitable, but there is a wide range of possible scenarios.

Projections developed by the United Nations (United Nations 1998) for the year 2025 range from a low variant of 7.3 billion to a medium variant of 7.8 billion and a high variant of 8.4 billion, depending on assumptions about future mortality and (more important) future fertility. By comparison, ten years earlier (United Nations 1988) the *low* projection for 2025 was 8.5 billion, slightly above the current *high* projection. This substantial downward revision reflects a general optimism that the threat of a world population explosion has largely receded. (It also implies that little credibility should be attached to longer-term projections, and for that reason this article will not cite projections beyond 2025.)

All the current projection scenarios assume that fertility will decline. The lowest estimate is based on an assumption that it will decline to below-replacement levels very soon, after 2005, and will decline steadily thereafter. This assumption is highly improbable, but even the medium variant assumes that worldwide fertility will be below replacement by 2030. This is a remarkable change from earlier projections, because prior to the late 1990s almost all scenarios assumed that fertility would ultimately converge to replacement level, with uncertainty only about when that would occur. Now that better data are available on actual changes during the 1980s and 1990s, it is considered likely that fertility will fall *below* replacement level early in the twenty-first century.

The net reproduction rate is currently less than 1.0 (that is, fertility is below the long-term level needed to balance mortality) in virtually all the more developed countries. The one-fifth of the world's population that resides in those countries will increase scarcely at all, and much of that growth will be the result of immigration from

developing countries. Around the year 2000, compared to a standard of replacement fertility, Europe is at 68 percent of replacement level and North America is at 93 percent, while Asia is 10 percent above replacement, Latin America is 20 percent above, and Africa is 84 percent above. (These percentages come from estimates and medium-variant projections for 2000 by the United Nations [1998].) It is projected that low growth in Europe will cause the median age to rise to the mid-forties by 2025, with a fifth of the population above 65 years of age, a situation that the United States will approach a few years later. An excellent discussion of the causes and effects of future population change, and of many of the other topics in this article, can be found in Gelbard and colleagues, Haub, and Kent (1999).

Although world growth has been the preoccupation of recent decades, the possibility of population decline has long been acknowledged in Europe. In the United States, fertility has been below replacement since approximately 1970, and if it were not for high levels of immigration, this country would also face the prospect of population decline. Policies directed at increasing fertility in European countries have met with little success (see Calot and Blayo 1982; van de Kaa 1987). In urban settings with a high standard of living, children lose much of their earlier value as a source of economic activity, household wealth, and security in old age. They become increasingly expensive in terms of direct costs such as clothing, housing, and education, and in terms of opportunity costs such as forgone labor force activity by the mother.

In brief, there are probably two main reasons why fertility has not declined even further in the developed countries. One is the adherence to a powerful norm for two children that was consolidated around the middle of the twentieth century. Surveys show an overwhelming preference for exactly two children—preferably one boy and one girl, especially in the United States—with little flexibility either above or below that number. Actual childbearing often departs from the norm, more commonly by being below two children, so that fertility is below replacement. A high proportion of childbearing beyond two children is due to a desire for at least one child of each sex. Reliable methods to achieve the desired sex composition would result in a noticeable reduction of third and later births.

Second, children provide parents with a primary social group. There is no longer an expectation that they will provide support in old age, nor an important concern with carrying on the family name, but children do provide psychic and social rewards. To bear children is to emulate the behavior of one's parents and to replicate the family of orientation. However, this goal can be largely attained with only one child, as is being demonstrated in the lowest-fertility countries of Europe and in urban China. As increasing numbers of women opt for no children or only one child, it is possible that the widespread preference for two will weaken, even in the United States. For further discussion of fertility preferences in the United States, see Schoen and colleagues (1997).

Although the world as a whole is far from experiencing a decline in population, the low reproductivity of some countries and subpopulations raises questions about future mechanisms for restraining an indefinite decline in fertility, and eventually in population (see Teitelbaum and Winter 1985; Davis et al. 1986). It is reasonable to speculate on whether the cultural and social props for replacement fertility will continue to hold, or whether, as in the low and medium UN projections, worldwide fertility will decline to below-replacement levels early in the twenty-first century.

Major reductions in fertility in the past have been the result of delayed marriage and contraception and have been motivated at the level of the household. Maintenance of equilibrium in the future will require an increase in desired family size and less use of contraception. Many household-level factors associated with economic development would seem to support a projection of continued decline in fertility—for example, increased labor-force participation and autonomy for women, declines in marriage rates, increased costs for the education of children, and increased emphasis on consumption and leisure. It is easier to project a continued decline in fertility, rather than a significant upturn, in the absence of major changes or interventions in the microeconomy of the household. However, it also seems plausible that children will take on an increased (noneconomic) value as they become scarcer, or that subpopulations that favor high fertility will come to dominate, in which case the world will return to the previous pattern of long-term homeostasis at some level, or

will establish a new pattern of very gradual growth, rather than allowing an inexorable decline.

THOMAS W. PULLUM

PORNOGRAPHY

Most societies have some kinds of sexually explicit words, images, and other materials that are disapproved, prohibited, illegal, or restricted in circulation; that are portrayed in a manner that is generally unacceptable; and that are classified as pornography. The term *pornography* often denotes subjective disapproval of materials rather than their content or effect.

Historically, attitudes toward pornography tend to be cyclical. The most recent expansion in the United States of the availability of such materials began in the 1960s, as a result of larger social trends, including the civil rights movement, the counterculture and antiwar movement, approval of the contraceptive pill, and liberal U.S. Supreme Court decisions providing access to previously banned novels and films. These trends contributed to continuing discussion on whether new forms of social control would be necessary to cope with pornography, and federal government investigations into pornography's impact were launched in 1968 and 1985.

Both the President's Commission on Obscenity and Pornography (1971) and the Attorney General's Commission on Obscenity and Pornography (1986) felt that it was not possible to define pornography clearly. The term has no legal definition, although certain sexual content is not protected by the free speech guarantees of the First Amendment to the U.S. Constitution and can be prosecuted under federal and state laws regulating obscenity.

Over the last several decades, the connotations of pornography have changed from a generic descriptor of explicit sexual content to more pejorative representations of sexual material. Pornography is often distinguished from erotica, which is

a more tender, humanistic, and artistic type of sexual representation.

The divergence in opinion on how to deal with the pornography problem could be seen in the different recommendations of the two federal commissions established to examine it. The President's Commission recommended that the laws on obscenity should be repealed, because the material represented an insignificant social problem and had no lasting negative effect on its users. The report of the Attorney General's Commission urged that the obscenity laws should be strictly enforced, because the material had significant negative impact and constituted an important national problem. One possible reason for this disagreement was the change in the market for explicit materials between 1970 and 1986, but another factor could have been differences in the time available, composition, and resources of the two commissions.

Because sexually explicit content is often initially excluded from mainstream channels of communication, its creators have usually been alert to newly emerging outlets for distribution. One of the first books to appear in print after Gutenberg developed printing around 1448 was Boccaccio's erotic masterpiece, *The Decameron*. Soon after Edison developed moving pictures in 1891, underground "blue" movies began to appear. Super 8mm movies presenting sexually explicit content could be found in 1970, the very first year that the new technology appeared.

In the 1980s, soon after deregulation of the telephone business, many sex telephone services offered both recorded messages and the opportunity to have individualized "audiotext" conversations. Around the same time, sexually explicit movies became available via pay-per-view cable systems servicing homes and hotel chains.

In 1979, when fewer than 1 percent of American homes had videocassette recorders (VCRs), 80 percent of VCR owners bought or rented sexually explicit tapes. Some stores boosted sales of VCRs by giving a sexually explicit videotape as a gift with every purchase. During the 1990s, perhaps one-third of adult males and one-fifth of adult females have seen a sexually explicit videotape in a given year. The VCR is especially popular for viewing sexual content because it permits the user to speed up, slow down, replay, or freeze images. America is

the world's largest producer of sexually explicit videotapes, churning out approximately 7,500 per year. The huge growth in the explicit video market during the 1980s and 1990s paralleled an increase in the number of large strip clubs around the country. The videos have become a way of promoting the careers of the actresses who appear at the clubs, who also can be seen in men's magazines.

CD-ROM and Internet income from sex-related content cannot be accurately measured but is believed to be enormous. A series of U.S. Supreme Court decisions has established the Internet as a public forum that is entitled to the highest level of protection by the First Amendment, including the representation of sexually explicit materials. Several laws that restricted access of children to the Internet have been declared unconstitutional by federal courts.

Rating systems represent one approach to social control of sexual content. The 1968 original movie rating system, by assigning sexually explicit materials to a special Adult X category and the development of similar kinds of ratings for television programs and popular music, further helped legitimate sexual content.

Within several years after the movie rating system began, X-rated films began to be shown at major theaters. The X-rated *Last Tango in Paris*, starring Marlon Brando, the country's most celebrated actor, was one of the most popular films of 1973, the same year in which *Deep Throat* became a national sensation because of its enormous commercial success and humor. The X-rated *Midnight Cowboy* had already received an Academy Award as Best Picture in 1969.

In addition to ratings, technological approaches have been used as a way of regulating children's access to sexual content. A special chip was developed so that parents could block children's access to objectionable materials on television. Such approaches attempt to strike a balance between the American abhorrence of censorship and parents' concern about their children's exposure to inappropriate material.

The ultimate weapon in blocking the availability of offensive sexual material has always been the application of the laws against obscenity. Three

criteria for obscenity were promulgated by the U.S. Supreme Court in the case of *Miller v. California* (413 U.S. 15, 1973): the material had to be patently offensive; it must appeal to the prurient interest of the average adult applying contemporary standards; and it must have no literary, artistic, political, or scientific value.

Because the Court no longer wanted to deal with the stream of cases that it had been handling, "community" was newly defined to be a local county, state, or federal court district, so that each area could have whatever level of sexual material it found acceptable. The number of indictments and convictions declined after 1973 because of juries' reluctance to convict, prosecutorial predictability, changes in the political climate that led to antipornography becoming a less salient and less attractive political theme, and communities' views that criminal justice resources should give less attention to obscenity and focus more on crimes against persons.

The decline in implementation of criminal justice sanctions encouraged new entrepreneurs to produce and distribute sex-oriented materials. Another spur to entrepreneurs, in the 1980s, was the Federal Communications Commission's decision not to regulate cable television, and this was followed in 1984 by the television networks' decision to eliminate their national code of broadcast standards. The continuing competition for audiences between media further increased the likelihood that sexual content would receive more prominence, in a situation in which administrative barriers to representation of sex content were clearly diminishing.

Instead of criminal prosecution of materials for violation of the obscenity laws, a number of cities adopted a totally different approach in the 1990s. These communities use zoning laws against theaters, strip clubs, bookstores, and other sex-related industries in order to break up their concentration and minimize visual pollution. The new approach accepted these establishments' right to sell sexually explicit products or services but challenged their right to maintain their location.

The zoning laws rely on a U.S. Supreme Court decision which held that if "adult" businesses could be shown to have adverse secondary effects

(decline in real estate values and quality of life and increase in crime), the community could make zoning changes, provided that reasonable alternative avenues of communication were available to the businesses (*Playtime Theatres v. City of Renton*, 106 U.S. 925, 1986).

An example of the zoning approach could be seen in New York City where a 1997 law required that "adult" bookstores, strip clubs, peepshows, and theaters be at least 500 feet from each other and at least 500 feet from residences and public buildings, thus eliminating the concentration of such establishments in Times Square. Any challenges to such zoning changes have been handled in the civil rather than the criminal courts.

One way in which producers of these materials attempt to minimize legal problems is to make publications, movies, and videotapes in both hard-core and soft-core versions, for targeted distribution to specific markets. The hard-core materials usually show some form of actual sexual interaction and the soft-core content generally presents simulated interaction. Any representation of sexual material involving children has been the target of intensive law enforcement and is very scarce.

There seems to be no relationship between sexually explicit materials and prostitution; consumers of these materials are not likely to be customers of prostitutes, because of differences in the gratifications provided by the two activities. There also seems to be no significant relationship between the production and distribution of such materials and organized crime. There are now so many producers and distributors and the prices are so competitively low that organized crime groups cannot make a large enough profit to justify participation in the business.

Although there is no unified and consistent feminist attitude toward pornography, feminist opposition to pornography has generated much attention. One sustained feminist attack on pornography, jointly led by writer Andrea Dworkin and attorney Catherine A. MacKinnon, argued that pornography is misogynistic and dehumanizing, graphically presenting the sexually explicit subordination of women. They developed a model ordinance for Indianapolis that represented a civil rights approach, which identified pornography as

a violation of the equality guarantee of the Fourteenth Amendment. However, the ordinance was found to be unconstitutional by a federal appeals court (*American Booksellers Association v. Hudnut*, 771 F. 2d, 7th Circuit, 1985). A comparable approach was upheld by the highest court in Canada (*Butler v. The Queen*, 1 SCR 452, 199, 1992), where it has been primarily used to prosecute gay publications.

A collateral approach involved dissemination of feminist writer Robin Morgan's slogan, "Pornography is the theory, rape is the practice." Around the same time that feminist theorists were arguing that the growing availability of misogynistic pornography was the direct cause of increasing rates of rape, a number of mass communication researchers conducted laboratory experiments that attempted to prove the connection between exposure to such materials and the development of callous attitudes toward women and rape. One of the problems with these studies is that they were usually conducted with college students, who were exposed to materials that they would not ordinarily see. There is also the possibility of an experimenter effect and the difficulty of proving the carrying over of an attitude from viewing a film to a real rape situation. Several researchers have expressed the view that to interpret their largely laboratory-based studies as confirming a causal nexus between exposure to sexually explicit films and subsequent sexually violent behavior would represent overgeneralization.

Another problem in arguing for such a nexus is that no large-scale content studies prove that there has been any increase in the amount of sexual violence in the media. An examination of the available data suggests that there has been a decline since 1977 in the amount of sexual violence in the media, but there has probably been an increase in violence in nonpornographic fare, such as action, slasher, and horror films. To single out pornography for stringent legal action and to ignore ideas about rape and violence that are otherwise so pervasive in our culture is not justified by the available evidence.

A number of natural experiments have provided information on the possible relationship between media sex content and rape and other sex crimes. In the United States, four states that eliminated all obscenity statutes and had a concomitant

increase in the availability of sexually explicit materials for varying periods between 1973 and 1986 were studied. During the period of obscenity nonprosecution, the mean annual arrest rates for sex offenses in these four states declined significantly in comparison to the other forty-six states. A study of the first three countries to legalize sexually explicit materials (Denmark, Sweden, Germany) concluded that legalization did not lead to increased sexual violence in any of them.

Researchers using other indirect measures have similarly attempted to correlate sex offenses with previous exposure to sexually explicit materials. A large-scale study by the Kinsey Institute for Sex Research of convicted sex offenders found no relation between sex crimes and offenders' exposure to such materials. Another study of nonincarcerated sex offenders reported no significant differences between the exposure to such materials of the offenders and the general adult male population. Whether on an individual, a regional, or a national basis, empirical studies have failed to find any consistent correlation between availability of and exposure to explicit materials and sex crimes against women.

A number of producers are actively distributing sexually explicit materials targeted for women consumers, and other producers have developed such materials for feminist audiences. Some feminists have produced their own explicit films and others have made videotapes for women and couples that are sold in mainstream superstores and direct mail catalogs. A number of performers who became known from appearing in explicit movies and tapes are obtaining roles in mainstream studio or independent films.

Research has identified a number of functions served by sexually explicit materials. They provide information that is not otherwise available, as well as fantasy outlets and sexual stimulation. They also provide reassurance about one's body and about shame or guilt relating to specific practices. The materials can desensitize people so that they are better able to consider and discuss sexual matters, and can facilitate communication between sexual partners. The materials may provide a socially acceptable functional equivalent for masturbation and for acting out otherwise socially harmful sexual behavior. For members of a group audience, as

in a strip club or a movie theater, the social context can reinforce the experience. The materials and performers also may provide a vehicle for connoisseurship.

Plausible next steps in sociological investigations of pornography could include cross-media content analyses, naturalistic studies of effects, systematic case studies of the role of the various interest groups involved in promoting or blocking pornography, investigation of the structure of the pornography industry, and studies of the role of the home environment in contributing to how explicit materials are used.

In Denmark, the first country to legalize pornography (1969), the market for such materials declined sharply, as a result of satiation of the audience. Tracking the cycle of acceptance of pornography in America, to see whether the Danish experience is relevant, could represent an important study. A collateral study could determine whether there are specific subgroups in the population for whom these materials are becoming more or less important. The extent to which pornography continues to be a feature of the political culture wars and a vehicle for obtaining support for larger economic and policy initiatives represents an important social indicator, as is the alliance between feminists and moral conservatives in opposing pornography. Another activity that will surely bear watching in the future is how the effort to regulate pornography on the Internet, for children or adults, can be accomplished by a state or a country that does not have legal jurisdiction over the global information network that is the Internet.

POSITIVE MENTAL HEALTH

The concept of positive mental health was developed by Marie Jahoda, who argues that positive mental health can be viewed as an enduring personality characteristic or as a less permanent function of personality and the social situation (Jahoda 1958). This article summarizes Jahoda's approach to positive mental health, reviews other discussions of the concept, describes a challenge to the assumption that positive mental health requires the accurate perception of reality, examines the value assumptions inherent in the concept, and compares the notions of normality and positive mental health.

In her classic book, *Current Concepts of Positive Mental Health* (1958), Jahoda identified the following six approaches to the definition of positive mental health, which are described in detail below: (1) attitude toward own self; (2) growth, development, and self-actualization; (3) integration; (4) autonomy; (5) perception of reality; and (6) environmental mastery.

1. Acceptance of self, self-confidence, and self-reliance characterize the mentally healthy person. An important attribute of positive mental health includes the understanding of one's strengths and weaknesses, coupled with the conviction that one's positive characteristics outweigh the negative traits. Independence, initiative, and self-esteem are other indicators of positive mental health.

2. The realization of one's potential is the underlying assumption of this dimension of positive mental health. Maslow (1954) explains that

self-actualization is a motive that encourages the person to maximize capabilities and talents. It is hypothesized that growth motivation is related to positive mental health. Rather than meeting basic human needs, self-actualization implies movement toward higher goals. This dimension of positive mental health also implies an investment in living—a concern with other people and one’s environment, rather than a primary focus on satisfying one’s own needs.

3. The person with positive mental health has a balance of psychic forces, a unified outlook on life, and resistance to stress. Psychoanalysts view integration as the balance of the id, the ego, and the superego. This balance is viewed as changeable, with flexibility as the desired end result. Positive mental health refers to integration at the cognitive level, which implies a unifying philosophy of life that shapes feelings and behaviors. Finally, resistance to stress characterizes the integrated person. The mentally healthy person can adapt to stress without deteriorating. Everyone experiences anxiety when encountering a stressful situation. A mentally healthy response to anxiety and stress suggests some tolerance of tension, ambiguity, and frustration.

4. Autonomy refers to self-determination and independence in decision making. The concept suggests that the person with positive mental health is self-directed and self-controlled. The individual acts independently of the outside world; behavior is not dictated by environmental circumstances.

Jahoda points out that some authors have a different interpretation of autonomy. Autonomy may be defined as having freedom of choice about conforming to societal norms. This perspective implies that the person is not independent of the environment, but does have free choice to decide how to respond to societal demands.

5. “As a rule, the perception of reality is called mentally healthy when what the individual sees corresponds to what is actually there” (Jahoda 1958, p. 49). Mentally healthy reality perception includes perception free from need distortion. A mentally healthy person views the world without distortions, fitting the perception to objective cues that are present, and does not reject evidence because it does not fit his or her wishes or needs.

Jahoda argues that this dimension of positive mental health implies the ability to perceive others in an empathetic manner. This social sensitivity enables a healthy person to put himself or herself in another person’s place and anticipate that person’s behavior in a given social situation.

6. Mastery of the environment refers to achieving success in some social roles and appropriate function in those roles. Positive mental health also includes the ability to have positive affective interpersonal relations. The social roles involved in environmental mastery may include sexual partner, parent, and worker. Environmental mastery suggests the ability to adapt, adjust, and solve problems in an efficient manner.

OTHER DEFINITIONS OF POSITIVE MENTAL HEALTH

Jourard and Landsman propose similar criteria for positive mental health: positive self-regard, ability to care about others, ability to care about the natural world, openness to new ideas and to people, creativity, ability to work productively, ability to love, and realistic perception of self (1980, p. 131).

Jensen and Bergin (1988) conducted a nationwide survey of 425 professional therapists (clinical psychologists, marriage and family therapists, social workers, and psychiatrists) to determine values associated with mental health. Eight themes were identified as important for a positive, mentally healthy lifestyle: (1) competent perception and expression of feelings (sensitivity, honesty, openness with others); (2) freedom/autonomy/responsibility (self-control, appropriate feelings of guilt, responsibility for one’s actions, increasing one’s alternatives at a choice point); (3) integration, coping, and work (effective coping strategies, work satisfaction, striving to achieve); (4) self-awareness/growth (awareness of potential, self-discipline); (5) human relatedness/interpersonal and family commitment (ability to give and receive affection, faithfulness in marriage, commitment to family needs, self-sacrifice); (6) self-maintenance/physical fitness (healthful habits, self-discipline in use of alcohol, drugs, tobacco); (7) mature values (purpose for living, having principles and ideals); and (8) forgiveness (making restitution, forgiving

others) (Jensen and Bergin 1988, p. 292). They found a high level of consensus among the practitioners. Many of these values are consistent with the six approaches identified by Jahoda in 1958.

ILLUSIONS AND POSITIVE MENTAL HEALTH

The validity of one of the components of positive mental health has been questioned (Snyder 1989). Is accurate reality perception the hallmark of positive mental health? Taylor and Brown argue that "certain illusions may be adaptive for mental health and well being" (1988, p. 193). They explain that mentally healthy persons have an unrealistic positive self-evaluation. Normal individuals are more aware of their strengths and less aware of their weaknesses, perceiving themselves as better than the average person and viewing themselves more positively than others see them.

Another illusion held by mentally healthy persons is an exaggerated sense of self-control. Taylor and Brown (1988) cite evidence that depressed individuals are more likely to have realistic perceptions of personal control than are nondepressed persons. Positive illusions of personal control over the environment, self-worth, and hopefulness about the future imply mental health, and these illusions enable people to function in an adaptive manner.

According to Taylor and Brown (1988), illusions can promote several criteria of mental health, including happiness or contentment, the ability to care for others, and the capacity for intellectually creative and productive work. While mentally healthy people learn from negative experiences, their illusions help them to cope with stresses and strains (Taylor et al. 1989).

Taylor and Brown conclude, "the mentally healthy person appears to have the enviable capacity to distort reality in a direction that enhances self-esteem, maintains beliefs in personal efficacy, and promotes an optimistic view of the future" (1988, p. 204).

THE ROLE OF UNDERLYING VALUE ASSUMPTIONS

Jahoda (1980) argues that the definition of positive mental health depends upon underlying value

assumptions. Schwartz and Link explain, "What is viewed as good and functional is often dependent on who is doing the viewing and what value hierarchy is being applied" (1991, p. 240). The definition of positive mental health varies across societies. In addition, there may be variance across social groups within one society (e.g., social class, gender, race, and ethnicity). It is also the case that the definition of positive mental health may be a function of the situation.

Different societies have their own definition of positive mental health. In some societies, a mentally healthy individual is supposed to be autonomous, while in other societies, the mentally healthy person is expected to be compliant, conforming to particular rules imposed by others.

Variance across social groups within one society is illustrated by evidence that there are different standards of positive mental health for men and women. Broverman et al. (1981) report sex role stereotypes in the clinical judgments of mental health among seventy-nine psychotherapists. The therapists were asked to identify the characteristics that portrayed healthy, mature, and socially competent adults. Broverman et al. found "that healthy women differ from healthy men by being more submissive; less independent; less adventurous; more easily influenced; less aggressive; less competitive" (1981, p. 92).

The definition of positive mental health is situational. While a particular behavior is mentally healthy in one situation, it may represent mentally ill behavior in another situation. For example, behavior in a life-threatening situation may be defined as adaptive, given the stresses of the environment. In normal everyday life the same behavior may be defined as bizarre. This observation leads Foote and Cottrell to ask, "What are the psychologically relevant attributes of an environment which permit the manifestations of psychologically healthy behavior?" (1959, p. 44).

Finally, according to Jahoda (1988), the definition of positive mental health is also influenced by the following four assumptions: (1) the criteria for judging health and illness are debatable; (2) neither mental illness nor mental health can be defined by the absence of the other; (3) there are degrees of mental health; and (4) a low level of mental health is not synonymous with mental illness.

NORMALITY OR POSITIVE MENTAL HEALTH?

There is continued debate on the definition of and relationship between normality and positive mental health. There is general agreement among researchers who study normatology that the definition of psychopathology is more precise than the definition of normal behavior (Offer and Sabshin 1991; Strack and Lorr 1997). While psychiatrists have developed sets of very specific criteria for defining mental illness (American Psychiatric Association 1994), there are no set criteria for defining either normal behavior or positive mental health. As is the case for the definition of positive mental health, the determination of normality varies across societies, subgroups within one society, and situations. What is normal (or positive mental health) in one time and place is abnormal (or mentally ill) in another. Both concepts are fluid in nature. Additional research is needed to understand how the definitions of positive mental health and normality are created. What are the underlying assumptions of these definitions, and how do they vary across societies and situations?

While normality implies the absence of psychopathology, positive mental health goes *beyond* normality. Researchers agree that positive mental health is more than the absence of mental illness; it represents the enhancement of human potential. Although a person may not have symptoms of mental illness, he or she may not have positive mental health, especially in the absence of self-confidence, self-actualization, integration, autonomy, reality perception, and environmental mastery. To have positive mental health implies fulfilling one's potential to the fullest. One might argue that positive mental health is a moving target, representing goals that are established, evaluated, and then revised as a person's circumstance change. The concept of positive mental health is utopian. While many strive to achieve positive mental health, only a few fulfill the goal of maximizing their potential.

JANET HANKIN

POSITIVISM

The concept of “positivism” was originally used to denote the scientific study of social phenomena, but today the term *positivism* has become vague. Most often, it is used as a pejorative smear for certain kinds of intellectual activity in the social sciences, sociology in particular. Most frequently, at least within sociology, positivism is associated with such undesirable states as “raw empiricism,” “mindless quantification,” “antihumanism,” “legitimation of the status quo,” and “scientific pretentiousness.” With few exceptions (e.g., Turner 1985), sociologists are unwilling to label themselves “positivists.” Yet, the titular founder of sociology—Auguste Comte—used this label as a rallying cry for developing formal and abstract theory that could still be used to remake society; so, the current use of the term does not correspond to its original meaning. If anything, the term connotes almost the exact opposite of Comte’s vision (1830–1842). It is proper, therefore, to review Comte’s original conception of positivism and its use in early sociology, and then we can discover how and why the meaning of positivism changed.

In *Cours de philosophie positive*, Comte began by asserting that “the first characteristic of Positive Philosophy is that it regards all phenomena as subject to natural *Laws*” (1830–1842, p. 5). Moreover, he emphasized that “research into what are called *causes*, whether first or final,” is “in vain” (1830–1842, p. 6); and by the time he was well into *Cours de philosophie positive*, he stressed that a “great hindrance to the use of observation is the empiricism which is introduced into it by those who . . . would interdict the use of any theory whatever” because “no real observation of any kind of phenomena is possible, except in as far as it is first directed, and finally interpreted, by some theory” (1830–1842, p. 242). Rather, the goal of positivistic sociology is to “pursue an accurate discovery of . . . Laws, with a view to reducing them to the smallest possible number,” and “our real business is to analyze accurately the circumstance of phenomena, to connote them by natural relations of succession and resemblance” (1830–1842, p. 6). Comte’s exemplar for this advocacy was Newton’s law of gravitation, an affirmation of his early preference to label sociology as “social physics.” Moreover, such laws were to be used to

reconstruct society; and while Comte went off the deep end on this point, proclaiming himself, late in his career, to be the “high priest of humanity” (Comte 1851–1854), it is difficult to see Comte’s positivism as antihumanistic, as conservative, or as legitimating the status quo.

How, then, did Comte get turned on his head? The answer to this question cannot be found in nineteenth-century sociology, for the most positivistic sociologists of this period—Herbert Spencer (1874–1896) and Émile Durkheim ([1893] 1947; [1895] 1934)—could hardly be accused of “raw” and “mindless” empiricism, nor could they in the context of their times be considered antihumanistic, conservative, and apologists for the status quo (the label “conservative” for these thinkers is imposed retrospectively, through the refraction of contemporary eyeglasses). Moreover, early American sociologists—Albion Small, Frank Lester Ward, Robert Park, William Graham Sumner, and even the father of statistical methods and empiricism in American sociology, Franklin Giddings—all advocated Comtean and Spencerian positivism before World War I. Thus, the answer to this question is to be found in the natural sciences, particularly in a group of scientist-philosophers who are sometimes grouped under the rubric “the Vienna Circle,” despite the fact that several intellectual generations of very different thinkers were part of this circle.

Before the “circle” was evident, the nature of the issues was anticipated by Ernst Mach (1893), who argued that the best theory employs a minimum of variables and does not speculate on unobservable processes and forces. Mach emphasized reliance on immediate sense data, rejecting all speculation about causes and mechanisms to explain observed relations among variables. Indeed, he rejected all conceptions of the universe as being regulated by “natural laws” and insisted that theory represent mathematical descriptions of relations among observable variables. Although Mach was not a member of the Vienna Circle, his ideas framed the issues for those who are more closely identified with this group. Yet, his ideas did not dictate their resolution. Many in the Vienna Circle were concerned primarily with logic and systems of formal thought, almost to the exclusion of observation (or, at least, to the point of subordinating it to their primary concerns). A split thus developed in the Vienna Circle over the relative

emphasis on empirical observation and systems of logic; a radical faction emphasized that truth can be “measured solely by logical coherence of statements” (which had been reduced to mathematics), whereas a more moderate group insisted that there is a “material truth of observation” supplementing “formal truths” (Johnston 1983, p. 189). Karl Popper, who was a somewhat marginal figure in the Vienna Circle of the 1930s, is perhaps the best-known mediator of this split, for he clearly tried to keep the two points of emphasis together. But even here the reconciliation is somewhat negative (Popper 1959, 1969): A formal theory can never be proved, only disproved; and so, data are to be used to mount assaults on abstract theories from which empirical hypotheses and predictions are formally “deduced.”

Why did the philosopher-scientists in the Vienna Circle have any impact on sociology, especially American sociology? In Europe, of course, sociology had always been firmly anchored in philosophy, but in American sociology during the 1920s and 1930s, the rise of quantitative sociology was accelerating as the students of Franklin Giddings assumed key positions in academia and as Comtean and Spencerian sociology became a distant memory. (It should be noted, however, that Marx, Weber, and Durkheim had yet to have much impact on American sociology in the late 1920s or early 1930s.) But American sociology was concerned with its status as science and, hence, was receptive to philosophical arguments that could legitimate its scientific aspirations (Turner and Turner 1990). Mach was appealing because his advocacy legitimated statistical analysis of empirical regularities as variables; and Popper was to win converts with his uneasy reconciliation of observation and abstract theory. Both legitimated variable analyses; and for American sociologists in the 1930s and later from the 1940s through the early 1960s, this meant sampling, scaling, statistically aggregating, and analyzing empirical “observations.” Members of the Vienna circle had even developed an appealing terminology, *logical positivism*, to describe this relation between theory (abstract statements organized by a formal calculus) and research (quantitative data for testing hypotheses logically deduced from abstract statements). The wartime migration of key figures in the late Vienna Circle to the United States no doubt increased their impact on the social sciences in the United States (despite the

fact that the “logical” part of this new label for “positivism” was redundant in Comte’s original formulation). But logical positivism legitimated American empiricism in this sense: The quantitative data could be used to “test” theories, and so it was important to improve upon methods of gathering data and analyzing methodologies in order to realize this lofty goal. Along the way, the connection of theory and research was mysteriously lost, and positivism became increasingly associated with empiricism and quantification, *per se*.

There was a brief and highly visible effort, reaching a peak in the late 1960s and early 1970s, to revive the “logical” side of positivism by explaining to sociologists the process of “theory construction.” Indeed, numerous texts on theory construction were produced (e.g., Zetterberg 1965; Dubin 1969; Blalock 1969; Reynolds 1971; Gibbs 1972; Hage 1972), but the somewhat mechanical, cookbook quality of these texts won few converts, and so the empiricist connotations of positivism were never successfully reconnected to abstract theory. Even the rather odd academic alliance of functional theory with quantitative sociology—for example, Merton and Lazarsfeld at Columbia and Parsons and Stouffer at Harvard—was unsuccessful in merging theory and research, once again leaving positivism to denote quantitative research divorced from theory.

Other intellectual events, anticipated by various figures of the Vienna Circle, created a new skepticism and cynicism about the capacity to develop “objective” science, especially social science. This skepticism stressed the arbitrary nature of symbols and signs and hence their capacity to represent and denote the universe independently of the context in which such signs are produced and used. Such thinking was supplemented by Kuhn’s landmark work (1970) and by the sociology of science’s emphasis (e.g., Whitley 1984) on the politico-organizational dynamics distorting the idealized theory-data connection as advocated by Popper (1969). Out of all this ferment, a new label increasingly began to appear: *postpositivism*. This label appears to mean somewhat different things to varying audiences, but it connotes that Comte’s original vision and Popper’s effort to sustain the connection between empirical observations and theory are things of the past—just as “rationalism” and “modernity” are giving away to “postmodernism.” Thus, one hears about a

“postpositivist” philosophy of science, which, despite the vagueness and diversity of usages for this label, is intended to signal the death of positivism. Curiously, this postpositivism is meant as an obituary for the older Comtean positivism or its resurrection as logical positivism by the Vienna Circle, where abstract logic and observation were more happily joined together.

The result is that the term “positivism” no longer has a clear referent, but it is evident that, for many, being a positivist is not a good thing. It is unlikely, then, that “positivism” will ever be an unambiguous and neutral term for sociological activity revolving around the formulation and testing of theory and the use of plausible theories for social engineering (or in more muted form, for “sociological practice”). Other labels are likely to be employed in light of the negative connotations of positivism in an intellectual climate dominated by “post-isms.”

Despite this apparent eclipse of positivism by various post-isms, positivistic sociology remains a vibrant activity, albeit by other names. Because of the pejorative use of the label “positivism,” few are willing to embrace it, but many practice positivistic sociology. What, then, are the main tenets of positivism? This question can be answered under ten general points.

First, positivism assumes that there is a “real world” that can be studied scientifically. The social world is not an illusion, or a total fabrication of sociologists’ imaginations. It is there; it has properties amenable to investigation.

Second, positivism assumes that there are fundamental properties of the social universe that are always operative when people act, interact, and organize. While the properties can manifest themselves in a wide variety of forms in varying contexts, they nonetheless exist; and they are what drive the dynamics of the social universe. The goal of positivism is to uncover these fundamental properties, to see how they work, to develop theories on their operation, and to test these theories with systematically collected data.

Third, the theories developed by positivists should strive for some degree of formality. The making of formal statements need not invoke mathematics or some other system of formal argument; rather, all that is necessary is that concepts

denoting processes be explicitly defined and that relations among concepts be stated clearly. These goals can be met with ordinary language, although if they can be converted into mathematics, this is seen by most positivists as useful though not absolutely necessary.

Fourth, in defining concepts formally, these definitions should denote aspects of the social universe such that what is encompassed by the concept is clear and, equally important, what is not is also explicit. In stating relations among concepts denoting fundamental properties of the social world, these relations can be stated in three basic ways. One is functional (in the mathematical sense), whereby variation in one concept is seen to be related to another (e.g., the level of differentiation in a population is a positive function of its size). A second way to state relations is through analytical models that specify the direct, indirect, and reverse causal effects among those forces of the universe that are seen as connected. A third procedure is historical in which events at earlier points in time are seen to cause directly, or in combination with other events, an outcome. A fourth, though less desirable (and at best, preliminary), procedure is to find the place of particular forces in an abstract category system that juxtaposes phenomena (e.g., the periodic table in chemistry or Parsonian four-functions analysis).

Fifth, the goal of all positivistic theories statements is parsimony. Reducing theories to their simplest form is always desired, whether this be a simple equation, an analytical model, a historical sequence of cause, or even a simple set of categories.

Sixth, at the same time that statements move toward parsimony, they should become ever more abstract and should seek to explain as large a portion of reality as is possible. The goal is always to explain as much of the social universe with as few principles and models as can do justice to the dynamics of the social world.

Seventh, all theoretical statements must be testable, at least in principle. Some statements can be tested directly with existing methodologies; others must be transformed (e.g., from deductions to hypotheses); and still others may have to wait for new methodologies or for specific classes of events to occur. The critical criterion is that theories be testable, now or in the future.

They must suggest by their formulation ways of operationalization.

Eighth, theories can be tested by all relevant methods: historical, comparative, experimental, survey, observational, and even simulational. No one method identifies positivism; all are useful in assessing the plausibility of theories.

Ninth, tests must always be used to assess the plausibility of theories. When tests do not support the theory, the theory must be rejected and/or revised.

Tenth, theories that remain plausible constitute, for the time being, the best explanations of the social universe. And the more theories remain plausible, the more they are made parsimonious, and the more new theories are developed to explain what has not yet been explained, the more knowledge of the nature and operative dynamics of the social universe accumulates.

POSTINDUSTRIAL SOCIETY

Postindustrial society is a concept used to characterize the structure, dynamics, and possible future of advanced industrial societies. Like the more recent concepts of postmodern and radically modern society, the concept of postindustrial society attempts to make sense of the substantial changes experienced by advanced industrial societies since the end of World War II. In providing a depiction of the character and future of these societies, analyses usually attempt to shape the futures they describe. Such efforts illustrate an awareness among sociologists of the “reflexive” character of much social science—that is, an awareness that analyses of society become elements of the social world that have the potential to shape the future.

Social analysts have long been aware of the potential effects of their ideas, at times engaging in work precisely because it may have an effect on the future through such mechanisms as social engineering, social movements, and the application of technology. The nineteenth-century theorists of “industrial” society, like postindustrial theorists a century later, tried to make sense of the diverse changes surrounding them, oftentimes in an effort to help shape the future. In the early nineteenth century, Claude-Henri de Saint-Simon attempted to provide an image of what was then a barely emerging industrial society, an image he hoped

would enable scientists and industrialists to see the crucial roles they were to play in a society consciously directed by scientific knowledge. Similarly, in the mid-nineteenth century, Karl Marx and Friedrich Engels were outlining the characteristics of industrial capitalism, including the revolutionary role of the proletariat, when the factory system in England was still in its infancy, and the workforce “was still heavily concentrated in agriculture and domestic service, with the remainder mostly employed in the old craft industries.” (Kumar 1978, p. 133) Although theorists of industrial society may not have been fully correct in all areas, their recognition of some major correlates of industrialization provided a surprisingly accurate portrait of a form of society qualitatively different from prior modes of human organization. The emerging industrial society was one that increasingly utilized technology and machinery for work; a society with substantial increases in communications, transportation, markets, and income; a society within which urbanism became a way of life, and the division of labor became increasingly complex; a society marked by an increasing role for the state, and bureaucratization in government and the economy; and a society marked by increasing secularization and rationalization.

The concept of postindustrial society indicates significant changes in some of these central characteristics of industrial society. In probably the earliest use of the concept, the Guild Socialist Arthur Pentty (1917) called for development of a postindustrial state that reversed key characteristics of industrial society. Pentty called for development of a mode of organization reflecting the artisan workshop, in which work, leisure, and family would be once again brought together. Although Pentty may have been the first to use the concept of postindustrial society, it was not until the 1960s that the concept took on its present character, focusing on quantitative changes separating postindustrial from industrial society. Interest in the future, and in postindustrial society, developed at this time as a response to the dramatic changes occurring in advanced industrial societies. These changes included the technological and organizational expansion accompanying economic growth in the post-World War II era, the expansion of the welfare state and an increased concern over the dark side of industrialism. An array of terms emerged to characterize the social

milieu of advanced industrial societies, including the technocratic era (Brzezinski 1970), service class society (Dahrendorf 1967), personal service society (Halmos 1970), postscarcity society (Bookchin 1971), posteconomic society (Kahn and Wiener 1967), knowledge society (Drucker 1969), postmodern society (Etzioni 1968), and postindustrial society (Touraine 1971; Richta et al. 1969). Although differing in focus, the analyses overlapped considerably with Daniel Bell’s work on postindustrial society (1973, 1989), which has been considered the best known and most complete analysis (Kumar 1978). Thus, the following effort to characterize postindustrial society uses Bell’s analysis as the organizing framework. This is followed by an examination of the related concepts of postmodern and radically modern society.

CHARACTERISTICS OF POSTINDUSTRIAL SOCIETY

For analytical purposes Bell divides society into three parts: social structure, culture, and the polity. The concept of postindustrial society focuses primarily on changes in social structure, that is, changes in the economy, in technology, and in occupational structure. Although the social structure, polity, and culture may influence one another, it is not assumed there is a harmonious relation between the three. In fact, changes in any one may pose problems for the others (Bell 1976).

Bell’s depiction of postindustrial society (1973, 1989) focuses on two dimensions: the centrality of codified theoretical knowledge, and the expansion of the service sector, especially professional and human services. The centrality of theoretical knowledge is viewed as the most important dimension, or axial principle, of postindustrial society. The institutions that most embody this dimension are the university and the research institute. In postindustrial society major innovations are more a product of the application of theoretical knowledge (e.g., Albert Einstein’s discussion of the photoelectric effect for the development of lasers, holography, photonics), than the product of persons skilled in the use of equipment (e.g., Alexander Graham Bell and Thomas Edison). The use of theoretical knowledge increases the importance of advanced education, reflected in substantial enrollments in colleges and universities, as well as substantial numbers of scientists, engineers, and

persons with advanced degrees. For example, between 1939 and 1964, as the United States moved from an industrial to a postindustrial society, the number of scientists and engineers increased over fivefold, from 263,000 to 1,475,000 (Bell 1973). Relatedly, the percentage of 20- to 24-year-olds studying for college degrees went from 4 percent in 1900 to 15 percent in 1940, 26 percent in 1950, and 34 percent in 1960 (estimated from Bell 1973, table 3-4). Related estimates show tertiary enrollment rates going from 32 percent in 1960 to 56 percent in 1980 and 81 percent in 1993 (World Bank 1980, 1997). Accompanying the importance of science and theoretical knowledge is an occupational structure in which more persons are involved in services, with professional and helping services especially important. This includes increased employment in education, science, and engineering, which is a natural consequence of a society committed to science and education. It also includes expansion of the number of white-collar workers and professionals in government and the helping services, resulting from an expanded welfare state and increased attention to health care. Such trends are illustrated in the following data (Table 1) on employment trends in the percentage of the workforce in white-collar and professional occupations in the United States, and in seventeen developed countries (twelve western European countries, plus Canada, Australia, New Zealand, Japan, and Israel) (U.S. Bureau of the Census 1975, 1998; ILO 1965-1988, 1997). Also included are related data for agriculture, mining, and manufacturing for the United States.

Increased employment in white-collar and professional occupations occurs largely at the expense of agricultural employment and, to a lesser extent, of manufacturing employment. The economic dynamic behind such changes consists of shifts in relative demand toward services as disposable income increases (Clark 1960), and to the greater responsiveness of agriculture and manufacturing to technical innovation (Fuchs 1968). As incomes rise, the *percentage* of total income used for food and agricultural products declines, and the need for basic manufactured products is more easily met. Thus, relative demand for health, education, and an array of other services may increase. At the same time, technical innovations increase productivity in agriculture and manufacturing, lowering the demand for labor in these sectors. However,

technical change is less able to displace workers in services, even though technical advances aid productivity. This is most clearly seen in health care, where technical change may increase the services available and the need for personnel to provide new services. Thus, economic and technical developments shift relative consumer demand and labor toward services. Such economic dynamics point out that development of an increasingly service-oriented postindustrial economy does not mean agriculture and manufacturing are ignored (Cohen and Zysman 1987). It means that technology takes over much of what people formerly did, and shifts productive efforts and labor toward services.

Accompanying the rising importance of theoretical knowledge and the service sector are several other changes. These include changes in women's roles, especially increased participation in the formal labor force. Additionally, the class structure of postindustrial society comes to increasingly center around education and technical expertise, creating possible tensions between expertise and populist sentiments. New political issues and attitudes concerned with the environment and quality of life move onto the political agenda (Ingelhart 1977; Lipset 1976). Technocratic rule may begin to take hold in organizations, and confront the problem of rationalized means becoming ends. Corporations may come under pressure to take into account objectives other than profit maximization. Efforts at social planning increase, and confront the problem of establishing a rational calculus for maximizing benefits throughout the society. The society becomes more politicized and conflictive as citizenship expands and groups seek a place in the polity.

Such conditions provide the basis for changes in consciousness and cosmology, as individuals confront a world of information and expanding specialized knowledge. The world becomes less one in which the individual interacts with nature and machines, and more one of persons interacting with persons. The reciprocal consciousness of self and other becomes increasingly important in defining the world. The culture may come to show contradictions between values of self-restraint, discipline, and work as a calling, on the one hand, and emerging postindustrial values of consumption and the negation of traditional bourgeoisie life, on the other (Bell 1976).

POSTINDUSTRIAL SOCIETY

	1900	1940	1960	1970	1980	1990	1995
Percentage of White-Collar Occupations							
United States	17.6	31.1	40.1	44.8	48.0	59.9	61.8
Percentage of Professional Occupations							
United States	4.3	7.5	10.8	13.8	14.1	16.5	17.6
Seventeen Developed Countries			6.1	9.1	14.3	18.5	
Percentage of Agriculture, Mining, Manufacturing							
United States			31.4	26.5	21.3	19.2	

Table 1

The image of postindustrial society provided by Bell and other social analysts is one in which technological advances have made possible development of a society characterized by the expansion and use of theoretical knowledge, and the concomitant expansion of white-collar and especially professional employment. A commitment to human welfare and social planning facilitates expansion of the welfare state and human services, further increasing white-collar and professional employment. Yet, such a society is not without tensions and conflict, both within the social structure and between the social structure, polity, and culture. It is by pointing out such tensions and problems that postindustrial theorists attempt not only to describe the present and the future but also to shape the future. In one of the more recent contributions to the postindustrial literature, Fred Block is clear about the role social analysis plays in shaping the future. He points out that “[social theory] has real consequences, because individuals cannot do without some kind of conception of the type of society in which [they] live” (Block 1990, p. 2). Block’s book represents a return to the analysis of postindustrial society after a brief hiatus during the 1980s that Block attributes to the breakdown of mainstream and leftist social theory, and the reemergence of a tradition of economic liberalism quiescent since the Great Depression. Block’s analysis carries forward the focus of prior postindustrial theory on social structure, yet gives scant attention to the role of codified theoretical knowledge, the university and professional groups. Instead, Block looks at key aspects of the changing postindustrial economy of the United States in an effort to develop alternative possibilities for the future. He notes that a postindustrial economy utilizing advanced technology, and having a substantial service sector, would be most productive if it kept some distance from the dictates of classical

economic theory. Specifically, productivity is likely enhanced by: (1) relatively low levels of marketness, allowing for greater predictability and more accurate information; (2) labor relations emphasizing cooperation between labor and management, since skilled labor in technologically sophisticated industries and the professions has substantial knowledge and is expensive to replace; (3) treating capital not merely as a physical asset, but as part of a productive process that includes the organization of persons working with capital; (4) developing measures of economic well-being that incorporate positive and negative utilities currently excluded from measures like gross national product (e.g., child care and pollution as positive and negative utilities); and (5) using various hybrid forms of market, state, and other regulatory mechanisms to enhance quality growth.

Block’s work provides a useful extension of postindustrial theory into the more traditional economic domains of labor, capital, and measured economic output. The book may represent a revival of analyses of postindustrial society, perhaps under the alternative concept of postmodern society. However, before considering the notion of postmodern society, some criticisms of the concept of postindustrial society need to be mentioned. Much of the critical literature focuses on Bell’s work, since it is viewed as one of the best expressions of postindustrial theory. One criticism of postindustrial theory is that it overemphasizes the role of theoretical knowledge in decision making. Although critics acknowledge that formal knowledge is more important than ever before, they contend that technical experts and scientific knowledge have not come to play the central role in decision making in government or corporations that postindustrial theorists said they would. Within government, political dynamics of the industrial era persist, and within the corporation “the expert

and his knowledge are, for the most part, embedded in the corporate bureaucracy" (Cohen and Zysman 1987, p. 260). Also, critics point out that while there may be more scientists, more persons with advanced education, and more money spent on research and development, these may be only tenuously related to increases in the amount and effective use of theoretical knowledge (Kumar 1978).

Critics also question the attention given by postindustrial theorists to the service sector, and to white-collar and professional work. As with theoretical knowledge, critics agree the service sector has grown, yet question the focus of postindustrial theorists. Critics remind us that the service sector has always been a major segment of preindustrial and industrial society (Hartwell 1973), that most service employment is in low-skilled, low-paid work, and that increases in white-collar and professional employment are a consequence of dynamics embedded in industrial society. Relatedly, most of the increases in white-collar and professional employment are in clerical positions and jobs like teaching and nursing, jobs that carry less autonomy and income than traditional professional occupations. Perhaps most important, critics argue that a focus on the service sector fails to adequately acknowledge the key role that manufacturing would play in a postindustrial economy, including the dependence of the service sector on a dynamic manufacturing sector (Cohen and Zysman 1987).

One response to these and other criticisms (e.g., see Ritzer 1989; Frankel 1987) would be to point out that postindustrial theory often acknowledged points made by critics, such as the fact that the political order could check trends in the economy; that the bulk of services are in low-skilled, low-paid labor; and that a sophisticated and dynamic manufacturing sector is important for an economy as large as that of the United States. Postindustrial theory merely chose to focus on other developments that may hold insights into the future of advanced industrial society. A related response to criticisms is to point out that critics have frequently acknowledged the validity of postindustrial claims of an increasing role for formal and theoretical knowledge, the increasing importance of technical developments in information processing, and the rise of a service sector with a good number of white-collar and professional workers. The points of contention between postindustrial theory and

its critics appear to center on the general portrait of society provided by postindustrial theorists: Is this society best seen as a new type of society, or as a logical extension of advancing industrialization (Kumar 1978; 1988; 1995; Ritzer 1989; Giddens 1990)? Also, what are the implications of this image of society, not only for describing the present and future, but for shaping both?

POSTMODERN SOCIETY

Recent discussions of the character and future of advanced industrial societies have been framed within the concept of postmodern society. Although the variety of work dealing with postmodern society makes a clear definition difficult (Smart 1990; Kumar 1995), it seems reasonable to say postmodern society differs from postindustrial society in having the more nebulous reference point of a type of society coming after "modern" society. Whereas studies of postindustrial society understandably give substantial attention to technical and economic factors, studies of postmodern society broaden the focus to bring political and especially cultural phenomenon more to the center of analysis (Kumar 1995). This shift in focus helps explain why analyses of the cultural dynamics of postindustrial society are frequently considered in terms of the dynamics of postmodern society (e.g., Baudrillard 1983), and why studies of the economic characteristics of postmodern society look very much like studies of postindustrialism (e.g., Clegg 1990). For many authors, postmodernism is the culture of a postindustrial society (e.g., Lyotard 1984; Lash 1990; Jameson 1992; Mandel 1978).

Analyses of postmodern society may differ from postindustrial analyses not only in substantive focus, but also in basic presuppositions regarding the nature of social reality. While studies of postmodern society can reflect a standard social science framework, what has come to be called postmodern theory often includes a critique of science that undermines traditional social scientific inquiry (Turner 1998; Bogard 1990). Although the central tenants of postmodern theory are still unclear (Smart 1990; Ritzer 1997; Rosenau 1992), it is possible to note some major themes. Reflecting the influence of literary criticism, postmodern theory often views "social and cultural reality, and

the social sciences themselves [as] linguistic constructions" (Brown 1990, p. 188). Authoritative images of what is real are seen to emerge through rhetorical processes in which "people establish repertoires of categories by which certain aspects of what is to be the case are fixed, focused, or forbidden" (Brown 1990, p. 191). Postmodern theory critiques the notion that signs and symbols adequately capture reality, and posits that signs and symbols are the only reality we truly know (Brown 1987). The reality of the social world described by social scientists is viewed as inseparable from the discourse through which social scientists come to signify some descriptions of the world as more legitimate than others (Lemert 1990). The traditional hierarchy in which reality occupies a privileged status separate from the symbols used to describe it is broken down, or deconstructed. The deconstruction project of postmodern theory not only critiques the separation of reality from symbols describing it, but also critiques other hierarchies, such as those separating expert knowledge from common knowledge, and high culture from low. The project even moves to deconstruct the very possibility of a generalizing social science, and the idea of a social world (Foucault 1980; Baudrillard 1983). In such bold forms a postmodern sociology becomes a contradiction in terms, undermining its own basis for existence (J. H. Turner 1998; B. Turner 1990; Smart 1990; Bauman 1988). However, although a postmodern sociology may be difficult to establish, a sociology of postmodernism that examines postmodern society, and draws from postmodern theory, is possible.

Attempts to characterize postmodern society reflect the contributions of postmodern theory, as well as more conventional sociological approaches. From postmodern theory comes a view of postmodern society as a technologically sophisticated high-speed society, with access to vast amounts of information, and fascinated by consumer goods and media images. Mass consumption of goods and information is seen as facilitating a breakdown of hierarchies of taste, and development of an explicit populism. Technology and speed blur lines separating reality from simulation, as television, videos, movies, advertising, and computer models provide simulations of reality more real than real. People may realize this hyperreality is simulation, yet be fascinated by it, and come to

make it part of their lives, thus transforming much of reality into simulation (Baudrillard 1983). Under such conditions history comes to have little meaning, and the fast-paced present becomes increasingly important. People may attempt to come to grips with such a world, but the world comes to undermine major assumptions, or grand narratives, of rationality and progress, thus generating a sense of exhaustion (Lyotard 1984). An acute sense of self-consciousness and unease may develop, as "the current age stumbles upon the very transvaluation of Western values and vocabularies that Nietzsche urged more than a century ago" (Baker 1990, p. 232).

Views of postmodern society from more conventional social science frameworks echo some of these themes. For example, both Daniel Bell (1976) and Christopher Lasch (1979) point to the development of cultural themes in postindustrial society emphasizing consumption and personal gratification at the expense of themes emphasizing self-restraint, work, commitment, and a sense of historical connection and continuity. In a Marxist analysis, Fredric Jameson (1984) points to the loss of a sense of historical connection in the consumer-oriented world of late capitalism.

One productive approach to postmodern society starts from the assumption that a central process defining modern society is differentiation. Thus, the type of society coming after modern society is viewed as reversing this process. The process of de-differentiation is illustrated in the cultural arena in the conflation of high and popular culture noted above, as well as the general deconstruction project of postmodernist theory (see also Lash 1988). Within the economic arena de-differentiation appears in the reversal of the processes of bureaucratization and the division of labor characteristic of the assembly line (Clegg 1990). Such trends have been viewed as part of the changing character of production in the world economy since 1960, and have been examined under such terms as the second industrial divide (Piore and Sable 1984), or the emergence of disorganized capitalism (Lash and Urry 1987). The changes frequently include a shift to smaller organizations or subunits of organizations, a less formalized and more flexible division of labor, increased variation in the character of products, more decentralized managerial structures, and the use of computers. Such organizations are engaged

in services, information processing, or production using computer controlled flexible production techniques (Burris 1989; Heyderbrand 1989; Clegg 1990). The postbureaucratic character of these organizations is made possible by computers that do routine tasks, as well as by the need to respond flexibly to diverse clientele and markets, and the sophisticated capabilities of employees that operate complex manufacturing equipment and provide professional services.

Although postmodern production techniques and organizations are becoming more prominent and important in advanced industrial societies, they may express themselves in different ways and do not eclipse other forms of production and organization. Low-skilled tasks in manufacturing and services will likely compose a substantial segment of the workforce far into the future, creating the possibility of increased variation in skill and income in postmodern society. Also, postmodern organizations can vary substantially among themselves. For example, Clegg (1990) argues that Japan and Sweden stand as alternative expressions of postmodernist futures. Sweden provides the more optimistic democratic scenario with fairly broad representational rights of workers in organizations. Japan represents a less optimistic view with an enclave of privileged workers formed on exclusive principles of social identity, such as gender, ethnicity, and age.

RADICALLY MODERN SOCIETY

Much as critics of the concept of postindustrial society pointed out that postindustrial trends were best seen as the logical extension of major characteristics of industrial society, so Anthony Giddens (1990) has questioned the notion that postmodern trends actually represent a break with modern society. Giddens acknowledges current trends of complexity and widespread change accompanied by lack of a clear sense of progress, and would also likely admit to trends of de-differentiation in some organizations. However, Giddens does not see this as constituting postmodernity. Instead he refers to such trends as characterizing radically modern societies, for these societies represent the logical extension of three essential characteristics of modernity. The first characteristic is an increase in complexity, as the major processes of industrialization, class formation, and rationalization proceed

apace and shape one another. The second key element of modernity is the separation of much of what humans experience as social reality from concrete instances of time and space. Thus, money represents an element of social reality that designates a mechanism of exchange not bound to any specific instance of exchange. Even more abstractly, experts and expert systems represent specialized knowledge that may be called upon for a variety of purposes at a number of times and places. Science is one of the clearer expressions of such knowledge, with its esoteric and changing images of the character of the natural and physical universe. As societies become more modern, humans are viewed as increasingly experiencing the world through such abstract, or "disembedded," categories as money, expertise, and science. Realization of the disembedded nature of social life helps facilitate development of the third characteristic of modernity, its reflexivity. As noted earlier, *reflexivity* refers to the fact that efforts and information used to understand social reality become part of reality, and thus help shape the present and the future. According to Giddens, awareness of reflexivity is not confined to social scientists, but is embedded in the nature of modernity. Modern societies generate theories of what they are, which become important constitutive elements that shape society, including the future character of theories. All three of the characteristics of modernity find expression in each of four interrelated institutional complexes: capitalism, the nation-state, the military, and industrialization. Thus, radically modern societies are those in which major institutions are highly complex, abstract or disembedded, and reflexive. Such societies will be more difficult for individuals to concretely understand; will require substantial amounts of "trust" in abstract and expert systems; and will generate high levels of self-consciousness, as persons seek to use personal resources to more reflexively construct personal identity and meaning. Thus, radically modern societies may produce the unease and sense of powerlessness that some postmodern theorists see in postmodern societies. By avoiding the concept of postmodern society, Giddens is able to illustrate how current trends are part of the logic of modernity, and is able to provide a view of the future more optimistic than the view of some postmodern theorists by underscoring the reflexive and transformative power of ideas and action.

POSTMODERN SOCIETY AND THE WORLD SYSTEM

Most analyses of postindustrial, postmodern, and radically modern societies carry with them a view of societal change occurring within an increasingly interconnected world system. Giddens is quite explicit in this regard, pointing out how the complexity, abstractness, and reflexive character of modernity moves beyond the nation-state to become a world-level phenomenon (1990). This is most clearly expressed in the development of a world capitalist system, a nation-state system, a world military order, and an international division of labor. Although Giddens does not systematically consider the dynamics of these aspects of the world system in discussing radical modernity, his conceptualization is a useful reminder of the possible utility of considering multiple dimensions of the world system in efforts to understand postmodern societies. As the review of postindustrial and postmodern literature suggested, most analyses consider the role of the world system in terms of economic exchanges (Bell 1989), new technologies, and new modes of economic organization (Piore and Sable 1984; Lash and Urry 1987; Clegg 1990).

Recently, analysts have drawn increasing attention to cultural dimensions of the world system (e.g., Featherstone 1990; Boli and Thomas 1997), pointing out how themes associated with modern, postmodern, and postindustrial society have become elements of an emerging world culture (Meyer et al. 1997; Meyer 1991; Smith 1990; Robertson 1989, 1990). Giddens touched on these themes when he noted how the abstract and reflexive character of modernity has become a global phenomenon, making theories of modernity part of contemporary culture. Meyer (1980, 1991) and others (Meyer et al. 1997) also note the role that ideologies of modernity and postindustrialism may play in the contemporary world, pointing out how rationalized conceptions of modern society, including social scientific discourse, have become part of a contemporary world cultural framework. For example, modern images of society that view economic development, national integration, and personal and societal progress as the product of individuals with specialized knowledge are said to have become a world-level assumption, and generated expansion of educational enrollments between 1950 and 1970 (Meyer et al. 1977; Boli and

Ramirez 1986; Fiala and Lanford 1987). Relatedly, postindustrial images of the role of specialized knowledge in society are viewed as an important factor affecting the worldwide expansion of higher education and professional employment in the post-World War II era (Meyer and Hannan 1979). Such images may account for part of the increase from 3.7 percent to 9.2 percent between 1960 and 1990 in the percentage of the labor force employed in professional occupations among twenty-two developing countries, a significant increase considering the substantial population and labor-force growth during this period. This contrasts with the increase from 6.1 percent to 18.5 percent for the seventeen developed countries reported earlier, and with the increase from 10.8 percent to 16.5 percent for the United States. While economic growth may account for some of these increases in professional employment, the substantial expansion for developing countries, especially compared to the United States, indicates other variables likely play a role. It seems plausible that postindustrial images regarding the importance of specialized knowledge and personnel may have an effect.

CONCLUSION

Efforts to understand the character and future of advanced industrial societies in the latter half of the twentieth century have been done under the rubric of at least three major concepts. The concept of postindustrial society focused attention on social structural or economic dimensions of society, especially the changing character of technology, knowledge, occupations, and the market. The concept of postmodern society continued to bring attention to structural and economic aspects of society, yet gave increased attention to political, cultural, and psychological dimensions, at times with an explicit critique of standard social science methodology. The concept of radically modern society underscored the links between contemporary changes and the basic dynamics of modernity, while introducing the useful idea that radically modern societies are characterized by high levels of abstractness and reflexivity. Each of the three concepts acknowledges that changes are occurring within an increasingly interconnected world system.

The current review clearly illustrates the reflexive character of much social science. In

postindustrial theory this was largely a recognition that formal scientific knowledge may shape the future. In postmodern theory, and especially in radically modern theory, this reflexivity also became part of the culture itself, affecting the consciousness of much of the population. This creates a vastly more complex image of society, with a diverse array of possible futures, and may account for the unease postmodern theory sees as characterizing postmodern society.

While work on postmodern and radically modern society offers insightful ideas, most empirical research has been done on postindustrial society, and economic aspects of postmodern society. Future studies should attempt to examine some of the major elements of postmodern and radically modern approaches, as well as continue to clarify areas of ambiguity within postindustrial theory. For example, within the postindustrial framework, attention should be given to understanding the influence of various segments of a knowledge class on specific institutions in society, and to trying to explain national variation in the expansion of various types of service employment.

Within the postmodernist framework, it would be informative to assess claims of pessimism, self-consciousness, and declines of grand narratives, noting their variation across social groups and societies. Examination of variation across time and space in the way individuals, communities, and societies experience exposure to media might help clarify the provocative hypothesis of the increasing salience of simulation in social life. Efforts to rethink extant research in terms of the simulation hypothesis could also prove informative.

Drawing from the view of radically modern societies, it would be useful to examine the idea that modern cultures increasingly incorporate reflexive elements. Analysis of the changing role of evaluation studies, news presentations and commentaries, and economic projections and predictions could help clarify the developing reflexive character of human societies.

Last, to assess hypotheses regarding the effects of world cultural themes, research could examine the effects of an ideology of specialized knowledge and expertise on expansion of professional employment. The data presented above suggest the plausibility of such an effect, yet do not offer firm support.

Issues such as those above are but a few of the avenues of research that may help provide a clearer image of the character and future of advanced industrial societies. In posing the issues, and in providing answers, social science will likely help shape the future it describes.

ROBERT FIALA

POSTMODERNISM

In 1959, C. Wright Mills speculated that “the Modern Age is being succeeded by a post-modern period” in which assumptions about the coherence of the Enlightenment values of scientific rationality and political freedom were being challenged (1959, p. 166). Critical theorists had earlier speculated about how the revolutionary potential

of the urban laboring classes of the nineteenth century was co-opted by the shift to a postindustrial twentieth-century society, a society characterized by mass consumerism and war economies. The characteristics of postindustrial societies were explored more recently in Daniel Bell’s analysis of contemporary capitalism (1976). In the modern information societies, Bell argues that the class forces that drove nineteenth-century social change have been replaced by new processes. Under welfare capitalist states, scientists, technicians, managers, and bureaucrats formulate social tensions as administrative and technical issues based on political consensus. For Bell, postindustrial societies with their information bases hold the key to social harmony and the end of misery.

Alain Touraine’s view (1984) is different. He also stresses how class antagonism has changed under welfare capitalism, but for Touraine the information managers, guided by technological thinking, tend to “steer the entire social order toward the perfectly programmed society, the ultimate technocratic prison” (Baum 1990, p. 5). Touraine also writes that the categories of basic sociological analysis have become out of touch with changes in contemporary societies. In particular, he rejects the modernist supposition of evolutionary progress over time, culminating in what he calls “the impoverishing homogeneity of modern civilization” (Touraine 1984, p. 38), the sociologist’s conception of the national states as units of analysis, and the gradual expunging of the cultural diversity of traditional societies. The collapse of modernism arises from a failure of sociology to keep abreast of the developing autonomy of cultural products, the globalization of capital, and the rise of new forms of social control and of public resistance to them. In this analysis, “the crisis of modernity . . . is not all-encompassing . . . the crisis in modernity is not considered to be total or terminal but limited in scope, if deep” (Smart 1990, p. 408). Though Bell and Touraine have been associated with critiques of postindustrial societies, the meaning of “postmodernism” has become far more radical, and draws on earlier sources.

De Saussure’s “structural” theory of linguistics (1959) distinguished the “sign” from the “signified” and developed a science based on the discovery that symbolic systems might have formal properties that were unrelated to the meanings of

the objects they signified but that might hold across different systems of symbols. The system for describing, for example, the animal kingdom and the protocols for siting teepees might reflect the same logic—without any inherent equivalence to the things they described or organized (Giddens 1987). “Poststructuralism” deepened this disinterest in the signified objects by dismissing any link binding words/symbols to things. Things were only the hypostatizations of language. All analysis was “deconstruction,” or unmasking of phenomena in terms of their underlying rhetorical conventions. For poststructuralists, texts only pointed to other texts. The world was viewed as an intertwining of systems of representation without any derivation from or basis within “terra firma.” Everything became text—including violent speech and violent symbolic acts such as incest, war, or spousal abuse.

The postmodern twist is the application of the linguistic implications of poststructuralism to the three core principles connecting contemporary civilizations with the project of the Enlightenment: scientific knowledge (Truth), aesthetics (Beauty), and morality (the Good). The Enlightenment project—“modernism”—refers to the rise of the Age of Reason. It was characterized by the gradual shift away from religious sensibilities and to scientific objectivity, the rational exploitation of nature for human needs, the perspectival representation of nature in art and humanistic truth in fiction, and the struggle for a humane society. Modernism was realist in its epistemology and progressive in its politics. Truth could be attained—particularly with scientific advances. Beauty could be distinguished from trash. Humanism could nurture moral conduct and decent conditions of life. And history was purposive and progressive.

Postmodernism is the sensibility that arises when the credibility of these “master narratives” is questioned. The postmodern period, as described by Lyotard (1984) and Baudrillard (1983), is the one we now confront. Though it is often dated as a creature of the post-World War II period, it is thought only to have become generalized with mass consumerism in the age of electronics and to have been initiated by dramatic changes in contemporary capitalism. Capitalism has ushered in global communication and exchange, and has created a self-sustaining cybernetic system that almost

completely transcends the ability of individual governments to control their directions and objectives. As a result, postmodernity is sometimes referred to as posthistorical society in the sense that the mission or sense of purpose that guided nation-states in the past through events such as the French Revolution has been overtaken by global consumerism. The view of history as a struggle for the gradual liberation of humanity and progressive evolution of more humane societies is dismissed by Lyotard as mythic. In addition, the transcendence of communities by electronic representations makes the idea of “the social” purely illusory (Bogard 1990). The objectivity of societies, nation-states, communities, and history is viewed only as “narratives” or “simulacra” (Baudrillard 1983). Referents disappear in favor of a world of simulations, models, performatives, and codes—in short, “information” (broadly conceived), which becomes the predominant phenomenon of exchange among the masses through the mass media.

One of the important theoretical aspects of the postmodernist position is its explicit rejection of Marxism in general and Habermas’ theorizing about creating a rational society through communicative competence. Where Habermas (1973, p. 105) speculates that a rational community might be able to “arrive at the conviction that in the given circumstances the proposed norms are ‘right,’” Lyotard rejects the myth of reason behind the Habermasian project. The project implies that there is a correct moral and scientific standard to which communities ought to aspire. Enforcement of such standards valorize conformity and, as witnessed in the fascist European states in the 1920s and 1930s, promote terrorism to extract it. This introduces a tension within postmodernism that has not been worked through (Frank 1990). On the positive side, the supposition of “multivocality” in scientific and moral discourse promotes the “excavation” of minority voices and minority experiences which have been occluded in “master” modernist ways of thinking. Every point of view can be heard, none can be privileged. On the other side, postmodernism seems ill equipped to distinguish between any particular moral or objective position and any other, including the fascist discourse that is associated with modernism. Choosing between Holocaust history and Holocaust denial would seem in principle to be a matter of rhetorical preference—which is clearly nihilistic.

When we move away from epistemology to postmodernity's impact on art and architecture, the situation is different. Postmodernism celebrates a rejection of hegemonic traditions and styles by mixing elements from competing schools and by bringing the rim of representation into focus as an organic element of the depiction. Novels exploit the discontinuities in perspective and the fragmentations in contemporary society. In architecture, postmodernism represents a repudiation of high-density ("efficient") functionality based on centralized city planning with an emphasis on no-frill construction. Decentralized planning emphasizes collage and eclecticism and the development of spaces to heighten aesthetic possibilities (Harvey 1989). The globalization of experience encourages such exchanges and experimentation. However, the replacement of "efficient" spaces like public housing, with their brutalizing side effects, with more particularistic designs is part of the emancipatory interest of modernity—so that at least here, postmodernity is still part and parcel of the Enlightenment. This raises three questions.

First, to what extent has the case been made that the changes in capitalism during the past two decades have been so profound as to represent a destruction of modernist society and a disappearance of history and "the social" (i.e., real face-to-face community)? Some critics dispute the claim (Baum 1990); others point out that Baudrillard's evidence is unconvincing since his own postmodern manner of exposition is self-consciously rhetorical, inflationary, and, consistent with the idiom, only one possible reading of recent history (Smart 1990). Second, if we have no careful (i.e., modernist) analysis of the factors that have contributed to the demise of our confidence in the "master narratives" of modernism, would it not seem to be impossible to discern which ones have been shaken, and how seriously our confidence in them has been eroded? Skepticism is insufficient. Finally, under these circumstances, is it not predictable that there is no consensus about the meaning of postmodernism? Arguably this dissensus is inherent in the perspective. For Baudrillard (1983), postmodernism spells the end of sociology (and other modernist subjects); for Bauman (1988), it is simply a new topic—a sociology of postmodernism, but not a postmodern sociology. For Brown (1990), it is an opportunity to rethink the continuing

relevance of the role of rhetoric in politics and science in order to employ knowledge in guiding human conduct. Under these circumstances, the proclamation of the death of modernism would seem premature.

Over the past decade two debates have emerged which raise questions about the postmodern project and which deal respectively with the issues of (1) epistemology, or the postmodern struggle with truth and the special standing of the natural sciences, and (2) of morality and the struggle to define and achieve the "good society" within democratic politics.

The first issue is raised by the famous hoax perpetrated by Alan Sokal, professor of physics at New York University, a left-leaning radical who taught math in Nicaragua under the rule of the Sandanistas. His "transformative hermeneutics of quantum gravity" was a spoof of the pretentious claims about science running through the leading figures of the French intellectual establishment—Derrida, Lacan, and Lyotard—spiked, according to Sokal, with the usual nonsensical and impenetrable jargon and buzzwords (Sokal 1996b). The parody was published in a special issue of *Social Text* designed by the editors to rebuke the criticisms of their antiscientific agenda by leading scientists. Sokal published an exposé at the same time in *Lingua Franca* (1996a). The hoax ignited a storm of criticism on both sides which some have referred to as "the science wars" (Natoli 1997, pp. 115 ff.; Kingwell 1999). The hoax continues to provoke debate today (see <http://www.physics.nyu.edu/faculty/sokal/index.html>). Although Sokal abused the good faith of the editors of a journal in a humanities discipline, he justified his behavior by reference to the naïveté of those editors, whose credentials could scarcely permit them to draw the conclusions about the purely rhetorical foundations of science or to discredit centuries of scientific progress. Yet in neither side was the "demonstration" definitive. The validity of the scientific method is neither established by the hoax, nor rubbished by what Richard Dawkins writing in *Nature* dubbed "the vacuous rhetoric of montebanks and charlatans" on the Left Bank (1988, p. 141). Nor is it undermined on this side of the Atlantic by Steven Seidman's claims in *Contested Knowledge* that the scientific community in eighteenth-century Europe prevailed over aristocracy and the

Church because it provided the forces of liberalism with a convenient but essentially vacuous cudgel with which to rout the older order: "Is the claim that only science ensures true knowledge . . . not merely another ruse on the part of a rising social elite wishing to legitimate their own aspirations for privilege? . . . [S]cience, just like religion, rests upon a series of assumptions that cannot be scientifically proven . . . Enlightenment science is as weak a guarantor of truth as religion." (1994, p. 24). Science for Seidman and the other postmodernists is just faith in a secular vein without any special epistemological leverage. The proponents of the Enlightenment were simply replacing priests with scientists, and religion with another form of superstition. Sokal and Bricmont's *Fashionable Nonsense* (1998) calls the postmodernists' bluff on such charges. At this point, it is premature to draw conclusions about the future of this controversy. Suffice it to say for the time being that poetry and physics should be cataloged separately.

On the issue of morality and everyday politics, John O'Neill's *The Poverty of Posmodernism* takes a similarly critical view of "the academic trendiness" of advocates of cynicism and fragmentation who have forsaken humanism and the critique of social injustice as part of the postmodern turn. "Today we are told to jettison the old-fashioned belief in unique values . . . we are wholly ruled by prejudice and politics . . . we are asked to believe that human beings are now so speciated by gender and race—though we are silent about class—that there can be no universal knowledge, politics, or morality." As O'Neill stresses, "these ideas have not grown up among the masses who have sickened of the injustices and exploitation that grinds their life . . . it is not these people who have abandoned idealism, universalism, truth and justice. It is those who already enjoy these things who have denounced them on behalf of the others" (1995, p. 1)—the new "illiterati" of the simulacrum, the Disney World theorists and the esthetes of the radically chic. "Too much of the world still starves, dies young and is wasted by systematic greed and evil for anyone to write the obituaries of philosophy, ideology and humanism" (p. 196). O'Neill argues that there are good philosophical foundations in the phenomenology of everyday life, the transcendental instinct of reason to fasten on the contradictions of existence, and commonsense scepticism

to keep alive the distinction between truth and falsity, freedom and slavery, and justice and injustice. The idea that political discourse has been reduced to mere perspective, that there is nothing outside language or that there is no "extratextuality" deny the vision of history and community, and exhaust culture with cultural industry, communication with fashion. "The claim that there are no longer any grand stories capable of under-writing common sense . . . gives comfort only to those who lack community at any level of society other than intellectual fashion" (p. 198). O'Neill's own inspiration for criticizing the antirationalism of postmodernism is founded on what he describes as the tension between language and vision, between elites and masses, between reality and possibility. The static linguisticity of postmodernism is a trap, an illusion. The current celebration of relativism by what used to be the progressive left is not only ill founded but politically nihilistic. It valorizes only minoritarianism while leaving unexamined the consequences of globalization and the dismantling of the welfare state by the political right. That state, with all its blemishes, has been an achievement in which civic democracy took root, in which politics was driven in part for reasons other than naked self-interest. In his vision, O'Neill says that postmodernism undermines our sense of cultural debt to the past and removes the duty which each generation has to pass on what it has learned to the future. "Those of us who own knowledge, who enjoy literacy, health, self-respect and social status have chosen to rage against our own gifts rather than to fight for their enlargement in the general public. We have chosen to invalidate our science, to psychiatrize our arts, to vulgarize our culture, to make it unusable and undesirable by those who have yet to know it. We honour no legacy. We receive no gifts. We hand on nothing" (1995, p. 2). Yet if O'Neill's critique of antirationalism is sound, all this changes and his self-flagellation is premature.

The moral and epistemological concerns of O'Neill and Sokal are quite different from the critiques of commodity esthetics in George Ritzer's *The McDonaldization of Society*, which provides a useful point of comparison. Following Weber's insight about the intrusiveness of rationalization, Ritzer shows how the McDonald fast-food franchise led to a widespread adoption of commodity

production and consumption based on standardization, efficiency, leveling of tastes, and the stifling of worker experiences that has come to set the model for our individual relationships with the market, if not the world generally. But McDonaldization calls forth that critical posture which Veblen labeled “the instinct of craftsmanship” ([1899] 1962, p. 75), without which waste and conspicuous consumption would be unbridled. Like Veblen, Ritzer applauds the resistance to such trends; but his perspective is Weberian and transcendental. By contrast, for students of postmodernism, scientific truths and emancipatory projects are merely further commodities, fashions, or fictions caught up in the McDonaldization of empirical truth and the social good. Sokal and O’Neill represent the opening of serious dialogues on these engaging issues.

AUGUSTINE BRANNIGAN

POVERTY

Scholarly as well as ideological debate has long centered around the most elementary questions concerning poverty. What is poverty? How can it be measured? What causes it? Is it a natural phenomenon or a symptom of a poorly ordered society? Though answers to all these questions abound, there is no definitive answer to any one of them, nor can there ever be, for the questions are not purely demographic, but moral, ethical, and political as well. Poverty is a concept, not a fact, and

must be understood as such. Even though no definitive answers are possible, this does not mean that all answers are thereby equal; many are based on ignorant assumptions and ill-formed judgments. Sociologists involved in poverty research seek to make sure that all understand the meaning and consequences of various points of view, and that both theoretical and policy research is based soundly upon clear definitions and reliable data.

Even the definition of "poverty" is problematic. The word is derived from the French *pauvre*, meaning "poor." Poverty is simply the state of lacking material possessions, of having little or no means to support oneself. All would agree that anyone lacking the means necessary to remain alive is in poverty, but beyond that there is little agreement. Some scholars and policy makers would draw the poverty line at the bare subsistence level, like Rowntree's "the minimum necessities for the maintenance of merely physical efficiency" (1901, p. viii). Others argue for poverty definitions that include persons whose level of living is above subsistence but who have inadequate means; among those holding to the latter, further arguments concern the definition of adequacy. Social science cannot resolve the most basic arguments. For example, the level of living implied by the poverty threshold in the United States would be seen as desirable and unattainable in many other countries, yet few would suggest that poverty in the United States be defined by such outside standards. Sociologists can evaluate the demographic and economic assumptions underlying standards of poverty, but not the standards themselves.

CONCEPTIONS OF POVERTY

Poverty can be defined in absolute or relative terms. The subsistence line is a good example of an absolute definition (i.e., below this line one does not have sufficient resources to survive). A criterion based on some arbitrary formula, such that poverty equals some fraction of the median income or below, is a good example of a relative definition (e.g., "All persons earning less than 25 percent of the median income are poor"). In all industrial societies an absolute definition will have far fewer persons officially in poverty than will a relative definition, creating natural political pressure for absolute definitions. For example, a study in 1976 revealed that if poverty was defined as

having 50 percent of the median income, data on income distributions would show that an unchanging 19 percent of the population had been poor for almost the past two decades (U.S. DHEW 1976). Absolute definitions show declines in poverty over time in industrial nations. There are valid arguments for both types of definitions. Some argue that relative definitions of poverty render the term meaningless in affluent societies, and make cross-national comparisons difficult—for example, in an advanced industrial society, 50 percent of national median income could leave one adequately provided for, while the same percentage in many less industrialized societies would not provide basic necessities to sustain life. On the other hand, within societies there is evidence that most people see poverty in relative terms rather than as an absolute standard (Rainwater 1974; Kilpatrick 1973). That is, popular conceptions of what level of living constitutes poverty have been found to change as general affluence goes up and down. Advocates of relative measures point out that any absolute measure is arbitrary and thus meaningless. A reasonable definition of the poor, they argue, should be one that demarcates the lower tail of the income distribution as the poor, whatever the absolute metric represented by that tail, for those persons will be poor by the standards of that time and place. As the average level of income rises and falls, they argue, what is seen as poverty will, and should, change. Advocates of absolute measures of poverty do not deny that perception of poverty is intimately tied to distributional inequality, but argue that relative definitions are too vague for policy purposes. An absolute standard, defined on some concrete level of living, is a goal that can possibly be attained. Once it is attained, they say, a new goal could be set. Eliminating poverty as defined by relative standards is a far more difficult goal, both practically and politically. T. H. Marshall noted, "the question of what range of inequality is acceptable above the 'poverty line' can only marginally, if at all, be affected by or affect the decision of where that line should be drawn" (1981, p. 52).

Relative versus absolute poverty is a distributional distinction, but there are other important distinctions as well. A social distinction, and one with considerable political import, is usually made between the "deserving poor" and the "undeserving poor." In their brief summary of the historical

origins of this distinction, Morris and Williamson (1986, pp. 6–12) maintain that it became significant in the fourteenth century, when, for a variety of reasons (the decline of feudalism, the rise of a market economy with concomitant periodic labor dislocations, bubonic plague–induced regional labor shortages), the poor became geographically mobile for the first time. Before that, the local Catholic parish, with its “Blessed are the poor” theology, was the primary caretaker of the indigent. Mobility caused an increase in the number of able-bodied individuals needing temporary assistance, and troubles arising from their presence contributed to a growing antipathy toward the able-bodied poor.

Katz (1989) also traces the origins of the “undeserving poor” in part to demographic factors. He points out that, prior to the twentieth century, poverty was a seemingly unalterable fact of life, and most people would spend their lives in it. Thus no moral taint was attached to poverty. The only policy question usually involved the locus of responsibility for aid, and the answer was a simple one: Responsibility was local, and those needy persons not belonging to the community could be “resettled.” Increased population mobility made the settlement provisions unworkable, and the original distinction between the genuinely needy and “rogues, vagabonds, and sturdy beggars” hardened into a moral distinction between the poor, who needed no public relief, and “paupers,” those needing assistance because of personal failings (Katz 1989, pp. 12–14).

Feagin (1975, chap. 2) locates the origins of negative attitudes toward the poor in the Protestant Reformation. Under Protestantism, he notes, the “work ethic”—the ideology of individualism—became a central tenet of the Western belief system. Poverty, in the extreme Calvinist version of this viewpoint, is largely a consequence of laziness and vice, and can even be regarded as just punishment from a righteous God. The rise of Puritan thought contributed to the increasing disfavor with which the unemployed and destitute were regarded. It became a matter of faith that poverty was individually caused and must thereby be individually cured. These ideas became secularized, and programs to aid the poor thereafter focused on curing the individual faults that led to poverty: Potential problems in the structure of society that caused unemployment and underemployment were

not to be scrutinized in search of a solution. The notion of poverty continues to be in flux. As Marshall (1981) noted, the concept has been with us since antiquity, but its meaning has not been constant through the ages.

Most sociologists today distinguish among three major types of explanations of poverty: individual, situational, and structural theories. Individual theories attribute the primary cause of poverty to individual failings or, more neutrally, to individual differences—the central argument being that the poor are different from the nonpoor in some significant way. Situational theories agree that the poor are different from the nonpoor, but argue that the differences are a result of poverty, not a cause of it. Structural theories see differences in individual attributes as irrelevant, and argue that poverty has only societal-level origins: The characteristics of economic systems create poverty, not the characteristics of individuals.

THEORY AND POLICY

The epitome of the individual viewpoint in the social sciences was the once-dominant “culture of poverty” explanation for destitution. Oscar Lewis (1961, 1966) is usually credited with this idea, which sees poverty not only as economic deprivation, or the absence of something, but also as a way of life, the presence of specific subcultural values and attitudes passed down from generation to generation. Lewis saw the structure of life among the poor as functional, a set of coping mechanisms without which the poor could not survive their harsh circumstances. But there were negative consequences of the value system as well, he noted. Family life was disorganized, there was an absence of childhood as a prolonged lifecycle stage, a proliferation of consensual marriages, and a very high incidence of spouse and child abandonment—all of which left individuals unprepared and unable to take advantage of opportunities. Exacerbating the problem, the poor were divorced from participation in and integration into the major institutions of society, leading to constant hostility, suspicion, and apathy. Many have maintained that the culture-of-poverty viewpoint dovetailed perfectly with a politically liberal view of the world. It blamed the poor as a group for their poverty, but held no single person individually responsible, nor

did it blame the structure of the economy or the society. This view of the poor led to antipoverty policies directed at changing the attitudes and values of those in poverty, so that they could “break out” of the dysfunctional cultural traits they had inherited. It led political liberals and radicals to attempts to “organize the poor.” Political conservatives transformed the explanation into one that held the poor more culpable individually and the problem into one that was intractable—“benign neglect” being then the only sensible solution (Banfield 1958, 1970; Katz 1989). There were many problems with the culture-of-poverty explanation. Most serious was the fact that the cultural scenario simply doesn’t fit. Only a minority of the poor are poor throughout their lives; most move in and out of poverty. Also, a substantial proportion of those in poverty are either women with children who fell into poverty when abandoned by a spouse, or the elderly who became poor when their worklives ended: Neither event could be explainable by the culture of the class of destination. Many studies falsified specific aspects of the culture-of-poverty thesis (for a review, see Katz 1989, pp. 41 ff.), and Hyman Rodman’s influential notion of the “lower-class value stretch” (1971) offered an alternative explanation (the poor actually share mainstream values, but must “stretch” them to fit their circumstances—remove the poverty, and they fit neatly into dominant culture—attempts to alter their “culture” are unnecessary, and meaningless, since “culture” is not the problem). Nonetheless, the culture-of-poverty thesis was (and to some extent still is) a very popular explanation for poverty. This is probably so in part because it fits so well the individualistic biases of most Americans. Surveys of attitudes toward poverty have shown that most persons prefer “individualistic” explanations of poverty, which place the responsibility for poverty primarily on the poor themselves. A minority of Americans subscribe to “structural” explanations that blame external social and economic factors, and this minority consists largely of the young, the less educated, lower income groups, nonwhites, and Jews (Feagin 1975, p. 98).

A more sophisticated recent treatment incorporating some of the explanatory power of the culture of poverty argument without that theory’s untenable assumptions is William Wilson’s depiction of the “underclass” (1987). This recent work

by Wilson on the underclass has been criticized by some as a return to classical culture of poverty theory in a new guise. It is not, of course, and represents a very different type of explanation. Wilson defines the underclass as an economically disadvantaged group whose marginal economic position and weak attachment to the labor force is “uniquely reinforced by the neighborhood or social milieu” (Wilson 1993, p. 23). Changes in the geography of employment, industrial specialization, and other factors have resulted in a rise in joblessness among urban minorities, which has in turn led to an increase in other social dislocations. Primary among those other factors has been the steady out-migration of working-class and middle-class families from the inner cities, which groups would normally provide a social buffer. Wilson notes: “in a neighborhood with a paucity of regularly employed families and with the overwhelming majority of families having spells of long-term joblessness, people experience a social isolation that excludes them from the job network system that permeates other neighborhoods and that is so important . . . other alternatives such as welfare . . . are not only increasingly relied on, they come to be seen as a way of life” (1987, p. 57). The 1990 U.S. Census showed that about 15 percent of the poor lived in neighborhoods where the poverty rate was at least 40 percent (O’Hare 1996). In these neighborhoods, where few are likely to have resources or job networks, reside Wilson’s “underclass.” Unlike the culture-of-poverty theory, Wilson’s theory analyzes the structural and cultural resources of poor places, rather than the socialized attitudes and values of poor people. Wilson contends that “ghetto-specific cultural traits” are relevant in understanding the behavior of inner-city poor people, but these traits, *contra* culture-of-poverty theory, do not have a life of their own. That is, they are an effect of deprivation and social isolation, not a cause of it, and they command very little commitment—they are not self-perpetuating. “Social isolation,” Wilson’s key concept, implies not differential socialization of the inner-city poor, but rather their lack of cultural resources supporting the desirability and possibility of achieving culturally normative aspirations. The individual characteristics normally associated with a culture of poverty argument represent expected and even rational responses to adverse environments, not socialized belief systems.

While Wilson's work has been very influential in the social sciences, one of the most politically influential recent works on poverty policy has been that of Murray (1984). Murray argued that the viewpoint that individuals ultimately cause their own poverty changed in the 1960s to the viewpoint that the structure of society was ultimately responsible. This alteration in the intellectual consensus, which freed the poor from responsibility for their poverty, was fatally misguided, he argues, and caused great damage to the poor. Despite enormously increased expenditures on social welfare from 1965 on, he maintains, progress against poverty ceased at that point. In the face of steadily improving economic conditions, the period 1965–1980 was marked by increases in poverty, family breakdown, crime, and voluntary unemployment. Murray argues that this occurred precisely because of the increased expenditures on social welfare, not despite them. Work incentive declined during these years because of government policies that rewarded lack of employment and nonintact family structure. It is a standard economic principle that any activity that is subsidized will tend to increase. Murray's arguments have had policy impact, but have been subject to extensive criticism by students of the field.

As evidence of the disincentive to work brought about by social welfare payments, Murray cites the Negative Income Tax (NIT) experiments. These were large social experiments designed to assess the effects of a guaranteed income. The first NIT experiment was a four-year study in New Jersey from the late 1960s to the early 1970s. In this study, 1,375 intact "permanently poor" families were selected, and 725 of them were assigned to one of eight NIT plans. It was found that the reduction in labor-market activity for males caused by a guaranteed income was not significant, but that there were some reductions for females (5–10 percent of activity), most of which could be explained by the substitution of labor-market activity for increased child care (home employment). In a larger NIT study conducted throughout the 1970s, the Seattle-Denver Income Maintenance Experiment (usually referred to in the literature as the SIME-DIME study), much larger work disincentives were found, about 10 percent for men, 20 percent for their spouses, and up to 30 percent for women heading single-family households (see Haveman 1987, chap. 9, for an excellent summary of the

many NIT experiments). Murray offered these findings as evidence that existing welfare programs contributed to poverty by creating work disincentives. Cain (1985) pointed out that the experiments provided much higher benefits than existing welfare programs, and also noted that, given the low pay for women at that level, the 20 percent reduction for wives would have a trivial effect on family income. If it resulted in a proportionate substitution of work at home, the reduction could actually lead to an improvement in the lives of the poor. Commentators have presented arguments against almost every point made by Murray, insisting that either his measures or his interpretations are wrong. For example, Murray's measure of economic growth, the gross national product (GNP), did increase throughout the 1970s, but real wages declined, and inflation and unemployment increased—poverty was not increasing during good times, as he argues. His other assertions have been similarly challenged (for summaries, see McLanahan et al. 1985; Katz 1989, chap. 4), but though his arguments and empirical findings simply do not stand up to close scrutiny, the broad viewpoint his work represents remains important in policy deliberations, probably because they offer pseudoscientific support for the biases of many.

MEASURES OF POVERTY

In the United States, official poverty estimates are based on the Orshansky Index. The index is named for Mollie Orshansky of the Social Security Administration, who first proposed it (Orshansky 1965). It is an absolute poverty measure, based on the calculated cost of food sufficient for an adequate nutritional level and on the assumption that persons must spend one-third of their after-tax income on food. Thus, the poverty level is theoretically three times the annual cost of a nutritionally adequate "market basket." This cost was refined by stratifying poor families by size, composition, and farm/nonfarm, and by creating different income cutoffs for poverty for families of differing types. Originally there were 124 income cutoff points, but by 1980 the separate thresholds for farm families and female-headed households had been eliminated, and the number of thresholds reduced to 48. Since 1969 the poverty line has been regularly updated using the Consumer Price Index (CPI) to adjust for increased costs. The

original index was based on the least costly of four nutritionally adequate food plans developed by the Department of Agriculture. Since a 1955 Department of Agriculture survey of food consumption patterns had determined that families of three or more spent approximately one-third of their income on food, the original poverty index was simply triple the average cost of the economy food plan. This index was altered for smaller families to compensate for their higher fixed costs, and for farm families to compensate for their lower costs (the farm threshold began as 70 percent of the nonfarm for an equivalent household, and was raised to 85 percent in 1969). Originally, the poverty index was adjusted yearly by taking into account the cost of the food items in the Department of Agriculture economy budget, but this changed in 1969 to a simple CPI adjustment (U.S. Bureau of the Census 1982).

Over the years there have been many criticisms of the official poverty measure and its assumptions (for summaries and extended discussion, see U.S. DHEW 1976; Haveman 1987). The first set of problems, some argue, come from the fact that the very basis of the measure is flawed. The economy food budget at the measure's core is derived from an outdated survey that may not reflect changes in tastes and options. Further, the multiplication of food costs by three is only appropriate for some types of families, other types must spend greater or lesser proportions on food. Some estimates indicate that the poor spend half or more of their income on food; the more well-to-do spend one-third or less. Even if the multiplier was correct, the original Department of Agriculture survey discovered it for posttax income; in the poverty measure it is applied to pretax income, though the poor pay little in taxes. Other problems often cited include the fact that the "economy budget" assumes sufficient knowledge for wise shopping—a dubious assumption for the poor—and the fact that the poor are often locked into paying much higher prices than average because of a lack of transportation. An additional problem is that the poverty thresholds are not updated by using changes in the actual price of food, but instead by changes in the CPI, which includes changes in the price of many other items such as clothing, shelter, transportation, fuel, medical fees, recreation, furniture, appliances, personal services, and many other items probably irrelevant to

the expenses of the poor. Findings are mixed, but it is generally agreed that the losses in purchasing power suffered by the poor in inflationary periods is understated by the CPI (see Oster et al. 1978, p. 25). A second set of problems derives from the fact that the definition is based on income only. Both in-kind transfers and assets are excluded. Excluding in-kind transfers means that government-provided food, shelter, or medical care is not counted. Excluding assets means that a wealthy family with little current income could be counted as poor.

DEMOGRAPHY OF POVERTY

In 1987 the average poverty threshold for a family of four was \$11,611 per year (all figures in this paragraph are from U.S. Bureau of the Census 1989a, p. 163; 1989b, p. 166; 1990). This means the assumed annual cost of an adequate diet for four persons was \$3,870.33, or about 88 cents per meal per person. For a single person the poverty threshold was \$5,778, and the food allowance \$1.76 per meal. In 1986 the poverty threshold was \$11,203, allowing 85 cents per meal, and in 1988 it had risen to \$12,091, or 92 cents per meal. In the United States in 1987 there were 32,341,000 persons below the poverty threshold, or 13.4 percent of the population. In 1988 there were 31,878,000, or 13.1 percent, almost a half-million fewer persons below official poverty than the year before. These figures underestimate official poverty somewhat, since they are based on the Current Population Survey, which is primarily a household survey and thus does not count the homeless not in shelters. The decline from 1987 to 1988 in the number in poverty is part of a long-term trend. In 1960 there were 8 million more—39,851,000 persons—who by today's guidelines would have been counted as officially in poverty, representing 22.2 percent of the population. By the official, absolute standard, poverty has greatly decreased over the past three decades, both in terms of the actual number of persons below the threshold and, even more dramatically, by the percentage of the population in poverty (U.S. Bureau of the Census 1989). This decrease actually took place over two decades, since the number of people in poverty in 1970 had declined to only 25,420,000, or 12.6 percent of the population, and the number and percentage have risen since then, but never back as high as the 1960 levels. Poverty is not evenly spread over the population. Of those below the

official poverty level in 1988, 57.1 percent were female, 29.6 percent were black, and 16.9 percent were Hispanic. Female-headed families with children were disproportionately poor. In poverty in 1988 were 38.2 percent of all such white families and 56.3 percent of all such black families (this is a gender phenomenon, not a single-parent one, since in 1988 only 18 percent of male-headed single parent families were below the poverty threshold). The age composition of the poor population has changed. In 1968, 38.6 percent of those in poverty were of working age (18–64), while twenty years later 49.6 percent of those in poverty were of working age. From 1968 to 1988 the percentage of the poor population over 65 declined from 18.2 percent to 10.9 percent, and the percentage who were children under 18 declined from 43.1 percent to 39.5 percent. A higher percentage of working-age poor is seen by some as a sign of worse times. It almost certainly reflects not only economic downturns but also in part ideological biases toward helping the presumably able-bodied poor; most antipoverty programs have been specifically aimed at the old or the young. O'Hare (1996) points out that the poverty rate and the number of poor in the 1990s exceed those figures in the 1970s. He notes that all the dramatic postwar decline in poverty rates occurred before 1973. After that, poverty rates in the United States rose through the early 1980s, then declined, but never back to the 1973 level.

Despite extensive debate about the policy implications of various definitions of poverty, and the inherent difficulty of locating this population, one can have confidence that the poor are being counted with reasonable precision. More than one generation of social scientists have contributed to the refinement of the measures of poverty, and existing statistical series are based on data collected by the U.S. Bureau of the Census—an organization with very high technical competence. Nonetheless, there is one group, the extremely poor, whose numbers are in doubt. All current measurement relies on the household unit, and assumes some standard type of domicile. As Rossi puts it, “our national unemployment and poverty statistics pertain only to that portion of the domiciled population that lives in conventional housing” (1989, p. 73). An extremely poor person living, perhaps temporarily, in a household where other adults had sufficient income would not be counted

as being in poverty. Even more important, the literally homeless who live on the street, and those whose homes consist of hotels, motels, rooming houses, or shelters are not counted at all in the yearly Current Population Survey (the decennial census does attempt to count those in temporary quarters, but the 1990 census was the first to even attempt to count those housed in unconventional ways or not at all). The studies of Rossi and his colleagues indicate that the number of extremely poor people in the United States (those whose income is less than two-thirds of the poverty level) is somewhere between four and seven million. The number of literally homeless poor people, those who do not figure into the official poverty counts, must be estimated. The best available estimate is that they number between 250,000 and 350,000, about 5–8 percent of the extremely poor population (Rossi 1989). The number of extremely poor people has more than doubled since 1970, while the population was increasing only by 20 percent (Rossi 1989, p. 78). The extremely poor are at considerable risk of becoming literally homeless. When they do so, they will disappear from official statistics (just as the unemployed cease being officially unemployed soon after they give up the search for work). To see that official statistics remain reliable in the face of increasing extreme poverty is the most recent methodological challenge in the field.

POVERTY IN LOW-INCOME COUNTRIES

Most of the discussion thus far has concerned poverty in the United States. Comparing poverty across countries is a difficult enterprise, but is important to do if one is to put poverty in any individual country in perspective. Poverty in the United States and in other highly industrialized countries simply does not fall into the same category as poverty in less industrialized nations. Many of those classified as in poverty in the United States would be seen as reasonably well off by international standards. This means that, although many countries report a “percentage-in-poverty” figure for their populations, these figures cannot be sensibly compared, since the concept of what constitutes poverty varies so widely. Statistics from the United Nations Development Program 1998 Human Development Report can illustrate this stark contrast. In 1998, in the forty-four countries the U.N. classifies as “least developed,” about 29

percent of the population was not expected to survive to age 40. Compare this to the 5 percent not expected to survive to that age in the industrial countries. In the least developed countries, 43 percent of the population has no access to safe water, 64 percent no access to sanitation, and 51 percent no access to health services (considering all developing countries rather than just the poorest, those figures would be 29 percent, 20 percent, and 58 percent, respectively). This level of living is characteristic of very few people in industrial nations, making poverty comparisons almost meaningless. The World Bank has attempted to provide international comparisons of poverty by creating a measure of the percentage of a country's population living on less than \$1 a day, calculated in 1985 international prices and "adjusted to local currency using purchasing power parities" (World Bank 1999, p. 69). The \$1-a-day figure was chosen because this is the typical poverty line in low-income countries. World Bank figures indicate that about 1.3 billion people live on less than \$1 a day. Twenty-seven countries in which over 25 percent of the population lives with resources at less than this level were counted, as were fourteen countries (Guatemala, Guinea-Bissau, Honduras, India, Kenya, Lesotho, Madagascar, Nepal, Niger, Peru, Rwanda, Senegal, Uganda, Zambia) where approximately half or more of the population lives on less than \$1 a day.

It is clear that while relative poverty is a serious moral and political issue in industrial countries, absolute poverty—at levels unheard of in industrial countries—is a far more serious problem in much of the rest of the world.

The study of poverty is a difficult field, and is not properly a purely sociological endeavor. As even this brief overview shows, a thorough understanding requires the combined talents of sociologists, economists, demographers, political scientists, historians, and philosophers. All these fields have contributed to our understanding of the phenomenon.
