PRAGMATISM

Pragmatism, the Greek root word of which means "action," grew out of a turn-of-the-century reaction in American philosophy to Enlightenment conceptions of science, human nature, and social order. Generally, it has sought to reconcile incompatibilities between philosophical idealism and realism. In the former, reality is conceived of as existing only in human experience and subjectivity, and is given in the form of perceptions and ideas. In the latter, reality is proposed as existing in

the form of essences or absolutes that are independent of human experience. These two traditions have grounded different approaches to empiricism and in their extremes can be found, respectively, in the solipsism of the British philosopher George Berkeley and the positivistic embracement of natural law by the French sociologist Auguste Comte.

As a response and an alternative to these traditions, pragmatism has not been developed as a unified philosophical system. Rather, it has existed as a related set of core ideas and precepts that are expressed as versions or applications of pragmatic thought. Variation within that thought ranges across the realism–idealism continuum and is largely a function of different analytical agendas. Despite that variation, however, pragmatism has become quite broad in its application to theoretical and research problems. Acknowledged as the most distinctive and profound contribution of American intellectual thought, its influence can be found in all contemporary disciplines in the humanities and social sciences. Its intellectual roots are described in Rucker (1969), Martindale (1960), and Konvitz and Kennedy (1960), and its core ideas are described in Shalin (1986), Rochberg-Halton (1986), and Rosenthal (1986).

MAIN IDEAS AND VARIATIONS

In summary form, the main ideas embodying the thrust of pragmatism are as follows. First, humans are active, creative organisms, empowered with agency rather than passive responders to stimuli. Second, human life is a dialectical process of continuity and discontinuity and therefore is inherently emergent. Third, humans shape their worlds and thus actively produce the conditions of freedom and constraint. Fourth, subjectivity is not prior to social conduct but instead flows from it. Minds (intelligence) and selves (consciousness) are emergent from action and exist dialectically as social and psychical processes rather than only as psychic states. Fifth, intelligence and consciousness are potential solutions to practical problems of human survival and quality of life. Sixth, science is a form of adjustive intelligibility and action that is useful in guiding society. Seventh, truth and value reside simultaneously in group perspectives and the human consequences of action. Eighth, human nature and society exist in and are sustained

by symbolic communication and language. In these core ideas can be seen the neo-Hegelian focus on dialectical processes and the concurrent rejection of Cartesian dualisms, the Darwinian focus on the emergence of forms and variation through adjustive processes, and the behavioristic focus on actual conduct as the locus of reality and understanding. These ideas were embraced and developed by a variety of scholars and thinkers, including Ralph Waldo Emerson, Percy Bridgman, C. I. Lewis, Morris Cohen, Sidney Hook, Charles Morris, Charles Peirce, William James, Charles Horton Cooley, John Dewey, and George Herbert Mead. Of these, Peirce, James, Cooley, Dewey, and Mead will be reviewed here for purposes of assessing the relevance of pragmatism to social science and sociology.

Charles S. Peirce (1839–1914) is generally credited as the originator of the term *pragmatism* and the formulation of some of its basic tenets. One of his earliest statements (1877–1878) pertained to methods for resolving doubt about conclusions, in which he argued in favor of science because of its flexibility and self-correcting processes. This view contrasts sharply with the Cartesian basis of science in subjectivism and individualism proposed by Descartes. Rather than focusing on belief and consciousness as definitive, Peirce focused on probability. Both truth and scientific rationality rest in a community of opinion in the form of perpetual doubt and through a process of revisions are measured in terms of movement toward the clarification of ideas. The emphasis in this process is both evolutionary, since Peirce saw modes of representing knowledge moving from chance (firstness) to brute existence (secondness) to generality or order (thirdness), and pragmatic, since truth is meaningful only in terms of future consequences for human conduct (the “pragmatic rule”).

William James (1842–1910) was driven by the problem of determinism and free will. This problem was expressed in his monumental *Principles of Psychology* (1890), in which he established a functional view assimilating biology and psychology and treated intelligence as an instrument of human survival, and in his brilliant analysis of consciousness (1904), in which he characterized human experience as an ongoing flow instead of a series of psychic states. Pragmatist principles were sharply articulated in these works. James accepted

Peirce’s pragmatic rule that the meaning of anything resides in experimental consequences. Accordingly, the distinction between subject and object as fundamental was denied and was replaced with the idea that relations between the knower and the known are produced by and in ongoing experience. This more dialectical conceptualization informed his theory of emotions, which stressed bodily responses as producers of emotional responses (e.g., we feel afraid because we tremble) and his theory of the self, emphasizing the “I” (self as knower) and the “Me” (self as known) as tied to multiple networks of group affiliation. His focus throughout was on the operations of ongoing experience, and his formulations not only specified and elaborated pragmatist principles but anticipated or contributed to behaviorism, gestalt psychology, and operationalism.

Charles Horton Cooley (1864–1929), building on the work of James, rejected the legitimacy of all dualisms. In his famous statement that “self and society are twin-born,” he asserted the inseparability of individuals and society. Individuals, he proposed, are merely the distributive phase and societies the collective phase of the same social processes. The indissoluble connection of self and society, which was the dominant theme of Cooley’s writings, is manifested in their necessary interdependence. His theory of the social self held that self-concepts are behaviorally derived through reflected appraisals of the actions of others—the looking-glass self. Especially important in the process of self-acquisition are primary groups (family, friends), which link the person to society. Correspondingly, society significantly exists in the form of personal imaginations or mental constructs; society, Cooley stated, is an interweaving and interworking of mental selves. Cooley’s approach was thoroughly holistic and organic, with human consciousness and communication being the most critical processes, and his work added further to the pragmatist’s dismantling of the Cartesian split between mind and society.

John Dewey (1859–1952) was perhaps the most influential and prolific of the early pragmatists. Coming philosophically to pragmatism from Hegelianism, he emphasized intelligence, process, and the notion that organisms are constantly reconstructing their environments as they are being determined by them. He contributed forcefully to the critique of dualistic thought in his analysis of

stimulus-response theory (1896). Instead of constituting an arc, in which the stimulus leads to a response (a dualistic conception), Dewey argued that they are merely moments in an overall division of labor in a reciprocal, mutually constitutive process (a dialectical conception). Central to those dialectics was communication, which according to Dewey was the foundation and core mechanism of social order. He developed an instrumentalist theory of language (1925)—language as a tool—which was generalized into a broader instrumentalism. One of his central interests was moral and social repair through the application of intelligence and scientific methods. He merged theory and practice in the view that ideas are instruments for reconstructing and reconstituting problematic situations. Those ideas may be moral judgements or scientific findings, but both take the general form of hypotheses, which are proposals for action in response to difficulties. Dewey thus built upon Peirce's and James's pragmatic rule by arguing that validity and truth statements, whether theological or scientific, are established by examining the consequences of action derived from hypotheses.

George Herbert Mead (1863–1931) sought understanding of emergent human properties, such as the ability to think in abstractions, self-consciousness, and moral and purposive conduct. His central argument was that these properties are grounded in the development of language and social interaction as humans adjust to the conditions of their environments and group life (Mead 1934). His position is said to be one of social behaviorism, in which the social act is the unit of analysis and out of which minds and selves develop. The act has covert and overt phases. It begins in the form of an attitude (an incipient act), is constructed through role-taking processes (imaginatively placing oneself in the position of others), and is manifested in overt conduct. All social behavior involves a conflation of subjective and objective processes through which persons adjustively contend with the facts of their environments and simultaneously create social situations. Mead's explicit theory of time and sociality places these adjustments squarely in the dialectics of continuity and discontinuity (Maines et al. 1983).

In these five brief summaries can be seen how the early pragmatists wove together strands of

scientific method, evolutionary theory, language, and behaviorism into a radically new perspective. Pragmatism provided a clear alternative to perspectives based on Cartesian dualisms and reconstituted science, morality, aesthetics, political theory, and social development in terms of dialectical transactions. Philosophical idealism and realism were brought into a common framework in the proposition that human experience and facts of nature and society (the “world that is there,” as Mead called them) are only phases of ongoing social processes that mediate persons and their environments in terms of transacted meanings. The variation within pragmatism hinges largely on individual affinities for idealism and realism: James and Cooley tended toward idealism, Peirce toward realism, and Dewey and Mead toward a transactional midpoint between the two. Moreover, there is variation in pragmatism's influence in the social sciences and humanities. Dewey has been enormously influential in education and communication, Mead and Cooley in sociology and social psychology, Peirce in semiotics, and James in psychology. That variation, however, only represents modal tendencies, since pragmatism as a whole has had a significant impact across disciplines.

INFLUENCE IN SOCIAL SCIENCE

Since 1980 there has been a major resurgence of interest in pragmatism (Bernstein 1986). Its compatibilities with quantum mechanics and relativity theory have been articulated, as has its relevance for the development of a more social semiotics and discourse analysis (Perinbanayagam 1986). The relation of pragmatism to hermeneutics, from the tradition of German Idealism, has been reexamined (Dallmayr 1987), as has its relation to critical theory in the work of Jürgen Habermas (McCarthy 1984), literary criticism (Rorty 1982), phenomenology (Ricoeur 1985), cultural studies (Carey 1989), and modernization theory (Rochberg-Halton 1986). According to some, such as Richard Bernstein and more recently John Diggins (1994), this resurgence indicates that the early pragmatists were ahead of their time. Some scholars in the 1990s have continued to revise pragmatist thought on its own terms. Wiley (1995) has proposed a sophisticated modification of Mead's theory of the self through Peirce's triadic,

semiotic perspective. Joas (1993), while not writing on pragmatism, per se, has shown how pragmatist precepts have been intrinsic both to classical and contemporary theory. He also (Joas 1996) has retheorized creativity, long at the heart of pragmatism's emphasis on novelty and indeterminism, for dominant sociological models based on structural differentiation, rational adaptation, and self-enhancement.

Other scholars have sought to reinvigorate pragmatism's relevance for contemporary political and cultural agendas. Noting that the seeds of a feminist pragmatism existed in the work and practices of the classical thinkers (Mead, Dewey, James), Seigfried (1996) politicizes pragmatism in the common struggles of women, ethnic minorities, and the sexually marginalized. While retaining the traditional center of the perspective, she seeks to move it toward a reconsideration of contextual ethics and reciprocal moral responsibility and to promote the search for pragmatic truths that would emancipate people from distorted beliefs and values that become sedimented into accepted fact. These scholars also include Cornell West (1989), who articulated his version of "prophetic pragmatism" in *The American Evasion of Philosophy* and followed it with his influential *Race Matters* (1994), which was more politically engaged and contributed to a more vibrant democracy that better empowers local participation in institutional concerns. Still others have sought more radical revisions of pragmatism. Denzin (1992, 1996), drawing in part from West, provides a revision of pragmatism in postmodernist, cultural studies terms that seeks to transform it into a mechanism of cultural critique. Such works find audiences in humanistic circles, but have met with mixed reactions among social scientists. Farberman (1991) and Lyman (1997) reject the postmodernist project partly on the grounds of its nihilistic implications, Van Den Berg (1996) because of its limited vision of Enlightenment philosophy, and Maines (1996) because its core concepts are already contained in pragmatist thought. Others, such as Seidman (1996) have attempted more even-handed critiques and seek the common ground of postmodernism and pragmatism. Regardless of recent interpretations of pragmatism, the collapse of hegemonic theories and the corresponding import of post-positivistic debate in social scientific theorizing has brought

the basic tenets of pragmatism back into the search for new paradigms in social theory.

These recent influences and developments notwithstanding, there has been a long tradition of direct influence of pragmatism on social science research and theory. Sociology's first research classic was Thomas and Znaniecki's (1918–1920) study of Polish immigrant adaptation to American urban life. They were interested in questions of personal adjustment, family relations, neighborhood formation, delinquency, and cultural assimilation, and they used the principles of pragmatism, especially as expressed by G. H. Mead, to answer those questions. Their monumental five-volume work presented their attitude-value scheme as a general theory of the adjustive relations between individuals and society. "Attitudes" referred to the individual's tendencies to act and represented human subjectivity; "values" referred to the constraining facts of a society's social organization and represented the objective social environment. Both are present in any instance of human social conduct, they argued, but the relationships between the two are established in processes of interpretation that they called "definitions of the situation." Thomas and Znaniecki thus placed human agency at the center of their explanations, and they conceptualized society as the organization of dialectical transactions.

That research contained pragmatist ideas pertaining to the social psychological and social organizational aspects of human behavior. These aspects were developed during the 1920s and 1930s at the University of Chicago by Ellsworth Faris and Robert Park. Faris (1928) examined attitudes, especially in terms of the nature of their influence on behavior. He argued that human subjectivity is a natural datum for sociological research and proposed that wishes and desires, not attitudes, have a direct bearing on overt conduct. Park (1926) was more interested in large-scale historical issues such as urban organization and racial stratification. He directly applied Dewey's focus on society as communication to his research on urban communities. These communities, he argued, have objective spatial patterns, but those patterns are not separable from human consciousness. Urban ecology thus has a moral dimension composed of meanings that collectivities attribute to urban areas. The pragmatist roots of Park's sociology recently has been reemphasized

in his theory of human ecology (Maines et al. 1996), his influence on applied sociology (Reitzes and Reitzes 1992; see also Maines 1997), and as a framework for describing and theorizing urban public space (Lofland 1998).

The pragmatist themes of individual/society inseparability and human behavior as transactions were pursued by other sociologists. In 1937, Herbert Blumer coined the phrase *symbolic interaction* to refer simultaneously to how humans communicate and to a sociological perspective. He applied that perspective to a wide range of research areas such as social psychology, collective behavior, race relations, and social problems (Maines 1989). Blumer's posthumous volume on industrialization and social change (1990) elaborates the Thomas and Znaniecki formulations by presenting a conceptualization of causal influences that hinge on human agency and interpretation. Stone's research on clothing and fashion (1962) similarly focuses on human behavior as transactions. In particular, his analysis of identity establishment identifies dialectical processes of communication through which individuals are located and placed in the social organization of society. His treatment of interpersonal identities is sympathetic to Cooley's emphasis on the importance of primary groups, while his treatment of structural relations corresponds with Thomas and Znaniecki's concept of values and predates contemporary social psychological research on individuals and social structure.

Studies of social organization have been directly influenced by pragmatist principles, as previously mentioned, but that influence has been especially apparent since the early 1970s (see Hall 1987 and Fine 1993 for summaries). Anselm Strauss's research on occupations and formal organizations has been prominent in this recent work and has led to the development of the "negotiated order" perspective (Strauss 1978). Negotiations, he argues, are processes through which collective actions occur and tasks are accomplished. These processes are influenced by actor characteristics, the immediate situation, and larger structural contexts. However, those larger contexts are also influenced reciprocally by actual negotiations and their situations. Strauss's model of social organization thus is a recursive and dialectical one. Stryker (1980) presents a slightly different version but one that is no less pragmatist. He incorporates

traditional role theory to argue that social structural arrangements limit options and opportunities by channeling people into status and role positions. So located, people construct their identities in terms of social meanings that are hierarchically organized. Both Strauss's and Stryker's applications of pragmatism have stimulated considerable research and theoretical development.

Such development has continued with some vigor throughout the 1990s. Pestello and Saxton (2000) draw on explicit principles of pragmatism to reframe the study of deviance in terms of the dialectics of inclusion and exclusion. While closer to the classical statements, they share with the neo-pragmatists such as West, Seigfried, and Rorty the interest in reclaiming the vision of emancipatory democracy that has always been present in the perspective. Other scholars have used pragmatist principles to further develop areas of sociological theory. Fine (1992) addresses the relationship between agency and structure, and theorizes both the obdurate and interpretive dimensions of the relations among contexts of action. Musolf (1998) shows how agency and structure relations are expressed in an array of standard sociological areas (socialization, gender, deviance, power, society), while Hall (1997) offers an updated version of his earlier conceptual framework (Hall 1987) that allows analysts to better specify dimensions of agency-structure relations. Five dimensions are identified: strategic agency, rules and conventions, structuring situations, culture construction, and empowering delegates. He then shows how power is expressed along these dimensions and links together situations and contexts.

In a related approach to matters of agency and structure, Strauss (1993) builds on his earlier theory of negotiations to focus analysis on ordering processes. He begins by articulating over a dozen assumptions drawn from pragmatism that guide his analysis. He then presents a "processual order" theory that focuses on how larger scale processes and structures condition organizations and situations within which people interpret and construct their conduct and how local decisions have consequences for larger scale processes and structures. This theory has been used in research by Fischer and Dirsmith (1995) to examine organizational strategies and technology use in large accounting firms. Ulmer (1997) also has used the theory to

explain how state sentencing guidelines are filtered through state and local political processes, and how local court communities set “going rates” for actual criminal sentencing. Ulmer’s research is especially relevant because it simultaneously presents data on statewide sentencing outcomes and the contextual practices that produce those outcomes.

Yet another related line of development has focused on what W. I. Thomas ([1927] 1966) called “situational analysis,” which examines the interplay of actors’ interpretations and the obdurate qualities of situations. Katovich and Couch (1992) draw on Mead’s theory of time to show how pasts are used by people to become socially situated. Situations, they argue, are not merely settings in which human conduct occurs, but rather are forms of conduct themselves and exist as transactions of pasts and futures. Gusfield (1996) presents his long line of research on alcohol problems, and addresses how those problems are constructed. He discusses various claims-makers within the alcoholism movement, and then dissects actual alcohol problems in terms of their situations—situations of drinking, of driving, of accountability—and the ideologies and logics-in-use that connect them. Hall and McGinty (1997) analyze educational policy processes from the “transformation of intentions” perspective. In a statewide study of the Missouri career ladder program, they show how various contexts (state legislature, advisory committees, bureaucratic offices, school districts, local schools) influence the original intended policy. Actual policy effects, accordingly, are strongly influenced by situational contingencies that render policy processes themselves less-than-rational. Similarly, Deutscher and colleagues (1993) analyze the contradictory findings from decades of attitude-behavior research, and provide a situational approach for explaining the inconsistencies between attitudes (what people say about themselves) and behavior (what people do). To understand consistency and inconsistencies between attitudes and behavior, they argue, we must understand the situations that produce those kinds of relationships.

One of the distinctive characteristics of social science research and theory that has been grounded in pragmatism is the reluctance to give credence to dualisms such as micro-macro or individual-society. While issues of scale have always been acknowledged and used, as the work of Park, Blumer,

Stone, Stryker, Strauss, Hall, and Fine has demonstrated, the focus has been on the examination of social processes that produce, maintain, and change social orders. These social processes have generally been conceptualized as communicative in nature, and the central thrust has been on how large- and small-scale phenomena are simultaneously or similarly transacted by individuals and groups. The focus on those processes has maintained the action orientation of pragmatism, and the central precepts of the perspective are finding increasing currency and relevance in contemporary work in the social sciences and humanities.

DAVID R. MAINES

PREDICTION AND FUTURES STUDIES

PREDICTION AND SOCIETY

Meaning. Prediction (*previsione*) is "seeing beforehand" how the future will be; that is, the situation that will come about in the short, medium, and long term. This, however, is a "seeing beforehand" that is not content with simply knowing what the final situation will be but it is also concerned with knowing with how it will be reached. It is concerned not only with the end-point but also with the process that the present situation will undergo to transform itself into (or remain as) the end-point. This two-part nature of prediction (end-point and development/process) enables us to take prediction into a scientific dimension, because the process by which the end-point is reached is comprehensible by means of the elaboration of a standardized method of identifying variables and their positions in a model of relationships that

connect the before to the after, and carry the before to the after, and lead from the starting point to the end-point. Without this scientific attention to the passage from the former point to the latter, prediction could simply be a matter of taking the present and reading its evolution by means of an external "operator," such as a magic formula, casting stones, or the interpretation of animal innards.

This scientific attention to the process leading to the end-point—the prediction—is so crucial because by identifying elements of the process we can modify their developments to bring about the prediction we postulated. In other words, the variable now to be discovered and defined is not so much the prediction (with the extrapolative method) as the scientific process to be predicted so as to achieve a situation we desire (with the normative method).

In the light of the above, the term "prediction" as a name for this discipline is clearly less appropriate than others, such as "futurology," "future thinking," or "futures studies." A distinction may be drawn between two of these in that "futurology" is more of a disciplinary name and "futures studies" is more of an agenda of scientific activity aimed at achieving and discriminating between possible, probable, and desired futures.

In fact, if prediction is all of these things, it is of fundamental importance for taking action; that is, for deciding a priori how to achieve a given objective or to discover what a particular action will lead to.

Prediction is basically a scientific process in both of the senses just described, but it is also strongly related to other cognitive dimensions, such as ideology, ideas of utopia, action, and change. The theories underpinning prediction therefore combine or conflict with the theories and cognitive dimensions of reality. The links between these concepts should therefore be made clear.

Prediction, Utopia, and the Future of Traditional Society. A link of some kind between prediction, ideas of utopia, planning, and change certainly exists. We shall try to highlight it, starting from the problematic identified for prediction. Utopia is a "nonplace" in which is located a perfect society (perfect for he who first conceives it) dominated by a "cold synchrony," that is, by mechanical

relations that serve only to maintain the utopian system without creating the emotional “warmth” or interests, including conflicting interests, whose relational outcome is unpredictable and therefore transforms the time-one system into something different from the time-zero system. Utopia is therefore the end-point of prediction, static and without relations, whose outcome cannot be predicted—an absolute end-point beyond which is nothingness. And between the present and the utopian state is “non-sense,” that is, a black box whose contents do not interest us—the contents being the process that enables us to pass from the past to utopia.

What relation is there between prediction and utopia? We can interpret utopia as a residue of traditional society in which everything is tied to the past, but experienced in the pre-modern European society of the fifteenth and sixteenth centuries. In traditional society, real prediction, and therefore the future situation, is *deduced* by the past: Action is prescriptive, change is an aberration, organizations are similar because they all have the same structural contents and perform the same functions. Everything comes from the past: Rules are written in the past and actions are already perfected in the past. In these conditions, the process generating the future is a *dejà-vu*—not a perfect one, but a human condition and a destiny. The end-point that is different from such a prediction is not of this earthly condition but of the other life, in heaven or in hell. Utopia represents a sort of rebellion against the placing of heaven beyond earthly life—it is the secular dream of human omnipotence because it dares to place social perfection “not here” but nonetheless on earth. This utopia, an expression of the rebellion—no matter how fantastic—of traditional man, comes to represent a piece of “heaven” brought to earth, in which relations between people and social structures are so “sweet and delicate” as to strengthen the sweetness we have inside us rather than producing new situations and without automatically creating new equilibriums and new states. Because of all this, we can understand why constructors of utopia do not need to know the process enabling us to pass from the present to the future (because it is a copy of the past) and why it is dominated by a static equilibrium that does not change once it has been achieved.

Thus prediction, utopia, and change in a society in which change is an aberration mean at the

most bringing the perfection of the nonearthly world into the earthly world, but leaving it detached from reality, which also remains immutable. In other words, prediction is a game left to forces that are untameable and therefore ineluctable and at bottom mechanical, perpetuating positive and negative flows *ad infinitum*.

Prediction and the Objective as a Reference for the Plan: Ideology and the Future of Modern Society. Prediction becomes practically useful—able not only to reveal what will be but how this future may be controlled—when we lose sight of the perfections of the state we have called utopia and it takes on the role of an objective to be striven for, when an active value is ascribed to social ideals and single individuals’ capacity for action. Here, society activates ideology as a resource and at the same time recognizes the ability of individual action, and above all the synthesis of individual actions, to create new situations.

Modern society thus shifts the focus from *the perfection of utopia*, which needs no modification since it is by definition perfect, and which is (an unreachable) vaguely defined objective, to the *laboratory of process*, which is concerned with relations and objectives to be achieved. If such an objective happens to be clearly defined, it is so accepted as provisional and therefore “adjustable,” because certainty is only to be found in highly generic values such as justice, equality, and self-fulfillment in a fair, egalitarian, individual-enhancing society. This process of achieving the desired or probable prediction is guided by two resources activated by society. The first is ideology, the cognitive representation of the world used to guide practical action toward the objective that is the subject of prediction. The second resource is trust in the individual whose initiative may contribute to achieving the prediction, with the proviso that the action of this individual must be combined with that of other individuals to thus produce positive results for the predicted state of interpersonal and social relations.

In this view of modern society, it seems that the focus—aside from the objective defined in the probable or desired prediction that in its most complete form takes on the configuration of a plan—shifts for the most part to the process from which the prediction (and the predicted plan) emerges and thus to how this process is rationally

manifested, how it may be scientifically explained, and what may be done to bend it to the achievement of the prediction.

All this comes about in modern society because change is conceived as normal, a factor built into the trajectory toward the future, tendentially and plausibly different from the present and above all from the past. All that remains of the past is the genetic origin of the present and a certain limited influence on it. If we have thus conceptually severed the deterministic link (at least in ideological terms) between past and future, modern society clearly has to focus very sharply on the processes and interdependent relations of the present in order to predict and dominate the future.

Determinism and Creativity in Prediction.

To understand how prediction is to be orientated and manifested, rationality and the scientific method are essential because rationality and the scientific method provide the most effective and efficient ways of bringing about the realization of what we want to happen or what “must” happen. Hence the importance of method in obtaining a prediction and controlling it.

Methods have both deterministic components and creative components that are selected and embedded into techniques proper; these will be considered below. For the time being, it is sufficient simply to mention some features of these components. Deterministic components ground the formation of the end-point (prediction) in relations among the social, economic, environmental, and value structures defined in a model. Creative components include those that highlight the identification and pursuit of new and “invented” ways of controlling or accelerating the achievement of a prediction. Around such components, objective or subjective methodological techniques are developed that highlight the workings of a model and its simulation or formation of decisions.

METHODS OF PREDICTION

The Scientific Problem of Prediction. Not only is the scientific nature of social sciences considered suspect by people outside the social sciences, but certain social scientists themselves consider the social disciplines nonscientific because the most they can do is provide a way of “reading” a social reality composed of individuals, groups, mutual

relations, and formal organizations. For such people, the social sciences are not sciences but opinions. The reason is that—apart from some concepts providing interpretative keys for human, social and organizational action, mutual relations, and the products of those relations—interpretative theories stand the test of falsifiability only for a short time, often only until an event outside the phenomenon under investigation undermines the equilibrium and internal stability achieved by the phenomenon and explained by the theory. In the short term, the interpretative weakness of the theory even throws doubt on the ability of social science to explain the phenomenon. And this weakness of explanation obviously affects the strength of the prediction and consequently what has to be done to change it, that is, what is to be done to carry the present into the future.

Yet particular attention has been focused on four of the activities or purposes of which science is composed: (1) description as a pre-scientific stage and (2) explanation, (3) prediction, and (4) control as scientific activities proper. In point of fact, causal explanation is the central activity of the scientific process, since prediction is deduced from explanation and control is a “political” manipulation (and as such outside the phenomenon explained) of the variables of the explanatory model, undertaken deductively to achieve a modification of the prediction.

It may therefore be said that induction is at the root of description and explanation and deduction is at the root of prediction and control. But it is for precisely this reason that the first two activities are “more scientific,” in that they are caught up in the bond between theory and theory-testing empirical research, whereas prediction and control are more rooted in utilization and change, in the final analysis in technical application. It is probably in this logic that we should see the contradiction between prediction as a science, whereby methods and techniques are elaborated as a deductive extension of methods for description and explanation or the perfection of methods, and prediction as techniques to help elites who have to make decisions to modify predictions and the explanatory picture deriving from them.

In other words, making predictions becomes scientific activity on the basis of data that are

absent but that are plausible or possible or probable or desired, and whose relations may give rise to situations and scenarios that are equally possible, probable, and desired, but not certain.

The scientific nature of prediction is therefore based on rationality and the logic implicit in the links between events that have already come about and implicit in the possible reactions of, or to, a behavior that may come about. It is thus a matter of *reasoning by analogy*: Such-and-such has happened before in certain situations, so it may happen now in similar situations.

The scientific nature of prediction is also based on the fact that from the level of spatial analogy (if we have verified that an effect comes about *here*, we may infer that it will come about *there* in culturally analogous conditions) we may pass to the level of temporal analogy (if we have verified in the causal explanation that something comes about *today*, we may infer that it will come about *tomorrow*).

In more general terms, in prediction there is a “low-profile science,” which becomes the rational study of what could happen in the future and above all how this might be more adequately dealt with so as best to guide or govern it.

Given these epistemological premises for prediction, the techniques that manifest its methodological paths are the result of the combination of certain features of the methods: qualitative and quantitative, those based on objective data or the opinions of elites (of power or knowledge), and extrapolative or normative. The predictive specificity of these three features increases from the first to the third. *Quantitative and qualitative* refer to the level of research and knowledge concerning a given phenomenon; the higher the level, the greater the chance of having indicators that are tried and tested and therefore more practically defined. *Objective data and elite opinions* are more closely tied to the usefulness ascribed to prediction. The objective datum reconstructs the model in a system, identifies the causal process and objective to which it leads, and starts from the assumption that it is “technically” possible to act on the structure of the process to modify its consequences. Leaders’ opinions are privileged in that the basic assumption is that it will be their ideas and expectations, “true” or “false” as they may be, that condition, or even produce, the change in the

objective/end-point. In the first of these approaches, there is extreme confidence in the scientific character of the epistemological canons of science; in the second, there is substantial lack of confidence that science can produce reality control—it becomes merely a formal exercise, though rationally useful. The *extrapolative and normative* features introduce action aimed at controlling the objective/end-point: Extrapolation is the projection of present processes and mechanisms into the future to postulate how it may possibly and probably be configured; the normative feature is fixing the desired future to identify the processes and mechanisms to achieve it. This is a dual approach to the future that is complementary rather than contradictory, in that its second (normative) part begins where the first (extrapolative) has served its purpose.

Table 1 shows the various techniques of prediction in relation to the three dimensions defined by the three features: qualitative–quantitative, objective–leaders’ opinions, and normative–exploratory.

This plotting enables us to make some statements and develop some assessments of methods, especially of their function in establishing the various dimensions of prediction in terms of future studies.

Objective and Quantitative Techniques. Objective and quantitative techniques are common to all research. They are standardized and consolidated in practice. Scenarios, time series, causal models, simulations, and so on provide potent instruments for translating quantitative results into explained variance and high probability, although their considerable rigidity leaves them unable to cope with interference from new and sudden exogenous variables. These highly statistical methods are more effective in short-term prediction and for circumscribed rather than global events. They are also used in combined form to achieve both exploratory and normative prediction. Here the methodology may be used to explain the causal process by means of which a given trend is manifested, after which a “mission” is decided upon—a defined objective, such as a plan—and modifications are introduced into the contextual variables and their relational flows in order to achieve the objective. An example of these combined methodologies may be found in the research carried out

on the Italian situation by Alberto Gasparini under the auspices of the Istituto di Sociologia Internazionale di Gorizia (ISIG) (Gasparini et al. 1983, 1988).

The first research project set out to identify how to meet the housing needs of a metropolitan area in accordance with a preestablished norm, which in this case was the habitation standard expressed in terms of the acceptable ratio between living space and family sizes. Housing needs were identified by applying several habitation standards,

after which exploratory techniques were used, simulating natural demographic and social trends, simulating new housing markets and vacant housing markets, introducing factors such as filtering and vacancy chains. The result was the determination of how much of future housing needs (for example, ten years later) would remain with no intervention, that is, by leaving the area's housing situation to develop under its own impetus. Subsequently interventions were carried out on single variables: incentives for building new housing or for putting vacant housing on the market or for

restoring existing housing or for providing financial help for needy families, and so on. The observation of the effects of interventions on the variables of the housing needs model indicated whether the objective had been achieved and, if it had not, provided indications as to the most appropriate modifications to be applied to single variables in order to achieve the objective.

The second project was on the quality of the environment in daily life in Italian towns. The questions were the following: What type of environment is it? How can quality be defined? What is the current state of environmental quality? How can high environmental quality be achieved in the daily life of the town? To answer these questions, prediction was developed over the following stages: (1) Quality of the environment was defined according to people's expectations in terms of services (number) and their spread or concentration in the town area, all placed in relation to individual and community values expressed by the local inhabitants. Surveys were carried out in each town by giving a questionnaire to 137 samples in as many communities, for a total of 33,000 interviewees. The result was the *model of desired environmental quality for daily life* as derived from subjective data converted into objective data. (2) This desired model was applied to each town (how many and what services existed and their location), which gave the *model of environmental quality for daily life lived*. (3) Observations were carried out on the context in which the above model was placed and the variables producing it, in order to identify the variables that influence the quality of the environment in it. These independent variables (clusters of multiple variables reduced in number by factor analysis and causally related to environmental quality through canonical analysis) represented the various features of community life: population, town territory, values, economic structure, social structure, local government, endogenous resources, exogenous resources, communications with the outside world, and so on. (4) The achievement of the desired environmental quality for daily life was explored by intervening on the variables that were causally most important for environmental quality (as they emerged from stage 3) and by simulating the effects that these interventions would have on environmental quality. This may entail further interventions on single variables until the

achievement of the desired environmental quality, which is the subject of the prediction.

A third project was the definition of task environments and their dynamics in agricultural production organizations. This research was basically exploratory in nature, concluding with normative assessments. The exploration was not carried out by inquiring into how company task environments are modified over time (an inquiry into process), because the starting theory (to be subjected to verification) was that proposed by Emery and Trist (1965), whereby task environments are modified as companies expand and become increasingly causally important and disruptive, introducing irrationality into the decisions companies have to make. In this research, then, predictive exploration was not based on the projection of variables into the future, but on the investigation of two situations (small-company and large-company task environments) and their comparison in accordance with the Emery-Trist theory, reconstructing the dynamics by comparing the two potential stages of a single company that grows from a small one into a large one (Gasparini 1983). By means of defining the role of the agricultural entrepreneur and his relations with the task environment organizations, synthesising these into a few factors (by factor analysis) and linking them through canonical analysis, task environments were identified and articulated according to their influential and direct relations with the company, according to contacts not generating real influences in that relations were based on sporadic contacts, and so on. One substantial difference emerged between small and large companies. In small companies, there are few influential relations and a great many casual and sporadic contacts. In large companies, the relational task environment is very rich in relations, influences, and dependency on company decisions; the structure of the sporadic contact task environment is by contrast marked by relational links that are weak and few and far between. This exploratory projection produced by the hypothetical transformation of a small company into a large one therefore showed a radical change in the functional and power relationships of the task environment. The identification of concrete relations and contacts and their respective influence clearly leads to the intention to intervene according to the normative objective, which in this case is a rethinking of

entrepreneurship, or an operational intervention in the agricultural economy to make sure that small and large entrepreneurs retain the power and responsibility assigned to them by the theory.

These three research examples show the great versatility of quantitative and objective techniques, that they need to be integrated with one another, and that they can be used in the exploratory dimension and some normative functions. These techniques are inextricably intertwined, as is exemplified by the fact that the exploratory dimension itself must be defined by reference to the *criterion* implicit in the normative dimension.

Leader's Opinions and Qualitative Techniques. The methods and techniques based on leaders' opinions, be they decision makers or experts in a particular field, are fundamentally qualitative in nature, that is, they are based on assessments that can be conventionally ordered in numerical values from which relations can then be highlighted. This can be done, as in the case of cross-impact analysis, but it should not be forgotten that the quantitative values manipulated are derived from percentages attributed intuitively to the occurrence of one event rather than another. Nevertheless, there are slightly differing degrees of formalization between these methods, and they are expressed in terms of their internal logic, reasoning experience that discriminates the more possible from the less possible, the ability to progressively refine judgments (the Delphi method), the compatibility between the reasoning and the context in which it is used, and the compatibility that has to give rise to the prediction for the phenomenon placed in the context.

This type of technique also contains scenarios, but they derive more from leaders' judgments than from the (highly implicit) model at the basis of the issues at stake and therefore of the variables defining the features of the model itself.

These are thus methods that can be used for the study and prediction of phenomena whose details are not known and/or which are relatively new, which means that recourse is made to qualified individuals equipped, for one reason or another, to see their own knowledge and predictions through the prism of research experience or familiarity with decision-making processes. If such is the case, the next step might be to transform the

results of these subjective predictions into indicators and formal explanatory models, to be tested with exploratory methods and normative methods to obtain a (concrete) measurement of the projection or process required to achieve the predetermined objective-norm-criterion.

But it may also be the case that the simple results derived from these opinions are considered sufficient (expressed to various degrees of sophistication by means of in-depth interviews, the Delphi method, cross-impact analysis and the qualitative scenario), and this happens because, or probably because, the scientific component in the prediction is not held to be very important; it is considered as a set of rational instruments for reasoning about the plausibility of the prediction itself. Taking into account that these rationalized judgments come from policymakers (at the summit of the decision-making process) or opinion makers, this ascientific factor is even more worrisome.

In this case, the implicit conviction is that these are the players who will have a major role in the achievement of their own prediction—in which case, we are faced squarely with the principle of self-fulfilling prophecies.

Techniques in a Band of Abivalence. From Table 1 we still have to analyze the two intermediate bands in which predictive techniques are to be placed. Though these are conceptually different in some respects, they are also instrumentally contiguous, which in practice means that they often overlap, or are at least complementary, when being used. Objective qualitative methods indicate that phenomena are analyzed structurally with no measured data; methods that are quantitative but based on leaders' opinions provide judgments strongly based on facts, or at least measurable data, which involves a strong tendency to apply leaders' opinions to a concrete context.

Prediction techniques placed in these two bands of ambivalence are very similar to those devised for the predictive analysis of leaders' opinions, but they rely heavily on a detailed knowledge of context. Thus they also make use not only of the Delphi method, cross-impact analysis, and scenarios, but also simulation in objective quantitative methods. However, the most typical of these two bands are relevance trees, science fiction, and tendency impact.

An example of predictive research in this context of ambivalence is condensed in what Igor Bestuzhev-Lada (1997) calls “technological prediction.” It comprises seven procedures that use methods which are both quantitative and qualitative, objective and subjective. The procedures are: program elaboration, construction and analysis of the starting model, construction and analysis of the predictive background model, exploratory prediction, normative prediction, prediction verification, and formulation of recommendations for a proper management of technological prediction. Indicators are often measured quantitatively, but their treatment and assessment are mostly qualitative.

In summary, the combination of the three criteria detailed in Table 1 indicates the following:

1. There are more specific techniques in the objective–quantitative methods and the leaders’ opinions–qualitative methods.
2. In the ambivalence band, methods that are typically objective and bound to opinion leaders tend to extend toward the quantitative and qualitative.
3. The exploratory and normative methods are not alternatives but are fairly well integrated with one another. An exploratory projection is implicit in the normative method, and the exploratory method requires a criterion that is able to be transformed into the desired prediction–norm.
4. Many methods are multivalent in prediction in that they are used to construct many types of prediction, but also in that they are technically versatile because they can be used with measured data and opinions alike. The most important example of this is the scenario.
5. The effectiveness of the methods varies according to the type of prediction in question. For short-term predictions and those on a circumscribed subject, the quantitative–objective method is most effective. The longer the period involved and the broader the subject, the more effective are qualitative methods and methods based on leaders’ opinion. This means that a broad to medium to

long-term framework analyzed with qualitative methods contains specific short-term subjects studied with mathematical formalization.

6. The scientific nature of prediction methods therefore varies with the variation of frames and times of reference, or at least there is a variation of the forms of expression of the scientific activities of description, explanation, and control.

From the above it thus emerges that the complexity of *prediction of the future* entails a multiplicity of studies because the future expresses itself in very different ways. This is why it is more than legitimate to speak in methodological terms of *futures studies*.

THE DISTRIBUTION OF FUTURES STUDIES IN TIME AND SPACE

It is well known that studying the future becomes a strongly felt need in times of transition. The rules of the past no longer hold, and the rules for the future do not yet exist or are still untried. In addition, globalization accentuates the need to build niches within which some form of autonomy may be regained. But what does niche autonomy mean when globalization bombards it with the upheaval external to it, upheaval which is therefore experienced as irrational?

This question gives rise to the need to predict and to achieve prediction through studies on the future or futures. It is hardly surprising that many public and private institutions have set up study centers for prediction. An indicator of this growth is provided by the large number of Web sites for such centers, which are being put together to form a *Futures Studies Internet Society*.

An ISIG study (Apuzzo et al. 1999) has found that worldwide two hundred and eight institutions working in futures studies have Web sites. Of these, one hundred and forty publish papers, one hundred and twenty-three provide links, sixty-nine publish their own journals on-line and conduct training, sixty-four advertise books, fifty-seven provide on-line shopping, forty-seven pass on chat news, thirty-eight make available projects, thirty-four are concerned with software, and twenty-eight deal with methods and techniques.

Most of the sites are American (one hundred and seventeen futures studies institutes) and only twenty-three are international; fourteen are in Britain; eleven in France; eight in Australia; six in Sweden; five in Canada; three each in Germany, Finland, Belgium, Norway, and Italy; two in Switzerland; and one each in Argentina, Denmark, Zaire, Austria, Israel, and Russia.

There can be no doubt that the future, especially in the United States, is strongly perceived as a subject requiring analysis. We have interpreted this as a way of finding autonomous futures for individual niches in the context of sweeping globalization. But it may also happen that despite this intention, the incipient Futures Studies Internet Society will accentuate the very standardization of feeling, thinking about, and planning the future that such great efforts are being made to curtail.

PREGNANCY AND PREGNANCY TERMINATION

Pregnancy is one of the most important events in a woman's life. For many women, pregnancy defines, enhances, or determines their economic, social, or personal value. Pregnancy and childbearing can be highly desired for personal reasons, or to meet social expectations. In some circumstances, childlessness may be grounds for suspicion, divorce, or worse. Pregnancy in the wrong situation may be undesirable to an equivalent degree. Traditionally, the woman with an unacceptable pregnancy may be abandoned, lose her prospects for marriage, be forced into prostitution, or suffer an even worse fate. Other pregnancies, even though they occur within a socially sanctioned circumstance, may result in loss of opportunities for social or economic advancement. Control over the occurrence and outcome of pregnancy is integral to women's control over their lives. This concept was strongly stated at the International Conference on Population and Development in Cairo in 1994.

Menarche, the first menstrual period, marks the beginning of a woman's reproductive period, and menopause, the last menstrual period, marks the end. Menarche occurs between ages 8 and 14 for most well-nourished women, but may come later if there is malnutrition or chronic disease. If the first menstrual period follows ovulation (release of an egg or ovum from the ovary), the woman may be fertile before menarche has occurred. For most women, fertility increases rapidly in the first year after menarche, as ovulation becomes more regular, so that as many as 95 percent of women in their late teenage years may be fertile. Infertility in the first years after menarche may be due to malnutrition, malformations of the uterus and reproductive organs, hormone abnormalities

leading to anovulation, or genetic diseases. After the early twenties, fertility declines, as sexually transmitted diseases; endometriosis (occurrence in abnormal sites of tissue normally found in the lining of the uterus); and other inflammatory, infectious, and vascular diseases affect reproductive organs. Menopause occurs between ages 40 and 55 in most women, but most women over 40 are infertile, and very few live births occur to women over 45.

PREGNANCY

Pregnancy is typically divided into trimesters, which are uneven in length. Obstetricians invariably refer to "weeks" of pregnancy, meaning the number of weeks from last menstrual period, or when the last menstrual period should have occurred. The first trimester lasts from 3 to 12-14 weeks, the second from 12-14 to 24-26, and the third from 24-26 to delivery. The terminology is confusing, as menstrual age (the time since the last period) is not the same as gestational age (the time since fertilization, the union of the sperm and ovum). Therefore gestational age will be 2 weeks less than menstrual age. The system evolved in an era when many or most women could recall a last menstrual cycle, but few knew when conception or fertilization occurred. Now, more women may be aware of the date when conception occurred, and some pregnancies occur after assisted reproductive technologies (ART), when the time of fertilization may be known exactly. Either way, pregnancy itself begins immediately after implantation. This occurs about 3 weeks after the menstrual period and about 1 week after fertilization (therefore the first trimester starts at 3 weeks). A blood pregnancy test becomes positive within a day or two of implantation, and a urine test becomes positive a few days later. By the time the menses are missed, 4 weeks after the last menses, a urine pregnancy test will be positive if fertilization occurred at the expected time.

Between 10 percent and 40 percent of pregnancies result in *spontaneous abortion* in the first trimester. The wide variation in incidence reflects difficulty in recognizing very early abortion as well as differences in abortion rates among different age groups. Most spontaneous abortions are the result of chromosomal or developmental abnormalities of the pregnancy and are unavoidable; 1-2 percent of pregnancies abort spontaneously in

the second trimester, often due to infection, and about 1 percent of pregnancies have serious anomalies. About 1 percent of pregnancies are *ectopic*, occurring outside of the uterus. Most *ectopic pregnancies* require medical or surgical treatment to avoid hemorrhage. Ectopic pregnancy is one of the major causes of maternal mortality; in the United States, it is still associated with about 10 percent of maternal deaths (Cunningham et al. 1997).

RESPONSE TO PREGNANCY

Women typically pass through several stages of reaction to pregnancy. The first reaction may be denial, particularly when the pregnancy is unwanted, or delight, when the pregnancy is wanted. Later, desired or planned pregnancy may still be accompanied by periods of ambivalence or anxiety (Affonso 1997). The concern may be about personal or work changes, financial stresses, health concerns, or concern about fetal health. At some point in the pregnancy, typically first or second trimester, the pregnancy is usually accepted. The fetus is visualized as a baby, and planning for birth and beyond ensues (Taylor 1980).

The pregnancy may not be accepted; the woman may choose to abort the pregnancy, or she may deny existence of the pregnancy, or she may never accept it even though she eventually gives birth. The lack of acceptance may follow a situation where abortion was unavailable; this may be an individual situation or a matter of political policy. During wartime, impregnation of "enemy" women (which may be accompanied by denial of abortion) is a form of terrorism (Swiss 1993).

Pregnancy itself does not impart any ability to deal with stress, nor does it decrease ability to manage stress. Women who have difficulty caring for themselves adequately when not pregnant, such as adolescents and women with severe psychiatric or developmental handicaps, may have difficulty caring for themselves while pregnant, to the detriment of the fetus. Pregnancy may be an incentive to stop self-abusive behavior such as drug use, but while pregnancy may be the motivating factor, it does not supply the emotional organization to change behavior. Domestic abuse of women does not usually stop with pregnancy; it often escalates (American College of Obstetricians and Gynecologists 1995b).

PREGNANCY AND BIRTHRATES

The *pregnancy rate* is the number of pregnancies occurring per 1,000 women of reproductive age (considered to be ages 15–45 inclusive), per year. The *fertility rate* is the number of all births (liveborn and stillborn) per 1,000 women age 15–45 per year; this is the *birth rate for reproductive-age women*. The term *birthrate*, unmodified, usually means the number of live births per 1,000 population (male and female of all ages).

Pregnancy rates increase during the teenage years and generally peak during the late twenties in most societies, before declining in the thirties and forties. Birthrates follow a similar trend, although the peak birthrate may occur later than the peak pregnancy rate, and the difference between pregnancy rates and birthrates is more pronounced at the extremes of reproductive life. At the beginning and the end of reproductive life more pregnancies are likely to be terminated by abortion.

More pregnancies than are wanted occur. Some are mistimed, occurring earlier than wanted, and some are unwanted at any time. In the United States, between 40 percent and 50 percent of pregnancies are unintended (Horton 1995; Henshaw 1998a). Overall, mistimed pregnancies are more frequent than unwanted pregnancies, but the relationship may be reversed in some groups, such as women over 40. Rates of unplanned pregnancy are generally lowest in countries with wide availability of effective contraception combined with public education, such as western Europe (Paul 1999). Unplanned pregnancy may occur because of contraceptive failure or non-use of contraception. In the United States noncontracepting women, about 8 percent of women at risk for unintended pregnancy, account for about 50 percent of unplanned pregnancies (Gold 1990).

Unplanned pregnancy may result in birth, spontaneous abortion, or induced abortion. The *abortion ratio* (ratio of pregnancies aborted to pregnancies occurring) in the United States for unplanned pregnancy is about 0.5 (Gold 1990). In other countries the rates may be lower, where unplanned pregnancies are accepted or abortion is not readily available, or higher, where unplanned pregnancy is not tolerated personally, socially, or economically (Henshaw et al. 1999).

Teenage pregnancy rates have been of concern because of adverse medical and economic outcomes, which are intertwined (Fraser et al. 1995). For most of the century, pregnancy rates for U.S. teenagers have been declining. Rates began to rise in the 1980s, reaching a recent high of 117 per 1,000 (women ages 15–19) in 1990 (Alan Guttmacher Institute 1999). By 1997 rates had declined about 10 percent to 97 per 1,000. Birthrates have shown a parallel decline from 60 per 1,000 to 54 per 1,000, and abortion rate declined as well.

In contrast to teenage women, women in their twenties have higher pregnancy and birthrates. Birthrates are currently about 110 per 1,000 women in this age group (National Center for Health Statistics 1999). Crude abortion rates are similar to those of adolescents, 20–30 per 1,000 women. Since adolescents have fewer pregnancies and births, the abortion ratio is higher than for women in their twenties or thirties. Overall, more than 40 percent of teenage pregnancies resulted in induced abortion. There are large variations in pregnancy, birth, and abortion rates by state, ethnic group, and age (Horton 1998). Nineteen-year-olds have a much higher pregnancy rate than 15-year-olds. Nonwhite and black teenage pregnancy rates are approximately twice those of white teenage rates. Nonwhite and younger teenagers are more likely to have induced abortions (National Center for Health Statistics 1999).

Comparison of birth and abortion rates can be cumbersome. Distribution of women's age, ethnic group, geographic location, time of collection of statistics, event definition, and accuracy of reporting will affect rates.

CONDUCT OF PREGNANCY

A comprehensive discussion of pregnancy is outside the scope of this encyclopedia; for more complete information, an obstetrics textbook (e.g., Cunningham et al. 1997; Gabbe et al. 1996) should be consulted.

The first trimester of pregnancy is often accompanied by nausea and vomiting, which is typically short-lived but may be severe enough to interfere with daily activities. Some women have hyperemesis, vomiting which is severe enough to result in dehydration or even death; it is treated

with intravenous fluids, antinausea drugs, and sometimes intravenous feeding. Although a link between hyperemesis and ambivalence or anxiety about pregnancy has been postulated, the strength and the relevance of any such link is uncertain.

Women often note changes in food likes and dislikes, but there is no medical reason to restrict types of food. There are often cultural restrictions and prescriptions, and there is seldom any reason to interfere with custom. In the second half of pregnancy many women have heartburn, because of the pressure of the pregnancy on the bowel and stomach, and because of relaxation of the esophagus. Changes in diet or eating habits, or using antacids, may help.

Women need additional calories during the second 2 trimesters; the amount is about 300 kcal per day for most women, the equivalent of a modest sandwich. The additional calories should consist mostly of complex carbohydrates; most Americans have adequate protein intake. Women who receive protein supplements may have higher rates of preterm birth than women receiving carbohydrate supplements or no supplements at all. The U.S. Department of Agriculture administers a food supplement program called WIC (Women, Infants, and Children), which provides food to low-income pregnant and lactating women, infants, and children up to 5 years of age. Supplementation is associated with small decreases in the rate of low-birthweight delivery and a decrease in cost of caring for newborns (Merkatz 1990).

Folic acid, a vitamin, has been shown to decrease the incidence of neural tube defects, a complex of birth defects of the brain or spine. Since the neural tube fuses in the fifth menstrual week, often before pregnancy is noticed, women should take adequate folic acid before pregnancy (Czeizel and Dudas 1992; Rosenberg 1992). The recommended daily allowance of folic acid prior to pregnancy, 400 mg, is easily achieved with a well-balanced diet. Since bread and cereals are now fortified with folic acid, it is becoming harder to avoid adequate folic acid. However, residents of closed communities, producing their own food may not have access to fortified food. Overconsumption of most vitamins is harmless, and the excess is excreted in urine. However, fat-soluble vitamins may accumulate and reach levels

that are toxic to the fetus. Iron is useful for women who are anemic because of iron deficiency.

Prenatal medical care is available to most women in the United States through a patchwork of public and private funding (Alan Guttmacher Institute 1994). Public funding has increased over the last decades as it became evident that the cost of caring for low-birthweight infants could be decreased by providing prenatal care (Merkatz 1990). The relative importance of individual facets of prenatal care is not certain (e.g., Crane et al. 1994; Higby et al. 1993), and some usual practices are probably useless but are persistent (AAP and ACOG 1997; Merkatz 1990). Efforts to assess prenatal care are complicated by the observation that women who actively seek prenatal care have better outcomes than those who do not, even when the latter group receives the same care.

OUTCOMES OF PREGNANCY

A normal pregnancy lasts 38–42 menstrual weeks (*term*). Infants over 37 weeks are considered *full-term*. Infants under 37 weeks are considered *pre-term*. *Low birthweight* (or under 2,500 grams at birth), includes both preterm infants and full-term infants who weigh less than expected. The *low-birthweight rate* is the percentage of births under 2,500 grams.

The low-birthweight rate is an indicator of maternal health and of the effectiveness of prenatal and intrapartum care. However, the low birthweight numbers may be affected by the definition of live births. In some locations, live births are considered to be births over 28 weeks and/or 750 or 1,000 grams. In the United States the usual definition is any birth over 500 grams or showing movement or cardiac activity after birth; birth of a fetus under 500 grams without movement is classified as a spontaneous abortion. However, the definition varies by state and some states have adopted 350 grams as the threshold (Horton 1998). A 350-gram threshold will appear to raise the rate of low birthweight and the mortality rate of low-birthweight infants, as virtually no fetus born between 350 and 500 grams will survive (see ACOG 1995a).

Low birthweight is the leading cause of *perinatal death*. Perinatal deaths consist of *ante-partum deaths* (in which the fetus dies before delivery), *intra-partum death* (in which the fetus dies during labor or

delivery), and *neonatal deaths* (in which a liveborn infant dies in the first 28 days). In contrast to the low-birthweight rate, which is usually expressed as a percentage, the death rate is usually expressed as the rate per thousand births (both live and stillbirths). Death rates vary according to policies on inclusion of the smallest fetuses and infants.

A *viable fetus* is a fetus that can survive outside the uterus. Viability may affect a decision to use an intrauterine treatment versus delivery and treatment of the infant. Viability has also played a role in some debates about abortion, as the gestational age of viability has decreased with advances in perinatal care.

For most healthy women, the physical stress of pregnancy is easily managed. Pregnancy is much more dangerous to women with underlying anemia, heart, or kidney disease, who cannot manage the necessary increase in blood supply and circulation, and to women who do not have adequate nutrition. Family planning, by allowing adequate nutrition before pregnancy and recovery between pregnancies, is critical to women's health status during pregnancy (Alan Guttmacher Institute 1997). Women who are poorly nourished or ill have a much higher chance of delivering a low-birthweight baby, who in turn is more likely to have chronic illnesses and disabilities.

Delivery has additional risks to all women. In the nineteenth century, with the best available care, maternal mortality was about 1 percent per pregnancy, and it remains at that level, or higher, in some parts of the world. It is estimated that each year 600,000 women die from pregnancy and childbirth (Berg et al. 1996; WHO 1998a). The three most common causes of morbidity and mortality are hemorrhage, infection, and pre-eclampsia (high blood pressure and blood vessel disease unique to pregnancy). Morbidity and mortality from all 3 of these situations are less likely where there are trained birth attendants (midwives or physicians) with access to a short list of medications (Rooks 1997). Relatively simple interventions may make a major difference in outcome (e.g., Wallace et al. 1994). In contrast, the incremental increase of complex technology is relatively small, although it may be dramatic in some situations. The widespread application of some technologies has been harmful by creating additional problems, such as interference with normal

Some Commonly Used Prenatal Tests		
Test	Rationale	Limitations
Anemia screening	Allows supplementation.	
Gonorrhea	Treatment prevents infection of the fetus.	Screening cost-effective in high-prevalence populations.
Syphilis	Treatment prevents infection of the fetus.	
Human immunodeficiency virus (HIV)	Allows treatment with anti-retroviral medications during delivery, planning for infant feeding	Effective if antiretroviral drugs are available and safe alternatives to breastfeeding are available.
Bacterial vaginosis	Treatment prevents preterm labor.	Data on effectiveness are conflicting.
Glucose	Identify diabetic women early enough for treatment.	Effective in high-prevalence groups; may not be cost-effective in low-prevalence groups.
Rubella	Identification of nonimmune women identifies pregnancies at risk.	Vaccination of most young women has reduced incidence.
Hepatitis B	Identification of carrier women allows vaccination of infants.	In high-prevalence areas universal vaccination without screening is cost-efficient and simpler.
Rh typing	Identify fetuses at risk for Rh disease, and prevent sensitization.	
Alpha-fetoprotein	Identify fetuses with spine and brain malformations.	Can identify 90% of affected fetuses. 2-5% of women will need additional testing
"Triple screen"	Screen for Down syndrome.	Can identify 60% of affected fetuses; 5% of women will need additional testing.
Ultrasound	Identify twins, fetal defects, nonviable pregnancy.	Will identify most twins. Screening for birth defects not supported by randomized controlled trial.
Amniocentesis	Identify chromosomal abnormalities in fetus.	Carries some risk, expensive. CVS more versatile and faster.
Chorionic villus sampling (CVS)	Identify chromosomal and metabolic abnormalities in fetus.	May be riskier than amniocentesis, less available.

Table 1

labor by restriction of movement (Butler et al. 1993) or by diversion of resources from other beneficial programs.

Births are classified as *spontaneous* (vaginal), *operative vaginal*, or *operative abdominal*. Spontaneous birth includes births that are assisted by a birth attendant's hands. Operative vaginal births include forceps and vacuum extractor (suction cup applied to the baby's head); rates range from as low as 1 percent to 30 percent or higher in some settings. Operative abdominal births are "cesarean sections," and rates vary widely. In western

Europe rates are generally 8–15 percent of total births. In the United States, rates had risen steadily for several decades before decreasing very slightly in the last several years to about 22 percent of all births (National Center for Health Statistics 1999). In some cities throughout the world there is a local demand for elective abdominal delivery as an alternative to labor, generally restricted to women who can afford to pay for the request. With such widely varying rates of operative intervention there is no consensus on optimal rates, although there are many opinions. For instance, there has been no decline in the rate of mental retardation in the

United States, although both fetal monitoring and operative delivery were purported to prevent at least some retardation (ACOG 1992; Rosen and Dickinson 1992).

After birth, women and babies do best when they are kept together and allowed to establish lactation (WHO 1998b). Separation of mother and baby as practiced in many hospitals is not only unpleasant, but inappropriate in terms of infection control and infant nutrition. The effect of labor and delivery routines on “bonding” or attachment has been debated; whether any simple intervention can influence parenting is questionable at this point. The social and educational support of trained lay women has measurable success in some studies on labor outcome and breastfeeding success (Rooks 1997). More intensive programs of pregnancy, delivery, and postpartum peer care have not been fully evaluated (O’Connor 1998).

TERMINATION OF PREGNANCY

Abortion is an event, other than a birth, that terminates a pregnancy. Abortion may be *spontaneous*, if it begins without intervention from the woman and without medical intervention, or *induced*, if some agent or procedure is used to cause the abortion. Induced abortion may also be classified as *legal* or *illegal*. Other terminology is neither uniform nor clear. *Therapeutic* abortion may refer to all legal induced abortions performed under medical supervision, or to those performed for medical indication such as severe illness in the woman. Spontaneous abortion may be classified as *inevitable* if it has not yet occurred but will occur, as *incomplete* if the pregnancy has been partially passed, or as *complete* if all tissue has been expelled or removed.

A *viable pregnancy* may refer to a pregnancy in which the baby is apparently healthy and growing; the pregnancy would be expected to continue if there were no intervention. A *nonviable pregnancy* will result in spontaneous abortion. Nonviable pregnancies are also called *blighted ovum* (which is technically incorrect since the ovum or egg has already divided), *empty sac*, or *fetal demise*. Abnormal pregnancies are sometimes detected by ultrasound or by blood testing, before there are any symptoms of spontaneous abortion.

Most abortions are requested because the pregnancy was unwanted, but there are other reasons, some of which are listed in Table 2.

In the United States, 90 percent of abortions occur in the first trimester; half of all women request abortion before 8 menstrual weeks. Ten percent of women request abortion after 12 weeks. Between 1 and 2 percent of all abortions performed are for fetal malformations; these are almost all second-trimester procedures. Fewer than 1 percent of abortions are performed in the third trimester. Generally, as the length of gestation increases, the cost of abortion increases, and the number of providers decreases (Gold 1990).

There are several types of procedures in use (for a more complete discussion, see Paul 1999). In the first trimester, there are both medical and surgical techniques. Surgical techniques consist of variations of suction curettage. In this procedure the cervix is stretched open if necessary; in very early pregnancy (fewer than 6 menstrual weeks) no opening may be necessary. The inside of the uterus is suctioned using a plastic tube and a vacuum created by an electric or manual pump. “Sharp” curettage, the traditional dilatation and curettage (D&C) is more traumatic and has been largely replaced by suction curettage.

Several medications are used for early medical abortion, depending on availability. Methotrexate is a medication that blocks folic acid, a vitamin. Several days later the woman takes a second drug, misoprostol (a prostaglandin drug), which makes the uterus contract and expel the pregnancy. The process is similar in both timing and feeling to a spontaneous abortion. The exact time sequence is difficult to predict; about 75 percent of women abort within 1 week. Vaginal bleeding occurs for a mean of about 10 days, but may last longer. The medication may fail to produce an abortion about 1 percent of the time, and about 1 percent of women need a suction curettage because of heavy bleeding. Methotrexate can be used up to 7 or 8 menstrual weeks, and is the most common agent in use in the United States, because it is FDA approved for other uses, and therefore easily available.

Mifepristone (formerly called RU 486) has been used in millions of women in China, France, Sweden, and the United Kingdom for medical

abortion since 1986, but has had to overcome numerous political roadblocks in the United States. Mifepristone, a different class of medication from methotrexate, blocks progesterone hormone binding sites. It requires use of a second drug, a prostaglandin drug such as misoprostol, several days later to expel the pregnancy. In contrast to methotrexate, 75 percent of women abort within 2 days, and 90–95 percent abort within 1 week. Mifepristone can be used up to 7 to 9 menstrual weeks depending on the selection of the second drug.

After 7 to 9 menstrual weeks, suction curettage is the main technique. At the end of the first trimester and in second trimester, opening the cervix sufficiently becomes more challenging. Osmotic dilators are used over several hours or several days; osmotic dilators are placed in the cervix, where they absorb water and swell. Preparation for abortion in the mid- and late second trimester may take several days. Surgical procedures, often called dilatation and evacuation (D&E), are variations of early pregnancy techniques using suction and extraction instruments. After 16 weeks, medical (induction) techniques can be used to induce labor. All the agents—prostaglandin, oxytocin, and saline—are unpredictable, may take several hours to several days, and may involve a curettage to remove placenta if it is not completely expelled. Hospitalization is the rule, and therefore induction techniques are more costly than surgical techniques in an out-patient setting.

Legal abortion has very few serious complications. Term pregnancy has a death rate at least ten times higher than first-trimester abortion (10–12 deaths per 100,000 versus 0.5–1.0 deaths per 100,000 women in the United States) (Berg et al.

1996; Paul et al. 1999), and a morbidity rate (serious medical outcomes such as major operations) hundreds of times higher. There is virtually no situation in which it is safer for a woman to continue a pregnancy than to abort a pregnancy, although there are sometimes situations in which abortion should be delayed briefly. However, abortion is safest if it is performed early (Gold 1990; Paul et al. 1999). Early abortion by suction curettage does not have an effect on future fertility. Abortion itself is not associated with adverse psychological sequelae; unwanted pregnancy may have adverse associations regardless of whether the pregnancy is aborted or continued. In second trimester the medical risks are higher than in first trimester (Paul et al. 1999).

It is difficult to ascertain the numbers and types of abortions performed in the United States. In most states abortion is a reportable procedure; however, many procedures are not reported, probably for reasons of confidentiality of both provider and patient (Fu et al. 1998). Some abortions may be misclassified as treatment of a spontaneous abortion, since the suction procedure is identical; or the reverse may be true. In hospitals, some induced abortions may be classified as spontaneous abortion. The Alan Guttmacher Institute estimates abortion procedures using both governmental and nongovernmental sources. The CDC also publishes “Abortion Surveillance” as a supplement to *Mortality and Morbidity Weekly Review*. Small variations in abortion rates may be related to reporting and surveillance issues as well as varying rates of pregnancy and abortion.

Currently, early medical abortion accounts for fewer than 1 percent of all abortions in the United States, as methotrexate is the only agent available. In other countries, medical abortion may account for up to a third of all abortion procedures. In France, half of all women seeking abortion request abortion early enough to be eligible for medical abortion, and two-thirds of them choose medical abortion. This shift to medical abortion in France has been accompanied by a shift to earlier abortion in general, while overall abortion rates have remained the same (Paul et al. 1999). Medical abortion is highly acceptable to women in many countries. Acceptability studies consistently estimate that 60–80 percent of women would choose medical abortion over surgical abortion were it available (Winikoff 1994).

However, despite the preference for medical abortion over surgical abortion, surgical abortion remains the only method available to most women, if they have access to any method at all. In the United States the number of abortion providers has dropped over the last two decades. Abortion is available in a minority of counties in the United States, most of them in urban areas (Lichter et al. 1998). The majority of abortion procedures take place in free-standing medical facilities, many of them primarily devoted to abortion provision (Henshaw 1998b). Planned Parenthood clinics provide about 12 percent of all abortions. About 10 percent of abortions occur in hospitals or hospital-affiliated clinics. At least 5 percent of abortions occur in doctors' offices that are not identified as providing primarily abortion-related care.

Most physicians providing abortions in the United States are obstetrician-gynecologists, but other physicians provide abortions. Only about a third of gynecologists provide abortions, so most women needing abortion are referred to an unfamiliar caregiver. First-trimester abortions are also provided in several states by physicians' assistants (PAs) and midwives. Most states have "physician-only" statutes that limit the provision of abortion to physicians. However, these statutes were written before the increase in utilization of advanced practice nurses, such as midwives, and "physician extenders," such as PAs, who currently perform other procedures of comparable complexity and skill (Freedman et al. 1986). In a few countries (e.g., Bangladesh) midwives provide most abortion services.

Costs for abortions range from several hundred dollars for a first-trimester procedure in an office or clinic setting, to thousands of dollars for procedures performed in hospitals. Many insurance policies cover abortion, although reimbursement rates vary. Some forms of insurance do not cover abortion at all, for example, insurance provided to U.S. federal employees. Publicly funded insurance for indigent women covers "medically indicated" abortions in some states but not others. Finally, many women requesting abortion do not have any insurance at all, most commonly because their employment does not provide insurance. Women who need specialized procedures because of underlying medical illnesses may have additional barriers; there are several states in which no hospital will allow an abortion to be performed.

In the United States the majority of people polled supported the availability of abortion, but many were in favor of some restrictions. Parental consent laws for minors have been passed in nearly half the states. Any such law must contain a "judicial bypass" to be considered constitutional, so that minors can petition a judge if they cannot tell a parent (Paul et al. 1999). In practice, most minors do involve a parent with or without parental consent laws. The main effect of such laws is to delay abortion for those minors without good family support.

In the United States there is a vocal and well-funded minority with the goal of criminalizing abortion. Mandatory waiting periods and mandatory consent processes have also been passed. These increase the amount of time and expense necessary for a woman to obtain an abortion, particularly where there are few providers. Other quasi-legal attempts to decrease abortion include passage of laws that are either unenforceable or unconstitutional. These include restrictions on the type of facility that can perform abortion and "partial-birth abortion" laws. The resulting legal challenges are expensive, and this tactic can be considered a sustained economic assault (Reproductive Freedom News 1999). Antiabortion groups in the United States have been increasingly involved in terrorist activities, including harassment, arson, violence, and even murder. Several thousand incidents of harassment and arson are reported annually to the National Abortion Federation (National Abortion Federation 1999).

Abortion is generally legal in most European countries and in much of Asia, but is illegal in most of South America and Africa (WHO 1998b). The effect of government-sanctioned denial of abortion rights is not to decrease the number of abortions significantly. Abortion rates are correlated with multiple factors such as patterns of sexual activity, type of contraceptive use, desired family size, and tolerance of unwanted pregnancy. In the United States it has been estimated that the number of abortions performed annually before widespread legalization was 600,000 to 1.2 million per year (Gold 1990). The number reported the first year after legalization was 615,831 (Koonin et al. 1996). The effect of criminalizing abortion is to delay abortion for some women and to make it riskier for almost all women, resulting in increased

death rates (Population Reports 1997). As an example, after abortion was criminalized in Romania, the death rate from abortions quintupled; while maternal mortality doubled (WHO 1998b). In South American and East Africa, the rates of illegal abortion are similar, about 35 per 1,000 women of childbearing age, but death rates are dissimilar (0.3 percent and 1.5 percent, respectively, of women undergoing abortion), related to underlying health status and access to postabortion care (WHO 1998b).

Increases in the provision of contraceptive services are associated with decreases in abortion rates (Henshaw et al. 1999; Estrin 1999). However, the United States has consistently refused to fund contraceptive services adequately, particularly services in developing countries, because of right-wing political pressure (Alan Guttmacher Institute 1996).

Pregnancy carries an intrinsic risk to women's health, which can be minimized by appropriate medical care to women who are in good health to start. Family planning is essential to women's health during pregnancy, and essential to the health of their infants. Women who do not want to be pregnant will risk health and life to end the pregnancy. Denying or criminalizing abortion care results in additional health risks for women while diverting health resources that could be used for maternity services for other women.

LYNN BORGOTTA

PREJUDICE

Gordon Allport, in his classic *The Nature of Prejudice*, defined prejudice as "an antipathy based upon a faulty and inflexible generalization" (1954, p. 9). This phrasing neatly captures the notion that both inaccurate beliefs and negative feelings are implicated in prejudice. To these "cognitive" and "affective" dimensions of prejudice, some analysts add "conative," referring to action orientation (Klineberg 1972) and prescription (Harding et al. 1969). Allport's circumspection on the conative implications of prejudice—he said "(prejudice) may be felt or expressed" (1954, p. 9)—foreshadowed our growing understanding that the correspondence of behavior with cognitions and feelings is uncertain, a research issue in its own right (Schuman and Johnson 1976).

Racial and ethnic prejudice was Allport's primary interest. Emerging social issues have brought

expanded attention to other forms of prejudice—against women, the elderly, handicapped persons, AIDS patients, and others. This discussion will focus on racial prejudice among white Americans, in the expectation that parallels and points of contrast will continue to make race relations research relevant to other forms of prejudice.

TRENDS AND PATTERNS

For many years, derogatory stereotypes, blatant aversion to interracial contact, and opposition in principle to racial equality were seen as the central manifestations of race prejudice, virtually defining the social science view of the problem. Indicators of these beliefs and feelings show a clear positive trend (Jaynes and Williams 1989; Schuman et al. 1997). White Americans' belief in the innate intellectual inferiority of blacks declined from 53 percent in 1942 to about 20 percent in the 1960s, when the question was discontinued in major national surveys. The percentage of whites who said it would make no difference to them if a Negro of equal social status moved into their block rose from 36 percent to 85 percent between 1942 and 1972. White opinion that blacks should have "as good a chance as white people to get any kind of job" climbed from 45 percent in 1944 to 97 percent in 1972. Thomas Smith and Paul Sheatsley sum up this picture without equivocation: "Looking over this forty-year span, we are struck by the steady, massive growth in racial tolerance" (1984, p. 14).

Recurrent outbursts of overt racial hostility and public acts of discrimination (Feagin 1991) serve as unfortunate reminders that some white Americans still cling to blatant prejudice. More importantly, even the majority of whites, those on whom Smith and Sheatsley focus, appear unambiguously tolerant only if attention is confined to such traditional survey indicators as those described above. A confluence of developments has broadened the study of race prejudice and transformed our understanding of white racial attitudes. First, evidence of widespread, subtle prejudice has been revealed in research using disguised, "nonreactive" methods. Second, "social cognition" scholarship, paramount for two decades in the psychological wing of social psychology, has been powerfully

applied to intergroup relations. Recent scholarship is broadened and balanced by its acknowledgment of the crucial role of affect along with cognition. Third, evolution of the struggle for racial equality in the United States has shifted attention to a new domain of racial policy-related beliefs and feelings. These perspectives provide ample evidence that white racial prejudice is not a thing of the past, but exists today in complex forms that have yet to be thoroughly charted.

Evidence from "Nonreactive" Studies. Given the clear dominance of "liberal" racial norms evinced in public opinion data, it might be expected that needs for social acceptability and self-esteem would lead many whites to withhold evidence of negative racial feelings and cognitions whenever possible. Disguised, "nonreactive" research (Webb 1981) provides substantial evidence that, indeed, traditional survey approaches underestimate negative racial feeling. Field experiments reveal that whites often provide less help to victims who are black (Crosby et al. 1980), sometimes redefining the situation so as to justify their lack of response (Gaertner 1976). Such elements of nonverbal behavior as voice tone (Weitz 1972) and seating proximity (Word et al. 1974) have been found to reveal negative racial feelings and avoidance. Recent reaction time and word completion studies similarly document the existence of "implicit" racial prejudice among many whites who score low on self-reported "explicit" prejudice (Dovidio et al. 1997). Thus, accumulating American evidence reveals that "microaggressions" (Pettigrew 1989) often accompany self-portrayals of liberalism. Parallel research in western Europe has uncovered similar forms of microaggression against that continent's new immigrant minorities (Den Uyl et al. 1986; Klink and Wagner 1999; Sissons 1981).

Social Cognition Perspectives, Now Acknowledging the Role of Affect. In recognizing aspects of prejudice as predictable outgrowths of "natural" cognitive processes, Allport (1954) was ahead of his time. A wave of social cognition research on intergroup relations was set in motion by Henri Tajfel (1969), who demonstrated that mere categorization—of physical objects or of people—encourages exaggerated perception of intragroup homogeneity and intergroup difference. Even in

“minimal groups” arbitrarily created in psychology laboratories, these effects of social categorization are often accompanied by ingroup favoritism and outgroup discrimination (Brewer 1979, 1991; Hamilton 1979). Accumulating evidence of the negative consequences of ingroup/outgroup categorization has spurred research aimed at identifying conditions of intergroup contact that are likely to decrease category salience and promote “individuation” or “decategorization” (Brewer and Miller 1988; Wilder 1978), or at least to reduce the negativity of outgroup stereotypes (Rothbart and John 1985; Wilder 1984). Recent attention to the role of motivation in guiding cognition (Fiske 1998) contributes to this effort.

The study of attributional processes (Heider 1958) also has been usefully applied to intergroup relations, calling attention to such issues as whether white perceivers believe that black economic hardship results from discrimination or lack of effort. Research evidence has linked stereotypic thinking to attributions of outgroup behavior (David L. Hamilton 1979). Specific predictions are developed in Pettigrew’s discussion of the “ultimate attributional error” (1979a), the tendency to hold outgroups personally responsible for their failures, but to “discount” their responsibility for successes, attributing successes to such factors as luck or unfair advantage.

The intense research scrutiny given cognitive factors meant that the critical affective component of prejudice was often ignored. That imbalance is being corrected. The 1993 publication of *Affect, Cognition, and Stereotyping*, edited by Mackie and Hamilton (1993), marked the dramatic shift in emphasis in social psychology. Varied research, from American laboratory experimentation (Stangor et al. 1991; Dovidio et al. 1989) to European surveys (Pettigrew 1997; Pettigrew and Meertens 1995), demonstrates that emotional factors not only are central to intergroup prejudice but have special characteristics of their own and are highly predictive of policy attitudes. One attempt at synthesis outlines a tripartite conception of prejudice as stereotypes, affect, and “symbolic beliefs” (Esses et al. 1993; Zanna 1994).

Expanding the Racial Attitude Domain to Policy Views. Over the past twenty-five years, evolution in the struggle for racial equality has brought new complexity to the public debate about racial

issues. Notions that barriers to black equality consist solely of white hostility and aversion, and formal denial of rights, now appear naive. Advocates insist that structural barriers far more complex and far more pervasive than formal denial of access prevent actual desegregation and equality of opportunity, making questions about acceptance by white individuals a moot point for millions of black Americans.

In the current era of U.S. race relations, traditional manifestations of race prejudice recede in relevance, and different forms of race-related belief and feeling take center stage—reactions to agitation for change, recognition and interpretation of continuing inequality, and support for proposed remedies. By all indications, such white “perceptions, explanations, and prescriptions” (Apostle et al. 1983, p. 18) show far less consensus and support for racial change than appeared in traditional race survey data. Asked about specific policies and programs designed to increase racial equality—fair housing guarantees, school desegregation plans, affirmative action in hiring and college admission—white Americans show substantially less support than they voice for racial equality in principle (Pettigrew 1979b; Schuman et al. 1997). Many white Americans exaggerate recent black gains and benefits of affirmative action (Steeh and Krysan 1996) and underestimate the remaining inequality (Kluegel and Smith 1982). There is substantial white resentment of black activism and perceived progress (Bobo 1988a; Schuman et al. 1997).

Attribution research in social psychology and earlier societal analyses (Ryan 1971; Feagin 1975) converge with recent studies of racial policy opinion to tell a clear story: Whites explain the economic plight of black Americans more often as the result of such “individualistic” factors as lack of motivation than in terms of such “structural” factors as discrimination (Apostle et al. 1983; Kluegel and Smith 1986). In addition, individualistic attributions along with denial of discrimination are linked to a variety of policy-relevant beliefs and opinions, including opposition to affirmative action (Bobo and Kluegel 1993; Kluegel and Smith 1983, 1986).

CHARACTERIZATIONS OF WHITE RACIAL ATTITUDES

Efforts to characterize the complex pattern of racial attitudes held by white Americans emphasize an array of themes, as discussed below.

“Natural” Cognitive Processing. As noted earlier, social cognition analyses claim that a substantial part of the racial prejudice once thought to have sociocultural or psychodynamic roots actually stems from ordinary cognitive processing, particularly categorization (David L. Hamilton 1979). Social cognition portrayals increasingly acknowledge motivational and social influences (David A. Hamilton and Tina K. Trolier 1986; Fiske 1987, 1998). And there are recent powerful calls to acknowledge the joint influence on prejudice of cognition and affect (Esses et al. 1993; Pettigrew 1997; Smith 1993).

Strain Between Individualism and Egalitarianism. Current racial policy issues are said to pull whites between two cherished American values, individualism and egalitarianism (Lipset and Schneider 1978). *Qualified* support for social programs exists, in this view, because egalitarian sentiments prevail only until a proposal challenges individualistic values.

Ambivalence. Adding psychodynamic flavor to the individualism/egalitarianism value strain idea, some analysts describe current white feelings as an ambivalence that produces an unpredictable mix of amplified positive and negative responses (Katz et al. 1986).

“Aversive” Racism. A desire to avoid interracial contact, muted negative feeling, and egalitarian self-concept are the mix Kovel (1970) characterized as aversive racism. The outcome is avoidance of positive interracial behavior when the situation can be defined to permit it, and expression of negative feelings when there are ostensible nonracial justifications (Gaertner 1976; Gaertner and Dovidio 1986).

“Symbolic” or “Modern” Racism and “Racial Resentment.” Antiblack affect instilled by childhood socialization and the sense that racial change threatens fondly held individualistic values, *not* self-interest, are claimed as the twin foundations of Sears’s “symbolic” racism (1988). “Modern”

racism contains the added ingredient of denying continuing racial inequality (McConahay 1986). “Racial resentment” (Kinder and Sanders 1996) is a recent addition to this family of “new racism” constructs. The label serves as a reminder that whatever the roots of new racism, a primary manifestation is anger that blacks’ gains have exceeded their entitlement.

“Subtle” Prejudice. Using probability survey data from western Europe, Pettigrew and Meertens (1995) developed scales for both blatant and subtle prejudice that proved highly predictive of attitudes toward immigrants across four nations, six target outgroups, and seven samples. Their conception of subtle prejudice contains three components: perceived threat to traditional values (similar to symbolic racism), exaggeration of intergroup differences, and the absence of positive affect (admiration and sympathy) for the outgroup. Rejecting the claims of Sniderman and his colleagues (1991), Meertens and Pettigrew (1997) demonstrate that their subtle prejudice is distinctly different from political conservatism.

“Dominant Stratification Ideology.” A belief that opportunity is plentiful and equally distributed, and thus effort is economically rewarded and economic failure is deserved—these compose the “dominant stratification ideology” (Huber and Form 1973; Kluegel and Smith 1986), a sociological elaboration on the individualism theme. Although personal status and strands of American “social liberalism” also play a role, unyielding adherence to this American “dominant ideology” is portrayed as a major impediment to public support for redistributive claims in general, and to calls for racial change in particular (Kluegel and Smith 1986). On a backdrop of ignorance bred of social segregation, whites’ own experiences of economic success work to prevent recognition of the continuing barriers to full opportunity for black Americans (Kluegel 1985).

Self-Interest. Collective self-interest is sometimes identified as the primary basis of whites’ interracial beliefs and feelings (Jackman 1994; Wellman 1993). If zero-sum assumptions prevail, redistribution in favor of blacks will be seen as a losing proposition to whites. Self-interest is at the heart of what Bobo (1988b) called an “ideology of bounded racial change” and what Bobo and colleagues (1997) have dubbed “laissez-faire racism”: White

acceptance of racial change and efforts to promote it end when continued change is perceived to threaten the well-being of whites.

PRESCRIPTIONS FOR MODERN PREJUDICE

When the lessons from cognitive social psychology are counterposed with those from other perspectives on modern race prejudice, an apparent dilemma is revealed. Though social cognition findings indicate that category salience can promote stereotype change under some circumstances (Cook 1984; Pettigrew 1998), much of the cognitive literature insists that categorization is a central contributor to race prejudice and negative race relations: Color consciousness is often portrayed as an evil, color blindness the ideal. From other scholars of modern prejudice, the analysis and prescription are nearly a mirror image of this view. Color blindness is said to impede forthright problem solving in desegregated institutions (Schofield 1986); to represent ignorance of the structural barriers faced by black Americans (Kluegel 1985); and to be used as a weapon by those opposing black claims of collective rights (Jackman and Muha 1984; Omi and Winant 1986). The solution implied or stated by these analysts is for whites to adopt a color consciousness that fully acknowledges the historical impact of racial subordination and the continuing liabilities of direct and indirect discrimination. The two streams of advice present this challenge: How to promote a racial understanding in the white public that minimizes the psychological liabilities of ingroup/outgroup categorization while acknowledging the full sociological implications of the past and continuing color line.

PROBABILITY THEORY

Sociologists, as much as researchers in any field perhaps, use a variety of approaches in the investigation of their subject matter. Quite successful and important are the historical and exegetical approaches and those in the traditions of anthropology and philosophy. Also of great importance are the systematic approaches that use mathematical models. Here the social investigator proposes a model, a mathematical depiction of social phenomena. A successful mathematical model can be very powerful, providing not only confidence in the theory from which the model was derived, giving us an explanation of the phenomena, but producing as well a method for predicting, giving us a practical means for controlling or affecting the social phenomena.

The social mathematical model is first of all a description of the relationship of the properties of social objects—groups, states, institutions, organizations, even people. If the model is derived from a theory, or if it contains features implied by a theory, and if the model fits data (i.e., has been found to satisfy some criterion of performance), the model can in addition be regarded as evidence to support that theory. In this case we can think of

a true, underlying model that generated the observations we are studying and a proposed model that will be tested against data. Quantitative analysis begins, then, with some theoretical understanding of the properties of groups of social objects; this understanding leads to the specification of a model of the interaction of these properties, after which observations of these properties on a sample of the objects are collected. The performance of the model is then evaluated to determine to what degree the model truly describes the underlying process.

The measurement of a property of a social object is called a *variable*. Variables can be either fixed or random. Fixed variables are those determined by the investigator; they usually occur in experiments and will not be of concern in this chapter. All other variables are random. The random nature of these variables is the unavoidable consequence of two things; first, the fact that our observations are *samples*, that is, groups of instances of social objects drawn from a population (that is, a very large number of possible instances to be observed); second, the fact that our theories and data collection are often unable to account for all the relevant variables affecting the variables included in the analysis. Probability theory in social models, or, equivalently, random variables in social models, will derive from these two subtopics: sampling and the specification of residual or excluded variables in the models.

A certain philosophical difference of opinion arises among probability theorists about the nature of the true source of the randomness in nature. One group argues that these features are inherent in reality, and another argues they are simply the consequence of ignorance. The primary modeling tool of the former group is the *stochastic process* (Chung 1974), while that of the latter is the *Bayesian statistical model* (de Finetti 1974).

MAIN CONCEPTS

Probability is a name assigned to the relative frequency of an event in an event space, that is, a set of possible events. For example, we might define the event space as the two sides of a single coin labeled heads (*H*) and tails (*T*): {*T*, *H*}. The actual outcome of a coin flip is a random variable, *X*, say, and the probability of the outcome *H* is $P(X = H)$. The probability distribution function (or PDF)

assigns a quantity to this probability. By definition, for a fair coin $P(X = H) = .5$. Since the event space is composed of only two events, then $P(X = T) + P(X = H) = 1$, that is, one or the other event occurs for certain, and $P(X = T) = 1 - P(X = H) = .5$. Thus the probability of *T* is equal to the probability of *H* and the coin is fair.

In general we assign numbers to the events in our event space, allowing us to use mathematical language to describe the probabilities. For example, the event space of the number of people arriving at a bank's automatic teller machine (ATM) is {0, 1, 2, . . .} over a given time interval Δt . Given certain assumptions, such as that the arrival time of each person is independent of anyone else's, we can derive a theoretical PDF. For a given time interval Δt , the probability of the number of people *X* can be shown to be

$$P(X = k | \Delta t) = \frac{(\lambda \Delta t)^k e^{-(\lambda \Delta t)}}{k!}$$

where λ is the mean rate of people arriving at the ATM over the time interval Δt , and $k = 0, 1, 2, . . .$

Suppose from bank records we are able to determine that 100 people per hour complete a transaction at a particular ATM during normal working hours. For Δt equal to one minute or 1/60 an hour, the PDF is

$$P(X = k) = \frac{1.6667^k e^{-1.6667}}{k!}$$

For some selected values of *k* we have

k	P(X = k)
0	.1889
1	.3148
2	.2623
3	.1457
4	.0607
...	...

If we assume that each person spends about a minute at the ATM, we should expect one or more people standing in line behind someone at the

ATM about 50 percent of the time since the probability of two or more people arriving during a one minute interval is

$$P(X \geq 2) = 1 - P(X = 0) - P(X = 1) = .4963$$

The event spaces for the examples above are discrete, but continuous event spaces are also widely used. A common PDF for continuous event spaces is the normal distribution:

$$p(X = x) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

where μ and σ^2 , commonly called the mean and variance respectively, are parameters of the distribution, and x is a real number greater than minus infinity and less than plus infinity. The normal PDF is the most widely used distribution in social models, first because it had advantageous mathematical properties and second because its specification in many cases can be justified on the basis of the central limit theorem (Hogg and Tanis 1977, p. 155).

Other important concepts in probability theory are the *cumulative distribution function* (or CDF), *joint distributions* (distributions involving more than one variable), and *conditional distributions*. The CDF is the probability of X being less than or equal to x , that is, $Pr(X < x)$. An accessible introduction to probability may be found in Hogg and Tanis (1977).

SAMPLING

In physics all protons behave similarly. To determine their properties, any given instance of a proton will do. Social objects, on the other hand, tend to be complex, and their properties can vary considerably from instance to instance. It is not possible to draw conclusions about all instances of a social object from a given one in the same manner we might from single instance of a proton. Given equivalent circumstances, we cannot expect everyone to respond the same way to a question about their attitudes toward political issues or to behave the same way when presented with a set of options.

For example, suppose we wish to determine the extent to which a person's education affects his

or her attitudes towards abortion. Let A_i represent a measurement of the attitude of some person, labeled the i th person, scored 0 if they are opposed to abortion or 1 if not. Let B_i be the measurement of the person's education, scored 0 for less than high school, 1 for high school but no college, or 2 for at least some college.

Given measurements on a sample of people, we would find that they would be distributed in some fashion across all the six possible categories of the two variables. Dividing the number that fall into each category by the total number in the sample would give us estimates of the empirical distribution for the probabilities: $PR(A = 0, B = 1)$, $PR(A = 0, B = 2)$, and so on. We might also model this distribution. For example, an important type of model is the loglinear model (Goodman 1972; Haberman 1979; Agresti 1990), which models the log of the probability:

$$\log PR(A = i, B = j) = \lambda_i^A + \lambda_j^B + \lambda_{ij}^{AB}$$

where λ_i^A , λ_j^B and λ_{ij}^{AB} are parameters (actually sets of parameters). In this model the λ_{ij}^{AB} parameters represent the associations between A and B , and an estimate of these quantities might have important implications for a theory.

Given a sample distribution, computing an estimate of λ_{ij}^{AB} is straightforward (Bishop, Fienberg, and Holland 1975). It is important, however, to realize that such an estimate is itself a random variable, that is, we can expect the estimate to vary with every sample of observations we produce. If the sample is properly selected, in particular if it is a simple random sample in which each person has an equal chance of being included in the sample, it can be shown that the estimates of λ_{ij}^{AB} have, in large samples at least, a normal distribution (Haberman 1973). Our estimates, then, are themselves parameters of a distribution, usually the means of a normal distribution. It follows that the fundamental parameters upon which a theory will depend can never be directly observed and that we must infer its true value from sample data.

All research on social objects is unavoidably research on samples of observations. Therefore all such research will necessarily entail at the very least a probabilistic sampling model, and the conclusions drawn will require properly conceived statistical inference.

MODELS WITH EXCLUDED VARIABLES

The Regression Model. The most well-known and widely used statistical model is the regression model. It is a simple linear hypersurface model with an added feature: a disturbance term, which represents the effects on the dependent variable of variables that have not been measured. To the extent that the claims or implications of a theory may be put into linear form, or at least transformed into linear form, the parameters (or regression coefficients) may be estimated and statistical inference drawn by making some reasonably benign assumptions about the behavior of the variables that have been excluded from measurement. The key assumption is that the excluded variables are uncorrelated with included variables. The failure of this assumption gives rise to *spurious* effects; that is, parameters may be under- or over-estimated, and this results in faulty conclusions. The statistical inference also requires a homogeneity of variance of the disturbance variables, called *homoscedasticity*. The variation of the excluded variables must be the same across the range of the independent variables. This is not a critical assumption, however, because the consequence of the violation of this assumption is inefficiency rather than bias, as in the case of the spurious effects. Moreover, the underlying process generating the heteroscedasticity may be specified, which would yield efficient estimates, or a modified inference may be computed, based on revised estimates of the variances of the distribution of the parameter estimates (White 1980).

For example, a simple regression of income, say, on years of education may be described, $y_i = b_0 + b_1x_i + \epsilon_i$, where y_i and x_i are observations on income and years of education, respectively, of the i th person b_0 and b_1 are regression coefficients, and ϵ_i is the disturbance term. Estimates of b_0 and b_1 may be found (without making any assumptions about the functional form of the distribution of ϵ_i by using perhaps the most celebrated theorem in statistics, the Gauss-Markov theorem, and they are usually called *ordinary least squares estimates*.

If we gather the observations into matrices, we can rewrite the regression equation as functions of matrices: $Y = XB + E$, where Y is an $N \times 1$ vector of observations on the dependent variable. X an $N \times K$ matrix of observations on K independent variables, B a $K \times 1$ vector of regression coefficients,

and E an $N \times 1$ vector of disturbances. With this notation the estimates in B may be described $B^{\wedge} = (X'X)^{-1} X'Y$, where; the “ \wedge ” over the B emphasizes that they are estimates of the parameters.

Our observations are samples, and since our estimates of B will vary from sample to sample, it follows that these estimates will themselves be random variables. Appealing again to the Gauss-Markov theorem, it is possible to show that the ordinary least squares estimates have a normal distribution with variance-covariance matrix equal to $\text{VarCov}(\hat{B}) = \sigma_{\epsilon}^2 (X'X)^{-1} X'Y$, where σ_{ϵ}^2 is estimated by $\sigma_{\epsilon}^2 = (Y - XB)'(Y - XB)/(N - K - 1)$.

Other models. The regression model in the previous section is a “single equation” model, that is, it contains one dependent variable. A generalization of the regression model incorporates multiple dependent variables. This model may be represented in matrix notation as $BY = \Gamma X + Z$, where Y is an $N \times L$ matrix of L *endogenous* variables (i.e., variables that are dependent in at least one equation), B is an $L \times L$ matrix of coefficients relating endogenous variables among themselves, X is an $N \times K$ matrix of K *exogenous* variables (i.e., variables that are never dependent), Γ is an $L \times K$ matrix of coefficients relating the exogenous variables to the endogenous variables, and Z is an $N \times L$ matrix of disturbances. Techniques have been developed to produce estimates and statistical inference for these kinds of models (Judge et al. 1982; Fox 1984).

Measurement error is another kind of excluded variable, and models have been developed to incorporate them into the regression and simultaneous equation models. One method for handling measurement error is to use multiple measures of an underlying *latent* variable (Bollen 1989; Jöreskog and Sörbom 1988). A model that incorporates both measurement error and excluded variable disturbances may be described in the following way:

$$\begin{aligned} Y &= \Lambda_y \eta + \epsilon_y \\ X &= \Lambda_x \xi + \epsilon_x \\ B\eta &= \Gamma \xi + \zeta \end{aligned}$$

where Y and X are our observations on the endogenous and exogenous variables respectively, Λ_y , and Λ_x are coefficient matrices relating the underlying variables to the observed variables, η and ξ are the

latent endogenous and exogenous variables respectively, B and Γ are coefficient matrices relating the latent variables among themselves ε_γ and ε_ζ are the measurement error disturbances, and ζ is the excluded variable disturbance.

This model incorporates three sources of randomness, measurement error disturbance, excluded variable disturbance, and sampling error. Models of the future may contain a fourth source of randomness: a structural disturbance in the coefficients. These latter models are called random coefficient models and are a special case of the most general kind of probabilistic model called the *mixture model* (Judge et al. 1982; Everitt 1984).

The models described to this point have been linear. Linearity can be a useful approximation that renders the problem tractable. Nonlinearity may be an important aspect of a theoretical specification, however, and methods to incorporate nonlinearity in large-scale models have been developed (Amemiya 1985). It also appears to be the fact that most social measures are not continuous, real variables, which is what is assumed by the regression and simultaneous models described above. Thus, much work is now being devoted to the development of models that may be used with measures that are limited in a variety of ways—they are categorical, ordinal, truncated, or censored, for example (Muthén 1984; Maddala 1983). Limited variable methods also include methods for handling variations on the simple random method of sampling.

Probability theory has had a profound effect on the modeling of social processes. It has helped solve the sampling problem, permitted the specification of models with excluded variables, and provided a method for handling measurement.

PROBATION AND PAROLE

The criminal justice system is the primary institution responsible for the formal social control of criminal deviance. Those who violate the criminal law are subject to a variety of sanctions, ranging from the reprimand of a police officer to execution by hanging. Most offenders are not apprehended, and among those who are arrested many are not prosecuted nor convicted of a crime. For offenders who are found guilty, either by trial or

more often by negotiated guilty plea, the sentence handed down by the court typically mandates correctional supervision, usually either some form of probation or incarceration with early release to some form of parole.

Even though probation and parole have been integral components of corrections since the nineteenth century, the differences between them are not always clear. Both are postconviction alternatives to incarceration that include supervision in the community by a probation or parole officer, who, depending on the jurisdiction, may be the same person. They are conditional releases to the community that are contingent on compliance with stipulated conditions, which if violated, may lead to revocation. Many probation and parole programs are similar (e.g., intensive supervision) or they share clientele. Last, as alternatives to incarceration, both are less expensive, less punitive, and probably more effective strategies of crime control.

The major difference between probation and parole is that probationers are sentenced directly to community supervision without being incarcerated, while parolees serve part of their sentence incarcerated before they are released to parole. Parole is a conditional release from confinement, whereas probation is a conditional suspension of a sentence to confinement. In both cases, a new crime or technical violation of conditions may lead to enhanced restrictions or incarceration. A general definition of *probation* is the conditional supervised release of a convicted offender into the community in lieu of incarceration (Allen et al. 1985). *Parole* is the conditional supervised release of an incarcerated offender into the community after serving part of the sentence in confinement (Clear and Cole 1986).

PROBATION

Before informal probation was created in Boston in 1841 by philanthropist John Augustus, and the first statewide probation law was enacted in Massachusetts in 1978, convicted offenders were typically fined or imprisoned, often serving their full sentence. Probation was instituted as an alternative to incarceration at a time when jail and prison overcrowding became a critical management and humanitarian issue. Probation was considered a front-end sentencing solution to overcrowding,

intended specifically for less serious, first-time, and juvenile offenders amenable to "rehabilitation."

Over the years, rehabilitation has remained the primary goal of probation, and to this end, probation facilitates behavioral reform in a variety of ways. First, the often negative practical and symbolic consequences of the stigma of being an "ex-con" are neutralized. As less notorious and visible "probationers," the label will have less deleterious effects on the rehabilitative process. Second, the contaminating effects of imprisonment are avoided. This is particularly important for the less experienced offender, who may learn more about crime from more sophisticated, and sometimes predatory, inmates. The "pains of imprisonment" also produce anger, resentment, hostility, cynicism, and many other dysfunctional attitudes and feelings that make it more difficult to reform. Third, probation supports the existing social integration of the offender in the free community of noncriminals, including family, neighbors, employers and coworkers, friends, teachers and classmates, and others who are critical to the informal social control of crime. The offender released from incarceration will have the more difficult task of "reintegration." Fourth, the rehabilitative programs and services available to probationers are generally less coercive and more varied, flexible, and effective than those provided for prisoners. Fifth, the implied trust in leaving an offender in the community to demonstrate the ability to conform reinforces a positive attribution of self and expectations of appropriate behavior. Probation is more likely than incarceration to contribute to a self-fulfilling prophecy of rehabilitation.

Secondary goals of probation are more punitive. Probation is a penal sanction by virtue of the restrictions placed on the freedom of the offender. The conditions range from very lenient (e.g., weekly phone contact with a probation officer) to very punitive (e.g., twenty-four-hour home confinement), depending on the nature of the offense and offender characteristics. The goal of crime control can also be addressed by enhanced monitoring of probationers' compliance with the terms of probation, particularly their whereabouts. This can be accomplished by increasing the number and duration of meaningful (namely, face-to-face) contacts between probationer and probation officer, in the department's office, at home, at work,

in a residential or nonresidential program facility, or anywhere else in the community. More comprehensive control is possible with electronic monitoring devices; for example, transmitter anklets can verify the location of a probationer within, or outside of, a stipulated free movement area. The goal of deterrence is served to the extent that rehabilitation and punishment succeed in preventing probationers from committing more crimes and returning to the criminal justice system. Finally, justice is achieved when probation is the appropriate sentence for the offense and offender, and its application is equitable and uniform across race, sex, and socioeconomic status categories (McAnany et al. 1984).

The decision to grant probation is the product of a complex organization of legal actors, sentencing procedures, decision criteria, and system capacity. The decision may be initiated by the prosecutor, who negotiates a guilty plea in exchange for a recommendation to the judge that the defendant be sentenced to probation. Or it may await conviction at trial. In either case, a presentence investigation report prepared by a probation officer may support the recommendation by providing background information on the offender and an assessment of the public risks and prospects for probation success.

There are intense organizational pressures to minimize the number of trials and to divert convicted offenders from incarceration: There are huge case backlogs in the courts (Meeker and Pontell 1985) and tremendous overcrowding in jails and prisons, as evidenced by the almost forty states in 1988 that were under court order to reduce inmate populations in order to meet a variety of correctional standards (Petersilia 1987). Incredibly, it has been estimated that more than 90 percent of convictions for felonies are the result of negotiated guilty pleas (McDonald 1985), and a high percentage of those receive probation since, by state, from 25 to 70 percent of convicted felons are sentenced to probation (Petersilia 1985). It is clearly in the personal and organizational interests of the defendant, prosecutor, judge, and even the jailer and prison superintendent to support "copping" a plea for probation.

Whether the conviction is negotiated or decided at trial, the judge sentences the offender, within

the constraints imposed by the sentencing model and guidelines used in the jurisdiction. Most states use indeterminate sentencing, where judges have substantial discretion in rendering sentences and parole authorities are responsible for release decisions of incarcerated offenders. The trend is toward determinate sentencing, where judges and parole boards have much less influence on sentence and release decisions. In both models, probation is a widely used sentencing option, especially for less serious offenders but even for many serious offenders: Nationally, as high as 20 percent of violent offenders receive probation, including 13 percent of defendants convicted of rape and 9 percent of those convicted of homicide (Lisefski and Manson 1988).

Despite the confluence of the trend toward determinate sentencing, more pervasive justice model practices in corrections, and increased public pressure to be more punitive with criminals, there are relatively more offenders on probation than incarcerated or on parole than there were two decades ago (Petersilia et al. 1985). More serious offenders are being incarcerated for more fixed sentences, but the concomitant institutional overcrowding has produced a greater utilization of probation, as well as a variety of types of probation designed to meet the needs of both less serious and middle-range offenders, who in the past would have been more likely to be incarcerated. In addition to "standard probation," characterized by assignment to a probation officer with a caseload of as many as two hundred probationers and nominal contact, supervision, and rehabilitative services, a whole range of "intermediate sanctions" has been created that includes programs that are typically more punitive, restrictive, intensive, and effective than standard probation (Petersilia 1987; Morris and Tonry 1990). Judges now have a diversity of probation alternatives at sentencing: intensive supervised probation, home confinement, electronic monitoring, residential centers (half-way houses), and split sentences (jail/probation). These alternatives are often combined and coupled with other probation conditions that require restitution to victims, employment or education, payment of program costs, random urinalysis, specialized treatment or classes (e.g., Alcoholics Anonymous), or community service. Many of the intermediate sanctions are also used in the supervision of parolees.

PAROLE

Like probation, parole in the United States was created to relieve the serious overcrowding problem in prisons at the beginning of the nineteenth century. Years before informal probation began, some prison wardens and correctional administrators were releasing prisoners before their full sentence was served. They were either released outright, much as if they had received a pardon, or monitored informally by the police. Based on the European correctional innovations of “good time” and “ticket of leave,” formal parole emerged toward the end of the nineteenth century, with the first indeterminate sentencing law passed in 1876 in New York (Champion 1990).

Until Maine abolished parole in 1976, all states had indeterminate sentencing and parole authorities. In general, within these systems a prisoner earns good time by productive participation in institutional programs and good conduct. The accumulated good time is subtracted from the sentence to determine the time incarcerated. This decision is typically made by a parole board, which is often a group of political appointees from a variety of occupations and constituencies. The offender is then released (or awarded a leave) to the supervision of a parole officer. If an offender does not commit a new crime or violate the conditions upon which release to parole is contingent, he or she can complete the remainder of the sentence as a parolee, to the time of discharge and freedom.

The goals of parole are anchored in indeterminate sentencing and the tenets of the rehabilitative ideal. It is assumed that offenders are amenable to reformation, through both the rehabilitation provided by the prison’s treatment, educational, and vocational programs and the reintegration back into the free world facilitated by the transitional programs and services of parole. These twin primary goals of “rehabilitation” and “reintegration” drive the decisions and actions of the parole system. Parole is granted when the prisoner is considered ready for release, based on behavior during confinement, the extent to which rehabilitation is evident, and the apparent risk to public safety. In practice, many offenders spend a relatively small proportion of their sentence incarcerated; for instance, a convicted murderer with a life sentence

may “do hard time” for as few as, say, ten years and serve the rest of the sentence on parole. Parole is revoked, or modified, when there are indications that reintegration is in jeopardy or unlikely, owing to violation of parole conditions. A new crime, in particular, but even a technical violation may be sufficient for the parole board to reincarcerate a parolee. The parole board also has the discretionary authority to set dates for parole hearings, fix minimum terms and release dates, determine good time credits, and specify parole conditions and requirements.

Like probation, the secondary goals of parole include punishment, crime control, and deterrence. After all, parole is a part of the penal sanction defined by the sentence to imprisonment, and, depending on the type of parole and stipulated conditions, the parole experience can be very restrictive and quasi-custodial. Effective rehabilitation, supervision, and monitoring of parolees should also produce deterrent effects—the combination of reformation and punishment should prevent future criminal conduct among parolees.

Unfortunately, by the mid-1970s, evidence had accumulated that suggested that parole was not an especially effective crime control strategy (Martinson 1974), and the shift away from the rehabilitative ideal to a more punitive justice philosophy (von Hirsch 1976) began in earnest. About one-third of states have returned to some form of determinate sentencing, and more are likely to follow. The discretionary power of judges in rendering sentences and of parole boards in implementing them has been abridged, in order to make decisions more rational and fair by linking them to the severity of the offense rather than the characteristics of the offender. Offenders are now more likely to be serving sentences in confinement; since 1980, the rate of incarceration has increased by 76 percent (Bureau of Justice Statistics 1989). They are also less likely to be placed on parole by a paroling authority; between 1977 and 1987, releases from imprisonment decided by parole boards dropped from about 70 percent to 40 percent of all releases, while mandatory releases increased from roughly 5 percent to 30 percent of the total (Hester 1988). With determinate sentencing, many states simply do not have paroling authorities or parole supervision in the community.

These changes have also affected the types of parole that are still available in a majority of states. Although many parole and probation programs are similar, the usually more serious offenses and criminal histories of parolees and the shift toward more punitive correctional systems have led to a hardening of the conditions of (cf. U.S. Sentencing Commission 1987), less utilization of "standard parole," and a greater emphasis on protecting public safety by extending custody from the institution to the community. The goals of rehabilitation and reintegration have become less important, while crime control and deterrence have become more important. Consequently, there is greater reliance on transitional programs that maximize monitoring and supervision, while providing opportunities and services (e.g., employment, school, counseling, drug treatment) intended to facilitate reentry into the community and desistance from crime during parole and, ultimately, after discharge from correctional supervision. These programs are more intensive and custodial, often involving residential placement in a halfway house, intensive parole supervision, or home confinement with electronic monitoring. From these community bases, parolees may participate in work or school releases, home furloughs, counseling, religious services, and a variety of other reintegrative activities.

Although parole is not used to the extent that it was before the advent of determinate sentencing, and there are those who believe that it should be abolished in all states, some research suggests that determinate sentencing is no more a panacea than prior correctional reforms. There may be a leveling of sentencing disparities, and more offenders are being incarcerated. But they, on the average, are doing less time and, after release, may be as likely to be reconvicted and reincarcerated (Covey and Mande 1985).

RESEARCH

While the research evidence on the efficacy of determinate sentencing may be sketchy, there are many studies of other issues in probation and parole that have produced more substantive results. Social scientific research on probation and parole has tended to revolve around a set of related issues that are common to both: program effectiveness, recidivism, and classification and

prediction. The overriding empirical and policy question is "What works?" Attempts to address the question vary in rigor and quality, and the answers are neither direct nor simple.

There are innumerable studies of program effectiveness, most of them not producing useful, much less compelling, evidence of program success or failure. For example, many studies conclude that a probation program is successful because 30 percent of participants recidivate or that a parole program is successful because 40 percent of participants recidivate. There are serious problems with those kinds of studies. First, they do not compare the program being evaluated with others, either with other probation or parole programs, or across correctional alternatives (e.g., release, probation, incarceration, and parole).

Second, without comparison groups, one can only evaluate program effectiveness in relation to some standard of success. But preordained acceptable levels of recidivism are determined normatively, not empirically. Normative criteria of success cannot be applied uniformly across the incredible variation in probation and parole programs. For instance, some probation programs, because of the very low risk participants, should probably generate recidivism rates that are closer to 5 percent than 30 percent.

Third, recidivism is often not defined or measured adequately. Generically, recidivism has come to mean "reoffending," particularly by offenders who have had contact with the criminal justice system, as measured typically by rearrest, reconviction, reincarceration, or some variation or combination thereof. But what does a probationer or parolee relapse to, and what is the most appropriate and accurate measure? The answers are complicated by the fact that probation and parole can be revoked if an offender commits a crime that becomes known to criminal justice authorities or by a noncriminal violation of release conditions (a "technical violation"). Paradoxically, practically all studies ignore the substantial amount of successful criminal behavior that remains hidden from officials, but many use both revocation criteria as measures of recidivism. Which measure is used can dramatically affect judgments about program effectiveness. Evaluations of three intensive probation supervision programs show that technical violations, as compared to new crimes, account for

the majority of revocations. The revocation rates due to technical violations for these programs were 56 percent, 70 percent, and 85 percent, respectively. However, if the technical violations are not counted in the recidivism rates, the rates drop to 7 percent, 8 percent, and 5 percent, respectively (Petersilia 1987). Depending on program objectives, recidivism, no matter how measured, may not be the only or most appropriate criterion of program effectiveness. What may also be useful is assessment of relative costs and savings, impacts on jail and prison overcrowding, effects on public perceptions of safety, performance at school or in the workplace, changes in offenders' attitudes and self-concept, and so on.

More rigorous studies utilize comparison groups in order to assess the relative effectiveness of different correctional strategies. A typical study compares the recidivism rates of various combinations of offenders on probation, incarcerated, and on parole, and concludes that probationers are least likely and ex-prisoners are most likely to recidivate. Of course, one would predict those results based on the differences between the groups in their risk to recidivate. The selection biases of the court place the least serious, low-risk offenders on probation and the most serious, high-risk offenders in institutions. The observed differences in recidivism do not reflect the relative effectiveness of the programs, but the original differences in the recidivism risks of the comparison groups.

Some studies attempt to produce more comparable groups by using more objective probation and parole prediction instruments to classify and then compare offenders by level of recidivism risk across programs. That is, they try improve comparability by "matching" offenders within the different program groups. For example, a study of the relative effectiveness of standard probation, intensive supervision probation, and incarceration with parole classified offenders within each group into low-, medium-, high-, and maximum-risk levels. Comparisons of recidivism, measured by rearrest, reconviction, and reincarceration, across the three program alternatives for each of the four categories of offenders (namely, least likely to most likely to recidivate) show that parole is least effective in preventing recidivism at all levels of recidivism risk. The differences between standard and intensive probation are not as consistent: no matter how recidivism is measured,

the rate is higher among intensive supervision probationers who are low- and high-risk offenders; among medium-risk offenders, it varies by the measure of recidivism; and for maximum-risk probationers, there seems to be little difference in the effectiveness of standard or intensive supervision, except for the somewhat higher reincarceration rate among intensive supervision probationers (Erwin 1986).

The equivocal findings of this and many similar studies reflect the difficulty in predicting recidivism risk with any degree of accuracy. The most comprehensive and statistically sophisticated techniques (e.g., cluster analyses, linear models, complex contingency tables) are not much more accurate than bivariate tabular procedures developed seventy years ago by Ernest Burgess. And no technique is able to predict recidivism with higher than 70 percent accuracy, with most slightly better than chance (Blumstein et al. 1986). Therefore, it is virtually impossible to make groups comparable on the basis of recidivism risk, or any other prediction criteria, which compromises the validity of the findings regarding differential program effectiveness.

The mixed results probably also reflect the paradox of intensive supervision programs in general: Increasing supervision and monitoring may increase, rather than decrease, the probability of recidivism. The offender is at greater risk to recidivate, simply because there is a better chance that unacceptable conduct will be observed. However, depending on the declared program goals, this may indicate success rather than failure: If intensive supervision of probation and parole are intended to enhance crime control and public safety, rather than to rehabilitate, higher rates of recidivism may demonstrate program effectiveness (Gottfredson and Gottfredson 1988).

Research on probation and parole effectiveness cannot produce compelling findings from studies that depend on comparisons of typically noncomparable groups. What is necessary are "equivalent" groups that are created through random assignment within experiments. Unfortunately, experimental designs are usually more expensive and more difficult to implement and complete in natural settings. Consequently, they are extremely rare in research on probation and parole. For instance, there are more than one hundred

studies of the effectiveness of intensive probation supervision, but none have an experimental design with random assignment to program conditions (Petersilia 1987). There are some current efforts to implement studies of probation and parole that have experimental designs, but if the objective is to produce valid and useful knowledge on "what works," there must be a greater commitment on the part of the criminal justice system, funding agencies, and the social science research community.

The field of probation and parole research and study will continue to be important for social scientists. While there is no indication that the description and analysis presented here is changing at this time, the concern with the issues is active. Some more recent writings add to the character of the presentation here, and are well worth reviewing for persons who wish to pursue the development of the field. PROFESSIONS

The idea of a “profession” did not exist in ancient times. Although there were people who did what is currently denoted as professional work, these “professionals” often labored in dependent positions. For example, physicians in the Roman Empire were slaves in wealthy households, and architects worked as salaried public employees. Lawyers in ancient Greece were merely friends of the litigants who spoke before a gathering of their peers. Neither lawyers nor physicians received formal training (Carr-Saunders and Wilson 1937). By medieval times, the three classic professions—medicine, law, and the clergy (which included university teaching)—began to approximate more closely the modern conception of professions. With the development of universities, then under religious auspices, would-be professionals completed lengthy training in their chosen fields. They also began to constitute a new class of intellectuals. As society increasingly secularized, the professions emerged from under religious control and began to organize professional associations. By the eighteenth century, they had achieved independent status.

In the nineteenth century, middle-class occupations such as dentistry, architecture, and engineering began to professionalize, aspiring to the gentlemanly status of the classic, learned professions (Dingwall and Lewis 1983). “Gentlemanly” was the appropriate description, since the majority of professionals were men. It was not until the 1970s that women began to make significant inroads into these occupations, and even today men predominate in the status professions.

In the nineteenth and early twentieth centuries, professionalism developed in concert with the increasing division of labor and rationalization characteristic of industrializing Europe and the United States. As competitors in market economies, occupational incumbents sought to

professionalize to improve their status. In addition, they wanted to better their economic positions by securing occupational niches for their services (Ritzer and Walczak 1986). In the United States, at least, universities played the key role of transferring both the technical know-how and the culture of professionalism to new generations of professional aspirants (Bledstein 1976).

WHICH OCCUPATIONS ARE PROFESSIONS?

Today the term “profession” includes a range of occupations arrayed along a continuum of high to medium levels of prestige. At the high end of the continuum are the classic, or “status,” professions of medicine, law, clergy, and university teaching. Incumbents in these occupations usually receive high incomes, exercise job autonomy, and receive deference from the public and those lower in the status hierarchy. Although women have begun to gain entry into some of the professions, most professions remain predominantly male: in 1998, women’s representation among physicians, lawyers, and the clergy was 27, 28, and 12 percent, respectively. Women have made more progress moving in to college and university teaching, representing 42 percent of incumbents by 1998 (all 1998 data are from U.S. Bureau of Labor Statistics 1999, Table 11).

Somewhat lower on the continuum are the “newer” professions such as dentistry, engineering, accounting, and architecture, which also command respect and relatively high salaries. Men also predominate in these occupations: 20, 11, and 18 percent of dentists, engineers, and architects, respectively, were women in 1998. Only in accounting have women made significant inroads: 58 percent of all accountants and auditors were women in 1998. This feminization is attributable largely to accounting’s dramatic occupational growth in the 1970s (Reskin and Roos 1990, pp. 40–41).

Still lower on the professional continuum are the “marginal professions” (e.g., pharmacy, chiropractic) and the “semiprofessions” (e.g., nursing, public school teaching, social work, librarianship). These occupations exhibit some characteristics of the classic professions but have not acquired full professional status because of opposition from

established professions and an inability to convince the public that they command unique expertise. These occupations are less prestigious and their incumbents are paid less than those in either the classic or the new professions. Moreover, because they are concentrated in bureaucratic settings, these professionals exercise less job autonomy than higher-status professionals. An important difference between the marginal professions and the semiprofessions is that males are in the majority in the former (although pharmacy, an occupation that has feminized rapidly in recent years, is now 44 percent female), whereas semiprofessions have long been predominantly female (in 1998 women composed 92, 75, 68, and 83 percent of nurses, public school teachers, social workers, and librarians, respectively).

Paraprofessionals work with, but as subordinates to, members of the other professions. They are generally technicians associated with various professional occupations. Paralegals, for example, work closely with lawyers, and physicians delegate certain tasks and responsibilities to physicians' assistants. As in the semiprofessions, women tend to predominate in paraprofessional occupations. These data clearly show the sex-stratified nature of professional occupations, but these occupations are also stratified by race: in 1998, for instance, 5 percent of physicians were black, 6 percent of college and university teachers, 4 percent of lawyers, and 9 percent of clergy, notably less than their 11 percent representation in the labor force as a whole. Blacks are overrepresented, relative to their labor-force representation, in the following professions: dietitians (18 percent); respiratory therapists (12 percent); prekindergarten and kindergarten teachers (14 percent); educational and vocational counselors (13 percent); social workers (23 percent); recreation workers (16 percent); athletes (13 percent).

THE PROCESS OF PROFESSIONALIZATION

Given the stratification of the U.S. occupational structure, it is clear why workers desire to professionalize. Professionalization brings higher income, higher prestige, greater job autonomy, and higher job satisfaction. It also protects incumbents from competition. The "process of professionalization" posits a common sequence of development that occupations undergo. Some

scholars accept Harold Wilensky's depiction of this process (1964). First, people begin to work full time at a specific set of tasks that will form the new occupation's core jurisdiction. Second, those in the occupation establish a university-affiliated training program, and some incumbents undertake the responsibility for training new generations of practitioners. Third, practitioners and teachers combine to form a professional association that identifies the occupation's core tasks and makes claims regarding skill jurisdiction. Fourth, occupational incumbents seek to protect their jurisdictional claims by political means. Professionals lobby for legal protection, in the form of licensing and certification requirements, to generate labor-market shelters that ensure their monopoly of skills. Finally, incumbents develop a formal code of ethics that embodies rules to protect clients, eliminate the unqualified, and spell out the occupation's service ideal. As we shall see, later theorists have come to question this linear sequence of events.

APPROACHES TO THE STUDY OF THE PROFESSIONS

What distinguishes the professions from other occupations? Theoretical approaches in studying this question have changed over time and remain in flux. Scholars have also developed new methods to address these questions.

The Trait Approach. After World War II, the trait approach was dominant in scholarship on the professions (Freidson 1986). Scholars—mostly American academics—tried to define the professions by generating an exhaustive list of characteristics. These traits, scholars hoped, would distinguish professions from nonprofessions and higher-status professions from those of lower status. The main method used was the case study.

Scholars carefully scrutinized particular occupations to determine how well they approximated the four major criteria, or traits, of the ideal-typical profession (Hodson and Sullivan 1990). First, professionals are experts with abstract, esoteric knowledge and skills that set them apart from others. Second, because of their unique expertise, professionals exercise autonomy on the job. Codes of ethics help to ensure autonomy from outside control by permitting professionals to police misconduct internally. Third, their esoteric knowledge

allows professionals to claim authority over their clients and subordinate occupational groups. Finally, the professions are altruistic, that is, service-rather than profit-oriented. Underlying these four traits is a fifth: the public must recognize the occupation as a profession. Regardless of an occupation's claim of unique expertise, if the public does not view the occupation's knowledge as abstract, it is difficult for those working in it to claim professional status and the perquisites that accompany it.

Scholars used these criteria to differentiate among the professions, most particularly in comparing the female semiprofessions to the typically male status professions. While the semiprofessions have a body of knowledge, they lack a monopoly over that knowledge. They also have a difficult time convincing the public that their skills are professional. The public is less likely to recognize their expertise (e.g., teaching children, servicing library patrons) as particularly esoteric. Semiprofessionals typically work in bureaucratic settings and, as a consequence, are subject to heteronomy, or supervision by organizational superiors and professional colleagues. Their ability to claim autonomy is limited.

The Power Approach. In the 1960s, scholars in the United States and Great Britain began to criticize the trait approach as static and ideological. Recognizing the salience of culture and social structure, power theorists also shifted to historical methods to understand the sources of professional power. They argued that occupations we view as professions do not necessarily exhibit the requisite traits, but rather have the power to convince the public that they do. Power theorists viewed the professions as monopolistic organizations intent on gaining and retaining professional control and ensuring their status in the stratification system. Eliot Freidson (1986), for example, focused on how professions establish protected labor markets for their services. Magali Sarfatti Larson (1977) argued that the professions are market organizations in the capitalist economy, explicitly seeking to dominate the market for their expertise.

For these theorists, the so-called objective characteristics of the trait approach are ideological attempts to preserve the professions' status and privilege (Freidson 1986). Rather than being truly altruistic, professional incumbents create the myth

of service orientation to gain public goodwill, enhance their status, and minimize external control. According to this view, professionals sometimes abuse their autonomy by failing to police themselves, and incompetent doctors and lawyers fleece the public with little fear of reprisal from their peers. Finally, the professional's authority over clients has also declined in recent years as a more educated public has become active in activities seen as the province of professionals (e.g., getting second opinions on medical recommendations and becoming more educated consumers regarding medical and legal issues).

The historical battles between physicians, on the one hand, and pharmacists and chiropractors on the other, illustrate how an established profession exercises power against competing occupations (Starr 1982). When the pharmacist's traditional task of compounding drugs shifted to pharmaceutical companies, they lost their diagnostic expertise (and hence monopoly over their knowledge). With respect to chiropractors, the American Medical Association restricted access through licensing laws or blocked reimbursement from private insurance companies. As a consequence, pharmacy and chiropractic have yet to become fully professional.

What enables professions to wield power? Theorists point to the occupational characteristics indeterminacy and uncertainty (Ritzer and Walczak 1986). The professions that have achieved and maintained power are those whose tasks cannot be broken down or otherwise routinized (indeterminacy). Similarly, those that deal with areas of uncertainty are also likely to preserve their power. As Wilensky (1964) described it, professional knowledge involves a "tacit" dimension, in Polanyi's (1967) terminology. Their lengthy training and years of practical application ensure that physicians "know" what treatments to use for which symptoms. Similarly, lawyers "know" what legal strategies work best and college professors "know" what instructional strategies are most effective in enhancing student learning. Reading a textbook or consulting computerized data bases is not equivalent to tacit knowledge. This kind of knowledge—expertise refined by years of experience—is not easily routinized. Physicians and lawyers also deal with areas of high uncertainty for their clients, the former with physical health and the latter with legal affairs. Clients need these

professionals to translate medical and legal jargon into everyday language they can more readily understand.

The System of Professions. Andrew Abbott's (1988, 1995) theory of professions critiqued the notion that professions undergo a common process of development. Employing historical and comparative methods, Abbott provided a wealth of evidence that the history of the professions is much more complicated than that represented in a linear process of professionalization. Rather than a history of professions that established systems of control (e.g., schools, professional associations, licensing and certification), Abbott's account is of ongoing interprofessional competitions, squabbles over jurisdictions, and professional births and deaths.

Abbott contended that professions make up an interdependent "system of professions." Understanding modern professions entails articulating their histories of conflict with other professions. Comprehending the realities of modern medicine, for example, depends more on investigating its historical conflicts with closely related professions such as psychiatry and chiropractic than on the particulars of medieval or nineteenth-century medicine.

Recognizing the interdependence of professions is important because it clarifies that professions emerge, grow, change, and die within the historical context of competition with other professions. This competition takes the form of jurisdictional disputes over the control of abstract knowledge. Professionals can use their abstract knowledge to define a core set of tasks (their jurisdiction), defend that jurisdiction from others, or appropriate the tasks of others. Interprofessional boundary wars reflect professions' attempts to "enclose" jurisdictional tasks within the boundaries of their profession's sphere of influence (Abbott 1995, p. 553; see also Witz 1992). One recent example of such a jurisdictional dispute was pediatric medicine's partially successful attempt to expand their sphere of influence to include children's psychosocial disorders (Halpern 1990). Whether professions succeed or fail in such jurisdictional disputes, any changes reverberate throughout the system. The professions reequilibrate, with some occupations accepting a subordinate or advisory role, some agreeing to split jurisdictions or clients, and others exiting the professions altogether. To

adequately theorize and model jurisdictional disputes, Abbott (1993, p. 205) advocated a multilevel analysis that links micro-level information on careers, to meso-level data on the network structure of careers and jobs, to the macro-level work and occupational structures.

SEX DIFFERENCES IN THE PROFESSIONS

In 1998, women composed 46 percent of the employed labor force and 53 percent of professionals, suggesting that women do quite well in the professions. However, a closer look reveals a different story. As noted, women are heavily concentrated in the semiprofessions (as nurses, public school teachers, social workers, and librarians) and men in the higher-status professions (as physicians, lawyers, and engineers). Incumbents in the former earn less and exercise less autonomy than in the latter. As in the occupational structure as a whole, the professions are highly segregated by sex.

Even within the higher-prestige professions, women work in different, lower-paying, and less prestigious jobs than men. Women lawyers, for example, work in government jobs, in research rather than litigation, and in certain specialties such as trust and estates; women physicians are more likely than men to specialize in pediatrics and to work in health maintenance organizations (HMOs); female clergy specialize in music or education (Reskin and Phipps 1988; see also Tang and Smith 1996).

Part of the reason for this differential job distribution by sex has to do with a characteristic unique to the professions. The high level of uncertainty inherent in prestigious professional jobs means that employers are careful to choose recruits who "fit in" with those already on the job. Thus, as Rosabeth Moss Kanter (1977) suggested, employers tend to recruit people much like themselves, a process she calls "homosocial reproduction." The predominance of males in the status professions thus helps to reproduce sex segregation.

Other factors reducing women's access to high-status professions are entrance restrictions such as certification and licensing. Physicians, for example, consolidated their control over medical jurisdictions by successfully pressing for legislation to outlaw midwives and prohibit the licensing of those trained at "irregular" schools, activities that

disproportionately affected women. In 1872, the Supreme Court restricted women's ability to practice law, arguing that "the natural and proper timidity and delicacy which belongs to the female sex unfits it for many of the occupations of civil life" (Reskin and Phipps 1988, p. 192). Male professionals were thus able to establish labor-market shelters to protect themselves from competition from women as well as other "undesirables."

Since 1970, women have gained greater entry into some of the professions, including occupations such as medicine, law, and pharmacy. Indications are, however, that internal differentiation within the professions perpetuates job segregation by sex (Reskin and Roos 1990). For example, Polly Phipps (1990) found that women's representation in pharmacy nearly tripled (from 12 to 32 percent) between 1970 and 1988, and has continued to increase since then, reaching 44 percent by 1998. However, women pharmacists concentrate in the lower-paying hospital sector, while men predominate in the higher-paying retail sector. Similar ghettoization exists in other professions that are admitting more women (see, for example, Reskin [1990] on book editors; Donato [1990] on public relations specialists; Roos and Jones [1993] on academic sociologists; and Roos and Manley [1996] on human resource managers and professionals).

THE CHANGING PROFESSIONS

Some view the future of the professions as bleak, predicting that ongoing proletarianization or deprofessionalization will eliminate the professions' unique traits. The proletarianization thesis argues that an increasing division of labor and a bureaucratization within the professions are routinizing knowledge and transferring authority from professionals to organizational superiors. The deprofessionalization thesis documents declines in the professions' monopolistic control over their knowledge, their exercise of autonomy on the job, their ability to protect their jurisdiction from encroachments, and the public's deference to professional authority (Ritzer and Walczak 1986).

Some occupations, of course, have lost some of their professional status. As noted, as pharmaceutical companies increasingly absorbed the compounding of drugs, and as chains replaced independent pharmacies, pharmacists lost some of

their autonomy and monopoly of their knowledge to physicians. Taking a broad view of the professions, however, Freidson (1984; 1994, p. 9) argued that professionalism has been "reborn" in a hierarchical form in which bureaucratization and professionalization are often quite compatible. Working in organizations, he argued, has been the norm for many professions from their inception, with engineers the most obvious example. In addition, organizations that employ professionals tend to diverge enough from the ideal-typical bureaucracy to protect professional privilege. For example, professionals in organizations often exercise a lot of autonomy, working under senior members of their own profession rather than nonprofessional managers. Freidson thus portrayed most organizations as working to accommodate professionals, and operating under an "occupational principle" of authority, as opposed to an "administrative principle" of organizing and controlling work (1994, p. 61). Wallace (1995) also described how some bureaucratic work systems—specifically a "corporatist" model of control—can be quite compatible with professionals' self interests.

Like Freidson and Abbott, Brint (1994) viewed the professions as social forms that evolve historically in conjunction with other occupations and work organizations. Rather than look to professions interacting through jurisdictional disputes, however, Brint contextualized changes in the professions within the workplace itself, in the occupationally and organizationally based ties professionals have, and the markets in which they work (see also Leicht and Fennell 1997). He described the ascendance of a new, organizationally based profession—expert professions—that relaxes traditional assumptions about professional work. Pursuing profits, closer interconnections with business, and lesser attention to larger public interests, are all hallmarks of "expert professionalism" (Brint 1994, p. 8), which Brint juxtaposed with "social trustee professionalism," the traditional conception of professions as the trustees of socially important knowledge (p. 4). In Brint's view, the professional class has splintered into highly skilled experts in resource-rich organizations as opposed to professionals with less marketable skills in resource-poor organizations, especially in the public and nonprofit sectors (p. 11). These differing organizational locations have predictable consequences for incumbents' political and social views.

Even with such changes, Freidson (1984, 1994) found no evidence that the prestige of the professions as a whole has declined. Nor did he find that public trust in professionals has deteriorated relative to other American institutions. Moreover, the professions' continuing ability to erect labor-market barriers to competition is important evidence of their enduring power. Professionals today remain strong enough to exert their will against others lower in the occupational hierarchy. Professional privilege remains intact in the American occupational structure.

As the professions change, theorizing must evolve as well. Some have begun to call for a broader, synthetic theory of occupations, one that situates the professions in a comparative way within the larger occupational structure (e.g., Abbott 1993; Freidson 1994). Central to such a broader theory is a method that sets occupations not only in their historical, comparative contexts, but also in the organizational and market context in which occupational incumbents work (e.g., Brint 1994). Freidson (1994, p. 21) has argued for moving beyond a theory that defines professions by fiat, to one that recognizes the professional aspirations of a variety of other nonprofessional occupations. In Freidson's terminology, how do ordinary occupational incumbents invoke their day-to-day work activities so as to claim professional status, regardless of whether the larger public would recognize them as professionals? Such a conceptualization opens up the possibility that other occupations can organize in their own self-interest to generate their own "professional projects." Claiming a unique expertise or specialized knowledge, developing professional associations, and convincing the state that certification is appropriate are first steps toward claiming professional status. Ultimately, the true test of professional status will be to convince others that the expertise one has entitles one to professional privilege, and to the right to establish labor market shelters. Only then will professional status and earnings rise to accompany claims of professional privilege.

PROTEST MOVEMENTS

Protest movements have been of high interest to sociological research since the inception of the

discipline in the mid-nineteenth century, during the periods of great industrial and urban development in Europe and North America. In the context of massive changes in the economic structure and mass rural-to-urban and cross-national migration, a variety of protest movements developed. They caught the attention of Comte, Le Bon, Weber, and other early sociological analysts. In the United States, the first widely used introductory sociology textbook, developed by Chicago School sociologists Robert Park and Ernest Burgess in the 1920s, was organized around the concepts of collective behavior. Protest movements occupied a substantive part of the text.

Sociologists' interest in protest movements reflects the high interest of many who are not sociologists and are not research oriented. Such movements have the potential of affecting lives in substantial ways. This is particularly so when a protest touches on wide public concerns. In American society, the recognition of the potential impact of protest movements is encompassed within the framework of the U.S. Constitution's First Amendment guarantee of the right of the people peaceably to assemble and to petition the government for redress of grievances.

The language of the First Amendment, including the right to "peaceably" protest, is in recognition that protest movements can turn violent. Rebellion on taxes and other violent protest in the 1780s had strongly influenced the desire of those at the Constitutional Convention in 1787 to expand democratic public expression while outlawing violent means of bringing about protest movement changes. The language of the First Amendment reflects the potential power of protest ideas. Any consideration of protest movements needs to include the effects of those, like James Madison and Thomas Jefferson in the case of the amendment language, whose articulated ideas about grievances provide a key element in active protest emergence.

While most protest movements in the United States and in other democratically based societies have been mostly peaceful, there is a stream of protests which have not been peaceful. There are many examples of protest movements with no or little violence, including the multiple women's protests for more rights and opportunities throughout the nineteenth and twentieth centuries; the

food and drug protection movement in the early twentieth century; the early- and late-twentieth century environmental protest movements for cleaner air, water, and protection of endangered species and open spaces; and the protest marches of 1998 in many communities and in Washington, D.C., which resulted in new record public expenditures for cancer research at a time of budget cutbacks in most government programs. In contrast, examples of protest movements that generated periodic violence include the labor movement protests to nonresponsive corporations and legislatures from the late nineteenth century through the 1930s, the racial- and ethnic-led civil rights protest since the mid-twentieth century, and the anti-Vietnam War protest movement of the late 1960s and the early 1970s.

As not all protest movements succeed, or may succeed at a frustratingly slow pace for participants, protest activists in these protests went beyond democratically legitimate means of protest. When that occurs generally, the basis exists for violent protest episodes. Protest movements may also generate violence in opposition to a protest movement from those whose perceived vested interests and way of life are threatened. Such violence may occur to intimidate people and prevent them from engaging in protests, one clear aim of the hundreds of lynchings of black citizens in the first half of the twentieth century. Violence may occur in the context of a counterprotest movement to reverse a successful movement, as in the case of the bombings and physician killings at abortion clinics following the successful establishment of the legal right of women to seek and have an abortion.

Whether violent or nonviolent, protest movements have the potential of being an interim form of collective challenge to some aspect of the social status quo. The protest continuum ranges from localized groups and crowds that organize around specific and short-term delimited grievances to mass protest movements about social conditions and perceived injustices. These mass protests are designed to generate comprehensive and fundamental changes in a society and sometimes across societies. More so than localized acting crowds and less so than systemic social movements, protest movements encompass mass behavior that extends beyond a localized situation, and they have the potential of generating social movements

when a variety of conducive conditions exists (Gusfield 1968; Smelser 1962; Tilly 1978).

The twentieth century has been characterized by a wide variety of protest movements. In the United States, industrial protests were common for the first third of the century, as were anti-immigration protests. The suffragette protest movement early in the century was a precursor to the women's movement for equal treatment and opportunity in the last third of the century. The civil rights movement, led by blacks in the 1950s and 1960s, precipitated countermovements—a common characteristic of protest movements—including the White Citizen's Council protests and the reemergence of the Ku Klux Klan. Poor people in Chile, El Salvador, Nicaragua, and other Latin American countries have protested the privileges of an elite economic class as vestiges of an unproductive and rigid class colonial structure. Such protest movements are evident globally, with protest occurrences in Africa, the Middle East, and Asia.

A common thread through the wide variety of protest movements is their political nature. In various ways governmental authority is challenged, changed, supported, or resisted in specific protest movements. To advance their prospects for success, protest movement leaders often engage in coalition politics with more powerful individuals and groups who, for their own interests and values, support the challenge raised by the movement. When protest movements succeed in generating sufficient public support to secure all or most of their goals, governments may offer policy legitimization of the movement as a means of adapting to, coopting, or modifying a movement's challenge to the state of premovement affairs.

Such political legitimation has taken a variety of forms. The labor protest movements culminated in the passage of the National Labor Relations Act of 1935, which legitimized labor-management collective bargaining and negotiated agreements. The suffragette movement resulted in passage of the Nineteenth Amendment to the Constitution, guaranteeing that the right to vote in the United States could not be denied or abridged on account of sex. The civil rights movement attained support with passage of the comprehensive Civil Rights Act in 1964 and then the Economic Opportunity Act and the Elementary and Secondary Education Act, both in 1965. All these system-modifying acts,

which affect the lives of millions in American society, have continued in effect during relatively high and low periods of public support. This gives evidence of the long-term societal legitimation of these acts, which grew out of protest movements.

Success of these and other movements is often tempered by countermovements, participants in which perceive their relative positions and interests to be threatened. For instance, the women's movement experienced a series of challenges from religious groups, often fundamentalist, that adhered to a male-dominated patriarchy. As a consequence, women's progress was slowed in winning various forms of equal treatment and opportunity in educational, economic, political, and social areas of life, and in the 1970s and the 1980s Congress failed to pass the Equal Rights Amendment (ERA) to the U.S. Constitution, which was supported by the women's movement.

More generally, after passage of civil rights legislation in the mid-1960s, a series of protest movements within the Democratic and, more extensively, the Republican parties resulted in growing administrative, legislative, and judicial resistance to equality in educational, occupational, and housing opportunities. The countermovement result has been a reentrenchment of a long-established economic structure of racism and low-income class rigidity that functions independently of personalized racist feelings and beliefs (Wilson 1987). A reflection of such countermovement pressure is the growth in perception among white males that affirmative action educational and occupational policies directed toward racial and ethnic minorities and women constitute a form of reverse, or affirmative, discrimination (Glazer 1989).

Countermovements have generated their own counterprotest movements. This countermovement variation of Hegelian dialectic does not result in a return to whatever constituted premovement normalcy. In conventional political terms the results are more conservative, reactionary, liberal, or radical than what existed before the protest movement. When protests and counterprotests result in social change, such change generally affects the participants in a specific protest movement as well as established authorities in ways often not fully anticipated. While a predominant orientation may exist among protest activists and another among established authorities, in complex, mass modern

societies, a range of political orientations is usually contending among protestors and their supporters and among established authorities and their supporters, against whom the protest is directed.

The U.S. civil rights movement of the 1950s and 1960s can be viewed in historical terms, if not contemporary terms, as a primarily conservative movement. The predominant, although not all-encompassing, aim of activists and organizations was to enable blacks and other minorities to break into the democratically value-based, but not fully practiced, political and economic system. Most protest leaders and participants did not aim to break the established system. In contrast, the late 1980s and early 1990s liberal to radical protest movements in Poland, Hungary, Rumania, and other eastern European countries did have as their goal the breakdown of the system of exclusive authoritarian political and economic domination.

In the United States, protest ideologies are largely reminiscent of established, liberal, democratic political ideals. This is evidenced in the way many protest groups adopt language from the Declaration of Independence to advance their aims. For example, the Black Panthers, popularly perceived as a radical group, adopted a statement of purpose that held, "We hold these truths to be self-evident, that all black and white [sic] men are created equal and endowed by their creator with certain unalienable rights." Similarly, the National Organization for Women inserted into its declaration of purposes the wording that "men and women" are created equal.

Protest movements attain mixed and sometimes changed results. These results occur because of institutional inertia, in which certain things have been done certain ways over a long period of time, and because of countermovements within institutional centers such as schools; businesses; and local, state, and national government offices. In the United States, reactions to the civil rights movement have resulted in private and public attitudes and behavior that have combined to support inclusion of some minority members while disadvantaging more severely the lowest-income racial and ethnic minorities (Wilson 1987). The result is that the countermovement resistance to educational, economic, and political advances for minority status groups has adversely affected the poorest racial and ethnic minority members. At

the same time, census bureau reports document a growing number and proportion of blacks, women, and other minority group members moving into educational institutions, occupational settings, and political positions from which they were formerly excluded *de jure* or *de facto*.

Examples from history and other cultures demonstrate the mixed potential and results of protest movements. The German Nazi protest movement in the 1920s illustrated that a movement could be radical *and* reactionary, in that case toward further destabilization of the Weimar Republic's democratic government, which was perceived as being decreasingly effective and legitimate by growing sectors of the German public (Shirer 1960). After the Nazis succeeded in countering various democratic and communist protest movements, Germany saw a more comprehensive institutionalization of Nazi ideological and authoritarian control during the 1930s. An historic, more recent example is the 1989 Chinese student democratic movement in Tianenmen Square that resulted in a government-sponsored countermovement that physically shattered the student protest and created a system of political, economic, and educational controls that were more comprehensively rigid than those that existed before the protest movement. Yet, the underlying educational, economic, and political forces that generated the Chinese student activists continued to affect the dynamics of Chinese society, with the potential for further protest activation.

In these and other protest movements, there is a wide range of participants and of protest methods employed. Along with the nature of the social context and historical influences, the characteristics of protest participants and the methods they employ are consequential and have been central concerns of research on such movements.

PROTEST PARTICIPANTS AND METHODS OF PROTEST

If protest participants could alleviate their grievances or sense of injustice individually, there would be no likely motivation for them to become active in a protest movement. Protest participants thus have two central characteristics: (1) they have insufficient influence to gain a desired change in their circumstances, and (2) they seek active association with relatively like-minded persons to gain relief from their aggrieved state.

These two characteristics can be seen among protest participants over time and in different locales. In the 1960s civil rights movements in the United States, leading activists—including blacks, Hispanics, Native Americans, and women—expressed a strong sense of unequal treatment and opportunity while associating with and supporting activists to achieve equal opportunities in schools, jobs, elected offices, and other social settings. College students, the most active participants in the civil rights movement, could not generally be characterized in these minority status terms. Yet, they were not yet an established part of the economic and political order being challenged and were in a position to be critical of that order (Lipset 1971). Other participant supporters, such as labor unions, selected corporate leaders, and religiously motivated persons, often saw protest-related change needed in terms of their own long-term interests and worked either to help the civil rights movement succeed or to preempt or coopt it (Gamson 1990, pp. 28–31). The broad political support base for the comprehensive 1964 Civil Rights Act had all these protest movement participant elements.

The individuals who are most likely to initiate and support a protest movement tend to be those with long-developed grievances within a society. A case in point is Solidarity, the labor group that precipitated the successful 1980s protest movement against communist rule in Poland and that helped precipitate other successful eastern European protest movements. The initial work stoppage, instrumental in offering a political challenge to Polish and Soviet authority, occurred at the Lenin shipyard in Gdansk, a center of Cassubian ethnic residence. For generations Cassubians have held a minority status in Polish society (Lorentz 1935). As the protest movement proceeded to secure broad-based support among Polish citizens, it was no accident that Cassubians, who have experienced prejudice and discrimination beyond communist rule in Poland, would be at the forefront. It is not surprising that Solidarity was led by a Cassub, Lech Walesa. It is also noteworthy that the protest movement received strong support from another Cassub, Pope John Paul II, whose original name of Karol Wojtyła ends with a Cassubian “a” rather than the more typical Polish “ski.”

In the United States, the civil rights movement was manifestly initiated and led by blacks. Jews,

who have experienced more prejudice and discrimination than most other whites in American society, where they constitute less than 2 percent of the population, composed the largest group of whites in the movement. In the Congress of Racial Equality (CORE), one of the leading mass civil rights protest organizations, almost one-half of the white participants identified themselves as Jewish or as secularists whose parents were Jewish (Bell 1968).

The methods employed by protest participants and leaders tend to reflect a lack of institutionalized power. When such institutionalized power is available, it can be exercised to redress grievances without resorting to mass protests. Within democratic political processes in the United States and in other democratic societies much organized protest on such issues as trade policies, road construction and placement, and taxation can be viewed in more normative, adaptive terms.

When such normative activities do not result in a resolution of grievances, the potential for a protest movement increases. In such a context, legitimized guarantees of the right to protest, as embedded in the U.S. Constitution's First Amendment guarantee of the right to assemble and petition for redress of grievances, do not preclude protest strategies that go beyond legal or normative boundaries of protest behavior.

Methods of protest are related to prospects of success and levels of frustration. When a protest movement or a countermovement has broad public support and is likely to receive a positive response from targeted authorities, protest activities are likely to be peaceful and accepted by such authorities. Such is the case with pro-choice protest on the abortion issue; protest for clean air; and protest in support of Christian, Jewish, and other minority religious status groups in the Soviet Union. All these protest activities have relatively broad American support, even when they experience a minority activist opposition.

A variety of nonlegitimate strategies are used when protest movements address issues and involve participants with relatively little initial public support and active opposition. One such nonlegitimate strategy is Ghandi's nonviolent protest confrontation with British authorities in India. Adapted by Martin Luther King, Jr., and most other black civil rights protest leaders in the 1950s and early 1960s, the strategy of nonviolence was

designed to call general public attention in a nonthreatening manner to perceived injustices experienced by blacks. With such techniques as sit-ins at racially segregated lunch counters and boycotts of segregated public buses, this nonviolent method generated conflict by breaking down established social practices. The aim of such nonviolent methods is to advance conflict resolution by negotiating a change in practices that produced the protest. A particularly famous case is the 1955 Montgomery, Alabama, bus boycott, which was one of several major precipitants of the national black-led civil rights movement.

Other, violent forms of protest include both planned strategies and unplanned spontaneous crowd action. In either case such activity tends to be perceived by authorities and their supporters as disorderly and lawless mob behavior. Masses of protest participants are likely to be drawn to violent action when the general perception, or emerging norm (Turner and Killian 1986, pp. 21-25), develops that redress of felt grievances is believed to be unattainable either in normal conditions before protest activation or by peaceful means. The history of violent protest is extensive in many societies, as exemplified by the forcible occupation of farms and fields by landless French peasants in the eighteenth century, American attacks on British possessions and military posts prior to the Declaration of Independence, and bread riots by Russian urban dwellers in World War I. The particular centuries-long history of violent protest movements in American society was documented in context of the urban race riots and anti-Vietnam War protest in the 1960s by the presidentially appointed National Commission on the Causes and Prevention of Violence in the United States (Graham and Gurr 1969).

Violent protests usually concern specific issues such as taxes, conscription into the military, and food shortages, issues that are confined to particular situations and times. Although these types of protest do not evolve into major social movements, they may have severe and immediate consequences. In 1863, for instance, during the Civil War, Irish Catholics protested what they perceived as the unfair nature of the military draft in New York City. This protest left several hundred dead. Likewise, many college students in the late 1960s and the early 1970s revolted against the draft during the unpopular Vietnam War, and the

results included loss of student lives at Kent State University.

Unplanned violence may also be a form of protest. As reported by the National Advisory Commission on Civil Disorders and other research on over two dozen urban racial riots in the 1960s in the United States, these riots, which resulted in over a hundred deaths and over \$100 million in property damage, were disorganized extensions of the black civil rights movement. These violent events closely fit Davie's J-curve thesis (1974), which argues that rising expectations, such as those generated by legal successes in mid-1960s by the black civil rights movement, were frustrated by the declining urban ghetto environments and growing Vietnam War tensions, both of which were related to the fact that large numbers of blacks were being drafted while most white college students were exempted.

Overall, protest movements are more frequent in societies that legitimize the right of protest. In such societies, social conflict generated by protest movements is often functional in resolving conflict over issues between challenging and target groups (Coser 1956). Still, urban and campus riots of the 1960s illustrate that formal rights of protest do not deter democratic authorities and their public supporters from responding with police force or from beginning a countermovement. Authoritarian societies may experience fewer protest movements, but when they do occur, such movements are far more likely to be intense and to have the potential for massive social movements designed to transform the society. This could be seen in widely disparate societies, including most eastern European nations and the Soviet Union, El Salvador, Nicaragua, South Africa, Iran, and mainland China.

CONSEQUENCES OF PROTEST MOVEMENTS

Given the long and continuing history of protest movements, there has been growing interest in the long-term consequences of such movements. Some assessments concentrate on historical, comparative analysis such as Snyder and Tilly's analysis (1972) of French collective violence in response to government-sponsored repression between 1830 and 1968, or Bohstedt and Williams's analysis

(1988) of the diffusion of riotous protests in Devonshire, England, between 1766 and 1801. Other studies of long-term consequences make empirical assessments of the aftermath of more contemporary protest movements. Examples include Gordon's community-based assessment (1983) of black and white leadership accommodations in the decade following the Detroit race riots of 1967 and Morris's assessment (1980) of the decade-long impact on national public values of the environmental movement of the late 1960s.

The need for more short- and long-term assessment of the consequences of protest movements is evident in reviews of past movements. William Gamson's consideration of fifty-three protest movements in the United States between the 1830s and 1930s illustrates the need. Gamson categorized each movement's own specific goals in one of four ways: coopted, preempted, full response success, and collapsed failure (Gamson 1990, pp. 145-453). Gamson assessed each protest movement's success in achieving its goals during its own period of organized activity. For instance, Gamson assessed such groups as the German American Fund (1936-1943), the American Proportional Representation League (1893-1932), and the Dairyman's League (1907-1920).

Of the fifty-three identified protest movements, twenty-two, the largest single proportion, were categorized as being collapsed failures, twenty as achieving full response success, six as being preempted, and five as being coopted. Protest movements categorized as collapsed failures and full response successes demonstrate the need for assessment of protest movements long beyond their activist periods. Listed under collapsed failures were major long-term successful movements including the abolitionist North Carolina Manumission Society (1816-1834) and the American Anti-Slavery Society (1833-1840). In contrast, among full response success movements was the American Committee for the Outlawry of War (1921-1929), a major force in the achievement of the international Kellogg-Briand Pact of 1928, which outlawed war between nations, a short-lived success that for at least most of the rest of the twentieth century proved a grand failure.

Successful or unsuccessful in the short or the long term, protest movements are periodically a part of social change at local, national, and global

levels and in situational, institutional, and cross-cultural contexts. In the United States and other modern mass urban societies, the long-term trend has been for protest movements to become more professionalized with increased mobilization of resources to more effectively challenge entrenched interests (Tilly 1978). Modern communication systems, global economic interdependence, and economical movement of masses of people over great distances assures that protest movements of the future will increasingly be characterized by a combination of ideas, people, and organization across all these areas of social life.

In contemporary terms, the historical end of the global Cold War at the end of the twentieth century with the collapse of the Soviet Union generated a basis for increased localized protest movements. This was initially evident in the former Soviet Union's sphere of influence in eastern European societies and within Russia itself. On the eve of the twenty-first century, evidence of this broadening localized protest activism was to be seen in many societies as exemplified by student-led protests in Indonesia, Chiapas Indian revitalization protests in Mexico, the Quebec separatist movement in Canada, the Queens' Borough protest to separate from New York City in the United States, and many others. In this context, the supply of localized protest issues is likely to proliferate. At the same time, some issues—such as protests associated with such transnational issues involving the environment and health—may touch upon many localized issues that coalesce into becoming national and global protest activities. Given massive economic, political, and social change forces in modern society and the potential for protest movements to directly affect the lives of many people, the concern of research specialists and publics with such movements can be expected to continue and to increase.

PUBLIC OPINION

Public opinion is characterized, on the one hand, by its form as elementary collective behavior (Blumer 1972) and, on the other, by its functions as a means of social control (Ross 1901). It comes into play in situations that are problematical or normatively ambiguous in one or more of several senses: The situation is novel and unprecedented, so that established ways of coping no longer prove adequate, people actively disagree over which of several conventionally acceptable practices should apply, or the conventions themselves have come under serious challenge by a dissident group. In the extreme case, controversy over what should be done can heat up to a point where order gives way to violent group conflict.

Interest in public opinion is historically linked to the rise of popular government. Although rulers have always had to display some minimum sensitivity to the needs and demands of their subjects, they felt little need, unlike most contemporary governments that must face voters in mandated elections, to anticipate their constituents' reactions to events that were yet to occur or to policies still to be implemented. But public opinion operates equally outside the relationship between citizens and the state. Its influence is felt throughout civil society, where, on many matters, including personal taste in dress, music, and house furnishings, people remain sensitive to the changing opinions of peers and neighbors. They court approval by showing themselves in step with the times.

Opinions have behind them neither the sanctity of tradition nor the sanctions of law. They derive their force from agreement, which is more tenuous than either of these. People do change their minds. Moreover, to label something as "opinion" implies a certain willingness to acknowledge the

potential validity of contrary views. Issues are settled by discussion and bargaining. Those who pay at least some attention and are ready to take sides make up a public. It expands in size as an issue heats up, only to contract again as the focus shifts to new problems. There are, in fact, as many publics as there are issues.

Social control through public opinion functions in subtle ways. All but the most intransigent partisans will recognize when an issue is settled to a point where further debate becomes not only superfluous but possibly disruptive of an underlying consensus. There are times when the need to display unity, perhaps in coping with a crisis, or moral fervor, whipped up in crusades against internal enemies, may unduly narrow the range of public discourse. Dissidents come under pressure to conform, at least outwardly, but not as completely as in the regimes that suppress public opinion by seeking control over all conversational channels through which ideologically deviant tendencies could spread.

Studies of public opinion have to contend with a broad range of beliefs. Located at one extreme are beliefs anchored in longstanding allegiances; at the other, the often fluctuating "gut" responses to whatever is current. The more general ideas that underlie the legitimacy of the political system have the greatest stability. They build on childhood experiences within the family, where children tend to adopt the views of their parents. Then, as the children become adults, these early beliefs are elaborated and modified in sustained contact with other major institutions, like school and church, and also (especially during major catastrophes affecting their country or its leaders) by the news media (Renshaw 1977). The content of the political culture from which opinions are derived differs from milieu to milieu.

Endemic cleavages related to position in social structure and in historical time are highlighted during controversies. Hence, public opinion often divides in predictable ways—by region, race, religion, ethnicity, class background, educational attainment, and so forth. If the differences in experience are sharp enough and each side raises nondebatable demands, public discourse can escalate to a point where the polity splits apart into two irreconcilable camps. Instead of reaching agreement, the more powerful group imposes its will.

Acquiescence does not qualify as rule by public opinion.

In the center of early sociological study of public opinion has been the question of competence. Analysts have sought to distinguish conceptually between the reasoned opinions developed in discussion and the clamor of a feared “mob” acting under the sway of emotion. Two works, one in Germany and one in America, coincidentally published the same year, analyzed the problem in structural terms.

Tönnies (1922) pointed to the press and to associations that usurped for themselves the role of articulating public opinion. He would have been even more critical of the public relations industry that has flourished since. For Lippmann (1922) there was a still more fundamental obstacle. He rejected as a false ideal the notion that ordinary citizens—even the most well-educated—had the time and incentive to acquire the expertise to grasp the complex problems of the day in the detail necessary to direct the course of public policy. Drawing on a wide range of literature, he showed how the public perceived the world through the stereotypes fed them by the press. This meant, he argued, that whenever the public attempted to intervene in the course of events, it inevitably did so as the dupe or unconscious ally of elite interests. Its role was properly limited to identifying the problem areas in need of remedial action and to deciding which party, institution, or agency should be entrusted with the solution. But the public was a potentially effective “reserve force” most effectively mobilized in support of the procedural norms of democracy. Contemporary contractualists, like Buchanan and Congleton (1998), have come to share Lippmann’s emphasis on generalized procedures about which near unanimity is more easily achieved than about policies that inevitably produce winners and losers.

The list of social scientists pointing from different perspectives to the limits of “rule by public opinion” under modern conditions includes Mannheim (1940), Schumpeter (1942), Schattschneider (1960), Bogart (1972), and Ginsberg (1986). An all-too-obvious gap between the expectation of an informed citizenry put forward by democratic theory and the discomfiting reality revealed by systematic survey interviewing is identified by Neuman (1986) as the “paradox of mass

politics.” Where pluralists see a public made up of many competing interests, each with its own leadership, Neuman discriminates among three levels of competence: an uncomfortably tiny percentage of citizens with some input into policy; uninterested and inactive know-nothings, who make up roughly one-fifth of the potential electorate; and a large middle mass whose members, if they vote, do so largely out of a sense of duty but with only a very limited understanding of the issues their vote is meant to decide. This discrepancy from the ideal, apparent in many polls on specific issues, can hardly be attributed to flaws in the method by which public opinion is ascertained.

PUBLIC OPINION POLLING

There are nevertheless some real questions about the momentary numerical majorities obtained in an opinion poll as a valid measure of public opinion. For one thing, polls vary in quality. How closely any particular poll reflects the distribution of opinion within a larger population hinges on three general factors: (1) who is interviewed, (2) the situation in which the interview takes place, and (3) the questions asked. Insofar as elections also provide a public record of “opinion,” the utility of polls as a research tool can be tested against the actual vote count.

Two fiascos in polling history have been painstakingly diagnosed. Never again will we see anything like the wildly incorrect 1936 forecast by the *Literary Digest* that Franklin D. Roosevelt, who won reelection by a landslide, would be voted out of office. It was based on 2.3 million returns from over 10 million straw ballots mailed to names on automobile registration lists and in telephone books. Poll takers learned the hard way that, especially when respondents are self-selected, sheer numbers do not guarantee accuracy. For one thing, the well-to-do, who owned cars and lived in homes with telephones, were somewhat less supportive of Roosevelt and his New Deal than those too poor to have either or both such conveniences. A second, actually more important, source of bias was self-selection; Republicans were more strongly motivated than Democrats to mail in their straw ballot as a protest against the party in power.

When in 1948 the pollsters, despite more rigorous sampling and face-to-face interviews,

wrongly predicted the defeat of incumbent President Harry Truman, this became the occasion for one of the most extensive inquiries into polling practices by a committee of the Social Science Research Council (Mosteller et al. 1949). Its report stressed the importance of random selection, in which every voter stands the same chance of being contacted, an objective often difficult to implement. Polling techniques have come a long way since and errors of such magnitude have not reoccurred. But, as shown by an investigation by Crespi (1988) of the factors associated with accurate prediction in 430 preelection polls during the 1980s, the extra effort invested in callbacks still pays off in greater accuracy. Persons missed because they are hard to reach or because they refuse to answer often differ from the rest in ways difficult to estimate.

As to the interview situation, answering the questions of a poll taker is hardly the same as casting a vote, all the more so when the election is months away. The large margins by which Truman had been trailing in the early fall of 1948 caused several pollsters to cease polling weeks before voting day. Thus, they never registered the strong Democratic rally taking place toward the end of the campaign. Another problem is determining how firm respondents are in their convictions and who will actually vote on election day. Despite refined techniques to ferret out likely nonvoters, predicting the outcome of a low-turnout election with little-known candidates and in referendums on questions beyond the understanding of many voters can be hazardous.

Public opinion research covers much more than elections, where the "issue" boils down to a clear split between parties, candidates, or those for or against a measure on the ballot. Issues come and go, and people do not necessarily have preconstructed views on everything about which polls may ask but tend to construct their answers in an ad hoc manner from information that, at the moment, strikes them as salient (Zaller 1992). Just as pollster have learned to omit from their tabulations of preelection surveys the likely nonvoters, so various "filters" are used to screen out persons who are generally unconcerned about politics, have given the particular subject little thought, and may not have even been aware of it except for the questions put to them. To avoid eliciting

"nonattitudes," as responses from such persons are called, they should be asked no further questions about the matter. This still leaves those reluctant to admit their unfamiliarity or lack of concern. One survey that deliberately inserted a question about a nonexistent bill allegedly under consideration by Congress had significant minorities respond that they had heard of it, with some even willing to fabricate an opinion about it.

Insofar as responses depend on how a question is phrased, different polls can provide dramatically different readings of where the public stands. Various polls on impeachment during Watergate, all about the same time, recorded levels of support ranging from a high of 53 percent on a question with the condition "if it were "decided that President Nixon was involved in the coverup" attached to a low of 10 percent on a question that offered resignation as an alternative to impeachment. Similarly, after Gallup modified its original question, which had coupled "impeachment *and* removal from office," by first explaining impeachment and then asking, "Given the various charges brought against the president, do you think impeachment charges should be brought against him or not?" support for impeachment jumped from 37 to 53 percent.

Views on many subjects are too nuanced to be caught in response to a single question. Few people are absolutists on most issues. On abortion, a highly contentious issue, it is not just being "pro choice" or "pro life" in all situations. One can deny that abortion is a constitutional right and still allow it under certain circumstances—when conception has resulted from rape or when abortion is necessary to save the life of the mother. Some legal restrictions are likewise acceptable for supporters of *Roe v. Wade*. Similar distinctions are called for in polling on "affirmative action," a term that stands for a welter of different policies. Explicit preferences, even as a redress for past discrimination, are endorsed by no more than a minority, but outreach programs to locate qualified minorities and/or women enjoy wide support. To correctly assess what is on people's mind requires a series of probing questions.

Nor do apparent majorities always speak as clearly as the student of public opinion would like. In a 1971 poll, a time when concern over American

involvement in Vietnam was higher than any other issue on the public agenda, two out of three respondents answered the question, "Do you favor or oppose the withdrawal of all American troops from Vietnam by the end of the year?" by declaring themselves in favor of withdrawal. But on another question in the same survey, about withdrawing all troops "regardless of how the war was going," these same respondents split with a plurality of 44 percent against and only 41 percent still for withdrawal. Does this 25-point difference between the 66 percent in favor of withdrawing on the first question and the 41 percent on the second identify a group ready to take back an off-the-cuff answer when reminded of the possible consequences of such a move? Or were those giving a "consistent" response confident that South Vietnam would not fall? There is still a third possibility: A lot of people no longer cared whether or not America was forced to withdraw in defeat. An undetermined number among them may, in fact, have welcomed such an outcome.

Sometimes the public does indeed hold views that seem contradictory, but the logic people follow may differ from that of the analyst, as it did during Vietnam, when polls were recording, at one and the same time, majorities in support of both immediate withdrawal and a stepped-up air war on the North. Others who considered American intervention in Vietnam a mistake still spoke out in favor of President Lyndon Johnson's Vietnam policy. Nor, for that matter, were self-styled "doves" necessarily in sympathy with student protests against the war.

For all their potential pitfalls, polls are one of the best ways for political leaders to maintain contact with their increasingly large and diverse constituencies—a more reliable reading for sure than such alternative indicators of public opinion as letters, telegrams, phone calls, and petitions to political leaders, which may reflect nothing more than the effort of a well-organized interest group. Yet even minorities, if implacable enough, should not always be ignored. A rise in the number who refuse draft calls or desert from the armed forces; a rise in certain crimes; and an increase in demonstrations, strikes, and other forms of protest are important clues, not necessarily to general opinion but at least to the unwillingness of the groups most affected by some problem to settle for the

status quo (Tilly 1978). They signal problems or injustice that call for recognition by the rest of society.

DYNAMICS OF PUBLIC OPINION

Changes in the basic attitudes that underlie public opinion usually occur slowly, partly through replacement and partly through the diffusion of new experience. Differential birth rates, migration, social mobility, and the succession of generations are processes that disturb the existing balance without any change on the individual level and despite evidence of significant political continuity between parents and offspring. Distinct intergenerational differences are believed to develop in response to certain critical experiences, like the encounter, in early adulthood before one's outlook has fully crystallized, with general poverty and war, or participation in social struggles (Sigel 1989).

Attitudes on race are a good example of how diffusion and replacement operate in conjunction with each other. Surveys taken over time show a distinct movement toward greater racial tolerance (Schuman and Bobo 1985). All groups moved in the same direction, even if at different speeds. The younger generation showed the way, often with tacit support from sympathetic parents not yet ready themselves to join a radical challenge to segregation. Rising levels of education and the increase in certain kinds of intergroup contact also contributed to the shift, as did mortality among the older, more conservative cohorts. Especially noteworthy is that, in regions where segregationist practices were most firmly entrenched, opinion changed more rapidly than in the rest of the country, once the full force of national public opinion had been brought to bear on them through television. The pervasive coverage the national media gave the campaign for civil rights conveyed to even the most intransigent southerners how the rest of the country viewed their continuing resistance. While issues relating to race continue to divide the polity, the terms in which they are debated were never to be the same again.

The day-to-day shifts in public opinion on matters great and small are even more subject to influence by the media of mass communication. Most of the public is not issue-oriented but reacts

to the general image of presidential performance. "Good" news of any kind tends to bolster that image, with one major exception: a national crisis. Such events typically generate a rally to the flag; critical voices are stilled, at least temporarily, in a show of patriotic unity. Effective political leadership under any condition requires access to the news media.

In their comprehensive review of American policy preferences over a half-century, Page and Shapiro (1992) show that, on thirty-two foreign and forty-eight domestic issues for which there were adequate data, the media coverage explained a large part of the movement of opinion in polls. However, they go on to note that opinions on none of these issues changed very much. The main influence of heightened media coverage, as repeatedly documented by communication research, is to move an issue or a problem into the public sphere, followed by an increase of concern and discussion, which then puts pressure on government to do something. When the press plays up crime, this helps create the impression of a crime wave, just as vivid details about a disaster drive home its magnitude. Serious discussion about the nature, causes, and consequence in the media of what came to be called "child abuse" facilitated its recognition as a social problem calling for intervention (Nelson 1984).

Once there is concern, the issue itself undergoes change. The actions of the principal actors involved in Watergate, as reported by the media, moved the debate away from Nixon's involvement in the illegal break-in into Democratic headquarters to his obstruction of justice, abuse of power, and contempt of Congress—the three counts on which the House Judiciary Committee voted for impeachment (Lang and Lang 1983). A similar kind of shift occurred in the "sex" scandal surrounding Bill Clinton. What began as the exposé of an improper affair with a White House intern was progressively redefined into whether the president had perjured himself and whether this felony, if committed by a president in connection with a civil suit later found without merit, rose to the level of an impeachable offense.

Media power is nevertheless limited. First of all, opinions, once they have crystalized, respond more to actual changes in circumstances than to

media messages. Second, the potential influence of the media varies according what they report about. It is obviously greater when they expose widespread corruption in high places, report on a mishap in foreign relations, or highlight something that hardly anyone would ever know about unless alerted by the news media. Far less dependent on media recognition are inflation, shortages, a severe economic downturn, and other events. Neither they nor specific grievances anchored in shared group experience will go away for mere lack of mention. Third, media managers are less than fully independent. They have to accommodate other actors intent on publicizing only those issues (or aspects of issues) that work in their favor. While competition among the various practitioners of the highly developed art of news management introduce some balance, public discussion, and (indirectly) public opinion do respond to media strategies not so much aimed at persuasion as bent upon seizing the right issues.

PUBLIC OPINION AND POLICY

As to the effects of opinion change, leaders of major institutions, whether elected or not, have proved distinctly sensitive to trends in public opinion. The measure most consistently repeated over the most years is the presidential approval ratings. Most presidents have experienced a gradual slide during their terms in office, which Mueller (1973) attributes to a coalition of all the minorities that, over the years, will have been antagonized by the many decisions a president as the chief executive is forced to make. At least two American presidents have been driven from office by clear evidence of a loss of public support. Lyndon Johnson, with the failure of his Vietnam policy glaringly evident to all, took himself out of the race for reelection, even though as an incumbent president he would have been assured renomination as the standard bearer of his party (Schandler 1977). Public outrage during Watergate forced Richard Nixon to make several concessions and, ultimately, to resign after the Supreme Court forced the release of tapes with the incriminating evidence that made his impeachment and subsequent removal from office a near certainty (Lang and Lang 1983). Twenty-five years later, a president's high approval, despite his publicly acknowledged wrongdoing, caused Republicans in both houses of Congress, who wanted to

hold him responsible, to frame the issue in the most narrow legal terms lest their moves backfire.

Congress, knowing that public opinion responds to events, sometimes even to the turn of a debate, often moves cautiously on potentially divisive issues. When Franklin Roosevelt tried to pack the Supreme Court and Nixon resisted the full exposure of Watergate, legislators were inclined to wait, watching to see which way the public tilted. And when it came to civil rights, major legislation was passed only after mass demonstration and media attention to discriminatory practices had created public concern and support for the principle had reached or exceeded the two-thirds mark. Laws subsequent to the initial pathbreaking legislation could then be enacted without direct pressure from below. But none of these things could have been achieved without effective political leadership responsive to the just demands of an obvious minority, which Johnson, still enjoying the honeymoon bequeathed an incoming president, was able to provide.

The accumulating evidence points to a basic congruence between public opinion on basic issues and legislative action (cf. Monroe 1998; Page and Shapiro 1983). Even the decisions of a judiciary with lifelong tenure are not entirely insulated from the political cross-currents that affect representative institutions. The U.S. Supreme Court, the most august of judicial bodies, as Marshall (1989) concludes, has been an essentially majoritarian institution. Of 142 decisions from the mid-1930s to the mid-1980s for which there existed corresponding opinion data, over four-fifths have been consistent with preferences expressed in polls. The linkage, strongest in times of crisis, reflects more the court's sensitivity to legislative and executive concerns that incorporate public opinion than direct to public pressure on the judges.

It is on the constitutional rights of dissident minorities that the Supreme Court has most consistently set itself against majority opinion. Other countermajority opinions have either articulated a rising trend, strengthened by the voice of the court, or been modified by later decisions that, in an apparent response to public opinion, carved out exceptions and introduced qualifications to the broad rule laid down in the original case. Public opinion continues to play a role in how

these court decisions are implemented. Following a decade of increasingly liberal attitudes toward abortion, the issue seemed settled once and for all by *Roe v. Wade*. Though the massive campaign proliferators have mounted since has had little impact nationally, states vary in their laws and practices. The states in which opposition to abortion has been strong have generally adopted more restrictive policies, resulting in lower abortion rates, than states in which the weight of public opinion was to make it a matter of choice (Wetstein 1996).

THE ERA OF POLLS

Elites have always been under some constraints, even in dealing with the more obscure issues typically resolved through specialized networks. Sheer prudence nevertheless commands that appearances be managed. This is done today, more than ever before, on the basis of increasingly accurate information from polls. Experts on polling have become members of the advisory staff not only of candidates for major offices but also of national party organizations. They also work in the White House and are consulted by presidents about proprietary polls which, unlike those sponsored by the media, especially during election season, the public rarely sees. There is little persuasive evidence so far about how the current high volume of polling activity has affected the political process.

One perhaps not very obvious consequence is the dissemination of a view on public opinion as statistics on a set of questions instead of a process to determine of what people will ultimately settle for. The public, too, is somewhat suspicious of polls. A large proportion of those queried on the subject believe that polls have effects and, particularly, that the majorities they record generate bandwagons even though these same people vehemently deny that the polls would have any effect on themselves. Nor has the variety of split-ballot polls and experiments, in which only one of two matched samples is informed about of the majority viewpoint, turned up differences large enough to support what many apparently fear. Noelle-Neumann (1984), in a more elaborate formulation, has shifted the emphasis away from direct bandwagons (i.e., people rushing to join the majority) to more complex sequences of events. She reasons that

people who perceive themselves as being in the minority, even if falsely, are reluctant to speak out against the dominant opinion, thereby creating a spiral of silence through which the apparent majority gains extra strength. Such spirals have no doubt occurred, for example during the repressive era remembered as McCarthyism. But to generalize from this and other instances is to overlook situations in which committed minorities have raised their voices to compensate for what they lack in number. Polls do function as a corrective by reporting on opinions that, although underrepresented in the forums which most public discourse takes place, are too important to ignore.

Polls have other significant consequences insofar as those who rely on them react strategically. They certainly influence the choice of candidates, the platform and program on which a candidate or party stands for election, and the policies an administration pursues. Candidates who can demonstrate electability attract the financial support, endorsements, and media coverage necessary for an effective campaign. Citizens, too, vote strategically whenever they abandon a likely loser in favor of a minimally acceptable second choice. This is what gives a front-runner in the polls the momentum to increase his or her distance from the pack of competitors early in the primary season (Bartels 1988). A strong showing can also have a potential downside: A victory by less than the anticipated margin, even in a small state with low turnout and therefore difficult to predict, has sometimes been read as a defeat. Hence, candidates often work to lower expectations regardless of what their own polls may show.

Polls on the concerns and issue preferences of the electorate allow campaign managers to maximize their candidates' appeal. Political actors who act rationally, rather than ideologically, will moderate the more doctrinaire positions cherished by their loyal followers, who have no other place to go. According to the spatial model of politics first outlined by Downs (1957), parties and candidates are impelled to move toward the political center to reach out to the still uncommitted. More and more do the modern catch-all parties, competing for an ever-larger share of the electorate, rely on general promises and finely honed advertisements. They differentiate themselves more by the image the party seeks to project than by any clearly defined policies. Practices of this sort are bound to

feed voter cynicism about the political system. One would also expect adverse effect on traditional party loyalties.

Republican leaders who heralded their success in 1994, an off-year election in which they took over both houses of Congress, as an endorsement of the party's Contract with America, quickly learned about the danger of being taken in by their own campaign slogans. At least their managers must have known that, as late as two weeks before the election, 65 percent of the public polled by the Gallup Organization had not yet even heard of the contract and that, according to another poll just days before the election, only 7 percent of those interviewed said they would be more likely to vote for the Republican candidate for Congress if he or she supported the contract. Acting as if they had a clear mandate, the Republicans in Congress made this their legislative agenda and, when embroiled in a budget dispute with the Democratic president, forced three closedowns of government. President Clinton's approval ratings rose sharply, and Republicans, who had misread the election results, lost credibility. By the same token, Democratic gains in 1998 plus polls showing clear majorities opposed to impeachment apparently misled the Clinton White House to underestimate the determination of House Republicans to bring down the president. Electoral results are not carbon copies of the public mood.

There is no question that elites are now in a better position than ever before to anticipate the public reaction to whatever they may do. Accurate information is all the more vital when the loosening of ideological bonds has forced an elected leader to engage in a continuous campaign for popularity. Such a leader has good reason to adopt the majority point of view on issues about which the public feels strongly and to save his political capital for other less salient issues, on which views have not yet crystalized. This is where Geer (1996) locates the opportunities for effective leadership. Informed by polls, a president now is in a better position to identify these issues than were presidents in previous eras, several of whom exercised what Geer calls "leadership by mistake." But although a democratic leader must accede to at least some of the wishes of his followers, failure to lead when possible would amount to more than a missed opportunity; it would be a serious mistake, because it cedes the territory to the opposition,

which presumably has access to the same information and no hesitation to exploit it.

Still, what counts in the long run are the results. A leadership too sensitive to what a majority prefers at a given moment may sidestep a problem that cries for remedies the public is not yet prepared to approve. The absence of serious policy debates becomes an open invitation to topple a leader with personal attacks on his character and by grasping at every sign of a possible scandal. Other complications stem from the fact that governing majorities are coalitions of sometimes rather diverse interests, many of them organized and in possession of expertise beyond the comprehension of most citizens. Things of overriding importance to one interest may be anathema to all the others. The voice of the people comes across most clearly when the multitude is truly stirred by an all too apparent failure of policy or misbehavior in high places. It is on these occasions that the power of the public as a "reserve force," wisely or otherwise, is felt most directly.

PUBLIC POLICY ANALYSIS

Public policy analysis is a large, sprawling intellectual enterprise involving numerous academic disciplines, private research organizations, and governmental agencies each sharing a common concern with the formulation, implementation, or consequences of public policy decisions. There are approximately thirty journals published in the English language alone and nearly twenty professional associations that are devoted more or less exclusively to policy analysis. Departments, centers, and institutes dealing in whole or in part with policy analysis can be found at over forty American universities.

As currently practiced, policy analysis involves contributions from the entire gamut of scientific disciplines. Much present-day public policy analysis is undertaken by scholars from the various applied physical and biological sciences (for example, environmental impact studies, technology assessments, seismic risk analyses, and the like). The focus here, however, is on public policy analysis as it is conducted within the social and behavioral sciences, principally economics, political science, and sociology.

The diversity of research work conducted under the rubric of "public policy analysis," even when restricted to the social science component, is perhaps the distinguishing characteristic of the subject; in the space available here we can do little more than indicate the range of topics and approaches with which policy analysts are concerned. Rogers (1989) has developed a typology of public policy research that is useful for this purpose; the following is adapted from his discussion.

PROBLEM DEFINITION OR NEEDS ASSESSMENT

Public policy usually addresses real or sensed problems, and a great deal of public policy analysis is therefore devoted to defining or clarifying problems and assessing needs. What are the health care needs of a particular neighborhood? What are the

housing or nutritional needs of the nation's poverty population? What social services do homeless persons require? It is obvious that the development and formulation of public policy will be enhanced when underlying needs have been adequately described and analyzed. There is a large literature on the theory and practice of problem definition and needs assessment; students seeking additional information will find Johnson and colleagues (1987) invaluable.

VALUE EXPLORATION OR CLARIFICATION

Given a demonstrated need, any number of policies might be developed to address it. Which policies, goals, or outcomes are most desirable? If an area is found to have unmet health needs, is it better to open freestanding clinics or to provide subsidized health insurance? Are the housing needs of the poor best addressed through public housing projects or through housing vouchers that can be used in lieu of rent? Should our policies with respect to the homeless attempt to ameliorate the conditions of a homeless existence, or prevent people from becoming homeless in the first place?

Assessing the relative desirability of policy options is only rarely an empirical matter; such decisions are more often ethical or ideological. MacRae (1985) stresses the unavoidable role of values in the process of policy analysis and the ensuing conflicts for the policy analyst. He identifies four principal "end values" widely shared throughout American society and against which policy decisions can be compared: economic benefit, subjective well-being, equity, and social integration. Sadly, policies that maximize equity may not maximize net economic benefit; those that enhance social integration may destroy subjective well-being. Thus, public policy analysis is not an arena for those who wish to pursue "value-neutral" science nor is it one for the morally or ideologically faint of heart.

CONCEPTUAL DEVELOPMENT

Much work in the area of public policy analysis consists of developing conceptual schemes or typologies that help sort out various kinds of policies or analyses of policies (such as the typology we are presently using). Nagel (1984) and Dubnick

and Bardes (1983) review numerous conceptual schemes for typifying policies and policy analyses, with useful suggestions for synthesis; the former is an especially good overview of the field as a whole.

POLICY DESCRIPTION

Adequate description of public policy is essential for proper evaluation and understanding, but many public policies prove frustratingly complex, especially as delivered in the field. "Poverty policy" in the United States consists of a vast congeries of federal, state, and local programs each focused on different aspects of the poverty problem (income, employment, housing, nutrition) or on different segments of the poverty population (women, children, women with children, the disabled, the elderly). The same can obviously be said of housing policy, tax policy, environmental policy, health policy, and on through a very long list. Even a single element of poverty policy such as Temporary Assistance to Needy Families (TANF) has different eligibility requirements, administrative procedures, and payment levels in each of the fifty states. Thus, accurate policy description is by no means a straightforward task. Outstanding examples of policy description, both focused on poverty policy, are Haveman (1977) and Levitan (1985).

POLICY FORMULATION

Social science has a role to play in the formulation of policy as well as its description or evaluation. Most of the issues that policy attempts to address have been the focus of a great deal of basic social science research: poverty, ill health, homelessness, crime, violence, and so on. Although the once-obligatory discussion of "policy implications" of basic research has abated in recent years, few social scientists who work on policy-relevant issues can resist the urge to comment on the possible implications of the results for policy formulation. Much more work of this sort needs to be done, as it is evident that many policies are formulated and enacted in utter disregard for the extant state of knowledge about the topic. Indeed, Peter Rossi has hypothesized that the major reason social programs fail is that they are typically designed by amateurs who are largely innocent of social science theory, concepts, and results. Various job programs, mental health interventions, and crime reduction policies represent obvious cases in point.

METHODOLOGICAL RESEARCH

Unlike much basic disciplinary research in the social and behavioral sciences, whose results are largely inconsequential except to a handful of specialists, the results of policy studies will often influence peoples' lives and well-being and the cost of being wrong can run into millions or billions of dollars. Thus issues of internal and external validity, errors of measurement and specification, proper statistical modeling, and the like are more than methodological niceties to the policy analyst; they are worrisome, ever-present and potentially consequential threats to the accuracy of one's conclusions and to the policy decisions that ensue. A technical error in a journal article can be corrected in a simple retraction; an equivalent error in a policy analysis might result in wrong-headed or counterproductive policies being pursued.

Much of the literature on public policy analysis, and especially on impact evaluation (see below), is therefore mainly methodological in character; indeed, many recent innovations in research procedure have been developed by scholars working on applied, as opposed to basic, problems. There are many texts available on the methodology of public policy analysis. Rossi and colleagues (1998) provide a comprehensive overview; Judd and Kenny (1981) are highly recommended for the more advanced student.

POLICY EXPLANATION

Much public policy analysis undertaken by political scientists focuses on the processes by which policy is made at federal, state, and local levels. Classic examples are Marmor's analysis of the passage of Medicare (1970) and Moynihan's study of the ill-fated Family Assistance Plan proposed early in the Nixon administration but never enacted (1973).

Explanations of how public policy is made are invariably replete with the "dirty linen" of the political process: competing and often warring constituencies, equally legitimate but contradictory objectives and values, vote trading, compromises and deals, political posturing by key actors, intrusions by lobbying, advocacy and special interest groups, manipulation of public sentiment and understanding—in short, the "booming, buzzing

confusion” of a fractious, pluralistic political system. For those whose understanding of such matters does not extend much beyond the obligatory high school civics lesson in “how a bill becomes a law,” the policy explanation literature is a revelation.

POLITICAL INTELLIGENCE OR PUBLIC OPINION

In a democratic society, public opinion is supposed to “count” in the policy formation process. Sometimes it does; often it does not. Policy analysis thus sometimes involves plumbing the depths and sources of support or opposition to various policy initiatives, and in a larger sense, explicating the process by which policy becomes legitimated.

There is no easy answer to the question whether (or under what conditions) public opinion dictates the direction of public policy. It is evident that policy makers are sensitive to public opinion; many presidents, for example, are morbidly fascinated by their standing in the polls (e.g., Sussman 1988). It is equally evident, however, that many policies with strong majority support are never enacted into law. An interesting study of the effects of public opinion on policy formation is Verba and Nie (1975).

EVALUATION RESEARCH

The ultimate analytic question to be asked about any public policy is whether it produced (or will produce) its intended effects (or any effects, whether intended or not). The search for bottom-line effects—impact assessment—is one of two major activities subsumed under the rubric of evaluation research. The other is so-called process evaluation, discussed below under “Implementation Analysis.”

There are many formidable barriers to be overcome in deciding whether a policy or program has produced its intended (or any) effects. First, the notion of “intended effects” presupposes clearly defined and articulated program goals, but many policies are enacted without a clear statement of the goals to be achieved. Thus, many texts in evaluation research recommend an assessment of the “evaluability” of the program prior to initiating the evaluation itself. A second barrier is the often-pronounced difference between the program-as-designed and the program-as-delivered. This

is the issue of program implementation, discussed below.

The most troublesome methodological issue in evaluation research lies in establishing the *ceteris paribus* (or “all else equal”) condition, or in other words, in estimating what might have happened in the absence of the program to be evaluated. In an era of declining birthrates, any fertility reduction program will appear to be successful; in an era of declining crime rates, any crime reduction program will appear to be successful. How, then, can one differentiate between program effects and things that would have happened anyway owing to exogenous conditions? (Students of logic will see the problem here as the *post hoc, ergo propter hoc* fallacy.)

Because of this *ceteris paribus* problem, many evaluations are designed as experiments or quasi-experiments. In the former case, subjects are randomly assigned to various treatment and control conditions, and outcomes are monitored. Randomization in essence “initializes” all the starting conditions to the same values (except for the vagaries of chance). In the recent history of evaluation research, the various negative income tax experiments (see Rossi and Lyall 1976) are the best-known examples of large-scale field experiments of this general sort. *Quasi-experiments* are any of a number of research designs that do not involve randomization but use other methods to establish the *ceteris paribus* condition; the definitive statement on quasi-experiments is Cook and Campbell (1979).

Nowhere is the trade-off between internal and external validity more vexing than in the design of program evaluations. Evaluation designs with high internal validity, such as randomized experiments, are excellent in detecting program effects but the experimental conditions may not generalize to real-world settings. Thus, one telling critique of the Negative Income Tax (NIT) experiments is that participants knew from the beginning that the program would end in three (or in some cases five) years, so the labor-force response may have been very different than it would have been if negative income taxation became a permanent element of national income policy. Likewise, as the research setting comes to more closely mimic real-world conditions (that is, as it develops high external

validity), the ability to detect real effects often declines.

A final problem in doing evaluation research is that most policies or programs are relatively small interventions intended to address rather large, complex social issues. The poverty rate, to illustrate, is a complex function of the rate of employment, trends in the world economy, prevailing wage rates, the provisions of the social welfare system, and a host of additional macrostructural factors. Any given antipoverty program, in contrast, will be a relatively small-scale intervention focused on one or a few components of the larger problem, often restricted to one or a few segments of the population. Often, the overall effects of the various large-scale, macrostructural factors will completely swamp the program effects—not because the program effects were not present or meritorious but because they are very small relative to exogenous effects.

The literature on the theory and practice of evaluation research is expansive; students seeking additional information will find themselves well served by Chambers and colleagues (1992), and by Rossi and colleagues (1998).

OUTCOME ANALYSIS

Assuming that a program has been adequately evaluated and an effect documented, one can then analyze that effect (or outcome) to determine whether it was worth the money and effort necessary to produce it. Outcome analysis thus examines the cost effectiveness or cost beneficiality of a given policy, program, or intervention.

Cost-benefit and cost-effectiveness analysis are intrinsically complex, technically demanding subjects. One complication lies in assessing the so-called opportunity costs. A dollar spent in one way is a dollar no longer available to use in some other way. Investing the dollar in any particular intervention thus means that one has lost the “opportunity” to invest that dollar in something that may have been far more beneficial.

A second complication is in the “accounting perspective” one chooses to assess benefits and costs. Consider the Food Stamp program. A recipient receives a benefit (a coupon that can be redeemed for food) at no cost; from the accounting

perspective of that recipient, the benefit-cost ratio is thus infinite. The Food Stamp program is administered by the United States Department of Agriculture (USDA). From the USDA perspective, the benefit of the program presumably lies in the contribution it makes to relieving hunger and malnutrition in the population; the cost lies in whatever it takes to administer the program, redeem the coupons once submitted by food outlets, etc. Accounted against the USDA perspective, the benefit-cost ratio will be very different, and it will be different again when accounted against the perspective of society as a whole. The latter accounting, of course, requires asking what it is worth to us as a nation to provide food to those who might otherwise have to go without, clearly a moral question more than an empirical or analytic one.

This last example illustrates another thorny problem in doing cost-benefit analyses, namely, the incommensurability of benefits and costs. The dollar costs of most programs or policies can be reasonably well estimated. (The dollar costs are usually not the only costs. There may also be ethical or political costs that cannot be translated into dollars and cents but that are, nonetheless, real. Let us ignore the nondollar costs, however.) Unfortunately, the benefits of most interventions cannot be readily expressed in dollars; they are expressed, rather, in less tangible (but equally real) terms: lives saved, improvements in the quality of life, reductions of hunger, and the like. If the outcome cannot be converted to a dollar value, then a strict comparison to the dollar costs cannot be made and a true benefit-cost ratio cannot be calculated.

Cost effectiveness analysis, in contrast, compares the benefits of one program (expressed in any unit) at one cost to the benefits of another program (expressed in the same unit) at a different cost. Thus, a program that spends \$10,000 to save one life is more cost effective than another program that spends \$20,000 to save one life. Whether either program is cost beneficial, however, cannot be determined unless one is willing to assign a dollar value to a human life.

Many texts by economists deal at length with these and related complexities; accessible overviews include Levin (1975) and Yates (1996).

IMPLEMENTATION ANALYSIS

“Much is the slippage between the spoon and the mouth.” A program as it is delivered in the field is rarely identical to the program as designed in the policy making process; sometimes, there is only a superficial resemblance. Since slippage between design and implementation might provide one explanation for the failure to achieve significant program effects, implementation analysis is an essential component of all capable policy evaluations.

There are many reasons why programs-as-delivered differ from programs-as-designed: technical impossibility, bureaucratic inertia, unanticipated conditions, exogenous influences. An elegantly designed policy experiment can fail at the point of randomization if program personnel let their own sentiments about “worthy” and “unworthy” clients override the randomizing process. Many educational policy initiatives are subverted because teachers persist in their same old ways despite the program admonition to do things differently. Welfare reform will mean little if caseworkers continue to apply the same standards and procedures as in the past. More generally, the real world finds ways to impinge in unexpected and often unwanted ways on any policy initiative; failure to anticipate these impingements has caused many a policy experiment to fail.

Loftin and McDowell (1981) provide a classic example of the utility of implementation analysis in their evaluation of the effects of the Detroit mandatory sentencing law. The policy-as-designed required a mandatory two-year “add on” to the prison sentence of any person convicted of a felony involving a firearm. Contrary to expectation, the rate of firearms crime did not decline after the law was enacted. Implementation analysis provided the reason. Judges, well aware of the overcrowded conditions in the state’s prisons, were loath to increase average prison sentences. Yet, state law required that two years be added to the charge. To resolve the dilemma, judges in firearms cases would begin by reducing the main sentence by two or so years and then adding the mandated two-year add-on, so that the overall sentence remained about the same even as the judges remained in technical compliance with policy. A more thorough discussion of the implementation problem can be found in Chambers and colleagues (1992, chap. 1).

UTILIZATION

A consistent frustration expressed throughout the literature is that policy analysis seems only rarely to have any impact on actual policy. Utilization is an ongoing problem in the field of evaluation research. A more detailed treatment of the utilization problem can be found in Chambers and colleagues (1992, chapter 1), Shadish and colleagues (1991, chapters 6, 7), and Weiss (1988). For examples of ways in which evaluation can impact practice, see articles by Gueron, Lipsey, and Wholey in *New Directions for Evaluation* (1997).

Many reasons for nonutilization have been identified. One of the most important is timeliness. Good research takes time, whereas policy decisions are often made quickly, well before the results of the analysis are in. The negative income tax experiments mentioned earlier were stimulated in substantial part by a Nixon administration proposal for a modified negative income tax to replace the then-current welfare system. The shortest of the experiments ran for three years; several ran for five years; none were completed by the time the Nixon proposal was killed mainly on political grounds.

A second factor in the nonutilization of policy studies is that research is seldom unequivocal. Even the best-designed and best-executed policy researches will be accompanied by numerous caveats, conditions, and qualifications that strictly limit the safe policy inferences one may draw from them. Policy makers, of course, prefer simple declarative conclusions; policy research rarely allows one to make such statements.

Finally, even under the most favorable conditions, the scientific results of policy analyses are but one among many inputs into the policy-making process. There are, in addition, normative, economic, political, ethical, pragmatic, and ideological inputs that must be accommodated. In the process of accommodation, the influence of scientific research is often obscured to the point where it can no longer be recognized. It should not be inferred from this that policy analysis is not utilized, only that the research results are but one voice in the cacophony of the policy-making process.

Weiss has written extensively on the utilization problem and ways in which evaluation can be

used effectively to change policy. She argues that “in its ideal form, evaluation is conducted for a client who has decisions to make and who looks to the evaluation for answers on which to base his decisions” (1972, p. 6). This is often not the case, however, as evaluation results seldom influence important decisions regarding programs and policies. Weiss’s general conclusion regarding utilization is that evaluation results affect public policy by serving as the impetus for public discourse and debate that form social policy, rather than through extensive program reform or termination.

QUALITATIVE METHODS

The term *qualitative methods* refers to a variety of research techniques and procedures associated with the goal of trying to understand the complexities of the social world in which we live and how we go about thinking, acting, and making meaning in our lives. These research practices, which emphasize getting close to participants and trying to understand how they (and we) view the world, include, among others, participant observation, interviews, life histories, and focus groups; autoethnographic, phenomenological, narrative, and most ethnomethodological and feminist approaches; particular forms of documentary, content, discourse, and conversational analysis research; and some action research.

Qualitative researchers may be placed along a broad continuum ranging from an orientation akin to positivist science to one more akin to art and literature. In between is a vast middle ground where elements of both orientations are present. Moving along the qualitative continuum from science to art and literature, one finds practitioners who see social life as something out there to be discovered independently of the researcher, those who view social life as something constructed through interaction and engagement with the world, and those who focus more closely on the person describing social life and the modes and practices of description (see Crotty 1998; Denzin 1997). Across the continuum, the focus changes from studying others who are assumed to be uniquely separate from the researcher, to examining interactions between the researcher and others, to

including the positionality, politics, and story of the researcher who interacts with others.

Currently qualitative work enjoys a burgeoning interest across social science disciplines including anthropology, sociology, communication, education, social work, and nursing. The result is a growing sense of a qualitative community unconstrained by disciplinary boundaries. As this community grows and forms its identity, the spectrum of possibilities broadens, creating new alternatives for qualitative research and, in the process, raising vexing and controversial questions (see Denzin and Lincoln 1995; Snow and Morrill 1995). Given the interpretive turn (Rabinow and Sullivan 1987) in social science, more and more researchers are applying art-based criteria to their work; at the same time, new computer programs, such as NVivo, allow for more systematic and rigorous coding of qualitative data. We view these differences and ensuing conversations as strengthening qualitative research and representing a coming of age for qualitative work (Bochner and Ellis in press).

We organize our discussion of qualitative methods according to three ideal types representing points on the qualitative continuum from the science/causal pole through the middle ground to the artful/interpretive pole. These categories are intended as a useful means of dividing the territory, but they are also arbitrary and should not be taken as a literal map of the field. Rather, we encourage readers to envision a wide expanse of methodological approaches and to view the boundaries we have constructed as permeable, flexible, and fleeting, with many qualitative researchers

likely to position themselves in more than one category. As the authors, both of us have engaged in middle ground and artful/interpretive qualitative work; our current allegiance lies primarily in the artful/interpretive region of the continuum.

QUALITATIVE RESEARCH AS SCIENCE

At one end of the qualitative spectrum, researchers approach qualitative research as an extension of quantitative inquiry. Their goal is to produce propositional knowledge about human behavior generalizable to specific populations. They see truth as something "out there" to be discovered and explained by the researcher. Positioning themselves as neutral, disinterested parties in the research process, they want to be able to control and predict subsequent behavior of samples within the population being investigated. These researchers follow the building-block, foundational model of scientific knowledge, viewing inquiry as a linear progression, with each new discovery adding on to available explanations. Qualitative researchers in this tradition express many of the same concerns as their quantitative counterparts, including an interest in random sampling, reliability, validity, and ethical issues. The language they use to present and discuss results applies many of the familiar lines of the hypothetico-deductive model.

Random sampling of the studied population (regardless of specific research tools to be used) provides assurance that the qualitative researcher has obtained a representative and unbiased sample of research subjects (Lindlof 1995, p. 121). Since researchers want to claim that their findings can be generalized to the selected population, it is critical that the demographic characteristics of the sample match those of the population defined in the study. For example, Lowry and Towles (1989), in their study of the portrayal of sex and its consequences in afternoon soap operas, randomly sampled episodes of soap operas from each TV network in order to be able to draw conclusions about soap opera content in general.

Using an approach similar to that of quantitative research, qualitative researchers in this tradition examine variables that relate to specific behaviors, traits, or characteristics that are narrowly defined in as specific a manner as possible. They manipulate the independent variables and measure the outcome of the experiment in terms of

dependent variables, those defined behaviors, traits, or characteristics thought to exist in relationship to the independent variables. Before they conduct experiments, researchers form a hypothesis about the relationship between the variables. Data interpretation then centers on determining whether the hypotheses are negated by the results; researchers do not generally examine data for themes or issues unrelated to the predetermined focuses of the study. Based on a review of relevant literature, Chavez (1985), for example, hypothesized that writers treat men and women differently in comic strips. She then collected a sample of comic strips, coded the gender, settings, and activities of the characters, and concluded that her hypothesis was supported.

This process of hypothesis formation and testing often is less formal, however, even among those striving to maintain a scientific approach to their research, and it can take many different forms. In the study of the realism of aggression on television by Potter et al. (1995), for example, the authors laid out a set of premises about what would constitute a realistic (similar to the real world levels of violence in numbers and context) portrayal of aggression. They then collected a sample of television programming, coded the various acts of aggression, and compared the numbers and types of aggression in their sample to the premises they had developed.

Even those researchers who do not convert their data into numerical form often go to great lengths to assure that their findings are valid and reliable. For researchers at this end of the qualitative continuum, validity means that the concepts they examine are those intended to be examined and not confounded or overlapping with other concepts not intended to be included. A study is reliable if researchers find, or could expect to find, the same, or very similar, results when they conduct the study again. For example, Waitzkin (1990) provides criteria to establish reliability and validity of qualitative data: (1) discourse should be selected through a sampling procedure, preferably a randomized technique; (2) recordings of sampled discourse should be available for review by other observers; (3) standardized rules of transcription should be used; (4) the reliability of transcription should be assessed by multiple observers; (5) procedures of interpretation should be decided in advance, should be validated in relation to theory,

and should address both content and structure of texts; (6) the reliability of applying interpretive procedures should be assessed by multiple observers; (7) a summary and excerpts from transcripts should accompany the interpretation, but full transcripts should also be available for review; and (8) texts and interpretations should convey the variability of content and structure across sampled texts (pp. 480–482).

Waitzkin's criteria (1990) emphasize three specific concerns associated with reliability and validity from a scientific perspective. First, the collective decisions and interpretations of multiple researchers would be closer to an "objective" reality than a presumably more biased perspective of a single individual. Second, it is important to consider the whole body of available data as the basis for interpretation to avoid making general statements that reflect only a subset of the data; the emphasis is on what is common throughout the data, not on that which is unusual, distinctive, or unique. Third, written transcripts must be publicly available for verification.

Qualitative researchers working in this tradition use a system of coding to categorize videotaped or observed behaviors, written responses to survey questions, verbal responses to an interviewer, or other data (Wimmer and Dominick 1997). Once labeled, the observed behaviors can be counted, sorted, and analyzed statistically. Coding schema can be standardized typologies that are used by other researchers, or they can be developed in light of a specific research question or body of data. Chavez (1985), mentioned above, developed a typology of settings and activities (e.g., child care or working in an office) for the cartoon characters based on what she found in her comic strip data set. To aid in the analysis of transcript data, specialized computer software programs, such as NUD*IST, Ethnograph, or NVivo (a new program that integrates text, image, sound, and video data sets), are available. A critical component to coding is establishing intercoder agreement; that is, a measure to ensure that the coding schema can be consistently applied to the same set of data by different coders and the same or very similar results obtained (Wimmer and Dominick 1997).

Ethical issues at this end of the continuum, similar to those in quantitative research, focus on methodological procedures, in particular honesty

and thoroughness in data collection and analysis. Authors often elaborately spell out their research procedures in their publications, making the procedures and data available for scrutiny in order to justify claims or conclusions they draw. In science-oriented qualitative research, authors stay behind the scenes, portraying themselves as trustworthy and credible through their disembodied discussion of methods without showing in their texts their own involvement or self-interest.

Those engaging in scientific approaches to qualitative research usually adhere closely to the writing style used by quantitative researchers. A passive voice shadows the presence of the author and obscures the "I" of the researcher (Gergen 1994). Statements such as "It was found that . . ." and "The data revealed that . . ." reinforce the notion of neutral authors who have discovered preexisting ideas, and who, without contaminating the material with their own perspectives, then pass it along for readers to receive as knowledge. Of course, researchers who see their work as scientific often acknowledge that the author is not a blank slate without values and beliefs, but their use of a disinterested, passive voice remains a sign of how important they view the ideal of distance and objectivity, even if it is not fully attainable.

MIDDLE-GROUND APPROACHES TO RESEARCH

Between science and art, one finds a sprawling middle ground of qualitative researchers, who seek to analyze events, find patterns, and create models from their data (Neuman 1997). Here, researchers do not adhere rigidly to the rules of empiricism; but they are not likely to experiment with narrative, poetic, or literary forms of writing either. In the middle, researchers seek some combination of scientific rigor and artistic imagination. How these two goals intersect differs for various researchers and often connects to the author's specific location relative to art and science on the qualitative continuum.

Middle-ground researchers use a variety of methodologies to gather data for analysis, including unstructured or semistructured interviewing (Fontana and Frey 1994; Mishler 1986), focus groups (Kitzinger 1994), participant observation or fieldwork (Lincoln and Guba 1985; Lofland and Lofland 1995), textual analysis (Reinharz 1992),

and analysis of narrative (M. M. Gergen 1992; Riessman 1993). While there are many ways to go about selecting a sample, those in the middle ground of qualitative research often use purposeful sampling (Miles and Huberman 1984), in which they try to obtain cases that are information rich, or a “snowball” approach (Reinharz 1992), in which they ask current participants to identify other possible participants.

One of the most useful and widely applied strategies associated with the middle ground is an approach, developed by Glaser and Strauss (1967), called *grounded theory*. In this approach, researchers emphasize the generation of categories and theory from systematic coding and analysis of qualitative data (often transcripts) (Charmaz 1990; Glaser and Strauss 1967; Janesick 1994). This method of inductive reasoning differs from traditional social science in which researchers use previously established theory and test it deductively with data to see whether the theory can be sustained.

Methodological concerns are very important to grounded theory researchers, who often hold to the belief that if you apply a valid and systematic methodological approach, you’ll get closer to an accurate representation of what’s actually going on. In analyzing the data, some adhere rigidly to formal steps in grounded theory research—data notes, sort and classify, open coding, axial coding, selective coding, with memo writing occurring throughout the process (Charmaz 1990; Neuman 1997; Strauss and Corbin 1994). The more the researcher adheres to systematic analysis, the greater the likelihood of using computer programs to assist in coding. Other theorists, in the middle of the continuum, who think of themselves as grounded theorists, “eyeball” the data in less systematic ways, perhaps not even completely transcribing or coding data into categories. Yet they too seek patterns among the data they have collected, though they view the process as more subjective and intuitive than scientific and objective.

While some middle-ground researchers may place less emphasis on scientific precision, they usually adhere to criteria or guidelines concerning the processes of data analysis, though these rules may vary widely (see, for example, Charmaz 1997; Glaser 1978; Strauss and Corbin 1997). Tompkins (1994), for example, refers to representativeness,

consistency (for public and private texts), and recalcitrance (sanction by research participants or a similar group) as standards for evaluating data used in qualitative research (see also Fitch 1994). Working closer to the interpretive pole, Lather (1986) argues that validity in openly ideological research can be established through four guidelines: *triangulation* of multiple data sources, methods, and theoretical perspective; *assessment* of construct validity through use of systematized reflexivity between the daily experiences of people and the theoretical constructs being developed; *establishment* of face validity through sharing analysis with respondents and refining analysis with their input; and *determination* of catalytic validity, that is the potential for bringing about positive change and social transformation (p. 67). These different criteria are similar insofar as they provide standards for bridging researcher and participant perspectives, so that findings reflect the meanings of the people whose lives were examined.

Ethical issues for those in the middle group focus on research practices such as covert research, deception, informed consent, anonymity, confidentiality, and revealing knowledge about the less powerful. These issues then lead to ethical questions about what should be studied, how, and by whom (see Lofland and Lofland 1995).

Most middle-ground researchers note the positionality of participants, such as race, class, and sexual orientation, in order to avoid obscuring these factors. For example, Ellingson and Buzzanell (1999) studied a group of white, middle-class, heterosexual breast cancer survivors in a small Midwestern city. They acknowledged that these demographic characteristics impacted the results of the study; a more racially mixed group, or a group composed of lesbians, for instance, most likely would have produced a different set of findings.

Just as those in the middle ground acknowledge the positionality of participants, they also sometimes acknowledge their standpoint, personal background, politics, and interests in the topic (Collins 1991). Insofar as they see knowledge as “constructed” rather than discovered, middle-ground researchers discuss their personal perspectives or political commitments as an acknowledgment that all knowledge is generated from a

specific social position and reflects the perspectives of the researchers involved. Researchers in the middle ground may try to decrease the power disparity between themselves and the people they study (DeVault 1990; Ellingson and Buzzanell 1999). They generally refer to those in the study as research participants or informants rather than subjects, indicating a degree of respect for the people whose lives are being studied (Reinharz 1992).

In the middle ground, researchers study a variety of topics, including complex issues that are difficult or impossible to address with quantitative methodology, such as understanding hierarchy in groups (Whyte [1943] 1993) or awareness contexts in death (Glaser and Strauss 1964). Some seek to make visible previously invisible aspects of the lives of women and other groups underrepresented in traditional social scientific research such as ethnic and racial minorities, gays and lesbians, and people with disabilities (Spitzack and Carter 1989). Others examine groups that are hidden, unknown, or inaccessible to most people, such as mushroom gatherers (Fine 1992) or white supremacists (Mitchell 1998). As the topics get more complex and oriented toward meanings, subjectivity, and emotionality, it becomes more difficult to invoke older, more traditional, systematic "scientific methods" and apply them.

Writers in this tradition alter some of the conventions of scientific writing. They may include standpoint statements within the introductory section of articles, indicating their personal interest in the topic. They may use a conventional format but preface the article with vignettes or include excerpts from participant narratives in the discussion of findings or in an appendix to add texture and authenticity to the work. To acknowledge their presence in the work, authors may write in the first person. Nevertheless, researchers in this tradition usually privilege theory generation, typicality, and generalization to a wider world over evocative storytelling, concrete experience, and multiple perspectives that include participants' voices and interpretations. They tend to write realist tales in an authorial, omnipotent voice. Snippets of fieldwork data then represent participants' stories, primarily valued for illustrating general concepts, patterns, and themes (see Van Maanen 1988).

RESEARCH AS ARTISTIC ENDEAVOR

During the last two decades, many qualitative researchers have moved toward an emphasis on the artistic aspects of qualitative work (Wolcott 1995). Working from an orientation that blends the practices and emphases of social science with the aesthetic sensibility and expressive forms of art, these researchers seek to tell stories that show experience as lived in all its bodily, cognitive, emotional, and spiritual aspects. The goal is to practice an artful, poetic, and empathic social science in which readers can keep in their minds and feel in their bodies the complexities of concrete moments of lived experience. These writers want readers to be able to put themselves in the place of others, within a culture of experience that enlarges their social awareness and empathy. Their goals include: evoking emotional experience in readers (Ellis 1997); giving voice to stories and groups of people traditionally left out of social scientific inquiry (DeVault 1990); producing writing of high literary/artistic quality (Richardson in press); and improving readers', participants', and authors' lives (see Denzin 1997; Fine 1994).

According to Bochner, Ellis, and their colleagues (Bochner 1994; Bochner et al. 1998; Ellis 1997), the interpretive, narrative, autoethnographic project has the following distinguishing features: the author usually writes in the first person, making herself or himself the object of research (Jackson 1989; Tedlock 1991); the narrative text focuses on generalization within a single case extended over time (Geertz 1973); the text is presented as a story replete with a narrator, characterization, and plot line, akin to forms of writing associated with the novel or biography; the story often discloses hidden details of private life and highlights emotional experience; the ebb and flow of relationship experience is depicted in an episodic form that dramatizes the motion of connected lives across the curve of time; a reflexive connection exists between the lives of participants and researchers that must be explored; and the relationships between writers and readers of the texts is one of involvement and participation.

Rather than believing in the presence of an external, unconstructed truth, researchers on this end of the continuum embrace narrative truth (Spence 1982), which means that the experience as described is believable, lifelike, and possible.

Through narrative we learn to understand the meanings and significance of the past as incomplete, tentative, and revisable according to contingencies of present life circumstances (Crites 1971). In this research, authors are concerned about issues of validity, reliability, and generalizability, but these issues may be redefined to meet the goals of the research.

Ellis and Bochner (in press), for example, define *validity* to mean that the work resonates with readers and evokes in them a feeling that the experience has verisimilitude. A story is valid if it stimulates readers to enter the experience described or to feel and think about their own, whether in memory, anticipated, or lived. Validity might be judged by whether it offers readers assistance in communicating with others different from themselves, or a way to improve the lives of participants and readers or even the author's own. Since writers always create their personal narrative from a situated location, trying to make their present, imagined future, and remembered past cohere, orthodox *reliability* does not exist in narrative research. But reliability checks are still important. Researchers often take their work back to participants and give them a chance to comment, add materials, change their minds, and offer their interpretations. Since we all participate in a limited number of cultures and institutions, lives are typical and generalizable, as well as particular. A story's *generalizability* is constantly being tested by readers as they determine whether the story speaks to them about their own experiences or about the experiences of others they know. Likewise, does it tell them about people or lives about which they are unfamiliar? Does a work bring "felt" news from one world to another and provide opportunities for the reader to have vicarious experience of the things told (Stake 1994)?

Interpretive research reflects the messiness of lived experience and emotions. Unlike researchers at the scientific end and in the middle ground, artful or interpretive researchers do not look for common denominators and generalities, but instead examine experience that is unique, particular, moving, and possible. They embrace their own subjectivity not to acknowledge bias but to celebrate positionality and their particular construction of the world. While some of these writers employ traditional analysis in their work, examining stories for concepts, patterns, and themes,

others argue for the importance of thinking *with* a story, not just about a story. Thinking *with* a story means to allow yourself to resonate with the story, reflect on it, become a part of it (see Frank 1995b). Others argue that theory is embedded in the story (Ellis 1995b), that all good stories make a theoretical point.

Arguments about methods are not nearly as prevalent here as in the other two groups. Methods articles are much more likely to emphasize flexibility and emergence than to offer strict rules for how to proceed (Ellis et al. 1997). One of the most discussed methodological issues is whether researchers should attempt to follow the rules of traditional ethnographic methods or whether narrative research should be approached more like writing fiction. One's position on that question most likely intersects with one's stance regarding the role of criteria in evaluating narrative writing. In the former, traditional ethnographic criteria might be more commonplace; in the latter, narratives might be judged by their usefulness, the compassion they encourage, and the dialogue they promote (Ellis and Bochner in press). Seeking to position interpretive texts as an intersection of social science and art form, Richardson (in press) discusses five criteria she uses to evaluate interpretive ethnography: (1) *Substantive contribution*: Does the work contribute to an understanding of the text? (2) *Aesthetic merit*: Is the text artistically shaped, complex, and satisfying? (3) *Reflexivity*: Does the writer reflect on the production of the text so that the reader can make judgments about the point of view employed in the text? (4) *Impactfulness*: Does this work affect me and move me to respond or act? (5) *Expression of Reality*: Does this work seem a credible account of the real?

Rather than method and criteria, most articles about interpretive/artful ethnography grapple with issues of writing. For narrative researchers, writing (the form) is inseparable from the process of data interpretation (the content). As Richardson (in press) phrases it, writing in interpretive qualitative research is not a "mopping-up" activity at the end of a research project but an integral part of data analysis; authors write to find out what they have to say about their data and their experiences. The voice of the author is as central to the text as the voices of those "being studied." Writers experiment with approaches and writing conventions to

dislodge assumptions about science and incorporate the artistic into representations of data.

Interpretive research embraces a range of processes and approaches, including biographical method (Denzin 1989), observation of participation (Tedlock 1991), ethnography (Van Maanen 1988), autoethnography (Ellingson 1998; Reed-Danahay 1997), interactive interviewing (Ellis et al. 1997), systematic sociological introspection (Ellis 1991), co-constructed methods (Bochner and Ellis 1992), personal experience methods (Clandinin and Connelly 1994), narrative analysis (Bochner 1994), and feminist methods (Reinharz 1992).

Examples of creative representation include layered accounts (Ronai 1995), ethnographic fiction (Angrosino 1998), personal essays (Krieger 1991), impressionist tales (Van Maanen 1988), co-constructed narratives (Bochner and Ellis 1992), poetic representation of data (Austin 1996; Glesne 1997; Richardson 1992, 1994), writing stories (Richardson 1997), ethnographic performance or ethnodrama (Jones 1998; Mienczakowski 1996), and polyvocal texts (Lather and Smithies 1997).

A particularly controversial narrative writing practice and form is autoethnography, which is an autobiographical genre of writing and research that displays multiple layers of consciousness as it connects the personal to the cultural. Several autoethnographic genres currently exist side by side (Ellis and Bochner in press): (1) Reflexive ethnographies focus on a culture or subculture, but authors use their own experiences in the culture reflexively to bend back on self and look more deeply at self-other interactions. Reflexive ethnographers ideally use all their senses, their bodies, moment, feeling, and their whole being to learn about the other (Jackson 1989). (2) In native ethnographies, researchers who are natives of cultures that have been marginalized or exoticized by others write about and interpret their own cultures for others. (3) In personal narratives, social scientists take on the dual identities of academic and personal selves to tell autobiographical stories about some aspect of their daily life.

In all these forms of qualitative writing, narrative researchers use fiction-writing techniques such as dramatic recall, dialogue, flashback, strong imagery, scene setting, character development, interior monologue, suspense, and a dramatic plot line that is developed through the specific actions

of specific characters with specific bodies doing specific things. They ask readers to relive the events with the writer and then to reflect on their emotional responses and life experiences, and on the moral questions and concerns that arise. Yet, the work differs from fiction in that the writing and publishing conventions used arise out of social science traditions, and in that the work often, though not always, has more of an overt analytic purpose and more of an analytic frame than fiction has.

Ethical concerns include matters of how we go about doing our research and what we owe those who become characters in and readers of our stories (Ellis 1995a). How do we deal with issues of confidentiality when including people, such as family members, who can be easily identified? What do we do if characters in our stories disagree with our interpretations or want us to omit material about them? How do we include multiple voices and perspectives within our stories? What is the role of the traditional authorial voice of the author? How do we stay true to our participants yet not deceive our readers (Josselson 1996; see also Chase 1996)? Is there value in working from an ethic of care, empathy, and responsibility, rather than informed consent, and is that ever possible in the world of research (Collins 1991; Denzin 1997)? How do we make our projects therapeutic for ourselves as well as our participants and readers? What do we want the world to be? How can we contribute to making it that way and, in the process, become better human beings?

CONCLUSION

Qualitative methods is a rich and varied set of approaches to research. Journals such as *Qualitative Inquiry*, *Qualitative Sociology*, *Symbolic Interaction*, and the *Journal of Contemporary Ethnography*, as well as a number of research annuals such as *Studies in Symbolic Interaction* and *Cultural Studies: A Research Annual*, along with subfield-specific journals, such as *Qualitative Health Research*, showcase examples of qualitative research in sociology and provide forums for discussion of methodological issues. The joy (and sometimes the frustration!) of qualitative methods is the promotion and valuing of a wide spectrum of methods, none of

which should be viewed as the only way to conduct research in sociology. It might be more comforting if there was one set of rules to follow, but that comfort would come with the tragic price of close-mindedness, silencing of voices, and narrowing of vision. We agree with Rorty (1982), who says we ought to learn to live with differences without feeling we have to resolve them.

QUALITATIVE MODELS

Qualitative models describe structure and metamorphoses among things or events or among properties of things or events. Sociologists have several ways of formulating qualitative models.

Qualitative modeling based on *logic* involves the following ideas. Propositions are simple sentences such as "All humans are mortal" and "A dictator is a human." Propositions can be true or false, and negation of a proposition transforms truth into falsity, or falsity into truth. Compound statements are formed when two or more propositions are placed in disjunction or conjunction, signified in English by the words *or* (or *nor*) and *and* (or *but*). Compound statements are true if all their component propositions are true, and compound statements are false if all their component propositions are false. Disjunction of true and false propositions yields a compound statement that is true, whereas conjunction of true and false propositions yields a compound statement that is false. These definitions are sufficient for logical analyses, but a supplementary definition is useful: the conditional "P implies Q," or "If P, then Q," means that whenever proposition P is true, proposition Q is true also, but when P is false, Q may be either true or false.

Set theory corresponds closely with logic, to the point that logic formulations can be interpreted in terms of sets, and information about the existence of elements in sets and subsets can be interpreted in terms of logic. Logic also can be translated to Boolean algebra (which operates as does ordinary algebra except that there are only two numbers, 0 and 1, and $1 + 1 = 1$), so any formulation in terms of logic can be transformed to an algebraic problem and processed mathematically.

Logic models have been used to define sociological constructs. Balzer (1990), for example, employed logic plus some additional mathematical ideas in order to construct a comprehensive definition of social institution. Logic models also can be used to compare competing sociological theories. Hannan (1998), for example, formalized different "stories" about how organizational age relates to organizational demise, and he used a computer program for automated deduction to

prove that various empirical observations can be derived from different theoretical assumptions.

Znaniecki (1934) systematized *analytic induction* as a method for deriving logic models from statements known to be true as a result of sociological research. For example (alluding to a study by Becker [1953] that applied the method), field research might have disclosed a set of fourteen males who are marijuana users, all of whom were taught to enjoy the drug; a set of three females who use marijuana though they were never taught to enjoy it; and a set of six males who were taught how to enjoy marijuana, but who do not use it. Implicitly it is understood that other people were never taught to enjoy marijuana and do not use it. From this information one might conclude that for males like the ones who were studied, using marijuana implies being taught to enjoy the drug. Robinson's critique of analytic induction (1951) led to a hiatus in the development of logic models in sociology until modeling difficulties were understood better.

Ragin (1988) developed a method for constructing logic models from cross-sectional data. Empirically valid propositions about all cases in a population are conjoined into a complex compound statement, transformed into Boolean algebra format, and processed by a computer program. The result is a reduced compound statement that is empirically true for the cases and the propositions studied. The approach differs from statistical analysis of multifold tables in ignoring count information (other than whether a cell in a table has zero cases or more than zero cases), and in describing data patterns in terms of logic statements rather than in terms of the effects of variables and their interactions.

Abell (1987) and Heise (1989) developed a logic model approach for *event sequence analyses*. Logic models for sequences do not predict what will happen next but instead offer developmental accounts indicating what events must have preceded a focal event. A narrative of events is elicited from a culturally competent consultant who also defines prerequisites of the events in terms of other events within the happening. Since prerequisites define implication relations, a logic model is obtained that accounts for sequencing of events within the happening and that can be tested as a possible explanation of event sequencing in other happenings. Routines that appear to have little

surface similarity may be accountable by abstract events in a logic model; for instance, Corsaro and Heise (1990) showed that an abstract model accounted for observed play routines among children in two different cultures. Abell (1987) suggested that abstraction involves homomorphic reduction: That is, abstract events categorize concrete events that have identical logical relations with respect to events outside the category. Abbott (1995) reviewed logic models and other approaches to sequence analysis.

Careers are sequences in which the events are status transformations. Heise's logic model analysis of careers (1990) emphasized that individuals' sequences of status transformations are generated in limited patterns from institutional taxonomies of roles. *Guttman scaling* can be employed as a means of analyzing individual experiences in order to infer logic models that generate career sequences (e.g., see Wanderer 1984). Abbott and Hrycak (1990) applied *optimal matching* techniques to the problem of comparing career sequences, with the similarity of two sequences being measured as the minimum number of transformations required to change one sequence into the other; clusters of similar sequences discovered from the similarity measures are identified as genres of career patterns.

A *formal grammar* defines sequences of symbols that are acceptable in a language, being "essentially a deductive system of axioms and rules of inference, which generates the sentences of a language as its theorems" (Partee et al. 1990, p. 437). A grammar, like a logic model, is explanatory rather than predictive, interpreting why a sequence was constructed as it was or why a sequence is deviant in the sense of being unprincipled. Grammars have been applied for modeling episodes of social interaction, viewing sequences of social events as symbolic strings that are, or are not, legitimate within a language of action provided by a social institution (Skvoretz and Fararo 1980; Skvoretz 1984). The grammatical perspective on institutionalized action can be reformulated as a *production system* model in which a hierarchy of if-then rules defines how particular conditions instigate particular actions (Axten and Fararo 1977; Fararo and Skvoretz 1984).

Case frame grammar (Dirven and Radden 1987) deals with how syntactic position within a set of

symbols designates function. For example, syntactic positioning in a sentence can designate an event's agent, action, object, instrument, product, beneficiary, and location (e.g., "The locksmith cut the blank with a grinder into a key for the customer in his shop"). Heise and Durig (1997) adapted case frame grammar to define an *event frame* for theoretical and empirical studies of social routines. The case-grammar perspective also informed Heise's (1979) symbolic interactionist modeling of social interaction by providing an agent-action-object-location framework for analyzing social events. Guttman's *facet mapping sentences* (see Shye 1978) implicitly employ a case grammar framework for analyzing a conceptual domain in terms of sets of concepts that fit into different syntactic slots and thereby generate a large number of propositions related to the domain. For example, Grimshaw (1989) developed a complex mapping sentence that suggested how different kinds of ambiguities arise in conversation and are resolved as a function of a variety of factors.

The mathematics of *abstract groups* provide a means for modeling some deterministic systems. Suppose a few different situations exist, and combining any two situations establishes another one of the situations; the result of a string of combinations can be computed by combining adjacent situations two at a time in any order. Also suppose that any situation can be reproduced by combining it with one particular situation, and this identity situation can be obtained from any other situation through a single combination. Then the set of situations and the scheme for combining them together constitute a group, and the group describes a completely deterministic system of transformations. Kosaka (1989) suggested a possible application of abstract groups by modeling the aesthetic theory of a Japanese philosopher in which there are sixty-four defined transformations, such as "yabo" (rusticity) combines with "hade" (flamboyance) to produce "iki" (chic urbanity).

A classic sociological application of groups involved kinship. Classificatory kinship systems (which are common in aboriginal cultures) put every pair of people in a society into a kinship relationship that may have little relation to genetic closeness, and each person implicitly is in a societywide kinship class that determines relationships with others. White (1963) showed through

mathematical analysis that classificatory rules regarding marriage and parentage generate clans of people who are in the same kinship situation and that the resulting classificatory kinship system operates as an abstract group; then he demonstrated that existing kinship systems accord with analytic results.

Models of social networks sometimes employ the notion of *semigroup*—a set of situations and a scheme for combining them (i.e., a group without an identity situation). For example, Breiger and Pattison (1986) examined economic and marriage relations among elite families in fifteenth-century Florence and showed that each family's relations to other families constituted a semigroup that was part of the overall semigroup of family relations in the city; they were able to identify the allies and enemies of the famous Medici family from the structure of family relationships. Social network research, a sophisticated area of qualitative modeling in sociology, employs other algebraic and graph-theoretic notions as well (Marsden and Laumann 1984; Wasserman and Faust 1994).

In general, qualitative models describe systematic structures and processes, and developing qualitative models aids in interpreting nebulous phenomena. Creating and manipulating qualitative models confronts researchers with technical challenges, but software providing computer assistance is lessening the difficulties.

QUALITY OF LIFE

Although the concept of quality of life (QL) is not new, quality of life as an area of research and scholarship dates back only to the 1960s. Schuessler and Fisher (1985) noted that President Dwight Eisenhower's 1960 Commission on National Goals and Bauer's book on social indicators (1966) are often credited as providing the impetus for the development of QL as an area of research. Campbell (1981) suggested that the 1960s were favorable times for the development of QL research because of the emergence then of a belief that people must examine the quality of their lives and must do so in an environment that goes beyond providing material goods to foster individual happiness. Campbell quotes President Lyndon Johnson, who stated in 1964:

The task of the Great Society is to ensure our people the environment, the capacities, and the social structures which will give them a meaningful chance to pursue their individual happiness. Thus the Great Society is concerned not with how much, but with how good—not with the quantity of goods but with the quality of their lives. (Campbell 1981, p. 4)

Schuessler and Fisher (1985) note that the Russell Sage Foundation promoted QL and research on social indicators in the 1960s and 1970s and that the Institute for Social Research at the University of Michigan and the National Opinion Research Center at the University of Chicago have

conducted QL research since the late 1960s. Despite the high volume of QL research during the 1960s and 1970s, it was not until 1979 that “quality of life” became an index entry in *Sociological Abstracts*.

The emerging QL research in the 1970s provided a departure from previous work that focused on objective indicators, primarily economic in nature, of individual well-being. The book *The Quality of American Life: Perceptions, Evaluations, and Satisfaction*, published by Campbell and colleagues in 1976, particularly promoted the use of subjective or psychological indicators of well-being. The work reported was founded on the conviction that the relationship between objective and subjective well-being indicators was weak and poorly understood. Moreover, the rising affluence of the post-World War II era had been accompanied by steady increases in social problems afflicting American society as well as other Western societies.

The year 1976 also saw the publication of another major work focusing on subjective indicators of well-being. *Social Indicators of Well-Being: Americans' Perceptions of Life Quality* by Andrews and Withy (1976) reported findings from interviews with representative samples of more than 5,000 Americans. The interviews focused on satisfaction with the quality of various life domains. A more recent volume, titled *Research on the Quality of Life* and edited by Frank Andrews (1986), brought together a variety of papers originating at a symposium honoring the memory of Angus Campbell, one of the founders of the Institute for Social Research. Although this volume included important papers on cross-national differences in life satisfaction and papers on African-Americans and Hispanics, a number of the papers had no direct relationship to QL research. Rockwell (1989) noted that a useful focus of the field was lost in this volume, the focus on subjective indicators of the quality of life. Andrews also noted that support for large-scale, wide-ranging surveys had become increasingly difficult in the 1980s in the United States, resulting in a lack of replication of the national surveys conducted in the previous decade by the Institute for Social Research.

Parallel to the large national surveys of subjective well-being during the 1970s, there was a proliferation of studies focusing on the subjective well-being of the elderly. In a useful article, Larson

(1978) reviewed three decades of research that focused on the psychological well-being of older people. Perhaps no other area of research in the emerging field of gerontology had received as much attention during the 1960s and 1970s as the area of life satisfaction, morale, mental health, and psychological well-being in general. Much of this research was spurred by the lively debate over the merits of disengagement theory (proposed by Cumming and Henry 1961) and activity theory (identified with various authors, including Havighurst et al. 1968; Maddox 1968, 1970) in predicting “successful aging.” Gerontological work in the 1980s showed a marked decline in the number of articles predicting life satisfaction and morale and an increase in articles focusing on specific dimensions of psychological well-being, such as depression and psychological distress, positive and negative affect (Lawton 1996), as well as articles focusing on the prediction of physical health outcomes (Markides 1989).

An exception to the general decline of sociological studies of QL in the 1980s was a study by Thomas and Hughes of racial differences in QL in the United States (1986), in which they found significantly lower subjective well-being among African-Americans than among whites over the period 1972–1984. In their recent extension of their work to 1996 using data from the General Social Survey, Hughes and Thomas (1998) found that African-Americans continue to have a lower subjective QL than whites, as expressed in terms of happiness, life satisfaction, marital happiness, and self-rated health. This was in contrast to other recent work that challenged the notion that African-Americans had lower subjective well-being. However, much of this work had examined such indicators of QL as psychiatric disorders, including depression (Kessler et al. 1994; Williams et al. 1992). Moreover, one analysis did not find that race magnified the negative effect of socioeconomic status on psychiatric disorders (Williams et al. 1992). Hughes and Thomas conclude that their findings suggest that their measures of subjective QL capture separate dimensions of life rather than measures of psychiatric disorder and that African Americans in all social classes express lower QL of “social life experience” (1998, p. 792). This is an example of how different measures of QL can produce substantially different results.

The relative decline in research on the subjective QL of Americans in general, as well as on the subjective well-being of the elderly during the 1980s, was accompanied by a marked increase in QL research in medicine, which continued to accelerate during the 1990s, both in North America and in Europe. This development has included the publication of the massive *Quality of Life and Pharmacoeconomics in Clinical Trials* (Spilker 1996), the journal *Quality of Life Research*, the *Quality of Life Newsletter*, and the establishment of the *International Society for Quality of Life Research*. In medicine, as in the social sciences, the field of QL is conceptually weak. As Leplège and Hunt (1997) recently argued, a problem has been the overwhelming emphasis of the medical model on function and health status at the expense of attention to social and psychological aspects of QL as expressed by patients themselves.

Within medicine, there has been particular interest in studying the quality of life of cancer patients. Before 1970, cancer research focused almost exclusively on survival and life extension. With extended survival from cancer becoming the rule, research has given increasing attention to the quality of life of the surviving patients afflicted with cancer or patients treated for cancer. In 1987, for example, a volume entitled *The Quality of Life of Cancer Patients* was published. The volume, edited by Aaronson and Beckman (1987), contains papers from researchers in a number of European countries as well as the United States. More recently, Gotay and Muraoka (1998) reviewed thirty-four studies published in English language journals from 1980 to 1998 on the quality of life of long-term survivors of adult-onset cancers.

Another parallel to this work has been the focus on active life expectancy. The work has gone beyond predicting extension of life in general to investigating the extent to which recent extensions of life expectancy have been accompanied by extensions of "active" life. A recent variant of this work is the concept of health expectancy or the proportion of life expectancy that consists of healthy years (Olshansky and Wilkins 1998).

DEFINITIONS OF QUALITY OF LIFE

As seen in the previous section, there has been a movement in recent decades away from objective,

quantitative research and toward subjective, qualitative assessments of QL in sociology and other fields. Even within these broad approaches to QL, there appears to be little agreement about an appropriate definition of QL.

Some writings include under QL research the social indicators movement. Land (1971) noted that in the early years of the movement, the most popular definition of social indicators was given in *Toward a Social Report*:

A social indicator . . . may be defined to be a statistic of direct normative interest which facilitates concise, comprehensive and balanced judgements about the condition of a major aspect of a society. It is in all cases a direct measure of welfare and is subject to the interpretation that, if it changes, in the "right" direction, while other things remain equal, things have gotten better, or people are "better off." Thus statistics on the number of doctors or policemen could not be social indicators whereas figures on health or crime rates could be. (U.S. DHEW 1969, p. 97)

Land criticized the above definition and proposed a broader one that treats social indicators as both "outputs" and "inputs" in "a sociological model of a social system or some segment thereof" (1971, p. 324). Thus, for example, the number of doctors is essential to understanding the health of the population, as are other factors. Land's definition has been largely accepted by the social indicators movement (Mukherjee 1989, p. 53).

This article gives only limited attention to social indicators, because a separate article is devoted to the topic. Yet the term "social indicators" is often used interchangeably with "quality of life," at least with respect to what Mukherjee calls "need-based" quality of life research (1989, p. 49). Moreover, the journal *Social Indicators Research* is subtitled *An International Journal of Quality of Life Measurement*.

In his book *The Quality of Life Valuation in Social Research*, Mukherjee notes that QL researchers employ several dichotomies, such as "quantity" and "quality," "behavior" and "perception," and "objective" and "subjective" indicators. He argues:

Economists and planners . . . are almost exclusively concerned with behavioral research

on the basis of quantitative variables to improve the quality of life of the people. In that context, they ignore qualitative variations in the appraisal of a better quality of life or treat these variations as introducing a classificatory . . . distinction in the field of enquiry. They also equate the individual-wise subjective perception of reality to a group-wise "objective" perception by experts. Their appraisal of social reality in this manner leads them to formulate what the people need in order to improve their quality of life. (1989, pp. 37-38).

The dependent variables of this research tend to be items or scales measuring satisfaction or happiness. Milbrath, for example, argues: "I have come to the conclusion that the only defensible definition of quality of life is a general feeling of happiness" (1978, p. 36). Even though such global evaluations have been common, much of the research has focused on describing and explaining satisfactions with various life "domains" such as work, family, and housing.

In discussing subjective indicators of QL, Land notes the difficulties in relating them to objective indicators. He notes, for example, that while income levels tend to be associated with satisfaction and happiness within given countries and at given times, "higher per capita levels of national income do not produce higher average levels of national satisfaction over time or cross sectionally" (1983, p. 5). He goes on to suggest that from the standpoint of generating theory of social change, it is not clear that satisfaction indexes provide an unambiguous criterion for the formulation of public policy.

According to O'Boyle (1997), a more focused definition of QL favored by those in the health field has its origins in the original definition of health by the World Health Organization (WHO) that emphasized the presence of social, mental, and physical well-being instead of only focusing on the absence of disease. The WHO Quality of Life Group offered the following definition:

Quality of life is defined as the individual's perception of their position in life in the context of the culture and value systems in which they live and in relation to their goals, expectations, standards and concerns. It is a broad ranging concept affected in a complex way by a person's physical health, psychological

state, and level of independence and their relationships to salient features of their environment. (WHOQoL Group 1993, p. 5)

MEASURING QUALITY OF LIFE

The broadest and most commonly employed distinction in measures of QL is between objective and subjective measures. Among the former are indicators such as per capita income, average calorie consumption, percent of adult illiteracy, quality of air, average daily temperature, crime rates, life expectancy, and a myriad of other indicators that are best seen as causes of quality of life.

Any one of the above has shortcomings. For example, gross national product (GNP) per capita has been acknowledged to suffer from many well-known limitations, including that it may not capture the spending power of the masses but rather that of a small minority (Mukherjee 1989, p. 42). To overcome the limitations of single indicators, researchers have proposed a number of composite indexes, such as the Physical Quality of Life Index (PQLI; see Morris 1977), which includes, among other variables, life expectancy at birth, infant mortality, and literacy. The purpose of the PQLI is to rank countries by physical well-being. Yet it has limitations, as its proponent acknowledges, including that "it is based on the assumption that the needs and desires of individuals initially and at the most basic level are for larger life expectancy, reduced illness, and greater opportunity" (Morris 1977, p 147).

Another composite index of objective indicators of QL is the Index of Social Progress (ISP) proposed originally by Estes (1984) and revised more recently by the same author (Estes 1988). The latest version (ISP83) consists of thirty-six indicators and is divided into ten subindexes covering "education, health status, status of women, defense effort, economic, demographic, political participation, cultural diversity and welfare effort" (Estes 1988, p. 1). A number of equally important indicators (e.g., crime rates, suicide rates, maldistribution of wealth) were not included because reliable data were not available on the 124 nations studied.

There has also been a lively interest in developing indexes consisting of objective indicators to rank quality of life of American cities on the basis

of such domains of QL as economic, environmental, health, education, social, and political. Such rankings of cities elicit national attention and often surprise individuals about how high or low their community ranks. Rankings also do not often correlate with each other. For example, Berger and colleagues (1987) found that their revealed-preference rankings had a correlation of -0.075 with those proposed by Boyer and Savageau (1981) and a correlation of 0.048 with Liu's rankings (1976).

There have been numerous subjective measures of QL, with most relating to happiness or life satisfaction. Some measures are global in the sense that they aim at capturing happiness or satisfaction with life as a whole, while others pertain to happiness or satisfaction with certain life domains. The studies by Andrews and Withy (1976) and by Campbell and colleagues (1976) include measures of both domain-specific and global life satisfaction and employ the former as predictors of the latter. In general, they find that the best predictors of global satisfaction are marriage and family life, leisure activities, work and finances, housing, the community, and friendships.

Well before these landmark studies, W. Wilson (1967) reviewed prior literature on subjective well-being and concluded that the "happy person emerges as a young, healthy, well-educated, well-paid, extroverted, optimistic, worry-free, religious, married person with high self-esteem, high job morale, modest aspirations, of either sex and of a wide range of intelligence" (1967, p. 294). He also concluded that little progress had been made in understanding happiness since the time of the Greek philosophers. Diener (1984) noted that between W. Wilson's 1967 article and 1984, over seven hundred studies on subjective well-being had been published. In general, Wilson's conclusions regarding predictors of well-being appeared to be supported by the literature, including that little theoretical progress had been made in the field since the ancient Greeks.

This voluminous literature on subjective well-being has employed a variety of single-item and multiple-item measures of happiness and life satisfaction. Among the best-known single-item measures are: Cantril's "self-anchoring ladder" (1965), which asks respondents to place themselves on a nine-rung ladder ranging from "best possible for

you" to "worst possible for you"; Gurin and colleagues's item (1960), "Taking all things together, how would you say things are these days?" with possible response choices being "very happy," "pretty happy," and "not too happy"; and Andrews and Withy's item (1976), "How do you feel about how happy you are?" with seven choices ranging from "delighted" to "terrible."

A problem with single-item measures is that because internal reliability estimates cannot be computed, the only way of assessing their reliability is through temporal correlation, which makes it difficult to separate measurement error from true change. However, convergence with other measures of well-being has suggested that these single-item measures enjoy moderate levels of validity. They do suffer from other limitations, however, such as positive skewness, acquiescence, and inability to capture the various dimensions of well-being (Diener 1984).

There have also been a variety of multi-item scales employed. Some of the best-known general scales include: the Affect Balance Scale (Bradburn 1969), which consists of ten items capturing positive and negative well-being. Respondents are asked whether in the past few weeks they felt: "particularly excited or interested in something," "so restless you couldn't sit long in a chair," "proud because someone complimented you on something you had done," "very lonely or remote from other people," "pleased about having accomplished something," "bored," "on top of the world," "depressed or very unhappy," "that things were going your way," and "upset because someone criticized you." Summing the positive items provides a positive score and summing the negative ones a negative score. An "affect balance score" is obtained by subtracting the negative score from the positive score. The two subscales have been found to be relatively independent of each other and are sometimes used as different scales of positive and negative affect.

Another multi-item scale is Campbell and colleagues' Index of General Affect (1976), which asks respondents to describe their present lives using semantic differential scales (miserable-enjoyable, hard-easy, boring-interesting, useless-worthy, lonely-friendly, discouraging-hopeful, empty-full, disappointing-rewarding, and doesn't give me a chance-brings out the best in me).

Although happiness and satisfaction are often used interchangeably, many writers believe they are distinct measures of well-being. George, for example, suggests that "happiness refers to an affective assessment of quality of life," while "life satisfaction refers to an assessment of the overall conditions of life, as derived from a comparison of one's aspirations to one's actual achievements" (1981, p. 351). Campbell and colleagues (1976) prefer satisfaction measures over happiness measures because they are more sensitive to intervention. While happiness tends to be transitory and volatile, life satisfaction changes gradually and systematically in response to changing life conditions (see also Stull 1987). Satisfaction scales have been particularly popular in gerontology.

QUALITY OF LIFE IN THE ELDERLY

An area in which lively interest has been shown in subjective indicators of QL has been the field of gerontology. As mentioned earlier, use of subjective measures of well-being was particularly high during the 1960s and 1970s, when social gerontologists were occupied with assessing the merits of disengagement and activity theories. In the late 1970s, Larson (1978) reviewed three decades of research and concluded that the most consistent predictors of subjective well-being are self-reports of health.

Although gerontological studies have employed general well-being measures (e.g., the Affect Balance Scale), they have also employed scales specifically developed for use with older people. The two best known are the Life Satisfaction Index A (Neugarten et al. 1961) and the Philadelphia Geriatric Morale Scale (Lawton 1975). The Life Satisfaction Index A consists of twenty items, with which respondents indicate agreement or disagreement. A combined life satisfaction score is obtained by summing scores on all twenty items. Twelve items are positive (e.g., "I am just as happy as when I was younger," "I expect some interesting and pleasant things to happen to me in the future," "As I look back on my life, I am fairly well satisfied") and eight items are negative (e.g., "When I think back over my life, I didn't get most of the important things I wanted," "Most of the things I do are boring and monotonous," "Compared to other people, I get down in the dumps too often").

Because the index covers a variety of areas, including happiness, satisfaction, and "activation level" (see Cherlin and Reeder 1975), the combined score confounds separate dimensions of well-being (Stull 1987).

The Philadelphia Geriatric Center Morale Scale (PGCMS) originally consisted of twenty-two items (Lawton 1972), and the revised version consisted of seventeen items (Lawton 1975). Like the Life Satisfaction Index, the PGCMS consists of positive items (e.g., "I am as happy now as I was when I was younger," "As I get older things are better than I thought they would be," "I have as much pep as I did last year") and negative items (e.g., "Things keep getting worse as I get older," "I sometimes feel life is not worth living," "I sometimes worry so much I can't sleep"). Factor analyses have produced three dimensions: agitation, attitude toward own aging, and lonely dissatisfaction. The scale has problems similar to those of the Life Satisfaction Index, such as the confounding of satisfaction and happiness. The two scales are in many ways similar (in fact, they share some items) and have been found to be highly intercorrelated ($r = 0.76$; see Lohman 1977).

Liang (1985) attempted to integrate the Life Satisfaction Index A and the Affect Balance Scale by selecting seven items from the former and eight from the latter. His analysis yielded four factors (congruence, happiness, positive affect, and negative affect) that correspond to dimensions of well-being discussed by Lawton (1983). However, Liang acknowledged a gap between the operationalization of well-being and its theoretical operationalization: "Most instruments were developed with only a general conceptual definition, and the sampling of the item domain is usually based on intuition, experience, and empirical experimentation" (Liang 1985, p. 553).

After reviewing the voluminous literature on subjective well-being among the elderly, Gubrium and Lynott (1983) concluded that it was time to "rethink life satisfaction" in old age. One of their key concerns was that the dominant measures employed tended to dwell on the earlier years of people's lives and have less relevance for their current circumstances. In addition, "current measures do not allow for co-equal dialogue between subject and researcher about the content of items and responses" (Gubrium and Lynott 1983, p. 37).

Possibly because of these and other conceptual and methodological problems in subjective well-being measures, we have seen a substantial decline in published studies in major journals aiming at predicting life satisfaction, morale, and related concepts during the 1980s and 1990s. Social gerontologists have instead concentrated on predicting more narrow dimensions of well-being, such as psychological distress and depression (Ferraro and Su 1999; Lawton et al. 1999; Lawton 1996), and are increasingly employing a life-course perspective that involves examination of main and interactive effects of stress, social support, coping styles, and related factors (e.g., George 1989). Measures of depression and psychological distress are being employed more frequently, perhaps because they are perceived as more amenable to intervention than are measures of life satisfaction and morale.

A general conclusion of the field of subjective well-being in the elderly is that most elderly people, particularly those who have reasonably good health and finances, and are socially engaged, report relatively high levels of well-being. According to some literature, elderly people may even report higher levels of subjective QL than do people in younger age groups (Lawton 1996).

STUDIES OF QUALITY OF LIFE IN MEDICINE

Perhaps the most activity in the area of quality of life is currently found in medicine, much of it conducted by behavioral and social scientists. Interest in QL after medical treatments is based on the realization that chronic diseases cannot be cured, and, therefore, the goal of much therapy becomes to limit the effects of illness so that patients may live productive, comfortable, and satisfying lives. Traditionally, success of medical treatment was evaluated in terms of lengthening lives and post-treatment complications. However, there has been a realization that medical and surgical treatments may extend survival but often reduce quality of life (Eisman 1981).

Hollandsworth (1988) reviewed studies evaluating the impact of medical treatment on QL during the period 1980 to 1984 and compared his results with those of studies conducted during 1975 to 1979 (Najman and Levine 1981). Hollandsworth's comparison (1988) revealed a

marked increase between the two time periods in both quantity and quality of studies. Although recent studies tended to be more sophisticated, the majority nevertheless relied on convenience samples. One marked improvement in the recent research is the increase in use of subjective measures of quality of life, with 60 percent of the recent studies employing at least one such measure, compared to only around 10 percent in the earlier period.

Another interesting outcome of Hollandsworth's analysis (1988) was the increase over time in the proportion of studies that do not report favorable outcomes. Studies published in the late 1970s were almost unanimous in claiming favorable outcomes of treatment, but this optimism must be tempered by the many methodological limitations of these studies (Najman and Levine 1981). Of the more sophisticated studies published from 1980 to 1984, almost one-half reported either negative outcomes or at least mixed results. In fact, it appeared that the probability of reporting negative outcomes (or lack of positive results) tended to be correlated with the methodological sophistication of the studies (Hollandsworth 1988).

The impact of a variety of medical treatments have been examined, including cardiovascular therapies (e.g., Jenkins et al. 1983; Wenger et al. 1984), end-stage renal disease (e.g., Evans et al. 1985) and chronic obstructive pulmonary disease (e.g., McSweeney et al. 1982). However, by far the most frequently studied area is that relating to outcomes of cancer treatment (see Aaronson 1989; Aaronson and Beckman 1987; Cella and Cherin 1988). Aaronson noted that while "there is no universally accepted definition of the quality of life concept, in oncology it is most often used to describe such aspects of health status as physical symptoms, daily activity level, psychological well-being, and social functioning" (1989, p. 69). This increasing use of subjective QL indicators is becoming an integral part of evaluation in clinical cancer research, but a major challenge facing researchers is the development of measures capturing all dimensions of QL while meeting rigorous standards of reliability and validity (Aaronson 1989).

In a recent review, Gotay and Muraoka (1998) observed that recent studies of cancer survivors have increasingly been using standardized instruments relying primarily on self-reports to assess

QL. They identified thirty-four studies published in English-language journals during 1990 to 1998 that focused on the QL of patients surviving five or more years. A variety of standardized instruments were used measuring a variety of aspects of QL. As in other studies of patients, a popular instrument has been the Short-Form 36 Health Survey (SF-36) (Ware and Sherbourne 1992). The SF-36 is a 36-item short form of the Rand Corporation's Medical Outcomes Study. It was designed to be a general measure of health status that can be used in community studies as well as in studies of patients. It consists of multi-item scales measuring eight dimensions of health: general perceptions of health, physical functioning, activity limitations due to physical health problems, bodily pain, social functioning, psychological well-being, activity limitations due to emotional problems, and energy/vitality.

During the 1990s the SF-36 has become the instrument of choice in studies of health-related QL in both community surveys and studies of patients. Like other abbreviated instruments of general health status and QL, the SF-36 has been criticized on a number of grounds, including that it covers some areas only superficially (McDowell and Newell 1996, p. 454).

In their recent critical assessment of QL measurement in medicine, Leplège and Hunt (1997) have criticized the field for relying on instruments (like the SF-36) that have physical, emotional, and social functioning components. While these, according to the authors, are measuring health status, it is not clear that they are measuring QL. This overwhelming emphasis on function, they argue, ignores the person's perspective on the meaning and importance of functions and roles under study. They go on to cite evidence that many physically disabled people do indeed consider their QL to be high despite severe limitations (Leplège and Hunt 1997).

Leplège and Hunt (1997) are also critical of the economic model of QL as expressed in the notion of Quality Adjusted Life Years (QALYs). The concept has evolved over the years as a tool for health policy. Typically, the utility value of specific health status measures, including function and symptoms, during a given period of time is combined with survival data. This perspective usually

assumes that rational human beings, if given a choice, would prefer a shorter but relatively healthy life, to a longer life with serious discomfort and handicap. Leplège and Hunt argue that:

the methods used for the valuation of health states do not encompass the fact that the same people value the same state differently at different times, while different people have different preferences that become meaningless if aggregated. The concept of utility . . . operatively addresses what people think they might (or should) do under artificial circumstances and not what they actually do in the real world. (1997, p. 48)

An overview of the literature on medical treatment outcomes does indeed reveal increasing use of subjective QL measures. As in the broader QL field, many studies tend to employ single-item global indicators capturing life satisfaction or happiness. However, an increasing number of studies are employing the general multiple-item measures discussed earlier, such as the Affect Balance Scale and the Life Satisfaction Index Z. Other scales capturing more specific and narrow dimensions of QL include measures of mood, anxiety, self-concept, and depression (Lawton 1996) as well as more comprehensive instruments that capture physical, emotional, and social functioning, such as the McMaster Health Index Questionnaire (Chambers et al. 1982) and the SF-36. A general conclusion of much of the research is that most patients, including cancer patients, demonstrate an incredible capacity to cope with and adapt to the challenges of life-threatening disease and disability. A welcome recent addition to the field has been the development of a variety of disease-specific QL measures (Bowling 1995).

CONCLUSION

This brief and selective overview of the field of quality of life indicates a variety of perspectives employed within sociology and in related fields. In fact, it may be said that there is more interest in QL outside the mainstream of sociology, as, for example, in the area of medical treatment. While much of the pioneer work and many of the large-scale national studies in the 1970s were conducted by sociologists, research on quality of life remains

very much outside the mainstream of sociology. For example, Schuessler and Fisher's review (1985) uncovered only one article (Gerson 1976) explicitly on quality of life, which was published in the *American Sociological Review* way back in 1976. More recently, we noted the work of Thomas and Hughes published in 1986 and 1998.

This overview also reveals some patterns and trends in QL research in the last four decades. First, there have been two broad approaches, one focusing on objective indicators and one focusing on subjective indicators. Related dichotomies noted by Mukherjee (1989) include quantity versus quality and behavior versus perception. It is clear that there has been a trend away from relying simply on objective indicators and toward relying increasingly on people's subjective reports about the quality of their lives. Objective measures have been the domain primarily of the social indicator movement, with subjective approaches to QL increasingly perceived as the domain of QL research.

Within the subjective QL approach, we also see a trend away from single-item indicators capturing global happiness and life satisfaction and toward multiple-item scales such as the Affect Balance Scale and the Life Satisfaction Index Z. At the same time, there have been attempts to measure subjective quality of life in specific life domains, and there has been continuing interest by sociologists, economists, and others (including popular magazines) in ranking urban areas according to a variety of objective QL indicators.

During the 1960s and 1970s a great deal of subjective QL research was conducted by social and behavioral gerontologists, who used measures of life satisfaction and morale as indicators of successful aging. For a number of reasons, gerontologists began abandoning research on life satisfaction and morale in favor of measures more amenable to intervention, such as measures of psychological distress, depression, and physical health function. Perhaps the most exciting research on QL currently being conducted is in the area of medical treatment outcomes, particularly cancer treatment. In this field, as in others, there is considerable disagreement about what constitutes quality of life and how it should be measured.

It is becoming increasingly difficult to obtain funding to conduct large-scale national surveys of

subjective quality of life such as those conducted during the 1970s. The future of QL research is uncertain, at least as a broad unified field of inquiry. Studies ranking urban areas are likely to continue, because of the immediate and broad appeal they elicit. It is also safe to predict that the concept of quality of life will continue to have some appeal in social gerontology. The most exciting work may well take place in the area of medical intervention outcomes. Sociologists and other behavioral scientists are increasingly conducting research related to medicine, and much of this research relates to quality of life. It is becoming apparent that medical interventions (as well as other factors) are enabling us to live longer, but it is not clear that the added years of life are "quality" years. There will be increasing interest in finding ways to improve the quality of the added years, and sociologists have an opportunity and a responsibility to help find ways of accomplishing that.

QUASI-EXPERIMENTAL RESEARCH DESIGNS

The goal of most social scientific research is to explain the causes of human behavior in its myriad forms. Researchers generally attempt to do this by uncovering causal associations among variables. For example, researchers may be interested in whether a causal relationship exists between income and happiness. One might expect a positive

association between these two variables. That is, an increase in income, the independent variable, produces an increase in happiness, the dependent variable. Unfortunately, observing a positive correlation between these two variables does not prove that income causes happiness. In order to make a valid causal inference, three conditions must be present: (1) there must be an association between the variables (e.g., income and happiness); (2) the variable that is the presumed cause (e.g., income) must precede the effect (e.g., happiness) in time; and (3) the association between the two variables cannot be explained by the influence of some other variable (e.g., education) that may be related to both of them. The purpose of any research design is to construct a circumstance within which a researcher can achieve these three conditions and thus make valid causal inferences.

Experimental designs are one of the most efficient ways to accomplish this goal of making valid causal inferences. Four characteristics are especially desirable in designing experiments. First, researchers *manipulate* the independent variable. That is, they actively modify persons' environment (e.g., provide some people with money they otherwise would not have received)—as contrasted with passively observing the existing, “natural” environment (e.g., simply measuring the amount of income persons normally make). Second, researchers have complete control over *when* the independent variable is manipulated (e.g., when persons receive supplementary income). Third, researchers have complete control over *what* they manipulate. That is, they can specify the exact content of the different “treatment conditions” (different levels) of the independent variable to which subjects are exposed (e.g., how much supplementary income persons receive and the manner in which they receive it). Fourth, researchers have complete control over *who* is assigned to which treatment condition (e.g., who receives the supplementary income and who does not, or who receives higher versus lower amounts of income).

Of these four characteristics important in designing experiments, only manipulation of the independent variable and control over who receives the treatments are essential to classify a study as a true experimental design.

Control over who receives treatment conditions is especially powerful in enhancing valid

causal inference when researchers use the technique of *random assignment*. For example, in evaluating the effect of income on happiness, investigators might randomly assign individuals who are below the poverty level to treatment groups receiving varying levels of supplementary income (e.g., none versus \$1,000).

Table 1 (a) illustrates this example. It depicts an experimental design in which subjects are randomly assigned to one of two groups. At time 1, researchers manipulate the independent variable (X): Each subject in group 1 receives \$1,000 in supplementary income. Conversely, no subjects in group 2 receive any supplementary income. At time 2, researchers observe (measure) the average level of happiness (O) for group 1 versus group 2. The diagram $X \rightarrow O$ indicates an expected increase in happiness when supplementary income increases. That is, the average happiness score should be higher for group 1 than for group 2.

By assigning each subject to a particular treatment condition based on a coin flip or some other random procedure, experimental designs ensure that each subject has an equal chance of appearing in any one of the treatment conditions (e.g., at any level of supplementary income). Therefore, as a result of random assignment, the different treatment groups depicted in Table 1 (a) should be approximately equivalent in all characteristics (average education, average physical health, average religiosity, etc.) except their exposure to different levels of the independent variable (i.e., different levels of supplementary income). Consequently, even though there is a large number of other variables (e.g., education, physical health, and religiosity) that might affect happiness, none of these variables can serve as a plausible alternative explanation for why the higher-income group has higher average happiness than does the lower-income group.

For example, due to random assignment, physically healthy versus unhealthy persons should be approximately equally distributed between the higher versus lower supplementary income treatment groups. Hence, a critic could not make a plausible argument that the treatment group receiving the higher amount of supplementary income (i.e., group 1) also has better health, and it is the better health and not the greater income that is producing the higher levels of happiness in that treatment

group. Indeed, this same logic applies no matter what other causal variables a critic might substitute for physical health as an alternative explanation for why additional income is associated with greater happiness.

In sum, strong causal inferences are possible where social scientists manipulate the independent variable and retain great control over when treatments occur, what treatments occur, and, especially, who receives the different treatments. But there are times when investigators, typically in “field” (i.e., nonlaboratory, natural, or real-world) settings, are interested in the effects of an intervention but cannot do randomized experiments. More specifically, there are times when researchers in naturally occurring settings can manipulate the independent variable and exercise at least some control over when the manipulation occurs and what it includes. But these same field researchers may have less control over who receives the treatment conditions. In other words, there are many real-world settings in which *random assignment is not possible*.

Where randomized experiments are not possible, a large number of potential threats to valid causal inference can occur. Under these less-than-optimal field conditions, investigators may resort to a number of alternative research designs that help reduce at least some of the threats to making valid causal inferences. These alternative procedures are collectively referred to as *quasi-experimental designs*. (See also Campbell and Stanley 1963; Cook and Campbell 1979; Cook and Shaddish 1994; Shaddish et al. in preparation.)

None of these designs is as powerful as a randomized experiment in establishing causal relationships, but some of the designs are able to overcome the absence of random assignment such that they approximate the power of randomized experiments. Conversely, where the designs are particularly weak in establishing causal relationships, Campbell and Stanley (1963) have described

them as *preexperimental designs*. Furthermore, social scientists describe as *nonexperimental designs* those studies in which the researcher can only measure (observe) rather than manipulate the independent variable. As we shall see, however, one type of nonexperimental design—the “panel”—may surpass preexperimental designs and approach the power of some quasi-experimental designs in overcoming threats to valid causal inference.

Below we describe common threats to “internal validity” (i.e., the making of valid causal inferences) in field settings, the conditions under which such threats are likely to occur, and representative research designs and strategies used to combat the threats. Later we briefly examine threats to “external validity,” “construct validity,” and “statistical conclusion validity,” and strategies used to reduce these threats. As we shall see, whereas randomized experiments are the exemplary design for enhancing internal validity (causal inference), they often suffer in comparison to other research designs with regard to external validity (generalizability across persons, places, and times) and construct validity (whether one is measuring and manipulating what one intended).

THREATS TO INTERNAL VALIDITY

Where researchers are unable to assign subjects to treatment conditions randomly, a large number of threats to internal validity (causal inference) can occur. These potential threats include effects due to history, maturation, testing, instrumentation, regression to the mean, selection, mortality, and reverse causal order. (See Cook and Campbell 1979, and Shaddish et al. in preparation for more elaborate lists.)

Research designs vary greatly in *how many* and *which* of these potential threats are likely to occur—that is, are likely to serve as plausible alternative explanations for an apparent causal relationship between an independent and a dependent variable. As an example of a weak (preexperimental)

research design in which most of the various threats to internal validity are plausible, consider the “one-group pretest-posttest design” (Campbell and Stanley 1963). Furthermore, assume that researchers have adapted this design to study the effect of income on happiness. As depicted in Table 1 (b), investigators observe the happiness ($O_{\text{happiness}}$) of persons at time 2 following a period (during time 1) in which subjects (all below the poverty line) receive no supplementary income ($X_{\$0}$). Subsequently, subjects receive a \$1,000 “gift” ($X_{\$1,000}$) at time 3, and their happiness is remeasured ($O_{\text{happiness}}$) at time 4.

The investigators find that posttest happiness (i.e., time 4 $O_{\text{happiness}}$) is indeed substantially higher than pretest happiness (i.e., time 2 $O_{\text{happiness}}$). Accordingly, an increase in supplementary income is associated with an increase in happiness. But is this association due to supplementary income’s *causing* an increase in happiness? Or is the association due to some alternative explanation?

Given this weak, preexperimental research design, there are a number of threats to internal validity that serve as plausible alternative explanations for increases in happiness other than the \$1,000 gift. These plausible threats include effects due to history, maturation, testing, instrumentation, and regression to the mean, with less likely or logically impossible threats due to selection, mortality, and reverse causal order.

History effects refer to some specific event that exerts a causal influence on the dependent variable, and that occurs at roughly the same time as the manipulation of the independent variable. For instance, during the period between the pretest (time 2) and posttest (time 4) measure of happiness as outlined in Table 1 (b), Congress may have declared a national holiday. This event could have the effect of elevating everyone’s happiness. Consequently, even if the \$1,000 gift had no effect on happiness, researchers would observe an increase in happiness from the pretest to posttest measure. In other words, the effects of the \$1,000 gifts are totally confounded with the effects of the holiday, and both remain reasonable explanations for the change in happiness from time 2 to time 4. That is, a plausible rival explanation for the increase in happiness with an increase in income is that the holiday and not the additional income made people happier.

Maturation effects are changes in subjects that result simply from the passage of time (e.g., growing hungrier, growing older, growing more tired). Simply put, “people change.” To continue with our current example using a weak, preexperimental research design, assume that individuals, as they grow older, increase in happiness owing to their improved styles of coping, increasing acceptance of adverse life events, or the like. If such developmental changes appear tenable, then maturation becomes a plausible rival explanation for why subjects’ happiness increased after receiving the \$1,000 gift. That is, subjects would have displayed an increase in happiness over time even if they had *not* received the \$1,000 gift.

Testing effects are the influences of taking a pretest on subsequent tests. In the current study of income and happiness, pretest measures of happiness allow participants to become familiar with the measures’ content in a way that may have “carryover” effects on later measures of happiness. That is, familiarity with the pretest may make salient certain issues that would not be salient had subjects not been exposed to the pretest. Consequently, it is possible that exposure to the pretest could cause participants to ponder these suddenly salient issues and therefore change their opinions of themselves. For example, people may come to see themselves as happier than they otherwise would have perceived themselves. Consequently, posttest happiness scores would be higher than pretest scores, and this difference need not be due to the \$1,000 gift.

Instrumentation effects are a validity threat that occurs as the result of changes in the way that a variable is measured. For instance, in evaluating the effect of income on happiness, researchers may make pretest assessments with one type of happiness measure. Then, perhaps to take advantage of a newly released measure of happiness, researchers might use a different happiness measure on the posttest. Unless the two measures have exactly parallel forms, however, scores on the pretests and posttests are likely to differ. Accordingly, any observed increase in happiness may be due to the differing tests and not to the \$1,000 gift.

Regression to the mean is especially likely to occur whenever two conditions are present in combination: (1) researchers select subjects who have extreme scores on a pretest measure of the

dependent variable, and (2) the dependent variable is less than perfectly measured (i.e., is less than totally reliable owing to random measurement error). It is a principle of statistics that individuals who score either especially high or low on an imperfectly measured pretest are most likely to have more moderate scores (i.e., regress toward their respective mean) on the posttest. In the social sciences, almost all variables (e.g., happiness) are less than perfectly reliable. Hence, whenever social scientists assign subjects to treatment conditions based on high or low pretest scores, regression to the mean is likely to occur. For example, researchers may believe that those persons who are most unhappy will benefit most from a \$1,000 gift. Therefore, only persons with low pretest scores are allowed into the study. However, low scorers on the pretest are likely to have higher happiness scores on the posttest simply as a result of remeasurement. Under such circumstances, regression to the mean remains a plausible rival explanation for any observed increase in happiness following the \$1,000 gift.

Selection effects are processes that result in different kinds of subjects being assigned to one treatment group as compared to another. If these differences (e.g., sex) affect the dependent variable (e.g., happiness), then selection effects serve as a rival explanation for the assumed effect of the hypothesized causal variable (e.g., income). Because there is not a second group in the one-group pretest-posttest design illustrated here, the design is *not* subject to validity threats due to selection. That is, because the same group receives all treatment conditions (e.g., no gift versus a \$1,000 gift), the characteristics of subjects (e.g., the number of females versus the number of males) remain constant across treatment conditions. Thus, even if females tended to be happier than males, this effect could not explain why an increase in happiness occurred after subjects received the \$1,000 gift.

Mortality effects refer to the greater loss of participants (e.g., due to death or disinterest) in one treatment group compared to another. For instance, in the study of the effects of income on happiness, the most unhappy people are more likely than other subjects to drop out of the study before its completion. Because these dropouts appear in the pretest but not the posttest, the average level of happiness will increase. That is, an increase in happiness would occur even if the

supplementary income had no effect whatsoever. Mortality is *not*, however, a plausible alternative explanation in the current example of a study using the one-group pretest-posttest design. Researchers can simply exclude from the study any subjects who appear in the pretest but not the posttest measure of happiness.

Reverse causal order effects are validity threats due to ambiguity about the direction of a causal relationship; that is, does *X* cause *O*, or does *O* cause *X*? The one-group pretest-posttest design is *not* subject to this internal validity threat. The manipulation of the independent variable (giving the \$1,000 gift) clearly precedes observation of the dependent variable (degree of happiness). In general, where research designs manipulate rather than measure the independent variable, they greatly reduce the threat of reverse causal order.

As an overview, the reader should note that the various threats to internal validity, where plausible, violate the last two of three conditions necessary for establishing a valid causal inference. Recall that the three conditions are: (1) an association between two variables is present; (2) the presumed cause must precede the presumed effect in time; and (3) the association between the two variables cannot be explained by the influence of a “third” variable that may be related to both of them.

Only the violation of the *first* condition is *not* covered by the list of specific threats to internal validity. (But see the later discussion of threats to statistical conclusion validity.) Reverse causal order is a threat to internal validity that violates the *second* condition of causal inference. Furthermore, history, maturation, testing, instrumentation, regression to the mean, selection, and mortality are all threats to internal validity that one can broadly describe as the potential influence of a “third” variable—that is, threats that violate the *third* condition of causal inference. That is, each of these threats represents a specific type of third variable that affects the dependent variable and coincides with the manipulation of the independent variable. In other words, the third variable is *related* to both the independent and dependent variable. Because the third variable affects the dependent variable at the same time that the independent variable is manipulated, it will *appear* that the independent variable causes a change in the dependent variable. But in fact this apparent causal

relation is a *spurious* (i.e., noncausal) by-product of the third variable's influence.

As an illustration, recall how validity threats due to history can produce a spurious correlation between income and happiness. In the example used earlier, Congress declared a national holiday that increased subjects' happiness and coincided with subjects receiving a \$1,000 gift. Hence, the occurrence of a national holiday represents a "third" variable that is related both to income and happiness, and makes it appear (falsely) that income increases happiness.

Research, in its broadest sense, can be viewed as an investigator's attempt to convince the scientific community that a claimed causal relationship between two variables really exists. Clearly, the presence of one or more threats to internal validity challenges the researcher's claim. That is, the more likely a validity threat seems, the less convincing is the investigator's claim.

When confronted with the specific threats to internal validity in field settings, investigators can attempt to modify their research design to control one or more of these threats. The fact that a specific threat is *possible* for a given research design, however, does not mean it is *plausible*. Implausible threats do little to reduce the persuasiveness of researchers' claims. Therefore, the specific design researchers' use should be determined in large part by the specific threats to validity that are considered most plausible.

Furthermore, as noted earlier, each research design has a given number of possible threats to internal validity, and some designs have more possible threats than do other designs. But only a certain number of these threats will be plausible for *the specific set of variables under study*. That is, different sets of independent and dependent variables will carry different threats to internal validity. Thus, researchers may select weaker designs where the plausible threats for a given set of variables are relatively few and not among the possible threats for the given design. Campbell and Stanley (1963) note, for example, that the natural sciences can often use the one-group pretest-posttest design despite its long list of *possible* threats to internal validity. Given the carefully controlled laboratory conditions and focus on variables measuring nonhuman phenomena, *plausible* threats to internal validity are low.

The next section examines some common quasi-experimental designs and plausible threats to internal validity created by a given design. The discussion continues to use the concrete example of studying the relationship between income and happiness. Examples using a different set of variables might, of course, either reduce or increase the number of plausible threats for a given design.

QUASI-EXPERIMENTAL DESIGNS

When researchers have the opportunity to make more than a single pretest and posttest, some form of *time series design* becomes possible. Table 1 (*d*) illustrates the structure of this design. The *O*'s designate a series of observations (measures of happiness) on the same individuals (group 1) over time. The table shows that subjects receive no supplementary income ($X_{\$0}$) through the first two (times 2 and 4) observational periods. Then at time 5 subjects receive the \$1,000 gift ($X_{\$1,000}$). Their subsequent level of happiness is then observed at three additional points (times 6, 8, and 10).

This quasi-experimental design has a number of advantages over the single-group pretest-posttest (preexperimental) design. For instance, by examining the trend yielded by multiple observations prior to providing the \$1,000 gift, it is possible to rule out validity threats due to maturation, testing, and regression to the mean. In contrast, instrumentation could still be a threat to validity, if researchers changed the way they measured happiness—especially for changes occurring just before or after giving the \$1,000 gift. Moreover, artifacts due to history remain uncontrolled in the time series design. For example, it is still possible that some positive event in the broader environment could occur at about the same time as the giving of the \$1,000 gift. Such an event would naturally serve as a plausible alternative explanation for why happiness increased after the treatment manipulation.

In addition to eliminating some threats to internal validity found in the one-group pretest-posttest design, the time series design provides measures of how long a treatment effect will occur. That is, the multiple observations (*O*'s) following the \$1,000 gift allow researchers to assess how long happiness will remain elevated after the treatment manipulation.

In some circumstances, the time series design may not be possible, owing to constraints of time or money. In such cases, other quasi-experimental designs may be more appropriate. Consequently, as an alternative strategy for dealing with some of the threats to internal validity posed by the single-group pretest-posttest (preexperimental) design, researchers may add one or more *comparison groups*.

The simplest multigroup design is the *static-group comparison* (Campbell and Stanley 1963). Table 1 (c) provides an illustration of this design. Here observations are taken from two different groups (G_1 and G_2) at the same point in time. The underlying assumption is that the two groups differ only in the treatment condition (a \$1,000 gift versus no gift) they receive prior to the measure of happiness. In many instances, this is not a safe assumption to make.

The static-group comparison design does reduce some potential threats to internal validity found in the single-group pretest-posttest design; namely, history, testing, instrumentation, and regression to the mean. That is, each of these threats should have *equal* effects on the two experimental groups. Thus, these threats cannot explain why experimental groups differ in posttest happiness.

Conversely, the static-group comparison design adds other potential threats—selection, reverse causal order, and mortality effects—not found in the single-group pretest-posttest design. Indeed, these threats are often so serious that Stanley and Campbell (1963) refer to the static-group comparison, like the single-group pretest-posttest, as a “pre-experimental” design.

Selection effects are generally the most plausible threats to internal validity in the static-group comparison design. That is, in the absence of random assignment, the treatment groups are likely to differ in the type of people they include. For example, researchers might assign poverty-level subjects to the \$1,000 gift versus no gift treatment groups based on physical health criteria. Subjects in poor health would receive the supplementary income; subjects in better health would not. Note, however, that poor health is likely to reduce happiness, and that less healthy—and therefore less happy—people appear in the \$1,000 treatment condition. Hence, it is possible that this selection effect based on physical health could *obscure* the increase in happiness due to the

supplementary income. In other words, even if the \$1,000 gift does have a positive effect on happiness, researchers might make a false causal inference; namely, that supplementary income has *no* effect on happiness.

This result illustrates the point that threats to internal validity are not always ones that refute a claim that a causal effect occurred. Threats to internal validity can also occur that refute a claim that a causal effect did *not* happen. In other words, threats to internal validity concern possible false-negative findings as well as false-positive findings.

The preceding example showed how false-negative findings can result due to selection effects in the static-group comparison. *False-positive* findings can, of course, also occur due to selection effects in this design. Consider, for instance, a situation in which researchers assign subjects to treatment conditions based on contacts with a particular governmental agency that serves the poor. Say that the first twenty subjects who contact this agency on a specific day receive the \$1,000 gift, and the next twenty contacts serve as the no-gift comparison group. Furthermore, assume that the first twenty subjects that call have extroverted personalities that made them call early in the morning. In contrast, the next twenty subjects are less extroverted and thus call later in the day. If extroverted personality also produces higher levels of happiness, then the group receiving the \$1,000 gift would be happier than the no-gift comparison group even before the treatment manipulation. Accordingly, even if supplementary income has no effect on happiness, it will appear that the \$1,000 gift increased happiness. In other words, extroverted personality is a “third” variable that has a positive causal effect on both level of supplementary income and happiness. That is, the more extroversion, the more supplementary income; and the more extroversion, the more happiness. These causal relationships therefore make it appear that there is a positive, causal relationship between supplementary income and happiness; but in fact this latter correlation is *spurious*.

Reverse causal order effects are another potential threat to internal validity when researchers use the static-group comparison design. Indeed, reverse causal order effects are really just a special case of selection effects. More specifically,

reverse causal order effects will occur whenever the dependent variable is also the “third” variable that determines who is assigned to which treatment groups.

By substituting happiness for extroversion as the “third” variable in the preceding example, one can demonstrate how this reverse causal order effect could occur. Recall that subjects who contacted the government agency first were the most extroverted. Assume now, instead, that the earliest callers were happier people than those who called later (because unhappy people are more likely to delay completing tasks). Under these conditions, then, prior levels of happiness comprise a “third” variable that has a positive causal effect on both level of supplementary income and subsequent happiness. That is, those subjects who are initially happier are more likely to receive supplementary income; and those subjects who are initially happier are more likely to experience subsequent (posttest) happiness. These causal relationships hence make it appear that there is a positive, causal association between supplementary income and happiness. In fact, however, this correlation is spurious. Indeed, it is not supplementary income that determines happiness; it is happiness that determines supplementary income.

Mortality is another possible threat to internal validity in the static-group comparison design. Even if the treatment groups have essentially identical characteristics before the manipulation of the independent variable (i.e., no selection effects), differences between the groups can occur as a consequence of people dropping out of the study. That is, by the time researchers take posttest measures of the dependent variable, the treatment groups may no longer be the same.

For example, in the study of income and happiness, perhaps some individuals in the no-gift group hear that others are receiving a \$1,000 gift. Assume that among those people, the most likely to drop out are those who have a “sour” disposition, that is, those who are likely to be the most unhappy members of the group in general. Consequently, the no-gift comparison group will display a higher posttest measure of happiness than the group would have if all members had remained in the study. Thus, even if the \$1,000 gift increases happiness, the effect may be obscured by the corresponding, “artificial” increase in happiness

in the no-gift comparison group. In other words, mortality effects may lead researchers to make a false causal inference; namely, that there isn’t a causal relationship between two variables, when in fact there is.

One of the most common quasi-experimental designs is the *nonequivalent control group design*. This design is an elaboration of the static-group comparison design. The former is a stronger design than the latter, however, because researchers administer pretests on all groups prior to manipulating the independent variable. Table 1 (*e*) illustrates this design.

A major advantage of the pretests is that they allow researchers to *detect the presence* of selection effects. Specifically, by comparing pretest scores for the different treatment groups before the manipulation of treatment conditions, it is possible to discern whether the groups are initially different. If the groups differ at the time of the pretest, any observed differences at the posttest may simply be a reflection of these preexisting differences.

For instance, in the income and happiness study, if the group receiving the \$1,000 gift is happier than the no-gift comparison group at the time of the pretest, it would not be surprising for this group to be happier at posttest, even if supplementary income had no causal effect. The point is that the nonequivalent control group design, unlike the static-group comparison design, can test whether this difference is present. If there is no difference, then researchers can safely argue that selection effects are not a threat to internal validity in their study.

The inclusion of pretest scores also permits the nonequivalent control group design to detect the presence or absence of other threats to internal validity not possible using the static-group comparison design—namely, mortality and reverse causal order. Recall that threats due to reverse causal order are a special subset of selection effects. Thus, the ability of the nonequivalent control group design to detect selection effects means it should also detect reverse causal order effects. Selection effects occur as a consequence of differences in pretest measures of the dependent variable. Therefore, in the present example, differences between groups in pretest happiness would

indicate the possibility of reverse causal order effects. In other words, the amount of pretest happiness determined the amount of supplementary income subjects received (\$1,000 gift versus no gift), rather than the converse, that the amount of supplementary income determined the amount of posttest happiness.

Furthermore, the pretest scores of the nonequivalent control group design also allow assessment of mortality effects. Regardless of which subjects drop out of which treatment condition, the researcher can examine the pretest scores for the remaining subjects to ensure that the different treatment groups have equivalent initial scores (e.g., on happiness).

In sum, the nonequivalent control group design is able to reduce all the threats to internal validity noted up to this point. Unfortunately, it is unable to detect one threat to internal validity not previously covered—*selection by maturation interactions*. (For a more complete list of interactions with selection, see Cook and Campbell 1979, and Shadish et al. in preparation.) This threat occurs whenever the various treatment groups are maturing—growing more experienced, tired, bored, and so forth—at different rates.

For example, consider a situation in which the pretest happiness of the group receiving no gift is as high as the group receiving the \$1,000 gift. Moreover, the pretest measures occur when both groups are in stimulating environments, in contrast to the boring environments for the posttest measures. Assume now that there is a greater proportion of people who become bored easily in the no-gift group as compared to the \$1,000-gift group. That is, there is a selection effect operating that results in different kinds of people in one group compared to the other. But this difference doesn't manifest itself until a nonstimulating environment triggers the maturational process that generates increasingly higher levels of boredom. The differential rates at which boredom occurs in the two groups result in higher levels of boredom and corresponding unhappiness in the no-gift as compared to the \$1,000-gift group. In other words, the group receiving the \$1,000 gift will display higher levels of posttest happiness than the no-gift

group, even if supplementary income has no effect on happiness.

The *multiple time series design* incorporates aspects of both the nonequivalent control group and the time series designs. Table 1 (f) illustrates the results of this combination. By extending the number of pretest and posttest observations found in the nonequivalent control group design, the multiple time series design can detect selection-maturation interactions. For instance, if differential reactions to boredom explain why the group receiving the \$1,000 gift has higher happiness than the no-gift group, then we should expect to see these differences in at least some of the additional pretest measures (assuming that some of these additional group comparisons occur in nonstimulating environments). We would also expect the differential reaction to boredom to manifest itself in the additional posttest measures of the multiple time series design. That is, whenever researchers take posttest measures in stimulating environments, they should observe no group differences. Conversely, whenever researchers take posttest measures in nonstimulating environments, they should observe higher happiness among the group receiving the \$1,000 gift.

Furthermore, by adding a second group to the original, single-group time series, the multiple time series reduces the threat of history that is a major problem with the single-group design. Events (e.g., national holidays) that coincide with the manipulation of the independent variable (e.g., \$1,000 gift versus no gift) should have equal impacts on each group in the analysis.

By incorporating multiple groups with pretests and posttests, the multiple time series and nonequivalent control group designs can be effective at reducing a long list of internal validity threats; but in order to actually reduce a number of these threats, researchers must assume that the different treatment groups are functionally equivalent prior to manipulating the independent variable. Pretest scores allow researchers to detect, at least in part, whether this condition of equivalence is present; but what if the groups are not initially equivalent? Under these conditions, researchers may attempt

to equate the groups through “matching” or other, “statistical” adjustments or controls (e.g., analysis of covariance). However, matching is never an acceptable technique for making groups initially equivalent (see Nunnally 1975; Kidder and Judd 1986). And statistical controls are a better but still less-than-desirable procedure for equating groups at the pretest (see Lord 1967; Dwyer 1983; Rogosa 1985).

In sum, an overview of pre- and quasi-experimental designs using multiple groups indicates the importance of establishing the equivalence of the groups through pretest measures. Further, researchers should try to obtain as many additional observations as possible both before and after manipulating the treatments. When groups are nonequivalent at the outset, it is extremely difficult to discern whether treatment manipulations have a causal effect.

In certain field settings, however, ethical considerations may *mandate* that groups be nonequivalent at the outset. That is, researchers must assign subjects to certain treatment conditions based on who is most “needy” or “deserving.” If the dependent variable (e.g., happiness) is associated with the criterion (e.g., physical health) that determines who is most needy or deserving, then the experimental groups will not display pretest equivalence (e.g., the people with the worst health and hence lowest pretest happiness must be assigned to the group receiving the \$1,000 gift).

Fortunately, the *regression-discontinuity design* (Thistlethwaite and Campbell 1960; Cook and Campbell 1979) often allows researchers to make relatively unambiguous interpretation of treatment effects, even where groups are not initially equivalent. Indeed, evidence indicates that this design, when properly implemented, is *equivalent* to a *randomized experiment* in its ability to rule out threats to internal validity (Cook and Shadish 1994; Shadish et al. in preparation).

To continue with the example of income and happiness, researchers may feel compelled to give the \$1,000 gift to those individuals with the poorest health. The investigators would therefore begin by developing a scale of “need” in which

participants below a certain level of physical health receive the gift and those above this cutting point do not. This physical health scale constitutes the “pseudo”-pretest necessary for the regression-discontinuity design. The usual posttest measures of the dependent variable—happiness—would follow the manipulation of the no-gift versus the \$1,000-gift treatment conditions. Researchers would then regress posttest happiness measures on “pretest” measures of physical health. This regression analysis would include the calculation of separate regression lines for (1) those subjects receiving the \$1,000 gift and (2) those subjects not receiving it.

Figure 1 provides an illustration of the results using the regression-discontinuity design. (The structure of the design does not appear in Table 1 due to its relative complexity.) If the \$1,000 gift has a discernible impact on happiness, a “discontinuity” should appear in the regression lines at the cutting point for “good” versus “poor” health. An essential requirement for the regression-discontinuity design is a clear cutting point that defines an unambiguous criterion (e.g., degree of physical health) by which researchers can assign subjects to the treatment conditions. It is the clarity of the decision criterion, not its content, that is important.

An interesting characteristic of the regression-discontinuity design is that it works even if the decision criterion has no effect on the outcome of interest (e.g., happiness). Indeed, as the variable that forms the decision criterion approaches a condition in which it is totally unrelated to the outcome, the decision criterion becomes the functional equivalent of *assigning subjects randomly* to treatment conditions (Campbell 1975). Even where the criterion is strongly related to the outcome, the regression-discontinuity design, when properly implemented, can still approximate a randomized experiment in reducing threats to internal validity.

There are, however, several threats to internal validity that can occur in using the regression-discontinuity design (hence the use of the above qualifier: “when properly implemented”). One threat emerges when the relationship between the pseudo-pretest measure (e.g., physical health) and

Figure 1. Regression-Discontinuity Design Showing Treatment Effect of Income on Happiness (Dashed line indicates projected happiness scores for group 1 if the \$1,000 treatment had no effect on happiness.)

the posttest measure (e.g., happiness) does not form a linear pattern. In fact, a curvilinear relationship near the cutting point may be indistinguishable from the discontinuity between the separate regression lines. Moreover, another threat to internal validity arises if the investigators do not strictly adhere to the decision criterion (e.g., if they feel sorry for someone who is close to qualifying for the \$1,000 and thus gives that person the “benefit of the doubt”). Additionally, if only a few people receive a given treatment condition (e.g., if

only a few \$1,000 awards can be made, for financial reasons), the location of the regression line may be difficult to estimate with any degree of accuracy for that particular treatment condition. Accordingly, researchers should include relatively large numbers of subjects for all treatment conditions.

In summary, quasi-experimental designs allow researchers to maintain at least some control over how and when they manipulate the independent variable, but researchers lose much control over who receives specific treatment conditions (i.e.,

the designs do not permit random assignment). Quasi-experimental designs differ in how closely they approximate the power of randomized experiments to make strong causal inferences. As a general rule, the more observations quasi-experimental designs add (i.e., the more *O*'s, as depicted in the diagrams of Table 1), the more the designs are able to reduce threats to internal validity.

NONEXPERIMENTAL DESIGNS

In contrast to quasi-experimental designs, *nonexperimental designs do not manipulate* the independent variable. Thus, researchers have no control over who falls into which category of the independent variable when there is a change from one to another category of the independent variable, or what content the various levels of the independent variable will contain. Rather than serving as an agent that actively changes (manipulates) the independent variable, the researcher must be content to passively observe (measure) the independent variable as it naturally occurs. Hence, some social scientists also refer to nonexperimental designs as *passive-observational designs* (Cook and Campbell 1979).

When researchers can only measure rather than manipulate the independent variable, threats to internal validity increase greatly. That is, reverse causal order effects are much more likely to occur. There is also a much greater probability that some "third" variable has a causal effect on both the independent and the dependent variables, therefore producing a spurious relationship between the latter two variables.

To illustrate these points, consider the most widely used research design among sociologists; namely, the static-group comparison design with measured rather than manipulated independent variables—or what we will refer to here as the *passive static-group comparison*. Table 1 depicts the structure of this nonexperimental, cross-sectional design. Researchers generally combine this design with a "survey" format, in which subjects self-report their scores on the independent and dependent variables (e.g., report their current income and happiness).

Note that the structure of this nonexperimental design is basically the same as the static-group

comparison design found in Table 1 (c). To better capture the various levels of naturally occurring income, however, the diagram in Table 1 expands the number of categories for income from two *manipulated* categories (\$1,000 gift versus no gift) to three *measured* categories (high, medium, and low personal income). Furthermore, whereas the original static-group design manipulated income *before* measuring happiness, the passive static-group design measures both personal income and happiness at the *same time* (i.e., when subjects respond to the survey). Consequently, the temporal ordering of the independent and dependent variable is often uncertain.

Indeed, because researchers do not manipulate the independent variable, and because they measure the independent and dependent variables at the same time, the threat of reverse causal order effects is particularly strong in the passive static-group comparison design. In the present example, it is quite possible that the amount of happiness a person displays is a determinant of how much money that person will subsequently make. That is, happiness causes income rather than income causes happiness. What is even more likely is that both causal sequences occur.

Additionally, the passive static-group comparison design is also especially susceptible to the threat that "third" variables will produce a spurious relationship between the independent and dependent variables. For example, it is likely that subjects who fall into different income groupings (high, medium, and low) also differ on a large number of other (selection effect) variables. That is, the different income groups are almost certainly nonequivalent with regard to characteristics of subjects in addition to income. One would expect, for instance, that the higher-income groups have more education, and that education is associated with greater happiness. In other words, there is a causal link between education and income, and between education and happiness. More specifically, higher education should produce greater income, and higher education should also produce greater happiness. Hence, education could produce a spurious association between income and happiness.

As noted earlier, researchers can attempt to equate the various income groups with regard to

third variables by making statistical adjustments (i.e., controlling for the effects of the third variables). But this practice is fraught with difficulties (again, see Lord 1967; Dwyer 1983; Rogosa 1985).

It is especially sobering to realize that a design as weak as the passive static-group comparison is so widely used in sociology. Note, too, that this design is a substantially weaker version of the static-group comparison design that Campbell and Stanley (1963) considered so weak that they labeled it “preexperimental.” Fortunately, there are other nonexperimental, longitudinal designs that have more power to make valid causal inferences. Most popular among these designs is the *panel design*. (For additional examples of passive longitudinal designs, see Rogosa 1988; Eye 1990.)

Table 1 depicts the structure of this longitudinal survey design. It is very similar to the nonequivalent control group design in Table 1 (e). It differs from the quasi-experimental design, however, because the independent variable is measured rather than manipulated, and the independent and dependent variable are measured at the same time.

In its simplest, and weaker, two-wave form (shown in Table 1), the panel design can address at least some threats due to reverse causal order and third variables associated with the independent and dependent variable. (This ability to reduce threats to internal validity is strengthened where investigators include three and preferably four or more waves of measures.) The most powerful versions of the panel design include data analysis using structural equation modeling (SEM) with multiple indicators (see Kessler and Greenberg 1981; Dwyer 1983; and for a more general introduction to SEM, see Kline 1998). Simultaneous equations involve statistical adjustments for reverse causal order and causally linked third variables. Thus, the standard admonishments noted earlier about using statistical control techniques apply here too.

Finally, Cook and his associates (Cook and Shadish 1994; Shadish et al. in preparation) have noted a real *advantage* of nonexperimental designs over randomized experiments. Specifically, experimental designs lend themselves to studying causal linkages (i.e., “descriptions” of causal conditions) rather than the *processes* accounting

for these linkages (i.e., explanations of causal effects). In contrast, nonexperimental designs lend themselves to using causal (path) modeling to study “process”—that is, intervening variables that “mediate” the effect of the independent on the dependent variable. The field of causal modeling using nonexperimental designs has developed at a tremendous pace, dominated by the very flexible and sophisticated data analytic procedure of SEM (Kline 1998).

RANDOMIZED EXPERIMENTS REVISITED

The great problems that nonexperimental designs encounter in making causal inferences help illustrate the increased power researchers obtain when they move from these passive-observational to quasi-experimental designs. But no matter how well a quasi-experimental design controls threats to internal validity, there is no quasi-experimental design that can match the ability of randomized experiments to make strong causal inferences. Indeed, threats to internal validity are greatly reduced when researchers are able to randomly assign subjects to treatment groups. Therefore, the value of this simple procedure cannot be overstated.

Consider the simplest and most widely used of all randomized experiments, the *posttest-only control group design* (Campbell and Stanley 1963), as depicted in Table 1 (a). Note that it is similar in structure to the very weak, preexperimental, static-group comparison design in Table 1 (c). These two designs differ primarily with regard to whether they do or do not use *random assignment*.

The addition of random assignment buys enormous power to make valid causal inferences. With this procedure, and the manipulation of an independent variable that temporally precedes observation of the dependent variable, reverse causal order effects are impossible. Likewise, with the addition of random assignment, other threats to internal validity present in the static-group comparison design dissipate. Specifically, selection effects are no longer a major threat to internal validity. That is, selection factors—different kinds of people—should appear approximately evenly distributed between categories of the independent variable (e.g., \$1,000 gift versus no gift). In

other words, the different groups forming the treatment conditions should be roughly equivalent prior to the treatment manipulation. Further, given this equivalence, threats due to selection-maturation interactions are also reduced.

Conversely, given that pretest measures of the dependent variable (e.g., happiness) are absent, mortality effects remain a potential threat to internal validity in the posttest-only control group design. Of course, for mortality effects to occur, different kinds of subjects have to drop out of one experimental group as compared to another. For example, in the study of income on happiness, if certain kinds of subjects (say, those who are unhappy types in general) realize that they are not in the group receiving the \$1,000 gift they may refuse to continue. This situation could make it appear (falsely) that people receiving the \$1,000 gift are less happy than those not receiving the gift.

Naturally, the probability that *any* subjects drop out is an increasing function of how much time passes between manipulation of treatment conditions and posttest measures of the dependent variable. The elapsed time is generally quite short for many studies using the posttest-only control group design. Consequently, in many cases, mortality effects are not a plausible threat.

In sum, one may conclude that random assignment removes, at least in large part, all of the major threats to internal validity. (But see Cook and Campbell 1979, Cook and Shadish 1994, and Shadish et. al. in preparation for some additional qualifications.)

Two more points are noteworthy with respect to random assignment. First, it is important to realize that this procedure *does not ensure* that third variables that might influence the outcome will be evenly distributed between groups in any particular experiment. For instance, random assignment does not ensure that the average level of education will be the same for the group receiving the \$1,000 gift as for the group receiving no gift. Rather, random assignment allows researchers to *calculate the probability* that third variables (such as education) are a plausible alternative explanation for an apparent causal relationship (e.g., between supplementary income and happiness). Researchers are generally willing to accept that a causal relationship between two variables is real if the relationship could have occurred by chance—that is, due

to the *coincidental* operation of third variables—less than one time out of twenty.

Some researchers add pretests to the posttest-only control group design in order to evaluate the “success” of the random assignment procedure, and to add “statistical power.” According to Nunnally (1975), however, the use of a pretest is generally not worth the attendant risks. That is, the pretest may sensitize subjects to the treatment conditions (i.e., create a treatment-testing interaction). In other words, the effect of the independent variable may not occur in other situations where there are no pretest measures. Thus, any gain from pretest information is likely to be offset by this threat to “construct validity.” (For an example of a treatment-testing interaction, see the section on threats to construct validity, below).

Second, random *assignment* of subjects is different from random *selection* of subjects. Random assignment means that a subject has an equal probability of entry into each treatment condition. Random selection refers to the probability of entry into the study as a whole. The former issue bears on internal validity (i.e., whether observed outcomes are unambiguously due to the treatment manipulation); the latter is an issue of external validity (i.e., the extent to which the results of the study are generalizable).

THREATS TO EXTERNAL VALIDITY

Whereas internal validity refers to whether or not a treatment is effective, *external validity* refers to the conditions under which the treatment will be effective. That is, to what extent will the (internally valid) causal results of a given study apply to different people and places?

One type of threat to external validity occurs when certain treatments are likely to be most effective on certain kinds of people. For example, researchers might find that a \$1,000 gift has a strong effect on happiness among a sample of young adults. Conversely, a study of extremely elderly persons might find that the \$1,000 has no effect on happiness (say, because very old people are in general less stimulated by their environment than are younger age groups). Cook and Campbell (1979) label this external validity threat an *interaction between selection factors and treatment*.

Researchers sometimes mistakenly assume that they can overcome this threat to external validity by *randomly selecting* persons from the population across which they wish to generalize research findings. Random samples do not, however, provide appropriate tests of whether a given cause-effect finding applies to different kinds of people. Obtaining a random sample of, say, the U.S. population would not, for instance, reproduce the above (hypothetical) finding that a \$1,000 gift increases happiness among younger but not older people. Combining younger and older persons in a representative sample would only lead to an averaging or “blending” of the strong effect for youths with the no-effect result for the elderly. In fact, the resulting finding of a “moderate” effect would not be an accurate statement of income’s effect on happiness for either the younger or older population.

Including younger and older persons in a random sample would only increase external validity if the researchers *knew* to provide separate analyses for young and old—among an infinite variety of *possible* human characteristics that researchers might choose to do subsample analyses on (e.g., males and females). But if researchers suspected that the treatment might interact with age, then they could simply make sure that their nonrandomly selected, “convenience” sample contained sufficient numbers of both youths and elderly to do separate analyses on each age group.

Additionally, threats to external validity occur because certain treatments work best in certain settings. Giving \$1,000 to a person at a shopping mall may increase their happiness substantially compared to the same gift given to someone stranded on a desert island with nowhere to spend the money. Cook and Campbell (1979) label this external validity threat an *interaction between treatment and setting*. Given that quasi-experimental designs are most often located in “real-life,” field settings, they are somewhat less susceptible to this threat than are randomized experiments—which most often occur in “artificial,” laboratory settings.

Note that threats to external validity are concerned with restricting cause-effect relationships to particular persons or places. Therefore, the best procedure for reducing these restrictions is to *replicate* the findings on different persons and in different settings—either within a single study or

across a series of studies (Cook and Campbell 1979; Cook and Shaddish 1994).

THREATS TO CONSTRUCT VALIDITY

Construct validity refers to the accuracy with which researchers manipulate or measure the construct intended rather than something else (Cook and Campbell 1979; and for updates, see Cook and Shaddish 1994; and Shaddish et al. in preparation). Thus, for example, investigators might establish that their manipulation of a variable labeled “income” does indeed have a causal effect on their measure of the outcome labeled “happiness.” That is, the researchers have avoided plausible threats to internal validity and, consequently, have presented a convincing claim for a cause-and-effect relationship. Critics might question, however, whether the manipulation labeled “income” and the measure labeled “happiness” do in fact represent the concepts that the investigators claim they have manipulated and measured, respectively.

For instance, in providing supplementary income to selected subjects, researchers might also have manipulated, say, the perception that the researchers really are concerned about the welfare of the subjects. It may be subjects’ perceptions of this “caring attitude,” and not an increase in “economic well-being,” that produced the effect the \$1,000 gift had on happiness. In other words, investigators were manipulating a dimension in addition to the economic dimension they intended to manipulate.

Likewise, in asking subjects to answer a questionnaire that purportedly measures “happiness,” researchers may not be measuring happiness but rather the degree to which subjects will respond in socially desirable ways (e.g., some subjects will respond honestly to questions asking how depressed they are, and other subjects will hide their depression).

Cook and Campbell (1979) provide an extensive list of threats to construct validity. The description of these threats is rather abstract and complicated. Hence, the following discussion includes only a few concrete examples of potential threats. For a more complete list and discussion of these threats, the interested reader should consult the original article by Cook and Campbell, as well

as the update to their book (Shadish et al. in preparation) and other volumes on the construct validity of measures and manipulations (e.g., Costner 1971; Nunnally and Bernstein 1994).

One type of threat to construct validity occurs in research designs that use pretests (e.g., the nonequivalent control group design). Cook and Campbell (1979) label this threat an *interaction of testing and treatment*. This threat occurs when something about the pretest makes participants more receptive to the treatment manipulation. For example, in the study of income and happiness, the pretest may make salient to participants that “they don’t have much to be happy about.” This realization may, in turn, make subjects more appreciative and thus especially happy when they later receive a \$1,000 gift. In contrast, the \$1,000 gift might have had little or no causal impact on happiness if subjects were not so sensitized, that is, were not exposed to a pretest. Accordingly, it is the combination of the pretest and \$1,000 gift that produces an increase in happiness. Neither condition alone is sufficient to create the causal effect. Consequently, researchers who use pretests must be cautious in claiming that their findings would apply to situations in which pretests are not present. Because quasi-experimental designs are dependent on pretest observations to overcome threats to internal validity (i.e., to establish the initial equivalence of the experimental groups), researchers cannot safely eliminate these measures. Thus, to enhance the construct validity of the manipulation, researchers should strive to use as unobtrusive measures as possible (e.g., have trained observers or other people familiar with a given subject secretly record the subject’s level of happiness).

Another set of potential threats to construct validity concerns what Campbell and Stanley (1963) describe as *reactive arrangements*. Cook and Campbell (1979) have subsequently provided more specific labels for these threats: *hypothesis-guessing within experimental conditions*, *evaluation apprehension*, and *experimenter expectancies* (see also Rosenthal and Rosnow 1969). Threats due to reactive arrangements result as a consequence of the participants’ knowing they are in a study, and therefore behaving in a way that they might not in more natural circumstances. With regard to this phenomena, Orne (1962) used the term “demand characteristics” to refer to the totality of cues that affect a

subject’s response in a research setting in the sense that certain characteristics “demand” certain behaviors. For instance, subjects receiving the \$1,000 gift may guess the hypothesis of the study when they are subsequently asked to respond to questions about their state of happiness. Realizing that the study may be an attempt to show that supplementary income increases happiness, participants may try to be “good subjects” and confirm the experimental hypothesis by providing high scores on the happiness questionnaire. In other words, the treatment manipulation did in fact produce an increase in the assumed *measure* of “happiness,” but the measure was actually capturing participants’ willingness to be “good subjects.”

A classic example of reactive arrangements is the Hawthorne effect (see Lang 1992 for a more comprehensive review). The Hawthorne effect was named for a series of studies conducted between 1924 and 1932 at the Hawthorne Works of the Western Electric Company near Chicago (Mayo 1933; Roethlisberger and Dickson 1939). Researchers attempted to determine, among other things, the effects of illumination on worker productivity. The results were puzzling. There was no clear relationship between illumination and worker performance. Every change, even seemingly adverse changes in which normal lighting was reduced by 50 to 70 percent resulted in increased productivity. In addition, productivity often remained high even after workers were returned to their original working conditions. Even more confusing was the fact that not all the studies reported increased productivity. In some studies, depending upon the factors being manipulated, the effect was even reversed, with workers apparently deliberately reducing their output.

The three most common explanations for the Hawthorne effect are: (1) subjects in studies respond to special attention; (2) awareness of being in a study affects subjects’ performance; and (3) subjects react to the novelty of certain aspects of the research procedures (Lang 1992). Subsequent research has not supported any of these explanations conclusively (Adair et al. 1989). Nor is there widespread evidence of the Hawthorne effect in either experimental or field settings (Cook and Campbell 1979). What is clear, however, is that employees, within organizations, are part of social systems that can affect behavior in research settings. Indeed, the Hawthorne studies provided

impetus to the development of the new field of “organizational behavior,” which has strong links to sociology.

No widely accepted model of the processes involved in subject reactivity presently exists. But to reduce threats to construct validity due to reactive arrangements, researchers may attempt, where feasible, to disguise the experimental hypothesis, use unobtrusive measures and manipulations, and keep both the subject and the person administering the treatments “blind” to who is receiving what treatment conditions. These disguises are generally easier to accomplish in the naturally occurring environments of quasi-experimental designs than in the artificial settings of laboratory experiments. Finally, there are additional, sophisticated structural equation modeling procedures for discerning where reactive arrangements may be present in a study, and for making “statistical adjustments” to correct for the bias that these threats would otherwise introduce (Blalock 1985).

THREATS TO STATISTICAL CONCLUSION VALIDITY

Before researchers can establish whether an independent variable has a causal effect on the dependent variable, they must first establish whether an *association* between the two variables does or does not exist. *Statistical conclusion validity* refers to the accuracy with which one makes inferences about an association between two variables—without concern for whether the association is causal or not (Cook and Campbell 1979; Shadish et al. in preparation). The reader will recall that an association between two variables is the first of three conditions necessary to make a valid causal inference. Thus, statistical conclusion validity is closely linked to internal validity. To put it another way, statistical conclusion validity is a necessary but not sufficient condition for internal validity.

Threats to statistical conclusion validity concern either one of two types of errors: (1) inferring an association where one does not exist (described as a “Type I error,” or (2) inferring no association where one does exist (described as a “Type II error”). Researchers ability to avoid Type II errors depends on the power of a research design to uncover even weak associations, that is, the power

to avoid making the mistake of claiming an association is due to “chance” (is statistically insignificant) when in fact the association really exists. Type II errors are more likely to occur the lower the probability level that researchers set for accepting an association as being statistically significant; the smaller the sample size researchers use; the less reliable their measures and manipulations; and the more random error introduced by (1) extraneous factors in the research setting that affect the dependent variable, and (2) variations among subjects on extraneous factors that affect the dependent variable (Cook and Campbell 1979).

Investigators can reduce Type II errors (false claims of no association) by: (1) setting a higher probability level for accepting an association as being statistically significant (e.g., $p.05$ instead of $p.01$); (2) increasing the sample size; (3) correcting for unreliability of measures and manipulations (see Costner 1971); (4) selecting measures that have greater reliability (e.g., using a ten-item composite measure of happiness instead of a single-item measure); (5) making treatment manipulations as consistent as possible across occasions of manipulation (e.g., giving each subject the \$1,000 gift in precisely the same manner); (6) isolating subjects from extraneous (outside) influences; and (7) controlling for the influence of extraneous subject characteristics (e.g., gender, race, physical health) suspected to impact the dependent variable (Cook and Campbell 1979).

Type I errors (inferring an association where one does not exist) are more likely the higher the probability level that researchers set for accepting an association as being statistically significant, and the more associations a researcher examines in a given study. The latter error occurs because the more associations one includes in a study, the more associations one should find that are statistically significant “just by chance alone.” For example, given 100 associations and a probability level of $.05$, one should on the average find 5 associations that are statistically significant due to chance.

Researchers can reduce threats of making Type I errors by setting a lower probability level for statistical significance, particularly when examining many associations between variables. Of course, decreasing Type I errors increases the risk of Type II errors. Hence, one should set lower probability

levels in conjunction with obtaining reasonably large samples—the latter strategy to offset the risk of Type II errors.

Research designs vary greatly in their ability to implement strategies for reducing threats to statistical conclusion validity. For example, very large sample sizes (say, 500 subjects or more) are generally much easier to obtain for nonexperimental designs than for quasi-experimental or experimental designs. Moreover, experimental designs generally occur in laboratory rather than naturally occurring settings. Thus, it is easier for these designs to control for extraneous factors of the setting (i.e., random influences of the environment). Additionally, experimental designs are generally better able than quasi-experimental designs to standardize the conditions under which treatment manipulations occur.

SUMMARY AND CONCLUSIONS

Quasi-experimental designs offer valuable tools to sociologists conducting field research. This article has reviewed various threats that researchers must overcome when using such designs. In addition, to provide a context in which to evaluate the relative power of quasi-experimental designs to make valid causal inferences, this article also reviewed examples of experimental and nonexperimental designs.

It is important to note that the quasi-experimental designs described here are merely illustrative; they are representative of the types of research designs that sociologists might use in field settings. These designs are not, however, exhaustive of the wide variety of quasi-experimental designs possible. (See Campbell and Stanley 1963, Cook and Campbell 1979, and Shaddish et al. in preparation, for more extensive reviews.) In fact, great flexibility is one of the appealing features of quasi-experimental designs. It is possible literally to combine bits and pieces from different standard designs in order to evaluate validity threats in highly specific or unusual situations. This process highlights the appropriate role of research design as a *tool* in which the specific research topic dictates what design investigators should use. Unfortunately, investigators too often use a less appropriate design for a specific research topic simply because they are most familiar with that design. When thoughtfully constructed, however, quasi-experimental designs can provide researchers with

the tools they need to explore the wide array of important topics in sociological study.

RACE

The study of race and race relations has long been a central concern of sociologists. The assignment of individuals to racial categories profoundly affects the quality and even the length of their lives. These assignments are ostensibly made on the basis of biological criteria, such as skin color, hair texture, and facial features. Yet the biological meaning of race is so unclear that many social and natural scientists argue that *race*, as a biological phenomenon, does not exist. Others take the position that while different races exist, extensive interbreeding in many societies has produced large numbers of people of mixed ancestry. The assignment of these people to racial categories depends on social, rather than on biological, criteria. Thus the social consequences of biologically inherited traits is the fundamental issue of the sociological study of race.

BIOLOGICAL CONCEPTIONS OF RACE

While the terms *race* and *ethnicity* are often used interchangeably, social scientists assign them distinct meanings. Scholars differ on the precise definition of ethnicity, but these definitions usually include some or all of the following criteria. First, ethnic groups are extended kinship groups, although kinship may be defined loosely, as based on a common homeland rather than common ancestry. Second, coethnics share a distinctive culture, marked by differences ranging from language and religion to styles of dress or cooking. A

distinctive culture need not be a matter of everyday practice, however. It may be primarily symbolic, as when a group's traditional language is no longer widely used, or its religious observance is confined to holidays. Third, an ethnic group shares a common history, in which key events such as immigration, colonization, and the like form a sense of collective memory. Finally, an ethnic group is marked by self-consciousness, in that its members see themselves as a people, and are seen as such by others (Cornell and Hartmann 1998).

For most of human history, ethnic groups living in close proximity did not differ significantly in physical appearance. Thus the observable biological differences associated with *race* were not used to distinguish friend from foe, and interracial antagonisms were virtually unknown. The rapid, long-distance migration required to bring members of different racial groups together is a comparatively recent phenomenon that was accelerated by trade and the large-scale European exploration and colonial expansion of the sixteenth through the nineteenth centuries (van den Berghe 1981). It was also during this period that Western science assumed a central role in the attempt to understand the natural and social worlds. Thus, as Europeans became aware of peoples who differed from them in culture and appearance, the concept of race entered the popular and scientific vocabularies as a means of classifying previously unknown groups.

Not content merely to classify people into racial groups, nineteenth- and early-twentieth-century scientists attempted to sort these groups into

a hierarchy. Darwin's theory of evolution, which holds that species are engaged in a struggle for existence in which only the fittest will survive, was gaining widespread acceptance during this period. Herbert Spencer, William Graham Sumner, and other early social theorists extended this evolutionary argument, suggesting that different social groups, including races, were at different states of evolution; the more advanced groups were destined to dominate groups less "fit." This idea, called *social Darwinism* (which Darwin himself did not support), provided justification for European imperialism and for America's treatment of its racial minorities.

Building on the notion that some races were at a more advanced stage of evolution than others, a number of scientists tried to measure differences between the races, especially in the area of intelligence. The first intelligence test was developed by Alfred Binet and Theodore Simon in 1905. Modified versions of this test were administered to approximately one million American soldiers in World War I, and the results were used to argue that there were large, genetically determined differences in intelligence between blacks and whites. Such a conclusion implied that blacks could not benefit from education to the extent that whites could; these findings were then used as a justification for the inferior education made available to blacks.

Binet himself rejected the notion that intelligence was a fixed quantity determined by heredity, or that intelligence could be measured with the kind of precision claimed by other intelligence testers, especially in the United States. Furthermore, other scholars demonstrated that the early tests were heavily biased against members of certain class, ethnic, and racial groups, including blacks. While the *average* scores of blacks have tended to fall below the average scores of whites, greater variation occurs within each group than between the two groups; that is, many blacks outscore many whites.

Charles Murray and Richard Herrnstein argue in *The Bell Curve* (1994) that much of the gap between black and white average scores can be attributed to heredity, rather than to environmental influences. These writers use an extensive array of studies on race and intelligence to support their claim. Yet their methods and conclusions have

been roundly attacked by leading scholars in the field, some of whom contend that intelligence is multidimensional, and cannot therefore be summarized in a single test score. Others point out that since intelligence tests measure academic achievement rather than innate potential, the impoverished background and substandard education of some African Americans offers a reasonable explanation for their lower average scores. Research has repeatedly failed to demonstrate that racial groups differ in terms of their innate capacity for learning. Today, therefore, the vast majority of social scientists reject the idea that any one race is superior in intelligence or any other ability, at least to the extent that such abilities are determined by heredity. (For interesting accounts of the race-intelligence controversy, see Gould 1981; Fraser 1995.)

Controversy continues also on the subject of race itself. In the nineteenth century the concept was defined quite loosely, and the idea was widely held that people of similar appearance but different nationalities constituted different races. As recently as World War II it was not uncommon to hear people speak of the "British race," the "Jewish race," and so on. Some physical anthropologists narrowed the concept to include three main racial groups: the Negroid, Caucasoid, and Mongoloid, or black, white, and Asian races.

Others argue that human populations have always exhibited some degree of interbreeding, and that this has greatly increased during the last few centuries, producing large groups of people who defy such racial classification. "Pure races" have probably never existed, and certainly do not exist now. According to this thesis, race is a cultural myth, a label that has no biological basis but is attached to groups in order to buttress invidious social distinctions. (For an interesting discussion on the biological meaning of race, see Begley 1995; the following section owes much to this work.)

IS RACE A MYTH?

At the most basic level, biologists sort organisms into species. A species is essentially a breeding boundary, in that it defines the limits within which interbreeding can occur. Thus golden retrievers can be bred with standard poodles, but not with pigs or cats. By this fairly straightforward criterion, all humans, regardless of appearance, belong to the same species. The difficulty arises when one

attempts to identify subspecies, the technical equivalent of races. In some species, this is relatively simple because their distinctive traits are “concordant.” That is, the same subgroups are produced using any of a number of traits: a golden retriever can be distinguished from a standard poodle on the basis of fur color and texture, ear shape, or body type. Among humans, however, identifying subspecies is not so simple, because the traits associated with human subpopulations are nonconcordant. In short, using one trait will result in one set of “racial” categories, while another trait will produce an entirely different set.

Consider the traits commonly used to divide humans into the three conventional races. These traits include skin color, hair color and texture, and facial features. Asians are usually identified primarily by the epicanthic eye fold, yet if this criterion were applied consistently, the San (Bushmen) of South Africa would be considered Asian. And while skin color certainly helps distinguish Swedes from the Masai of East Africa, it also distinguishes Swedes from Turks, both of whom are considered “white,” and the Masai from the San, whose olive complexion more closely resembles the Turk’s than the much darker Masai’s.

Humans are visual creatures, so that in categorizing others, we fixate on differences of appearance. But these criteria are biologically arbitrary; other, less obvious traits associated with human subpopulations might just as easily be used. A common anatomic trait among Asians is front teeth that are “scooped out,” or shovel shaped, in the back. Yet Swedes and Native Americans also share this trait, so we could divide the species into one race with shovel-shaped incisors, and one without. Considering biochemistry, some peoples produce lactase (an enzyme that aids milk digestion) into adulthood, while others do not. A “lactase-positive race” would include northern and central Europeans, Arabs, northern Indians, and many West Africans, while other Africans, Native Americans, southern Europeans, and Southeast Asians would be in the “lactase-negative race.” Genetics multiplies the possibilities even further: antimalarial genes, including but not limited to the sickle cell gene, could be used to distinguish a “malaria-resistant race” (in which Greeks and Italians would

be grouped with Southeast Asians, New Guineans, and tropical Africans) from the “malaria-susceptible race” (which would place Scandinavians with the Xhosa of South Africa). Because these various traits are nonconcordant, classifying the human species on the basis of one will produce a set of “races” entirely different from the set based on another trait.

Biologically speaking, then, all such classification schemes are both arbitrary and meaningless. The genetic variation contained *within* any identifiable human subpopulation, including the conventional “races,” is vastly greater than the variation *between* populations. That is, any two Asian people are likely to have less in common than either has with a randomly chosen white person. To put it in slightly different terms, Harvard biologist Richard Lewontin once observed that if a holocaust wiped out everyone on earth except a small tribe deep in the New Guinea forest, almost all the genetic variation found in the four (now five) billion people currently on earth would be preserved (cited in Gould 1981). Grouping people into racial categories tells us nothing about how biologically related they are. It tells us only that we perceive them to share some trait that we humans have chosen to consider important.

If racial categories tell us nothing meaningful about biology, however, they tell us a great deal about history, as we can see from another argument against the traditional view of race: that individuals’ racial identification can change as they move from one society to another. Americans are accustomed to thinking of black and white as two separate categories, and assigning people with any African ancestry to the former category. This is the “hypodescent rule,” in which the offspring of a mixed union are assigned to the lower-ranked group. In Brazil, however, black and white are poles on a continuum, and individuals can be placed at any point on that continuum, depending on their facial features, skin color, and hair texture. Even siblings need not share the same identity, which also to some extent depends on social class: the expression “money bleaches” reflects the fact that upward mobility can move a person’s racial assignment closer to the white end of the

continuum (van den Berghe 1967). Thus, a black American who is light skinned and well to do may find that in Brazil he is not considered “black” at all, and may even be labeled “white.” Should he go to South Africa instead, our light-skinned black American would be neither black nor white, but “coloured,” the term that denotes a person of mixed ancestry in that society.

Finally, consider this consequence of the hypodescent rule: in America, a white woman can give birth to a black child, but a black woman cannot give birth to a white child. This convention is biologically nonsensical and arbitrary; it can only be understood historically. In the United States, hypodescent was carried to the extreme of the “one-drop rule,” in which one drop of African blood was enough to designate a person as black. This practice evolved out of a desire to maximize the profitable slave population, and to maintain the “purity” of the white race. Clearly, the racial categories commonly used in America do not reflect an underlying biological reality, but rather the more grim chapters of our history. This point has important implications, as we can see by returning to the debate over the relationship between race and intelligence. If the precise nature and meaning of intelligence remains unclear, and if race itself has no biological significance at all, then how are we to interpret a statistical association between “race” and “intelligence”? It becomes little more than a mathematical exercise, yielding information of dubious value.

SOCIAL CONCEPTIONS OF RACE

While race may lack biological significance, it does have tremendous social significance. Sociologist W. I. Thomas’s famous dictum is certainly true of race: “If men define situations as real, they are real in their consequences” (quoted in Coser 1977, p. 521). Racial distinctions are meaningful because we *attach* meaning to them, and the consequences vary from prejudice and discrimination to slavery and genocide. Since people believe that racial differences are real and important, and behave accordingly, those differences become real and important. Hitler, for example, believed that Jews

constituted a distinct and inferior race, and the consequences of his belief were very real for millions of Jews. Thus the major questions confronting sociologists who study race relations concern the social consequences of racial categorization. To what degree are different racial and ethnic groups incorporated into the larger society? How can we account for variations in the economic, political, legal, and social statuses of different groups?

American sociologists have found their own society to be a natural laboratory for the study of these issues. The United States has a wide variety of racial and ethnic groups, and some of these have been more successful in American society than others. Within any group there is substantial variation in economic achievement, and the success of “model minorities” is often exaggerated. Still, considered as groups, Jews and the Japanese have been more successful in America, in material terms, than have blacks and Mexicans. One explanation for these differences that has found some acceptance both within and outside scientific circles is that the cultures and values of these groups differ. Some groups’ values are believed to be more conducive to success than others. Jews, for example, have traditionally been seen as valuing scholarship and business acumen; as a result they have worked hard in the face of discrimination, educated their children, and pulled themselves up from poverty. African Americans, by contrast, allegedly lacked these values; the result is their continued concentration in the poor and working classes.

Most sociologists reject this argument, which Stephen Steinberg (1981) refers to as the “ethnic myth.” Steinberg argues that this line of reasoning is simply a new form of social Darwinism, in which the fittest *cultures* survive. A closer look at the experiences of immigrants in America (including African Americans) reveals that not all immigrant groups start at the bottom; some groups arrive with the skills necessary to compete in the American labor market while others do not. Furthermore, the skills possessed by some groups are in high demand in the United States, while other groups find fewer opportunities. Thus Steinberg argues that the success of an immigrant group

depends on the occupational structure of its country of origin, the group's place in that structure, and the occupational structure of the new country.

Steinberg uses the case of American Jews to support his argument. In terms of education, occupation, and income, Jews have been highly successful. Thirty-six percent of the adult Jewish population had graduated from college in 1971, compared to 11 percent of non-Jews. Seventy percent of Jews were in business or the professions, compared with roughly a third of non-Jews. The median family income of Jews in 1971 was \$14,000, approximately 30 percent more than the average American family. Again, it is possible to overstate Jewish success, since many Jews are still poor or working class; middle-class Jews are concentrated in small business and the professions, and are nearly absent from corporate hierarchies. Furthermore, Jews have experienced a great deal of economic and social discrimination. Nevertheless, when compared with other ethnic and racial groups in America, they have been quite successful.

This success, Steinberg argues, is attributable in part to the origins of Jewish immigrants, most of whom came from Russia and eastern Europe, and arrived in the United States in the late nineteenth and early twentieth centuries. Since Jews in eastern Europe could not own land, they tended to live in cities; even those who lived in rural areas were mostly merchants and traders, rather than farmers. The urban concentration and above-average literacy rates of Jews affected their occupational distribution: 70 percent of Russian Jews worked as artisans or in manufacturing or commerce in 1897; even unskilled Jews worked in industrial occupations. Sixty-seven percent of Jewish immigrants who arrived in America between 1899 and 1910 were skilled workers, compared to 49 percent of English immigrants, 15 percent of Italians, and 6 percent of Poles.

Furthermore, Jewish immigrants were disproportionately represented in the garment industry, which was growing at two to three times the rate of other American industries. Jobs in the garment industry were better paid than other industrial jobs, and Jews, with their higher skill level, tended to have the better-paid jobs within the industry.

The garment industry also offered unusual opportunities for individual entrepreneurship, since little capital was required to start a small clothing business.

In sum, Jewish immigrants did well in America because they brought industrial skills to an industrializing country. Although the majority of Jewish immigrants arrived with little money and encountered widespread discrimination, American industry could not afford to ignore them completely. Steinberg concludes that while a case can be made that Jews have traditionally valued educational and occupational achievement, and that this contributed to their success, Jews do not hold a monopoly on these values. Furthermore, if they had encountered an occupational structure that offered no hope for the fulfillment of these aspirations, Jews would have scaled their goals down accordingly.

The inability of other racial and ethnic groups to match the success achieved by Jewish Americans has also been attributed to the cultures and values of those groups. Glazer and Moynihan (1970), for example, blame the persistent poverty of blacks on "the home and family and community. . . . It is there that the heritage of two hundred years of slavery and a hundred years of discrimination is concentrated; and it is there that we find the serious obstacles to the ability to make use of a free educational system to advance into higher occupations and to eliminate the massive social problems that afflict colored Americans and the city" (pp. 49, 50). Yet, as Gutman (1976) has shown, the black family emerged from slavery relatively strong and began to exhibit signs of instability only when blacks became concentrated in urban ghettos. Furthermore, for generations after emancipation, blacks faced extreme educational and employment discrimination; the notion that a free educational system provided a smooth path to the higher occupations is simply inconsistent with blacks' experience in America.

Most sociologists tend, like Steinberg, to locate the cause of African Americans' poverty relative to white immigrant groups in the structure of opportunity that awaited them after slavery. The South was an economically backward region where

blacks remained tied to the land and subject to conditions that were in many cases worse than those they had known under slavery. The vast majority of white immigrants settled in the North, where industry provided jobs and taxpaying workers provided schools. The more agricultural South had fewer educational opportunities to offer blacks or whites. Immediately after the Civil War, when they were provided access to education, blacks flocked to southern schools. This opportunity was short lived, however, since the scarcity of educational resources made it advantageous for whites to appropriate the blacks' share for themselves, a temptation they did not resist.

By the time large numbers of blacks migrated north, the industrial expansion that had provided so many jobs for immigrants was on the wane. Moreover, the newly freed slaves did not have industrial skills and were barred from industrial occupations. Given the generations of social, economic, political, and legal discrimination that followed, and the fact that blacks did take advantage of the opportunities that presented themselves, it is unnecessary to call on "inferior values" to explain the difference in achievement between African Americans and white immigrants. (For an interesting comparison of the struggle of blacks in the postbellum South and the North to that of black South Africans, see Frederickson 1981; for a comparison of the conditions faced by U.S. blacks and white immigrants, and the effects of these differences on each group's success, see Lieberman 1980.)

CONCLUSION

Ever since Darwin proposed that the evolutionary process of natural selection ensures that only the fittest species survive, social science has been bedeviled by the notion that some human groups, especially races, are more biologically or culturally fit than others. This extension of Darwin's principle to competition for survival *within* the human species, especially when applied to industrial or postindustrial societies, cannot withstand close scrutiny. While human subpopulations have evolved certain traits such as malaria resistance and the

retention of lactase into adulthood as adaptations to environmental conditions, these physical traits do not sort our species into consistent categories, and they are hardly relevant to performance in today's school or workplace.

Furthermore, cultural differences between groups can be identified, and these differences may have economic consequences, but they are more likely to reflect a group's historical experiences than the value its members attach to economic success. Thus, the current trend in sociology is to explain differences in the success of racial and ethnic groups in terms of the economic and political resources possessed by those groups, and by the groups with whom they are in competition and conflict.

One reason for the longevity of the biological and cultural forms of social Darwinism may be that for many years most natural and social scientists have been white, and middle class to upper class. While the objective search for truth is the goal of the scientific enterprise, race is an emotionally and ideologically loaded concept, and even the most sincere humanitarians have been led to faulty conclusions by their own biases. An important prospect for the advancement of the scientific study of race, then, is the recruitment of new scholars with a wide diversity of ethnic, racial, and national backgrounds. This increasing diversity will help to broaden the exchange of ideas so necessary to scientific inquiry, and will yield an understanding of race that is more balanced and less subject to bias than it has been in the past.

RATIONAL CHOICE THEORY

Rational Choice theory is typically seen as the use of economic reasoning in contexts that were traditionally the concern of disciplines other than economics, especially of political science, sociology, and anthropology. If we take a more nuanced historical view, however, we might as soon see mainstream economics as the stepchild of the kind of reasoning about larger social institutions, norms, behaviors, and so forth that was central to the Scottish Enlightenment in the works of David Hume, Adam Smith, and many others. The genius of these thinkers was to make sense of such institutions, norms, and so forth as the products

of individuals acting from their own private incentives. Their concern was that of James Coleman (1990), to explain macrophenomena from microchoices. Through most of the past two centuries, economists increasingly focused such reasoning on explaining the nature and working of the market, for example on prices and conditions for an equilibrium of supply and demand, and the earlier concern with broader sociological issues faded. The great classical economists, such as Smith, Alfred Marshall, and Vilfredo Pareto, were interested not only in the market but also in broader social institutions and practices. Much of their work can readily be counted among the great contributions to sociology in their eras.

Contemporary rational choice theory represents a resurgence of such earlier efforts. The efflorescence of such theory in our time has followed on the development of game theory by John von Neumann and Oskar Morgenstern, Kenneth Arrow's demonstration that individual preferences do not aggregate into analogous collective preferences, and Anthony Downs's analysis of democratic participation. The largest bodies of contemporary work are those on the study of group behavior, under the rubric of Mancur Olson's logic of collective action, and on political participation, which in part can be seen as merely a special case of collective action. Perhaps the fastest-growing area of inquiry today is in the analysis of institutions, much of it focused on historical institutions, as in the work of Douglass North.

A cognate area is social exchange theory, which had its contemporary origins well before the works of von Neumann, Arrow, and Downs. Its origins were also distinctively sociological, as in the work of George Homans, and anthropological.

A seemingly cognate area is economic sociology, although much of economic sociology is like the bulk of voting studies in that it takes the form of simple correlations of behaviors with personal characteristics—gender, age, ethnicity, education, occupation, nationality, religion, and so on. Much of economic sociology might therefore be counted as behavioralist. Rational choice analysis at least implicitly assumes intentionality. Hence, in effect,

rational choice theory is contrary to the behavioralism of much of sociology, especially political sociology, in the mid-twentieth century. The point of behavioralism is to avoid the use of mental or intentional explanations of behavior, to treat the mind as virtually a black box. Rational choice theory imputes preferences and intentions to actors. In part, of course, these might derive from or be explained by such sociological characteristics as race, gender, or religion. Although there is a large field of behavioral economics, economics in general was not centrally influenced by the behavioral movement just because it is largely about preferences and intentions. Indeed, much of the work on behavioral economics is directed primarily at establishing the nature and content of preferences and preference functions. It gives measures of the preferences that might go into intentionalist accounts of behavior.

Although much of rational choice theory explains behavior as a response to interests, such theory need not be so narrowly restricted. In its more general form, it explains behavior as the product of preferences, which can cover virtually anything from values to interests. For example, holding all else constant, you might prefer a higher to a lower income. But you might prefer a lower income with peace to a higher income in a state of war, even if your safety and livelihood are not at risk in the war. In many contexts, however, interests seem to be adequate to explain behavior, often because other values are not at stake in the behavior to be explained or because they are substantially less important than interests. Rational choice theory is commonly most compelling in contexts in which interests are predominant. In part, this is because interests can often be more systematically imputed to relevant actors than can other values, although this is not always true. For example, in a given population, particular religious values might regularly trump concern with interests to some substantial degree in some aspects of life. Even when we might suppose other values are very important, however, we might also suppose that analyzing the force of interests gives us a clear baseline for then coming to understand the import or weight of these other values in explaining behavior.

The value theory of rational choice theory is essentially the utility theory that has been developed over the past few centuries by economists and others. It is sometimes asserted that this is an empty value theory and that we can put almost anything we wish into utility functions. For example, I can put your pleasures or various normative commitments in my own utility function. While this is technically correct, most of the major results of rational choice analysis turn on the use of utility functions that are about as spare as we can imagine. They include nothing more than interests, which are conceived to be resources, such as money and time. The results surveyed here virtually all depend only on such simple utility functions. Or occasionally, in a somewhat fuller version, they require inclusion of some of the pleasure one gets from various consumptions, as in the account below of the norm of conformity to neighborhood tastes and manners.

Rational choice theory has been applied to so many diverse issues that a full survey of its characteristic results would be exhausting. I will therefore take up several applications, some of them especially important both in establishing rational choice theory and in recasting the nature of major problems that had already long been the focus of much research. I will first discuss the main methodological or fundamental theories behind rational choice theory. In applying such theory, I will begin with the grandest of sociological issues: the problem of social order. Then I will take up two major areas of research that got the contemporary field of rational choice theory under way: the study of group action and the corollary study of political participation. The first of these is historically a major focus of sociological research, while the second has naturally been the special domain of political science. Then I will take up three efforts that show the breadth of the approach. These are the analyses of institutions, norms, and functional explanation.

GAME THEORY

The methods of rational choice theory are essentially the methods of economics, including standard equilibrium analysis, price theory, econometrics, and game theory. Game theory is less a theory

than a format for presenting the array of choices and outcomes that face two or more actors whose outcomes are determined by the joint choices or actions of all of them. Games can be represented in many forms. In the matrix form, each player has a set of choices or strategies, and outcomes are determined by the intersection of the strategy choices of all players. Games in which two players have two strategies each are called two-by-two games. Such games can be pure coordination, pure conflict, or a mixture of these two, as represented in Games 1–3, in Table 1. In each of these games, Row has two strategy choices available and Column also has two choices. When both have chosen their strategies, an outcome is determined. The payoffs in each outcome are given in ordinal terms. 1 is the best payoff, 2 next best, and so forth. The first payoff in each outcome is to Row and the second payoff is to Column.

In the pure conflict game, one player can be better off only if the other is worse off. In the pure coordination game, both players achieve their best payoff together. Mixed games are commonly called

mixed-motive games. There are many different types. The one represented here is the prisoner's dilemma, which is surely the most studied of all simple games, probably because it represents ordinary exchange and is therefore ubiquitous and central in social interaction. In the prisoner's dilemma both players can be made better off together in the move from (3,3) to (2,2), so that the game has a strong element of coordination. But Row is made better off while Column is made worse off in the move to (1,4) from any other outcome, so that the game also has a strong element of conflict.

Unfortunately, the (3,3) outcome of a prisoner's dilemma is an equilibrium in the sense that we cannot move to the Pareto superior (2,2) outcome through individually beneficial or neutral moves, because my change of strategy from defecting to cooperating while you continue with your strategy of defecting makes me worse off. To move to the (2,2) outcome requires joint action. The prisoner's dilemma is the only one of the seventy-eight ordinarily distinct two-by-two games that has a Pareto-dominated equilibrium. Its solution therefore commonly requires incentives from outside a single play of the game. The incentive can be from the benefits of cooperative play in an iterated series of plays of the game or from external enforcement by other parties, as under a legally binding contract.

SOCIAL ORDER

There are three grand schools on social order. One of these is the conflict school associated with Plato's Thrasymachus, Karl Marx's class theory, Ralf Dahrendorf, and many others. Another is the shared-values school of John Locke, Émile Durkheim, and Talcott Parsons. A third is the school of exchange theory associated with Adam Smith, George Homans, and others. These can be characterized by the three classes of games represented above. Because there can be all these—and many other—classes of interactions in society, all these theories are partially right about social order. There is a fourth plausible account of much of the order we see, an account that fits the coordination game. We do not coordinate only because we share values; we can coordinate merely to stay out of

each other's way while we pursue our different values. (Indeed, in some sense we can share values—we both want the same thing—in such a way as to have severe conflict.)

One of the simplest of social coordinations is the coordination on driving that makes traffic flow much faster and with less mishap. In North America, we all drive to the right. That is merely one of two possible conventions that could work equally well. The other convention is that we all drive to the left; this convention is followed in the United Kingdom and many nations of the British Commonwealth. It is merely coordination that resolves the traffic problem. But when you and I coordinate on this convention, we do so not because we share any substantial values. We might each be utterly self-serving. The only value we share is to keep others out of our way as much as possible. This is characteristic of much of social order in contemporary liberal societies, in which rampant individualism and great diversity of values might seem to lead to great and disruptive conflict. Instead, it commonly gets channeled in ways that avoid conflict but that could hardly be called cooperative in the sense in which you and I might cooperate in building a house.

Coordination without confluence of values makes the problem of social order seem relatively simple, as it must be for many activities in which we spontaneously achieve order without either the imposition of power by authorities, as is required for the conflict school, or the relatively deliberate cooperation of the exchange school. While such coordination is not the original discovery of rational choice theory or game theory, it is made far more perspicuous by these because these give it a structure of motivation that makes sense of it in many contexts, just as they make the other major schools of social order clearer. Hume presented a clear account of coordination and convention in many social contexts in which stabilizing expectations is fundamentally important to social order. Game theory provides a framework for characterizing the interactions that we must govern if we are to achieve order. Most forcefully, perhaps, game theory suggests why we cannot ground an account of social order in merely one of the traditional

schools, because it displays the greater complexity of the forms of interaction that must be ordered.

GROUPS AND COLLECTIVE ACTION

There is a tradition, still alive today, in which it is supposed that if the members of a group share an interest in some result, they will act to provide themselves that result. For example, Karl Marx's theory of revolution requires this simplistic assumption coupled with his account of class consciousness. Against this tradition, Olson (1965) argued that, if our group interest requires for its achievement that each (or at least many) of us make a personally costly contribution to its achievement, then we commonly do not have individual incentive to act for the collective good. Each of us bears the full cost of our own contribution but receives only a minuscule part of the small piece of the larger collective good provided by that contribution. Typically, therefore, the collective benefit to me of my contribution to our collective provision will be less than the cost to me of that contribution. Hence, if I am narrowly self-interested, I will not make a contribution to the collective good but will hope merely to free ride on the provision that results from the contributions of others. If all other members of my group have my structure of interests, none of us will contribute and our collective good will not be provided. If we could vote to have ourselves compelled to contribute, we might all vote to do so. But if we must voluntarily contribute, none of us might do so. This is the logic of collective action.

Olson used standard micro-economic analysis to demonstrate this logic. He modeled the problem as an instance of Paul Samuelson's theory of public goods, in which the efficient price of access to the public good would be zero even though, at that price, there would be no voluntary supply of the good. Olson's logic can as well be demonstrated game theoretically as an instance of a large-number prisoner's dilemma (Hardin 1982). As in the discussion of game theory above, individually motivated action would not lead us out of the dismal equilibrium of no cooperation, even though the Pareto superior outcome in which all would

contribute might be enormously superior to the status quo equilibrium in which all defect.

A very large literature has been directed at explaining the collective action and the achievement of collective benefits that we see despite this logic. For example, we apparently see a great deal of collective action in the form of social movements that sometimes entail great individual costs and even severe individual risks. Much of this literature supposes that people are motivated by commitments beyond self-interest, such as social and moral commitments, but much of it supposes that there are incentives apart from the direct logic of collective action. For example, there may be specific personal benefits corollary to the collective benefit. Alternatively, our group might be provided its collective good but not through spontaneous individual actions. Rather, an entrepreneur might see the possibility of making a career out of leadership in providing our group its collective benefit. Such an entrepreneur might especially arise if our group's good could be provided by government without requiring our voluntary cooperation.

POLITICAL PARTICIPATION AND DEMOCRACY

There are two main lines of theory on political participation in a democratic system. One of these began with Kenneth Arrow's ([1951] 1963) impossibility theorem. That theorem essentially says that collective preferences cannot be modeled simply on individual preferences. We might each individually have well-ordered preferences over all the choices we face, and yet we might collectively not have such well-ordered preferences. Indeed, we can generally expect not to have such collective preferences over any complex realm of choice, such as we often face in normal politics over the large array of policies at issue. This has far broader implications than merely that democratic choice may have problems. It is an important and broadly interesting instance of the fact that the imputation of various characteristics of individuals, such as their pattern of preferences, to groups composed of individuals is a fallacy of composition.

The typical implication of Arrow's theorem goes back to the Marquis de Condorcet and to Lewis Carroll. It is that our collective preferences may cycle through some set of possibilities. For example, in majority votes we may collectively prefer A to B, B to C, and C to A. If our collective preferences were as well behaved as our individual preferences, the fact that we prefer A to B and B to C would entail that we prefer A to C. In majority votes, the majority who prefer A to B can be different from that who prefers C to A. For example, my preferences may be $A > B > C$; yours may be $B > C > A$; and a third person's may be $C > A > B$. These preferences yield the cycle above if the three of us vote by majority. Many institutional devices, such as legislative practices of opposing new laws against each other before opposing the winner of such a series against the status quo, tend to block any evidence of cyclic preferences; but such a device gives a strong conservative bias to collective choice.

The other main line of rational choice theory of democracy began with Joseph Schumpeter and was developed extensively by Downs (1957). There are two major classes of claims. First, Downs supposed that two parties or candidates in an election face an electorate that is divided along a left-right dimension. If the voters have a normal distribution about some central tendency on this dimension, the two candidates will want to place themselves at the peak of that normal distribution. Hence, the two candidates will tend to have quite similar positions. Second, he supposed each voter faces what is de facto a logic of collective action on whether to vote. Suppose there are some costs involved in casting a vote—waiting on line, traveling in foul weather, and paying a fee for registration. It follows that individual voters should see the election of candidate A over candidate B as essentially a collective good to be provided at individual cost to themselves. It is therefore subject to the perverse logic of collective action, and we should expect that many voters would not vote unless they have motivations that go beyond their own interests. Furthermore, if it is not in my interest even to vote, it is unlikely to be in my interest to learn enough about the issues to vote intelligently.

INSTITUTIONS

The rational choice analysis of institutions has roots in ancient accounts of the rise of civilization. Among many such accounts in the era of the Scottish Enlightenment is Smith's theory (1978) of the stages of development of society from very primitive, to pastoral, to more nearly modern society in his *Lectures on Jurisprudence* (these lectures were not published in Smith's time and have played little role in the development of such analyses since then). Smith's account turns very clearly on the incentives that individuals have to submit to various forms of social order and, eventually, government. His later analysis of the wealth of nations is itself a theory of one of the grandest of all institutions: the economy of a modern commercial society. Smith argued that the wealth of the nation is a function of the efforts of individuals to do well for themselves.

More recent work has gone in diverse directions. The two main directions are the microanalysis of institutions and the behavior of individuals within them and the more nearly macroanalysis of why certain institutional forms arise and prevail. The microanalysis is applied to a wide variety of institutions, most of them of relatively small scale, such as committee structures and formal organizations of many kinds. The macroanalysis is often broadly historical and is directed at accounting for the rise of economic and other institutions. For example, there is extensive work on the rise of devices for handling trade across a broad array of cultures in the absence of any centralized governmental authorities.

Much of the institutional analysis builds on accounts of transaction costs. According to the so-called Coase theorem, due to Ronald Coase, if there were no transaction costs, property rights assignments would have no effect on overall production. Introducing transaction costs can distort production substantially. Firms sometimes internalize functions for which transaction costs would be high if they had to deal with outside suppliers for those functions, and they externalize functions for which markets work well to reduce transaction costs so that competitive suppliers can drive down

production costs. Attention to the structure of transaction costs therefore can explain much of an economic organization's structure. Attention to changes in markets over time can also explain the evolution of such organizations' structures. While most transaction cost analysis has so far been done by economists, including economic historians, it is also increasingly done by sociologists and others.

North (1990, p. 131) argues that the use of standard neoclassical economic methodologies exacts a heavy price in our effort to understand institutions. Because such understanding must of necessity be developmental, it must include stories of how the institutions came to be what they are. Neoclassical price theory is concerned with allocations at a specific moment in time under particular institutional arrangements. Game theory lends itself more readily to developmental stories, but to some extent we lack the methodology for putting such stories into order.

A clear implication of the transaction cost analysis of institutions is that, once in place, institutions influence incentives and interests, so that one cannot simply take institutions as dependent on rational choice. They are, additionally, shapers of rational choice. This is conspicuously true, of course, for such institutions as those of government and law, part of whose function is specifically to give people incentive to behave in some ways rather than others. It is true far more generally of essentially all institutions that have significant value to us, even institutions whose purpose might be seen as merely to produce certain goods or services. This means that the actual set of institutions we have and the set of individual behaviors we see are partly determined by the order and the era in which institutions have developed. Some part of what is commonly referred to as culture is merely the happenstance dependency of such historical developmental patterns.

NORMS

Much of the study of norms has been psychological or even psychoanalytic, and perhaps most of it has assumed that the motive for following norms is

essentially normative or otherwise not self-interested. Efforts to explain the rise of norms, however, are often forced to take account of how the interests of at least some people are to act on and to enforce various norms. One way to characterize the problem of creating and maintaining a norm is as a problem of collective action. It would seemingly be in the interest of almost all of us if a certain norm prevailed, but it is in the interest of almost none of us actually to abide by the norm unless there is some sanctioning system to keep us in line. In some theories, norms are morally or psychologically internalized, so that the sanctioning system is internal to the actor. Such theories require a substantial account of just how the internalization works. No doubt, there is some internalization of norms, but many norms must still depend heavily on external sanctioning, either for them to work at all or for them to work very well. If that were not so, we could dispense with institutionalized law.

Against accounts that require external sanctions, it is sometimes supposed that sanctioning has costs, so that sanctioning a violator of a norm runs against the interests of those who would like to see the norm upheld. For many norms, this is apparently not true. For norms of exclusion, I may actually prefer to shun you if you violate our norm. Hence, I sanction you and benefit from doing so. For example, if you do not follow neighborhood norms of using a relevant slang or dressing in certain ways, I might actively prefer not to associate with you, because your behavior makes me uncomfortable. My reticence and that of others in our neighborhood affects you and damages the pleasures you might get from associating with us or even shuts you out of such association.

For universalistic norms the problem is more complex. Some of these, such as the norm of promise keeping or truth telling, are enforced between dyads or small numbers of participants. In these cases, it may commonly be my interest to sanction you by not cooperating with you on other matters if you break your promise to me on some current matter. Hence, these norms are like norms of exclusion in that they can also be backed by sanctions that serve the interest of the sanctioners.

For universalistic norms that govern large-number interactions that are essentially instances of collective action, there may be no sanctioning device that serves the sanctioner's interest, and such norms are, not surprisingly, relatively weak in comparison to dyadic universalistic norms and norms of exclusion (Hardin 1995).

FUNCTIONAL EXPLANATION

An example of the ways in which rational choice theory is applied to apparently contrary approaches is recent work on functional explanation. This work does not contribute to the older school of functionalism or structural functionalism, as represented in much of twentieth-century anthropology or in the sociology of Parsons and many others. Rather, it reconstructs functional accounts in terms of individual incentives, as did Robert Merton in his effort to be very clear about the logic of functional argument. Oddly, the most important contribution to this new work was intended as a dismissal of functional analysis. Jon Elster (1979) argued that, if the form of functional explanation is properly spelled out, then very few supposedly functional accounts fit that form.

Pared down to its essentials, Elster's account is as follows:

An institution or a behavioral pattern X is explained by its function F for group G if and only if:

1. F is an *effect* of X;
2. F is *beneficial* for G;
3. F maintains X by a causal *feedback* loop passing through G.

Many groups that benefit from some behavior on the part of their members induce that behavior through incentives that they give to their members.

As an example of a functional account of a major institution, return to the problem of social order, which is typically governed in substantial part by a legal system. A common view of much of law is that its function is to coordinate us or to facilitate our interactions. Hence in a functional explanation of law, F is coordination, X is law, and

G is our law-governed populace. The feedback loop passing through the populace is that our coordination by law enables us to coordinate to produce still further law to coordinate us still further. Hence, law is functional for us. But we would coordinate in such ways only because it is in our interest to coordinate. Hence, we can explain a major, pervasive, and seemingly all important social institution in functional terms as grounded in the rational choices of the actors.

CURRENT DIRECTIONS

Perhaps the easiest assessment of where the field of rational choice will go and where it should go is to extrapolate from current trends. Clearly, institutional work looms large for the near term and normative work seems likely to become more important. In both of these developments, one might hope and even urge that research in rational choice take the findings of other approaches seriously. Doing this would entail two quite different programs. The first and simpler program is merely to make extensive use of findings from other approaches. The second and intellectually more challenging program is to attempt to show the complementary relation of various other approaches to rational choice theory—or, alternatively, to demonstrate their incompatibility, which is often asserted but seldom shown. Sometimes, this might even entail showing that some other approach is, at least in some applications, equivalent to rational choice analysis. For example, work that has unpacked the logic of functional explanation often reveals the rationality of actors involved in replicating some supposedly irrational or extrarational behavioral pattern.

Perhaps the greatest challenge to rational choice theory is to fit it to vast bodies of behavioral research that does not focus on individual incentives and intentions. Part of the task here would be to impute incentives and intentions to relevant actors, perhaps by analogy from other studies and contexts. Another part of the task, as in the rational choice analysis of institutions, functional explanation, and norms, is to restructure the problems in ways that make their choice structures clear.

Unfortunately, rational choice theory is less well developed in sociology than in economics and even political science, in part because it is embattled. Despite the heyday of exchange theory in anthropology earlier in the twentieth century, rational choice theory is almost entirely absent from that discipline.

Finally, just because rational choice theory focuses on the incentives for microchoices that produce macroeffects, it is particularly suited to policy analysis. Empirical work on incentive systems and how they work can be put to use in designing policies to change behavior in productive ways. This is little more than common sense in many contexts, but a resolute focus on the relation of microincentives to macroresults is an especially natural part of rational choice analyses.

RELIABILITY

The reliability of a measured variable has two components, consistency and stability. *Consistency* is the degree to which two measures of the same concept provide the same assessment at the same time; consistency is based on “cross-sectional” research. *Stability* is the degree to which a measure of a concept remains unchanged across time; stability is based on “longitudinal” research. Let us illustrate consistency and stability on the measurement of height.

THE MEASUREMENT OF HEIGHT

As an example, we often measure how tall people are. Height, how tall someone is, is a measure of distance. In order to measure distance, we establish an arbitrary standard. A common arbitrary standard for measuring distance is the “yardstick.”

The yardstick is 36 inches long, and is broken down into feet, inches, and fractions of inches. Another common measuring rod is the “meterstick.” The meterstick is 100 centimeters long, and is broken down into decimeters, centimeters, and millimeters. If we know how tall someone is in inches, we can calculate how tall he or she is in centimeters, and vice versa. For example, rounding to two decimal places, a 70-inch-tall person is 177.80 centimeters tall (1 inch = 2.54 centimeters; $70 \times 2.54 = 177.80$). Conversely, rounding to two decimal places, if we know that someone is 160 centimeters tall, we also know that that person is 62.40 inches tall (1 centimeter = 0.39 inches; $160 \times 0.39 = 62.40$).

Indeed, the yardstick and the meterstick are highly consistent. With reasonable attention to proper measurement protocol, the correlation between height as measured by the yardstick and height as measured by the meterstick across a sample with sufficient variation in height would be very high. For all intents and purposes, the yardstick and the meterstick are interchangeable; the researcher need not establish their consistency. This leads to the *principle of consistency*:

If two measures of the same concept are perfectly consistent, they provide identical results. When this is so, the use of multiple measures is needlessly repetitive.

In this situation, the researcher need only use either the yardstick or the meterstick; using both sticks provides no additional information.

When babies are born, they are usually 18–24 inches “tall.” Parents (and developmental researchers) often measure how tall babies and children are as time passes. This over-time height measurement is a stability assessment. Ordinarily, children grow a rough average of 3 inches per year for 15 years, resulting in most 15-year-olds being between 63 and 69 inches tall. Then female height growth stops while male height growth continues. By the time females are 18 years old, they average about 66 inches tall, while males of the same age average about 72 inches. Their heights then remain roughly stable for the remainder of their adult lives. This leads to the *principle of stability*:

A measure of a concept is perfectly stable when it provides identical results at different points in time. When this is so, repeated measurement over time is needlessly repetitive.

Height measurement from year to year provides useful information for children but not for adults. This is because the children grow taller with the passage of time, but adults do not. Elderly people who suffer from osteoporosis (loss of bone density) will become shorter, but this decline in height is slight, compared to their growth when they were children.

Let us now turn to a discussion of how the principles of consistency and stability apply to the measurement of sociological concepts. We will first discuss the protocols of good sociological measurement. Then we will discuss the implications of these protocols for the assessment of the consistency of self-esteem and the stability of alienation.

PROTOCOLS OF GOOD MEASUREMENT

The Measurement of Self-Esteem. Researchers often attempt to measure how well people feel about themselves. Many decades ago, Charles Horton Cooley (1902) and George Herbert Mead (1934) theorized about the concept “self-esteem.” In offering the “looking glass self,” Cooley assumed that people develop a definition of themselves by evaluating what they believe others think of them. Mead differentiated between what a person actually is and what that person believes about himself or herself.

Rosenberg (1965) wished to measure self-esteem as conceptualized by Cooley and Mead. He did so by creating ten questionnaire items, each of which he believed would provide an empirical measure of the concept of self-esteem. His measurement attempt will be discussed in detail later in this paper. For now, let us assume that each of these items positively but imperfectly represents self-esteem. The positive representation implies that the concept “self-esteem” has a positive causal effect on each item. The imperfectness of the representation implies that there are other factors

that also cause each item. Under this condition, none of these ten different measures of self-esteem was nearly as consistent as the yardstick and the meterstick. That is, the correlations among these ten questionnaire items were far from perfect. When this is so, the use of multiple measures is more consistent than the use of any single measure alone. Thus, the *converse principle of consistency*:

If multiple measures of the same concept provide imperfect assessments of the same concept, then the use of multiple measures is more consistent than the use of any single measure alone.

Commonly, items presumed to measure sociological concepts do so imperfectly. Therefore, sociological researchers often turn to the use of multiple items in social surveys as indexes to represent concepts. Combining their substantive knowledge of the literature with their clinical knowledge of people who exhibit various aspects of the concept, these researchers design items to represent each of these aspects. Then researchers are faced with the tasks of evaluating the consistency and stability of the items as measures of their respective concepts. In order to do this, good researchers employ a set of protocols of good measurement. We now turn to a discussion of these good measurement protocols.

Good measurement of sociological concepts satisfies the following criteria:

- Clear definitions of concepts.
- Multiple items.
- Clear definitions of items.
- Strong positive interitem correlation.
- Score construction.
- Known groups validity.
- Construct validity.
- Consistency.
- Stability.

These protocols represent the state of the art not only in sociology (Mueller 1997), but also in a

wide variety of other scientific disciplines. A computer search of the literature revealed more than five hundred articles citing these protocols in the 1990s, including: political science (Jackman and Miller 1996); psychology (Hendrix and Schumm 1990); nursing research (Budd et al. 1997); the family (Grandin and Lupri 1997); sports and leisure (Riemer and Chelladurai 1998); computer information systems (McTavish 1997); management (Szulanski 1996); gerontology (Wright 1991); genetics (Tambs et al. 1995); social work (Moran et al. 1995); higher education (Aguirre et al. 1993); market research (Lam and Woo 1997); and preventive medicine (Saunders et al. 1997).

Let us briefly discuss each of these protocols in turn. Then we will focus the attention of the remainder of this paper on the two major focuses of reliability, consistency and stability.

Clear Definitions of Concepts. Good measurement protocol requires that each concept be clearly defined and clearly differentiated from every other concept. Good measurement protocol can document that an ambiguous concept is, indeed, ambiguous. Moreover, such protocol may suggest points of theoretical clarification. However, there is no substitute for clear theoretical thinking augmented by a thorough knowledge of the literature and a clinical immersion in the domain of content.

Multiple Items. Good measurement protocol requires that each aspect of a concept be assessed using multiple items. A single item, taken alone, suffers from measurement error. That is, the item is, in part, a representation of its respective concept. However, this same item may be a representation of other concepts, of systematic measurement error, and of random content. These other contents are called "error"; they reduce the degree to which the item accurately represents the concept it is designed to measure empirically. The rationale for the use of multiple items revolves around minimizing this measurement inaccuracy. That is, all items designed to measure a concept contain inaccuracies. If a single item is used to measure the concept, the researcher is, in essence, stuck with the specific inaccuracies of the single item. However, if multiple items designed to measure the same concept are used, the inaccuracies of

one item may be offset by different inaccuracies of the other items.

Clear Definitions of Items. Good measurement protocol requires that each item be designed to measure one and only one concept. The response categories should be constructed so that the higher the code of the response category, the more positive the respondent's attitude on that concept.

Strong Positive Interitem Correlation. When multiple items are designed to measure a single variable, the standard of the research industry has long been that the items should be coded in such a way that the higher the score, the more positive the empirical representation on the concept. Good measurement protocol requires strong positive intercorrelations among items designed to measure a concept. Ordinarily, these intercorrelations are presented in a correlation matrix. A visual inspection of the correlation matrix will be revealing. An item that correlates strongly (e.g., $r > .4$) with other items will generally emerge as a strong contributor to the reliability of the resulting score; an item that has a zero correlation with other items will not add to the reliability of the score; and an item that inversely correlates with other items (assuming that it has been coded such that the higher the score on the item, the higher the measure of the concept) will detract from the reliability of the score.

To the author's knowledge, the sole exception to this principle was articulated by Curtis and Jackson (1962, p. 199) who argued that "two equally valid indicators of the same concept may. . . be strongly related to one another, or they may be totally unrelated (or negatively related)." The difficulty with the Curtis and Jackson position is that it effectively invalidates the most powerful empirical argument that can be made for multiple items representing a single dimension—that of the equivalence established using convergence. Instead, the author would argue that if two items are unrelated or negatively related to one another, either they represent different dimensions, or they are reflecting a method artifact or both. For a more detailed discussion of this matter, see Zeller and Carmines (1980, p. 77–136) or Carmines and Zeller (1979).

Factor analysis is the major statistical technique designed to describe a matrix of item intercorrelatedness. As such, factor analysis enables researchers to (1) describe a large number of items in terms of a small number of factors and (2) select those items which best represent each of the identified concepts (see Bohrnstedt 1970, p. 96; and Zeller and Carmines 1980, p. 19–46). Items that have high factor loadings on a factor that represents a concept are then retained. These items are then used to construct a score to represent the concept.

In evaluating the degree to which a large set of items represents a small number of theoretical concepts, the application of factor analytic techniques is as much an art as it is a science. This is because there are numerous ambiguities in the measurement setting. The researcher defines one or more concepts and explores the degree to which the factors coincide with the hypothesized concepts. For each item, the researcher wants to know the degree to which it is a function of the concept it was designed to measure, other concepts, method artifacts, and random error.

Score Construction. Once the number of factors and which items define which factors has been established, the researcher needs to create scores. One score should be created to represent each concept empirically for each respondent. If the items defining a concept have roughly equal variances, the simplest way to create a score is to sum the items defining the concept. In practice, researchers can tolerate moderate variation in the item variances. For example, if the item variances for a set of Likert items range from, say, .8 to 1.4, summing the items seems to make the most sense. However, if the variation in the items is severe (say from .5 to 2.5), then the researcher should first create standardized scores using the following formula: $z = (\text{score} - \text{mean}) / \text{standard deviation}$. The standardized scores have equal variances (i.e., 1); the sum of these standardized scores will create each desired score.

Known Groups Validity. Once scores have been constructed, comparisons of scores between groups known to be high and low on the dimensions of the

concept should be made. Known groups validity is established if groups known to be high on the concept have substantially higher scores than groups known to be low on the concept.

Construct Validity. Construct validity is intimately related to theory testing. Construct validity involves (1) specifying theoretical relationships among concepts, (2) assessing empirical relationships among scores, and (3) interpreting how the evidence clarifies the validity of any particular measure. For more information on this concept, see Carmines and Zeller (1979, pp. 22–26).

Consistency. Good measurement protocol requires that the consistency among items designed to measure a concept should be strong. This means that the correlation between any two items designed to measure the same concept should positively and strongly correlate. We will apply the principle of consistency to Rosenberg's attempt to consistently measure the concept of self-esteem.

Stability. Good measurement protocol requires that, if a concept does not change over time, a score designed to measure that concept also does not change over time. The trick of consistency is that the researcher ordinarily does not know whether there is a change in the value of the concept over time. We will apply the principle of stability to the attempt by R. A. Zeller, A. G. Neal, and H. T. Groat (1980) to stably measure the concept of alienation.

When these protocols of good measurement are not followed, the researcher increases the risk of torpedoing the best of conceptual schemes and sentencing them to the intellectual trash heap, whether they belong there or not. High-tech statistical tools, such as structural equation modeling (SEM), make requirements that, by definition, are not present in the measurement development situation (Bollen 1989; Bollen and Long 1993; Hayduk 1987; and Hoyle 1995). That is, SEM requires both strong theory and strong measurement a priori. Indeed, SEM demands that the researcher know beforehand:

- How many factors there are.
- Which items represent which factors.

But these are precisely the major questions that the researcher wants to answer! The end result of

the factor analysis should be that the researcher has inferred how many factors are represented by the items, and which items define which factors.

We now turn to a discussion of the consistency of self-esteem.

CONSISTENCY OF SELF-ESTEEM

Good measurement protocol requires that the consistency be strong among items designed to measure each dimension of a concept. This means that the correlation between any two items designed to measure the same concept should positively and strongly correlate. Often different measures of the same concept have relatively modest positive intercorrelations.

In constructing the self-esteem scale, Rosenberg created ten items using the response categories “Never true,” “Seldom true,” “Sometimes true,” “Often true,” and “Almost always true.” Five of these were positive items; these items made a positive statement about self-esteem. The other five were negative items; these items made a negative statement about self-esteem. The response categories for the positive items were assigned the values 1 through 5, respectively, such that the higher the score, the higher that respondent’s self-esteem was inferred to be. These positively stated items were:

- “I feel that I have a number of good qualities.”
- “I feel that I’m a person of worth, at least on an equal place with others.”
- “I take a positive attitude toward myself.”
- “I am able to do things as well as most other people.”
- “On the whole, I am satisfied with myself.”

For the five negatively phrased items, a higher score indicated a lower self-esteem. These items had the same response categories as above, but the assignment of values was reversed. That is, the negatively stated items were assigned the values 5

through 1 respectively. That is, a “Never true” response to the item “I wish I could have more respect for myself” was assigned a 5 and an “Almost always true” response to that item was assigned a 1. These five negatively stated items were:

- “I wish I could have more respect for myself.”
- “I feel I do not have much to be proud of.”
- “I certainly feel useless at times.”
- “All in all, I’m inclined to feel that I am a failure.”
- “At times I think I am no good at all.”

Given the reverse scoring for these items, a higher score indicated higher self-esteem. In order to create a self-esteem scale, the scores were summed into a value that ranged from 10 representing the lowest measured self-esteem possible to 50 for the highest possible measured self-esteem.

How consistent are these items? We suggest the following as a *consistency rule of thumb* for a variable to be used in sociological research:

- If r is above .8, the score is highly consistent.
- If r is between .6 and .8, the score is modestly consistent.
- If r is less than .6, the score may not be used in research.

In the author’s research (Zeller and Carmines 1976), interitem correlations among the ten Rosenberg items designed to measure self-esteem ranged from a low of .05 to a high of .58 with a mean r of .32. These intercorrelations do not meet this rule of thumb. When properly analyzed, however, they will. We now turn to a discussion of the strategy for this analysis that will address this criterion of consistency.

Split-Half Consistency. The “split-half” approach to estimating the consistency of items designed to measure a concept is to divide the items into two subscores and calculate the correlation between those subscores. For example, the ten items can be

divided into two subscores of five items each. The resulting split-half correlation between the two subscores provides an estimate of consistency. If the average interitem correlation equals .3, a score created by summing the responses to the ten items into two five-item subscores would have a split-half correlation of .68.

However, it is well known that, given items whose intercorrelations are equal (i.e., $r = .3$), the greater the number of items, the higher the consistency of a score resulting from those items. Thus, a ten-item score will have more consistency than a five-item score when both scores are made up of items that intercorrelate .3. The split-half reliability correlation, however, does not represent the ten-item score, it is two subscores made up of five items each. Therefore, this split-half correlation will be lower than the actual consistency of the ten-item score.

Two researchers, Spearman (1910) and Brown (1910), independently recognized and solved this statistical estimation problem. Specifically, they noted that the split-half reliability correlation can be adjusted to project what the consistency of a ten-item score would have been if it had been calculated on the basis of two ten-item subscores instead of two five-item subscores. They shared attribution for this solution and called the result the *Spearman-Brown Prophecy*. It is presented in formula (1):

$$r_{xx''} = 2r_{xx'} / (1 + r_{xx'})$$

where

$r_{xx''}$ is the Spearman-Brown Prophecy formula. (1)

$r_{xx'}$ is the split-half correlation coefficient.

Using the example from above, we can see that the Spearman-Brown Prophecy formula projects the consistency of the entire ten-item scale using formula (1) as follows:

$$r_{xx''} = 2r_{xx'} / (1 + r_{xx'}) = (2)(.68) / (1 + .68) = 1.36 / 1.68 = .81$$

This .81 is an unbiased estimate of the consistency of the total score. Applying the above rule of

thumb, such a scale is quite consistent and can be used in sociological research.

In actual research, intercorrelations among score items vary substantially. In the self-esteem example, item intercorrelations varied from .05 to .58. Moreover, the researcher must decide which items to assign to which subscales. One assignment of items to subscales will produce a different reliability estimate than another. When this occurs, the split-half reliability correlation between the two subscales is beset with the *problem of equivalence*: Which items are assigned to which subscales? We now turn to a way of handling variations in intercorrelations among items.

Equivalence Consistency The researcher could assign the even-numbered items to one subscore and the odd-numbered items to the other; or items 1, 2, 3, 4, and 5 to one subscore and 6, 7, 8, 9, and 10 to the other; or items 1, 4, 5, 8, and 10 to one score and 2, 3, 6, 7, and 9 to the other. There are many combinations of assignments that could be made. Which one should the researcher use?

Lee Cronbach (1951) solved this dilemma by creating *Cronbach's Alpha*. Cronbach's Alpha uses the average of all possible split-half reliability correlations that are Spearman-Brown projected to the number of items in the score. This is presented in formula (2):

$$\alpha_{xx} = N(\text{Mean } r_{xx'}) / [1 + \text{Mean } r_{xx'}(N - 1)]$$

where

α_{xx} is Cronbach's Alpha. (2)

N is the number of items.

Mean $r_{xx'}$ is the mean interitem correlation.

Applying formula (2) to the ten-item score designed to measure self-esteem where the mean interitem correlation is .3, we get:

$$\alpha_{xx} = N(\text{Mean } r_{xx'}) / [1 + \text{Mean } r_{xx'}(N - 1)] = (10)(.3) / [1 + (.3)(9)] = 3 / 3.7 = .81$$

Thus, Cronbach's Alpha produces the same value that we obtained when we calculated a split-half correlation and applied formula (1), the Spearman-Brown Prophecy formula. This occurred because

all the items were, we assumed, equally correlated with each other.

Both the number of items and the average interitem correlations influence the value of Cronbach's Alpha as follows:

- As the number of equally intercorrelated items increases, Cronbach's Alpha increases.
- As the average intercorrelation among the same number of items increases, Cronbach's Alpha increases.

We now turn to the implications of these two patterns:

Number of Items The researcher often faces the question "How many items should I use to measure a concept?" The oversimplified answer to this question is, "More!" The more equally intercorrelated items a researcher uses to measure a concept, the higher the reliability will be.

The trick, of course, is that the items must be equally intercorrelated. In most research situations, items designed to measure a concept are not equally correlated. Some items will intercorrelate more strongly with the set of items than others. When this occurs, the researcher's judgment must be employed to decide how much of a reduction in interitem correlation offsets the increase in the number of items in the score. At a minimum, the researcher does not want to add an item which decreases the Cronbach's Alpha consistency of a scale. Standard computer software provides an option which allows the researcher to examine the Cronbach's Alpha if any item is removed from the score. When the alpha with the item removed is higher than the alpha when that item is included, there is consistency justification for the removal of that item from the scale.

This question can be posed in terms of how many items the researcher needs to meet specific alpha reliability thresholds given the mean interitem correlations. Table 1 addresses this concern. In Table 1, three alpha reliability thresholds (.7, .8, and .9) and eight mean interitem correlations (.1 through .8) are specified. We then solved formula

Sample Size Needed for Various Alphas with Various Mean Correlations

Mean <i>r</i>	CRONBACH'S ALPHA		
	.7	.8	.9
.1	21	36	81
.2	10	16	36
.3	6	10	21
.4	4	6	14
.5	3	4	9
.6	2	3	6
.7	1	2	4
.8	1	1	3

Table 1

(2) algebraically for the sample size needed to achieve each threshold, given each mean interitem correlation using formula (3):

$$N = \frac{[\alpha_{xx}(1 - \text{Mean } r_{xx})]}{[(\text{Mean } r_{xx})(1 - \alpha_{xx})]} \tag{3}$$

Using formula (3), the body of Table 1 presents the number of items needed for each Cronbach's Alpha threshold for each mean interitem correlation. For example, if the mean item intercorrelation is .2, sixteen items will be needed in order to achieve a Cronbach's Alpha of .8.

An examination of Table 1 reveals that when the mean interitem correlation is equal to .5, only three items are needed for an alpha of .7, four items for an Alpha of .8, and nine items for an alpha of .9. If the mean interitem correlation is .3, six, ten, and twenty-one items are needed for alphas of .7, .8, and .9, respectively. Moreover, if the mean interitem correlation is .1, twenty-one, thirty-six, and eighty-one items are needed for Alphas of .7, .8, and .9, respectively.

Thus, weak interitem correlations can be used to achieve consistency thresholds when many items are used. This is what ordinarily occurs in academic achievement tests. An exam of eighty-one items with a mean interitem correlation of .1 reaches the highly consistent .9 alpha; and an exam of only

thirty-six items with a mean interitem correlation of .1 is a reasonably consistent .8 alpha. At the same time, strong interitem correlations reach these thresholds with a small number of items. This harkens back to the observation that if two measures correlate strongly, the researcher merely picks the most convenient measure and uses it with little concern for consistency reliability.

However, the law of diminishing returns suggests that at some point, additional items with the same average intercorrelation with other items will not provide sufficient value in exchange for the effort to be expended to include those additional items. When the number of items is small, an additional equally correlated item adds substantial enough value to the reliability of the score to warrant the effort needed to include it.

Table 2 presents Cronbach's Alphas for various numbers of items with various mean interitem correlations. An examination of Table 2 illustrates the law of diminishing returns. When the mean interitem correlation is .9, the alpha is .98 with five items; adding additional items does not, indeed cannot, increase the consistency much. This is so because the maximum consistency is a perfect 1.0. When the mean interitem correlation is .3, the alpha of .68 with five items is only marginally consistent. However, the alpha increases to an acceptable .81 when ten items are used and to a highly consistent .9 when twenty items are used. Finally, the alpha for five items with a mean interitem correlation of .1 is .37. In order for a score made up of such items to be adequately consistent, the number of such items must be increased substantially.

Cronbach's Alpha can be calculated using formula (2) above. Standard statistical computer software packages can also be used for this purpose. However, care must be taken in using these packages to assure that all the items and only the items that define a specific score be included in the calculations. Indeed, the attentive researcher will want to produce the Cronbach's Alpha by hand, using formula (2), and by computer. When these two measures are identical, the researcher can take comfort that both are likely to have been done

properly. As a postscript on this discussion, we note that the Cronbach's Alpha consistency of Rosenberg's ten-item self-esteem score calculated on the data presented in Zeller and Carmines (1980, p. 92) was equal to a reasonably consistent .83. More advanced procedures which take into account which items are more highly correlated with the total score, such as theta and omega, have been omitted from this discussion. For a discussion of theta and omega, see Carmines and Zeller (1979, pp. 60-62) or Zeller and Carmines (1980, pp. 60-63). Rosenberg's self-esteem scale continues to attract academic attention (e.g., GrayLittle et al. 1997).

STABILITY OF ALIENATION

The Measurement of Alienation. The concept of alienation is one of the major "unit ideas" of sociology (Nisbet 1966). But the concept is so imbued with different meanings that some have come to question its usefulness as a sociological concept (Lee 1972). Seeman (1959) believed that the conceptual confusion surrounding the study of alienation can be addressed by construing it as multidimensional. Neil and Rettig (1967) have operationalized Seeman's original conceptualizations. Following the protocols of good measurement

described above, Neal and Groat (1974) theoretically defined and empirically confirmed powerlessness, normlessness, meaninglessness, and social isolation as the four dimensions of alienation. Specifically, they constructed items designed to measure each of the four dimensions of alienation, gathered data, conducted factor analyses, noted that the observed factor structure coincided with the conceptual dimensions, created factor-based scores, and conducted substantive analyses.

R. A. Zeller, A. G. Neal, and H. T. Groat (1980) conducted a consistency and stability analysis. Data on the same sample in 1963 and 1971 revealed that reliabilities ranged from .64 to .83 in 1963 and from .65 to .88 in 1971. The authors needed accurate consistency estimates because they wished to minimize the correction for attenuation. Correction for attenuation will be discussed shortly. Zeller and colleagues wished to describe the amount of stability in the dimensions of alienation over the turbulent years between 1963 and 1971. Specifically, they wished to assess the degree to which those who had high levels of alienation in 1963 would also have high levels of alienation in 1971. In order to do so, they created scores for each of the four dimensions of alienation in both 1963 and 1971. For each score, the correlation between the 1963 and the 1971 value represented the “stability” of that dimension over that time period. High correlations would suggest substantial stability in which respondents were alienated over that time period; low correlations would suggest substantial change.

Correction for Attenuation Due to Measurement Inconsistency. In order to assess the stability of the dimensions of alienation over time, Zeller et al. (1980) calculated correlation coefficients between the scale scores for each dimension of alienation. They found stability coefficients ranging from .40 for normlessness to .53 for social isolation. It would appear that there was substantial stability over the eight years under investigation. Before we jump to any conclusions, however, we must consider that measurement inconsistency attenuates (i.e., reduces) the observed correlation from what it would have been if each concept had been perfectly measured at each time point. That

is, they needed to correct their stability correlations for measurement inconsistency. Formula (4) presents the correction for attenuation:

$$r_{xtyt} = r_{xy} / \text{SQRT}(r_{xx} r_{yy})$$

where

r_{xtyt} is the correlation over time corrected for attenuation.

r_{xy} is the observed correlation between X and Y.

r_{xx} is the Cronbach's alpha for X.

r_{yy} is the Cronbach's alpha for Y.

$\text{SQRT}(r_{xx} r_{yy})$ is the square root of the product of the alphas at the two points in time.

Let us apply the correction for attenuation to Zeller and his colleagues' meaninglessness score. The meaninglessness stability correlation = .52; meaninglessness had an omega consistency of .64 in 1963 and of .65 in 1971. Substituting these estimates into formula (4), we get:

$$\begin{aligned} r_{xtyt} &= r_{xy} / \text{SQRT}(r_{xx} r_{yy}) = .52 / \text{SQRT}(.64 * .65) \\ &= .52 / .64 = .81 \end{aligned}$$

Similar analyses were conducted on the other dimensions of alienation.

This analysis led Zeller and colleagues (1980, pp. 1202–1203) to conclude that their data “indicate substantial stability in the dimensions of alienation over an eight-year period.” They believe that their longitudinal data “have provided evidence to suggest that operationalizing dimensions of alienation is not only feasible, but may be accomplished with a high degree of confidence in the (consistency) reliability of the measuring instruments. The obtained stability of alienation scores over a long period of time lends credence to the search for the causal, antecedent conditions.”

Method Artifacts in Longitudinal Research. There are several method artifacts that can artificially attenuate or inflate the estimation of stability. As noted above, score inconsistency attenuates the stability estimate. Memory tends to inflate the stability estimate. That is, if, at time 2, respondents remember what they answered at time 1 and wish

to present themselves as being stable in their answers, they will make the same response to the item at time 2 that they made at time 1. We do not believe that this “memory effect” operated to any great degree in the analysis by Zeller and colleagues, because we doubt that respondents would remember their specific response to a specific questionnaire item for eight years. However, when the interval between time 1 and time 2 is relatively short, memory becomes a problem.

A conventional wisdom in stability research is that the interval of time that elapses between time 1 and time 2 should be long enough that respondents will not remember their specific answers to specific items, but short enough that very little change (i.e., instability) takes place in the interim. We believe, on the contrary, that part of what we wish to estimate in stability research is how much change actually takes place. Given our perspective, it does not matter how much time elapses between time 1 and time 2.

Still, the threat of artifactual deflations and inflations to the stability estimate is real. Consider the effect of item-specific variance. The respondent may answer an item in a “stable” fashion over time not because of the stability of the concept it measures, but because of some idiosyncratic nuance of the item. Idiosyncratic nuances of items unrelated to the concept the item is designed to measure are systematic, not random, error. As such, idiosyncratic nuances of items threaten to inflate the stability estimate. We now turn to a statistically advanced discussion of the identification and removal of item specific variance from stability estimation. This section requires a working knowledge of path analysis as described in Asher [(1976), 1983].

COMBINING CONSISTENCY AND STABILITY INTO A MEASUREMENT MODEL

The path model presented in Figure 1 combines consistency and stability into a measurement path model. In this measurement model, X_1 and X_2 represent the value of the concept at time 1 and time 2; P_{21} is the theoretical causal path from X_1 on X_2 , it represents stability, the theoretical effect of X_1 on X_2 . This and the other effects in this model

Figure 1. Consistency and Stability in a Measurement Model

can be thought of as path coefficients. The x_{ij} represent the observations; specifically, x_{21} is item 2 at time 1; x_{32} is item 3 at time 2. The p_{ij} are the epistemic correlations, the effect of the concept on each respective measure; specifically, p_{21} is effect of X_1 on item 2 at time 1; p_{32} is the effect of X_2 on item 3 at time 2. The p_{ijt} are the item specific effects over time, the effects of an item at time 1 on that same item at time 2; specifically, p_{11} is effect of x_{11} on x_{12} over and above the effect mediated through the concept. For a more complete discussion of epistemic correlations, see Blalock (1969).

Figure 2 presents this consistency and stability measurement model where the stability effect is $P_{21} = .8$, the epistemic correlation are $p_{ij} = .7$, and the item-specific effects are $p_{ijt} = .3$. These are approximately the effect parameters for the meaningfulness measurement over time in Zeller and colleagues (1980).

Table 3 presents the correlation matrix that results from applying the rules of path analysis [Asher (1976) 1983] to Figure 2. Specifically, within the measurement model, the correlation between x_{11} is x_{21} is equal to the product of the path from X_1 to x_{11} times the path from X_1 to x_{21} . That is, $r = (p_{11})(p_{21}) = (.7)(.7) = .49$. In the same way, all the time 1 measures intercorrelate .49; all the time 2 measures correlate .49.

The correlation between the time 1 and time 2 items must differentiate between the correlations

Figure 2. Hypothetical Consistency and Stability Data in a Measurement Model

between different items over time and the correlations between the same item over time. Let us first address correlations between different items over time.

The correlation between x_{11} (item 1 at time 1) and x_{22} (item 2 at time 2) is equal to the product of the path from X_1 to x_{11} times the path from X_1 to X_2 times the path from X_1 to x_{22} . That is, $r = (p_{11})(P_{21})(p_{22}) = (.7)(.8)(.7) = .39$. In the same way, all the time 1-time 2 correlations among different items are .39.

The correlation between x_{11} (item 1 at time 1) and x_{12} (item 1 at time 2) is equal to the product of the path from X_1 to x_{11} times the path from X_1 to X_2 times the path from X_1 to x_{12} plus p_{11t} . That is, $r = (p_{11})(P_{21})(p_{12}) + p_{11t} = (.7)(.8)(.7) + .3 = .69$. In the same way, all the time 1-time 2 correlations for the same item are .69.

Using formula 2, we can solve for the Cronbach's alpha, at both time 1 and time 2, as follows:

$$\begin{aligned} \alpha_{xx} &= N(\text{Mean } r_{xx})/[1 + \text{Mean } r_{xx}(N - 1)] \\ &= (4)(.49)/[1 + (.49)(3)] = 1.96 / 2.47 \\ &= .79 \end{aligned}$$

Using the criteria described above, the score is modestly, and almost highly, consistent.

The correlation between two scores can be calculated using the correlation matrix with the following formula:

$$r = e / \text{SQRT}(a + 2b) \text{SQRT}(c + 2d)$$

where

r is the stability correlation between a score at time 1 and time 2.

a is the number of items in the time 1 score.

b is the sum of the correlations at time 1. (5)

c is the number of items in the time 2 score.

d is the sum of the correlations at time 2.

e is the sum of the intercorrelations between the measures at times 1 and 2.

Applying formula 5 to the data in Table 3, we get:

$$a = 4$$

$$b = (6)(.49) = 2.94$$

$$c = 4$$

$$d = (6)(.49) = 2.94$$

$$e = (12)(.392) + (4)(.692) = 7.472$$

and

$$\begin{aligned} r &= e / \text{SQRT}(a + 2b) \text{SQRT}(c + 2d) = 7.472 / \\ &\text{SQRT}[4 + (2)(2.94)]^2 \\ &= 7.472 / 9.98 = .756 \end{aligned}$$

Correcting this correlation for attenuation using formula 4, we get:

$$\begin{aligned} r_{xyt} &= r_{xy} / \text{SQRT}(r_{xx} r_{yy}) = .76 / \\ &\text{SQRT}(.79)^2 = .96 \end{aligned}$$

Thus, the stability coefficient is .96. But we specified this stability coefficient to be .8 in Figure 2! What is wrong with our procedures? Why did we overstate the stability of the model? We overstated the model's stability because we included the item specific effects as stability effects. That is, the observed correlations between the same item at time 1 and time 2 represented the effects of both stability and item-specific variance. We need to remove the item specific variance from our estimation of the stability coefficient.

We can estimate the item-specific effects by subtracting the mean of the correlations of different items at time 1 compared to time 2 (mean $r = .39$) from the mean of the correlations of the same item at time 1 compared to time 2 (mean $r = .69$). Then we use only the variance that is not item-specific in the same item correlations across time

x_{42}								—

Table 3

($r = .69 - .30 = .39$) as our estimate of what these correlations would have been if there had been no item-specific variance.

We now reapply formula 5 to the adjusted data in Table 3 to get:

$$a = 4$$

$$b = (6)(.49) = 2.94$$

$$c = 4$$

$$d = (6)(.49) = 2.94$$

$$e = (12)(.39) + (4)(.39) = 6.24$$

and

$$r = e / \text{SQRT}(a + 2b) \text{SQRT}(c + 2d) = 6.24 /$$

$$\text{SQRT}[4 + (2)(2.94)]^2$$

$$= 6.24 / 9.98 = .63$$

Correcting this correlation for attenuation using formula 4, we get:

$$r_{x1yt} = r_{xy} / \text{SQRT}(r_{xx} r_{yy}) = .63 / \text{SQRT}(.79)^2 = .80$$

Thus, the stability coefficient corrected for the removal of item specific variance is .80; despite rounding, this is equal to the .8 which was the stability coefficient specified in Figure 2.

Estimating the stability of concepts measured by scores across time is complex. A simple correlation between a measure at time 1 and the same

measure at time 2 is subject to a variety of influences. First, this stability coefficient is attenuated due to inconsistency of the item. We can address this by using multiple measures. The multiple measures allows us to estimate the consistency of the score and to correct the stability coefficient for the attenuation that occurs because the score is not perfectly consistent.

Second, the stability coefficient is artificially inflated because of item-specific variance. We can address this by estimating the size of the item-specific variance and removing it from the correlation matrix. Then we can correlate the score at time 1 and time 2 on the correlation matrix (with the item specific variance having been removed). This correlation, corrected for attenuation, is an unbiased estimate of the actual stability. For the past twenty years, the author has been searching in vain for someone who will solve for the model presented in Figure 2 from the correlation matrix presented in Table 3 using SEM techniques. Many have claimed to be able to do so, but so far, to my knowledge, no one has succeeded in doing so.

CONCLUSION

Thirty years ago, Hauser (1969, pp. 127-128) noted that “it is inadequate measurement, more than inadequate concept or hypothesis, that has plagued social researchers and prevented fuller explanations of the variances with which they are confounded.” We have come a long way since then.

The scientific community has given greater attention to the measurement properties of the variables we use. Our capacity to conduct numerous alternative data analyses on large and well-documented data sets has been substantially enhanced. At the same time, nature is jealous of her secrets and there are many land mines buried along the paths we need to follow (or blaze) in order to make sense of our social scene. Moreover, there are many who seek shortcuts to sociological knowledge. Hence, we continue to address the challenges of establishing the consistency and stability of our measures.

RICHARD A. ZELLER

RELIGION, POLITICS, AND WAR

The Peace of Westphalia (1648) marked the end of the Thirty Years' War and the beginning of the modern European state system. The development and evolution of the principles laid out in the Westphalian treaties made the territorially defined independent sovereign state the dominant political unit for managing and governing populations. Those principles also led to recognition of the state as the primary unit for interaction (including the "interaction" of war) between territorially bounded populations. By the end of the twentieth century, the state system had encompassed the entire globe.

An understanding of the relationship between religion, politics, and war begins with an analysis of regimes (Swanson 1967). A state governs a population by means of a regime. A regime is responsible for maintaining peace and securing justice within the territorial bounds of a state. A regime acts by exercising its own autonomous powers and by implementing and enforcing laws.

Regimes take many forms, including (but not limited to) absolute monarchy (France under Louis XVI), personality-centered dictatorship (Hitler's Germany), government by cabinet embedded in a constitutional monarchy (the United Kingdom), an executive presidential system linked through a division of powers to legislative bodies (United States of America), and rule by a single party (People's Republic of China).

The autonomous powers of a regime are, in principle, unlimited, and they include the legitimate use of force. The powers of a regime and a regime's performance can be (and usually are) constrained and directed by laws and limitations such as traditional rights, even where the regime is a monarchy or dictatorship. In that regard, a major question in the analysis of the state pertains to the relationship between a regime and a society's political system or body politic. Can interests (including religious interests) be legitimately organized and expressed within a political system in ways that effectively influence a regime's actions? Answers to this question can be framed within answers to another fundamental question. What is the direct relation between a regime and the religious institutions of a society, the relation that is not mediated through an aggregation of interests in civil society and their expression in a political system? This question defines the church-state problematic.

CHURCH AND STATE

Although the categories "church" and "state" are products of the history and experience of the West, they can be applied to the analysis of religion, regimes, and politics across the contemporary world (see Martin 1978). Two ideal-type models and their variants specify the range of relations between religion and the state. The *interpenetration model* assumes a high degree of church-state (or religion-regime) congruence and the effective unity of religious and political action. Important variants of this model include theocracy and caesaropapism. Where theocracy exists, the authority of religion is decisive for the state. In the case of caesaropapism the tables are turned and the state dominates religion.

The *separation model* posits institutional autonomy for both religion and the state. Variants include the two-powers and the strict separation

subtypes. The two-powers subtype recognizes the distinct jurisdictional domains of the state and religion within a framework of church-religion-state-regime accommodation that may include church establishment (the official recognition and support of a church by a state) but also may encompass mutual suspicion, struggle, and cross-institutional interference. Strict separation eliminates all traditional, legal, and organizational bonds and most forms of accommodation between the state and religion. Each institution is not only autonomous but also “out of bounds” with respect to the other.

Contemporary examples of the interpenetration and separation models include the Islamic Republic of Iran (theocratic), Russia (caesaro-papist), Poland (two powers), and the United States of America (strict separation). The 1979 revolution in Iran led by Ayatollah Ruhollah Khomeini imposed Twelver Shi'a Islamic law and tradition on the Iranian state. This move invigorated the Iranian masses and was hailed as progressive in many parts of the Muslim world. It also led to tension between the development of Iran as a modern state and the application of Islamic rules, principles, and laws as the authentic seal of the revolution (Arjomand 1993). The lawmaking power of the state dominates the law finding power of the traditional Shi'a jurists in Iran. Nevertheless the country can be classified as a theocracy because the resolution of disputes is constitutionally in the hands of those who have been trained in Islamic religious jurisprudence. As well, lay citizens may serve in lower offices including the Majlis (parliament), but only clerics (religious jurists) can occupy high political, administrative, or judiciary positions in Iran.

The reforms of Peter the Great, czar of Russia from 1682 to 1725, transformed the administration of the Russian Orthodox Church into an office of the state and, thereby, instituted a caesaro-papist regime. All religious activities were governed by regulations promulgated by the czar. The church was the state's instrument for controlling and educating the population. It remained so until the Bolshevik Revolution in 1917 and the foundation of the Soviet state. Under Communist Party rule, with Marxism as the official ideology of the regime, Russian caesaro-papism became a negative, eradicating, secularizing force. Church property was confiscated. The church was sheared of all

nonreligious functions. Religious practice was strictly controlled.

After the collapse of the Soviet state (1989–1991), a liberal constitution guaranteed freedom of expression and practice for all religions. No provision was made for an established church. Subsequently, however, the Russian Orthodox Church was recognized by the state as the preeminent church in Russia, thus formally linking the Russian state to the Russian church once again. In the former Soviet Union, the autocracy of the Communist Party replaced the autocracy of the Russian czar. In both cases there was a caesaro-papist relation between a regime and religion, a relation that persists in the recognition of the preeminence of the Russian Orthodox Church by the liberalized, post-Soviet Russian state.

Unlike the Russian Orthodox Church, the Roman Catholic Church in Poland has never acceded to nor successfully been forced into a caesaro-papist relation with the state. The two-powers variant of the separation model has always prevailed, even during the period of Communist rule (1948–1989).

In the early modern period, Poland did not develop a state controlled by an absolute prince. A protodemocratic republic of nobles resisted state autocracy and, thereby, prevented control of the church by a powerful, centralized regime. In the nineteenth century, Polish national identity was fused with Polish Roman Catholicism. Thus, the stage was set for the church to serve as the defender of the interests of the nation when those interests were at risk during the period of Communist rule.

Identified with the Polish nation, the Polish church stood against the Polish state in a two-powers relationship during most of the Cold War. The opposition of the church in Poland to the Communist regime made an important contribution to the downfall of communism in the Eastern bloc of European states. As one of the most powerful actors in the civil society of post-Communist Poland (having long organized itself as a hierarchic weapon in defense of its own interests), the Polish Roman Catholic Church now faces the challenge of dealing with the tendency “in victory” to become a quasitheocratic actor, a role that is inconsistent with the Vatican's position that national churches should be institutions with interests and

not would-be hegemony in contemporary liberal democratic societies (Casanova 1994).

Where Poland exemplifies the two-powers variant of the separation model, the United States is the primary example of strict separation. Constitutionally guaranteed free religious practice and a constitutional provision forbidding the establishment or state sponsorship of any religion underwrite the autonomy and differentiation of religion and the state in a historically exceptional pattern. Unlike the case of Russia, for example, where the post-Communist state recognized the Russian Orthodox Church as the preeminent national religious body, no part (legislative, executive, or judicial) of any American government (local, state, or federal) can grant legal privileges to a religious organization. By the same token, American governments can neither limit nor curtail religious practice, as happened in the former Soviet Union, nor can they pass and enforce laws that impose religious norms and rules on a population, as is the case in Iran.

Unlike Poland, where the post-Communist liberal constitution has not prevented the government from granting funds to the Roman Catholic Church in support of church-sponsored education, no church or religious body could successfully petition any government in America for material support. On the other hand, American churches and religious organizations are not taxed by governments unless they are, in effect, business organizations within the meaning and application of the law. Thus, although the state neither interferes with religious institutions nor provides recognition and material support for them, there is a pattern of passive accommodation in America whereby the state allows religious organizations to operate as untaxed nonprofit corporate bodies. Where strict separation holds, the state is not anticlerical, nor is it a direct, overt benefactor of religion.

The examples adduced above do not exhaust the range of historical detail and local variance that will be discovered where the fit of the interpenetration or separation models to a particular state is assessed. The models, themselves, however, do exhaust the range of possibilities for the regime-religion relation and, thus, can be used to classify any state and organize the history of its intercourse with religion.

RELIGION, REGIMES, AND POLITICAL SYSTEMS

The analysis of the church-state relation focuses on links between the governing center of a society (a regime) and religious groups and institutions in a society. The analysis of religion and political systems, on the other hand, addresses questions pertaining to the organization and expression of interests in a society. Variation in the form of political systems and the relations between political systems and regimes affects the organization of interests in a society and the impact that interests including religious interests can have on regimes.

Do most of the members of a society have a role in determining who controls the society's regime? Do most of the members of a society have a role in selecting those who make the society's laws? For most of human history, the answer to both questions has been no. Kings, queens, emperors, military despots, dictators, patriarchs, oligarchs, leaders of single-party states, religious autocrats, petty tyrants, and the like—those who attain office without the broad-based consent of the people whom they dominate—were the rule, not the exception, until well into the twentieth century. Today, the democratic election of state leaders and lawmakers is a global norm, although there are many departures from it in practice (see Meyer et al. 1997).

The extent to which religious interests in a democratic society are organized and expressed in the society's political system is conditioned on the regime-religion (church-state) relation. As well, the organization of democratic political systems varies in ways that are independent of the regime-religion relation and that can affect the political expression of religious interests. Also, the properties of a society's population can have an impact on the political expression of religious interests. Finally, a state and its society may face external conditions that influence the internal relation between religion and politics.

Canada, the United States, and Israel, for example, are all modern democratic societies, but there are significant differences between them regarding religion and politics—differences that reflect variations in the regime-religion (church-state) relation, the organization of political systems, the populations, and external conditions. An examination of these variations illustrates the

range of linkages between religion and politics in contemporary democracies.

A substantial majority of the population of Israel is Jewish. Where religious matters are politically salient in Israel, controversies and conflicts often reflect sharp differences between secular and observant as well as Zionist and non-Zionist Israeli Jews. Most Israelis do not identify themselves as religiously observant in a strict sense, although only about 20 percent of the population eschew all religious observance. The state was founded (in 1948) and continuously governed for many years by a social-democratic party (Labour) whose members were for the most part secularized Jews of eastern European origin. Immigration added a significant component of observant oriental Jews to the Israeli population. Notwithstanding the secular origins of the state and the persistent secular orientation of many Israelis, religion is highly salient in Israeli politics today (Liebman 1993).

The State of Israel does not have a written constitution. Thus, the relation between religion and the state is not formally defined in a constitutional sense. No legislative or administrative acts either separate religion and the state or establish a particular variant of Judaism as the religion of the state. This means, among other things, that the resources of the state can be allocated on an ad hoc basis to religious organizations, including schools and welfare organizations that are controlled by religious groups. In this circumstance, religious groups have formed political parties to obtain state support for their organizations and to secure political goals linked to religious ideologies.

Representation in the Israeli parliament (Knesset) is based on proportional voting for parties. Proportional voting enables small parties to win seats. This feature of the Israeli electoral system plus the absence of legal or constitutional provisions either specifying or restricting the use of state resources in support of religion have encouraged the development of religious political parties in Israel. In recent years both large secular parties (socialist Labour and Likud) and smaller religious parties have received enough votes to claim seats in the parliament, but no single party has secured enough seats (a majority) to form a government. In that circumstance a government is formed by bargaining between parties. The leader of the party with the most seats negotiates with other parties to

form a majority coalition. Cabinet positions are the important bargaining chips in the process.

By entering into agreements with large secular parties when they need votes to form a government, some religious parties in Israel have secured cabinet portfolios. The electoral successes of some religious parties have enabled them to pursue interests and goals that in some cases are at considerable variance with the sensibilities and inclinations of secular Israelis, especially with regard to territorial settlements and peace, but also in matters pertaining to religious observance and the public presence of religion in Israeli life.

Israel, then, is a qualified variant of the theocratic model of religion-regime relations in the sense that there are no constitutional restrictions on the implementation of politically salient derivations that could flow from the ideology of a governing party. No religious party in Israel has succeeded, so far, in becoming a governing party, but were that to happen, there is no constitutional limitation that would, in principle, prevent a religious governing party from imposing its prescriptions and practices on the population of Israel.

Both Israel and Canada are parliamentary democracies, but the presence of religion in the contemporary political life of Canada is subdued in comparison with its visibility in the Israeli public arena. Reasons for this difference include the form of the constitutionalization of the church-state relationship in Canada, the organization of the Canadian political system, the secularization of cleavages or political fault lines in Canada, and the religious composition of the Canadian population.

The constitution of Canada underwrites a "soft" version of the caesaro-papist subtype of the interpenetration model of church-state relations. There is both a guarantee of free religious practice and the recognition of a form of religious establishment whereby public funds flow in support of primary and secondary schools affiliated with some churches. As well, hospitals and other health care organizations owned by religious groups are publicly funded.

Where education and health care are constitutionalized provincial responsibilities, there are variations between provinces regarding patterns and levels of funding for church-related schools. Also,

provinces are free to expand support beyond constitutionally required levels or to withdraw support in some circumstances. Thus, until 1999 Roman Catholic secondary schools in Ontario were not funded at the same level as public high schools. Following a provincial referendum in Newfoundland, church-related school boards were abolished in 1999, although public funds continue to support religious instruction in all schools in the province.

Constitutional and legal provisions pertaining to the church-state relation in Canada circumscribe the possibilities for political action by religious actors. The state will not provide material support to any religion for the asking, although it does provide funds in support of the educational and health care activities of designated churches, of which the Roman Catholic Church is the most notable example. This pattern has roots in the accommodation of Roman Catholic francophone Canada and Protestant anglophone Canada and the political balancing act that has kept Canada together since the founding of the Canadian state in 1867. Essentially, federal governments act in ways that are designed to ensure continuing accommodation between divisive political actors. The form that the constitutionalization of the church-state relation has taken in Canada enables governments to control the fissiparous tendencies of religiously oriented political actors through quasi-establishment (the funding of religiously affiliated schools and health care facilities) and caesaro-papist policies that, in effect, limit the public, political expression of divisive religious views (Simpson 1985).

The organization of the Canadian political system also encourages the containment of religious expression as a form of political action. The electoral rule of “first past the post” (a plurality of votes) makes it unlikely that the candidates of small parties will win seats in the federal House of Commons. This is unlike, say, the case in Israel, where the proportion of votes obtained by a party provides small parties with an opportunity for representation in the Knesset. Views on issues including religious views that lack a broad base in the Canadian population are not likely to be represented in government.

A Canadian government is formed by the appointment of a cabinet of ministers (who are the

government) by the leader of the party with a majority of seats in the House of Commons. (Not every member of parliament is a member of a government.) Once formed, a government (as is the case in any parliamentary system) can work its will without bargaining with other parliamentary parties—assuming that it is a majority government, meaning that it has a majority of seats in the House of Commons. Typically, matters related to the country’s economy and the unity of Canadian confederation dominate federal elections in Canada and, thus, rise to the level of government policy making, where they obscure other issues, including those that have a base in sectarian religious sensibilities.

The pattern of church-state articulation and the mechanics of the electoral system work against a simple, direct relation between religion and politics in contemporary Canada. As well, there has been shift in the last forty years in the nature of the cleavage that divides Canada into the nation of Quebec and the rest of Canada, a shift that has had implications for the tie between religion and politics. The rapid institutional secularization of Quebec in the 1960s and parallel movements in Anglophone Canada transformed the religion-language duality of Canada into a culture-language duality. Culture burst the bounds of religion and church control (see Borduas 1948). By the 1970s, Canada was officially defined as a bilingual and bicultural society, an understanding that was constitutionalized in 1982 along with provisions that, in effect, recognized rights pertaining to cultural maintenance and expression for all groups in Canada.

By moving the “game” of Canada to the politics of language, culture, and national expression and away from the politics of the religion-language link that was associated with Anglo dominance and the power of the Roman Catholic clergy in Quebec (a pattern that had been in place since British ascendance in the 1760s), the secularization of Canada in the post-World War II period gradually pushed religion out of the central place it had once occupied in the Canadian political system (Simpson 1988). While religion is no longer in a commanding position, its voice is not dead in the contemporary Canadian public arena. The Roman Catholic Church, mainline Protestant denominations, and Jewish organizations provide a public conscience in matters related to economic and social justice, and they engage the political system

with pursuant representations that are underwritten by the pattern of elite accommodation that typifies the Canadian political system (Simpson and Macleod 1985).

In recent years, a number of highly charged issues pertaining to abortion, homosexuality, pornography, prayer in the schools, and extramarital sex have been thrust into the American political arena. While some of these matters have public visibility in Canada, they have not generated the same level of public attention and scrutiny that they have in the United States, nor have they been a source of sustained conflict and serious divisiveness within the political arenas of Canada. Why?

The sociomoral issues that have been politicized in America have a base in the moral practices of conservative, sectarian Protestants as well as those of Roman Catholics to some extent. The reincorporation of sectarian Protestants into the American presidential electoral party system in the late 1970s brought sociomoral issues into the American public domain with force (Simpson 1983). A comparison of the religious demography of the Canadian and American populations suggests why these issues, once they were defined as public concerns, have had more prominence in America than in Canada.

About 45 percent of Americans are conservative Protestant Christians, whereas less than 10 percent of the Canadian population falls into the same category. Mainline Christian churches (including Roman Catholic) account for about 65 percent of the Canadian population and 40 percent of the U.S. population (Simpson 1988; Kosmin and Lachman 1993). There are far fewer sectarian Protestants in Canada than in the United States. Canada, then, lacks the population base for generating, supporting, and sustaining a politics of sociomoral issues. In the United States, on the other hand, a substantial portion of the population resonates with sociomoral issues that provide a public presence for everyday moral sensibilities anchored in conservative Protestant beliefs and practices.

More than religious demography underwrites the presence and tenacity of sociomoral issues in the American political system. Once thematized as politically relevant, issues have staying power that can be traced to the organization of the American system of government and, for religiously anchored

sociomoral issues, to the constitutionalization of free religious practice and no establishment of religion. Regarding the latter, practices in civil society that are approved by many but have been legally undone because they are not constitutionally valid (for example, prayer in public schools) may be a source of political agitation. A sense of unresolvable grievance arises where unfettered religious practice in the circumstance of no establishment leads to voluntaristic integrity, strength, and, even, militance in pursuit of outcomes that can only be achieved by violating the rule (no establishment) that underwrites and sustains the integrity and strength of religious practice in the first place. Unresolvable grievances are the stuff of primordial political mobilization. A politician signals that she or he is "onside" and wishes that something could be done but that it cannot because it is unconstitutional. Where the principle of no establishment is constitutionally moot, as in Israel or Canada, for example, a sense of unresolved grievance pertaining to issues linked to religion is less likely to persist, since a problem can be solved, at least in principle, by political action that entangles religion and the state.

Issues including politically relevant sociomoral issues also persist because there are three centers of political authority in the American form of government: the president, the Senate, and the House of Representatives. Each center is elected separately, and law can be made only where there is agreement among them. In this circumstance, politicized issues have lives in multiple electoral jurisdictions that encompass local, state, and national publics.

Although the majority party organizes the business of the American House of Representatives and the Senate, it does not form a government as a majority party does in a parliamentary system (for example, Canada or Israel). A government in a parliamentary system does not need the agreement of other centers of political authority to make law since a parliamentary majority guarantees that the political will of the majority party leader and her or his cabinet can become law without external advice or consent. In parliamentary systems a politicized issue tends to have a "half-life" that is as long as the attention span of the leader of the government and her or his cabinet of ministers. Where the electorate, itself, is not attuned to issues by virtue of its demographic

characteristics—as is the case in Canada regarding religiously linked sociomoral issues—it is unlikely that issues will rise to the level of serious consideration by a government, and even if they do, a government may not pay much attention to them. In the U.S. system, on the other hand, there is a tighter fit between what is on the public mind and the exercise of political authority. As long as an issue persists in the media, it has a guaranteed hearing in multiple centers of political power at the federal level.

Variations in the links between religion and politics in modern democratic systems have been illustrated above with an analysis of Israel, Canada, and the United States of America. The analysis could be extended to other democratic states and, as well, to political systems that are not democratic—for example, to the People's Republic of China where single party, top-down government has imposed a strict caesaro-papist pattern of control on religion. In any case, an analysis will examine the social forms and properties that inscribe the details of the relationship between religion and politics: the religion-regime linkage, the organization of a state's political system, and the religious demography of a state's population.

RELIGION AND WAR

The state system that emerged from the treaties ending the Thirty Years' War in 1648 led to the contemporary global international system. In this system, a state and its regime are the elementary units of interaction. Diplomacy, trade, and war are the fundamental forms of international behavior.

By the time of World War I (1914–1918), the international system was a mix of nation-states and imperial powers with nation-state cores. Western nation-states and imperial powers controlled nearly all the inhabited world. World War I dissolved the Ottoman Empire and the Austro-Hungarian Empire. World War II (1939–1945) led to the rapid decline and breakup of the British Empire. It also led to the bipolar Cold War that pitted the West against the Soviet Union and its client states. The bipolar system came to an end in 1989.

The outcome of each of the major wars in the twentieth century, including the Cold War, led to the decline or collapse of imperial and international structures. Each such decline or collapse, in

turn, led to the formation of nation-states. Typically (but not always), states were constructed from the pieces of an imperial or a neo-imperial structure (the bipolar system of the Cold War). Thus, Turkey emerged from the Ottoman Empire and Hungary from the Austro-Hungarian Empire in the wake of World War I. India, Pakistan, Burma, and Indonesia were devolutions from the British Empire and the Dutch Empire, which were broken up following World War II. The end of the Cold War led to the formation or revival of nation-states that had been parts of the Russian empire constituted as the Soviet Union and the client states of the Warsaw Pact. They include (but are not limited to) the Baltic states (Estonia, Latvia, Lithuania), Ukraine, Georgia, Kazakhstan, and Azerbaijan.

The history of state formation in the twentieth century demonstrates a clear tendency for a nation—that is, a people who share territory, language, and religion—to form or seek to form a state in which the leash of imperial control or regional control with imperial-like features slackens or disappears. When the Cold War global structure collapsed, for example, so did the forces that were the basis for the integration of the former Yugoslavia, a regional, quasi-imperial power from the immediate post-World War II period to the end of the 1980s.

War and state formation in the former Yugoslavia followed the path of ethnoreligious differences. Slovenia (Roman Catholic) and Macedonia (Orthodox) were more or less peaceful devolutions. Serbs (Orthodox) and Croats (Roman Catholic) fought before the state of Croatia was secured. Serbs, Croats, and Bosnians (Muslim) fought in Bosnia-Herzegovina prior to a Western-imposed settlement. Having receded to the Orthodox provinces of Serbia and Montenegro, Serb-dominated Yugoslavia attempted to drive out the ethnic Albanian (Muslim) population from the region of Kosovo (a part of Serbia) before the North Atlantic Treaty Organization (NATO) intervened in 1999.

Beyond the former Yugoslavia there are other contemporary armed conflicts that are also rooted in ethnoreligious differences. These include sporadic border fighting between India and Pakistan, and armed civil conflicts of one variety or another—guerrilla war, terrorism, state military suppression—in the Philippines, Northern Ireland, Indonesia, and Sri Lanka. In the Middle East,

religiously oriented militant factions of Muslims and Jews have complicated the pursuit of peace. The successful testing of nuclear weapons by both India and Pakistan has fortified the division of the world along ethnoreligious lines.

Huntington (1996) argues that contemporary patterns of conflict in the world provide evidence that the ideologically based political divisions of the Cold War have been replaced by a set of differences that are grounded in the congruence of religion, language, and territory. These differences support, encourage, and sustain action that is rooted in collective and individual identities. At the global level, identities are embedded in civilizations, and civilizations, according to Huntington, are the key to understanding international order and disorder in the twenty-first century.

Analysis of the conflicts in the former Yugoslavia provides a sense of the developing pattern of global tension as envisioned by Huntington. Ethnoreligious divisions within collapsing Yugoslavia were replicated in the religious identities of the sources of support for the divisions in the outside world. Orthodox Serbia received economic, military, political, and diplomatic support from Orthodox Russia and Germany and, in particular, the heavily Roman Catholic state of Bavaria supported Roman Catholic Croatia. Bosnians and ethnic Albanians received sympathy and aid from sources in the Muslim world.

Jumping to the global level, Huntington argues that divisions in the world will increasingly congeal along civilizational lines. The central civilizational players (and their core states) in the intercivilizational global system of the twenty-first century, according to Huntington, include Orthodox civilization (Russia), Confucian civilization (China), Hindu civilization (India), Japanese civilization (Japan), Islamic civilization (no core state), and Western civilization (a consortium of core states consisting of the United Kingdom, France, Germany, and the United States). International conflicts and wars will tend to occur along civilizational fault lines with core states leading and/or abating intercivilizational hostilities.

If Huntington is right, conflict and war at the intercivilizational level in the twenty-first century will resemble the European wars of religion (Roman Catholics versus Protestants)—the so-called Thirty Years War—that ended with the Peace of

Westphalia in 1648. In each case, ethnoreligious or cultural identities have been the basis for the cross-state attribution of lethal patterns of “us versus them.” Whereas the modern state emerged from the seventeenth-century European wars of religion as the dominant political unit for governing and managing populations, it remains to be seen whether new forms of political organization will arise from the intercivilizational tumults of the twenty-first century.

RELIGIOUS FUNDAMENTALISM

See Religious Movements; Sociology of Religion.

RELIGIOUS MOVEMENTS

Most people do not perceive religious beliefs as changing very much over time. Religions, after all, are engaged in the propagation of eternal truths. While it is understandable that religious organizations may change, that process is perceived to occur only very slowly. Indeed, changes in beliefs are perceived to occur so slowly that adherents and leaders alike hardly notice.

Contrary to popular perceptions, both religious beliefs and religious organizations are dynamic, ever-changing phenomena. Changes in the beliefs and organizational structure of religions reflect adaptations, accommodations, and innovations to continuously changing cultural, political, and economic environments. Without more or less constant change, religions would become irrelevant to their environments, and would simply become defunct. Indeed, this has been the fate of many religions in the history of humankind.

Changes in both beliefs and organizational structure may occur as the result of actions taken by leaders empowered to make such changes, but even greater change occurs as the result of *religious movements*. How religious movements effect change, both within and outside religious organizations, is the subject of this essay. The essay unfolds in three parts. First, the classic scholarly literature about religious movements is examined within the framework of a simple typology that pivots on the origins and target of change sought by movements. Second, the phenomenon of religious fundamentalism is examined as an exemplar of religious

movements. Selection of fundamentalism is appropriate because it is one of the most important religious movements of the twentieth century. In the final part of the essay, the emerging theoretical work on religious movements is linked to some practical implications of religious movements and the future of religion in human cultures.

UNDERSTANDING RELIGIOUS MOVEMENTS

Religious movements may be understood as a subcategory of *social movements*—that is, *organized efforts to cause or prevent change*. There are three discrete types or categories of religious movements. First, *endogenous religious movements* constitute efforts to change the internal character of the religion. Second, *exogenous religious movements* attempt to alter the environment in which the religion resides. Third, *generative religious movements* seek to introduce new religions into the culture or environment.

Religions consist of beliefs, symbols, practices, and organizations. *Endogenous movements* seek to change one or more of these aspects of a religion. Some endogenous movements have had monumental impact on both history and culture—for example, the great schism that split Christianity into Western Catholicism and Eastern Orthodoxy in the eleventh century; and the Reformation, which developed in the sixteenth century and split Protestantism from Roman Catholicism. Other movements, while important to the participants, have been of little cultural significance.

Endogenous movements frequently result in a schism—the division of the religious organization into two or more independent parts. Protestantism has been particularly schism-prone. Melton (1996) has identified more than 750 Protestant groups in North America alone. New religious groups formed through the process of schism are known as *sects*. *Sectarian movements* tend to be led by laity, or lower-echelon clergy. Many religious movements result in reform rather than schism. *Reform* is a more likely outcome when movements are initiated by the religious leaders, or when the religious hierarchy responds to and coopts grass roots demands for change. Through the centuries, the Roman Catholic Church has been particularly

effective in coopting and reincorporating movements into the church. We see them today as religious orders.

Pope John XXIII called the Second Vatican Council (1962–1965) in response to strong internal pressures to modernize the Roman Catholic Church and improve relations with other faiths. The Council produced many wide-sweeping changes in the Catholic Church. In addition, it spawned many other religious movements within the Catholic Church (e.g., liberation theology, the movement for women’s ordination, and movements for greater lay participation).

A second important hierarchically initiated movement of the twentieth century was the Protestant *ecumenical movement*. After several centuries of denominational proliferation, mostly occurring as the result of schism, the second half of the twentieth century has witnessed a powerful ecumenical movement that has resulted in the union of diverse Protestant traditions.

Exogenous movements constitute a second general type of religious movement. They are concerned with changing some aspect of the environment in which a religious organization exists. All religious organizations bring four imperatives to the environments in which they exist: (1) survival, (2) economic viability, (3) status, and (4) ideology (Hadden 1980). As long as these interests are secure, the religious organization exists in equilibrium or harmony with its environment. This is the normal relationship between religions and the culture. In sociological literature, these groups are identified as *churches*, or *denominations*.

When a religious group’s interests are threatened, or the leadership seeks to enhance or expand interests, religious movements may ensue. Often, exogenous religious movements are indistinguishable from social movements. Indeed, they are frequently pursued in coalition with secular social movement organizations.

In addition to legitimating religious movements with transcendental principles, religious leaders are often enlisted by secular social movement leaders to legitimate their movements. As a general proposition, religious leaders are specialists in the legitimization of social movement causes.

In the second half of the twentieth century, liberal Protestantism has forged coalitions with

virtually every liberal cause on the scene. Evangelical (conservative) Protestantism, on the other hand, has coalesced with economically and socially conservative causes. In both instances, religious organizations engage in movement activity to promote some element of their ideology. At the same time, in doing so, they hope to enhance their status. Much of the exogenous social activism of evangelical Christian groups during the past quarter-century has been grounded in the presupposition that a morally corrupt society threatens the survival of culture itself.

The very essence of religious organizations is that they carry cultural values, ideals, customs, and laws that claim transcendental character. When religious leaders engage in exogenous religious movements, they almost always draw on these transcendental principles to legitimate their cause. The claim that movement objectives are part of a divine plan, or that God is on the side of the movement, may serve as a powerful motivation for adherents of the faith to participate. Witness, for example, the many occasions during the 1980s when Islamic leaders exhorted their followers to engage in *jihad* (holy war).

The civil rights movement in the United States was substantially a religious movement. It was led by black ministers, activities were organized in black churches, funds were raised in liberal white churches, white clergy bolstered the troops who marched and picketed, and idealistic black and white youth—motivated by their religious traditions—participated in civil rights campaigns and projects.

The strength of the movement came not only from the broad base of religious participation but also from the ability of the leaders to legitimate the movement constantly in terms of sacred religious principles. For example, civil rights leaders repeatedly quoted the passage in the Declaration of Independence that acknowledges the role of the Creator in human rights: “We hold these Truths to be self-evident, that all Men are created equal, that they are endowed by their Creator with certain unalienable Rights, that among these are Life, Liberty, and the Pursuit of Happiness. . . .”

The Solidarity labor movement in Poland, which was the first major social movement that led to the collapse of communism in eastern Europe, sought and received legitimacy from the Catholic

Church. Not only in Poland but also throughout eastern Europe, religious traditions were deeply involved in the movement for liberation from communism.

Not all exogenous religious movements are movements of liberation. Around the globe religious groups call on divine providence to help them in struggles against other religions, ethnic rivals, and unsympathetic governments.

There are literally hundreds of these movements around the world in various stages of ascendancy or abatement. In predominantly Hindu India, Muslims in the northern province of Kashmir seek independence or union with Pakistan, while Sikhs in the nearby province of Punjab have for many years waged a bloody confrontation with the government for independence. In Sri Lanka, just off India's southern shores, Tamils, members of a Hindu sect, seek an independent state in a nation that is predominantly Buddhist. In Northern Ireland, Protestants and Catholics have experienced periodic conflict since Protestant settlers arrived in the middle of the seventeenth century, but since 1968 the two rivals have been locked in a high level of tension punctuated with intermittent outbursts of violence.

The third type of religious movement is *generative*—a deliberate effort to produce a new religious movement. Either new religions are introduced to a culture externally by missionaries, or they are products of innovation (invention) by members of the culture. Whereas schismatic movements produce variations on an existing religion within a culture, new religions are novel to the host culture. Sociological scholars refer to these new religions as *cults*.

New religions are not necessarily newly created. Hare Krishnas, adorned in saffron robes and chanting on street corners, first appeared in the United States during the mid-1960s. The Krishnas brought with them Hindu beliefs and practices that were clearly novel to North America, but that had been first practiced in India in the sixteenth century. In contrast, the Reverend Sun Myung Moon, a Korean and founder of the Unification Church, created a religion that involved a blending of significantly reconstructed Christian beliefs with important elements of Eastern religions. In still another example, L. Ron Hubbard, a science fiction writer, published a book in 1950 titled

Dianetics, which outlined psychotherapeutic or mental health techniques. The book became a best-seller, and in 1954 Hubbard founded the Church of Scientology.

In these three groups we have examples of, first, the importation of an old religion based on sacred texts of Hinduism (Hare Krishna); second, a newly created religion based on reported revelation from the God of the monotheistic traditions of Judaism and Christianity (Unificationism); and third, an indigenous religion based on techniques of modern psychotherapy (Scientology). All are new and novel to North American culture.

The late 1960s and early 1970s produced a flurry of new religious movements in the United States. The youth counterculture of the 1960s provided a receptive environment for new religions. Equally important, the repeal of the Oriental Exclusion Acts in 1965 paved the way for many Eastern gurus to come to the United States as missionaries of their faiths. While not nearly as extensive, this activity can be compared to that of the Christian missionaries, who flocked to Africa and Asia, during the late nineteenth and early twentieth centuries, to seek converts to their faith.

This period of rapid cult formation was not particularly unique. The nineteenth century, for example, produced a large number of cult and sectarian movements in the United States. Christian Science, Mormonism, Seventh-Day Adventism, Jehovah's Witnesses, and Theosophy are but a few examples of groups that emerged in that time frame and that remain viable in the late twentieth century.

Significant social science literature exists on all three types of religious movements: endogenous, exogenous, and generative. The focus of inquiry has shifted significantly over time, and the discipline of the investigators has influenced the selection of questions addressed.

During the formative years of sociology much attention was devoted to discerning how new religions arise and evolve. This interest was motivated by the legacy of early sociological writing on the *church-sect* typology by Max Weber and Ernst Troeltsch. Sects develop as a result of dissent within churches, when the dissenters break away and form sects. Over time, they institutionalize and gradually become more like the churches they

earlier broke from, even as new sects are being formed. Sects tend to recruit disproportionately from the “disinherited,” or the economically deprived classes. Further, sectarian groups tend to socialize their members to the dominant middle-class values of society.

Until the mid-1960s, much of the sociological literature focused on movements that have here been identified as endogenous. Much of this literature concerned questions relating to the formation of religious movements and could be classified as consisting of theories of: (1) deprivation (socioeconomic and other), (2) social dislocation, and (3) socioeconomic change.

Historical work has focused on exogenous and generative movements. Norman Cohn’s monumental work *The Pursuit of the Millennium* concludes that revolutionary millenarian movements during the eleventh and sixteenth centuries drew their strength from groups on the margin of society. Cohn uses the term *marginal* to describe persons who are not just poor but who also have no “recognized place in society [or] regular institutionalized methods of voicing their grievances or pressing their claims” (1970, p. 282). Historical literature supports much sociological work that finds religious groups emerging on the fringe of society.

Anthropological literature tends to focus on generative movements. The question that dominates their inquiry was inherited from the evolutionary agenda of Social Darwinism in the late nineteenth century: What are the origins of religion? New religions, they conclude, emerge during periods of rapid social change, disorganization, and dislocation. In anthropological literature, this cultural strain is most often identified as the result of the invasion of an indigenous culture by a militarily advanced culture—the typical pattern of conquest and colonization by European cultures from the late fifteenth century forward.

The new religions are variously identified as “cargo cults,” “messianic movements,” “nativistic movements,” and “revitalization movements.” Anthropological literature postulates that new religions emerge as a means of dealing with cultural stress. La Barre (1972) generalizes from the scores of ethnographic studies of anthropologists to locate the origins of all religions in cultural crisis.

Lanternari, surveying anthropological and historical literature on new religions that emerged as a result of intercultural conflict, concludes that these religions “tend to seek salvation by immediate action through militant struggle or through direct and determined opposition to the foreign forces” (1965, p. 247).

Psychological literature has been much less concerned with religious movements. Following the logic of Sigmund Freud’s cultural bias against religion, many psychologists have identified the leaders of religious movements as psychopathological and their followers as psychologically defective. This literature has not been particularly productive of insights about religious movements.

The ferment of generative religious movements in the wake of the youth counterculture of the late 1960s stimulated a tremendous volume of sociological inquiry. In terms of sheer volume, research and theorizing about “new religious movements” eclipsed all other subtopics of inquiry in the social scientific study of religion during the 1970s and 1980s (Bromley and Hadden 1993). These studies examined (1) the organizational development of new religions, (2) the structural and social-psychological dynamics of affiliation and disaffiliation, and (3) the persistence of intragroup conflict between new and established religious traditions.

In addition, the 1980s saw significant theoretical developments in the conceptualization of the role of religious movements in sustaining religion in human cultures. By the early 1990s, this literature was beginning to be recognized as a distinct departure from, and a challenge to, the prevailing model of religion that dominated the social sciences for most of the twentieth century. Indeed, from the inception of the social sciences, scholars worked within an intellectual framework that viewed religion as incompatible with the modern world that is dominated by science and reason.

In 1993 Stephen Warner published an article that proclaimed a “new paradigm” in the sociology of religion. The key theoretical ideas in Warner’s argument were most closely identified with the work of Rodney Stark and his colleagues. Warner showed how support for the new paradigm has been mounting in much social research, but especially in the work of young social historians. We will return to the “new paradigm” in the

final section of this essay and examine how it has altered our understanding of the role of religious movements in human culture. Further, we will see how the new paradigm restructures the central task of the sociology of religion as the study of religious movements.

We turn next to an examination of *fundamentalism*, a religious movement that spans most of the twentieth century. Several reasons are offered for exploring fundamentalism in some depth. First, fundamentalism is one of the most important movements of the twentieth century and, thus, deserves to be examined in its own right. Second, the widespread cultural prejudice against this conservative manifestation of religion has spilled over into scholarly literature, with the result that little empirical understanding of fundamentalism developed until near the end of the century. Third, the foundation for a much better understanding of fundamentalism is now in place. We shall briefly discuss the literature that constitutes this foundational work, and point to some research tasks that are required before a mature scholarly understanding of fundamentalism can be achieved.

RELIGIOUS FUNDAMENTALISM AS EXEMPLAR

Fundamentalism is an important religious movement that dates from the early twentieth century. Fundamentalism may be understood as protest against the quest of liberal Protestant scholars to resolve the apparent contradictions between religious knowledge and scientific discoveries. Such an effort, it was believed, could lead only to Christianity's capitulation to the ontological superiority of science as a path to truth.

From the early years of fundamentalism, most persons who have stood outside the movement have seen it through stereotypical lenses—provided substantially by the mass media—and have failed to grasp the complexity, nuances, and implications of the movement. Thus, almost from the beginning of the movement, fundamentalism has been a concept associated with religions that are perceived to be backward and potentially dangerous.

Fundamentalism has four distinct meanings. The first three meanings were in place by the end of the first quarter of the twentieth century; the

fourth does not appear until the last quarter of the century. The different meanings are often intermingled in both mass media and scholarly usage, with the result of considerable confusion and misunderstanding of the phenomenon. Significant theological and historical literatures are available on fundamentalism, but neither a theoretical nor an empirical sociological literature is well developed. This section of the essay of religious movements first identifies the four distinct meanings of fundamentalism and locates each in historical context. It then turns to a discussion of how a seriously flawed construct might be employed to better understand the phenomenon, and especially its utility for comparative sociological research.

First, fundamentalism refers to a Christian *theological movement* that experienced its greatest strength in the first quarter of the twentieth century. This movement was concerned with defending the faith against an internal movement seeking to make changes to accommodate Protestant Christianity to the modern world. As a theological movement, fundamentalism sought to purge the teachings of “modernism” from churches and theological schools. Modernist teachings had emerged during the late nineteenth century as a means of accommodating Christian doctrine to the evidence and teachings of science.

The most basic teaching of fundamentalism is that the scriptures are *inerrant*—that is, literally true. Closely related is the doctrine of *millenarianism*, which prophesies the imminent return of Christ. In the early days of the fundamentalist movement, these theological battles were waged in the leading theological seminaries of the nation (e.g., Princeton Theological Seminary).

An important development in this struggle was the publication, between 1910 and 1915, of a series of twelve books that sought to defend and reaffirm “fundamental” Christian principles in the face of the teachings of liberal scholars that did not believe the Bible should be understood as literal truth. Leading scholars from the United States and England contributed articles to the books, titled *The Fundamentals*, which were published by two wealthy Christian brothers, Lyman and Milton Steward. Copies of *The Fundamentals* were distributed gratis to over a quarter-million clergy members, seminary students, and teachers

throughout the United States. These tracts provided the inspiration for the name of the movement. The term “fundamentalism,” however, was not coined until 1920 by Curtis Lee Laws, a Baptist newspaper editor.

Defense of the faith against the encroachment of modernist theological teachings was at the core of the movement. But the *holiness movement* profoundly influenced fundamentalism, which was just as concerned with *correct behavior* as fundamentalism was with *correct belief*. The personal piety and renunciation of “worldly” vices of the holiness movement was combined with the combative spirit of theological fundamentalism to produce a *political fundamentalism*, the second distinct meaning of fundamentalism.

Fundamentalism as a political movement has had several phases. The first wave of political fundamentalism was a short-lived but vigorous conservative movement with several agendas, including temperance and anticommunism. The critical and ultimately fatal crusade of the fundamentalist movement occurred in the arena of public education policy. Charles Darwin’s theory of evolution, which had gained popularity among scientists and teachers, was clearly incompatible with a literal reading of the Bible. Among other incompatible passages in the Bible, the Genesis story of creation states that the earth and all that dwells therein were created in six days. The fundamentalists launched a campaign to prohibit the teaching of Darwinism in public schools, a campaign that initially met with considerable success in several states.

The struggle came to a climax in 1925 in one of the most celebrated trials of the twentieth century. John Scopes, a substitute biology teacher, was charged with violating a Tennessee state law that prohibited the teaching of evolution. Dubbed the “Monkey Trial,” this epochal event drew two of America’s greatest trial lawyers to the tiny town of Dayton, Tennessee. Speaking for the prosecution was William Jennings Bryan, brilliant orator and presidential nominee of the Democratic Party on three occasions. Bryan was the unchallenged leader of the fundamentalist political movement. Clarence Darrow, a bitter foe of organized religion, defended Scopes. Darrow gained prominence as a defender of labor unions and in litigation against

monopolistic corporations. He was believed by many to be the outstanding trial lawyer in the nation.

The highlight of the trial came when, in a surprise move, Darrow called Bryan as a witness. While Bryan claimed to have been a scholar of the Bible for fifty years, his ability to defend some of the finer points and implications of fundamentalist theology proved wanting. In the end, his testimony was a debacle for the prosecution. George Marsden described the scene thus:

Bryan did not know how Eve could be created from Adam’s rib, where Cain got his wife, or where the great fish came from that swallowed Jonah. He said that he had never contemplated what would happen if the earth stopped its rotation so that the sun would “stand still.”
(Marsden 1980, p. 186)

The trial was quintessentially a confrontation between the emerging modern world and the forces of tradition. The drama was played out on the turf of traditionalism—a sleepy, small town in Tennessee—but journalists who were sages of the new modern order communicated the trial to the world. The fundamentalists were portrayed as fossilized relics from an era long past. Darrow himself portrayed the trial as a struggle of modern liberal culture against “bigots and ignoramuses” (Marsden 1980, p. 187).

John Scopes was convicted, but that fact seemed inconsequential. The forces of modernity and tradition had met face to face, and modernity triumphed. William Jennings Bryan collapsed and died a few days after the trial without ever leaving Dayton, Tennessee. In popular myth, Bryan died of a broken heart. Bryan had planned a national campaign to compel schools across the nation to teach evolution as a theory, not a scientific fact. There was no one else of Bryan’s stature to pick up the cause. The first wave of political fundamentalism died when Bryan was unable to defend its theological underpinnings.

The third distinct meaning of fundamentalism emerges from a melding of the theological and political movements to create a *popular caricature* of small-town Americans as culturally unenlightened religious fanatics. Journalists H. L. Mencken and Sinclair Lewis, writing in the second and third decades of this century, set the tone and style of a

genre of lambasting literature that subsequent generations of writers have admired and sought to emulate. Fundamentalists were portrayed as backwater fools preyed on by hypocritical evangelists, and as a withering species destined to disappear from the modern world. They could be meddling and annoying, but they were not viewed as politically dangerous. In time they would most certainly die off, even in the rural hinterlands of America.

The Scopes trial clearly marked the demise of the first wave of political fundamentalism. Fundamentalists in the major Protestant denominations lost ground to the modernists on the theological front. But biblical fundamentalism did not so much wane as pass from high public visibility. A number of leaders bolted from mainline Protestant churches and formed new denominations and seminaries. But out of the limelight of the press and mainstream culture, fundamentalism did not wither as had been forecast. Rather, it continued to grow, particularly in the Midwest and the South (Carpen-ter 1997).

Fundamentalists also were schism-prone, so that none of the scores of groups developed into large new denominations, such as occurred with the Baptists and Methodists in the nineteenth century (Finke and Stark 1992). This, too, served to diminish the fundamentalists' visibility. An important development occurred during the 1940s when fundamentalism effectively divided into two camps. The first, which was more insular and combative toward the larger culture, joined with Carl McIntire to create the American Council of Christian Churches (ACCC). McIntire was militantly antimodernist, and he viewed the ACCC as an instrument for doing battle with the liberal Federal Council of Churches (FCC), which in 1950 became the National Council of Churches.

A second and larger contingent of fundamentalists, who were neither with the militant McIntire contingent nor the modernist tradition aligned with the FCC, came together in 1942 to found the National Association of Evangelicals (NAE). Theologically the NAE might have considered themselves neofundamentalists, but they recognized the negative cultural stereotype associated with fundamentalism. The use of the term "evangelical" was a reappropriation of a term that most

Protestant groups used to describe themselves before the modernist-fundamentalist schism. Some of the leaders of the NAE later admitted that the name "evangelical" was a strategy to escape the negative cultural stereotypes against fundamentalism. The concept of evangelicalism was simply more respectable.

Publicly NAE leaders stressed their desire to emphasize the positive aspects of their beliefs in contrast to the highly negative and combative posture of the ACCC toward both theological modernism and political liberalism. The label "evangelical" has served well those millions of Christians whose theological beliefs are hardly discernible from those identified as fundamentalists. Billy Graham, perhaps the most respected religious leader of the second half of the twentieth century, is considered an evangelical. Theologically speaking, his basic beliefs are virtually indistinguishable from those of fundamentalist Jerry Falwell, or from those of the leadership of the Southern Baptist Convention, which staged a takeover of the Southern Baptist denomination during the 1980s.

While fundamentalism continues to be defined in terms of assent to biblical literalism, fundamentalism in the United States is highly varied in terms of the social organization, nuances of belief, and social class background of adherents. To the general public, however, fundamentalists are known in terms of the caricature that is the legacy of the Scopes trial debacle—people who are narrow-minded, bigoted toward persons different from their own kind, obscurantist, sectarian, and hostile to the modern world. The mass media dredge up enough examples of people exhibiting these traits to keep the stereotype alive.

From the 1930s forward there have been periodic flurries of right-wing political activity led by preachers and laypersons who have been labeled fundamentalists. During the Depression, William Dudley Pelley, Gerald B. Winrod, and Gerald L. K. Smith led movements that blended religion with anti-Semitism. For many decades from the 1940s forward, Carl McIntire was a strident anti-Catholic propagandist; Frederick C. Schwarz, Billy James Hargis, and Edgar Bundy were among the most visible anticommunist crusaders of the post-World War II era.

Liberal political pundits and scholars have always viewed fundamentalist groups with mixed

feelings. Some have unequivocally looked on them with great alarm, and that sense of alarm has always been greatest during periods when fundamentalist movements were highly visible. Outside periods of high visibility, the general consensus of scholars is that the fundamentalist right embodies doctrines and attracts an element that is on the fringe of the mainstream of American politics. While perhaps repugnant to the liberal ethos, they have not been widely perceived as a serious threat to democratic institutions.

This perception vacillated yet once more in 1979 when Jerry Falwell, a fundamentalist television preacher, founded a political organization named the Moral Majority. Initially the media paid little attention, but when Falwell and his fellow right-wing fundamentalists organized to help elect presidential candidate Ronald Reagan, interest picked up. When Reagan reached out and embraced the fundamentalists, attention escalated. Following the Reagan victory, along with the defeat of several ranking senators and congressmen, Falwell claimed responsibility. Pollster Lou Harris agreed that the fundamentalist vote was the margin of victory for Reagan. Postelection analysis did not support this claim (Hadden and Swann 1981), but the high media profile of Falwell and his fellow televangelists gave fundamentalism its highest public profile since the 1920s.

This wave of concern about the political power of fundamentalists might have blown over quickly were it not for the timing of the development with the rise of the Islamic imam Ayatollah Khomeini. Khomeini led a revolution that deposed the shah of Iran. Shortly thereafter, his followers held sixty-two Americans hostage for fourteen months. Political analysts concerned with the power of the fundamentalists in America were soon comparing the religious right in America with the followers of Ayatollah Khomeini and other radical Muslim factions in the Middle East. From these comparisons was born the concept of *Islamic fundamentalism*. This linkage was quickly followed by the labeling of selected politically active religious groups around the world as "fundamentalist."

Thus was born the concept of *global fundamentalism*, the fourth distinct meaning of fundamentalism. During the 1980s the idea of global fundamentalism became widely accepted by the mass media and scholars alike. But like previous uses of

the term, global fundamentalism has suffered from lack of systematic conceptualization and consistent application. The global application of the concept thus has many of the same underlying presuppositions of the popular caricature of fundamentalism in U.S. Protestantism.

"Global fundamentalism," thus, is an uncomplimentary epithet for religious groups that are viewed as out of sync with the modern world. Fundamentalism, whether the American variety or of some other culture and faith, is characterized by blind adherence to a religious dogma or leader, and by zealous rejection of the modern world. It is also widely assumed that fundamentalists are contemptuous of democratic institutions. The concept is not applied to religious movements that are perceived to be on the side of human betterment. Thus, *liberation theology*, which is global in character, is not considered to be fundamentalist in spite of the fact that it bears some considerable resemblance to movements that have been characterized as fundamentalist.

Inconsistencies in the application of the concept fundamentalism are readily apparent. This was nowhere so evident as the failure to apply the concept to Afghan Muslim guerrillas who fought the Soviet army to a standoff during the 1980s. Both theologically and politically the Afghan rebels were unmistakably Islamic fundamentalists, but they were almost never so identified in the Western press. Rather, these Afghans are almost always referred to as the *mujaheddin*, usually with positive references such as "courageous," "brave," and "freedom fighting." But seldom did anyone mention that *mujaheddin* means, literally, one who fights a *jihad* or holy war. This and other instances of inconsistent application suggest that the concept of fundamentalism is reserved for religious zealots who are disapproved.

In sum, popular use of the concept of global fundamentalism has tended to connote the same stereotypical content that the term conveys when it is applied to Protestant fundamentalists in the United States. Given this history, it might be argued that fundamentalism has not been a concept of great utility for sociological analysis and, thus, its use should be discouraged. In support of this argument, it can be said that the social scientists have done little work to define, conceptualize, or measure fundamentalism.

To propose that fundamentalism should be abandoned as a social science concept may be premature. The introduction of the idea of global fundamentalism has served to focus rather considerable attention on the phenomenon—whatever it may be. The suggestion that the phenomenon might exist across cultures and world religions invites comparative analysis that was lacking when the concept was restricted to American Protestantism.

By the late 1980s serious comparative analysis of fundamentalism had begun. One of the first things learned from comparative inquiry is that fundamentalism cannot be explained away as part of a broader conservative cultural resistance to innovation. Bruce Lawrence's research on Islam led him to the conclusion that fundamentalism is a product of modernity and, thus, is a phenomenon that did not exist prior to modernity.

To view fundamentalism as merely an unenlightened backwater resistance to innovation is to give it a misplaced emphasis. Lawrence argues that fundamentalism is a product of modernity, and "because modernity is global, so is fundamentalism" (Lawrence 1989, p. 3).

Shupe and Hadden (1989) similarly argue that "fundamentalism is a truly modern phenomenon—modern in the sense that the movement is always seeking original solutions to new, pressing problems" (p. 112). Further, the solutions they propose are new. Secularization, the cognitive counterpart to modernization, has progressively sought to compartmentalize religion from, and defined it as irrelevant to, other institutional spheres. Fundamentalism acknowledges that religion has lost authority in the secular world. Further, it perceives secular values to be seriously at variance with the sacred tradition it proclaims.

Fundamentalism may be seen as a movement that seeks to reintegrate religion into the mainstream of culture. Thus conceived, *fundamentalism* may be defined as *a proclamation of reclaimed authority of a sacred tradition that is to be reinstated as an antidote for a society that has strayed from its cultural moorings*. Sociologically speaking, fundamentalism involves (1) a refutation of the radical differentiation of the sacred and the secular that has evolved with modernization and (2) a plan to dedifferentiate this institutional bifurcation and thus bring religion back to center stage as an important factor of interest in public policy decisions.

Fundamentalism is clearly an assault on the cognitive components of modernization. Insofar as the process of modernization is not globally uniform, the development of fundamentalism may be expected to manifest a different character in different cultures. Thus conceived, the varieties of fundamentalism can be examined without the baggage of presuppositions that assume it is necessarily a regressive force in culture.

So conceived, fundamentalism is not antimodern. Fundamentalists, for example, are typically not against the use of modern technology, but rather certain applications of technology viewed to be at variance with the faith. Fundamentalists have proved themselves to be particularly adept at utilizing technology, particular communications technology, to their own ends. From the invention of radio to the development of syndicated television broadcasting, fundamentalists have dominated the use of the airwaves for religious broadcasting in the United States. They have also succeeded in developing a significant global presence. In terms of sheer volume, the four major international religious broadcasting organizations transmit more hours per week in more languages than the BBC, Radio Moscow, and the Voice of America together (Hadden 1990, p. 162).

The American Academy of Arts and Sciences launched the most ambitious comparative study of fundamentalism to date in 1987 with a substantial grant from the John D. and Catherine T. MacArthur Foundation. Over a period of five years, the Fundamentalism Project, led by historian Martin E. Marty, brought together scholars of religion from around the world to prepare studies of groups that have been identified as fundamentalist.

This project was important for several reasons. First, it both encouraged a large number of scholars to study the phenomenon seriously, and provided resources for them to do so. Second, by bringing these scholars together to critique one another's work, the project significantly leavened the individual and collective intellectual products. Third, the monumental five-volume work published by the University of Chicago Press, with over one hundred research papers, constitutes an enormous repository of information about fundamentalist and fundamentalist-like groups in every major faith tradition around the world. (See Marty and Appleby 1991, 1993a, 1993b, 1994, 1995.)

The one major fault of this otherwise marvelous inquiry into the nature and scope of fundamentalism is that the leadership early made a strategic decision not to define the subject matter. From the onset, project leaders spoke of *family resemblances*. If a group shared some family resemblances, it was an appropriate group for investigation. This strategy served to avoid long debates that would most certainly have ensued among scholars from many disciplines, cultures, and faith traditions. But in the end, the family resemblances became a proxy for a definition. The proxy, in turn, became a typology that suffers the same conceptual flaw as the *church-sect* typology—the indiscriminate mixing of correlates with attributes in a definition (Stark and Bainbridge 1979).

A serious result of this study design flaw is an inability to differentiate between fundamentalism and that which is not fundamentalism. The implications of the flaw become evident when, for example, one seeks to differentiate between fundamentalist and nationalist movements. This criticism notwithstanding, the Fundamentalism Project has given an enormous boost to an understanding of the nature, origins, and scope of a phenomenon that has been substantially shrouded in misunderstanding for almost a century. Clearly, this is a fine example of scholarly inquiry into the study of religious movements moving in the right direction. Further, the raw data in the form of five volumes of published papers is a valuable resource for others to use in advancing understanding of fundamentalism.

EMERGING THEORETICAL UNDERSTANDING OF RELIGIOUS MOVEMENTS

During the last two decades of the twentieth century, the study of religious movement became the cutting edge in the development of sociological theory about religion. To understand how and why this occurred, it necessary to back track just a bit to explore the development of the sociology of religion during the century.

For the better part of the twentieth century, the sociology of religion was presaged by the classic writings by the founding generation of social science: Emile Durkheim, Sigmund Freud, William James, Bronislaw Malinowski, Karl Marx,

Max Weber, and a few other notables. By midcentury, the advent of survey research added a new dimension of interest in studying religion. Much of this work could be characterized as applied, not very theoretical, and conducted by nonacademic scholars. In the academy, scholars of religions studied the classics with an eye toward fine-tuning the founding fathers' brilliance, or aligning their own work with classic writings.

In 1973 Charles Y. Glock and Phillip Hammond, working under the imprimatur of the Society for the Scientific Study of Religion, published a volume of essays entitled *Beyond the Classics?* The question mark in the title of this stock-taking volume reveals the negative conclusion—social scientists had not moved much beyond the classic statements about religion.

Insofar as their perceptions of religion were concerned, the classic scholars held highly variable views, but they tended toward a common assessment of the future of religion. The prospects of religion against the rising tide of rational thought, science, and modernity were highly precarious. *Secularization theory* was a template laid over the work of the classicists to explain the fate of religion. In a phrase, secularization is the process whereby human cultures and institutions are loosed from ecclesiastical dominance.

From the perspective of secularization theory, the concept *religious movement* almost has the quality of an oxymoron. Many scholars who studied modernization during the second third of the century viewed religious movements as a kind of “residual noise” that had no relevance to the main currents of social change. Anthropologists frequently viewed religion as a prime mover in the formation of “revitalization movements,” but the evidence of their case studies pointed to less than felicitous conclusions for aborigines; that is, in the end, modern cultures triumph over “primitive cultures.” And modern culture is secular. If religion is moving toward extinction, the study of this phenomenon is less interesting than if it were perceived to have a buoyant quality in the face of dynamic new ways of understanding the world and the human condition.

Beginning in the 1960s, several factors would serve to point intellectual thought in the sociology of religion away from the presuppositions of secularization theory. First, those who studied the

civil rights movement, and the human rights movements that quickly followed, could hardly ignore the role of religion both in leadership roles and as a force that legitimated movement activity. Second, the youth counterculture of the late 1960s began with young people's "freaking out" on drugs and then came to a conclusion with many of those same youths' "freaking out" on Jesus, or some guru from Asia. Third, the power of religion to energize large communities of people became increasingly evident in the late 1970s and early 1980s with the coincidence of a renewed fundamentalist political movement in the United States, and the politicized Muslim youth in Iran. Once scholars began to focus their attention beyond the United States, the presence of religious movements on every continent and in every faith tradition became increasingly clear.

Each of these developments drew the attention of scholars who found resources to investigate the phenomenon. In differing ways, each of these developments called attention to the incongruity of religion as a dynamic and vital force in culture and the inherited legacy of secularization theory that had long ago sentenced religion to extinction. If religion is dead, or about to slip into a comatose condition, why are religious movements thriving everywhere scholars turn?

In the discipline of sociology, more persons gravitated to the study of new religious (generative) movements than any of the other movements. Many scholars began their inquiries much as anthropologists might pursue ethnography, but soon they were engaged in comparative work, and looking at the history of new religions in the United States during the nineteenth century. Eventually the scholars of new religious movements would see the discordant implications of their work for secularization theory.

As noted in the conclusion to the first part of this essay, Warner has argued that the sociology of religion is in the midst of a process of ferment that he characterizes as a "paradigm shift." His argument is framed in Thomas Kuhn's classic statement, *The Structure of Scientific Revolutions* (1962). The accumulation of anomalous findings to the prevailing theory has mounted to the point of producing an intellectual crisis. Defenders of the old paradigm rally to shore up their position, while

new evidence accumulates that simply cannot be incorporated.

The tone of Warner's unrelenting presentation of evidence in support of a new paradigm appears early in his forty-page essay:

The emerging paradigm begins with the theoretical reflection on a fact of U.S. history highly inconvenient to secularization theory: the proportion of the population enrolled in churches grew hugely throughout the 19th century and the first half of the 20th century, which, by any measures, were times of rapid modernization. (1993, pp. 1048-1049)

Warner draws heavily on historians who collectively have accumulated enormous evidence that demonstrates American religious history simply does not fit the secularization model. Warner finds an explanation for this in the historical fact of *disestablishment*, that is, the separation of church and state in the American Constitution. By protecting the institutionalization of religion, but protecting no religion in particular, the Constitution creates an environment in which religions can compete and, thus, thrive and grow, or atrophy and die. Sociologically speaking, the Constitution legitimated a social structure in which *pluralism* is not only permitted but also encouraged. Whereas religious monopolies discourage the expansion of religion, pluralism promotes the growth of religion.

Warner is cautious in not making his claim for a paradigm shift beyond the U.S. boundaries, but his limiting of the argument to the United States seems clearly to be overly cautious (Hadden, 1995). The role of disestablishment in promoting the growth of religion is important in the case of the United States, and Warner's argument can be fully incorporated into a larger framework of a global paradigm.

Over the past two decades, the seminal work of Rodney Stark and his colleagues has galvanized the study of religious movements and contributed almost immeasurably to the development of the new paradigm that Warner invisions. As the senior scholar in the enterprise, Stark has surrounded himself with a group of exceptionally able collaborators. Together they have developed a theory, identified a research agenda, pursued that research agenda vigorously, and inspired others who

have joined the task of building a new model for understanding religion.

For almost a decade, Stark's principal collaborator was William Sims Bainbridge. Stark and Bainbridge's work together began in 1979 with an article that bore a modest subtitle, "Preliminary Concepts for a Theory of Religious Movements." In this paper they identified and defined key concepts for the study of religious movements. They then proceeded to fill in details with more than twenty published papers over the next five years. These papers were published together in 1985 under the title *The Future of Religion*. Two years later Stark and Bainbridge published *A Theory of Religion* (1987), a work of monumental importance. *A Theory of Religion* goes beyond religious movements to provide a comprehensive theory that accounts for the origins, dynamics, and persistence of religions in human cultures. Beginning with six axioms, these authors deductively create more than a hundred definitions and nearly three hundred and fifty propositions.

The theory has sweeping implications for an understanding of religion in the modern world. First, the theory deduces why religion must necessarily be ubiquitous in human cultures. Second, religious institutions are human constructions and, thus, subject to constant change. Third, religious movements are the principal mechanism through which religious change occurs. Hence, *if religious are constantly in flux, and religious movements constitute the principal mechanism for change, it follows that the core focus of inquiry for social science is the study of religious movements.*

The theory is clearly inspired by *rational choice theory*. Stark's collaborations with Roger Finke, a sociologist, and Lawrence Iannaccone, an economist, are especially rich with concepts and imagery from economics. They speak of a *religious economy* as embracing all the religious activity of a given culture, and they work comfortably with concepts like *markets, niches, supply-side religion, monopoly, and competition*. Still, both Stark and Bainbridge vigorously object to the criticism that the paradigm is "nothing more" than a wholesale borrowing from economics and rational choice theory. (See Bainbridge 1997, pp. 350–356; Stark and Finke 2000).

As of the writing of this essay, the new paradigm lacked a name and, hence, the reference to

the "new paradigm." Rational choice theory has emerged as a significant development within American sociology. The American Sociological Association now has a rational choice section, and there is a journal entitled *Rationality and Society*. This perspective has also been referred to as the "theory of religious economy," but this too implies a narrower perspective than either Stark or Bainbridge wishes to communicate. In 1994 Lawrence Young, of Brigham Young University, convened a conference on "Rational Choice Theory and Religion," at which the principal contributors to the "new paradigm" were participants. Stark's own reservations to the name "rational choice theory" are communicated in his opening essay to the proceedings, entitled "Bringing Theory Back In." His concluding remark captures his commitment to follow theory wherever it may lead to fruitful insights: "My goal is to bring real theories into sociology, not to found a new theoretical sect."

Rejecting the names "rational choice theory" and "theory of religious economy" would appear to be a wise strategy, at least for the present time. Many scholars who are presently studying religious movements would also reject the identification of their work with either of these names. Still, a very large proportion of the emerging scholarship about religious movements is informed by and also adds credence to the emerging new paradigm. RELIGIOUS ORGANIZATIONS

The social organization of religion in the United States is diverse and complex. Most religious organizations are local churches (congregations, parishes, synagogues) tied to national religious bodies (usually referred to as denominations). The *Yearbook of American and Canadian Churches* lists 189 denominations in the United States with a total of almost 360,000 churches. The membership reported by these churches equals almost 58 percent of the U.S. population (Lindner 1999). The largest denominations are the Roman Catholic Church (61,207,914 members in 1996), the Southern Baptist Convention (15,891,514 members in 1997), and The United Methodist Church (8,496,047 members in 1996). Most denominations are quite small. In all, the twenty-one denominations with membership in excess of one million members account

for more than 140,000,000 members—about 91 percent of all church members in the United States. In contrast, the seventy-seven denominations with fewer than 25,000 members account for about 586,000 members, fewer than one-half of 1 percent of church members (figures calculated from information in Lindner 1999).

Typically, local churches hold worship services at least once a week and also have educational activities, especially for children and youths. Most churches organize various groups within the church to accomplish particular tasks (for example, missions, evangelism, or community action), or for the association of persons with common interests (such as women, youths, or senior citizens). Women's groups are especially active. Many churches serve as community centers providing space for meetings of all sorts of neighborhood and community organizations. Ammerman's recent work (1997) shows the crucial role churches play in their communities. "Not only are they linked to other parts of the community through the multiple memberships and loyalties of their members, but they are also linked *as organizations* to larger organizational networks" (p. 360) that pursue community-based goals.

Local churches usually have a pastor (or a priest or rabbi) and a lay governing board. There is great variation from denomination to denomination on the authority of lay boards, and, within denominations, there is variation from church to church in informal power. Research has shown that control by inner circles of informal leaders is likely to emerge when formal mechanisms of control and official leaders are not performing effectively (Houglund and Wood 1979).

The degree of control of the denomination over the local church depends in large part upon the polity, or political structure, of the denomination. Students of religious organizations place denominations in three categories according to polity. *Congregational* polity is the weakest. In this polity the local church owns its own property and hires and fires its own pastor. In contrast, in a *hierarchical* (often *episcopal*) polity the national (or regional) body holds title to the property and controls the placement of pastors. An in-between category is often called *presbyterial*. There are a number of correlates of polity. For example, denominations with strong polities were more active

supporters of the civil rights movement and more aggressively pressed for the integration of their churches (Wood 1981).

Denominational polities continue to evolve as they adapt to changing social environments (Dykstra and Hudnut-Beumler 1992). Recent years have seen a growth in the influence of local congregations—with a concomitant gain in local control—even within the most hierarchical polities. Given the communications revolution, which allows the almost instant dissemination of information throughout the church, this trend toward local control is congruent with Michels' argument (1962) that leaders' control of information is a principal basis of hierarchical control. A major study being conducted by researchers at Hartford Seminary, "Organizing Religious Work for the 21st Century," will provide massive data for the understanding of how denominational polities are adapting to their changing environments.

Though the organization of Jewish synagogues is similar to that of many Protestant churches in the United States, the Jewish perspective on religious organization is somewhat different. In 1987 the officials of the congregational organizations of the Orthodox, Conservative, and Reform branches of Judaism reported 3,750,000 persons associated with their synagogues and temples. However, there are approximately six million Jews, who are seen as an ethnic, social, and religious community (Jacquet 1989, pp. 243–244). Daniel Elazar stresses that Jews see no meaningful line of separation between "churchly" purposes and other communal need, and hence Jewish organizations are not neatly divided into religious and nonreligious ones. "It is *not simply* association with a *synagogue* that enables a Jew to become part of the organized Jewish community. Affiliation with *any of a whole range of organizations*, ranging from clearly philanthropic groups to 'secularist' cultural societies, offers the same option" (Elazar 1980, p. 133). Elazar argues that local Jewish federations for welfare, educational, and cultural activities should be seen as religious organizations (p. 133).

RELIGIOUS ORGANIZATIONS IN SOCIOLOGICAL CONTEXT

Religious organizations provide patterns for the interaction of religious individuals. Social forces

change these patterns, but in turn, the collective action of religious people influences society. Sociologists looking at religious organizations have been interested especially in their importance as plausibility structures that foster specific beliefs and values (Berger 1967) and as structures of action that mobilize people to seek social change.

Until the 1970s the sociological approach to religious organizations was guided primarily by the church-sect typology. This theoretical framework helped to explain the number and variety of religious bodies and differences in their behaviors by reference to the social class of their adherents. Max Weber distinguished between a church, a continuously operating rational, compulsory association that claims a monopolistic authority, and a sect, “a voluntary association [that] admits only persons with specific religious qualifications” (Weber 1978, p. 56). “One becomes a member of the church by birth . . . [but a] sect . . . makes membership conditional upon a contractual entry into some particular congregation” (p. 456). Weber’s student, Ernst Troeltsch (1961), developed a typology from these concepts and some variation of the church-sect typology has been used repeatedly in studying U.S. religious organizations.

In the Weberian tradition, H. Richard Niebuhr stressed the sociological sources of sect formation and the way in which social forces tended to turn sects into churches. He argued that sects originate “in the religious revolts of the poor, of those who were without effective representation in church or state” (1954, p. 19) and who employed a democratic, associational pattern in pursuing their dissent because it was the only way open to them. Niebuhr observed that the pure sectarian character of organization seldom lasts more than one generation. As children are born to the voluntary members of the first generation,

the sect must take on the character of an educational and disciplinary institution, with the purpose of bringing the new generation into conformity with ideals and customs which have become traditional. Rarely does a second generation hold the convictions it has inherited with a fervor equal to that of its fathers, who fashioned these convictions in the heat of conflict and at the risk of martyrdom. As generation succeeds generation, the isolation of

the community from the world becomes more difficult. Furthermore, wealth frequently increases when the sect subjects itself to the discipline of asceticism in work and expenditure; with the increase of wealth the possibilities for culture also become more numerous and involvement in the economic life of the nation as a whole can less easily be limited. (Niebuhr 1954, pp. 19–20).

Nancy Ammerman’s work continues the research tradition that relates the evolution of churches to social class backgrounds. Ammerman traces the rise of fundamentalism in the Southern Baptist Convention to the erosion of cultural support for traditional beliefs. She finds that fundamentalism decreases with increased levels of education and with increased levels of income. But “many at the edges of this transition are likely to respond by embracing fundamentalist beliefs more vigorously than ever (Ammerman 1986, p. 487).

According to James Beckford, “The question of the degree to which any particular organisation was church-like or sect-like was taken seriously for what it implied about that organisation’s capacity to survive in the modern world” (1984, p. 85). The church-sect theorizing was dominated by considerations of rationalization and compromise. Beckford detected a shift in the focus of sociologists studying religious organizations in the 1970s toward “the capacity of religious organisations to foster a sense of personal authenticity, conviction and self-identity” (p. 85). The 1970s saw a great many studies about recruitment and mobilization by religious organizations. Many of these studies focused on the growth and decline of traditional organizations, but many others dealt with religious movements that were new, or at least new upon the U.S. scene. Beckford refers to a number of authors who have found that cultlike formations are appropriate to an age marked by rationalization, bureaucratization, and privatization. That is, small groups of people cultivating esoteric religion in private are flexible and adaptable to the conditions of highly mobile and rapidly changing societies. Some of these scholars have linked cults’ ability to inspire and mobilize their members to their distinctive forms of organization.

In recent years more emphasis is placed on applying general organization theory to religious

organizations. Many recent studies of religious organizations are characterized by an open-systems approach, which views organizations as adaptive organisms in a threatening environment (Scherer 1980). The questions of adaptability to the modern world and of inspiration and mobilization of followers come together in studies of the Roman Catholic Church. John Seidler and Katherine Meyer (1989) examine that denomination's accommodations to the modern world, many of which involve important structural changes, such as priest's councils, and other changes that allowed both priests and lay people to have more say in the operation of the church.

A relatively new theoretical perspective within the sociology of organizations and social movements—resource mobilization—has illuminated much of the current scene of new religious movements. Bromley and Shupe did a detailed resource mobilization analysis of the Unification Church. They argue that one key element in the church's establishment in the United States was the development of mobile fund-raising teams (1979).

CURRENT ISSUES

A more varied theoretical approach to religious organizations has allowed scholars to focus on different kinds of issues. A major concern has been the decline of the liberal mainline denominations and the significance of that decline (Roof and McKinney 1987; Hoge and Roozen 1979). The liberal mainline churches in the United States share with other churches in a vast mobilization of voluntary time and money in activities caring for individuals such as the poor, the sick, and the elderly. Churches are particularly effective at such mobilization because they instill philanthropic values and present information and opportunities for philanthropic activities in face-to-face settings such as worship services and Sunday School classes. The liberal churches have played the additional role of implementing socially liberal policies, that is, policies designed to change the structure of society so that, for example, income as well as opportunities for individual achievement are more widely distributed throughout society. The liberal social agenda also includes sharp criticism of the U.S. government's role as promoter of U.S. business interests abroad. Mobilizing individuals and

groups to press for the acceptance and implementation of a liberal social agenda may be these churches' most significant contribution to U.S. society (Wood 1990).

Social and cultural changes in the United States in the last three decades have led to important changes in most traditional denominations and to the decline of membership and resources in many of them. At the same time, a new form of religious organization—the megachurch—has spread rapidly. These large (usually having at least 2,000 members), multiservice congregations are rarely affiliated with any denomination. However, megachurches are often associated with one another in networks that provide some of the services that denominations provide their member churches. In the twenty-first century, megachurches and their networks continue to provide significant competition for denominations. Yet these churches are themselves not immune to social and cultural change. Already there are reports that some of the leading megachurches are finding it necessary to make major changes in their programs to attract post-baby boomers (Jorstad 1999).

Another issue related to denominational polity is the role of women in the ministry. Chaves (1997) argues convincingly that the great variability in denominations' approval of women's ordination can be explained as responses to the denominations' significant social environments.

In an era of rapid social and cultural change, religious organizations play a crucial role in the process of consensus formation in our society. Amitai Etzioni (1968) argues that a healthy society is one in which the relationship between citizens and national leaders is mediated by a large network of groups and organizations where multiple perspectives are reduced toward consensus. The effect of any direct appeal by national leaders or by mass media campaigns to individual citizens is determined largely by the multiple membership of the citizens in groups and organizations. This mediation protects against mass emotional manipulation. At the national level the many "legislatures" within the major religious bodies in this country are of enormous importance in shaping the working consensus that enables both the formulation and the implementation of national policies. The representative selection procedures for

national meetings and the deliberative consensus formation processes typical of the major denominations are an important contribution to informed public opinion in U.S. society.

At the local level, congregations provide forums in which differing opinions can be expressed in a context of mutual respect. David Knoke and James Wood (1981) show that a wide variety of nonreligious social influence associations did not attract people with views as diverse as those in the church. They suggest that "in most of these organizations, policy-dissatisfied members probably do not feel the social pressure to remain in the organization comparable to that felt by dissatisfied church members" (p. 103). Churches' multiple goals and their emotional and value ties provide holding power that keeps members with different views together in the same church. Voluntary associations in which individuals can debate the critical issues face to face encourage individuals to act out their selfless values rather than their selfish interests, and provide a bulwark against the manipulation of the public by computer-generated direct mailing and mass media campaigns for a particular group's vested interest in ideology, money, or power.

Wood (2000) argues that the consensus formation process described above is contributing to the resolution of the issue of homosexuality, one of the most controversial social issues in church and society today.

OTHER RELIGIOUS ORGANIZATIONS

Robert Wuthnow (1988) has described the rise of numerous special-purpose organizations that are rooted in religion, drawing legitimation and resources from the more traditional religious organizations but with the objective of achieving a quite specific purpose.

These organizations provide new options for religious people in addition to participation in local churches. A wide variety of purposes are pursued, including the advancement of nuclear disarmament and meeting the spiritual needs of senior citizens. Wuthnow suggests that "as far as the society as a whole is concerned, these organizations may be the ones that increasingly define the public role of American religion. Rather than

religion's weight being felt through the pressure of denominations, it may be exercised through the more focused efforts of the hundreds of special-purpose groups now in operation" (1988, p. 121). Though these special-purpose groups are in many ways a revitalizing influence on traditional religious organizations (denominations and local churches), they may also have important sociological implications. For example, while the traditional organizations have often held together people of diverse social backgrounds, special-purpose groups may have a tendency toward homogeneity.

There are also a number of important umbrella organizations, such as the National Council of Churches and the National Association of Evangelicals, that facilitate the cooperation of sets of denominations. The National Council of Churches was particularly important in mobilizing a segment of the church population into the civil rights movement (Wood 1972). There has also been a growth of community councils of churches.

NEW RELIGIOUS ORGANIZATIONS

In recent years a number of the religious organizations have been in the news are unrelated either to the Judaeo-Christian heritage or to immigrant groups. They draw their adherents largely from the broad center of the U.S. middle class. Robert Ellwood and Harry Partin (1988) discuss more than forty of these groups. None of them are very large and in most of them most of their members remain affiliated for less than a year. Perhaps their greatest importance from the sociological perspective is that they introduce new organizational models into the U.S. scene.

THE FUTURE

New immigrant people are bringing their religions with them to the United States. Islam in particular is growing rapidly. People in the United States may have to start thinking of themselves as a Protestant, Catholic, Jewish, *Islamic* nation. According to one source, in 1973 there were fifteen or twenty local centers of Muslim worship in the United States; by 1980 these centers were reported in all of the three hundred largest cities in the United States. Two million adherents were reported in 1980; at the end of the century most authorities

estimate that there are between three and four million Muslims in the United States (some estimates go as high as six million). Most Islamic organizations in the United States are local centers (variously called Islamic Societies, Islamic Centers, or Muslim Mosques). Each of these organizations provides a place of worship and a place for other religious, social, and educational activities. Islam does not have an organized hierarchy, but several regional and national groups help to coordinate the work of local groups and promote unity among them (Jacquet 1989). If, as Elazar contends, many Jewish organizations in addition to the synagogue play a religious role, in Islam it appears that the religious centers play many roles in addition to the religious one. Perhaps this is always the case with the churches of recent immigrants.

Stark and Bainbridge (1985) say that traditionally organized religion may decline drastically as more and more people pursue individualistic “careers” of going from one self-enhancement group to another. If they are correct, any societal influence of religious organizations would be felt more through influence on individuals than through collective action of large religious bodies. However, there is much evidence that the traditional structure of religious organization in the United States will persist in the twenty-first century.

JAMES R. WOOD

RELIGIOUS ORIENTATIONS

Sociologists generally conceive of religion as a system of symbols that evokes a sense of holistic or transcendent meaning (Bellah 1970, p. 16; Geertz 1973, pp. 90-125). This definition reflects sociology's claim that symbols are essential to the human capacity to experience and interpret reality (Berger and Luckmann 1966). Symbols are acts, objects, utterances, or events that stand for something—that is, that give meaning to something by connecting it to something else. Symbols give order and meaning to life. Without them, life would be experienced as senseless and chaotic. Indeed, research suggests that individuals are able to experience and understand only those aspects of their worlds for which they have symbols (Farb 1973).

Sociologists' emphasis on holistic or transcendent meaning as the defining feature of religion arises from their view that meaning is always contextual (Langer 1951). The meaning of a particular word depends on the other words that form its immediate context. For example, the word "courts"

means one thing if it appears with the word "tennis," but something different when the word "justice" or, the word "dating" is present. Similarly, in their daily lives people give meaning to their activities by associating them with various frames of reference. Hitting a tennis ball has meaning, for example, because it is associated with the rules of the game of tennis. Each frame of reference, moreover, has meaning because it can be placed within a more encompassing symbolic context (tennis, say, within the context of physical exercise and health). But if each symbolic framework requires a broader framework to have meaning, then, some form of holistic or transcendent symbol system that embraces all of life must be present. These are what sociologists call religious orientations or religious systems (Berger 1967; Roberts 1984).

The questions that typically invoke religious symbols involve the quest to make life itself meaningful. Such questions arise at the extremities of human existence: Where did I come from? Why am I here? What happens when I die? These questions, framed at the individual level, may also be asked about the collectivity to which one belongs or about humanity in general: How did our tribe originate? Where is humanity headed? Other questions focus on the absolutes or landmarks that make life recognizable in its most basic sense: What is beauty? What is truth? How can we know truth? What is essential about the human condition? There are also questions that arise because the events they deal with make no sense to us on the surface: Why must I die? Why is there suffering in the world? What is the reason for evil?

Transcendent symbol systems address these questions at a variety of levels. Elaborate philosophical and theological doctrines sometimes supply rational answers that satisfy canons of logic and empirical evidence. In daily life these questions are more likely to be addressed through narratives, proverbs, maxims, and iconic representations rich with experiential connotations. Religious orientations are likely to be structured less by abstract deductive reasoning than by parables that raise questions but leave open precise answers, by personal stories that link experience with wider realities, and by creeds and images that have acquired meaning through long histories of interpretation in human communities (Greeley 1982, pp. 53-70).

Like other symbol systems, religious orientations are thought to be the products of social interaction. Although the role of such factors as divine revelation cannot be ruled out, sociologists focus on the ways in which symbols come to have meaning through the interaction of individuals and groups in human communities. Sometimes these communities invent collective symbols to articulate powerful experiences they may have undergone. More commonly, communities borrow symbols available within their cultural traditions, but then adapt these symbols to their own use, giving them new meanings and interpretations. Communities also underwrite the plausibility of religions belief systems (Berger 1967, p. 45). They do so by providing evidence that such beliefs are not the product of individual imaginations alone, by encouraging the public expression of beliefs, and by creating occasions on which beliefs may be enacted and predictions fulfilled. Without the ongoing interaction of people in communities, it is doubtful whether belief systems could long be sustained. Research has also demonstrated that personal religious orientations are more likely to have behavioral consequences if these orientations are supported by communities of like-minded individuals (Roof 1978).

In defining religion as a symbol system that deals with ultimate questions, sociologists assume that humans have the capacity to question their experience and a desire to make sense of their worlds. Whether all people pursue this desire with equal intensity is more doubtful. It is possible, for example, to explain a plane crash by observing that a rivet came loose. It is also possible to let the incident raise questions about the meaning of pain, the frailty of human existence, or the meaning and purpose of one's own life. How much the quest for holistic meaning and transcendence enters into people's lives is, therefore, a matter of variation. Studies indicate that most people say they have thought about the meaning and purpose of life, but individuals vary in the extent to which they have been troubled by this issue. They also vary in the amount of explicit attention they have devoted to it and in their views about the possibility of arriving at definite answers (Stark and Glock 1968, p. 77). Agnosticism, for example, is a religious orientation that grants the importance of ultimate questions about meaning and purpose

but denies the possibility of finding answers to these questions.

The kinds of symbols that come into play in relation to such questions are also matters of variation. While all such symbol systems may perform functionally similar roles, it is useful to distinguish them substantively. These substantive distinctions are usually the basis on which religious orientations are delineated in popular discourse. At the broadest level, sociologists distinguish theistic meaning systems, which recognize the existence of a God or divine being, from atheistic systems, which do not acknowledge a divine being (Glock and Stark 1965, pp. 3–17). Christianity is an example of the former; Marxism, of the latter. Insofar as it addresses the same higher-order questions about the meaning of life, Marxism would be considered functionally similar to Christianity. But this does not mean that Marxism necessarily functions this way. Just as one might study Marxism to derive economic principles, so one might study Christianity simply as an example of literature. In neither case would it be appropriate to say that a religious orientation is at work. Only as they function to evoke holistic meaning and transcendence do symbol systems become religious orientations.

The distinction between theistic and atheistic meaning systems is useful when the relevant concept is the presence or absence of a divine entity. But this distinction may be less useful in other contexts. For example, contemporary discussions in theology and in science sometimes distinguish religious orientations on the basis of whether they posit a reality that is humanly knowable or ultimately mysterious, whether reality is empirical or includes a supraempirical dimension, or whether being implies something that is not being itself but the ground of being. In these debates the boundary between varieties of ultimate meaning systems is often ambiguous.

In contemporary societies religious orientations are often distinguished in popular belief according to the dominant force or power that people perceive as governing their lives (Wuthnow 1976). Some people may conceive of this force as God; others, as luck or fate. Natural or human causes may also be considered dominant; for example, the force of heredity, of scientific law, society, or individual willpower. Whether a part of

elaborate philosophical systems or simple pieces of folk wisdom, such understandings help people to make sense of their lives by identifying the causal agents that control human events.

Sociologists have insisted that religious orientations become important to the study of human behavior insofar as these orientations are internalized as part of the individual's worldview. A worldview can be defined as a person's guiding outlook on life. The essential aspects of a religious orientation are the person's beliefs and assumptions about the meaning of life and such matters as the existence and nature of God, goodness and evil, life beyond death, truth, and the human condition. These beliefs and assumptions help the individual make sense of life cognitively. They also have an emotional dimension, perhaps including a feeling of awe, reverence, fear, or peace, comfort, and security. In addition, they are regarded as behavioral predispositions that lead to various actions, each as participation in worship, prayer, or ethical decisions (Spilka et al. 1985).

The importance of religious orientations for ethical decisions has been of longstanding interest to sociologists. In the classical work of Max Weber (1963), religious orientations were conceived of as symbolic frameworks that made sense of the world, in part, by providing explanations for the existence of evil (also known as theodicies). Some religious orientations, for example, explained evil as a struggle between God and the devil, others saw evil as part of a cycle of regeneration and renewal, while still others attributed evil to the workings of an all-powerful but inscrutable deity. The implications for ethical action derived from the prescriptions for salvation implied by these different conceptions of evil. In one tradition, for example, people might be expected to pray and meditate in order to escape from the cycle of evil and regeneration; in another tradition, they might be expected to do good deeds as a way of siding with the forces of good against those of evil.

Much of the research by sociologists on religious orientations has dealt with their subjective aspects (Blasi and Cuneo 1986). Assuming that the important feature of symbolism is its meaning, researchers have tried to discover what religious symbols mean to individuals. Efforts have been made to tap the deeper predispositions presumed

to underlie such religious expressions as prayer and worship, to say how deeply implanted the religious impulse is, and to classify varieties of religious outlooks and experiences.

Recent developments in sociological theory have resulted in some rethinking of this emphasis on subjective religiosity. Current research is beginning to focus more on the observable manifestations of religious symbolism itself, rather than claiming to know what lies beneath the surface in the subjective consciousness of the individual (Wuthnow 1987). Discourse, language, gesture, and ritual have become more important in their own right (Tipton 1982). The contrast between this and the earlier approach can be illustrated by comparing two statements: "I believe God exists" and "God speaks to us through the Word." A subjective approach would treat both statements as manifestations of some inner conviction of the individual. The more recent approach would pay closer attention to the language itself, noting, for example, the more personalized style of the first statement and the collective reference contained in the second.

The value of the more recent approach is that it recognizes the public or social dimension of religious orientations. Observers may not know what goes on in the dark recesses of the believer's soul. But if that person tells a story, or participates in worship, the researcher can then study the observable manifestations of that person's faith.

To account for variations in religious orientations, sociologists usually look at the social conditions to which people are exposed. They assume that most people do not make up their own religions from scratch. Rather, they borrow from the various symbol systems that are available in their environment. The most significant borrowing occurs in early childhood. Family is thus an important factor, and it, in turn, is influenced by broader conditions such as social class, levels of education, race and ethnicity, and exposure to regional subcultures.

A generation ago, sociologists often held the view that scientific generalizations could be made about the relationships between social factors and religious orientations. For example, much work was inspired by the hypothesis that theistic religious orientations were more common among persons with lower levels of education than among

persons in better-educated social strata. Another common hypothesis suggested that religious orientations were likely to be associated with various kinds of social deprivation, since the deprived would presumably seek solace in otherworldly beliefs. Empirical studies have found some support for such hypotheses, but the ability to make generalizations has remained limited. Different relationships seem to be present in different communities and in different time periods.

More attention has turned in recent years, therefore, toward describing the rich and complex processes by which religious orientations and social environments intermingle. In one setting people without college educations may turn to religious views that shield them from the uncertainties of science and other modern ideas. In another setting people with high levels of education may also turn to religion, but do so in a way that combines ideas from science and Scripture or that focuses on the therapeutic needs of people working in the professions. In both settings, religious orientations provide answers to ultimate questions. But the composition of these orientations reflects ideas present in the different social settings.

An earlier generation of social theorists also sought to explain the variations in religious orientations in ways that often reduced them to little more than the by-products of social or psychological needs. Sociologists following in the tradition of Karl Marx, for example, regarded religion merely as a reflection of class struggles, while some following Émile Durkheim viewed it as a reflection of the corporate authority of society (Swanson 1960, 1967). The reductionism in these approaches consisted not only of regarding social structure as more basic than religion but also of implying that religion would gradually disappear as people became more aware of its origins (Fenton 1970). Recent work is decidedly less reductionistic in its assumptions about religion. It still assumes that religion fulfills human needs and that it is influenced by social conditions, but regards religion as a more active contributor to human experience and considers its future more viable.

In addition to the more general social conditions that may influence the religious orientations of individuals, sociologists have also been particularly interested in the institutions that devote specific energies to the promulgation of religious

orientations. These institutions supply the resources needed for religious orientations to be perpetuated. Leadership, producers of religious knowledge, specialists in the dissemination of such knowledge, organizational skills, physical facilities, and financial resources are all required for religious orientations to be maintained over time. Religious institutions must compete with other institutions, such as governments, businesses, and families, for these resources.

In most modern societies competition is also present among the adherents of various religious orientations (Wuthnow 1988a). When such competition has been recognized either governmentally or culturally, we say that a condition of religious pluralism exists (Silk 1988). Pluralism often becomes a kind of religious orientation itself, imposing norms of civility and tolerance on particularistic religious traditions. When multiple religious orientations are forced to compete with one another, the plausibility of any one such tradition may be diminished as a result of believers' seeing others who hold views different from their own. At the same time, pluralism appears to contribute to the overall vitality of religious orientations in a society by encouraging competition among them for adherents and by giving believers more options from which to choose (Christiano 1987).

It has been common in the past for individuals to choose one particular religious orientation with which to identify. Often these orientations have been defined by religious institutions, such as the Roman Catholic church, or by denominational organizations, such as the Presbyterian or Methodist churches (Greeley 1972). Increasingly, however, it appears that individuals in modern societies are exposed to a variety of religious institutions and orientations. As a result, they may pick and choose particular elements from several different faiths and traditions. Their religious orientation therefore takes on a more personalized character (Bellah et al. 1985, pp. 219-249; Roof and McKinney 1987, pp. 40-71).

Although some individuals work out highly coherent religious orientations that have internal consistency and integrity, it appears that the more common result of living in religiously pluralistic settings is a form of personalized eclecticism. People become heteroglossic—that is, they gain the capacity to speak with many religious voices. Their

religious orientations may not provide a guiding philosophy of life that maintains an orderly view of the world. Rather, religious orientations become tool kits (Swidler 1987) assembled from a variety of personal experiences, social contacts, books, sermons, and other cultural repertoires, and from which the individual is able to draw as he or she is confronted with the challenges of life.

At present, research studies indicate that large proportions of the population in societies like the United States hold theistic religious orientations (Wuthnow 1988a). In other societies where religious institutions have had fewer resources in the past, such orientations are less common. In all societies, though, theistic orientations are confronted by the humanistic orientations promulgated by secular institutions. The outcome appears to involve a balance between pressures to adapt, on the one hand, and tendencies by religious adherents to resist these pressures, on the other hand (Hammond 1985; Beckford 1989). Much of the struggle depends on the ability of religious leaders to articulate visions that grow out of particular confessional traditions in ways that appeal to the universalistic norms governing wider social audiences.

Although religious orientations have become more diverse and eclectic as a result of cultural contact and mass communication, evidence also suggests that in some societies a basic polarization has emerged between those whose orientation involves traditionalistic, fundamentalistic, or conservative norms, on one side, and those whose orientation involves progressive, modernistic, or liberal norms, on the other side (Wuthnow 1988a). Conservatives are characterized by adherence to the authority of traditional scriptural texts, while liberals emphasize more the relativity of these texts and the need for reason and experience in interpreting them. Liberal religious orientations have been nurtured by relativistic views in higher education, in the professions, and in the mass media in market-oriented societies, but conservative orientations have grown as well, not only in reaction to liberalism, but also as a result of conservatives gaining educational or political advantages and seizing on opportunities created by the ill effects of rapid societal change (Ammerman 1987; Hunter 1987). Whereas earlier discussions predicted the demise of fundamentalist religious orientations, current studies are more concerned

with the ongoing tensions between fundamentalist and more liberal or more humanistic religious orientations.

Research on religious orientations continues to be produced. Fundamentalism and evangelicalism have been examined comparatively and through quantitative studies (Marty and Appleby 1994; Shibley 1996; Smith 1998), and conflicts between fundamentalist or orthodox views and those of liberals or progressives have been examined (Hunter 1991; Wolfe 1997). Other important currents in recent research include studies emphasizing eclecticism, individualism, and instability in contemporary spiritual orientations (Roof 1993), the apparent shift in popular thinking from beliefs rooted in organized religion toward orientations emphasizing personal spirituality (Roof 1999), and the rising importance of spiritual practices in response to uncertainties about formal religious beliefs (Hall 1997; Wuthnow 1998).

REMARRIAGE

Remarriages have become almost as common as first marriages in contemporary America. In fact, in recent years, almost half of all marriages involved at least one spouse who had been married previously (U.S. Bureau of the Census 1998). Remarriage rates in the United States (the number of people remarrying each year per 1,000 persons divorced or widowed) increased during the 1960s, declined precipitously across the 1970s, and have continued to decline throughout the 1980s and 1990s, although at a much slower rate (Sweet and Bumpass 1988; U.S. Bureau of the Census 1998).

Contemporary remarriages are more likely to follow divorce, in contrast to earlier centuries, in which remarriage typically followed the death of a spouse. For example, Demos (1970) reported that in the Plymouth Colony, approximately 40 percent of men and 26 percent of women over the age of 50 had been married more than once, due primarily to the death of the first spouse. In contrast, throughout the twentieth century, remarriages following the death of a spouse have been increasingly outnumbered by remarriages following divorce, owing to the combination of the dramatic decrease in the mortality rate in the first few decades of the century and the increase in the divorce rate. In fact, by 1990, remarriages in which both parties had been divorced occurred twenty times more often than remarriages in which both parties had been widowed (Clarke 1995).

While remarriage rates are related to divorce rates, they do not always follow the same trend. For example, the rise in remarriage rates in the 1960s accompanied the rise in divorce rates, but the decline in remarriage rates in the 1970s occurred at a time when the divorce rates were still growing. This apparent incongruence in the 1970s and early 1980s can be explained to a great extent by an increase in cohabitation among formerly marrieds across the same period (Bumpass et al. 1991).

WHO REMARRIES?

Rates of remarriage vary substantially by age, gender, race and ethnicity, and marital status (i.e., divorced or widowed).

Age at the time of termination of the first marriage is clearly the best predictor of remarriage—particularly for women—with younger people remarrying at much higher rates. For example, almost 90 percent of women under the age of 25 when their first marriage ends remarry, while fewer than one-third of women over the age of 40 at the time of termination remarry (Bumpass et al. 1990).

Remarriage rates also differ by *race and ethnicity*. White non-Hispanic women are substantially more likely to remarry than are black women, and somewhat more likely than Hispanic women (U.S. Bureau of the Census 1998). White non-Hispanic

women also remarry much more quickly than do either black or Hispanic women. Based on 1988 data, 35 percent of white women had remarried within two years, compared to only 16 percent of black women and 17 percent of Hispanic women (U.S. Bureau of the Census 1998). Further, black and Hispanic women are less likely to cohabitate following divorce than are white women (U.S. Bureau of the Census 1998). Thus, the variations in remarriage appear to reflect a general tendency for white non-Hispanic women to be more likely than black or Hispanic women to establish new households following divorce.

Gender is a particularly important factor to consider when discussing remarriage, not only because remarriage rates vary by gender, but because gender interacts with several other factors that predict remarriage. Overall, three-quarters of divorced men and two-thirds of divorced women in the United States remarry (Cherlin and Furstenberg 1994). However, gender differences in likelihood of remarriage increase substantially across the life course. For formerly marrieds under 30 years of age, there is little difference in men's and women's likelihood of remarriage; however, by age 35, men are much more likely to remarry, and they are increasingly more likely in each successive age group. For example, among those aged 30–34, the rate of remarriage per 1,000 in the formerly married population is 138 for women, and 178 for men. In the age group 50–54, the gender discrepancy increases to a rate of 25 per 1,000 for women, and 75 per 1,000 for men. By age 65 and over, the rate of remarriage rate for women is only 2 per 1,000 formerly marrieds in the population, compared to 15 per 1,000 for men (Clarke 1995). Thus, women's likelihood of remarriage not only decreases considerably across the life course, but decreases particularly markedly compared to that of men.

Various explanations for the overall lower remarriage rates for women than men have been developed. The most commonly cited explanation focuses on the limited "marriage market," or field of eligibles, for women who experience the termination of their marriage through divorce or death. First, there are fewer men than women, and this discrepancy increases with age (U.S. Bureau of the Census 1998). Also, women tend to marry men who are older than themselves, further limiting

the pool of eligibles for women who are themselves older.

The effect of the *presence of children* on likelihood of remarriage also varies considerably by gender. In particular, the presence of children has much greater effects on the likelihood of remarriage for women than for men. For example, a recent study in New York State found that only 45 percent of divorced women with children remarried, compared to 67 percent of divorced men with children. Further, the likelihood of remarriage for women, but not men, declined as the number of children from the previous marriage increased (Buckle et al. 1996). About half of the women with one child remarried, but only about a quarter of the women with four children remarried. In contrast, about two-thirds of men with either one or four children remarried. It is possible to speculate that the lower rate of remarriage for women with children, particular those with multiple children, might be a function of the fact that women with several children are likely to be older than their childless counterparts; however, even when controlling on age (i.e., comparing women within the same age groups), the rate of remarriage is about one-quarter lower among mothers than among childless women (Bumpass et al. 1990).

Buckle and colleagues (1996) found that the presence of children also affected men's, but not women's, choice of a new partner. Divorced men who were childless were four times more likely to marry women who had not been married previously; in contrast, divorced men with children were almost twice as likely to marry a woman who had been married before. While divorced women were almost twice as likely to marry men who had previously been married than those who had not, this choice was not affected by whether the women had children.

Recent work by Sweeney (1997) suggests that the *age of children* must also be considered when examining the effect of children on their mothers' likelihood of remarriage. She found that preschoolers reduced women's likelihood of remarriage, while school-age children and teenagers had no effect, and children 18 years or older were associated with an *increased* likelihood of remarriage; these findings are similar to those reported by Koo and Suchindran almost twenty years earlier (1980),

suggesting little change across time in the effects of this factor on remarriage.

MATE SELECTION AMONG THOSE WHO REMARRY

One of the most striking patterns in first marriages is the tendency for individuals to marry others with similar social characteristics, such as age, educational attainment, religion, and socioeconomic background—a pattern known as homogamy. Although there is also a tendency toward homogamy in remarriage, the degree of similarity has been less than in first marriages, although this trend appears to be changing.

The differences in status similarity between first marrieds and remarrieds can be seen by examining partners' age discrepancies. Individuals who remarry tend to select mates from a wider field of eligibles compared to first marrieds, resulting in greater age difference between spouses in remarriage; however, the discrepancy appears to have decreased over the past two decades. Throughout the past thirty-five years, the groom in a first marriage has been, on average, two years older than the bride. Between the early 1960s and the mid-1970s, remarried grooms were, on average, four years older than their brides; however, since 1980, the discrepancy has declined to about three years (Clarke 1995). Thus, while there continues to be less age homogamy in remarriages than first marriages, the difference has become muted.

Individuals who are formerly married also appear to be increasingly likely to select a partner who shares the same marital status. For example, by 1990, divorced women were almost twice as likely to marry men who were also divorced as to marry men who had never been married (Clarke 1995). However, as in the case of age, homogamy of marital status was greater than in earlier years; in fact, the rate of divorced women marrying divorced men almost doubled from 1970 to 1990.

Socioeconomic factors appear to have somewhat different effects on patterns of first marriages and subsequent marriages—particularly for women. The women most likely to enter first marriages are those with greater socioeconomic prospects (cf. Goldscheider and Waite 1986; Lichter et al. 1992). However, the patterns are more complicated for remarriage. Haskey (1987) reported

that women with higher occupational prestige were *less* likely to remarry; however, more recent research by Sweeney (1997) suggests that the effect of women's occupational prestige on remarriage may be more complex. She found that, among women under the age of 25 at the time of separation, those with higher occupational prestige were less likely to remarry; however, among women separating at age 45, higher occupational prestige was associated with an increased likelihood of remarriage. Thus, it appears that the middle-aged women who are the least able to support themselves are also the women least likely to be able to achieve economic stability through remarriage, further increasing the risk of poverty for women in this age group.

For men, it is less clear whether socioeconomic prospects have differential effects on entry into first marriages and remarriages. As in the case of women, greater economic prospects increase men's likelihood of entering into first marriages (cf. Goldscheider and Waite 1986; Lichter et al. 1992); however, evidence on economic factors and remarriage are less consistent. While Haskey (1987) found that men with higher occupational prestige were more likely to marry, Sweeney (1997) found no effects for any dimension of men's socioeconomic prospects, including educational attainment, job status, occupational aspirations, and work commitment.

Taken together, these findings suggest that patterns of remarriage may be becoming more similar to patterns of first marriages in terms of some demographic characteristics, such as age and previous marital status, but not necessarily in terms of socioeconomic prospects.

DIFFERENCES BETWEEN FIRST MARRIAGES AND REMARRIAGES

Marital Quality. While the popular press has debated the relative happiness of first marriages and remarriages, scholarly research on this issue has failed to find important differences. The most comprehensive review of this research to date (Vemer et al. 1989) found that first marrieds report only slightly greater marital satisfaction than do remarrieds. Elizabeth Vemer and her colleagues suggest that even this small difference may be

accounted for by the fact that most studies combine data from individuals who had married twice with those who had married more than twice, and there is evidence that individuals in the latter group are less happy in general. Vemer and her colleagues also found that remarried men were more satisfied with their relationships than were remarried women; however, the differences were very small and paralleled the differences found between women's and men's satisfaction with first marriages. The absence of notable differences in marital quality between first marriages and remarriages has also been found in more recent investigations of this issue (cf. McDonald and DeMaris 1995). Thus, taken together, the findings indicate little difference in satisfaction between first marriages and remarriages for either men or women.

Division of Household Labor. The literature suggests that the division of household labor also differs for couples in first and subsequent marriages. Ishii-Kuntz and Coltrane (1992) found that husbands in remarriages contributed more to household tasks such as cooking, meal cleanup, shopping, laundry, and housecleaning than did men in first marriages, particularly when couples had only their own biological children. In families in which there were stepchildren, women performed a greater actual number of hours of household labor, but the *proportion* that they contributed relative to their spouses was still smaller than that of women in first marriages. Ishii-Kuntz and Coltrane suggest that this is because the "incomplete institutionalization" of remarriage leads to a reduction in gender traditionalism.

However, other studies suggest that whether the woman has been married previously may have more effect on the division of household labor than whether her husband has been married before. Funder (1986) found that women in second marriages perceived that household labor was shared more equally than in their first marriages; however, there was no such trend in men's perceptions. Further, Sullivan (1997) reported that women who had been previously married contributed a smaller proportion of household labor, but that men who were formerly married contributed no differently than did men in first marriages.

Children in Remarriages. The large majority of remarriages involve children. Not only do more

than half of formerly married individuals bring children to their new marriages (Buckle et al. 1996), but the rate of childbearing in remarriages is relatively high. Approximately half of all women who enter remarriage under 35 years of age bear at least one child during that marriage, generally within the first two years (Wineberg 1990).

One question that is often raised in both the popular and the scholarly literature is the effect of the presence of children on marital quality. The presence of children has generally been found to have a negative effect on parents' marital quality; however, the effects of children specifically on *remarried* couples is less clear. While White and Booth (1985) found that the presence of stepchildren was associated with somewhat lower marital quality, Martin and Bumpass (1989) found no effect, and both Albrecht and colleagues (1983) and Kurdek (1989) reported that the presence of stepchildren was weakly but *positively* associated with marital quality. The findings regarding mutual children are also inconsistent. Ganong and Coleman (1988) found that mutual children had no effect on marital quality, but Albrecht and colleagues (1983) found a weak but positive effect. Thus, it is unclear how the presence of either mutual children or stepchildren affects marital quality among remarrieds.

Another question that is often the focus of research on stepfamilies (or blended families as they are increasingly labeled) concerns the effect of the remarriage on children. These effects are of considerable importance, given that about 15 percent of all children live in blended families, and it is estimated that between one-third and one-half of today's young people will become stepsons or stepdaughters at some point (Glick 1989; U.S. Bureau of the Census 1997). In the majority of these cases, the children in stepfamilies live with a biological mother and a stepfather.

Remarriage presents several challenges to the family. Members must make numerous decisions and adjustments to living arrangements and family relationships. In addition, parenting approaches and activities may change following the remarriage. Further, remarriage creates a complex set of relationships between former spouses, between stepparents and stepchildren, between step- and half-siblings and extended kin. These relationships are

often ill defined and lack the support of social expectations and norms. The ambiguous nature of these relationships can be seen when members of blended families are asked whom they consider to be family. While only 10 percent of children fail to mention a biological parent when asked to define their family, over 30 percent do not mention a stepparent (Furstenberg and Cherlin 1991).

Some studies have found that the bonds between stepparents and stepchildren are somewhat less warm, more conflictual, and less enduring than those between biological parents and children, while others have found substantial levels of closeness between stepparents and stepchildren (Kurdek and Fine 1993; White 1994). Such variation is not surprising, considering the wide variety of roles that stepparents adopt within the family. Some stepparents adopt a parental role, including the formation and maintenance of close emotional bonds with their stepchildren. Others take on the activities and roles of more distant relatives such as aunts or uncles, and still others act like adult boarders in the home, having little involvement with or showing little affection for the children (Arendell 1997).

Several factors appear to influence the nature of the stepparent-stepchild relationship. In a 1994 review, Cherlin and Furstenberg concluded that the primary factor influencing the character of the stepparent-stepchild relationship is the effort made by the stepparent to forge kinlike relations. Further, it appears easier to be a stepfather than a stepmother, in part because children seem more willing to accept substitute fathers than substitute mothers.

Other factors also affect the quality of the stepparent-stepchild relationship. For example, the younger the child at the time of the remarriage, the more likely he or she is to come to view the stepparent as a "real" parent. The more frequent the contact between the nonresidential parent and the child, the less likely the child is to develop a parentlike relationship with the stepparent (Arendell 1997).

Following remarriage, children often must adapt to the presence of step-siblings and half-siblings, as well as to stepparents. Such siblings may present additional challenges for the child's adjustment. For example, children may be asked

to share space and material resources, as well as the attention of their biological parent. Children may also find that their positions in the household hierarchy have changed with the addition of step-siblings; for example, a child may suddenly find that he or she has lost the status of being the “oldest” or the “baby” of the family. Despite these changes, most step-siblings eventually adjust and form close relationships. In fact, even as adults, step-siblings often maintain contact, albeit on a less frequent basis than full siblings (White and Reidman 1992).

Research on blended families provides a mixed picture with regard to the degree to which stepfamilies differ from intact families in terms of children’s adjustment (for reviews, see Amato and Booth 1997; Amato and Keith 1991a, 1991b; Hetherington et al. 1998). Children in stepfamilies appear to be at greater risk than children in intact families. For example, children in divorced and remarried families are more likely than children in intact families to have academic problems; to be less socially responsible; to have lower levels of self-esteem; to be withdrawn; to be less happy; to have trouble concentrating; and to have troubled relationships with parents, siblings, and peers. Adolescents may experience the same negative outcomes; they may also be more likely to drop out of school, to become sexually active at an earlier age, to have children out of wedlock, to be involved in delinquent activities, to abuse drugs and/or alcohol, and to be unemployed. Further, adult offspring of divorced and remarried families have been shown to be less satisfied with their lives, to have higher levels of marital instability, and to have lower levels of socioeconomic attainment.

Fortunately, despite their increased risk, the majority of children from divorced and stepfamilies do not experience these problems, and some studies suggest that many of the detrimental consequences of divorce or remarriage on children are temporary (c.f., Chase-Lansdale and Hetherington 1990; Emery and Forehand 1994; Hetherington 1993).

It is also important to note that the magnitude of differences in well-being and behavioral outcomes linked to family structure is reduced when the well-being and adjustment of the child prior to divorce and remarriage are taken into consideration. Further, there is a tendency for studies of

children’s adjustment following divorce and remarriage to combine different categories of stepfamilies together. This is particularly problematic due to the set of children that experience multiple transitions in family status. Approximately 10 percent of children experience at least two divorces by their custodial parent before they reach the age of 16 (Furstenberg 1988). The inclusion of children of multiple divorces with those of parents who have divorced and remarried a single time may artificially inflate the risks for children associated with remarriage, since these children are at greatest risk for negative outcomes. In fact, Kurdek (1994) argues that it is the children of the multiple-divorce group—not the stepfamily group—that are most at risk for negative outcomes when compared to children of intact families.

Last, it is essential to point out that remarriage may help to compensate for some of the negative consequences of divorce. For example, remarriage improves the financial well-being of children and their divorced mothers. Only 8 percent of children in mother-stepfather households live below the poverty line, compared to 49 percent of children in single-mother households (Cherlin and Furstenberg 1994). Remarriage also provides an additional adult in the household, thus adding more opportunities for interaction between children and adults, taking some of the burden off the custodial parent, and providing another role model for the child. These factors may help to explain why some studies have found that children in blended families are at less risk for negative outcomes than are children in single-parent homes (Amato and Keith 1991b).

In sum, although there are special concerns and greater complexity in family relationships, many blended families manage to form relationships that are close, loving, and lasting, and to function as effective family units, with the same variation in relationship quality found in more traditional family forms.

Stability of Remarriages. Clearly, remarriages and first marriages differ in complexity. The remarried couple must develop ways of interacting with the former spouse; with children from the former marriage (regardless of whether the children are minors or adults); and, in some cases, with both the extended kin and the new partner of the

former spouse. In addition, the emotional history of the relationship with the first spouse, positive and negative, may carry over to influence the new relationship, regardless of whether the first marriage was terminated by death or divorce. Further, material possessions and financial considerations emanating from the first marriage often have a significant impact on second marriages.

This complexity, and perhaps the attendant problems, might help to explain the slightly higher rate of divorce among remarried couples. Whereas about half of first remarriages end in divorce, approximately 60 percent of remarriages do so (Ihinger-Tallman and Pasley 1987).

There are several explanations for the higher rate of divorce among the remarried. Cherlin (1978) has suggested that there is an "incomplete institutionalization" of remarriage. Remarriages, according to Cherlin, are more difficult than first marriages due to the absence of guidelines in language, law, and custom for remarried couples.

Another interpretation of the higher rate of divorce among the remarried is offered by Furstenberg and Spanier (1984), who identify the predisposition to divorce of the remarried as the key explanatory factor. According to this perspective, since remarried individuals have already demonstrated their willingness to leave an unsatisfactory marriage, they will be willing to do so again if dissatisfied with the current relationship. Therefore, it may not be the quality of the marital relationship that precipitates divorce but the propensity to leave an unsatisfactory relationship.

Last, Martin and Bumpass (1989) have suggested that another explanation for the higher rate of divorce among the remarried is that these individuals have sociodemographic characteristics that increased the likelihood that their first marriage would end in divorce. These characteristics, such as low educational level, income instability, and parental divorce, are then carried into the remarriage, also increasing its instability. Further, Martin and Bumpass suggest that individuals who remarry are disproportionately likely to have married as teenagers, which may indicate differences in personality or experiences that might make it more difficult to maintain a successful marriage. Consistently with Martin and Bumpass's argument, there is evidence that men who are socially disadvantaged

remarry more quickly than their counterparts who are more advantaged (Monk-Turner and White 1995).

In sum, while the literature on remarriage emphasizes differences between first marriages and remarriages, it is important to reiterate that, overall, there is substantially more similarity than difference between the two. The patterns of mate selection, marital quality, and marital stability of individuals who remarry do not differ markedly from the patterns of individuals marrying for the first time.

CONCLUSION

In conclusion, married life in America today often involves a sequence of marriage, divorce, and remarriage, sometimes followed by a subsequent divorce. Many sociologists suggest that the high rate of remarriage followed by a subsequent divorce in America society indicates a strong commitment to married life, albeit of a slightly different form. These scholars argue that contemporary Americans are not rejecting marriage, they are only rejecting specific relationships that became unsatisfying. Taken together, the literature on remarriage and stepfamilies suggests that the individuals who choose to follow this pattern have approximately as great a likelihood of finding a satisfying and stable relationship as do those who marry for the first time.

REPLICATION

Philosophers have long identified replication as an important facilitator of scientific progress. Several terms have been used to denote the ability to assess past work through replication, including “intersubjective testability,” “reliability,” and “verifiability by repetition.” Authors of scientific papers typically describe the methods and materials they used in their research so that, at least hypothetically, others can repeat the work and reproduce the reported results. Successful replication of their own and others’ work gives researchers confidence in its validity and reassures them about the fruitfulness of the general line of inquiry they are following. In contrast, inability to replicate one’s own or others’ results casts doubt upon the validity of the previous work. Critics argue that because sociologists infrequently attempt to replicate findings, they are both less able to identify valid lines of inquiry and more likely to follow spurious ones.

One can identify a continuum ranging from exact to weakly approximate replication. The former, also called repetition, consists of attempts to use the same materials and procedures as previous research to determine whether the same results can be obtained. Approximate replication, on the other hand, consists of using some but not all of the conditions of a previous study. By systematically varying research conditions in a series of approximate replications, it may be possible to determine the precise nature of a previous study’s results and the extent to which they also hold for different populations and situations (Aronson et al. 1998). Researchers usually value successful approximate replication more than successful exact replication because the latter contributes less to existing knowledge.

In the natural sciences, experimentalists are usually expected to carry out successful exact replications of their own work before submitting it for

publication. This reduces the likelihood of reporting spurious results and of misleading one's colleagues. Exact replications of others' research are often difficult and costly to execute, however, and natural scientists rarely attempt them except in cases where the original work is theoretically important or has high potential practical value, or where there is suspicion of fraud. Another disincentive for carrying out exact replications of already published work is that such work is usually difficult to publish. This is true not only because little new knowledge results from an exact replication, but also because the meaning of a failure to replicate exactly is often ambiguous. Failures can indicate that the original work was flawed, but they may also be due to inadequate specification of research procedures, the existence of a stochastic element in the production of results, or errors in the replication itself (Harry M. Collins 1985). By contrast, approximate replications, especially those involving the modification of research instruments and their application to new areas of inquiry, are common in the natural sciences, and this has led some to identify them as constituting a central element of "rapid-discovery, high-consensus science" (Randall Collins 1994).

Many hold that social scientists' opportunities to carry out replications, especially exact replications, are severely limited. This is partly because social scientists often use nonexperimental research techniques that are difficult to repeat exactly. In addition, changing social and historical contexts can influence studies' results. As a result, failures to obtain the same results as reported by previous studies are even more ambiguous in the social sciences than in the natural sciences (Schuman and Presser 1981). This ambiguity may account for social scientists' continued interest in concepts and theories stemming from studies whose results have repeatedly failed to be replicated (e.g., sex differences in fear of success and patterns of moral development).

Nevertheless, critics have long argued that behavioral scientists need to attempt more replications of previous research because their dependence on statistical inference produces many spurious reports of "statistically significant" results. Statistical inference allows researchers only to reject or fail to reject a null hypothesis. Each of these

two outcomes is subject to error due to the probabilistic nature of statistical hypothesis testing; sometimes researchers reject null hypotheses that are actually true (type one error), and sometimes they fail to reject null hypotheses that are actually false (type two error). However, failure to reject a null hypothesis does not justify accepting it, and studies that do not yield rejections therefore are often judged as contributing little. As a result, scholarly journals tend to publish only papers that report the rejection of null hypotheses, some of which are the result of type one errors (Sterling 1959). Furthermore, to ensure that they will be able to reject null hypotheses, researchers sometimes use inappropriate analytic procedures that maximize their chances of obtaining statistically significant results (Selvin and Stuart 1966), increasing the likelihood that published findings are due to type one errors. To counteract these patterns, some have argued that behavioral science editors should set aside space in their journals for the publication of replication attempts, and to publish studies that fail to replicate earlier results even when the replications themselves fail to reject null hypotheses.

Despite the calls for increased replication, behavioral science journals publish few papers reporting replication attempts. In an early examination of this issue, Sterling (1959) reported that among 362 articles in psychology journals, 97 percent of those reporting a test of significance rejected the null hypothesis, but that none was an explicit replication. Ironically, many have replicated Sterling's results (cf. Dickersin 1990; Gaston 1979; Reid et al. 1981). These studies probably underestimate the prevalence of replication, because they do not count papers reporting a set of experiments that comprise both an original result and one or more approximate replications of it. By not encouraging more replication, however, behavioral science journals may foster elaborate and vacuous theorizing at the expense of identifying factual puzzles that deserve theoretical analysis (Cook and Campbell 1979, p. 25).

Although the traditional view of replication entails the collection of new data—including data on additional cases or additional measures—statisticians and social scientists have suggested alternative replication strategies. One is to build replication into a study from the start. For example, a researcher can draw a sample large enough to allow its random partition into two subsamples.

Data from one subsample can then be used to check conclusions drawn on the basis of analyses of data from the other. Another approach, requiring the intensive use of computing resources, is to draw multiple random subsamples from already collected data and then use these subsamples to crossvalidate results (Finifter 1972). This general strategy, which includes such techniques as “jackknifing” and “bootstrapping,” is also used to assess sampling variances for complex sampling designs (see *Sampling Procedures*). Still another elaboration of the basic idea of replication is the general approach called *meta-analysis*. Here the analyst treats previous studies on a topic or relationship as a sample of approximate replications. By statistically analyzing whether and how studies’ results vary, one can determine how generalizable a finding is and the extent to which differences in study design account for variation in results (Hunter and Schmidt 1990). Finally, replication may also be fostered by the increased availability of already-collected data sets stemming from the establishment of data depositories, and funding agency requirements that data from supported projects be made accessible to other researchers. Access to previously collected data makes it possible to carry out both exact replications of previous analyses and approximate replications that alter the analytic procedures used by the original researcher.

RESEARCH FUNDING IN SOCIOLOGY

IMPORTANCE OF EXTERNAL FUNDING

Jesse Unruh, a well-known twentieth-century politician in California, is alleged to have said, “Money is the mother’s milk of politics.” Observers at the century’s close may have made similarly accurate comments about the importance of money in the conduct of research. Natural scientists (including those in fields ranging from basic biomedical science to space exploration) have traditionally depended on funds beyond the internal resources of the organizations at which they are employed. Major discoveries in the natural sciences would be unthinkable without funding for particle accelerators, field expeditions, and clinical research staffs. Social scientists and particularly sociologists may be moving toward similar dependence on funding from beyond the boundaries of their universities and institutes. Such resources appear crucial for truly significant investigations, at least those which require original empirical data.

Sponsorship citation in the leading sociology journals in 1997 and 1998 provides an indication of the importance of external research support to

sociologists. Volume 62 (1997) of the *American Sociological Review* (*ASR*) contains 55 articles. In 31 of these articles (56 percent), the authors cite sources of funding outside their home organizations. An additional 3 authors, all university based, cite internal sources of support (such as university research committees), which presumably grant awards through a competitive proposal process. *American Journal of Sociology* (*AJS*), volume 103 (1997 and 1998), contains 27 articles; 9 of these cite funding sources, 6 (22 percent) of which are clearly outside agencies or internal units distributing funds obtained from outside. At century's end, external research funding appeared to be a frequent if not ubiquitous part of the research process in sociology.

Review of research published a generation ago presents a similar picture. Volume 42 of *ASR* (1977) contains 59 articles, 23 (39 percent) of which cite outside funding sources. An additional 4 authors cite funding sources internal to their institutions. Volume 83 of the *AJS* (1977 and 1978) includes 38 articles, of which 24 (63 percent) cite funding from sources outside the authors' universities, institutes, or agencies. An additional 3 *AJS* articles cite internal sources.

SOURCES OF FUNDING

Sources named in the above-cited *AJS* and *ASR* volumes provide an indication of where sociologists obtain research funds. Among the articles published in 1997 and 1998 that cite external funding, a plurality (17 citations) named the National Science Foundation (NSF) as the sole or primary source of support. The second most frequently cited source was the National Institute of Child and Human Development (NICHD), with three citations, followed by the National Institute on Aging (NIA), with two citations. One article cited the National Institute of Mental Health (NIMH) and the remainder acknowledged a variety of private funders, such as the Ford, Rockefeller, and Guggenheim foundations.

Among 1977 and 1978 journal articles that cited external funding, the National Science Foundation (NSF) received the most frequent acknowledgement (16 citations), followed by NIMH (eight citations), the Office of Economic Opportunity (four citations), the Ford Foundation (four citations), the National Institute of Education (two

citations), and the Russell Sage Foundation (two citations). An assortment of federal agencies and private foundation received one citation each, including the Social Security Administration (SSA), the Department of Labor (DOL), the National Endowment for the Humanities (NEH), the National Institute for Drug Abuse (NIDA), and the Grant and Guggenheim foundations.

Comparison of funding patterns in *ASR* and *AJS* across the decades carries some risk. These journals do not necessarily represent the most important work of general sociology and may not reflect patterns of support (or its absence) in subdisciplines, such as medical sociology and sociology of religion. Conventions and habits prevailing among authors regarding citation of funding sources may have changed between the 1970s and the 1990s, but inspection of acknowledgements in the articles cited above suggests that external funding of major sociological research remained as common a phenomenon in the late 1990s, when 43 percent of *ASR* and *AJS* articles cited external funding, as it was in the late 1970s, when 47 percent of *ASR* and *AJS* articles acknowledged such support. Funding of the research leading to these articles depended somewhat more on public agency support in the late 1970s than in the late 1990s. About 80 percent of the above-referenced 1977 and 1978 *ASR* and *AJS* articles which acknowledged external funding cited public sources and 20 percent cited private sources. About 71 percent of comparable *ASR* and *AJS* articles in 1997 and 1998 acknowledged public funding, 29 percent citing private sources.

STRUCTURE AND OPERATION OF FUNDING ORGANIZATIONS

Public and private sources of research funding comprise different social worlds. Representatives of each evaluate research proposals according to different rules and criteria. These differences derive from the distinct institutional surroundings of public agencies and private organizations.

Public Funding Organizations. Procedures followed by the U.S. Public Health Service (PHS) illustrate the processes by which public research funding takes place and the organizational components which facilitate these processes. The PHS, a subunit of the Department of Health and Human

Services (DHHS), houses a large number of agencies making research grants. These include several of the sources cited in the above-mentioned *AJS* and *ASR* volumes, such as the National Institute of Mental Health (NIMH), the National Institute of Aging (NIA) and the National Institute of Child Health and Disease (NICHD). Other PHS subunits such the National Cancer Institute (NCI) and the Agency for Health Care Policy and Research (AHCPR) have funded significant sociological work, principally in the fields of organizational and medical sociology. It appears likely that other governmental funding organizations, such as NSF, operate in a manner similar to these PHS units.

The institutional background and functioning of AHCPR provide a paradigm applicable to all federal funding organizations. Federal legislation established AHCPR through the Omnibus Budget Reconciliation Act of 1989 (AHCPR 1992). The legislation authorizes the secretary of DHHS to undertake "research, demonstration, and evaluation activities" regarding delivery of health services in the United States. The AHCPR administrator acts as operational head of the agency and derives his or her authority via delegation from the secretary of DHHS. By statute, the administrator is advised by the National Advisory Council for Health Care Policy, Research, and Evaluation. The council recommends priority areas for research funding. In addition, it provides "secondary review" of grant proposals. All PHS awarding organizations have a similar administrative structure and advisory council.

The council's composition is mandated to include seventeen public (nonfederal) members who have voting power. These are primarily scientifically qualified individuals. The council also includes health practitioners; individuals drawn from business, ethics, law, and policy; and consumer representatives. In addition, the council includes seven federal officials with voting power, appointed to serve *ex officio*.

Of key importance in the process of research funding by AHCPR and analogous groups is the Initial Review Group (IRG), sometimes referenced as the "scientific review group" or "study section." As mandated by statute, the IRG advises the secretary of DHHS on the scientific and technical merit of research grant applications within AHCPR's areas of responsibility. The AHCPR administrator

officially invites individuals selected for IRG membership to join. Selection is made with assistance from the Office of Scientific Review (OSR), the administrative body within the agency with responsibility for organizing the review of applications for grant support and reporting IRG findings to the AHCPR administrator. Normally, IRG members are appointed to overlapping four-year terms.

Official criteria for IRG membership include scientific expertise in areas of concern to the agency, often indicated by a history of receiving funds under the agency's jurisdiction. IRG members cannot be employees of the federal government. In 1992, AHCPR operated four IRGs, each covering a different specialty area or agency concern. Agencies such as AHCPR occasionally appoint special panels to evaluate proposals obtained in response to Requests for Applications (RFAs) issued to solicit interest in new or unusual areas of scientific concern.

The IRG meets three times each year, a few months after regularly scheduled deadlines for submission of grant applications. An official of the Office of Scientific Review, known as the Scientific Review administrator, in consultation with the IRG chair, assigns committee members the task of reviewing each application received by the agency. For each application, the Scientific Review administrator appoints a primary reviewer and at least two secondary reviewers.

At IRG meetings, primary and secondary reviewers present evaluations of the scientific merit of the proposals which they have been assigned. Discussion then takes place among all members of the IRG. The chair then requests a recommendation from the primary reviewer to assign a "priority score" to the proposal, defer discussion, or remove the proposal from further consideration. Priority scores are assigned ranging from 1.0 (most meritorious) to 5.0 (least meritorious). Following the reviewers' reports and ensuing discussion, all voting members of the IRG formulate priority scores according to their own judgment and submit them to the chair. Composite priority scores and summaries of the IRG's findings regarding scientific merit are reported to the council and the grant applicant.

The agency establishes a "pay line" indicating the priority score below which proposals are likely

to receive funding. In the late 1990s, pay lines varied between priority scores of 1.80 and 2.20, criteria stringent in comparison with the early 1970s, when pay lines were often in the 300s. Strictly speaking, the findings of the IRG are advisory to the council and ultimately to the secretary. Rarely, the council or a high official may elect to fund a proposal "out of priority" due to extraordinary merit or urgent public need.

Government research organizations such as AHCPR review all grant applications that are complete and received on time. In a mid-1992 funding cycle, IRGs (including all those of AHCPR, the National Institute of Health [NIH], and related agencies) reviewed 8,017 applications (NIH Division of Research Grants 1993). Three such cycles occur annually. IRGs usually award priority scores resulting in funding of between 10 and 20 percent of the applications they review. Structure and procedures at the National Science Foundation appear somewhat simpler but similar in form to those of the PHS. Proposals are reviewed by technical staff (an NSF program officer) with the aid of outside reviewers. Final award decisions are made at the senior management level.

Private Funding Organizations. If review of funding sources cited in *ASR* and *AJS* provides a valid indication, most nongovernment funding for sociological research comes from private foundations. None of the journal articles acknowledge funding from corporations, which are major sources of research support in some fields, such as engineering and pharmacy.

A private foundation is a nongovernmental, nonprofit organization with funds from a permanent portfolio of investments known as an endowment. Typically, an endowment originates from a single source, such as an individual, a family, or a corporation. Legally, foundations are chartered to maintain or aid social, educational, religious, or other charitable activities serving the common good. They are owned by trustees who hold the foundation's assets "in trust" for the people of the jurisdiction in which they are chartered. Governance is carried out by a board of directors. Trustees usually sit on boards of directors, but directors are not always trustees. Foundations of significant size employ staff to recommend policy, evaluate applications for funding, and perform day-to-day administrative tasks.

Like federal agencies, private foundations identify areas of interest and disseminate this information to the grant-seeking community. New interests and areas of emphasis emerge periodically through initiation by staff or discussion among directors and trustees. Large foundations such as Robert Wood Johnson and W. K. Kellogg seem to change their areas of emphasis approximately every decade or upon accession of a new president. Foundations often develop initiatives articulating interests focused on specific concerns and issue program announcements and RFAs in these areas.

The process of evaluating grant requests appears considerably less formal in private foundations than it is in government. Typically, foundations advise potential grant applicants to submit short letters of interest as a first step. Typically, lower-level staff read these letters, screening them for conformity with the foundation's interests, credibility of the prospective applicant, and such nonstandard criteria for consideration as the foundation might maintain. Letters that pass this screening process are transmitted to higher-level staff, which may ask the applicant for a detailed proposal. Some foundations assemble review panels and hire outside consultants to evaluate proposals of a technical nature. More typically, though, foundation officials discuss full-scale proposals among themselves and formulate recommendations to the governing board, which makes final award decisions.

The percentage of letters of interest which result in eventual funding is quite low. Most letters of inquiry generate a notice of rejection via form letter. Likelihood of funding appears roughly comparable with federal sources. In 1999, the Robert Wood Johnson Foundation's Web site advised potential applicants that their chances of success were 1 in 20. In the 1990s, this foundation operated an investigator program in health policy. Each year, this program received over 400 letters of inquiry and awarded no more than 10 grants.

Some features of the private foundation's informality appear advantageous to applicants. Federal grant application forms are extremely long and detailed, requiring significant effort for completion. Foundation forms tend to be simpler. Many foundations require no standard form. Generally, though, federal agencies provide larger

amounts of money to grantees than private foundations. In the late 1900s, for example, few Ford Foundation grants exceeded \$100,000. Several AHCPR awards approached \$1 million. Generous overhead recovery rates provided by federal grants are attractive to university officials. Many private foundations severely restrict overhead payments or allow no such funds in grantee budgets.

THE POLITICS OF RESEARCH FUNDING

The bureaucratic structure of public funding organizations clearly aims at promoting accountability and fairness. Legally, much of the grant award process is visible to the public. All successful grant applications may be obtained through the Freedom of Information Act. IRG deliberations, the venue in which key funding decisions take place, tend to be conscientiously conducted discussions in the manner of serious graduate-level seminars.

Key features of the operation of agencies such as AHCPR, though, raise questions about the degree to which awards are made strictly according to scientific merit. Deliberations of the Scientific Review Administrator and the agency administrator which result in IRG membership selection are subject to the same uncertainty as all dyadic interactions. Disciplinary bias, partiality to particular questions and approaches, and personal ties may affect IRG membership appointments. IRG membership, of course, strongly affects the agency's funding pattern.

Assignment of primary review responsibilities by the Scientific Review administrator and the IRG chair can also have a profound effect on funding decisions. Positively or negatively biased assignment of the primary reviewer responsibility can determine favorable versus unfavorable outcome. Although all IRG members are expected to read all applications, only the primary and secondary reviewers are expected to do so in detail. IRG members look to these individuals for guidance in their determination of priority scores. Given the competitiveness of funding, most applications have no chance of receiving priority scores below the pay line without strong support by their primary reviewers. In a sense, the primary reviewer must function as an advocate for the applicant. Officials

prejudiced against a particular investigator or approach could ensure selection of a primary reviewer who shared their negative inclination.

Advocacy plays a role of similar importance in private foundation funding. Communication with a foundation official is a virtual necessity prior to submission of a letter of interest. Established relations with these officials is necessary to avoid the screening process that eliminates most grant-seekers and to promote favorable action at each step in the decision-making process.

RETIREMENT

Retirement is primarily a twentieth-century phenomenon that developed through a convergence of public and private employment policies, a restructuring of the life span relative to work activity, and a redefinition of the terms of monetary compensation for work performed. It may be tempting to view retirement as the "natural" development of a social institution matched to the needs of older people experiencing declines in capacity; but the invention of a distinctive nonemployment status called *retirement* was not simply a response to human aging. Rather, in reconciling a transformed economy to an aging population with an increasing amount of surplus labor, an explicit policy of job distribution was produced. Retirement policies incorporated age as a characteristic that served

as both a qualifying and an exclusionary principle for work and income. The fact that these policies were age-based can be linked to the social production of age as a predictor of individual capacity and potential, a production that had ideological roots in the science and larger culture of the time.

HISTORICAL DEVELOPMENTS

Whereas *retirement contracts* existed in both Europe and colonial America, Plakans (1989) argues that preindustrial retirement was a gradual transition. The head of a household transferred legal title to an heir in exchange for some combination of monetary payments, material provisions, and services as stipulated by the aged person or couple. These contracts were typical of agrarian economies in which land was the main factor in production; they represented the final step in a long and sometimes elaborate process of property transfer. These “stepping-down” practices were therefore most immediately linked to inheritance patterns; they could be used to ensure that family control of the land was maintained (Sorensen 1989).

Between 1790 and 1820, American legislatures introduced policies of mandatory retirement for certain categories of public officials. By the late 1800s, the majority of businesses still had no formal policies of fixed-age retirement. Instead, informal policies eliminated older workers from the labor force (Fischer 1977). This decline in the demand for older workers can be linked to changes in the structure of American capitalism. During the late 1800s the structure of American capitalism began to change from small-producer, competitive capitalism to large-scale corporate capitalism (Sklar 1988). Part of this reconstruction involved attempts to rationalize age relations in the workplace, a process that was embedded in a more general disenchantment with older workers and a devaluation of their skills. Indeed, the employment rates for men aged 65 and older showed a steady decline during this period, from 80.6 percent in 1870 to 60.2 percent in 1920 (Graebner 1980). According to Graebner’s analysis, retirement became the impersonal and egalitarian method adopted by both public and private employers for dealing with superannuated workers. It allowed employers to routinize the dismissal of older workers, thereby restructuring the age composition of their workforces in a way they believed

would enhance efficiency, a belief supported by the principles of scientific management. Pension plans legitimized this process and, at the same time, served as an effective labor control device.

The first pension plan (1875) is credited to the American Express Company, but benefits were restricted to permanently incapacitated workers who were at least 65 years old with a minimum of 20 years of service (Schulz 1976). In 1920, the first general piece of retirement legislation, the Civil Service Retirement Act, provided pension coverage for federal civilian employees. One year later, the Revenue Act of 1921 encouraged businesses to implement private plans by exempting both the income of pension and profit-sharing trusts and the employer contributions to these trusts from income tax liability. Nevertheless, coverage remained concentrated in a few industries, and 85 percent of the workforce continued to be without pension coverage.

By the 1930s, the problem of superannuated workers was coupled with the more general problem of managing surplus labor. The changing technology of the workplace helped transform the labor process. A subsequent increase in worker productivity and the growing recognition of the cyclical crises inherent in industrial capitalism broadened the concern beyond that of simple superannuation to that of job distribution and consumption capacity.

The Depression of the 1930s greatly exacerbated the growing problem of old-age poverty and unemployment. By 1935 unemployment rates among those 65 and older were well over 50 percent. Even those with pension benefits did not escape poverty; trade union plans were collapsing, and state and local governments were reducing or discontinuing pension payments (Olsen 1982). Legislative proposals for alleviating some of these problems included the Townsend Plan and the Lundeen Bill. The Townsend Plan proposed a flat \$200 monthly pension for older Americans; recipients had to spend the pension within thirty days. The Lundeen Bill proposed benefits at the level of prevailing local wages for all unemployed workers aged 18 and older (including the elderly) until suitable employment was located. Neither of these plans was directly related to a retirement transition. The Townsend Plan granted equal benefits to all nonemployed persons over age 60. The Lundeen

Bill focused more on job creation for workers of all ages than on limiting labor supply through age exclusions.

In 1934, President Franklin Roosevelt appointed the Committee on Economic Security (CES) to develop legislation to address the problems of old-age poverty and unemployment. The Social Security Act of 1935 offered a solution that based benefits on the level of workers' contributions to a general trust fund. Upon their retirement, covered workers (primarily those in manufacturing) could draw retirement benefits, assuming they met the age and work eligibility requirements.

For the CES, retirement referred to complete withdrawal from the labor force. As stated by Barbara Armstrong, an original member of the CES, "[r]etirement means that you've stopped working for pay." According to Armstrong, the option facing the Roosevelt administration pitted older workers against younger workers (Graebner 1980, p. 186). Retirement would reduce unemployment by moving older workers out of the labor force, allowing industries characterized by surplus labor to transfer jobs from older to younger workers. The federal government could facilitate this process by shifting the focus of older workers' financial dependency from the wage contract to a federal income maintenance program. In that sense, the Social Security Act of 1935 established what was primarily a program of old-age relief; its limited coverage and low benefit levels precluded its serving as an effective instrument of retirement. However, in establishing a measure of income support for retired older workers, the act reinforced the view that in the competition for jobs, age was a legitimate criterion, and youth had the "higher claim" (Graebner 1980). Ironically, the mobilization for World War II created job opportunities for older workers, as it did for women. Even though these opportunities proved temporary, they challenged the connection between retirement and superannuation, a connection that was asserted more emphatically when the supply of labor exceeded the demand.

During the next several decades, considerable growth in private pension plans occurred; coverage increased from 4 million workers in the late 1930s to 10 million workers in 1950 and 20 million workers in 1960. The expansion was spurred by a

number of factors including the desire of firms to encourage loyalty and reduce turnover, favorable tax treatment, and the 1949 Supreme Court decision to uphold a National Labor Relations Board (NLRB) ruling that pensions were appropriate issues of negotiation through collective bargaining (Schulz 1976). During this same period, Social Security coverage was extended to more workers, and Congress continued to raise benefits in response to changes in the cost of living, although real benefit levels remained relatively low (Derthick 1979).

DECLINING RATES OF LABOR-FORCE PARTICIPATION

Early research on retirement was centrally concerned with the question of voluntarism in the retirement transition, as well as with the financial, social, and psychological consequences of leaving the labor force. Even though the expansion of both government and employer-based pensions had improved the economic situation of older people in retirement, poverty rates among the elderly were still high. By 1960, 35.2 percent of persons aged 65 and older were below the poverty line, compared with 22.4 percent of the general population. Poverty was the norm for older white women and older African Americans (U.S. Bureau of the Census 1987).

During the 1950s, the Social Security Administration began studying the characteristics of newly entitled beneficiaries. Initial reports stated that early retirement occurred primarily because of poor health and difficulties finding and keeping jobs; the availability of Social Security retirement benefits played a secondary role (Wentworth 1945; Stecker 1955). Although these studies relied on beneficiary-reported reasons for retirement, a measurement strategy that was criticized because of its susceptibility to social desirability bias, the findings cannot be totally discounted. Retirement in the 1950s was not a financially attractive status for many older workers. Given that retirement income programs offered "fixed" benefits (benefits that remained nominally the same but, with inflation, declined in real terms), the financial security of middle- and working-class retirees was in jeopardy.

During the 1950s, retirement became more common. Insurance companies led the way in

developing “retirement preparation” programs, as researchers attempted to define strategies for “successful aging.” In an era of postwar prosperity, retirement came to be viewed as a “period of potential enjoyment and creative experience which accrues as a social reward for a life-time of labor” (Donahue et al. 1960, p. 361). Researchers investigating the effect of retirement on life satisfaction found that “retirement does not cause a sudden deterioration in psychological health as [had] been asserted by other writers” (Streib and Schneider 1971, p. 161). Rather than rejecting retirement, advocacy groups for the elderly lobbied for improved conditions of retirement, including more generous pension benefits. Mandatory retirement had not yet become an issue. Instead, the trend was in the direction of earlier retirement, that is, before the age of 65. In 1956 women and in 1962 men were allowed to retire at age 62 by accepting actuarially reduced Social Security benefits.

During the mid-1960s, in the context of Lyndon Johnson’s War on Poverty, the issue of old-age poverty was again addressed. In the Older Americans Act of 1965, Congress established a “new social contract for the aged” (Achenbaum 1983, p. 85) by specifying a series of objectives that, if met, would significantly improve the quality of life enjoyed by older people. Among these objectives was an “equal opportunity to the full and free enjoyment of . . . an adequate income in retirement in accordance with the American standard of living . . . [and] retirement in health, honor, and dignity” (U.S. Department of Health, Education, and Welfare 1976, p. 2).

Richard Nixon’s presidency inaugurated the era of modern retirement. Whereas previous amendments to the Social Security Act had brought more and more workers into the system, they had not significantly improved the level of retirement benefits (Munnell 1977). The presumption that Social Security benefits should serve as retirement income supplements rather than as the primary source of income had not been challenged. But the persistently high rates of old-age poverty lent credence to the charge that benefits were inadequate. During the decade following passage of the Older Americans Act, benefits were increased five times and indexed to changes in the consumer price index. Both the “real” level of benefits and

the replacement rate of benefits to previous earnings were improved. Enhanced retirement benefits allowed workers to maintain their standard of living across the retirement transition and helped redefine retirement as a legitimate nonwork status that average-income workers could afford to enter voluntarily. During the 1970s, employer-sponsored pensions were also being reorganized. The 1974 passage of the Employee Retirement Income Security Act (ERISA) regularized vesting plans and provided workers with some protection against benefit loss. Private sector initiatives aimed at inducing early retirement were also increasingly common (Barfield and Morgan 1969). Until the 1970s, workers choosing early retirement virtually always accepted reduced benefits. During the 1970s, however, employers began to offer early retirement incentive plans. Not only did these plans pay benefits at younger ages, but the present value of the benefits often exceeded that of normal retirement benefits.

The parallel changes in labor-force participation rates and in poverty rates among the elderly are noteworthy. In the latter part of this century, labor-force participation rates at older ages declined significantly. During the 1970s, rates for men aged 55–64 dropped from 83 percent (1970) to 75.6 percent (1975) to 72.1 percent (1980) (U.S. Department of Labor 1983). In addition, at the beginning of the decade, 24.6 percent of those aged 65 and older were living below the poverty line, twice the 12.1 percent that characterized the general population. By the end of the decade, the poverty rate among the elderly had dropped to 15.2 percent, compared to an overall poverty rate of 11.7.

As Figure 1 illustrates, the changes in labor-force participation rates (derived from the Current Population Survey) differ by both age and gender. Rates for men and women aged 65 and older appear to have stabilized and perhaps marginally increased from their lowest point. Rates for men aged 55–59 and 60–64 show overall declines with recent hints of a slight upturn. In contrast, rates for women in these age ranges have steadily increased during the last quarter-century, with rates for women in their late fifties surpassing rates for men in their early sixties during the last decade.

DETERMINANTS OF RETIREMENT

Most current research examining retirement is of one of two types: national longitudinal studies that address the behavior of workers across a wide variety of occupations and industries (e.g., Quinn and Burkhauser, 1994; Hayward et al. 1989) and studies of specific firms that assess the retirement behavior of workers who share substantial commonality in workplace features (e.g., Hardy et al. 1996; Stock and Wise 1990). The former design maximizes variation in both work context and individual characteristics, using statistical controls to assess the relative impact of individual and job characteristics on retirement transitions. Because of the sampling strategy, results from these studies can be generalized to the national population of older workers. The second design—the case study—limits observations to workers who share a particular work context and attempts to explain variation in workers' responses to a common decisional matrix.

In both these designs, individualized models of retirement have been dominant, although the

relative emphasis of “sociological” versus “economic” models may differ. Retirement models proposed by economists have emphasized the financial considerations involved in exchanging one income flow (e.g., wages and salary) for alternative sources of income (e.g., pensions and income from savings and investments). They have proposed measurement strategies based on the calculation of the present discounted values of the various income streams to attempt to disentangle relative effects. Sociological studies of retirement frequently focus either on the social psychological consequences of retirement or on the importance of occupational structure in shaping behavioral contingencies. Both opportunities and constraints are unequally distributed across workers. Whereas unionized manufacturing jobs may protect older workers through seniority systems, they also provide early retirement incentives through employer-based pension plans. Older workers are also vulnerable to plant closings and job dislocations that accompany mergers, downsizing, and cutbacks. This theoretical framework views retirement transitions as a career characteristic, with

late-career behaviors being at least partially contingent on earlier career opportunities. In addition, retirement behavior is embedded in more general macroeconomic conditions. Rates of unemployment, changes in both government and employer pension programs, and the age structure of both the population and the labor force are implicated. Combining insights from both disciplines leads to models in which the financial trade-off is captured by the relative effects of current earnings and the present value of pension benefits; human capital (and, indirectly, the probability of alternative employment) through education, health status, skill level, and age; characteristics of career through years of seniority, history of recent layoffs, and overtime work; and family situation through marital status and the presence of children in the home.

MEASURING RETIREMENT

As the nature of retirement transitions changed, the question of measurement became more difficult. Armstrong's definition of "no longer working for pay" was being replaced by a variety of definitions oriented toward transitions out of career employment or full-time work, changes in major income sources (the receipt of Social Security or employer pension benefits), or changes in identity structures (e.g., through self-identification as a retiree). As definitions of retirement shifted toward receipt of pensions and the inclusion of part-time workers, the concerns of government turned toward the escalating cost of retirement and the advisability of delaying it. It became important to distinguish among exiting the labor force through "early" retirement, "regular" retirement, or disability, since these distinctions have implications for income replacement as well as labor-force reentry. Professionals, managers, and salespeople tend to delay retirement, whereas skilled and semiskilled blue-collar workers move more rapidly into retirement; clerical workers move more quickly into both retirement and disability statuses; and service workers experience relatively high rates of disability and death out of employment (Hayward et al. 1989). In addition, reentry into the labor force has become more common, with estimates of as many as one-third of retirees becoming reemployed, often within one to two years of their retirements. In short, the heterogeneity of what it means to be retired has increased considerably: it encompasses a broader age range;

it involves diversity of income sources; and it allows for some level of postretirement employment.

ISSUES OF GENDER AND RACE

The development of retirement policy has been primarily oriented around the work careers of men, predominantly white men. The original Social Security program excluded industries in which women and blacks were concentrated. Although later amendments eventually covered these categories of workers, the benefit structure continued to reward long and continuous attachment to the labor force and to penalize workers for extended or frequent work interruptions. The temporal organization of women's lives relative to work and family, paid and unpaid labor, put women "off schedule" in accumulating claims to retirement income.

Spousal and survivors' benefits were designed to support couples and (primarily) widows during their later years. Research on women's retirement often focused on unmarried women and found that the determinants of retirement for women were similar to the determinants that had been identified for men. Although unmarried women and men differed in occupational locations, wages, health, and access to employer-sponsored pensions, these determinants appeared to sort unmarried women into retirees and workers in much the same way as they sorted men.

The pattern of women's labor-force participation has changed in recent decades, and more women—particularly more married women—are in the labor market. In fact, the trends in rates of labor-force participation for older women reflect both the increasing employment rates for successive cohorts of women and the tendency for more recent cohorts of older working women to retire at younger ages. The increase in dual-earner couples suggests that retirement decisions may be interdependent, with age differences, relative earnings, and the relative health of spouses figuring into joint decisions about careers, retirement, and postretirement employment.

Work and income disadvantages that are experienced at earlier stages of the life course cast a shadow on retirement transitions among minority group members. Lower earnings, lower job status, and discontinuity in labor-force attachment all

undermine the financial platform for retirement. Work histories characterized by frequent spells of unemployment, illness, or temporary disability are linked to lower average retirement benefits and lower rates of savings and asset accumulation. In addition, African Americans are less likely to be married than whites and therefore more likely to be limited to their individual earnings and retirement resources. African Americans are more likely to exit work through disability and also more likely to continue to work intermittently after retirement. Gibson (1987) argues that disability can be used as another pathway to retirement for older African Americans, one that offers financial advantages. Because work histories can appear sporadic in old age as well as youth, establishing the timing of retirement as an event also can be difficult (Gibson 1987).

INTERNATIONAL COMPARISONS

Industrialization, economic development, demographic shifts, and politics are implicated in international comparisons of both the prevalence and the financing of retirement. Pampel (1985) reports that, among advanced industrial nations, a pattern of low labor-force participation among aged males is related to the level of industrialization and population aging. Cross-national comparisons of employment-to-population ratios demonstrate a continued decline in labor-force participation between 1970 and 1990 for men aged 55 and older. This decline is not, however, consistent across all age groups. Employment rates for men aged 55–59 have not shown the same proportional decrease as rates for men aged 60–64, or for those aged 65 and older. Compared to other Organization for Economic Cooperation and Development (OECD) countries (see Figure 2), Canada, Finland, Japan, Sweden, and the United States have relatively high rates of labor-force participation for men and women aged 65 and older.

Despite an overall downward trend in average age of retirement, nations continue to differ in the patterns of labor-force exits. Early retirement in European countries such as France, the Netherlands, and Germany remains the norm, with one-half to three-quarters of 60–64-year-old men out of the labor market (Guillemard and Rein 1993). Whereas early retirement in the United States was

primarily financed through early retirement incentive programs (ERIPs) offered by private firms, more severe problems of unemployment in Europe fueled early retirement through expanded eligibility for state programs. Among some countries of western Europe and North America, disability programs also can operate as pseudo-retirement programs that allow workers to exit prior to normal retirement age. In contrast to the pattern of western Europe, Canada, and the United States, labor-force participation rates in Japan for men in all three age groups have been more resilient. Rates in 1990 remained relatively high, with more than one-third of men aged 65 and older participating in the labor force (Quinn and Burkhauser 1994). Cross-national comparisons of women's retirement patterns are more complicated. Whereas some countries show little change since 1970 (e.g., Canada, Australia, Italy, Japan, and the United States), others show patterns of labor-force withdrawal that parallel the trends for older men (e.g., Finland, France, West Germany, Spain, and the United Kingdom).

When comparing rates of labor-force participation, it is important to take into account national differences in census procedures, the definition of the labor force, and the kinds of activities that constitute "work." Because countries differ in the pathways workers take to retirement, using pension receipt as an indicator is also flawed. In Germany, for example, disability benefits and intermediate unemployment benefits also provide access to early retirement. Comparisons based on rates of labor-force participation confound country differences in full-time versus part-time employment, complete versus partial retirement, and unemployment and employment. In addition, cross-sectional figures do not allow a comparison of rates of withdrawal or reentry that would allow us to distinguish relatively stable from volatile labor markets.

Within each nation, policy development and social dynamics exert an important influence on retirement behavior. Recent debate in the United States and other countries has centered on the financial burdens of supporting a growing population of retirees and the desirability of reversing the trend toward early retirement. In 1983 the United States amended the Social Security Act to legislate a gradual increase in the age of full entitlement from 65 to 66 by 2009 and to 67 by 2027. Germany

(1992 Pension Reform Act) and Italy have made similar policy changes. Japan tried to raise the retirement age from 60 to 65 but failed in their initial attempt. In 1990 Sweden succeeded in blocking the early retirement pathway through the disability fund, but in 1992 failed to abolish the partial retirement pension system. Even in France, where “old age is seen as a time of life when work is illegitimate (Guillemard 1983, p. 88) and where the legal retirement age was lowered to 60 in 1982, it is likely that the retirement age will be raised. This type of political reaction to demographic aging is one way of trying to shift the cost of early retirement from government programs to firms and individuals.

Other workplace policies linked to demographic aging, such as flexible retirement systems, are also being considered in countries like Germany, France, and Great Britain. Countries with lower rates of early exit, such as Japan and Sweden, provide an alternative approach to labor-market withdrawal which may alleviate the pressures of demographic aging. These countries structure retirement as a gradual process involving lowering

wages, reducing hours, and reassigning workers. To some extent this model is already in place in the United States through “bridge jobs,” in Sweden through partial retirement pensions, and in Japan through wage reduction arrangements.

DIRECTIONS FOR RESEARCH

Sociologists are also interested in the social context in which retirement decisions are made and retirement policies are developed. Family contexts, work contexts, economic contexts, and historical contexts all provide important frames of reference in which these behaviors are negotiated. To date, retirement research has refined both the measurement of concepts and the complexity of the behavioral models. Many of these refinements have involved the economic dimensions of retirement. The financial trade-off between pensions and wages, the changes in accumulated pension wealth, and the age-earnings profiles of different occupations have been captured in current models. What models of retirement continue to lack, however, is sensitivity to the social frames of reference (e.g., the shop floor, the office, the firm, the

family, and the community). Studies that have addressed some of these issues (e.g., Hardy and Hazelrigg 1999) suggest, for example, that firm level features may be implicated in both the rate and the determinants of early retirement.

Retirement behavior may be primarily motivated by financial considerations. But given a threshold of financial security, perhaps the unfolding of the retirement process also involves the culture of the workplace, family dynamics, and societal values. Our first task is to theorize the social aspects of these decisions so that we can develop hypotheses. To test these hypotheses, a different data collection strategy is required—one that samples a sufficient number of observations of individual workers within sufficient numbers of organizational or, more generally, cultural contexts that can themselves be measured in terms of their salient characteristics. What has become clear is that retirement decisions are shaped by individual preferences, but that these preferences are shaped by the opportunities and constraints that workers encounter.

REVOLUTIONS

Revolutions are rapid, fundamental transformations of a society's socioeconomic and political structures (Huntington 1968). Social revolutions differ from other forms of social transformation, such as rebellions, coups d'état, and political revolutions. *Rebellions* involve the revolt of society's subordinate classes—peasants, artisans, workers—but do not produce enduring structural changes. *Coups d'état* forcibly replace the leadership of states but do not fundamentally alter state structures. *Political revolutions* transform state structures but leave social structures largely intact. What is distinctive to social revolutions is that basic changes in social structures and political structures occur in a mutually reinforcing fashion (Skocpol 1979). A social revolution is more than a change in the state. It is a change in the state of an entire society.

Recent sociological work on revolutions recognizes their importance in the making of the modern world order and the opportunities revolutions offer for building theories of social and political change. These opportunities were most emphatically embraced by Marx, who placed the study and the making of revolution at the center of his lifework. Virtually all theories of revolution

since Marx share his concern with three separate yet interrelated phenomena: (1) the social conditions that lead to revolution or its absence, (2) the character of participation in revolutions, and (3) the outcomes of revolutions (see Tucker 1978). This review examines Marx's theories in light of significant contemporary analyses of revolution, in order to evaluate how well his theories have stood the test of time and to consider how much of his legacy may endure in future sociological work.

First, Marx understood modern revolutions to be by-products of economic advance. Revolutionary situations emerged when contradictions between the forces of production (how the means of existence are produced) and the relations of production (how labor's product is distributed) within an existing mode of production reached their limits. For Marx, the coming of the 1789 French revolution lay in the irresolvable contradiction between feudal restrictions on land, labor, and credit and emerging capitalist arrangements advanced by an ascending bourgeoisie. Revolutions brought the resolution of these contradictions by serving as bridges between successive modes of production, enabling the ascent of capitalism over feudalism and later the replacement of capitalism by socialism.

Second, Marx held that revolutions were accomplished through class struggle. In revolutionary situations, conflict intensified between the existing dominant class and the economically ascendant class. Under feudalism, class conflict pitted the aristocracy against the ascendant bourgeoisie. Under capitalism, the differing situations of segments of society determined their revolutionary tendencies. Some classes, such as the petite bourgeoisie, would become stakeholders in capitalism and allies of the dominant bourgeoisie. Others, such as the peasantry, that did not fully participate in wage labor and lacked solidarity, would stay on the sidelines. The industrial proletariat would be the midwife of socialist revolution, for wage labor's concentration in cities would generate solidarity and collective consciousness of the proletariat's exploitation by the bourgeoisie. Class consciousness was a necessary (though not a sufficient) condition for revolution.

Third, Marx believed that revolutions so thoroughly transformed class relations that they put in place new conditions enabling further economic

advance. Revolutions were locomotives of history that brought in train new structures of state administration, property holding, and political ideology. Reinforcing the fundamental changes in class relations, these transformations culminated the transition from one mode of production to another.

In sum, Marx's theory identified the conditions that spawn revolutionary situations, the classes that would make revolutions, and the outcomes of revolutions. How well has Marx's analysis served later generations of scholars and revolutionaries? Many of the sociopolitical transformations since his death were unanticipated by Marx. In light of these events, contemporary sociologists have reconsidered his thinking.

Consider first the social conditions making for revolution or its absence. Social revolutions are rare. Modern capitalist societies have experienced severe economic crises that intensified class conflict and gave the appearance of revolutionary situations, but they have skirted actual revolution. Modern capitalist economies have great staying power, and reform rather than revolution is the rule in advanced nations. Indeed, the great revolutions of France, Russia, and China, and those in Third World societies such as Cuba, Vietnam, and Nicaragua, have occurred in predominantly agrarian economies where capitalist relations of production were only moderately developed. The 1917 Russian Revolution stands as proof of Lenin's claim that revolution was possible in Russia despite its failure to develop a fully capitalist economy in the manner of the western European states Marx saw as the likely candidates for socialist revolution.

Rather than growing from contradictions between the forces and the relations of production, revolutionary situations arise in political crises occasioned by international competitive pressures. States with relatively backward economies are vulnerable to military defeats, as occurred in Russia in 1917, and to financial crises like that of 1789 France after a century of costly struggle with Britain and Continental Powers. Nation-states that are disadvantaged within the international states system are most at risk to externally induced crises and to the possibility of social revolution.

A state's vulnerability to crisis, however, depends fundamentally on its autonomy, that is,

the extent of its dependence on elites, whether nobles, landlords, or religious authorities. State managers are forever caught in a vice between their obligation to increase revenues to meet international competitive challenges and the resistance of angry elites to resource extraction. States that are weakly bureaucratized, where elites control high offices and key military posts, cannot act autonomously. When powerful elites paralyze the state's resource accumulation, severe crises occur, as in the English, French, and Chinese revolutions (Goldstone 1986).

However, externally induced crises may initiate an "elite revolution," as occurred in Japan's 1868 Meiji restoration and Atatürk's 1919 revolution in Turkey. In such regimes, a bureaucratic elite of civil and military officials emerged that lacked large landholdings or ties to merchants and landlords. In the face of Western military threats to national sovereignty and, consequently, to their own power and status, these elites seized control of the state apparatus. With the aim of resolving economic and military difficulties, they transformed existing sociopolitical structures through land reform, leveling of status distinctions, and rapid industrialization (Trimberger 1978). These transformative episodes, sometimes called "revolutions from above," are distinguished by the absence of popular revolts "from below."

Neopatrimonial regimes are highly vulnerable to revolutionary overthrow (Eisenstadt 1978). Examples include pre-1911 Mexico, pre-1959 Cuba, and pre-1979 Nicaragua. Centered on the personal decisions of a dictator, each of these regimes operated through extensive patronage networks rather than through a bureaucratized civil service and a professionalized military. Their exclusionary politics made reform nearly impossible and, in the event of withdrawal of support by stronger states, invited challenges that might overwhelm corrupt armed forces.

In contrast, revolution is unlikely in open, participatory regimes typical of modern capitalist democracies. By enfranchising new groups, these systems incorporate potential challengers. By redistributing wealth and opportunity—or appearing to do so through open markets and meritocracy—they are able to mute class antagonisms.

In sum, contradictions between the state apparatus and a society's dominant classes have been

crucial to the onset of revolutionary situations. State bureaucrats are caught in the cross pressures between meeting the challenges of the international states system and yielding to the competing claims of elites. Consequently, state structures differ in their vulnerability to political crises.

Consider next the character of participation in revolutions. Critics of Marx's voluntarist theory assert that no successful social revolution has been made by a self-consciously revolutionary movement. They allow that revolutionaries do guide the course of revolutions, but assert that they do not create revolutionary situations which emerge from externally induced political crises. These critics also offer a different reading of the roles of social classes in revolution. Urban workers, favored by Marx's theory, played important parts in revolutions. However, their numbers were small and their protests lacked the impact of uprisings by peasants who composed the vast bulk of producers in agrarian societies. Indeed, peasant revolts provided the "dynamite" to bring down old regimes when political crises immobilized armies and upset food supplies and distribution (Moore 1966). Peasant revolts against the landed upper classes made it impossible to continue existing agrarian class relations and thereby reduced the prospects for liberal reforms or counterrevolution. It was the conjunction of political crisis and peasant insurrection that brought about the fundamental transformations identified with social revolutions in France, Russia, and China (Skocpol 1979).

But peasants do not act alone. A key difference between Old Regime revolutions and revolutions in the Third World is the importance of coalitions in the latter (Tilly 1978). Peasants in France and Russia lived in solitary and relatively autonomous village communities that afforded them the solidarity and tactical space for revolt (Wolf 1969). In the twentieth century, professional revolutionaries provided leadership and ideologies that cemented dispersed local groups with disparate interests into potent national movements. The success of their efforts depended in part on the breadth of the coalition they were able to realize among peasants, landless and migrant laborers, rural artisans, and sometimes landlords (Goodwin and Skocpol 1989).

Add to that the importance of urban groups which played crucial parts in making Third World

revolutions. In Cuba and Nicaragua, students, professionals, clerics, and merchants joined workers and peasants in coalitions that toppled dictatorial regimes. Similarly, the 1979 overthrow of the Shah of Iran resulted from the mobilization of a broad coalition of merchants and workers, students and professionals, that met little resistance from powerful military forces (Farhi 1990).

Finally, revolutionary leaderships have not come from the ranks of an ascendant bourgeoisie or a risen proletariat. Rather, marginal political elites were most likely to consolidate power, for they were both skilled in the running of state organizations and tied by identity and livelihood to the aggrandizement of national welfare and prestige. Their role is clearest in revolutions from above but is no less prominent in social revolutions.

Consider, last, the outcomes of revolutions. For Marx, revolutions were bridges between successive modes of production. Bourgeois revolutions marked the transition from feudalism to capitalism; socialist revolutions opened the way for the transition from capitalism to communism, history's final stage. Through the dictatorship of the proletariat and the abolition of private property, socialist revolution would bring the end of class struggle and the disappearance of state power.

Revolutions did transform class structures, economic arrangements, and political institutions, however, in all successful social revolutions, the transformations were accomplished by new state structures. The state did *not* wither away. Moreover, the new states were more centralized and bureaucratized than their predecessors. For example, liberal parliamentary regimes appeared in the early phases of the 1789 French and 1917 Russian revolutions. In the face of threats to sovereignty from abroad and counterrevolutionary threats at home, these regimes gave way to centralized governments which rationalized the machinery of state for national defense and internal control. Liberal parliamentary regimes were similarly short-lived during revolutionary episodes in post-World War II Europe, Asia, Africa, and Latin America.

Indeed, what changed most in revolutions was the mode of social control of the lower strata as regimes centralized political power. All social revolutions ended with the consolidation of new mass-mobilizing state organizations through which peasants and urban workers were for the first time

directly incorporated into national economies and polities. While they aimed for independence from colonial powers, national liberation movements in Asia and Africa shared with these newly formed revolutionary states the project of state-centered mass mobilization.

Last, and vastly more important than the ways that individual revolutions changed sociopolitical institutions where they occurred, is the collective legacy of four centuries of revolution for the modern world. The legacy is clear in ways that revolutions transformed the workings of the world order and altered our sense of human prospects and limits. Through new political institutions, revolutions created our vocabulary of citizenship and its opposite, the machinery of tyranny. Through new structures of labor and investment, revolutions boosted agricultural and industrial output. By breaking old alliances and creating new ones, they altered the international states system and the shape of world markets. With wars and depressions, revolutions rightfully became the major markers of world history. Past revolutions are a benchmark from which we reckon humankind's advance or descent. In all these ways, revolutions helped shape the structures and consciousness we know as modernity.

For a century, sociologists who study revolutions have pursued a project of revision. Informed by the study of recent sociopolitical transformations and by new interpretations of past revolutions, their work questions and qualifies much of Marx's analysis. It considers national revolutions in the context of the world economy and the international states system. It places the relations between states and social classes in a new light, and it examines how social transformations in the recent or distant past weigh on the course of revolutionary events. On balance, it largely affirms and continues the main thrust of Marx's perspective, notably his focus on actors embedded in concrete organizational settings within historically specific circumstances. This perspective—rather than a focus on personality, collective mentality, or system dysfunction—distinguishes the sociology of revolution. It owes much to Marx's legacy.

What future sociologists will take from Marx's legacy is an open question. Are revolutions in the coming century likely to differ in their causes, dynamics, or outcomes from the revolutions of

centuries past? Will revolutions become unlikely as global prosperity shrinks the now yawning gap between rich and poor? Is it possible that new state structures, either more responsive or more repressive than those we now know, will bring revolutions to an end? These are questions for the next generation of theorists.

Their search for answers will surely cover old ground. There is no "Y2K problem" for revolutionary theory. Changing the calendar does not change the world. The familiar masterplots that made modern world history—notably, the globalization of markets, communications, and culture, the international states system, and persistent inequalities in power and resources—suggest the shape of revolutions to come.

Indeed, for many sociologists, the past is prologue. For example, in an analysis of revolution and rebellion in Europe, China, and the Middle East from 1500 to 1850, Goldstone (1991) links population growth and state breakdown. He identifies a process in which population growth overwhelms the administrative capacities of agrarian states, bringing inflation and fiscal crisis, intralite conflicts, popular unrest, and delegitimation of traditional regimes and their policies. Starting in roughly 1850, the underlying conditions changed when new forms of investment and infrastructure that accompanied urbanization and industrialization enabled modern states to manage population growth and prices. In much of the contemporary Third World, however, urbanization and industrialization did not strengthen the hand of state managers, but had the opposite effect. There, population growth and price pressures—often the unintended consequences of failed development schemes—continued to court state crises.

Nevertheless, Goldstone and other analysts assert revolutions will be rare. This is so because revolutions are not the result of a single cause, such as population pressure, but arise only when several causal elements, such as state crisis, elite withdrawal, and mass mobilization, converge in a rare revolutionary conjuncture. The worker masses of Sergei Eisenstein's films and massed peasants of Hollywood spectacles give a misleading impression of revolutionary causation. There have been many popular uprisings—some of them large and quite violent—which did not bring revolutionary transformations.

Lachmann (1997) calls attention to the pivotal role of elites. He develops an explanation for revolutionary outbreak and success in terms of varying combinations of elite unity or conflict and mass participation or quiescence. Lachmann finds that single, unified elites are immune to mass revolutionary challenges (as happened in Hungary in 1956 and Czechoslovakia in 1968). Conversely, mass mobilization succeeds at moments of heightened elite conflict (as in 1789 France). These conditions are self-reinforcing. By creating opportunities and potential alliances, elite conflict encourages nonelite mobilization (sometimes accidentally, sometimes intentionally), which, in turn, can alter the system of political domination and economic exploitation through which elites rule and live.

The study of mass-elite relations signals a turn toward understanding the importance of agency and ideology in making revolutions. The turn follows a generation of structural theories which spotlighted the crises through which revolutionary situations come, but left us unenlightened as to how revolutionary outcomes are realized in the actions of millions of men and women. For example, Markoff (1996) shows how in 1789 France, the abolition of feudalism was not foreordained by the state's fiscal crisis, but a contingent outcome of the interplay of waves of rural insurrection, Parisian mobs, and legislative concessions. Through their dialogue with the "people," revolutionary legislators created a form of discourse that defined the revolution as a watershed moment between the old order and the new. Markoff shows that words, as well as deeds make revolutions. While the French revolution was more than talk, talk became the frame in which action was interpreted and given form.

Revolutionary outcomes, though, depend on more than the unfolding of actions and the shaping of ideologies by the makers of revolution. History shows that revolutionary outcomes are constrained by global circumstances. Contrasting the outcomes of the Mexican (1910–1917) and Bolivian (1952) revolutions, Eckstein (1976) shows the impact of U.S. foreign investment and military assistance on class structure, party formation, and national well-being. While both modernized their economies, Mexico had greater economic diversification, productivity growth, and political stability than Bolivia. Their revolutions did not alter their

standing relative to stronger states, leaving Bolivia with its weaker postrevolutionary state (and important tin mines) open to U.S. foreign aid and military assistance. Subsidized and schooled by the United States, the armed forces played the decisive role in the 1964 overthrow of the Bolivian regime that the United States had supported in 1952.

Revolutions will not disappear as long as nation-states remain the dominant form of world political organization. While the globalization of markets, communications, and culture seems to augur a new world, we live with the legacy of the capitalist world order. Ours is still a world of states, albeit one increasingly structured by regional alliances, multinational corporations, and international bodies like the United Nations. What Marx recognized in the late nineteenth century will likely hold in the century ahead: that persistent inequalities in power and resources between masses and elites and among the world's nation-states will shape revolutionary prospects and processes.

ROLE THEORY

Role theory concerns the tendency for human behaviors to form characteristic patterns that may be predicted if one knows the social context in which those behaviors appear. It explains those behavior patterns, (or *roles*) by assuming that persons within a context appear as members of recognized social identities (or *positions*) and that they and others hold ideas (*expectations*) about behaviors in that setting. Its vocabulary and concerns are popular among both social scientists and practitioners, and role concepts have generated both theory and a good deal of research. Nevertheless, conflicts have arisen about the use of role terms and the focus of role theory, and different versions of the theory have appeared among groups of authors who seem to be unaware of alternative versions. Role theory has been weakened by association with controversial theories in sociology, as well.

HISTORY, DIFFERENTIATION, AND CONFUSION

Role theory arose when social scientists took seriously the insight that social life could be compared with the theater, in which actors played predictable "rôles." This insight was pursued independently by three major contributors in the early 1930s with somewhat different agendas. For Ralph Linton (an anthropologist), role theory was a means for analyzing social systems, and roles were conceived as "the dynamic aspects" of societally recognized social positions (or "statuses"). In contrast, George Herbert Mead (a social philosopher) viewed roles as the coping strategies that individuals evolve as they interact with other persons, and spoke of the need for understanding others' perspectives ("role taking") as a requisite for effective social interaction. And Jacob Moreno (a psychologist) saw roles as the habitual, sometimes harmful, tactics that are adopted by persons within primary relationships, and argued that imitative behavior ("role playing") was a useful strategy for learning new roles.

Additional insights for role theory were generated by other early authors, particularly Muzafer Sherif's studies of the effects of social norms; Talcott Parsons's functionalist theory, which stressed the importance of norms, consensus, sanctioning, and socialization; Robert Merton's analyses of role structures and processes; the works of Neal Gross, Robert Kahn, and their colleagues, which discussed role conflict and applied role concepts to organizations; Everett Hughes's papers on occupational roles; Theodore Newcomb's text for social psychology, which made extensive use of role concepts; and (in Europe) the seminal monographs of Michael Banton, Anne-Marie Rocheblave, and Ragnar Rommetveit, as well as Ralf Dahrendorf's essay "Homo Sociologicus."

The contrasting insights of these early contributors affected many subsequent writers, and various traditions of role theory have since appeared. Unfortunately, advocates for (or critics of) these differing traditions often write as if they are unaware of other versions. In addition, advocates may propose inconsistent uses for terms, or contrasting definitions for concepts, that are basic in role theory. To illustrate, for some authors the term "role" refers only to the concept of social position, for others it designates the behaviors

characteristic of social position members, and for still others it denotes shared expectations held for the behaviors of position members. Such inconsistent uses pose problems for the unwary reader.

Also, role theorists may disagree about substantive issues. For example, some authors use role concepts to describe the social system, whereas others apply it to the conduct of the individual. Again, some writers assume that roles are always tied to functions, whereas others conceive roles as behaviors: that conform to expectations, that are directed towards other in the system, that are volitional, that validate the actor's status, or that project a self-image. Such differences in stance have reflected both accidents of intellectual history and the fact that role theorists have wrestled with differing social system forms.

Despite these differences, role theorists tend to share a basic vocabulary, an interest in the fact that human behavior is contextually differentiated and is associated with the social position of the actor, and the assumption that behavior is generated (in part) by expectations that are held by the actor and others. This means that much of role theory presumes a thoughtful, phenomenally aware participant, and role researchers tend to adopt methods that call for the observing of roles and for asking respondents to report about their own or others' expectations. Moreover, it also means that role theory may be contrasted with alternative theoretical positions that give stronger emphasis to unconscious motives or behavior-inducing forces of which the actor may be unaware (such as mechanisms that are not obvious but that serve to maintain structured inequalities of power, wealth, or status).

FUNCTIONALIST ROLE THEORY

One early perspective in role theory reflected functionalism. Functionalist thought arose from the contributions of Talcott Parsons and was, at one time, the dominant orientation in American sociology. This theory made use of role concepts, and some authors continue, today, to write as if role theory was or is largely an attempt to formalize functionalism.

Functionalist theory was concerned with the problem of explaining social order. Stable but differentiated behaviors were thought to persist

within social systems because they accomplished functions and because actors in those systems shared expectations for behaviors. Such consensual expectations (or "roles") constituted norms for conduct, and actor conformity to norms was induced either because others in the system imposed sanctions on the actor or because the actor internalized them. In addition, those in the system were thought to be aware of the norms they held and could be counted on to teach them to (i.e., to socialize) neophytes as the latter entered the system.

Functionalist thought has been under attack since the 1950s, and many of its basic assumptions have been challenged. Critics have pointed out that persisting behaviors may or may not be functional for social systems, that norms for conduct are often in conflict, that actor conformity need not be generated by norms alone but can also reflect other modes of thought (such as beliefs or preferences), that norms might or might not be supported by explicit sanctions, that norms internalized by the actor may be at odds with those supported by external forces, and that processes of socialization are problematic. Above all, critics have noted that social systems are not the static entities that functionalist thought portrayed, and that human conduct often responds to power and conflicts of interest in ways that were ignored by functionalists. As a result of these attacks, interest in functionalist role theory has declined, although it is still possible to find writers who advocate (e.g., Bates and Harvey 1975) or denounce (Connell 1979) role theory as if it were merely a gloss for functionalism.

ROLE CONFLICT AND ORGANIZATIONAL ANALYSIS

Interest in organizational role theory began with the works of Neal Gross, Robert Kahn, and their associates, which questioned the assumption that consensual norms were required for social stability. Instead, these writers suggested that formal organizations were often characterized by *role conflict* (i.e., opposing norms that were held for actors by powerful others), that such conflicts posed problems for both the actors and the organizations in which they appeared, and that strategies for coping with or "resolving" role conflict could

be studied. These insights stimulated both texts that applied role concepts to organizational analysis and many studies of role conflict and role conflict resolution in organizational contexts (see, for example, van de Vliert 1979; Van Sell et al. 1981; Fisher and Gitelson 1983).

In addition, the concept of role conflict has proven attractive to scholars who wanted to conceptualize or study problems that are faced by disempowered persons, particularly married women who must cope with the opposing demands of the workplace, home maintenance, and support for their husbands (Stryker and Macke 1978; Lopata 1980; Skinner 1980). Unfortunately (for the argument), evidence suggests that role conflicts are not always shunned by disempowered persons (see Sales et al. 1980) and that “resolving” those conflicts does not necessarily lead to empowerment.

Despite these problems, research on role conflict within the organization continues actively, and some proponents of the organizational perspective have recently turned their attention to the events of role transition—that is, to phenomena associated with entry into or departure from a role (see Allen and van de Vliert 1984; Ebaugh 1988).

THE STRUCTURAL PERSPECTIVE

Another use of role concepts has appeared among structuralists and network theorists. This third perspective reflects the early contributions of anthropologists such as S. F. Nadel and Michael Banton, sociologists such as Marion Levy, and social psychologists ranging from Dorwin Cartwright and Frank Harary to Oscar Oeser. As a rule, structuralists concern themselves with the logical implications of ways for organizing social systems (conceived as social positions and roles) and eschew any discussion of norms or other expectation concepts.

To date, much of the work in structural role theory has been expressed in formal, mathematical terms (see Burt 1982; Winship and Mandel 1983). This means that it has had greater appeal for scholars who are mathematically trained. It also constitutes one form of network analysis (although other network perspectives have appeared that do not use role concepts).

ROLE THEORY AMONG SYMBOLIC INTERACTIONISTS

Interest in role theory has also appeared among symbolic interactionists who were influenced not only by George Herbert Mead but also by Everett Hughes, Irving Goffman, and other influential figures. In general, symbolic interactionists think of a role as a line of action that is pursued by the individual within a given context. Roles are affected by various forces, including preexisting norms applying to the social position of the actor, beliefs and attitudes that the actor holds, the actor’s conception and portrayal of self, and the “definition of the situation” that evolves as the actor and others interact. Roles need not have common elements, but they are likely to become quite similar among actors who face common problems in similar circumstances.

These concepts have been applied by symbolic interactionists to a host of interesting concerns (see, for example, Scheibe 1979; Gordon and Gordon 1982; Ickes and Knowles 1982; Stryker and Serpe 1982; Zurcher 1983; Hare 1985), and a continuing and useful contribution has flowed from Ralph Turner’s interest in the internal dynamics of roles and the fact that roles tend to evolve over time (1979, 1990).

Unfortunately, some persons within this perspective have also been guilty of tunnel vision and have produced reviews in which role theory is portrayed largely as an extension of symbolic interactionist thought (see Heiss 1981; Stryker and Statham 1985). In addition, symbolic interactionism has attracted its share of criticism—among other things, for its tendencies to use fuzzy definitions, recite cant, and ignore structural constraints that affect behaviors—and some of these criticisms have tended to rub off on role theory.

COGNITIVE PERSPECTIVES IN ROLE THEORY

Empirical research in role theory has been carried out by cognitive social psychologists representing several traditions (see Biddle 1986, for a general review). Some of this work has focused on role playing, some of it has concerned the impact of group norms, some of it has studied the effects of anticipatory role expectations, and some of it has examined role taking.

In addition, cognitive social psychologists have studied conformity to many forms of expectations, including instrumental norms, moral norms, norms attributed to others, self-fulfilling prophecies, beliefs about the self (such as those induced by identity projection or labeling), beliefs about others, and preferences or “attitudes.” These studies suggest that roles are often generated by two or more modes of expectational thought, and several models have also appeared from cognitive theorists reflecting this insight (see, for example, Bank et al. 1985).

Unfortunately, much of this effort ignores expectations for social positions and concentrates, instead, on expectations for individual actors. Cognitive role theory also tends to ignore the implications of its findings for structural analysis, and thus appears to be atheoretical from a sociological perspective. However, Bruce Biddle (1979) has authored a broad vision for role theory that uses information from cognitive research to build models for social system analysis.

RECENT TRENDS IN ROLE THEORY

Four recent trends in the development of role theory should be noted. First, although the term “role” continues to appear in most textbooks for basic courses in sociology and social psychology, it normally does not appear by itself as a major concept but rather is likely to surface in chapters on such topics as “the self,” “groups,” “institutions,” and “role taking.” In contrast, extensive discussions of roles and related concepts may be found in texts for various types of advanced courses for these fields. To illustrate, consider recent texts for courses on group dynamics. In the latest edition of his highly successful work, Donelson Forsyth (1999) devotes an entire chapter to “norms,” “roles,” and related issues, and in her new text, Joann Keyton (1999) focuses a major chapter on “group member roles,” “group norms,” and associated materials. As a rule, portrayals of role theory in such sources is straightforward: “roles” are deemed to refer to specific patterns of behavior that are associated with individuals or recognized identities; “norms” are shared expectations for conduct that may apply to all persons in the group or only to certain identities (such as “leaders”); and related concepts such as “socialization” and “role conflict” appear frequently.

Second, many authors continue to employ role concepts for discussing social relations within a specific institution or for portraying the lives of those who share an occupational identity. For example, a substantial literature has now appeared concerned with “the role of the school principal,” and a useful summary of this work may be found in a recent review by Ronald Heck and Philip Hallinger (1999). In another example, Biddle (1997) provides an extensive overview of recent research on “the role of the school teacher.” Again, much of this applied work makes clear use of concepts from role theory, with the “role” term normally used to refer to differentiated behaviors, whereas notions about behaviors that are thought to be appropriate for roles are normally termed “norms” or “role expectations.”

Third, for at least a generation, authors who have written about differences between the conduct, problems, or outlooks of men and women have used role theory as a vehicle for interpreting their findings, and this interest continues. To illustrate, for years a key journal that publishes studies concerned with gender and its problems has borne the title *Sex Roles*, but recently a particularly strong advocate for using role theory to interpret evidence about gender differences in behavior has appeared in the person of Alice Eagly (1987, 1995). Eagly asserts that such differences appear as a result of structural forces in societies—hence may differ among countries—but are sustained and reproduced because men and women develop role-appropriate expectations for those behaviors. Given the earlier, pioneering studies of Margaret Mead, such assertions would seem unexceptionable, and yet they have touched off a storm of criticism from evolutionary psychologists who prefer to believe that gender differences in conduct are hard wired and culturally universal, and have arisen from the mechanisms of Darwinian selection. (See, for example, Archer [1996].) Unfortunately, in her 1987 book on the subject, Eagly did not make clear that her argument involved only one version of role theory, and it has seemingly not occurred to her evolutionary critics that there might be other versions of the role story that would also bear on their concerns. So, in criticizing her, they have made foolish assertions about “the scope of social role theory,” and have condemned it for assumed stances that most role theorists would not advocate.

Fourth and last, every few years interesting works are published by authors who have apparently just discovered some version of role theory and are intrigued with its potential for generating insights or resolving problems in cognate fields. A good example of this type of work appears in a recent article by James Montgomery (1998). Montgomery begins by noting that, in a widely cited work, Granovetter (1985) had argued that economic action is embedded in social relationships and that rational choice theorists have subsequently explored this insight through research on prisoner's dilemma games in which long-term interaction is thought to be governed by general assumptions about "calculative trust." Empirical support for this thesis has been weak, and—drawing on work by James March (1994)—Montgomery argues that a stronger case can be made for assuming that, when engaged in long-term interaction, persons make assumptions about the social identities which they and others have assumed, and that these identities are associated with shared expectations about behaviors that are appropriate in the relationship. To illustrate, Montgomery suggests that expectations are far different when one assumes the other to be a "profit-maximizing 'businessperson'" than when the other is assumed to be a "nonstrategic 'friend.'"

Montgomery's arguments are well wrought, and their implications are spelled out through techniques of formal logic. Moreover, Montgomery points out how his arguments relate to recent work on various cognate concerns such as identity processes, artificial intelligence, situation theory, and cognitive psychology. So far so good, but (like too many recent converts) Montgomery seems not to be familiar with the bulk of work in the role field, and this leads him to make foolish errors. To illustrate, he refers to social identities as "roles" and shared expectations about behaviors as "rules"—idiosyncratic uses that will surely confuse readers. Worse, he seems not to be familiar with prior work by role theorists on his topic, including major works within the structural role theory tradition; with Ralph Linton's writings on the evolution of roles; and with the fact that much of his argument was actually made *forty* years ago by John Thibaut and Harold Kelley (1959). It does not help work in any field if scholars are unwilling to familiarize themselves with prior work on their subject, and one wonders how role theory is to make progress

in the future if even its advocates are unwilling to do their homework.

ROLE THEORY AND THE FUTURE

As the foregoing examples suggest, role theory is currently weakened by terminological and conceptual confusion, diffuse effort, and the narrow visions of some of its proponents and critics. Nevertheless, role theory concerns central issues for sociology and social psychology, and assumptions about social positions, role behaviors, and expectations for human conduct appear widely in current social thought. Role theory will prosper as ways are found to discuss these issues with clarity, consistency, and breadth of vision.

ROLE THEORY: FOUNDATIONS, EXTENSIONS, AND APPLICATIONS

Role theory provides conceptual elements and dynamic relations across the social sciences. Indeed, the notion of *role* has become something of a “meta-construct” that has been adapted to the

scholarly focus and methodological predilections of fields such as sociology, psychology, anthropology, and management, to name just a few. Such broad application, while suiting testimony to the importance of role constructs in social theory, has led to some conceptual confusion, formulatic imprecision, and sharply diverging interpretations. Nevertheless, there remains a great deal of consensus about the integral nature of roles in the operation of social systems and the behavior of individuals.

Fundamentally, roles are organized behavioral patterns and expectations that attend a given position (hierarchical, functional, or social) or that accompany a specific situation. That is, roles encapsulate and invoke the accepted repertoire of individual conduct associated with a specific position or extant circumstance. In this way, roles provide behavioral guidelines, prescriptions, or boundaries in the form of *expectations*. These expectations can be formally assigned and explicitly stated—as in the case of occupational job descriptions—or informally assumed and tacit—as in the case of one who plays the “facilitator” role in a friendship clique. Additionally, by evoking behavioral expectations, roles affect how individuals cognitively frame, interpret, and process physical or social stimuli, and thus they further condition emotional responses. There is some controversy as to whether individuals are fully cognizant of the roles they play, but that is incidental to the underlying assumption that roles influence behavior, and thus are powerful predictors of individual action and key to understanding social systems.

This essay is not intended to provide a comprehensive review of role theory nor to propose new theoretical formulations. Rather, this essay will offer a framework for organizing role theory that hinges on *levels of analysis* and the particular *phenomenon of focus*.

There are two primary levels of analysis relevant to role theory. The first emphasizes how roles operate within and through *social systems*, such as societies or groups. The second level is concerned with how roles influence, or are influenced by, the *individuals* who inhabit them. This is essentially a classic *macro versus micro* distinction, the former being characteristic of sociological and anthropological inquiry, the latter of management and psychological inquiry (though there is, of course, some crossover). The phenomenon of focus refers

to the particular object of inquiry within each level of analysis. For instance, a researcher in the social systems tradition may focus on nations, ethnic heritage, or group cohesion, whereas a researcher in the individual tradition may focus on self-conceptions, cognitions, or conflict. The phenomena of focus vary widely within each level of analysis, and are discussed under subheadings.

SOCIAL SYSTEMS

The underlying assumption of role theory at the broadest level is that social systems—particularly societies, cultures, organizations, groups and families—are organized and operate through roles. Hence, roles function dynamically to structure the interaction of participants so as to maintain, defend, alter, innovate, or advance the purpose of social systems. In this way, roles become the primary linkage between the social system and the individual, and are designed to communicate the expectations of the larger concern to the particular actor. Roles, then, can be viewed as indispensable mechanisms that embody the values of the social system.

Societies and Stasis. One of the earliest uses of role theory in social science involved the proposal that societies, like organisms, have differentiated parts that function interdependently to allow the whole to operate. In any given society, those parts would include institutions like the state or the church, each of which carry out defined obligations that reflect the priorities of that society. However, institutions in and of themselves do not execute the role. To accomplish their purposes, institutions convey that responsibility to individuals through socialization and inculcation, who in turn are responsible for enacting them. Hence, roles become the primary theoretical construct for explaining *social stability*. That is, roles *function* in a manner conducive to social order and stasis. The term “function” is important here, as *functionalism* was the name given to the major school of thought at the time (Parsons 1951).

The chief concern of functionalism was how societies decided upon, designed, communicated, and enforced roles. This concern opened up a series of issues that have occupied sociological role theory, such as: which parties designate a role, the rationale for the privilege or status assigned given roles, the mechanisms by which the social system

inculcates roles, and how to ensure a role is faithfully enacted (see Biddle 1986).

Culture and Change. Role theory has found its way into the study of cultures primarily through anthropology. Here, the dramatic, theatrical flavor of roles is clearly evidenced. The basic thrust is that all cultures have forms of ritual, ceremony, and pageantry that encompass symbolic societal roles which in turn play crucial social functions. Unlike sociologists, who see such institutions and their prescribed roles as maintaining stasis and order, anthropologists, notably Victor Turner (1986), argue that the purpose of such social drama is *change*. Specifically, Turner contends that, whenever individuals act in accordance with social scripts (i.e., roles), the possibility exists for “liminality”: a lodgment in time and circumstance where individuals depart from proscribed patterns and initiate new ones. The very idea of roles is to trigger or generate novelty and creativity by stepping out from that which is expected, and thus bring new meaning to the dynamic represented in the social drama. It is the tension between norms and expectations and the stability they imply, versus the necessity for change for survival’s sake, that animates the alteration of roles, which is viewed as the engine of cultural development.

Organizations and Performance. Whereas the emphasis is respectively on stability or change when societies or cultures are the phenomenon of focus, when organizations are the focus, the emphasis is squarely on *performance* (typically operationalized as productivity, or the difference between inputs and outputs, or costs and profits). Role theory finds its way into management at the macro level with research concerned with organizational design. The major concern is the proper way to arrange an organization for optimal performance, which constitutes a structure through which the organization is managed. Principles involved in organization design include differentiation, integration, centralization, complexity, and formalization. But a key element in the erection of an structure is the formal designation of roles that organizational actors are assigned to play (see Hall 1991).

The roles that individuals assume in organizations are typically assigned based on expertise and previous experience. That is, an individual is specifically trained or has the background to execute

the relevant duties; he or she is prepared to fill a role. But beyond possessing the requisite skills, organizational roles are designed to place individuals into the particular structure of the organization. This is accomplished primarily through two formal mechanisms and one informal mechanism. The first is the job description, which is a detailed documentation of all duties and responsibilities. The job description, then, effectively posits expectations and sets strict behavioral boundaries. The second is the reporting relationship, which describes the hierarchical order of the organization, and thus dictates channels for approval and communication. The third, and informal, mechanism by which individual conduct is guided is the organizational culture. In this case, culture refers to the organizations climate as well as its tacit mores and traditions.

From the perspective of research in organizational design, the question is the relationship between structure and performance. For instance, in industries where there is a high rate of change, research suggests that looser structures, with fewer specifications for job descriptions and more open channels of communication, tend to perform better. Suffice it to say, nowhere are roles more formally communicated, monitored, and controlled than in the management of firm performance.

Groups and Functionality. Another area of inquiry where role concepts play a major part is groups. Defined as two or more interdependent individuals who have come together to achieve an objective, groups can include formal work teams, friendship cliques, and even families (though family relations is often treated as an independent, free-standing field of inquiry). The conceptual elements in group research are not fundamentally different from those involved in the study of societies, cultures, or organizations. That is, to accomplish its purpose—whether that purpose be completing an organizationally assigned task or comraderie—group members must function in a complimentary manner. That *functioning*, then, is typically arranged around roles that members are assigned or assume.

The role concepts most frequently employed in group research are role identity (the attitudes and behaviors consistent with a role), role perception (an individual’s view of how to behavior in a

given situation), role expectations (other's beliefs of how one should act in a given situation), and role conflict (the contradiction of two role's expectations). These concepts are then used to predict various group dynamics—such as conformity, status relations, and cohesiveness—and outcomes—such as performance, satisfaction, creativity, and efficiency (for a review, see Goodman et al. 1987).

INDIVIDUALS

Whether examining societies, cultures, organizations, or groups, roles are enacted by individuals. The term “enacted” is important here, since it belies the theatrical, dramaturgical roots of role theory (Simmel 1920). Moreno (1934) for instance, stressed the importance of *role playing* as a natural act of children in learning about themselves and their world, and an important aid for education as well as therapy. Perhaps the most memorable proposition is Goffman's powerful theatrical analysis (1959). Goffman's basic premise, not unlike that of Shakespeare's “all the world's a stage,” is that *all* human behavior is acted, with some allowance for the nature or type of audience. Although varying in the degree of their theoretical commitments, these thinkers underscore the central place that the metaphor of *stage acting* commands in role theory, especially as an explanatory and illustrative aid in understanding individual behavior.

Identity and Interaction. There is no question that individual identity—the self-conception and personality of the individual—is impacted by the society in which individuals live, the family into which they are born, the community in which they were raised, and the people with whom they associate. Identity is surely a complex, interwoven interaction of the person and his or her situation. And that roles exert a strong influence on individual identity is equally obvious in individuals' descriptions of themselves, which invariably involve roles (e.g., daughter, husband, student, lawyer). Individuals, then, show a marked propensity to understand themselves through the roles they have assumed.

The study of roles in identity formation was largely sparked by a school of thought known as *symbolic interactionism*. According to this perspective, identity evolves through the dynamic process of a communicating society. Here, society is not a

static structure that dictates roles and thus identity. Rather, it is built through interaction heavy in symbolic communication. Therefore, society is continually formed and reformed through the *reciprocal* influence of individuals taking into account one another's characteristics, and the symbolic meanings that emerge as they interact. Accordingly, neither society nor the individual ontologically precedes the other.

Traditional role theory (especially that which employees social systems as the level of analysis) and symbolic interactionism diverge on the precedence of the relationship between society, individuals, and roles. Traditional role theory assumes that roles are defined by society, which in turn logically determines identity. Symbolic interactionism, on the other hand, views roles as emerging from symbolic communication in a reciprocal relationship between the society and the individual. Here, individuals are credited with being active, creative, mindful, and volitional in their identity.

Symbolic interactionism is grounded in the philosophy of the American pragmatists (e.g., W. James, J. Dewey, and C. S. Pierce) and subsequent social scientists like G. H. Mead, C. H. Cooley, and E. Goffman. The basic premise is that the self emerges through symbolic interactions with socially recognized categories and the roles that correspond with those categories. Because roles *emerge* in relationship to others and society, the self does as well. The self is the way in which individuals understand themselves in relation to others (see Stryker and Statham 1985).

A practical implication of this is that how individuals think of themselves depends, to a great extent, on the social roles that they play. This is nicely captured by W. James: “Many a youth who is demure enough before his parents and teachers, swears and swaggers like a pirate among his tough young friends” (1890, p. 294). Also implicit is James's assertion that individuals have many selves and many social identities: “a man has as many social selves as there are individuals who recognize him and carry an image of him in their mind” (1890, p. 294). Thus, individuals can be said to have many linked selves as opposed to one united self.

The active and emergent nature of the self and identity is indicative of the work of those in the symbolic interactionism tradition. Individuals choose selves upon which to stake a claim and abandon

others which did not prove adaptive or failed to garner positive feedback. Thus, self-esteem is directly tied to the choice of selves to maintain or dismiss. In addition, roles and selves are not merely foisted upon individuals, but rather the options available open the opportunity for the exploration of *possible* selves. Recent papers, derived from James's formulations, contemporary theories of evolution, and performative dynamics, have proposed a model of the exploration and construction of possible selves (Bailey and Ford 1994; Yost et al. 1992).

Cognition and Schematic Processing. Roles affect individual perceptions, determinations and judgments of people, events, and causal relations through *schematic processing*. A schema is a highly ordered cognitive structure composed of knowledge, beliefs, and feelings about persons, objects, and events. Schemas, then, are mental frameworks that coherently organize memory and associations that in turn facilitate the efficient processing of information. Although there are many types of schemas—such as event schemas (e.g., the script individuals follow when dining at a restaurant) or person schemas (e.g., the knowledge, feelings, and expectations an individual has about another)—role schemas are those that organize proper behavioral patterns according to position or situation.

The notion of role schema is central to the role construct inasmuch as roles are behavioral guidelines. From a cognitive perspective, the question is how role schemas influence individual information processing. This influence occurs in both directions; that is, as *observer* and as *actor*. Research demonstrates that, when observing another, the activation of a role schema influences attention, memory, and attribution. For instance, when observing an elderly person, individuals tend to notice, recall, and render causal explanations that are consistent with an age-based role schema (e.g., the older gentleman crinkled his nose because he disapproved of the loud music). In this way, role schemas provide observers with a richly interconnected network of information by which they can categorize and thus interpret the behavior of others. Of course, as a means for comprehending others, role schemas sacrifice accuracy for the sake of efficiency, as is the case with stereotypes. As an actor, role schemas refer to the mental representations of the expectations that attend a role. Similarly, individuals access and process information

more quickly when it is related to the role they are occupying at the moment (see Fiske and Taylor 1991).

Transition and Alteration. Research on role transition acknowledges that individuals develop and move from one role to another in the course of their lives. Hence, role transition refers to the movement from one role to another, and specifically how individuals adapt to the transition. For instance, a promotion from staff programmer to project supervisor requires learning new duties and expectations, but also altering attitudes toward others. The same holds true for transitions from son or daughter to parent, from student to employee, and from child to adult. Such role transitions, then, challenge individuals to reconceptualize their notion of themselves, their relations to others, and their opinions and attitudes toward domain-relevant objects and events. Role transition has been examined in the management arena, with emphasis on how to facilitate the transition in order to improve performance, and in the psychological counseling arena, with attention to assuaging the emotional distress that often accompanies such periods of adjustment.

Role change can be defined as an *alteration* in the consensual understanding of the behavioral patterns of an established role. This is not a transition from one role to another, but rather a change in the expectations and boundaries of an established role. The assumption here is that roles are not static entities, but must *evolve* in order to adequately address the demands of the cultural milieu, economic conditions, or social situation (see Turner 1990).

There are three fundamental ways in which roles can change. First, roles can change according to shifting societal priorities or cultural patterns. For instance, gender roles have gone through considerable alteration as attitudes toward equal rights, access to career opportunities, and traditional obligations have been reconsidered and reconfigured in society. Second, roles can change because of formal dictates from authority. For instance, one's job responsibilities could be expanded quantitatively (e.g., supervising more people) or qualitatively (e.g., involving an entirely different skill set). Third, and perhaps the most interesting, roles can be changed by the individual who inhabits the role. For instance, individuals

may, because of either personal preferences or attitudes, redefine a "director" role to be less about planning and monitoring and more about mentoring and directing.

CONCLUSION

Role theory has come full circle. Early formulations, especially those of Parsons (1951), Moreno (1934), and Goffman (1959), have recently gained considerable currency. For instance, functionalism has proved useful as an analytic framework for describing alterations in emerging democracies. Moreno's emphasis on role playing has found its way into pedagogy in the form of classroom exercises to illustrate concepts and executive workshops for skill development, as well as a fruitful method for therapeutic intervention. And Goffman's reliance on stage acting has influenced current thinking on identity and even research methodology. What this suggests is that role theorists are acutely aware of their theoretical heritage and progenitors, and are willing to mine the past in order to better understand the present.

Roles change as broad conditions shift. Political, economic, and technological factors are especially volatile, each in its own way altering the social system in which individuals reside and the manner in which they understand themselves. Although role theory has not been as intensely researched in last decade—a victim of academic fashion—it continues to provide an intellectual and structural foundation for fields across the social sciences. Moreover, because the late twentieth century is marked as much by change as anything else, social conditions are changing at a dizzying pace. No theoretical construct is more suited to examine the impact of such changes on the social system and the individual than role theory.

RURAL SOCIOLOGY

Rural sociology is the study of social organization and social processes that are characteristic of geographical localities where population size is relatively small and density is low (Warner 1974). Thus, rural sociology can be defined as the sociology of rural society. Since rural societies do not exist in isolation, rural sociology also addresses the relation of rural society to the larger society. Therefore, it deals also with spatial organization and the processes that produce spatial allocations of population and human activities (Newby 1980; Newby and Buttel 1980).

There is a temptation to equate rural sociology with American rural sociology because the latter is most thoroughly institutionalized and there

are more practitioners in the United States than anywhere else in the world. While rural sociology, in its institutionalized form, originated in America, it has flourished in other regions of the world, especially since the end of World War II. No doubt this is due in large part to the “modernization” efforts in the many nations that gained independence since 1950. Outside North America, sociological investigations of rural society often are referred to as peasant studies, development studies, or village studies rather than rural sociology (Newby 1980). Moreover, some aspects of rural sociological analysis are closely related to other social science disciplines, such as settlement patterns with human geography, family and kinship systems with social anthropology, and land tenure and farming systems with agricultural and land economics.

ROOTS IN SOCIAL THOUGHT

Although the subject matter of rural sociology has been of keen interest to social thinkers for centuries, its treatment by the major nineteenth-century classical theorists led to a polarization that continues today (Duncan 1954; Hofstee 1963; LeFebvre 1953; Mendras 1969). Two points of view, both deeply embedded in the social thought and literature of Western culture, and both quite limiting if not erroneous, have predominated. The first tradition, an image drawn from the Arcadia of Greek mythology, has been the glorification of village life for the supposed pastoral virtue of its people. The second tradition has been that of the Enlightenment and modern Western rationalism, which viewed the technological and organizational character of urban industrial forces as being superior to the alleged backwardness of rural areas.

These two traditions were ultimately embraced in major nineteenth-century social theories (Nisbet 1966). Some theorists, typified by Emile Durkheim and by Karl Marx to a lesser extent, viewed the urban industrial complex as the center of a new civilization emerging from the social transformations of the industrial revolution. Rural society, in this perspective, was regarded as a residual of preindustrial society and increasingly to be relegated to a secondary status. Other theorists, such as Toennies [1887] (1957) and early-twentieth-century interpreters of Toennies (e.g., Sorokin

and Zimmerman 1929), viewed the emergent cities of industrial capitalism as monuments to the degradation of civilization. Both points of view are deeply imbedded in the social thought of Western culture and continue to shape the perspectives of rural sociology as a scientific enterprise.

RURAL SOCIOLOGY IN AMERICA

The roots of rural sociology in America lie in the social and political turmoil associated with America's version of the Industrial Revolution, which followed the Civil War. As industrial capitalism made its great surge, urban America was on the move, quickly surpassing earlier achievements of European nations—yet in the midst of obviously rising affluence there existed a paradoxical injustice of poverty and inequality, especially in rural areas (Goodwyn 1978). William Jennings Bryan was defeated in 1896 as the Populist Party candidate for president, but the political unrest in the countryside continued to be a source of concern to urban industrialists, who depended on farmers to provide a stable supply of cheap food for the growing army of industrial workers.

The Country Life Movement emerged at the turn of the century as an urban-sponsored alternative to the radical economic proposals of the rural Populists (Bowers 1974; Danbom 1979; Swanson 1972). It was a social, cultural, and moral reform movement that adopted the view that rural society was backward, lagging behind the evolution of an advanced urban society. The problems of rural people were viewed as stemming from a lack of organization, failures of rural social institutions, inadequate infrastructures, and technological backwardness, rather than from the failures of the industrial capitalist system, as the Populists claimed.

In 1908 President Theodore Roosevelt gave legitimacy to the reform movement by appointing the Commission on Country Life. Spurred by the President's Commission and the Country Life Movement, Congress in 1914 passed the Smith-Lever Act, which created the Cooperative Extension Service to modernize rural America (Hooks and Flinn 1981). In 1925 Congress passed the Purnell Act, which provided colleges of agriculture and agricultural experiment stations with funds to support rural sociological research. Shortly thereafter, departments of rural sociology began to emerge

within universities, often separated from departments of sociology (Sewell 1965). The institutionalization of rural sociology was given further impetus in 1936, when rural sociologists established their own journal, *Rural Sociology*, and during the following year, when they divorced themselves from the American Sociological Society (now the American Sociological Association) by forming the Rural Sociological Society. During the Depression, rural sociology received substantial support for research regarding the socioeconomic status of farm families and the effectiveness of various New Deal federal programs (Larson et al. 1992).

Because of its historical roots, rural sociology has been an active participant in two conflicting social policies derived from the opposing views of rural society in social thought. The institutional separation of rural sociology from sociology, its organizational location in colleges of agriculture, and its functional integration with cooperative extension have given American rural sociology a strong attachment to technologically driven modernization. For many of its institutional sponsors, whose primary goal has been the technological advancement of agriculture, the predominant justification for supporting rural sociology research has been its presumed ability to enhance the process of modernization of rural society.

Two important consequences have followed from this sponsorship. First, the research agenda of rural sociology has been significantly influenced by politicians and administrators of colleges of agriculture and agricultural experiment stations. Thus, American rural sociological research has tended to be driven primarily by the need to be "useful" in solving practical problems involved in transforming rural society. Second, theoretical development within rural sociology has atrophied. Theoretical work that may contradict the prevailing social policy dogma and thereby threaten its financial and institutional support has been particularly uncommon. Thus, the practice of American rural sociology has been part of an explicit social policy of transforming rural society (Newby 1980).

The opposing cultural theme portrays rural society as a way of life that is superior to existence in the cities and threatened by urban industrial capitalism (Sorokin and Zimmerman 1929). It has protagonists within rural sociology and in society

for whom the problem is how to preserve the wholesome qualities of rural society against the encroachments of urban industrial capitalism (e.g., how to avoid community disintegration, loss of local autonomy, the collapse of the family farm, the decline of the traditional rural way of life, degradation of the rural landscape, and depletion of nonrenewable natural resources). These Jeffersonian values of community, individualism, family entrepreneurship, and grass-roots democracy inspire private and public sponsorship of many rural sociological endeavors (Gilbert 1982). Thus, American rural sociology has been significantly involved in two explicit and conflicting social policies. First, it has contributed to positivistic social science by providing the basic descriptive information about rural populations, institutions, and social processes that have guided the development of programs to transform rural society. Second, it has served those committed to preserving selected elements of rural society, a practice that often is perceived by agricultural administrators and proponents of technological innovations as creating barriers to progress.

MAJOR RESEARCH TOPICS

Within the context of these conflicting and vacillating social policy orientations, rural sociology in America has generated a substantial body of research. Some research topics have emerged principally in response to the social policy of transforming rural society and have followed the paradigm of positivism. Other topics are associated more clearly with the preservationist policy orientation and the paradigm of critical sociology. While the alignment of social policy and scientific paradigms is not perfect, there is a clear pattern of association. Both sets of orientations have existed within rural sociology since its inception, with the modernization-positivism orientation clearly dominating the research enterprise until recently.

Modernization-Positivism—Oriented Research.

One of the primary concerns of the Commission on Country Life was the lack of complete and accurate information about the conditions of life in rural America. Thus, study of the rural population was one of the first research topics to emerge (Brunner 1957). Initially research was devoted primarily to description of the rural population,

not only in an effort to provide more accurate counts of people but also to report on their characteristics in greater detail and to describe demographic processes more accurately. Population studies continue to be extremely important in providing the basic descriptive information about the rural population that is needed to guide the development of programs to transform rural society (Fuguitt et al. 1989; Garkovich 1989).

To the extent that rural population studies depart from purely demographic analyses and venture into sociological investigations, they are usually guided by the systemic perspective of human ecology (Hawley 1950, 1986). In this more sophisticated systems model, population size and density are treated as interdependent with the environment, the level of technology, and the social organization of a locality. It is presumed that population size and density will expand to the maximum possible within the constraints imposed by the other components of the system, especially the technology of transportation and communication. While the perspective offers promise of merging social and spatial analysis, the results have been only partially successful. Rural population studies cum human ecology have yet to integrate the social and spatial levels of reality.

As more information about rural populations became available, comparisons with urban populations became possible, and there followed a prolific production of research to examine the belief that population size and density set the conditions of social action and social organization. This was a fundamental premise of the romanticists among the classical sociological writers noted earlier, and it was translated sociologically into the "rural-urban continuum" of Sorokin and Zimmerman (1929) and later the "folk-urban continuum" of Redfield (1947). The evidence that there are universal differences in the cultural and social characteristics that may be derived from differences in population size and density has not been convincing (Pahl [1966] 1970). Thus, while comparisons are drawn between rural and urban populations, the causality argument associated with the rural-urban continuum has been discarded by most rural sociologists.

Rural sociologists have conducted hundreds of community studies that serve as a major source

of information for the design of community development programs (Bell and Newby 1972; Summers 1986, Luloff and Swanson 1990; Wilkinson 1991). From Galpin's pioneering study in 1915 until the mid-1960s, the study of community was almost synonymous with rural sociology in the United States. By that time the rural-urban continuum, which was the chief frame of reference for many investigators, was falling into disrepute (Pahl [1966] 1970). Their studies were being criticized for their impressionistic methodologies and their excessively descriptive nature (Colin Bell and Newby 1972). Moreover, proponents of the mass-society thesis argued that communities had been eclipsed by the forces of urbanization, bureaucratization, and centralization (Stein 1964; Vidich and Bensman 1958; Warren 1963). Community was alleged to be no longer a meaningful locus of social decision making. It was presumed that the increased presence of extralocal forces in the community (vertical integration) had destroyed the horizontal integration of communities and rendered small rural communities powerless in the face of broad and powerful forces of mass society. Although the tradition of holistic community studies has not returned to its former status, evidence clearly supports the argument that increased vertical integration does not necessarily destroy horizontal integration (Richards 1978; Summers 1986). Rather, it is more consistent with the empirical data to view local autonomy as a variable, and the impact of changes in vertical integration as varying according to a complex matrix of variables characterizing the external agent and the community.

In 1897, W. E. B. DuBois began a series of analyses of economic conditions among rural black groups and their relation to agriculture (DuBois 1898, 1901, 1904). Indeed, as we will stress later, since the turn of the century rural sociologists have been studying the "sociology of agriculture," although that expression did not come into use until the 1970s (Buttel et al. 1990). Land tenure and types of farming enterprises were studied to understand the relations of farming and agriculture-based businesses to the conditions of rural living. The methodology of these studies was often that of the community survey, and consequently there was much overlap with population and community studies. Most of these studies were descriptive in nature, and they generated taxonomies of

farming enterprises, which provided further refinements of farm family and farming community characteristics. The resulting social maps of farming communities provided detailed information to guide modernization programs, especially those of the Cooperative Extension Service, with its offices in virtually every rural county in the United States.

Although technological innovations have been occurring in agriculture for centuries, technological change was revolutionized with the introduction of hybrid corn (Ryan and Gross 1943). With this innovation, adoption and diffusion research became a new research field led by rural sociology. The first research focused on identifying which farmers had the highest rates of adoption of hybrid corn and how the adoption process was diffused to other farmers. Soon the research encompassed other innovations and spread to other countries with the modernization era at the end of World War II (Rogers 1995; Fliegel 1993). The basic processes of adoption and diffusion are now reasonably well understood, and training programs based on this knowledge are being implemented worldwide in areas of human behavior that reach well beyond farming practices to include health and nutrition, resource conservation, business management, and many other areas.

Preservationist–Critically Oriented Research.

By the 1960s there was a strong and growing disillusionment with the societal consequences of positivistic social science and the absence of a structuralist perspective (Newby and Buttel 1980). It was claimed that theory and research had become uncoupled, with theory being excessively abstract and research exhibiting a mindless empiricism. Several rural sociologists involved in international development research offered challenges to the Western development orthodoxy by claiming that modernization was serving the interests of the powerful and wealthy rather than improving the social and economic well-being of peasants and poor people (Havens 1972; Havens and Flinn 1975; Thiesenhusen 1978). In North America and Europe similar claims were being expressed in the environmental, civil rights, and other social justice movements of the late 1960s. The emerging research topics in rural sociology manifest the intellectual ferment of a more critical perspective on existing public policies, especially

in relation to established institutions of agricultural and rural research and programs claiming to improve rural communities and institutions. The emergent critical perspective incorporates a diversity of theoretical views that recognize the active role of the state in public policy and argue that it is subject to the influences within society of powerful interest groups that often are formed along the lines of class, race, ethnicity, or gender. Thus, the contemporary theoretical debates within rural sociology draw heavily on neo-Marxist and neo-Weberian orientations, with the result that rural sociology and sociology are closer intellectual partners today than at any time in the past fifty years. Although virtually all facets of rural social organization and processes are subjected to the emergent critical perspective, some areas have received more attention than others.

As we note below, the most distinctive feature of this “new rural sociology” (Newby and Buttel 1980) was the prominence of Marxist and neo-Marxist interpretations of the social differentiation of agriculture. This critical new rural sociology was applied most extensively to understanding the paradox of the growth of large-scale capitalist agriculture accompanied by the persistence of the small-scale family or subfamily farm. Efforts to understand this duality of agricultural structure has led to sharp debates about the barriers to capitalist transformation of agriculture, the role of small-scale and part-time farms in a functionally integrated capitalist industrial and agricultural system, and the role of the state in promoting capitalist agriculture. These critical perspectives have also been directed to understanding the social significance of the research apparatus of the land grant university system itself, particularly as to whether land-grant agricultural science has essentially served as a state policy that has helped to underwrite the growth of large-scale capitalist agriculture (Busch et al. 1991; Goodman and Redclift 1991; Kloppenburg 1988).

Until the late 1960s and early 1970s, rural sociology’s contribution to the sociology of development was confined largely to adoption-diffusion research related to new agricultural technologies in Third World countries (Hoogvelt 1997; Toye 1987; Webster 1990). Shortly thereafter, following on the growing disillusion with adoption-diffusion research, development-related inquiry in rural sociology shifted dramatically. Much of the

impetus behind criticism of the adoption-diffusion approach came from rural social scientists who did Third World research and who became acutely aware of its shortcomings as a vehicle for understanding agricultural change in the developing countries (Havens and Flinn 1975; George 1976; Lipton 1977; Flora 1990). The theoretical ferment in rural sociology in the 1970s and 1980s was to a large extent derived from new concepts in the sociology of development, such as the "development of underdevelopment," "dependent development," "core-periphery relations," and "capitalist world-system," which were developed as critiques of modernizationism as applied to the developing world.

The "post-diffusion" phase of the sociology of development has led to a far more diversified program of rural sociological research on development processes in the Third World. Although rural sociologists who do sociology of development research tend, not surprisingly, to give particular stress to agricultural development and its environmental implications, increasingly rural sociologists in the United States and other advanced countries do research on development processes that is often indistinguishable from that conducted by scholars who are not identified as rural sociologists. Also, as noted earlier, in many developing countries rural sociology is virtually synonymous with sociology of development, development studies, peasant studies, village studies, and so on.

To a certain extent this emerging research area overlaps the political economy of agriculture with its emphasis on technological change and its effects of distribution of ownership and control of resources, as well as equity in the distribution of benefits of new technologies (Field and Burch 1988). There is the additional concern with the depletion and pollution of nonrenewable resources (Schnaiberg and Gould 1994; Bell 1998). Social and economic impact assessment has emerged as a research activity that often is characterized by its critical perspective (Freudenburg 1986). A comprehensive theory has not yet emerged that links technological change in natural resource industries to the full range of its ramifications for the environment, its socioeconomic impacts, and its associations with industrial structures. However, the magnitude of its potential impacts and the

associated public concern suggests that this area of research has a viable future (Freudenburg 1992).

Since the 1920s, agriculture and natural-resource-based industries have been declining as sources of employment; the rate of decline accelerated dramatically after World War II. For a brief period during the 1970s manufacturing was a major source of employment growth in rural areas as industries sought cheaper land, lower taxes, and a nonunion labor force willing to work for lower wages and fewer benefits. Although this process continues, service industries have emerged as the major source of employment growth (Brown et al. 1988). These shifting labor demands have been accompanied by high unemployment in rural areas and a growth of temporary and part-time work, with resulting loss of wages and increasing levels of poverty. Rural labor market analysis has emerged as a new research area in rural sociology as a consequence (Summers et al. 1990). Much of the research is devoted to describing more precisely the nature and extent of rural unemployment and underemployment. However, the theoretical interpretations generally are sensitive to the linkages of rural labor markets to broader issues of economic restructuring. While labor demand-oriented and human capital explanations persist, there are attempts to understand the functioning of rural labor markets within the context of capitalist market institutions in a manner that is reminiscent of institutional labor economics.

Gender studies are not new to rural sociology; the role of women in farming has been a subject of research for at least a quarter-century (Haney and Knowles 1988). However, the past decade has witnessed the emergency of theoretical and empirical studies that attempt to explain how the institutions of capitalism, patriarchy, and the domestic ideology influence the work roles of men and women. A major focus of these recent studies has been the nature and extent of farm women's involvement in farm, household, and off-farm work. The rich descriptive detail of gender-based allocations of labor is being integrated into more comprehensive theoretical interpretations of structural changes in both agricultural and nonagricultural industries (Beneria 1985; Leon and Deere 1987; Sachs 1996).

For the past twenty-five years the United States has pursued a variety of programs and policies

intended to alleviate poverty (Sanderfur and Tienda 1988; Snipp 1989; Wilson 1987). In spite of these efforts, poverty persists at rates that are higher in rural areas than in urban areas, and the difference is increasing. Moreover, rural poverty is disproportionately concentrated in minority populations. Within the critical perspective it is argued that past and present institutional barriers limit the access of minority populations to the means of economic well-being. Persons of working age are disproportionately handicapped by deficiencies of human capital and discriminatory practices in the labor market. Moreover, these failures have produced a generation of elderly persons who are denied access to important public insurance programs such as Social Security because they were excluded from the labor market in years past or were employed in industries that were not covered by such programs. Thus, the state is called into question for its poor performance in developing and implementing adequate public policies, a failure that is alleged to benefit the interests of the wealthy and powerful classes of society (Summers 1991).

AGRICULTURAL CHANGE AND THE SOCIOLOGY OF AGRICULTURE

As social scientists and historians have begun to reflect on the momentous and often convulsive changes that have occurred during the twentieth century, many have noted that the most far-reaching social change of the century has arguably been the rapid decline of peasantries and of farm life, particularly since World War II (Hobsbawm 1994). The "depeasantization" of the advanced industrial countries has proceeded the farthest, but the very rapid decline of the peasant societies along with massive streams of rural-to-urban migrants that is now occurring in the developing world is, if anything, more stark (Araghi 1995).

The manner in which rural sociologists have conceptualized the processes and the significance of social-structural changes in agriculture has involved not only debate between the two overarching theoretical positions that have long characterized rural sociology, but also political and ideological positions on agriculture in society at large. Thus, on one hand, theories in the sociology of agriculture tend to fall within either the modernizationist

tradition (e.g., adoption-diffusion) or the critically oriented tradition (e.g., Lenin's and Kautsky's theories of capitalism and rural differentiation; see Goodman and Redclift 1982) discussed earlier. Over and above the differences and debates across theoretical traditions are changing sociopolitical views about agriculture and food.

We noted earlier that, from the beginnings of rural sociology around the turn of the twentieth century, agriculture was one of its most central subject matters. But what was considered interesting or important about agriculture has changed dramatically over time. Early rural sociology was largely focused on the sociology of agricultural communities. Rural sociology was later dominated by the adoption and diffusion of agricultural innovations. While these two traditions differed in their views of what it was about agriculture that was most worthy of study, both were modernizationist perspectives that tended to see the decline of family farming and restructuring of agriculture as being natural components of rural (and overall social) development.

The term "sociology of agriculture" can be best understood as a movement among rural sociologists in the mid- to late 1970s in reaction to two related but distinct components of modernizationism. The sociology of agriculture was, in the first instance, a reaction against rural sociological theories which, at least implicitly, accepted the inevitability and desirability of the demise and destruction of peasantries in the developing world and family farming in the industrial world. What Newby and Buttel (1980) meant by the notion of the "new rural sociology" was that a more adequate rural sociology required a more critical theoretical view about how and why farmers and other rural people were witnessing disintegration of their ways of life. The second defining feature of the new rural sociology was that it sought to take seriously the growing public and social movement concerns about the loss of family farms, the problems faced by agricultural communities, and the role of land-grant universities and public research.

The pattern of farm structural change that has occurred in the United States is not entirely typical of that of the rest of the industrial world, but the past century of changes in the American structure of agriculture typify the theoretical and broader

social issues at stake in the sociology of agriculture. In 1940, there were about 7 million American farms, home to about 30 million people (or about 25 percent of the U.S. population). By the end of the century there were only about 1.8 million farms, and the farm population (which numbered a little less than 7 million people) was less than 2 percent of the U.S. total. Even more striking is that fact that the last Census of Agriculture in the twentieth century (the 1997 Census) showed that a mere 26,000 farms with gross annual sales of \$1,000,000 or more (representing only 1.4 percent of the total number) accounted for about 42 percent of gross farm sales; by contrast, less than twenty years earlier, farms with gross annual farm sales of \$200,000 or more represented 3.3 percent of farms and about 44 percent of total sales (according to the 1978 Census of Agriculture). Thus, American farming has become increasingly concentrated. U.S. farm structure has also become highly dualistic; a handful of very large farms account for the bulk of output, while roughly 1.2 million small, "subfamily" (mostly part-time) farms account for the bulk of the farm population but very little of the output. In between, the middle stratum of farms—the prototypical medium-sized full-time family farm—has declined in numbers and percent of farm sales as the dualism of agriculture has been continued apace. Despite the rapid restructuring of agriculture from 1940 to the end of the century, nearly 95 percent of American farms continue to be family-proprietor or partnership farms. Thus, family farming—even if many of the largest and smallest family operations bear little resemblance to the traditional notion of a family farm—has persisted in the midst of otherwise convulsive change in agriculture and rural America.

The new rural sociology of agriculture in the late 1970s and early 1980s therefore ironically had two very different problematics—the decline/differentiation and the persistence of family farming—on which to focus its research. The new rural sociology drew on three major early-twentieth-century classical theories in focusing on these two problematics. V. I. Lenin tended to be the principal classical antecedent of theories of rural class differentiation (e.g., de Janvry 1980; Friedland et al. 1981; Havens et al. 1986), which tended to foresee agriculture undergoing differentiation into capital and labor, in much the same way that had

occurred in nonfarm industry. A. V. Chayanov and K. Kautsky were most influential in the work of scholars who sought to explain the persistence of family farming. Theories of the persistence of family farming generally explain the phenomenon in terms of the obstacles or the forms of resistance that exist to the development of capitalist agriculture (e.g., how the seasonal-biological nature of agriculture makes farming unattractive for large-scale investments [Mann 1990] or how independent commodity producers exhibit different rationalities [Mooney 1988] or enjoy certain advantages over capitalist producers [Friedmann 1978]).

While the agrarian differentiation/persistence debate dominated the sociology of agriculture through the early 1990s, the sociology of agriculture has made two significant shifts—toward studies of farming styles, on one hand, and the globalization of agriculture, on the other—over the last decade. The most recent versions of the sociology of agriculture have been partly a response to the current era of "globalization," trade liberalization, hypermobility of financial capital, World Bank–International Monetary Fund (IMF) imposition of structural adjustment reforms on the developing world, the rapid industrialization of certain sectors of farming (especially livestock and fresh fruits and vegetables), and the remarkable pace of concentration in the agricultural inputs and agro-food industries. It also became apparent to many scholars that most of the theories that dominated the sociology of agriculture in the 1970s through the early 1990s had two possible weaknesses: First, "new rural sociology" theories tended to be somewhat economic and deterministic. Second, these "new rural sociology" theories tended to locate the dynamics of agricultural change largely, if not entirely, within agriculture itself. These theories tended to give short shrift to the off-farm components of agro-food systems and to the global political-economic environment of agriculture.

The second generation of the sociology of agriculture can be understood as being a response to these two shortcomings of new rural sociology theories as well as to the intellectual and policy challenges posed by globalization. The first response has been the "farming styles" research tradition, and is often referred to as the "Wageningen School" approach because two of its most prominent researchers (van der Ploeg 1992; Long 1992)

are located at Wageningen University in the Netherlands. The Wageningen School perspective is a neo-Weberian or "actor-oriented" approach which stresses how diverse rural cultures interacting within diverse national economies and natural environments tend to give rise to diverse "farming styles." Thus, it is argued that there are multiple sources of diversity in farming structures, technologies, rationalities, and practices that serve to obviate the otherwise powerful political-economic processes of globalization and homogenization.

The second, and most influential, new approach in the sociology of agriculture—the agro-industrial globalization tradition—reflects a conviction that chief among the factors propelling agricultural change are matters such as national political-economic processes, the world economy, and geopolitics which lie outside of the realm of agriculture per se (see Friedmann 1982; Friedmann and McMichael 1989). Many scholars working within this new agro-industrial globalization tradition have emphasized the growing ascendancy on the part of agribusiness multinationals as post-World War II protectionist institutions and regulations have been dismantled. Studies in this genre emphasize how private firms are increasingly assuming the standard-setting and regulatory functions formerly undertaken primarily by governments, and how large corporations are playing a growing role in shaping the structure and performance of agro-commodity chains (e.g., Bonanno et al. 1994). Other scholars stress how the emerging structure of the new world food order reflects the growing role of monetary instability and Third World debt. Monetary disorder and debt have created the political-economic conditions for the liberalization of agricultural trade through international regimes such as the World Trade Organization (WTO) and the North American Free Trade Agreement (NAFTA). For example, by serving to justify structural adjustment policies which require that development countries adopt agro-food export policies and reduce food subsidies in order to repay their loans, monetary disorder and debt have been crucial factors in the late twentieth century restructuring of food systems (Friedmann and McMichael 1989; McMichael 1994). These new global food systems contrast sharply with the postwar national-type food order in which world nations tended to control their own agricultural systems and food

supplies through national food regulations and domestic agricultural policies.

CONCLUSION

These emergent research topics have not displaced those of an earlier period of rural sociology; they coexist. In doing so, rural sociology continues to serve two conflicting social policy agendas that reflect divergent views of rural society. The field has not escaped its origins in the social thought of nineteenth-century Europe. It does appear to be renewing its intellectual kinship with sociological theory.

The future of rural sociology as a research domain and as an intellectual endeavor appears to be very promising. Only a decade ago some observers were predicting its demise on the grounds that agriculture was declining as a source of employment and urbanization was continuing on a worldwide scale. However, predictions of the death of rural sociology seem to have been premature. The majority of the world population still lives in rural areas, and agriculture still plays a major role in the economies of most nations of the world. The globalization of food systems remains one of the most critical determinants of human well-being (Goodman and Watts 1997). The ending of the Cold War and the opening of the Eastern Bloc to greater scientific and intellectual exchanges create a vast new market for rural sociology, since all of these nations are predominately rural in composition. Finally, rural sociologists are expanding the scope of their work to include a much broader array of social phenomena and accepting the challenge of building the theoretical and empirical bridges between rural and urban aspects of society.

The growth of rural sociology professional associations is further evidence of its good health. In addition to the Rural Sociological Society, which was created in 1937, there are now the International Rural Sociological Association and independent associations in all the world's regions. Membership in all these associations is increasing; the Rural Sociological Society remains over 1,000, and annual meeting attendance has been in excess of 500 for most years in the 1990s.

SAMPLE SELECTION BIAS

In a linear regression model, sample selection bias occurs when data on the dependent variable are missing nonrandomly, conditional on the independent variables. For example, if a researcher uses ordinary least squares (OLS) to estimate a regression model in which large values of the dependent variable are underrepresented in a sample, estimates of slope coefficients typically will be biased.

Hausman and Wise (1977) studied the problem of estimating the effect of education on income in a sample of persons with incomes below \$15,000. This is known as a *truncated sample* and is an example of explicit selection on the dependent variable. This is shown in Figure 1, where individuals are sampled at three education levels: low (L), middle (M), and high (H). In the figure, sample truncation leads to an estimate of the effect of schooling that is biased downward from the true regression line as a result of the \$15,000 ceiling on the dependent variable. In a variety of special conditions (Winship and Mare 1992), selection biases coefficients downward. In general, however, selection may bias estimated effects in either direction.

A sample that is restricted on the dependent variable is effectively selected on the error of the regression equation; at any value of X , observations with sufficiently large positive errors are eliminated from the sample. As is shown in Figure 1, as the independent variable increases, the ex-

pected value of the error becomes increasingly negative, making these two elements negatively correlated. Because this contradicts the standard assumption of OLS that the error and the independent variables are not correlated, OLS estimates become biased.

A different type of explicit selection occurs when the sample includes persons with incomes of \$15,000 or more but all that is known about those persons is their educational attainment and that their incomes are \$15,000 or more. When the dependent variable is outside a known bound but the exact value of the variable is unknown, the sample is *censored*. If these persons' incomes are coded as \$15,000, OLS estimates are biased and inconsistent for the same reasons that obtain in the truncated sample.

A third type of selection that leads to bias occurs when censoring or truncation is a stochastic function of the dependent variable. This is termed *implicit selection*. In the income example, individuals with high incomes may be less likely to provide information on their incomes than are individuals with low incomes. As is shown below, OLS estimates also are biased when there is implicit selection.

Yet another type of selection occurs when there is *selection on the measured independent variable(s)*. For example, the sample may be selected on educational attainment alone. If persons with high levels of schooling are omitted from the model, an OLS estimate of the effect for persons with lower levels of education on income is unbi-

Figure 1

ased if schooling has a constant linear effect throughout its range. Because the conditional expectation of the dependent variable (or, equivalently, the error term) at each level of the independent variable is not affected by a sample restriction on the independent variable, when a model is specified properly OLS estimates are unbiased and consistent (DuMouchel and Duncan 1983).

EXAMPLES

Sample selection can occur because of the way data have been collected or, as the examples below illustrate, may be a fundamental aspect of particular social processes. In econometrics, where most of the basic research on selection bias has been done, many of the applications have been to labor economics. Many studies by sociologists that deal with selection problems have been done in the cognate area of social stratification. Problems of selection bias, however, pervade sociology, and attempts to grapple with them appear in the sociology of education, family sociology, criminology, the sociology of law, social networks, and other areas.

Trends in Employment of Out-of-School Youths. Mare and Winship (1984) investigate employment trends from the 1960s to the 1980s for young black and white men who are out of school. Many factors affect these trends, but a key problem in interpreting the trends is that they are influenced by the selectivity of the out-of-school population. Over time, that selectivity changes because the proportion of the population that is out of school decreases, especially among blacks. Because persons who stay in school longer have better average employment prospects than do persons who drop out, the employment rates of nonstudents are lower than they would be if employment and school enrollment were independent. Observed employment patterns are biased because the probabilities of employment and leaving school are dependent. Other things being equal, as enrollment increases, employment rates for out-of-school young persons decrease as a result of the compositional change in this pool of individuals. To understand the employment trends of out-of-school persons, therefore, one must analyze jointly the trends in employment and school

enrollment. The increasing propensity of young blacks to remain in school explains some of the growing gap in the employment rates between blacks and whites.

Selection Bias and the Disposition of Criminal Cases. A central focus in the analysis of crime and punishment involves the determinants of differences in the treatment of persons in contact with the criminal justice system, for example, the differential severity of punishment of blacks and whites (Peterson and Hagan 1984). There is a high degree of selectivity in regard to persons who are convicted of crimes. Among those who commit crimes, only a portion are arrested; of those arrested, only a portion are prosecuted; of those prosecuted, only a portion are convicted; and among those convicted, only a portion are sent to prison. Common unobserved factors may affect the continuation from one stage of this process to the next. Indeed, the stages may be jointly determined inasmuch as legal officials may be mindful of the likely outcomes later in the process when they dispose cases. The chances that a person will be punished if arrested, for example, may affect the eagerness of police to arrest suspects. Analyses of the severity of sentencing that focus on persons already convicted of crimes may be subject to selection bias and should take account of the process through which persons are convicted (Hagan and Parker 1985; Peterson and Hagan 1984; Zatz and Hagan 1985).

Scholastic Aptitude Tests and Success in College. Manski and Wise (1983) investigate the determinants of graduation from college, including the capacity of the Scholastic Aptitude Test (SAT) to predict individuals' probabilities of graduation. Studies based on samples of students in colleges find that the SAT has little predictive power, yet those studies may be biased because of the selective stages between taking the SAT and attending college. Some students who take the SAT do not apply to college, some apply but are not admitted, some are admitted but do not attend, and those who attend are sorted among the colleges to which they have been admitted. Each stage of selection is nonrandom and is affected by characteristics of students and schools that are unknown to the analyst. When one jointly considers the stages of selection in the college attendance decision, along with the probability that a student

will graduate from college, one finds that the SAT is a strong predictor of college graduation.

Women's Socioeconomic Achievement. Analyses of the earnings and other socioeconomic achievements of women are potentially affected by nonrandom selection of women into the labor market. The rewards that women expect from working affect their propensity to enter the labor force. Outcomes such as earnings and occupational status therefore are jointly determined with labor force participation, and analyses that ignore the process of labor force participation are potentially subject to selection bias. Many studies in economics (Gronau 1974; Heckman 1974) and sociology (Fligstein and Wolf 1978; Hagan 1990; England et al. 1988) use models that simultaneously represent women's labor force participation and the market rewards that women receive.

Analysis of Occupational Mobility from Nineteenth-Century Censuses. Nineteenth-century decennial census data for cities provide a means of comparing nineteenth- and twentieth-century regimes of occupational mobility in the United States. Although one can analyze mobility by linking the records of successive censuses, such linkage is possible only for persons who remain in the same city and keep the same name over the decade. Persons who die, emigrate, or change their names are excluded. Because mortality and migration covary with socioeconomic success, the process of mobility and the way in which observations are selected for the analysis are jointly determined. Analyses that model mobility and sample selection jointly offer the possibility of avoiding selection bias (Hardy 1989).

MODELS OF SELECTION

Berk (1983) provides an introduction to selection models; Winship and Mare (1992) provide a review of the literature before 1992. We start by discussing the censored regression, or tobit, model. We forgo discussion of the very closely related truncated regression model (Hausman and Wise 1977).

Tobit Model. The censored regression, or tobit, model is appropriate when the dependent variable is censored at an upper or lower bound as an artifact of how the data are collected (Tobin

1958; Maddala 1983). For censoring at a lower bound, the model is

$$Y_{1i}^* = X_i\beta + \varepsilon_i \quad (1)$$

$$Y_{1i} = Y_{1i}^* \quad \text{if } Y_{1i}^* > 0 \quad (2)$$

$$Y_{1i} = 0 \quad \text{if } Y_{1i}^* \leq 0 \quad (3)$$

where for the i th observation, Y_{1i}^* is an unobserved continuous latent variable, Y_{1i} is the observed variable, X_i is a vector of values on the independent variables, ε_i is the error, and β is a vector of coefficients. We assume that ε_i is not correlated with X_i and is independently and identically distributed. The model can be generalized by replacing the threshold zero in equations (2) and (3) with a known nonzero constant. The censoring point also may vary across observations, leading to a model that is formally equivalent to models for survival analysis (Kalbfleisch and Prentice 1980).

Standard Sample Selection Model. A generalization of the tobit model involves specifying that a second variable Y_{2i}^* affects whether Y_{1i} is observed. That is, retain the basic model in equation (1) but replace equations (2) and (3) with

$$Y_{1i} = Y_{1i}^* \quad \text{if } Y_{2i}^* > 0 \quad (4)$$

$$Y_{1i} = 0 \quad \text{if } Y_{2i}^* \leq 0 \quad (5)$$

Variants of this model depend on how Y_{2i} is specified. Commonly, Y_{2i}^* is determined by a binary regression model:

$$Y_{2i}^* = Z_i\alpha + U_i \quad (6)$$

$$Y_{2i} = 1 \quad \text{if } Y_{2i}^* > 0 \quad (7)$$

$$Y_{2i} = 0 \quad \text{if } Y_{2i}^* \leq 0 \quad (8)$$

where Y_{2i}^* is a latent continuous variable. The classic example is a model for the wages and employment of women where Y_{1i} is the observed wage, Y_{2i} is a dummy variable indicating whether a woman works, and Y_{2i}^* indexes a woman's propensity to work (Gronau 1974). In a variant of this model, Y_{2i} is hours of work and equations (6) through (8) are a tobit model (Heckman 1974). In both variants, Y_{1i}^* is observed only for women with positive hours of work. One can modify the model by assuming,

for example, that Y_{1i} is dichotomous. If ε_i and v_i follow a bivariate normal distribution, this leads to a bivariate probit selection model.

Estimation of equation (1) using OLS will lead to biased estimates. When $Y_{2i}^* > 0$,

$$\begin{aligned} Y_{1i} &= X_i\beta + E[\varepsilon_i | Y_{2i}^* > 0] + \eta_i \\ &= X_i\beta + E[\varepsilon_i | U_i - Z_i\alpha > 0] + \eta_i \end{aligned} \quad (9)$$

The OLS regression of Y_{1i} on X_i is biased and inconsistent if ε_i is correlated with $v_i - Z_i\alpha$, which occurs if ε_i is correlated with v_i or Z_i or both. If the variables in Z_i are included in X_i , ε_i and Z_i are not correlated by assumption. If, however, Z_i contains additional variables, ε_i and Z_i may be correlated. When $\sigma_{\varepsilon v} = 0$, selection depends only on the observed variables in Z_i , not those in X_i . In this case, selection can be dealt with either by conditioning on the additional Z 's or by using propensity score methods (Rosenbaum and Rubin 1983).

Equation (9) shows how selectivity bias may be interpreted as an omitted variable bias (Heckman 1979). The term $E[\varepsilon_i | Y_{2i}^* > 0]$ can be thought of as an omitted variable that is correlated with X_i and affects Y_{1i} . Its omission leads to biased and inconsistent OLS estimates of β .

Nonrandom Treatment Assignment. A model intimately related to the standard selection model that is not formally presented here is used when individuals are assigned nonrandomly to some treatment in an experiment. In this case, there are essentially two selection problems. For individuals not receiving the treatment, information on what their outcomes would have been if they had received treatment is "missing." Similarly, for individuals receiving the treatment, we do not know what their outcomes would have been if they had not received the treatment. Heckman (1978) explicitly analyzes the relationship between the nonrandom assignment problem and selection. Winship and Morgan (1999) review the vast literature that has appeared on this question in the last two decades.

ESTIMATORS

A large number of estimators have been proposed for selection models. Until recently, all these estimators made strong assumptions about the distribution of errors. Two general classes of meth-

ods—maximum likelihood and nonlinear least squares—typically assume bivariate normality of ε_i and v_i . The most popular method is that of Heckman (1979), known as the lambda method, which assumes only that v_i in equation (6) is normally distributed and $E[\varepsilon_i|v_i]$ is linear.

For a number of years, there has been concern about the sensitivity of the Heckman estimator to these normality and linearity assumptions. Because maximum likelihood and nonlinear least squares make even stronger assumptions, they are typically more efficient but even less robust to violations of distributional assumptions. The main concern of the literature since the early 1980s has been the search for alternatives to the Heckman estimator that do not depend on normality and linearity assumptions.

Heckman’s Estimator. The Heckman estimator involves (1) estimating the selection model (equations [6] through [8]), (2) calculating the expected error, $v_i = E[v_i|v_i > -Z_i\alpha]$, for each observation using the estimated α , and (3) using the estimated error as a regressor in equation (1). We can rewrite equation (9) as

$$Y_{1i} = X_i\beta + E(\varepsilon_i|U_i > -Z_i\alpha) + \eta_i \tag{10}$$

If ε_i and v_i are bivariate normal and $\text{Var}(v_i) = 1$, then $E(\varepsilon_i|v_i) = \sigma_{\varepsilon v} v_i$ and

$$E(\varepsilon_i|U_i > -Z_i\alpha) = \sigma_{\varepsilon v} \phi(-Z_i\alpha) / [1 - \Phi(-Z_i\alpha)] = \sigma_{\varepsilon v} \lambda(-Z_i\alpha) \tag{11}$$

where ϕ and Φ are the standardized normal density and distribution functions, respectively. The ratio $\lambda(-Z_i\alpha)$ is the inverse Mills’s ratio. Substituting equation (11) into equation (10), we get

$$Y_{1i} = X_i\beta + \sigma_{\varepsilon v} \lambda(-Z_i\alpha) + \eta_i \tag{12}$$

where η_i is not correlated with both X_i and $\lambda(-Z_i\alpha)$. Equation (12) can be estimated by OLS but is preferably estimated by weighted least squares since its error term is heteroskedastic (Heckman 1979).

The precision of the estimates in equation (12) is sensitive to the variance of λ and collinearity between X and λ . The variance of λ is determined by how effectively the probit equation at the first stage predicts who is selected into the sample. The better the equation predicts, the greater the vari-

ance of λ is and the more precise the estimates will be. Collinearity will be determined in part by the overlap in variables between X and Z . If X and Z are identical, the model is identified only because λ is nonlinear. Since it is seldom possible to justify the form of λ on substantive grounds, successful use of the method usually requires that at least one variable in Z not be included in X . Even in this case, X and $\lambda(-Z_i\alpha)$ may be highly collinear, leading to imprecise estimates.

Robustness of Heckman’s Estimator. Because of the sensitivity of Heckman’s estimator to model specification, researchers have focused on the robustness of the estimator to violations of its several assumptions. Estimation of equations (6) through (8) as a probit model assumes that the errors v_i are homoskedastic. When this assumption is violated, the Heckman procedure yields inconsistent estimates, though procedures are available to correct for heteroskedasticity (Hurd 1979). The assumed bivariate normality of v_i and ε_i in the selection model is needed in two places. First, normality of v_i is needed for consistent estimation of α in the probit model. Second, the normality assumption implies a particular nonlinear relationship for the effect of $Z_{i\alpha}$ on Y_{2i} through λ . If the expectation of ε_i conditional on v_i is not linear and/or v_i is not normal, λ misspecifies the relationship between $Z_{i\alpha}$ and Y_{2i} and the model may yield biased results.

Several studies have analytically investigated the bias in the single-equation (tobit) model when the error is not normally distributed. In a model with only an intercept—that is, a model for the mean of a censored distribution—when errors are not normally distributed, the normality assumption leads to substantial bias. This result holds even when the true distribution is close to normal (for example, the logistic) (Goldberger 1983). When the normality assumption is wrong, moreover, maximum likelihood estimates may be worse than estimates that simply use the observed sample mean. For samples that are 75 percent complete, bias from the normality assumption is minimal; in samples that are 50 percent complete, bias is substantial in the truncated case but not in the censored case; and in samples that are less than 50 percent complete, bias is substantial in almost all cases (Arabmazar and Schmidt 1982).

The fact that estimation of the mean is sensitive to distributional misspecification suggests that

the Heckman estimator may not be robust and raises the question of how often such problems arise in practice. In addition, even when normality holds, the Heckman estimator may not improve the mean square error of OLS estimates of slope coefficients in small samples (50 or less) (Stolzenberg and Relles 1990). This appears to parallel the standard result that when the effect of a variable is measured imprecisely, inclusion of the variable may enlarge the mean square error of the other parameters in the model (Leamer 1983).

No empirical work that the authors know of directly examines the sensitivity of Heckman's method for a standard selection model. Work by LaLonde (1986) using the nonrandom assignment treatment model suggests that in specific circumstances the Heckman method can inadequately adjust for unobserved differences between the treatment and control groups.

Extensions of the Heckman Estimator. There are two main issues in estimating equation (12). The first is correctly estimating the probability for each individual that he or she will be selected. As it has been formulated above, this means first correctly specifying both the linear function $Z\alpha$ and second specifying the correct, typically nonlinear relationship between the probability of selection and $Z\alpha$. The second issue is the problem of what nonlinear function should be chosen for λ . When bivariate normality of errors holds, λ is the inverse Mills's ratio. When this assumption does not hold, inconsistent estimates may result. Moreover, since X_i and Z_i are often highly collinear, estimates of β in equation 12 may quite be sensitive to misspecification of λ .

The first problem is handled rather easily. In the situation where one has a very large sample and there are multiple individuals with the same Z , the simplest approach is to estimate the probability of selection nonparameterically by directly estimating the probability of being selected for individuals with each vector of Z 's from the observed frequencies. With smaller samples, kernel estimation methods are available. These methods also consist of estimating probabilities directly by grouping individuals with "similar" Z 's and directly calculating the probability of selection from weighted frequencies. Variants of this approach involve different definitions of similarity and/or weight (Hardle 1990). In both methods, the problem of

estimating how the probability of selection depends on Z is bypassed.

Semiparametric methods are also available. These methods are useful if their underlying assumptions are correct, since they generally produce more efficient estimates than does a fully nonparametric approach. These methods include Manski's maximum score method (1975), nonparametric maximum likelihood estimation (Cosslett 1983), weighted average derivatives (Stoker 1986; Powell et al. 1989), spline methods, and series approximations (Hardle 1990).

The problem in the second stage is to deal with the fact that one generally has no a priori knowledge of the correct functional form for λ . Since λ is simply a monotonic function of the probability of being selected, this is equivalent to asking what nonlinear transformation of the selection probability should be entered into equation (12). A variety of approaches are available here. One approach is to approximate λ through a series expansion (Newey 1990; Lee 1982) or by means of step functions (Cosslett 1991). An alternative is to control for λ by using differencing or fixed effect methods (Heckman et al. 1998). The essential idea is to control for the probability of selection by implicitly including a series of dummy variables in equation (1), with each dummy variable being used to indicate a set of individuals with the same probability of selection or, equivalently, the same λ . Generally, this will produce significantly larger standard errors of the slope estimates. This is appropriate, however, since selection increases uncertainty. With small samples, these methods can be generalized through kernel estimation (Powell 1987; Ahn and Powell 1990). Newey et al. (1990) apply a variety of methods to an empirical problem.

CONCLUSION

Selection problems bedevil much social science research. First and foremost, it is important for investigators to recognize that there is a selection problem and that it is likely to affect their estimates. Unfortunately, there is no panacea for selection bias. Various estimators have been proposed, and it is important for researchers to investigate the range of estimates produced by different methods. In most cases this range will be considerably broader than the confidence intervals for the

OLS estimates. Selection bias introduces greater uncertainty into estimates. New methods for correcting for selection bias have been proposed that may provide a more powerful means for adjusting for selection. This needs to be determined by future research.

SAMPLING PROCEDURES

The analysis of data from samples constitutes a major proportion of contemporary research in the social sciences. For example, researchers use sample data from the U.S. population to estimate, with specified levels of confidence and precision, quantities such as average household size, the proportion of Americans who are unemployed during a given month, and the correlation between educational attainment and annual earnings among members of the labor force. Sample-based estimates are called *sample statistics*, while the corresponding population values are called *population parameters*. The most common reason for sampling is to obtain information about population parameters more cheaply and quickly than would be possible by using a complete census of a population. Sampling also is used sometimes when it is not feasible to carry out a complete census. For example,

except perhaps in a few nations with population registers, attempts to carry out a census in large countries invariably fail to enumerate everyone, and those who are missed tend to differ systematically from those who are enumerated (Choldin 1994). In these cases sampling may be the only way to obtain accurate information about population characteristics.

Researchers can use sample statistics to make inferences about population parameters because the laws of probability show that under specified conditions, sample statistics are unbiased estimators of population parameters. For example, if one used the same procedure to draw repeated samples from a population and determine the proportion of females in each sample, the average value of the observed sample proportions would equal the actual proportion of females in the population. The laws of probability also show that one can use data from a single sample to estimate how much a sample statistic will vary across many samples drawn from the population. Knowing the variability of a sample statistic (in statistical parlance, its *sampling variance*) in turn makes it possible to draw conclusions about the corresponding population parameter even though one has data for only a single sample. The key condition that must be met for these conditions to hold is that the data must come from a *probability sample*, a sample in which each case in the population (cases may be individuals, households, cities, days, etc.) has a known and nonzero probability of being selected into the sample. To produce this type of sample, a sampling technique must employ a random selection mechanism, one in which only the laws of chance determine which cases are included in the sample.

Researchers sometimes use *nonprobability samples*, such as convenience samples, quota samples, and snowball samples, to avoid the costs in time and money of probability sampling. *Convenience samples*, which consist of cases chosen simply because they are readily available (such as pedestrians passing by a street corner and volunteers from a classroom), sometimes are used in exploratory research and in the development of questionnaires or interview protocols. Opinion polls sometimes use *quota samples*, in which interviewers are assigned certain types of people to interview (e.g., a white female over age 50 living on a farm or a black male aged 20 to 30 living in a central city) but

are free to select specific individuals fitting these criteria to interview, to gauge political opinions cheaply. *Snowball samples* are generated when investigators ask known members of a group to identify other members and subsequently ask those who are so identified to identify still other members. This procedure takes advantage of the fact that the members of certain small and hard to locate groups (for example, biochemists studying a particular enzyme) often know one another. None of these nonprobability sampling procedures ensures that all the cases in the target population have a known and nonzero probability of being included in a sample, however (Kalton 1983, pp. 90–93). As a result, one cannot be confident that these procedures will provide unbiased estimates of population parameters or make statistical inferences from the samples they yield. Unless cost and time constraints are severe, researchers seeking to estimate population parameters therefore nearly always use procedures that yield probability samples.

One should distinguish between the representativeness of a sample and whether it was drawn by using probability sampling procedures. Although probability samples have a decidedly better track record in regard to representativeness, not all probability samples are representative and not all nonprobability samples are unrepresentative. Political polls based on quota samples, for example, often produce results that come very close to the subsequent vote. However, there is usually no reason to believe that a nonprobability sampling procedure that has been successful in the past will continue to yield representative results. In contrast, probability sampling procedures are likely to produce representative samples in the future because they are based on a random selection procedure.

Sampling theory, a branch of statistical theory, covers a variety of techniques for drawing probability samples. Many considerations can influence the choice of a sampling procedure for a given project, including feasibility, time constraints, characteristics of the population to be studied, desired accuracy, and cost. Simple sampling procedures are often sufficient for studying small, accessible, and relatively homogeneous populations, but researchers typically must use more complicated procedures to study large and heterogeneous populations. Using complicated procedures requires

consultation with a sampling specialist at a survey organization (the University of Illinois Survey Research Laboratory provides a list of these organizations on its Web site: www.srl.uic.edu).

Any study in which a probability sample will be drawn must begin by defining the population of interest: the target population. The purpose of the study restricts the definition of the target population but rarely specifies it completely. For example, a study of characteristics of U.S. families obviously will define the population as consisting of families, but it will be necessary to define precisely what counts as a family as well as decide how to treat various cases from which it may be difficult to collect data (such as the families of U.S. citizens who live overseas). Sudman (1976, pp. 11–14) discusses general issues involved in defining target populations.

The next step in probability sampling is to construct a *sampling frame* that identifies and locates the cases in the target population so that they can be sampled. The most basic type of sampling frame is a list of the cases in the target population. Such lists are often unavailable, however, and so researchers usually must construct an alternative. For example, to draw a sample of U.S. public high schools, a researcher might begin with a list of U.S. census tracts, select a sample of those tracts, and then consult maps that indicate the locations of public high schools in the selected tracts. Here the sampling frame would consist of the list of census tracts and their corresponding maps.

A perfect sampling frame includes all the cases in the target population, no inappropriate cases, and no duplications. Most sampling frames are imperfect, however, with failure to include all the cases in the target population being the most serious type of *coverage error*. For example, telephone-number sampling frames, such as those employed in random-digit dialing procedures, do not cover people without a telephone, and sampling frames that are based on dwelling units do not cover homeless people. Undercoverage errors bias sample statistics, with the extent of the bias being positively related to (1) the proportion of the target population not covered by the sampling frame and (2) the magnitude of the difference between those covered and those not covered. Sampling experts have developed many methods to reduce coverage errors, including the use of

multiple frames, multiplicity techniques, and postsurvey adjustments. Kish (1995, pp. 53–59, 384–439) and Groves (1989, pp. 81–132) provide helpful discussions of sampling-frame problems and possible solutions.

BASIC PROBABILITY SAMPLING PROCEDURES

Characteristics of one's sampling frame influence the specific sampling procedure appropriate for producing a probability sample. For example, some sampling procedures require that the sampling frame list all the cases in the population, while others do not. In addition, sampling procedures often are combined in situations where the sampling frame is complex. In all situations, however, the key element required for producing a probability sample is the use of a formally random procedure for selecting cases into the sample.

Simple Random Sampling. Simple random sampling (SRS) is the most elementary probability sampling procedure and serves as a benchmark for the evaluation of other procedures. To use SRS, one's sampling frame must list all the cases in the population. Usually the researcher assigns a unique identification number to each entry in the list and then generates random numbers by using a random number table or a computer program that produces random numbers. If a random number matches one of the identification numbers in the list, the researcher adds the indicated case to the sample (unless it has already been selected). This procedure is followed until it produces the desired sample size. It is important that only the randomly generated numbers determine the sample's composition; this condition ensures that the sampling procedure will be unbiased and that the chosen cases will constitute a probability sample.

With SRS, all cases in the sampling frame have an equal chance of being selected into the sample. In addition, for a sample of size n , all possible combinations of n different cases in the sampling frame have an equal chance of constituting the sample. The formulas for standard errors found in nearly all statistics textbooks and those used in statistical programs for computers assume that SRS generated the sample data. Most studies of human populations use sampling procedures that are less efficient than SRS, however, and using SRS

formulas in these instances underestimates the sampling variances of the statistics. As a consequence, researchers frequently conclude that differences or effects are statistically significant when they should not do so, or they may report misleadingly small confidence intervals.

Systematic-Simple Random Sampling. When a sampling frame contains many cases or the size of the prospective sample is large, researchers often decide to economize by setting a sampling interval and, after a random start, using that interval to choose the cases for the sample. For example, suppose a researcher wanted to select a sample of n cases from a population of size N and $n/N = 1/25$. To use systematic simple random sampling (SSRS), the researcher would draw a random number, r , between 1 and 25 and, starting with the r th case, select every twenty-fifth case in the sampling frame (for more complicated examples, see Kalton 1983, p. 17). This procedure gives all the cases in the frame an equal probability of being chosen for the sample but, unlike SRS, does not give all combinations of cases equal probabilities of selection. In the above example there are only 25 possible combinations of cases that could constitute the resulting sample (for example, cases 105 and 106 could never be in the same sample).

When the order of the cases in the sampling frame is random with respect to the variables of interest in a study, this property of SSRS is inconsequential, but when the frame is cyclically ordered, the results of SSRS can differ significantly from those of SRS. For example, suppose one wished to sample starting players on college basketball teams to determine their average height and had a sampling frame ordered by team and, within each team, by position. Since there are five starting players on each team, a sampling interval of any multiple of 5 would yield a sample composed of players who all play the same position. There would be a 1 in 5 chance that these players would all be centers (usually the tallest players) and a 2 in 5 chance that they would all be guards (usually the shortest). Thus, in this instance the sampling variation of the players' mean height would be substantially greater than the variation that SRS would produce. However, there are also situations in which stratified random sampling SSRS is equivalent to (StRS) (see below) and yields samples that have smaller sampling variances than those from SRS (Kish 1995, pp. 113–23). In prac-

tice, most lists of entire populations have orderings, often alphabetical, that are essentially random with respect to the purposes of a study, and lists with potential problems usually are obvious or are quickly recognized. Thus, in most applications SSRS is essentially equivalent to SRS (Sudman 1976, pp. 56–57).

Stratified Random Sampling. When a sampling frame consists of a list of all the cases in a population and also contains additional information about each case, researchers may use StRS. For example, a list of people also might indicate the sex of each person. A researcher can take advantage of this additional information by grouping individuals of each sex into a sublist (called a *stratum*) and then sampling, using SRS or SSRS, from each stratum. One can use either the same sampling fraction for each stratum, in which case the procedure is called *proportionate* StRS, or different fractions for different strata (*disproportionate* StRS). In either case one usually attempts to use the additional information contained in the sampling frame to produce a sample that will be more efficient than one derived from other sampling procedures (i.e., it will need fewer cases to produce a sample with a given precision for estimating a population parameter).

Efficiency is commonly measured by a sampling procedure's *design effect*, the ratio of the sampling variance of a statistic based on that procedure to the sampling variance of the same statistic derived from an SRS with the same number of cases (Kalton 1983, pp. 21–24). The efficiency of proportionate StRS is directly related to the correlation between the variable used to stratify the sampling frame and the variable or variables being studied. Thus, if one wished to determine the mean individual income of a population of Americans, proportionate StRS based on sex would produce a more efficient sample than would SRS and would have a design effect smaller than unity, because sex is correlated with income. In the limiting case in which the stratifying variable is perfectly correlated with the variable or variables being studied—for example, if each woman earned \$15,000 per year and each man earned \$25,000—proportionate StRS would always yield a sample mean exactly equal to the population mean. By contrast, if sex were completely uncorrelated with income, proportionate StRS would be no more efficient than SRS, and the design effect of StRS

would equal unity. In practice it is usually difficult to obtain sampling frames that contain information about potential stratifying variables that are substantially correlated with the variables being studied, especially when the cases are individuals. As a result, the gains in efficiency produced by proportionate StRS are often modest.

Proportionate StRS often yields small sample sizes for strata that consist of small proportions of a population. Thus, when researchers want to estimate parameters for the individual strata in a population, they sometimes employ disproportionate StRS to ensure that there will be enough cases from each stratum in the overall sample. A second reason for using disproportionate StRS is to design an optimal sample, one that produces the most precise estimates for a given cost, when there are differences between the strata in terms of (1) the cost of sampling and obtaining data, (2) the variability of the variables under study, or (3) prior knowledge about the variables under study. Sudman (1976, pp. 107–130) discusses and gives examples of each of these situations. The benefits of disproportionate StRS may be hard to attain when one wants to draw a multipurpose sample with observations on many variables, however, because the optimal procedures for the different variables may conflict. In addition, although proportionate StRS cannot have a design effect greater than unity, the design effects for disproportionate StRS can be larger than unity, meaning that disproportionate StRS can produce samples that are less efficient than those derived from SRS (Kalton 1983, pp. 20–26).

Cluster Sampling. All the sampling procedures discussed above require that the researcher have a sampling frame that lists the cases in the target population. Unfortunately, such sampling frames rarely exist, especially for human populations defined by area of residence. One can still draw a probability sample, however, if the population can be organized in terms of a grouping principle and each case can be assigned to one of the groups (called *clusters*). For example, dwellings in cities are located in blocks defined by streets. Even if a list of dwellings does not exist, it is possible to draw a probability sample by constructing a sampling frame that consists of a listing of the blocks, drawing a random sample of the blocks, and then collecting data on the dwellings in the chosen blocks.

This procedure, which is called cluster sampling (CS), is also advantageous when one wishes to use face-to-face interviewing to survey geographically dispersed populations of individuals. In this case CS is less costly because it allows the survey to concentrate interviewers in a small number of locations, thus lowering traveling costs. However, CS usually produces samples that have larger sampling variances than those drawn from SRS. The efficiency of CS is inversely related to (1) the extent to which clusters are internally homogeneous and differ from each other and (2) the number of cases sampled from each cluster. CS is maximally efficient when a population can be divided into clusters that are identical, because each cluster will then be a microcosm of the population as a whole. When clusters are internally homogeneous and differ sharply from each other, as tends to be true for human populations clustered by area of residence, CS is considerably less efficient than SRS (Kalton 1983, pp. 30–33). In this situation, researchers usually attempt to select only a few cases from each of many clusters, but that strategy eliminates the cost savings of CS.

Multistage Sampling. Researchers who want to collect data through face-to-face interviews with a probability sample of people living in a certain area, such as the United States, a state, or even a city, usually combine elements of the procedures discussed above in a multistage sampling procedure. For example, to draw a probability sample of U.S. adults, one might begin by obtaining a list of counties and parishes in the United States and collecting data on several characteristics of those units (region, average household income, etc.). These variables can be used to group the units, called *primary sampling units*, into strata so that one can use StRS. In addition, one would obtain estimates of the number of residents in each unit so that they could be sampled with probabilities proportional to their estimated population sizes (Sudman 1976, pp. 134–50). After selecting a sample of counties in this fashion, the researcher might proceed to draw a series of nested cluster samples. For example, one could divide each selected county into subareas (perhaps townships or other area-based governmental divisions) and then select a cluster sample from these units, with probabilities once again proportional to estimated population size. Next the researcher might divide each of the selected units into subareas (perhaps on the order

of the U.S. Bureau of the Census's "blocks") and draw a cluster sample of them. For each chosen block, the researcher might obtain a list of dwelling units and draw another cluster sample. Finally, from each chosen dwelling unit the researcher would choose, according to a specified procedure (Kish 1995, pp. 396–404), an individual to be interviewed. It is crucial that the selection procedure at each stage of the sampling process be based on a formally random selection procedure. For more detailed discussions and examples of the selection of multistage sampling procedures, see Kish (1995, pp. 301–383), Moser and Kalton (1972, pp. 188–210), and Sudman (1976, pp. 131–170). Multistage sampling usually requires considerable resources and expertise, and those who wish to draw such samples should contact a survey organization. Studies of the *design effects* of multistage samples, such as those carried out by the University of Michigan's Survey Research Center, show that they usually vary from 1.0 to 2.0, with values around 1.5 being common (Kish 1995, p. 581). A design effect of 1.5 means that the standard error of a statistic is twenty-two percent larger than estimated by standard statistics programs, which assume simple random sampling. There is also variation across kinds of statistics, with univariate statistics, such as the mean, often having larger design effects than do bivariate statistics, such as regression coefficients (Groves 1989, pp. 291–292). Unfortunately, estimating standard errors for a multistage sample is usually a complicated task, and this complexity, combined with the fact that popular statistics programs for computers use only SRS formulas, has led most researchers to ignore the problem, producing many spurious "statistically significant" findings.

RECENT ADVANCES

Sampling practitioners have made considerable progress in developing techniques for drawing probability samples of rare or elusive populations for which there are no lists and for which conventional multistage sampling procedures would produce sufficient cases only at an exorbitant cost. Sudman et al. (1988) review procedures for screening clusters to determine those that contain concentrations of a rare population's members and also discuss how multiplicity sampling procedures and capture-recapture methods can be applied to this problem. Researchers also have begun to use

multiplicity sampling of individuals to draw probability samples of businesses and other social organizations to which individuals belong; Sudman et al. (1988) outline the general strategy involved, and Parcel et al. (1991) provide an informative discussion and an example. This approach also can produce "linked micro-macro samples" that facilitate contextual analyses.

Recent developments in statistical theory and computer software promise to make the calculation of standard errors for statistics based on multistage samples much easier. One approach to overcoming these difficulties is to use a computer program to draw many subsamples from an existing sample and then derive an overall estimate of a standard error from the many estimates given by the subsamples. There are several versions of this general approach, including "bootstrapping," "jackknife replication," and "cross-validation" (Hinkley 1983). A second approach is to develop computer statistical packages that incorporate information about the sampling design of a study (Wolter 1985, pp. 393–412, contains a list of such programs). The increased availability of such programs should produce greater recognition of the need to take a study's sampling procedure into account in analyzing the data the study yields.

There is now greater recognition that sampling error is just one of many types of error to which studies of human populations are subject. Nonsampling errors, including nonresponse error, interviewer error, and measurement error, also affect the accuracy of surveys. Groves (1989) comprehensively discusses both sampling and nonsampling errors and argues that minimizing one type can increase the other. Thus, decisions about sampling procedures need to take into account likely sources and magnitudes of nonsampling errors.

SCANDINAVIAN SOCIOLOGY

Scandinavian sociology emerged in its modern form as an academic discipline just after World War II, although its roots go back considerably further. In Helsinki, the sociologist, ethnologist, and philosopher Edvard A Westermarck (1862–1939) lectured on sociology in 1890; in Göteborg, Gustaf Fredrik Steffen (1864–1929) became a professor of economics and sociology in 1903.

In 1850, the Norwegian clergyman Eilert Sundt (1817–1875) published a study of Norwegian tramps and the lowest stratum of the rural population. Between 1850 and 1869, when he became a vicar, Sundt received state support for his demographic and sociological studies of Norwegian manners and customs, poverty, and living conditions. In demography he is remembered for "Sundt's law," which states that irregularities in the age distribution at a given time generate similar irregularities in the next generation (Ramsøy 1998).

Westermarck held chairs in applied philosophy until 1930, and between 1907 and 1930 he also had a chair in sociology in London. He belonged to the small group of leading European sociologists and philosophers in the early part of the century. His best-known works are studies of the

history of marriage (first volume published in 1891) and of the origin and development of moral ideas (1906–1908, 1932).

Between 1907 and 1913 the statistician A Gustav Sundbärg (1857–1914) directed “Emigration-sutredningen,” an official investigation of Swedish emigration, which was considered one of the most serious problems in Sweden at that time (Sundbärg 1913). The final report was presented in 1913, and between 1908 and 1912 twenty appendices by Sundbärg himself; Nils R Wohlin (1881–1948), secretary of the investigation; and others were published. The investigation contains a wealth of statistical information of great interest.

EARLY SOCIOLOGY

In Scandinavia in the 1940s, sociology was confronted with an established discipline of demography, a reliable and accessible population registration system, a positivistic philosophy, and a reformist policy in need of empirical studies of societal problems. Until the late 1960s, Scandinavian sociologists engaged in empirical studies, mostly quantitative, of social inequality, social mobility and the educational system, work conditions, problems of physical planning and social epidemiology, alcohol problems, and delinquency. The works of Allardt in Helsinki (1965), Carlsson in Lund (1958), Rokkan (1921–1979) in Bergen (Rokkan and Lipset 1967), and Segerstedt (1908–1999) in Uppsala (1955) are representative of early mainstream sociology, and those of Aubert (1922–1988) in Oslo (1965) had a qualitative approach. There was a strong American influence from Scandinavians who had studied at American universities, from journals and textbooks, and from visiting Americans; Norway in particular received a series of Fulbright scholars. Scandinavian sociology became strongly empirical, technical, sociopsychological, and survey-oriented. There was less interest in functionalism, Talcott Parsons, and the classics than in survey analysis and social exchange theory.

In the late 1960s and throughout the 1970s, new sociological voices were heard in Scandinavia, perhaps more in Denmark and Sweden than in Finland and Norway. They can be characterized as aggressively political and Marxist, antipositivistic, antifunctionalistic, and antiquantitative. In general, the “new” sociology was more theoretical and sociophilosophical and less empirical than the main-

stream versions. Conflict theories, critical theory, symbolic interactionism, and the labeling perspective came to the fore, as did socioanthropological and hermeneutic methods.

INSTITUTIONAL STRUCTURE

In Denmark, the German refugee Theodor Geiger (1891–1952) was appointed a professor of sociology at Aarhus University in 1938. In 1955, Kaare Svalastoga (1914–1997), a Norwegian historian with a sociological education from the University of Washington in Seattle, became professor of sociology at Copenhagen, where a graduate program in sociology was started in 1958. In the 1960s and 1970s, additional chairs were created at Copenhagen and Aalborg and in sociological subdisciplines at universities in Copenhagen, Aarhus, Aalborg, and Roskilde as well as at the Handelshøjskolen (School of Economics and Business Administration) in Copenhagen. Mostly as a result of problems at the two institutes at the University of Copenhagen, Danish sociology was in a state of crisis after the late 1960s. In 1986–1987 the government closed down the Copenhagen institutes, and by 1994 they had been reorganized into a new institute with two chairs. The institute offers (as did Aalborg after 1997) a three-year undergraduate program leading to a B.A., followed by a two-year master’s program. At present there are only eight chairs in sociology in Copenhagen, Aalborg, Roskilde, and Handelshøjskolen. Outside the universities, the most important institute in sociology is the Socialforskningsinstituttet (Institute for Social Research). With Henning Friis as director from its start in 1958 until 1979, the institute has carried out many social investigations using its own field organization, for instance, the 1976 and 1986 Danish Welfare Surveys and the report on the 1992 follow-up of the 1968 youth study (Hansen 1995).

In Finland, two of Westermarck’s ethnosociological students held chairs in sociology in Helsinki and Turku in the 1920s. In the mid-1940s, modern-type sociologists got chairs, such as the criminologist Veli Verkko (1893–1955) in Helsinki in 1946. Heikki Waris (1901–1989), professor of social policy from 1948 in Helsinki, also should be mentioned here. Sociology chairs were first established at Helsinki, Turku, Åbo Academy, and Tampere. At present, there are more than twenty

professors of sociology and its subdisciplines at eleven universities and colleges: eight chairs at Helsinki University, four at Tampere, and two each at Jyväskylä and Turku, plus one at Åbo Akademi, also in Turku. Undergraduate studies lead to a master's degree after five years. There also are important research institutes outside the universities. The National Research and Development Centre for Welfare and Health (STAKES), under the Ministry of Social and Health Care, was established in 1992. Within STAKES there is a Social Research Unit for Alcohol Studies that conducts research on four principal areas, including narcotics. The research directors are Hannu Uusitalo and Jussi Simpura. There also is the Finnish Foundation for Alcohol Studies, which was established in 1950, with Klaus Mäkelä as its leading researcher.

In Norway, Sverre Holm filled the first sociology chair in 1949 in Oslo, and chairs were added in Bergen, Trondheim, and Tromsø in the 1960s. At present there are some twenty-five professorships. A basic undergraduate program takes four years, after which a two-year program leads to a "cand.polit." degree. Several institutes are important in sociological research and education: Institutt for Samfunnsforskning (Institute for Social Research [ISF]) since 1950, the newly established NOVA (Norwegian Institute for Research on Childhood and Adolescence, Welfare, and Aging), FAFO (Trade Union Movement's Research Foundation), and Statistisk Sentralbyrå (Statistical Central Bureau [SSB]). Institutt for Anvendt Sosialforskning (Institute for Applied Social Research [INAS]), which was established in 1968, is now included in NOVA. Natalie R Ramsøy was its research director until 1981.

In Sweden, the educator and sociologist E. H. Thörnberg (1873–1961) never held a university position. Gunnar Myrdal (1898–1987) could claim to be the first modern sociologist, but Torgny T. Segerstedt (1908–1999) became the first professor of sociology by converting his chair in applied philosophy to sociology at Uppsala in 1947. Sociology is now taught at Uppsala, Stockholm, Lund, Göteborg, Umeå, and Linköping as well as in several colleges, of which those at Karlstad, Växjö, and Örebro have become universities. There are about thirty sociology professors at the universities. A bachelor's program in sociology is scheduled for three years, a master degree for a fourth year, and a "licentiat" degree for a fifth

year. Outside the universities, Arbetslivsinstitutet (the National Institute for Working Life); Folkhälsoinstitutet (the National Institute of Public Health), established in 1992; the National Council for Crime Prevention (BRÅ), starting in 1974; and Statistics Sweden are important in Swedish sociology. The Institute for Social Research ([SOFI] 1972, beginning in with five sociology chairs) and the National Center for Social Research on Alcohol and Drugs (since 1999), with Robin Room as research director, are parts of Stockholm University. Since 1992 BRÅ has published *Studies on Crime and Crime Prevention*, an international bianual journal.

There is considerable interaction among the Scandinavian sociological communities: Professors hold chairs in neighboring countries, such as the leading Finnish alcohol researcher Kjetil Bruun (1924–1985) who had a chair in Stockholm in 1982–1984 and Swedish sociologists from Lund who crossed the sound to Copenhagen; comparative studies of the Scandinavian countries are conducted; and there have been joint comparative projects with one editor from each of four countries.

The Scandinavian Sociological Association has some 2,500 members. Approximate memberships are 550 in Denmark, 50 in Iceland, 600 in Finland (in 1995), 700 in Norway, and 500 in Sweden. Since 1955 the association has published *Acta Sociologica*, a refereed quarterly journal. For the first twelve years Torben Agersnap of Handelshøjskolen in Copenhagen was the editor, and since then editorship has rotated among the countries, with three-year periods since 1985. Each Scandinavian country has a national sociological association. The Finnish Westermarck Society, founded in 1940, is the oldest and includes social anthropologists. There are also national journals: *Sociologia* (since 1990) in Denmark, *Sosiologia* in Finland, *Tidskrift for Samfunnsforskning* (since 1960) and *Sociologisk Tidskrift* in Norway, and *Sociologisk forskning* (since 1964) in Sweden.

Most foreign contacts are still with the United States, although interaction with European, especially British, French, and German, sociologists tends to be more frequent now. Polish, Hungarian, and Estonian contacts are important to Finnish sociology. Comparative studies including non-Scandinavian European or OECD countries (Erikson and Goldthorpe 1992; Korpi and Palme 1998)

are conducted frequently as a heritage from Stein Rokkan in political sociology. Comparisons often have been made with the United States and Canada, as occurred when Norway and Sweden were included in Tim Smeeding's and Lee Rainwater's so-called "Luxembourg Income Study" around 1980. Furthermore, several Scandinavian sociologists have been visiting researchers at the European Sociological Institute in Florence, Italy. The Danish welfare researcher Esping-Andersen (1990) has a chair at the University of Trent in Italy. Several Scandinavian sociologists have spent most or parts of their careers abroad, especially in the United States, for example, Aage Bøttger Sørensen from Denmark; the Norwegians Stein Rokkan, Jon Elster, and Trond Pedersen; and the Swedes Bo Andersson and Hans L. Zetterberg.

PRESENT SOCIOLOGY

Essays on Scandinavian sociology can be found in Bertilsson and Therborn (1997). New conceptions in Finnish sociology in the early 1990s and their relation to earlier structural-cultural traditions are discussed by Alapuro (1995), while Martinussen (1993) deals with present-day Norwegian sociology. Allardt et al. (1988) offer an official evaluation of Swedish sociology. Gunnlaugsson and Bjarnason (1994) describe Icelandic sociology.

Even after the wave of New Left sociology subsided toward the end of the 1970s, Scandinavian sociology remained diversified, with a continued interest in Marxism and the classics as well as in social exchange theory and a broad spectrum of data analysis. On balance, the focus now is somewhat more on theory and on macrosociology. Interest in theories of organizations (Ahrne 1994), economic sociology (Swedberg 1990), and, especially after Coleman's book (1990), rational-choice approaches (Hedström and Swedberg 1998) has been increasing. The statistical analytic orientation has held its own, at least partly because of the rapid development of personal computers and their programs, which permit more adequate analyses. At the same time, the old interest in qualitative methods has remained, especially in connection with the growing field of gender studies.

In Norway, Østerberg (1986, 1988) writes in the hermeneutic and humanistic essay tradition, Yngvar Løchen (1931–1998) carried out action research in medical sociology with relevance to the

lives of sociologists, and Elster is a well-known philosopher and social scientist (1989), favorably disposed to Marxism (1985) but closer to the rational-choice approach. In Sweden, Göran Therborn is an internationally respected Marxist and the social psychologist and essayist Johan Asplund has a prestigious position in the discipline; Antti Eskola is Finland's best known social psychologist.

A cluster of overlapping core areas concerning forms of inequality has remained central to Scandinavian sociology. Studies concern gender inequality as well as inequality among social classes and other groupings in regard to political, economic, educational, and social resources, which can be seen as constituting inequality of welfare in a broad sense; these studies present indicators of various welfare dimensions. Research institutes such as the Institute for Social Research in Copenhagen, INAS (now in NOVA) and ISF in Oslo, and SOFI in Stockholm have been important, as STAKES in Helsinki will be. One of the tasks of SOFI has been to follow up an officially commissioned 1968 study of low-income categories. The study was carried out by Sten Johansson, then at Uppsala, and his team, which published several reports in 1970–1971, creating considerable political commotion. SOFI has continued this study as a panel, *Levnadsnivåundersökningen* (Level of Living Study [LNU]), with new surveys in 1974, 1981, and 1991. A volume edited by Erikson and Åberg (1987) provided a partial summary. Comprehensive welfare studies (level-of-living studies) have been carried out in all Scandinavian countries since the 1970s (Erikson et al. 1987; Hansen et al. 1993). Statistics Sweden has conducted annual level-of-living surveys since 1974 (Vogel 1988). Studies by Gudmund Hernes in Norway have been influential both politically and sociologically. Hernes was the leading researcher in the first Norwegian level-of-living survey and in an official Norwegian 1972–1982 project on power in society (Hernes 1975, 1978, also involving exchange theory). The task force gave its final report in 1982 (Hernes 1982). The official Swedish study of societal power, ordered after the success of the Norwegian study, was run mainly by political scientists, historians, and economists, although Åberg (1990) was asked to repeat in modern form a community study from the 1950s (Segerstedt and Lundquist 1952, 1955). Here the different roles of Norwegian and Swed-

ish sociology may reflect differences in public opinion: Norwegian sociologists have easy access to the mass media and the political elite. The criminologist Nils Christie has become a well-known participant in public discussion of social policy issues, and Hernes was the Labor Party's minister of education and research.

Social stratification and social mobility have long been an area of strong interest in Scandinavian sociology (Carlsson 1958; Svalastoga 1959, 1965). Later works in the field include those of Alestalo (1986), Erikson (1987), Knudsen (1988), and Erikson and Goldthorpe (1992). More recently Erikson and Jonsson reported an officially commissioned investigation of social selection to higher education (Erikson and Jonsson 1993, 1996).

In political sociology Stein Rokkan's (1921–1979) far-reaching project (Rokkan and Lipset 1967; Rokkan et al. 1970; Rokkan 1987) was left unfinished. Other important works in this field include Korpi (1989), Therborn (1986, 1995), Martinussen (1988), Alapuro (1988), and Mjøset (1992).

Gender studies are an exceptionally strong field in Norway and fairly strong in Scandinavia generally. In the late 1960s, Holter (1970) analyzed gender roles and their impact on work life, political behavior, and education. Several Norwegian gender studies, among others those by Helga Hernes and Kari Waerness, were published in the series "Kvinnerens levkår og livsløp" (Women's Level of Living and Life Course). In Sweden Edmund Dahlström and Rita Liljeström and in Finland Elina Haavio-Mannila pioneered the field.

Outside the sociological core area of inequality there are neighboring fields and sociological specialties. The Finnish demographer Tapani Valkonen is known for skillful context analyses and epidemiological studies. To revitalize Swedish demography, which had stagnated in the 1970s, the Norwegian demometrician Jan M. Hoem was called in from Copenhagen in 1983.

In the lively sociological subfield of literature and mass media, Karl-Erik Rosengren is the leading Swedish researcher. To some extent through east European contacts, the life-course narrative as a research instrument has been developed into a Finnish specialty, mostly by J.P. Roos.

Deviance is another subfield. Usually it is not considered a sociological core area, although it has long-term credentials as a central field both from the classics and from early Scandinavian sociology. The study of deviance has remained an important part of Scandinavian sociology in terms of both applied and basic research. Since the Finnish State Alcohol Monopoly established its research institute in 1950, alcohol studies have been a strong Finnish field. Bruun (Bruun and Frånberg 1985) was its longtime director, and Mäkelä (1996) was his successor. Also Skog (1985) in Oslo and Köhlhorn (Köhlhorn and Björ 1998) and Norström (1988) in Stockholm are well known in the field of alcohol and drug studies. Mathiesen's penology (1987) is a part of Norwegian sociology, just as studies of crime and crime prevention have been a part of Swedish sociology since the official 1956 juvenile delinquency project (Carlsson 1972) and early BRÅ projects.

Gunnlaugsson and Bjarnason (1994) claim that the four fields of welfare research, stratification research, women's studies, and cultural studies do not capture the structure of Icelandic sociology, which centers on two broad themes: social conditions and social and cultural problems associated with the development of Icelandic society. These problems essentially concern crime, in particular incidental violence by strangers, alcohol abuse, and the perceived threat of drug abuse, that is, deviance.

Finally, access to an extensive and reliable population registration system has made good sampling frames available to surveys, and governmental microdata have been helpful in longitudinal data sets in Scandinavian behavioral projects. However, since the mid-1970s, statistically oriented behavioral researchers, especially in Sweden, have had problems with privacy-protecting data legislation. According to the pioneering Swedish Data Act of 1973, running data on identified persons by computer requires a permit from a Data Inspection Board (DI). The DI expanded the informed-consent condition for the permit to include the computer use of identified governmental microdata accessed according to the century-old right-of-access principle. Although this condition has been waived in some cases, it has led to frequent and well-publicized controversies between the DI and social researchers, with the media usually supporting the DI. In Sweden, the media debated privacy

issues mostly in connection with statistical data sets, whereas administrative files largely went unnoticed. Since the conflict came to a head in 1986 over the deidentification of the data set of Project Metropolitan, a longitudinal study of a cohort of Stockholmers, the tensions have smoothed out and access to register data has been made easier. The rich governmental microfiles, including the censuses, remain assets to Scandinavian sociology. In 1998, a new Swedish Personal Data Protection Act in line with EU regulations and modern Internet use was substituted for the 1973 Data Act.

CARL-GUNNAR JANSON

SCIENCE

Sociologists of science study the social organization of science, the relationships between science and other social institutions, social influences on the content of scientific knowledge, and public policy regarding science. The definition of the term “science” is problematic. Science can refer to a changing body of shared knowledge about nature or to the methods used to obtain that knowledge; in that form, science has existed for millennia. Research on “indigenous scientific knowledge” is reviewed in Watson-Verran and Turnbull (1995). Sociologists of science are more likely to define science in institutional terms, and most research in that area studies those who work in differentiated social institutions. The “demarcation” problem of distinguishing between science and nonscience persists. Gieryn (1995, 1998) argues that scientists and their advocates continually engage in contested “boundary work” to demarcate science. He discusses the rhetorical and organizational devices used in those contests; thus, scientists are likely to emphasize the disinterested search for knowledge in their attempts to distinguish science from technology and stress the utility of scientific knowledge in their attempts to distinguish it from religion. Gieryn argues against the notion that there are “essential” features of science that determine the outcome of those contests; these “essential features” are instead “provisional and contextual results of successful boundary-work” (1995, p. 406).

Unless the production of knowledge about the empirical world is delegated to relatively autonomous specialists, knowledge accumulates at a slow pace. When beliefs about nature are closely linked to major social institutions, institutional rigidity tends to produce cognitive rigidity (Znaniecki 1940; Parsons 1951, pp. 326–348). There were communities of relatively autonomous specialists in several great civilizations in the past, but most failed to produce stable institutions. Modern science dates from seventeenth-century Europe. Europe-

ans at that time believed in a deity that gave laws to nature as well as to people and expected to discover those laws. Seventeenth-century Europeans could build on the basis of a science produced by the medieval schoolmen. With the rise of capitalism, intellectual elites developed a strong interest in using new knowledge to improve material conditions and enrich themselves. Merton, the leading founder of the sociology of science, argued in 1938 (1970) that in addition to these conditions, Puritanism contributed to the scientific ethos through its emphasis on work in the everyday world, rationalism and empiricism, openness to free inquiry, and desire to glorify God by describing His creation. (This still-controversial thesis is reviewed in a symposium in *Isis* 1988. For a general review of theories about the scientific revolution, see Cohen 1994.)

A distinctive normative ethos was institutionalized in modern science. Merton (1973, chap. 13) identified four salient norms: (1) "Universalism" requires that scientific contributions be evaluated according to general impersonal criteria without regard to "irrelevant" characteristics of the contributors such as their race, religion, and nationality. It also requires that scientists be rewarded according to their scientific contributions without regard for those irrelevant criteria. (2) "Communism" requires that knowledge be shared, not kept secret. Thus, the only way a scientist can claim a discovery as "his" or "hers" is to make it known to others. In this regard, modern scientists differ from Renaissance mathematicians and magicians, who were often quite secretive. (3) "Disinterestedness" refers to the injunction that the procedures and products of science not be appropriated for private gain. This need not imply altruism, although scientists often are driven to discover as an end in itself, but in addition, situations usually are structured so that it is in a scientist's career interest to act in a disinterested manner. (4) "Organized skepticism" permits and encourages challenges to knowledge claims. Science tends to be unlike many other areas of social life, in which conformity in matters of belief is demanded as a sign of loyalty.

Merton's essay on the normative ethos of science, first published in 1942, has drawn fruitful criticism. While Merton argued that the scientific ethos was functional for the advancement of knowledge, Mitroff (1974) argued that scientists could invoke "counter-norms," for example, could fail

to be skeptical about their own theories, and this could be equally functional in some situations. Mulkay (1980) invoked ethnomethodological ideas to make an argument of general significance: "We should not assume that *any* norm can have a single literal meaning independent of the contexts in which it is applied. . . . Scientists *must* engage in inferential and interpretive work on norms. They are likely to do this *after* their actions, in order to construct acceptable accounts of their behavior. The norms don't determine behavior."

Ambiguity involving the norm of universalism was present at the birth of modern science: Which characteristics of those who advance knowledge claims are relevant or irrelevant? Shapin (1994) argues that in England only the testimony of "gentlemen" was accepted as valid, and not all gentlemen; those who rejected the empiricism of men such as Francis Bacon and Robert Boyle and accepted the arguments from first principles of men such as Thomas Hobbes were excluded from the scientific community (Shapin and Shaffer 1985).

Scientists in the seventeenth and eighteenth centuries were usually amateurs, such as Robert Boyle and Benjamin Franklin, or the intellectual servants of amateurs. In the later eighteenth and nineteenth centuries, science was professionalized. Scientists received formal education in universities; found full-time employment, often in the universities; formed self-governing associations; and developed the modern scientific journal and other means of communication. A case study of the process for the newly emerging discipline of geology in the 1830s is presented in Rudwick (1985), where it is linked with the conduct of intense disputes about geological history; the "professionals" in those disputes got no special respect. The more general process of professionalization is described by Ben-David (1984, 1991), who notes the importance of national differences in the organization of science. Ben-David shows that there was more competition among universities in Germany and the United States in the late nineteenth and twentieth centuries than there was in those in Britain and France and claims that this partly accounted for the greater productivity of science in the first two countries. Other organizational characteristics of American science also help account for its superior productivity in the past half century: Science is not highly centralized, the competitive units are large enough and heterogeneous

enough to provide a critical mass of closely interacting scientists, and senior scientists tend to have less authority over younger scientists than they have elsewhere. (For statistics on national science productivity, see U.S. National Science Board 1996.)

SOCIAL STRATIFICATION IN SCIENCE

Competition remains intense among organizations that engage in basic research in the United States, particularly universities. Organizational prestige is central; as is usually true when it is difficult to measure organizational outputs directly, social comparisons become more important. Periodic surveys of faculty members have been used to rate the prestige of research departments. While outputs are difficult to measure, departments with high prestige are more successful in obtaining research resources and have higher rates of research productivity.

Competition is also intense among individual scientists, who compete for recognition from their peers for being the first to make valued discoveries (Merton 1973, chaps. 14 and 15; Hagstrom 1965, 1974). Competition may lead to secretive behavior and premature publication; it also may encourage scientists to move into new areas where there is less competition. A common consequence of competition is simultaneous or multiply independent discovery (see Zuckerman 1988 and the references cited there). The frequency of such events shows the extent to which science is a social product. When apparently simultaneous discoveries occur, those involved often engage in priority disputes; they are often ambivalent in those disputes, torn between a desire for the recognition due to originality and the demand for humility, the recognition of their dependence on the work of others.

There is a great degree of inequality in the research productivity of scientists. The chances that a scientist will publish as many as n papers is $1/n^2$; in other words, about 6 percent of all scientists produce 50 percent of all published papers (Price 1986). This inequality is even greater if one looks at the distribution of citations of the work of scientists. With some reservations, the number of citations can be taken as a measure of the quality of scientific work; frequently cited papers are usually those which other scientists have found useful in their own research. If c is the number of citations, the chances that the work of a scientist will have c

citations is proportional to $1/c^3$; that is, about 3 percent of all scientists receive 50 percent of all the citations of scientific papers.

Most of the variation in scientific productivity can be explained in terms of individual characteristics of scientists, such as years required to earn a doctorate, and characteristics of their employers, especially departmental prestige. While men have been more productive than women (the difference has been declining), that difference is almost entirely the result of differences in background and employer characteristics (Xie and Shauman 1998). In the United States (more than in most countries), there is considerable mobility of scientists among organizations. High research productivity predicts mobility to institutions of higher prestige and to a higher rank, but employment in a high-prestige organization in turn causes higher productivity (Allison and Long 1990). In general, American universities tend to conform to universalistic norms in making appointments and promotions (Cole and Cole 1973). There is an apparent exception to this in the early phases of careers, when productivity is difficult to assess; the prestige of a scientist's doctoral department is strongly correlated with the prestige of the initial employer.

Inequality of productivity increases over the careers of scientists (Allison et al. 1982) as a manifestation of Merton's (1973) "Matthew effect": "For unto every one that hath shall be given, and he shall have abundance: but from him that hath not shall be taken away even that which he hath." Initially productive scientists obtain more and better resources for research, their work is more visible to others, and they are more likely to interact with other highly productive scientists.

WORK GROUPS, SPECIALTIES, AND DISCIPLINES

Scientific research is a nonroutine activity; outcomes and problems cannot be predicted, and it is difficult to plan research. As organization theories lead one to expect in such situations, scientific work tends to be done in small groups with few hierarchical levels and a small degree of control by supervisors (Hagstrom 1976). Most basic research in universities is done by groups of four to nine graduate students and technicians led by one to a few professors. Over the course of time, faculty

members have found it increasingly desirable to collaborate with their peers, and most publications are multiply authored. Some aspects of research can be routinized, and the extent to which this can be done varies among disciplines; for example, work is more readily routinized in chemistry than it is in mathematics (Hargens 1975). Thus, work groups are smaller in mathematics than in chemistry. Chemists can delegate tasks to assistants, whereas mathematicians cannot; while the number of assistants does not explain much of the variation in the productivity of mathematicians, it does so in regard to the productivity of chemists. In other areas of science, major changes in research methods have led to what is called big science, which is epitomized by high-energy physics. Despite the use of labor-saving devices, the work groups at high-energy particle laboratories can be very large, with well over 150 scientists. Such groups have a greater division of labor, a broader span of supervisory control, and greater centralization of decision making.

These work groups ordinarily are embedded in larger organizations such as universities and governmental or industrial establishments. They also are likely to be linked informally with other groups working on the same or related research problems in other establishments. These loosely linked and loosely bounded sets of work groups can be called "specialties" or, more evocatively, "invisible colleges" (Price 1986). Groups in a specialty simultaneously compete with one another and make contributions to one another's research. The number of groups in a specialty worldwide (there is a great deal of international collaboration) is ordinarily small, perhaps 50 on the average and seldom over 100, although specialties with over 500 groups exist. Scientists spend much of their time communicating with one another: writing papers, reviewing papers by others, attending meetings of scientific societies, and informally (Nelson and Pollock 1970).

The public nature of science tends to inhibit deviant behavior, but some deviance is to be expected. The extent of research fraud, such as forging and trimming data, is difficult to ascertain, as is the case in white-collar crime generally. Evidence and theories about such deviance are summarized in Zuckerman (1988). Fraud is most likely to occur when researchers are under pressure to get results (such as postdoctoral fellows and

nontenured faculty members) and when it is less likely to be detected (as in collaborative research with workers from different disciplines, where one is unable to evaluate the work of another); both conditions are especially likely to exist in experimental research in the biomedical sciences. Of courses, scientists with a high reputation also have engaged in research fraud; the case of the psychologist Cyril Burt is discussed in Gieryn (1998).

Scientific specialties usually exist within disciplines represented by their own university departments and scientific societies, but interdisciplinary research is common. The growth of an interdisciplinary area can lead to the differentiation of disciplines, and so the number of scientific disciplines has grown (Hagstrom 1965). The different scientific disciplines differ greatly in the degree of consensus about theories and methods; one indicator of this is variation in the rejection rates of manuscripts submitted to scientific journals, which is high in fields such as sociology and low in fields such as physics (Hargens 1975, 1988). Variations in consensus can affect the careers of scientists by affecting judgments of the merits of the work of individuals; it is easier to achieve early success in disciplines with a high degree of consensus. Disciplines also vary in the degree to which the work of scientists depends on and contributes to the work of others in their disciplines. This interdependence is related to Durkheim's concept of "organic solidarity." It is lower in mathematics than it is in the empirical sciences, as is indicated by fewer references in and citations of papers written by mathematicians, and it can be experienced as a problem by mathematicians (Hagstrom 1965).

THE SOCIOLOGY OF SCIENTIFIC KNOWLEDGE

The Structure of Scientific Revolutions by the historian Kuhn (1970), first published in 1962, strongly influenced the sociology of science. Kuhn made a distinction between normal and revolutionary science. Normal science is a puzzle-solving activity governed by paradigms. A paradigm consists of shared commitments by a group of scientists to a set of values, presuppositions about nature, methods of research, symbolic generalizations such as Newton's laws, and exemplars such as particular experiments. In normal science, researchers force nature into agreement with the paradigm; appar-

ently disconfirming evidence does not weaken commitment to the paradigm. Normally scientists are successful in explaining away apparently disconfirming evidence, but persistent critical anomalies can trigger a scientific revolution. In a successful revolution, one paradigm is succeeded by another paradigm with quite different presuppositions and exemplars. Kuhn (1970) argued that the contending paradigms in revolutionary situations are “incommensurable”; the choice between them is not and cannot be determined by evidence and formal decision rules alone. Kuhn illustrated his argument with evidence from major revolutions ranging from the Copernican Revolution of the sixteenth century to the revolutions that overthrew Newtonian physics in the twentieth century as well as smaller revolutions that affected the work of smaller sets of scientists.

The sociologists who developed the sociology of scientific knowledge, initially largely British, advanced radical arguments far beyond those of Kuhn. Not only are paradigms, or theories, “underdetermined” by data, theories are largely or entirely socially constructed. In Harry Collins’s words, “the natural world has a small or non-existent role in the construction of scientific knowledge. . . . [N]othing outside the courses of linguistics, conceptual and social behaviour can affect the outcome of these arguments” (quoted in Gieryn 1982). The constructivists have done a number of detailed case studies of changes in the content of science to support their claims. Their early work is summarized in Collins (1983), who shows how “data” were insufficient for resolving conflicts about an allegedly new type of laser. Others have studied cases such as disputes about gravity waves, the construction of quarks, and the history of statistics and genetics in the early twentieth century. In an ethnographic study of a laboratory that investigated neurohormones, Latour and Woolgar (1979) describe how facts were socially constructed. For example, initial claims constitute conjectures, and lower-order factual statements are qualified by the names of those making the claims. However, when they are successfully constructed, these qualifications are dropped and the facts are taken for granted, perhaps embedded in laboratory equipment or algorithms. Related work by other sociologists has involved detailed analyses of scientific discourse. Gilbert and Mulkay (1984) studied biochemists who did research on the process of

oxidative phosphorylation. Those authors showed that the sober prose of the scientific papers, where evidence and argument lead to conclusions, was contradicted by the informal discourse of the same scientists, who were partly aware that evidence and argument would be insufficient to persuade their opponents.

The constructivist position naturally leads to a relativistic position: If theories are social constructs, they could equally well be different. From his detailed study of the ways in which physicists constructed quarks in the period 1964–1974, Andrew Pickering (1984) concluded that “there is no obligation upon anyone framing a view of the world to take account of what twentieth century physics has to say. The particle physicists of the late nineteen-seventies were themselves quite happy to abandon most of the phenomenal world and much of the explanatory framework which they had constructed in the previous decade. There is no reason for outsiders to show the *present* HEP worldview any more respect.” This relativism leads constructivists to challenge the conventional demarcation between science and nonscience or pseudoscience. Thus, an article reporting a study of parapsychologists was titled “The Construction of the Paranormal: Nothing Unscientific Is Happening.”

These extreme claims have elicited much controversy. Representative criticisms by sociologists can be found in Gieryn (1982) and Amsterdamska (1990). Some natural scientists have argued that constructivism, along with several other “postmodern” schools of thought in the social sciences and humanities, represents a dangerous form of antisocialism; see Gieryn (1998) for a discussion of these “science wars.” Nevertheless, persuasive evidence has been produced about the importance of social factors in changing scientific knowledge. Stewart (1990) studied the recent revolution most widely known to the general public: plate tectonics in the 1950s and 1960s. He found strong resistance to the revolution. Earth scientists who had invested heavily in earlier perspectives were most likely to resist plate tectonics. Usually conversion to the new paradigm was gradual, sealed when scientists saw the relevance of the paradigm for their own research, but Stewart found some whose acceptance of plate tectonics came as the kind of “gestalt switch” described by Kuhn (1970).

In the conflicts accompanying the revolution, scientists on both sides deviated from conventional norms and used coercive methods to advance their positions and resist their opponents. Such intense conflict does not always accompany revolutions; in the one in physics that produced quarks, there was little acrimony or duress (Pickering 1984). In the earth sciences and physics, interests internal to the scientific disciplines affected the reception of theories. External interests also can have significant effects. Desmond (1989) shows how the interests of social classes interacted with religion in affecting the reception of Lamarckian ideas about evolution in England in the 1840s; the participants in the disputes were aware of the ideological implications of biological theories. Feminist sociologists of science have shown how gender interests have influenced perceptions of nature and the formulation of biological theories. See Keller (1995) for a review of some examples.

APPLIED RESEARCH AND DEVELOPMENT

The preceding discussion has concerned mostly basic research oriented primarily toward the advancement of knowledge. However, most research is done to advance other goals: corporate profits, weaponry, health, and human welfare. Of the 2 to 4 percent of their gross national products that advanced industrial countries devote to research and development (R&D), less than 10 percent is devoted to basic research (U.S. National Science Board 1996). Of the remainder, much is devoted to defense, particularly in the United States, where a substantial majority of federal R&D expenditures are devoted to that use.

Independent inventors are still an important source of innovations, but most applied scientists and engineers are salaried employees of corporations and mission-oriented government agencies. Such employees lack most of the autonomy of basic scientists. University-trained scientists are likely to chafe under this loss of autonomy, but successful applied research organizations have developed procedures for harmonizing their scientists' desires for autonomy with an organization's desire for useful knowledge (Kornhauser 1962). Engineers are important in translating knowledge into products and processes. Engineers are more pragmatic than scientists and are committed less

to paradigms and more to physical objects (when a scientist moves, he or she is likely to pack his or her journals first; when an engineer moves, she or he packs her or his catalogues). While scientists tend to seek autonomy in organizations, engineers tend to seek power; it is usually necessary to control organizational resources to do successful engineering work.

One of the conflicts that can occur between scientists and their industrial employers concerns communications. Scientists want to communicate their discoveries to their colleagues to gain recognition; their employers want to profit from the discoveries, and that may require keeping them secret. The patent system can provide an accommodative mechanism: Discoveries are made public, but those who wish to use the discoveries for practical purposes must pay royalties to the patent holder. The patent system represents one aspect of the commodification of knowledge. Marxist theories imply that in capitalist social formations, goods and services are produced for sale as commodities, not for use, and this is increasingly the case for scientific knowledge. Kloppenburg (1988) has applied Marxist thought effectively in his history of plant breeding. There were and are inherent problems in making seeds into a commodity, since seeds tend to reproduce themselves; they can be both objects of consumption and part of the means of production. Until recently, seeds seldom were produced as commodities; new varieties were exchanged among farmers or distributed to them by government agencies at little cost, and the farmers would then grow their own seeds. This changed first with the development of hybrid corn, where farmers could not use the corn they produced as seed and instead bought new seed from the seed companies each season. This process has since been extended to other crops. In addition, consistent with Marxist thought, the seed industry has become increasingly centralized and concentrated, with fewer and larger firms dominating it. Those firms also expand into world markets, acquiring germ plasm in third world countries and selling seeds as commodities in those countries. The development of biotechnology has increasingly taken this form. Rapid developments in this area blur the distinction between basic and applied research. The emerging pattern seems to be one in which research that cannot be used to generate a profit is done in universities and gov-

ernmental agencies, usually at public expense, while research that can be used for profit is done in corporations.

Modern science has led to massive changes in the lives of people in all countries, and it has the potential for further changes. For example, it has made major contributions to economic growth (Mansfield 1991). However, not all these changes have been beneficial, and not all beneficial changes are allocated equitably. While polls show high support for science in general, there are intense public controversies in many areas, from the use of animals in biomedical research, to global warming, to military technologies (Nelkin 1995). Sometimes research and development efforts can achieve considerable autonomy. MacKenzie (1993) shows how those who developed the inertial navigation system for submarine-launched missiles successfully “black-boxed” their efforts so that political officials would not interfere. The navigation technology could have had seriously destabilizing effects in the cold war, without any deliberation by elected officials. The autonomy of engineers sometimes achieve does not imply autonomy for scientists. Thus, while oceanographers have made major discoveries in the past forty years, their expensive research has been driven largely by the interests of the U.S. Navy and their autonomy has been constrained by its interests (Mukerji 1990). Attempts have been made to develop more democratic means for developing science policy. Collingridge (1980) argues for an approach of “disjointed incrementalism”: Since problems are rarely foreseen, policy making should be fragmented rather than centralized and will often be remedial; since it is not feasible to investigate all solutions, analysis and evaluation should be serial and incremental. Democratic governments have developed organizations to mediate between science and governmental institutions. These organizations can be nongovernmental, such as the National Academy of Sciences–National Research Council; part of the legislative branch, such as the Office of Technology Assessment of the U.S. Congress; or part of the executive branch, such as the Environmental Protection Agency. (For a description of these efforts in the United States and the difficulties they face, see Bimber and Guston 1995; Cozzens and Woodhouse 1995.) The growth and rapid change of science-based technologies present difficult problems in regard to support and

control. Knowledge about the organization of science and its relationships with other institutions can help in dealing with those problems.

SCIENTIFIC EXPLANATION

Science and scientific knowledge achieved high status in twentieth-century Western societies, yet there continues to be disagreement among scientists and those who study science (historians, philosophers, and sociologists of science) about the meaning of scientific explanation. Indeed, the use of the word "explanation" has been the subject of heated debate (Keat and Urry 1982).

One way to make sense of science is to "reconstruct" the logic scientists use to produce scientific knowledge. The reconstructed logic of science differs from what scientists actually do when they engage in research. The research process is seldom as clear, logical, and straightforward as the reconstructed logic presented in this article makes it appear. For a long time, the most popular reconstruction of the logic of the scientific process was the "hypothetico-deductive" model. In this model, "the scientist, by a combination of careful observation, shrewd guesses, and scientific intuition arrives at a set of postulates governing the phenomena in which he is interested; from these he deduces observable consequences; he then tests these consequences by experiment, and so confirms or disconfirms the postulates, replacing them, where necessary, by others, and so continuing" (Kaplan 1964, pp. 9-10; see also Braithwaite 1968; Nagel 1961). The description of scientific explanation presented here is broadly consistent with this model as it is used in the social sciences.

Scientific explanations can be contrasted to other, nonscientific types of explanation (Babbie 1989; Kerlinger 1973; Cohen and Nagel 1934). Some explanations obtain their validity because they are offered by someone in authority, for example, a police officer, the president, or parents. Validity also may rest on tradition. For instance, the correct way to do a folk dance is the way it has always been danced, handed down over the generations. This knowledge is not obtained by going through textbooks or conducting experiments but is stored in the memories and beliefs of

individuals. Another way of knowing is a priori, or intuitive, knowledge. This knowledge is based on things that "stand to reason," or seem to be obvious, but are not necessarily based on experience. People tend to cling strongly to intuitive knowledge even if the "facts" do not match their experience. Situations that contrast with strongly held beliefs are explained away as unique occurrences that will not happen again. For example, it "stands to reason" that if you are nice to other people, they will be nice to you.

The scientific method is a way of obtaining information, or knowledge, about the world. Theoretically, the same knowledge will be obtained by everybody who asks the same questions and uses the same investigative method. Scientific explanation uses theories, deductive and inductive logic, and empirical observation to determine what is true and what is false. Unlike authoritarian, traditional, or intuitive explanations, scientific knowledge is always supposed to be open to challenge and continual correction.

A theory is a hypothetical explanation for an observation or a question such as Why is the sky blue? or Why do victims of child abuse often grow up to be perpetrators? Scientists develop and test theories by using deductive logic, trying to show that empirical observations are instances of more general laws. Scientific theories are hypothetical explanations that state the possible relationships among scientific concepts. Theories consist of "a set of interrelated constructs (concepts), definitions, and propositions that present a systematic view of phenomena by specifying relations among variables, with the purpose of explaining and predicting the phenomena" (Kerlinger 1973, p. 9). Theories also are used by scientists to interpret, criticize, and bring together established laws, often modifying them to fit unanticipated data. They also guide the enterprise of making new and more powerful generalizations (Kaplan 1964, p. 295).

Scientific theories generally take the form of "If X happens, then Y will happen." For instance, Karl Marx's theory of surplus value suggests that as the level of surplus value in a capitalist society increases, so will inequality. This is an attempt to determine causal relations, so that theories not only predict what will happen in the world but also explain why it happens.

In general, scientific explanations are derived using nomothetic methods, which have the goal of making generalizations or of establishing universal laws. The experiment is perhaps the best known nomothetic method. Scientific theories try to generalize, or predict, beyond the specific data that support them to other similar situations. In contrast, some forms of the social sciences and humanities use idiographic methods, which are designed to provide knowledge of one particular event which may be unique. The best known idiographic method may be the case study. For example, both social scientists and historians investigate wars. A social scientist tries to explain what is common to all wars, possibly so that she or he can develop a general theory of intersocietal conflict. In contrast, a historian studies individual wars and tries to chronicle and explain the events and conditions that cause a specific war, and is generally not interested in a scientific theory of what may be common to all wars.

It seems that there is a paradox here: Scientific explanations are the best explanations that can be offered for an event, yet scientific theories are always open to correction by a better explanation or theory. What counts as a “better” explanation or theory has been the subject of debate in the philosophy of science. Some people believe that the better theories are those which can explain anomalies that previous theories could not. In other words, the new, “better” theory can explain everything the old theory could but also can explain some things that it left unexplained. There are many debates among philosophers of science about how to judge the “goodness” of a theory. They all admit that theories can never be confirmed definitively by any amount of observational material. The possibility always exists of finding an event that does not fit the theory, thus falsifying it. However, some theories have so much observational evidence on their side that they are said to be well confirmed, and the possibility of finding observations that falsify them is considered negligible.

However, the philosopher of science Popper said that while one can never absolutely *confirm* theories, one can definitively *falsify* them (1959). In other words, it is possible to find definite events that disconfirm, or falsify, a theory. However, other philosophers argue that this is not necessarily true, because it is always an open question whether it is the theory that is wrong or one of the

assumptions that is not tested when the theory is tested.

A famous example of this problem of falsification is provided by the philosopher of science Carl Hempel in his historical examination of the work of the Hungarian physician Semmelweiss (1966). Semmelweiss was concerned with the high rates of maternal mortality during childbirth. He theorized that those deaths resulted from blood poisoning, which was caused by infectious matter carried on the physician’s hands. Physicians were examining women right after performing dissections in the autopsy room. Semmelweiss’s hypothesis led him to believe that if the infectious matter was removed before the women were examined, the death rates would drop. To test this, he had doctors wash their hands in a solution of chlorinated lime *after* performing dissections and then examine women who had just given birth. As he predicted, the mortality rates fell as this procedure was practiced, providing evidence *confirming* his theory.

However, if the mortality rates had *not* fallen, that would not necessarily have meant that the theory was wrong. It could have meant that one of the unexamined assumptions, such as that chlorinated lime destroys infectious matter, was wrong. Thus, the theory would have been true but the experiment would not have provided evidence to confirm it because one of its untested assumptions was incorrect. Thus, falsification is a double-edged sword: When a theory is not confirmed, it is necessary to determine whether it is the thing that is being manipulated experimentally (the hand washing in chlorinated lime) that is the causal factor or whether one of the assumptions underlying the experiment is faulty (if it turned out that chlorinated lime did not kill infectious matter) (Hempel 1966, pp. 3–6). Scientists have to be careful not to give up on a theory too soon, even if early results appear to falsify it, because many major scientific achievements would not have occurred if they had been quickly abandoned (Swinburne 1964).

Whether philosophers of science hold to the confirmationist view or the falsificationist view of testing scientific theories, they agree on two things. The first is that scientific theories are universal statements about regular, contingent relationships in nature; the second is that the observations used to evaluate scientific theories provide an objective

foundation for science (Keat and Urry, 1982, p. 16). One of the goals of science is to develop and test theories, although some scientists believe that science proceeds inductively, purely by amassing facts and building theories from the amassed data.

Scientific laws fall broadly into two types: deterministic laws and stochastic (probabilistic) laws. For deterministic laws, if the scientist knows the initial conditions and the forces acting on a system and those factors do not change, the state of the system can be determined for all times and places. Deterministic laws are the ideal of the Newtonian, or mechanistic, model of science. In this model, it is assumed that causes precede effects and that changes come only from the immediately preceding or present state, never from future states. It is assumed that if two systems are identical and are subject to the same initial conditions and forces, they will reach the same end point in the same way. Deterministic laws assume that it is possible to make a complete separation between the system and the environment and that the properties of the system arise from its smallest parts. The smallest parts of a system are those about which nothing can be determined except their location and direction. There is nothing in the parts themselves that influences the system, and all changes in the state of the system come from the forces acting on it. Deterministic laws are based on the assumption that the universe is regular and that connections between events are independent of time and space. The idea with a scientific explanation is that all other things being equal (*ceteris paribus*), identical circumstances lead to identical results.

Stochastic laws are expressed in terms of probability. For large or complex systems, it is not possible to identify precisely what state the system will be in at any given time but only to assess the probability of its being in a certain state. Quantum physics, chemistry, card games, and lotteries utilize stochastic laws. Those laws are stated in terms of probability over time and apply to classes of events rather than to specific instances. Most relationships in the social sciences are stated in stochastic terms because individual behavior is very difficult to predict. The use of probability does not mean that events are viewed as random, or uncaused, simply that the behavior of the individual elements of a system cannot be predicted with perfect accuracy.

Scientific theories are systematically linked to existing knowledge that is derived from other generally accepted theories. Each scientist builds on the work of other scientists, using tested theories to develop new theories. The scientific method is dedicated to changing theories, and scientific knowledge progresses through the challenge and revision of theories.

Often a new theory is preferred not because it is based on facts (data) that are different from those on which the old theory was based but because it provides a more comprehensive explanation of existing data. For example, Newton's theory of the solar system superseded Kepler's explanation of planetary motion because Newton's theory included the theory of gravity (which predicted a gravitational attraction between all physical bodies in the universe) as well as the laws of motion. The two theories together provided many circumstances that could "test" the theory because they *predicted* not only where planets should be in relation to each other at given times but also phenomena such as falling apples and swinging pendulums. Newton's theory was more comprehensive and more economical, and although it provided more opportunities for falsification than did Kepler's (which made it more vulnerable), it also resisted falsification better and became the accepted scientific explanation (Chalmers 1982).

The premises, or propositions, in a scientific theory must lead logically to the conclusions. Scientific explanations show that the facts, or data, can be deduced from the general theory. Theories are tested by comparing what deduction says "should" hold if the theory is true with the state of affairs in the world (observations). The purpose of a theory is to describe, explain, and predict observations.

The classic example of deductive logic is the familiar syllogism "All men are mortal; Socrates is a man; therefore, Socrates is mortal." Deductive conclusions include only the information included in the propositions. Thus, deductive reasoning can be logically correct but empirically incorrect. If a theory is based on empirically false premises, it probably will result in empirically false conclusions. A scientific test of the truth of the conclusions requires a comparison of the statements in the conclusion with actual states of affairs in the "real" world.

Scientific explanations and theories are usually quite complex and thus often require more information than can be included in a deductively valid argument. Sometimes it is necessary to know that a conclusion is probably true, or at least justified, even if it does not follow logically from a set of premises and arguments (Giere 1984). Thus, there is a need for inductive logic, which is based on particular instances (facts or observations) and moves to general theories (laws).

Many sociologists and other scientists believe that scientific knowledge is produced mainly by induction (Glaser and Strauss 1967). For example, after one has observed many politicians, a theory might postulate that most politicians are crooked. Although this theory is based on many observations, its proof, or verification, would require observing every politician past, present, and future. Falsifying the theory would require finding a substantial number of politicians who were not crooked. The absolute and final verification of scientific theories is not possible. However, it should be possible to “falsify” any scientific theory by finding events or classes of events that do not support it (Stinchcombe 1987; Popper 1959).

Because inductive arguments are always subject to falsification, they are stated in terms of probabilities. Good inductive arguments have a high probability associated with their being true. This high probability comes from a large number of similar observations over time and in different circumstances. For example, although it is not absolutely certain that if someone in North America becomes a medical doctor, he or she will earn a high income, the evidence provided by observing doctors in many places and many times shows that a high probability can be assigned to the assertion that medical doctors earn high incomes.

Inductive arguments are not truth-preserving. Even with true premises, an inductive argument can have a false conclusion because the conclusions of inductive arguments generally contain more information or make wider generalizations than do the premises (Giere 1984). Science requires both deductive and inductive methods to progress. This progress is circular: Theories are developed and tested, and new data give rise to new theories, which then are tested (Wallace 1971).

Several steps are involved in testing scientific theories. Theories first must be expressed in both

abstract, verbal terms and concrete, operationalized terms. Concepts and constructs are rich, complex, abstract descriptions of the entity to be measured or studied. Concepts have nominal definitions (they are defined by using other words) and are specifically developed for scientific purposes. A variable is operationally defined to allow the measurement of one specific aspect of a concept. Operationalization is a set of instructions for how a researcher is going to measure the concepts and test the theory. These instructions should allow events and individuals to be classified unambiguously and should be precise enough that the same results will be achieved by anyone who uses them (Blalock 1979).

For example, one theory posits that the relationship between “anxiety” and test performance is curvilinear. This theory predicts that very little anxiety leads to poor performance on tests (as measured by grades), a medium amount of anxiety improves test performance, and very high anxiety causes poor test performance. If it were drawn on a graph, this curve would be an upside-down U. To test the theory, both anxiety and test performance must be measured as variables expressed in empirical terms. For an observation to be empirical means that it is, or hypothetically could be, experienced or observed in a way that can be measured in the same manner by others in the same circumstances.

As a concept, anxiety encompasses many different things. The measurement theory must specify whether anxiety will be measured as feelings, such as being tense, worried, or “uptight,” or as physical reactions, such as shortness of breath, heart palpitations, or sweaty palms. The researcher may decide to measure anxiety by asking subjects how worried or tense they felt before an examination. Racing hearts, sweating palms, and upset stomachs are part of the concept, but they are excluded from the operationalization. The researcher must decide whether this is or is not a valid (measures what it purports to measure) and reliable (obtains the same results on repeated tests) measure of anxiety, in part by comparing the results of the research to other research on anxiety and test performance. It is also necessary to strike a balance between the scope of the concept (the different things it refers to) and precision. The wider the scope of a concept, the more it can be generalized to other conditions and the fewer

conditions are required to construct a theory, making it more parsimonious. However, if the scope of a concept is too wide, the concept loses precision and becomes meaningless.

Scientific explanation involves the accurate and precise measurement of phenomena. Measurement is the assignment of symbols, usually numbers, to the properties of objects or events (Stevens 1951). The need for precise measurement has led to an emphasis on quantification. Some sociologists feel that some qualities and events that people experience defy quantification, arguing that numbers can never express the meaning that people's behavior holds for them. However, mathematics is only a language, based on deductive logic, that expresses relationships symbolically. Assigning numbers to human experiences forces a researcher to be precise even when the concepts, such as "anxiety" and "job satisfaction," are fuzzy.

Another important aspect of scientific explanations is that they attempt to be "objective." In science this term has two broad meanings. First, it means that observers agree about what they have observed. For example, a group of scientists observing the behavior of objects when they are dropped would agree that they saw the objects "fall" to the ground. For this observation to be objective, (1) there must be an agreed-on method for producing it (dropping an object), (2) it must be replicable (more than one object is released, and they all "fall"), and (3) the same results must occur regardless of who performs the operation and where it is performed (objects must behave the same way for all observers anywhere in the world). Scientific operations must be expressed clearly enough that other people can repeat the procedures. Only when all these conditions are met is it possible to say that an observation is objective. This form of objectivity is called "intersubjectivity" and it is crucial to scientific explanations.

The second use of the word "objective" in science means that scientific explanations are not based on the values, opinions, attitudes, or beliefs of the researcher. In other words, scientific explanations are "value-free." A researcher's values and interests may influence what kinds of things she or he chooses to study (i.e., why one person becomes a nuclear physicist and another becomes a sociologist), but once the problem for study is chosen the

scientist's personal values and opinions do not influence the type of knowledge produced. The value-free nature of science is the goal of freeing scientific explanations from the influence of any individual or group's biases and opinions.

The relationships in a theory state how abstract constructs are to be linked so that antecedent properties or conditions can be used to explain consequent ones. An antecedent condition may be seen as either necessary or sufficient to cause or produce a consequent condition. For example, higher social status may be seen as *sufficient* to increase the probability that farmers will adopt new farming techniques (innovation). It also could be argued that awareness and resources are necessary conditions for innovation. Without both, innovation is unlikely (Gartrell and Gartrell 1979).

Relationships may be asymmetrical (the antecedent produces the effect) or symmetrical (both cause each other): Frustration may cause aggression, and aggression may cause frustration. Relationships may be direct, or positive (an increase in knowledge causes an increase in innovation), or negative (an increase in stress leads to a decrease in psychological well-being). They may be described as monotonic, linear, or curvilinear. Sociologists often assume that relationships are linear, partly because this is the simplest form of a relationship.

Relationships between variables are expressed by using a wide variety of mathematical theories, each of which has its own "language." Algebra and calculus use the concepts of "greater than," "less than," and "equal to." Set theory talks about things being "included in," and graph theory uses "connectedness" or "adjacency between." Markov chains attempt to identify a connectedness in time or a transition between states, and symbolic logic uses the terms "union" and "intersection" to talk about relationships.

Scientific explanation is also very explicit about the units to which relationships between propositions refer. Sociologists refer to a host of collectivities (cultures, social systems, organizations, communities), relationships (world systems, families), and parts of collectivities (social positions, roles). There is strength in this diversity of subject matter but also potential weakness in failing explicitly to define the unit of analysis. Some properties cannot be attributed to all units of analysis. For example, "income" is a concept that can apply to an individ-

ual or a group (e.g., “average” income), but “inequality” is always a property of an aggregate. The “ecological fallacy” (Hannan 1970) involves the incorrect attribution of properties of aggregates to individuals. Aggregation is not a matter of simple addition, and some relationships between subunits (homogeneity, complexity, inequality) have complicated aggregation algorithms. Care must be taken in switching units of reference from social collectivities to individuals. For example, communities with high divorce rates also may have high homicide rates, but this does not necessarily imply that divorced people kill one another or are more likely to be homicide victims or perpetrators.

To test theories, the relationships among concepts are stated as hypotheses, linking variables in an operationalized form. Since the existence of a relationship cannot be proved conclusively, a scientist instead tries to show that there is no relationship between the variables by testing hypotheses that are stated in the “null” form. In the test performance and anxiety example, a null hypothesis would state, “There is no curvilinear relationship between the number of correct responses on tests and the reported level of worry and tension.” If this hypothesis was rejected, that is, found to be highly unlikely, the researcher would have evidence to support the alternative hypothesis suggested by the theory: There is a curvilinear relationship between the variables.

Social scientists use a variety of methods to study human behavior, including experiments, surveys, participant observation, and unobtrusive measures. In essence, experiments try to identify causal sequences by determining the effect of an independent variable (the stimulus) on a dependent variable. Experiments require stringent conditions that often are difficult to fulfill with human beings, sometimes for ethical reasons but more often because there is a wide variation in individual responses to the same stimulus (Babbie 1989; Kerlinger 1973; Cook and Campbell 1979).

Social scientists have developed other research methods, such as surveys and field research, which allow them to produce scientific knowledge without resorting to experimental manipulation. Statistical analysis of survey data allows social scientists to examine complex problems in large populations by statistically controlling several variables that represent competing explanations (Blalock

1964). The distinctive characteristic of survey research is that the subjects of the study tell the scientist about themselves.

Social scientists also use qualitative methods such as participant observation to conduct research in the “field” where phenomena actually occur. Field research focuses on the empirical richness and complexity of the whole subject in order to understand what is subjectively meaningful. Participant observation proceeds inductively rather than deductively. The researcher observes and participates in order to understand (subjectively) and then attempts to externalize the observations by constructing categories of responses, or theory. In contrast to other research designs, participant observation deliberately does not attempt to control conditions; the researcher strives to obtain an unbiased picture of how the subjects see things in their natural setting (Whyte 1961). The emphasis is on the richness of subjects’ understanding of events and on subjectivity rather than on objectivity. Theory developed from this type of research is called grounded theory (Glaser and Strauss 1967). Unobtrusive methods such as content analysis focus on the study of artifacts (newspapers, homes), partly to overcome reactivity by subjects and biases on the part of the researcher.

CRITIQUES OF THE HYPOTHETICO- DEDUCTIVE MODEL OF SCIENCE

In the 1930s and 1940s, the dominant view of science was “radical positivism,” which viewed science as a process based only on inductive generalizations and empirical verification. Abstract theoretical concepts that could not be observed were considered literally meaningless. The revision of positivism in the 1950s (logical empiricism) recognized the importance of abstract concepts and theories but continued to insist that all scientific statements be subject to empirical falsification. In short, the empiricists persisted in their belief that “facts” were purely objective entities and that what was viewed as a fact did not depend on theory or theoretical concepts. However, theories play as large a role in scientific change and knowledge production as do empirical observations. In part, this internal confusion laid the groundwork for a wide range of critiques of both positivism and empiricism (Alexander 1982; Bernstein 1976).

Reconstructed logic suggests that scientific knowledge can be accounted for by following formal rules of logic. The progress of knowledge is such that unscientific or prescientific explanations for phenomena are replaced successively by scientific explanations, which are ever closer approximations to the “truth.” It stresses that the knowledge produced by the scientific method is objective and value-free, corresponding to states of the world as it really is, not as it is seen by a particular group of people in a particular social and historical location.

However, the “facts” on which scientific explanations are based are not independent of “point of view” (Polanyi 1958; Hanson 1972). All scientific data are theoretically informed. What is “fact” and what is “theory” are what is convenient to the focus of scientific attention at a particular time. Because science is a social and cultural activity, it is grounded in an everyday, taken-for-granted reality. Scientists can perceive “facts” only in a particular social and cultural context. Observations take place in a cultural milieu that literally affects what the observer perceives, not just how it is interpreted. The totally objective, theory-free observation aspired to in science is not possible; to “see” something is always to see it “as” something. For example, to observe the medical “facts” in an x-ray, a physician must first learn what parts of the picture to ignore. The “fact” that objects “fall” to the ground is a fact only in a social context in which gravity is an accepted explanation for the behavior of falling objects. Scientific facts are constructed and developed through situated human labor; they do not have an independent, objective existence of their own (Fleck 1979).

Most twentieth-century philosophers of science have assumed that there is something called the scientific method that applies equally to all sciences and that sciences can be judged by their ability to adhere to that method. This is called the “unity of the sciences” model. However, the philosophy of science has ignored the actual behavior of scientists, concentrating instead on reconstructing the logic of science. The result has been an idealized and unrealistic picture of how scientific knowledge is produced. When the actual practice of scientists is observed, it is apparent that in different sciences, scientists reason in a wide variety of modes.

These different modes of reasoning were hidden by the philosophical approach of viewing scientific knowledge as resulting from the simple application of scientific logic to problems. Scientific knowledge is better seen as the outcome of an active, work-oriented process than as an uninvolved description of a “passive” natural world. This means that scientific knowledge production consists largely in activities in which scientists make decisions about how to proceed in different circumstances. This does *not* imply that scientific knowledge is “made up” and thus completely relative but instead, by looking at scientific practice rather than only scientific logic, that the view of science has shifted from science as a “representation” of nature to science as “action” or “work” (Knorr Cetina 1981).

The most definitive research into how the various sciences produce knowledge differently is represented by the work of the sociologist of science Knorr Cetina (1999). Knorr Cetina has examined the practical activity and “cultures of knowing” of two very different sciences: molecular biology and high-energy physics. She has focused on the “concrete, mundane, everyday practices of inquiring and concluding through which participants establish, for themselves and for others, knowledge claims” (1991, p. 108). Her research shows that what counts as “scientific method” differs radically between these two sciences. In other words, the cultural structure of scientific methodology varies from science to science (1991, p. 107).

Knorr Cetina demonstrates that the epistemic culture in a molecular biology laboratory is such that molecular biologists have to become “repositories of unconscious experience” and individual scientists have to develop an embodied sense of a reasonable response to different situations (1992, p. 119). A practicing molecular biologist literally *becomes* a measurement instrument. These scientists become highly skilled at seeing things others cannot see, and their bodies learn to perform delicate operations in loading gels and manipulating DNA that cannot be taught, only learned through experience. In their scientific work, individual molecular biologists often have to *guess* what procedure is best in a given situation. For this reason, the sense of what counts as a successful procedure depends heavily on an individual’s experience and the predictive ability “which indi-

viduals must somehow synthesize from features of their previous experience, and which remains implicit, embodied, and encapsulated within the person" (1992, p. 121). What counts as a successful procedure or as proper scientific method is implicit: It is a blend of the individual's experience and the culture in the laboratory. Knorr Cetina calls this kind of reasoning "biographical" because "it is sustained by a scientist's biographical archive and the store of his or her professional experience" (1991, p. 115).

In contrast to the highly individual and personalized culture of knowing in a molecular biology laboratory, high-energy physics laboratories are very different kinds of epistemic spaces. Their organization is best compared to that of a superorganism, such as highly organized colonies of bees, ants, or termites. High-energy physics involves more circularities and contingencies than does molecular biology; its experiments are long term and "supra-individual."

In high-energy physics (HEP) experiments, the work of producing knowledge is detached from the individual scientist and shifted to the group. These experiments can involve from 200 to 2,000 individuals from 200 different institutions around the world, all focused on a common goal, for up to twenty years (Knorr Cetina 1999, p. 160). Authorship belongs to the experiment as a whole; individual scientists feel that they are representatives of the whole, and there is a sense of collective responsibility among them. (Knorr Cetina 1995). Unlike the highly trained body and eyes of a molecular biologist, data interpretation in HEP is done not by individual scientists but by computers. In fact, individual scientists literally cannot run experiments. HEP experiments are huge, they take many years to run, and each experiment seeds new generations of experiments. High-energy physicists do not think in terms of individual achievements in months but of group successes over years and decades.

In HEP, forming a consensus about what counts as adequate scientific knowledge and the proper application of scientific method is very much a group process. In molecular biology, the group is involved in terms of the culture of the laboratory but each individual scientist is a highly skilled measuring instrument that makes most procedural decisions on his or her own. Thus, by examining

the organization of the laboratories and the working practices of the scientists in these two domains, Knorr Cetina has challenged the philosophical assumption of a unitary scientific method.

Science is now widely regarded as a social activity rather than an application of logic to nature. It is seen as an interplay between practical activity, empirical observations, and broad theoretical "paradigms" (Kuhn 1970; Fleck 1979). Paradigms dictate the valid questions for research as well as the range of possible answers and can be so powerful that contradictory data (anomalies) are explained away under the assumption that they can be brought into the theory at a later time. Confronted by contradictory empirical evidence that cannot be ignored, the adherents of a theory often develop ad hoc hypotheses and residual categories to account for anomalies. Thus, they encompass or explain observations that contradict their theories and often cling to those theories in dogmatic fashion. The reconstructed logic of science leads one to believe that theories would be rejected under those conditions.

However, sociological research has shown that "the data" do not and cannot speak for themselves and decide between competing scientific theories. Sometimes a theory wins out over its competitors because its survival is in the best interests of a group or researcher (Woolgar 1981; Shapin 1979). For example, when high-energy particle physicists were searching for the subatomic particles now known as quarks, two competing explanations were advanced: the "charm" and "color" theories. Both models were consistent with the data. The ultimate success of the charm model occurred because more people had an interest in seeing it succeed. Charm theorists were more successful in relating their theory to an existing body of practice and interests. The color theory was never empirically refuted but eventually "died" because its proponents were reduced to talking to themselves (Pickering 1982).

Part of the problem is that the decision about whether certain experiments or observations are critical to the proof or falsification of a theory is possible only after the fact, not before, and the possibility always exists that an experiment failed because it was not performed competently. It is difficult to establish the criteria for determining whether an experiment has been successful. To

know whether the experimental apparatus, the theory, and the competence of the researcher have combined to produce a successful experiment, it is necessary to know beforehand what the correct outcome is. However, the definition of a competently performed experiment is having a successful outcome, leading to the “experimenter’s regress” (Collins 1985).

The replication of results is an essential criterion for the stability of scientific knowledge, but scientific inquiry requires a high degree of tacit or personal knowledge (Polanyi 1958). This knowledge is by nature invisible, but its importance is strongly denied by a scientific community that bases its claims to validity on the potential for replication. Scientific developments often cannot be replicated unless there is direct, personal contact between the original researcher and the people attempting to do the replication. Few replications are possible using published results and procedures, and successful replication often rests on the original researcher’s tacit knowledge, which is not easily transferable (Collins 1985). To complicate matters, science reserves its highest rewards for original research rather than replication. As a consequence, there is little glory and less funding for replication, and the “replicability” requirement is reduced to demonstrating the possibility of replication.

Feminists have added their voice to critiques of science and the scientific method. The most successful feminist critiques of science are those identified as “feminist empiricist,” which attempt to restructure “bad science” and provide a more objective, gender-free knowledge (Harding 1986). Feminists have pointed out some androcentric (male-centered) categories in science and have identified the patriarchal social organization of “science as an institution.” Haraway has argued that there is no purely “objective” stance that can be taken; knowledge is always a “view” from somewhere (Haraway 1988). The concept of power based on gender has become a permanent category of analysis in feminist approaches (Smith 1987; Connel 1983).

By differentiating between “good science” and “bad science,” feminist empiricists strive to separate the wheat from the chaff by eradicating gender biases in the scientific process. The ultimate goal is to provide more objective, value-free knowl-

edge (Harding 1987). At the very least, feminist approaches often attempt to show the hidden biases in many scientific theories. The argument is that some types of knowledge are true only for certain social groups and do not reflect the experience of women, homosexuals, and many ethnic and racial groups, or other groups on the margins of society (Haraway 1988).

This perspective has had some success in the social sciences, perhaps because its revisions provide results that are intuitively appealing. By including categories that often are ignored, oppressed, and invisible to traditional sociology, feminist research gives a voice to what were previously “non-questions” under the mainstream, or as feminists call it, the male-stream model of science (Vickers 1982). For example, feminist research suggests that many women do not make a yes-or-no decision about having children but instead leave it to luck or time to decide. This type of decision-making behavior has implications for fertility and deserves the same theoretical status as the yes and no categories. However, a male-stream model of science that assumed that fertility decisions were the outcome of a series of rational cost-benefit analyses was blind to this conceptualization (Currie 1988).

It is ironic that while feminist empiricist criticisms of “bad” science aspire to strengthen science, they ultimately subvert the understandings of science they attempt to reinforce: “If the concepts of nature, of dispassionate, value free, objective inquiry, and of transcendental knowledge are androcentric, white, bourgeois, and Western, then no amount of more rigorous adherence to scientific method will eliminate such bias, for the methods themselves reproduce the perspectives generated by these hierarchies and thus distort our understandings” (Harding 1987, p. 291).

Another critique of science comes from the hermeneutic, or interpretive, perspective, which takes issue with the positivist assumption that the concepts, categories, and methods used to describe the physical world are applicable to human behavior. Human studies proponents insist that the universal categories and objective arguments required for prediction and explanation in the natural sciences cannot be achieved in the social sciences. The proper subject matter of the social sciences is the internal, or subjective, meanings of

human behavior that guide human action. Because these meanings are nonempirical and subjective rather than objective, they cannot meet the requirements for scientific explanation. Therefore, the goal of the social sciences is to understand rather than predict and explain human behavior (Hughes 1961; Habermas 1971; Gadamer 1976). Validation of interpretations is one of the biggest problems with the hermeneutic position because no firm ground exists from which to judge the validity of different interpretations of meaning and behavior. Hermeneutic explanations are ultimately subjective and in their extreme form focus solely on the explanation of individual, unique events (Alexander 1982).

The value-free nature of scientific knowledge also has been challenged by critical theory, which suggests that scientific knowledge is knowledge that is one-sided and specifically oriented to the domination and control of nature. This “interest” in domination and control does not lie in the application of scientific knowledge but is intrinsic to the knowledge itself. In contrast, communicative knowledge is knowledge that is oriented to reaching understanding and achieving human emancipation (Habermas 1984).

CONCLUSION

Although scientific explanation has been the subject of many critiques, it is still the most methodical, reliable form of knowledge. It is ironic that while the natural sciences are becoming less positivistic and are beginning to recognize nonempirical, subjective, and cultural influences on scientific knowledge, the social sciences continue to emphasize the refinement of methodology and measurement in an attempt to become more positivistic (Alexander 1982). The result is that in sociology, theoretical inquiry is increasingly divorced from empirical research. Paradoxically, this schism may be a source of strength if the two sides can learn to communicate. Sociology may be in a unique position to integrate critiques of the scientific model with ongoing empirical research, perhaps producing a hybrid that is neither relativistic nor positivistic.

SECONDARY DATA ANALYSIS AND DATA ARCHIVES

The creation and growth of publicly accessible data archives (or data banks) have revolutionized

the way sociologists conduct research. These resources have made possible a variety of secondary analyses, often utilizing the data in ways never anticipated by their creators. Traditionally, secondary data analysis involves the use of an available data resource by researchers to study a problem different from the one treated in the original analysis. For example, a researcher might have conducted a survey of workers' reactions to technological change and analyzed those data to evaluate whether the workers welcomed or resisted such change in the workplace. As a matter of secondary interest, the researcher collects data on workers' perceptions of the internal labor-market structures of their firms. She then lends those data to a colleague who studies the determinants of (workers' perceptions of) job-ladder length and complexity in order to understand workers' views on prospects for upward mobility in their places of employment. The latter investigation is a secondary analysis.

More recently, however, the definition of a secondary analysis has expanded as more data sets have been explicitly constructed with multiple purposes and multiple users in mind. The creators, or principal investigators, exercise control over the content of a data set but are responsive to a variety of constituencies that are likely to use that resource. The creators may undertake analyses of the data, addressing questions of intellectual interest to themselves while simultaneously releasing the data to the public or depositing the data resource in an archive. Data archives are depositories where data produced by a number of investigators are available for secondary analyses. The data bank generally takes responsibility for providing documentation on the data sets and other information needed for their use. The term also refers more generally to any source of data already produced that an investigator may uncover in the course of an investigation, such as government or business records housed in libraries. For example, the U.S. government archives thousands of government documents yearly in libraries around the world. The data in those documents cover a wide variety of topics and are often useful in sociological investigations. It remains the responsibility of the analyst to configure the data in a way that is useful to his or her investigation. This entry illustrates these expanded opportunities by describing one key data archive and indicating the extent and

breadth of data resources that this and other archives include. It then describes the process of conducting secondary analyses from resources such as these.

DATA ARCHIVES AND DATA SOURCES

One of the most important data archives for social scientists is the Interuniversity Consortium for Political and Social Research (ICPSR) at the University of Michigan, Ann Arbor. The ICPSR publishes an annual *Guide to Resources and Services* (much of this description was taken from the 1996–1997 volume). Additional information is available at the ICPSR Web site (www.icpsr.umich.edu). The consortium was founded in 1962 as a partnership between the Survey Research Center at the University of Michigan and twenty-one U.S. universities. In 1997 the holdings included over 3,500 titles, some of them capturing several panels of data on the same respondents or several waves of data involving comparable information. These titles are available to researchers at member institutions. The consortium charges fees on a sliding scale to academic institutions for membership privileges; researchers whose institutions are not members can obtain data for a fee. In 1997, over four hundred institutions in the United States, Canada, and countries throughout the world were members. While ICPSR originated as a service to political analysts, it currently serves a broad spectrum of the social sciences, including economics, sociology, geography, psychology, and history as well, and its data resources have been used by researchers in education, social work, foreign policy, criminal justice, and urban affairs.

Although ICPSR provides training in research and statistical methods and helps members in the effective use of computing resources, its central function is the archiving, processing, and distribution of machine-readable data of interest to social scientists. Although data capturing elements of the U.S. political process are well represented in its holdings, data are available on consumer attitudes, educational processes and attainment, health care utilization, social indicators of the quality of American life, employment conditions, workers' views on technology, and criminal behavior. The data come from over 130 countries, include both contemporary and historical censuses, and are not confined to the individual level but also provide

information on the characteristics of nations and organizational attributes. ICPSR actively seeks out high-quality data sets, and the user fees finance additional data acquisition as well as other operations. It also encourages investigators to deposit their data holdings in the archives to make them available to researchers for secondary analyses. Researchers whose data production efforts are funded by federal agencies such as the National Science Foundation are required to make their data publicly available after their grants have expired, and ICPSR is a logical depository for many data sets produced in the social sciences.

ICPSR maintains over ninety serial data holdings, including the earlier waves of the National Longitudinal Surveys of Labor Market Experience (NLS) (discussed below), the Survey of Income and Program Participation, the General Social Surveys, National Crime Surveys, the Panel Study of Income Dynamics, the Detroit Area Studies, the U.S. Census of Population and Housing, and the American National Elections Studies. These serial holdings include longitudinal surveys (in which the same respondents are interviewed repeatedly over time) such as the NLS and the Panel Study of Income Dynamics. These resources are particularly useful in determining the impact of earlier life events on later life outcomes, since the causal orders of all events measured on the data sets are clearly indicated. The holdings also include sets of cross-sectional studies conducted at regular intervals, such as the Detroit Area Studies and the General Social Surveys (GSS). These studies contain different cross sections from the same populations over time and are useful in charting trends in the attitudes of the respective populations over time, assuming that the same questions are repeated. Sources, such as the GSS, that ask the same questions over several years allow the researcher to pool samples across those years and obtain larger numbers of cases that are useful in multivariate analyses.

To illustrate one data set, consider the National Longitudinal Surveys of Labor Market Experience. These surveys are produced by the Center for Human Resource Research (CHRR) at Ohio State University. The CHRR produces a yearly *NLS Handbook*, and much of the following information regarding the NLS was taken from the 1998 *NLS Handbook*. These surveys began in 1966 with a study of older men aged 45–59 and a

survey of young men aged 14–24, continued in 1967 with a survey of mature women aged 30–44, and were followed up with a survey of young women aged 14–24 in 1968. In 1979, CHRR began a survey of over 12,000 youths aged 14–22, known as the NLSY79. In 1997, CHRR surveyed a new cohort of over 9,000 youths aged 12–16, called the NLSY97, and is continuing with yearly surveys of this cohort. The six major surveys contain a wealth of data on labor-force experience (e.g., labor-force and employment status, work history, and earnings) as well as investment in education and training, marital status, household composition and fertility, background material on respondents' parents, work-related attitudes, health, alcohol and drug use, and region of residence.

Each of these cohorts has been followed at varying intervals since the surveys' inception. For example, the Young Women were surveyed nineteen times between 1968 and 1997. The NLSY79 respondents were surveyed every year until 1994, when surveys in even-numbered years began. The Older Men were surveyed every year until 1983, and they or their widows were resurveyed in 1990. Data production for the Older Men and Young Men is complete; data production for the Mature Women and Young Women is ongoing biennially. In 1986 the NLS added a survey of the children of the NLSY79 cohort's women; that described the social, cognitive, and physiological development of those children and, given the longitudinal nature of the data on the mothers, allows an explanation of these child outcomes in terms of maternal background and current maternal characteristics. Surveys of the children occur in even-numbered years; this accumulated longitudinal database on child outcomes allows important inferences regarding the process of child development, with the numbers of children surveyed far exceeding those in most other sources. This additional resource has expanded NLSY79's usefulness to other disciplines, including psychology, and to other researchers interested in child development.

The NLS data sets are produced with the cooperation of CHRR, NORC (formerly the National Opinion Research Center) at the University of Chicago, and the U.S. Bureau of the Census. For example, for NLSY79, the CHRR takes responsibility for questionnaire construction, documentation, and data dissemination, while NORC has handled sample design, fieldwork, and data reduc-

tion. The Census Bureau has handled sample design, fieldwork, and data reduction for the four original cohorts. All data are available on CD-ROM from CHRR. Waves of data prior to 1993 are also available from ICPSR, as was noted above.

Social scientists from several disciplines, including sociology, economics, and industrial relations, have found the NLS to be a critical resource for the study of earnings and income attainment, human capital investment, job searches, fertility, racial and sex discrimination, and the determinants of labor supply. Inferences from these studies have been useful in regard to theory as well as policy formation. Other topics the data resource can usefully inform include family structure and processes, child outcomes, and aging processes. The CHRR estimates that by 1998 over 3,000 articles, books, working papers, and dissertations were produced using the NLS data. The 1998 *NLS Handbook* provides a wealth of detail regarding the designs of the surveys, survey procedures, variables, and CD availability. It also describes the extensive documentation available on the NLS data sets and lists references to key Web sites, including one that contains NLS publications. This handbook is indispensable for any researcher considering a secondary analysis using NLS data. The CHRR at Ohio State University disseminates the data and provides documentation and assistance to users with questions about the data sets. This summary gives a glimpse of the tremendous potential for secondary analyses of NLS data; this potential is multiplied many times over when one considers the number of other data sets available to researchers.

Because of the increase in resources devoted to survey research in sociology and related social sciences, the ICPSR holdings containing surveys of individuals have grown rapidly. However, ICPSR also archives data produced at varying levels of aggregation, thus facilitating secondary analyses in which the theoretically appropriate units of analysis are countries or organizations. For example, ICPSR archives the World Tables of Economic and Social Indicators, 1950–1992, provided by the World Bank. These data contain economic and social indicators from 183 countries, with the indicators including measures such as gross national product, value of imports and exports, gross national savings, value added across major industrial categories, net direct foreign investment, public

long-term debt, international reserves excluding gold, and gold holdings at the London market price. Demographic and social variables include population, total fertility rate, crude birthrate, percentage of the labor force in agriculture, percentage of the labor force that is female, and primary and secondary school enrollment rates. An older data set, also from the World Bank, contains similar measures from 1950 to 1981 as well as additional indicators not included in the data set covering the 1950–1992 period. Because these are also longitudinal data sets, there is the potential for pooling across time variation in these measures across the countries so that cross-sectional and longitudinal variations can be studied simultaneously.

ICPSR also maintains a small number of holdings useful for studying organizational processes. For example, a 1972 study of industrial location decisions obtained from the Economic Behavior Program of the Survey Research Center at the University of Michigan surveyed 173 industrial plants in Detroit, Chicago, and Atlanta. The interviewees were organizational informants such as president, vice president, general manager, and public relations director. The items included reasons for the location of the plant and the advantages and disadvantages of a location; other constructs measured included duration of plant operations, levels of sales and production, production problems, and plans for future expansion.

More recent arguments, however, have suggested that although sociology has invested considerably in surveys of individuals, it has invested insufficiently in surveys of organizations (Freeman 1986; see also Parcel et al. 1991). Kalleberg et al. (1996) present results from the National Study of Organizations, a National Science Foundation-sponsored study of a representative cross section of organizations that addresses their structures, contexts, and personnel practices. Although they demonstrate the utility of this design for addressing some questions regarding organizational functioning, these data cannot address issues of organizational change. A possible solution would be to produce a longitudinal database of organizations. The characteristics of a representative sample of organizations would be produced across time, analogous to the panel data sets of individual characteristics described above. Such a resource would enable researchers to study processes of organiza-

tional change with models that allow a clear causal ordering of variables. This type of resource also would permit analyses of pooled cross sections. Most important, the resource would allow organizational theories to be subjected to tests based on a representative sample of organizations, in contrast to the purposive samples that are used more frequently. To date, the resources have not been sufficient to approach the panel design suggested above. Clearly, the capacity to conduct secondary analyses at the organizational level is in its infancy relative to studies of individual-level processes and phenomena.

Finally, ICPSR also archives a variety of data sets that make possible historical analyses of social, economic, and political processes. For example, it archives the Annual Time Series Statistics for the United States, 1929–1968, which includes 280 variables for most of that period, although only 127 variables are available for the period 1947–1968. Available data include population characteristics, measures of political characteristics of the U.S. Congress, business and consumer expenditures, and expenditures by various federal government departments. ICPSR also archives Political Systems Performance Data for France, Sweden, and the United States, 1950–1965, in which the central constructs measured include size of public debt, gross national product (GNP), energy consumption, income tax rates, birthrates and death rates, labor force and unemployment, voting behavior, urbanization, and agricultural growth. Each of these historical data sources makes possible time series analyses of the macro-level phenomena they measure.

Additional major archives include the Roper Center for Public Opinion Research at the University of Connecticut and the Lewis Harris Data Center at the University of North Carolina at Chapel Hill. Kiecolt and Nathan (1985) provide additional information on the major archives, and Stewart (1984) outlines the extensive holdings in U.S. Government Document Depositories, especially the products of the U.S. Bureau of the Census. Other important archives include several in Europe with which ICPSR maintains a relationship, such as the Norwegian Social Science Data Services, the Australian Social Science Data Archives, and the Zentralarchiv für empirische Sozialforschung (ZA) at the University of Cologne. There is the potential for member institutions to

obtain from ICPSR data contained in those local archives as well. The International Social Survey Program (ISSP) has worked toward coordinating survey research internationally by asking common questions cross-nationally in given years, facilitating cross cultural analyses of social phenomena. For example, in 1990 social surveys in Austria, West Germany, Great Britain, Hungary, Ireland, Israel, Italy, the Netherlands, and Norway all included questions on work, including the consequences of unemployment, union activities, working conditions, and preferred job characteristics. A comparable module in 1987 focused on social inequality in Australia, Austria, West Germany, Great Britain, Hungary, Italy, and the United States. The 1993 module focused on nature, the environment, recycling, and the role of science in solving environmental problems. Data from the ISSP are available from ICPSR.

THE NATURE OF SECONDARY DATA ANALYSIS

The key advantage of secondary data analysis is also the key disadvantage: The researcher gains access to a wealth of information, usually far in excess of what he or she could have produced with individual resources, but in exchange must accept the myriad operational decisions that the investigators who produced the data have made. On the positive side, the researcher frequently is able to take advantage of a national sample of respondents or data produced on national populations when individual resources would have supported only local primary data production. The numbers of cases available in secondary resources often far outstrip the sample sizes individual investigators could have afforded to produce; these large sample sizes enhance the precision of parameter estimates and allow forms of multivariate analyses that smaller sample sizes preclude. A secondary analyst also can take advantage of the significant expertise concentrated in the large survey organizations that produce data sets for secondary analysis. This collective expertise usually exceeds that of any single investigator. Despite these advantages, the researcher must carefully match the requirements of the research project to the characteristics of the data set. When the match is close, the use of secondary data will enhance the research effort by making use of existing resources and taking advantage of the time, money, and expertise of others

devoted to data production. If the match is poor, the research project will fail because the data will not address the questions posed.

Because many secondary analyses are conducted on survey data, effective use of secondary survey sources frequently depends on knowledge of sample design, question wording, questionnaire construction, and measurement. Ideally, the researcher conceptualizes precisely what he or she wishes to do with the data in the analysis, since analytic requirements must be met by existing data. If the research questions posed are longitudinal in nature, the researcher must be sure that the survey questions are measured at time points that mirror the researcher's assumptions of causal order.

The researcher also must be certain that the survey samples all the respondents relevant to the problem. For example, analyses of racial differences in socioeconomic outcomes must use data sets in which racial minorities are oversampled to ensure adequate numbers of cases for analysis. The researcher also must be certain that a data set contains sufficient cases for the analysis she or he intends to perform. Kiecolt and Nathan (1985) stress the challenges for trend and cross-cultural studies that result from changes in sampling procedures over time. For example, suppose a researcher wants to ascertain whether more people support a voucher system for public education in 2000 compared with 1990. Changes in the sampling frame over the decade may introduce variations into survey responses that would not otherwise exist. These variations can be in either direction, and hypotheses regarding their direction are a function of the nature of sampling changes. Gallup surveys have increased their coverage of noninstitutionalized civilian adult populations over time, with the result that there has been an artifactual decrease in the levels of education they report (Kiecolt and Nathan 1985, pp. 62–63), since the later surveys have progressively included groups with lower levels of schooling. Sampling changes also can occur over time because of changes in geographic boundaries. Cities change boundaries owing to annexation of areas, and Metropolitan Statistical Areas (MSAs, formerly Standard Metropolitan Statistical Areas [SMSAs]) are created over time as increased numbers of counties meet the population and economic criteria for defining MSAs.

The most common problem in conducting secondary analyses, however, occurs in the questionnaire coverage of items needed to construct appropriate measures. It is likely that the original survey was constructed with one purpose and asked adequate numbers and forms of questions regarding the constructs central to that problem but gave only cursory attention to other items. A secondary researcher must evaluate carefully whether the questions that involve his or her area of central interest are adequate for measurement and for analytic tasks. The biggest fear of a secondary researcher is that some variables needed for proper model specification have been omitted. Omitted variables pose potentially severe problems of misspecification in estimating the parameters of the variables that are included in the models. In these cases the researcher must decide whether an adequate proxy (or substitute) variable exists on the data set, whether the research problem can be reformulated so that omission of that construct is less critical, or whether the initially chosen data set is unsuitable and another must be sought. Researchers can also purchase time on major social surveys such as the GSS administered by NORC. This strategy enables researchers with adequate financial resources to be certain that the questions needed to investigate the issues of interest to them will be included in a national survey. This strategy mixes primary data production with secondary analysis of a multipurpose data set. The entire data resource then becomes available to other secondary analysts.

Other challenges for secondary analysts occur as a function of the particular form of secondary analysis used. For example, Kiecolt and Nathan (1985) note that survey researchers who produce series of cross sections of data that are useful in studying trends may "improve" the wording of questions over time. In regard to the problem of voucher systems in public education, the researcher may observe increased percentages of survey respondents favoring this option over the period covered by the surveys but still may have difficulty eliminating the possibility that question wording in the later survey or surveys may have encouraged a more positive response. Such changes also can occur if the wording of the question remains the same over time but the nature of the response categories changes. Secondary analysts who conduct cross-cultural comparisons must be sensitive

to the fact that the same question can mean different things in different cultures, thus interfering with their ability to compare the same social phenomenon cross-culturally.

Dale, et al. (1988) note that in-depth studies of specific populations may be most realistic with national samples that provide sufficient cases for analyses of the subgroups while allowing the researcher to place those data within a broader empirical context. It is also possible that surveys produced by different survey organizations will produce different results even when question wording, response categories, and sampling procedures remain the same (Kiecolt and Nathan 1985, p. 67). A secondary analyst must be certain that the survey organization or individual responsible for producing the data set exercised appropriate care in constructing the data resource. As was noted above, detailed familiarity with the documentation describing the data set production procedures is essential, as is a codebook indicating frequencies on categorical variables, appropriate ranges for continuous variables, and codes for missing data.

There is often an interactive nature to the process of conducting a secondary data analysis. While the researcher's theoretical interests may be reasonably well formulated when he or she identifies a useful data set, the variables present in the data resource may suggest additional empirical opportunities of theoretical interest that the researcher had not previously considered. Also, familiarity with data resources can facilitate the formulation of empirical investigations that otherwise might not be initiated. Once a researcher is familiar with the features of a particular secondary source, accessing additional variables for the analysis of a related problem may require less investment than would accessing a new data resource. However, there is general agreement that data availability should never dictate the nature of a research question. Although it is legitimate for a researcher to use his or her awareness of data resources to recognize that analyses of problems of long-standing interest are now empirically possible, "data dredging" has a deservedly negative connotation and does not result in the advancement of social science. Hyman's (1972) classic treatment of secondary analyses of survey data richly chronicles the experiences of a number of sociologists as they interactively considered the matching of theoretic

cal interests and data availability in formulating and conducting secondary analyses. He also describes a number of ways in which secondary analysts can configure existing data to test hypotheses.

Recent developments in technology have streamlined several steps in secondary analyses that formerly were time-consuming and labor-intensive. Many secondary data sets are now available on CD-ROM (compact disk-read only memory); the NLS data discussed above are only one example. With many computers having attached CD readers, analysts can read the disks and extract from them the variables and cases they wish to study. Often the disks also contain searching devices that enable researchers to locate variables of interest easily. These "search engines" simultaneously enable analysts to select a sample and obtain the variables needed on each case. These capabilities totally bypass older technologies involving nine-track tapes containing data. In tape-based technologies, analysts had to write original computer programs to extract the needed variables and cases. A typical analyst no longer depends on a centralized computing facility for storing, mounting, and reading magnetic tapes.

The next steps in secondary analysis differ only slightly from the steps that investigators who produce primary data undertake. In both cases, data must be cleaned to remove coding errors that might result in erroneous findings. Similarly, both investigators need to address problems with missing data. The primary data producer is close enough to the actual data production not only to identify such problems but also to resolve many of them appropriately. For example, if the researcher is studying a single organization and notes that a respondent has failed to report his or her earnings, the researcher, knowing the respondent's occupation, may be able to obtain data from the organization that approximates that respondent's earnings closely. The secondary analyst would not have access to the original organization but might approximate the missing data by searching for other respondents who reported the same occupation but who also reported earnings. Variations on this theme involve the imputation of missing data by using mathematical functions of observed data to derive reasonable inferences about values that are missing (Little and Rubin 1987, 1990; Jinn and Sedransk 1989).

Both types of investigator have to be familiar with the descriptive properties of their data. For a primary investigator, observing distributions of respective variables as well as their central tendencies should be an outgrowth of data production itself. A secondary analyst has less familiarity with the data someone else produces but is under the same obligation to become familiar with the descriptive properties of the data in a detailed way. For both researchers, good decisions involving measurement of variables and model specification for multivariate analyses depend on knowledge of the descriptive properties of the data.

Within the respective multipurpose data sets, research traditions often arise from the sometimes unique suitability of certain resources for addressing given problems. These traditions derive from the fact that several investigators have access to the data simultaneously, a feature that distinguishes secondary data analysis from analyses undertaken by different primary investigators, each of whom has a unique data set. For example, in the late 1980s and into the 1990s, the NLSY79 with Mother and Child Supplements was virtually unique in combining a large sample size, longitudinal data on maternal familial and work histories, observed child outcomes, and oversamplings of racial minorities. Problems tracing the impact of maternal events on child outcomes are addressable with this data resource in a way that they were not with other resources. Investigators with an interest in these issues use the data and exchange information regarding strategies for measuring constructs and data analysis and then exchange their findings. Over time, bodies of findings emerge from common data sources where the findings are contributed by a number of secondary investigators, although the particular problems, theoretical frameworks, and empirical strategies represented in each one may differ markedly. As was suggested above, multipurpose data sets frequently allow secondary analyses by researchers from several disciplines. The products of these investigations bear the stamps of their respective disciplines. In addition, the NLSY79 with Mother and Child Supplements has served as a model for the Michigan Panel Study of Income Dynamics (PSID) in its 1997 Child Development Supplement on the PSID respondents. This new data resource, which combines longitudinal data on parents and developmental assessments of children from birth to age

12, will enable replication of key findings produced with the NLSY79 child data set as well as the production of new findings. For example, both data sets contain age-appropriate cognitive assessments for children, permitting findings produced with the NLSY79 child data set to be replicated with the PSID Child Development Supplement. The PSID, however, contains data on how children spend their time. These variables should allow researchers to understand the effects of children's time use on several developmental outcomes, something that the NLSY79 child data do not permit.

The wealth of secondary data sources also permits investigators to use more than one data source to pursue a particular line of inquiry. No single data set is perfect. Researchers can analyze several data sets, all with key measures but each with unique strengths, to check interpretations of findings and evaluate alternative explanations. McLanahan and Sandefur (1994) use this approach in their study of the effects of single parenthood on the offspring's academic success and social adjustment. Their data sources include the NLSY79, the PSID, and the High School and Beyond Study. The result is a stronger set of findings than those which could have been produced with any one of those sources.

Another model for conducting secondary research is suggested by researchers who use census data produced by the U.S. Department of Commerce. Census holdings cover not only information on the general U.S. population but also data on businesses, housing units, governments, and agricultural enterprises. Researchers who use these sources singly or in combination must be familiar with the questionnaires used to produce the data and with the relevant features of sample coverage. While some census data are available on machine-readable tape, other data exist only in printed form. In these cases, the researcher must configure the needed data into a form suitable for analyses, in many cases a rectangular file in which cases form row entries and variables form column entries. Data produced on cities from the County and City Data Books, for example, allow a variety of analyses that involve the relationships among urban social and economic characteristics. In these analyses, the unit of analysis is probably an aggregate unit such as a county or city, illustrating the applicability of secondary analysis to problems

conceptualized at a level of aggregation higher than that of the individual.

Another advantage of secondary analyses is the potential for those most interested in a particular set of findings to replicate them by using the same data and to introduce additional variables or alternative operationalizations as a method for evaluating the robustness of the first secondary investigator's findings. A classic example is Beck et al.'s 1978 investigation of differences in earnings attainment processes by economic sector. Hauser's (1980) reanalysis of those data suggested that most of the differences in sectoral earnings reported in the original study were a function of coding decisions for low-earnings respondents, since the differences disappeared when the code for low earnings was changed. Despite this criticism, the impact of the original investigation has been enormous, with many additional investigators exploring the structure and implications of economic sectors. The point, of course, is that such debate is more likely to occur when researchers have access to common data sets, although gracious investigators often lend their data resources to interested critics. Hauser (1980) acknowledges that Beck et al. shared their original data, although he could have obtained the original data set from ICPSR.

Secondary data sets can be augmented with additional data to enrich the data resource and allow the derivation of additional theoretical and empirical insights. Contextual analysis, or the investigation of whether social context influences social outcomes, is a key example. Parcel and Mueller (1983) used the 1975 and 1976 panels from the PSID to study racial and sex differences in earnings attainment. To evaluate the impact of occupational, industrial, and local labor-market conditions on workers' earnings, they augmented the PSID data with archival data from U.S. Census and Dictionary of Occupational Titles sources that were based on the occupations, industries, and local markets of respective PSID respondents. Illustrative contextual indicators included occupational complexity, industrial profitability, and local-market manufacturing-sector productivity. Analyses then suggested how these contextual, as well as individual-level, indicators affected workers' earnings differently depending on ascriptive statuses. Computer software is now available to correct for problems in estimating models that use contextual data.

The potential for many sociologists to use secondary analysis to conduct studies of theoretical and practical importance probably has contributed to a change in productivity standards in sociology, particularly in certain subfields. The fact that certain issues can be addressed by using existing data can result in enormous savings in time relative to the time that would be required if primary data had to be produced. Research-oriented departments either implicitly or explicitly take this into account in assigning rewards such as salaries, tenure, and promotion. The potential for secondary analyses thus may create pressures toward increased scientific productivity; whether these pressures work generally for the good of social science or against it may be a matter of debate.

It is undeniable that progress in addressing some of the most important problems in social science has been facilitated greatly by the existence of multipurpose data sets and secondary resources. It is also true that the resources needed to produce and disseminate these data are considerable and that the existence and continuation of these resources are vulnerable to changes in political climate and priorities when those priorities influence resource allocation. It is critical that such decisions on resource allocation, particularly those made at the level of the federal government, recognize the important role that secondary resources have played in furthering both basic social science and applications informing social policy.

SECULARIZATION

Secularization is the process by which the sacred gives way to the secular, whether in matters of personal faith, institutional practice, and political power. It involves a transition in which things once revered become ordinary, the sanctified becomes mundane, and the otherworldly loses its prefix. Whereas the term "secularity" refers to a state of

sacredlessness and "secularism" is the ideology devoted to that state, secularization is a historical dynamic that may occur gradually or suddenly and may be replaceable (if not reversible).

The concept of secularization has been both an organizing theme and a source of contention among scholars of religion since the beginning of the European "Enlightenment" in the seventeenth century. One might expect an increasing consensus on a matter so long on the scholarly agenda, but discord has crescendoed in recent years. Secularization has taken on different meanings in different camps. It matters whether the reference is to religion's displacement, decline, or change; to the sacred at the level of the individual, the institution, the community, or the culture; or to a pattern that is long term, linear, and inevitable or short term, cyclical, and contingent.

The object of this essay is to disentangle both the issues and the combatants. After describing the early protagonists and more recent sociological proponents of secularization, this article considers recent arguments against their theses. In the face of a seemingly intractable conflict, it is important to describe the issues in dispute. This will lead to a consideration of secularization and sacralization as opposite phenomena that actually are more mutually linked than mutually exclusive.

EARLY AND RECENT CONCEPTIONS OF SECULARIZATION

Any conception of the sacred is likely to engender skeptical—if often marginal—detractors. While both the process and the thesis of secularization have precursors early in Western history, it was the Enlightenment that provided their first codification.

The term "secularization" dates back to France in the mid-seventeenth century. The first high priest of this antichurch was the French bourgeois intellectual Voltaire (1694–1778). A professed "deist" whose belief in impersonal forces stood in sharp contrast to "theistic" conceptions of a personal God, Voltaire railed against the Catholicism's superstitions and ecclesiastical trappings (Voltaire 1756). However, Voltaire was not the most materialist figure of his day and he was distinguished more by the expression of his views than by their substance, including his sense that the end of religion was near, possibly in his life-

time. The main thrust of his views was shared by many Europeans and Americans, including Benjamin Franklin and Thomas Jefferson.

The prophets of secularization soon multiplied. By the second half of the nineteenth century, they included the father or at least namer of “sociology,” the French positivist Comte (1852). Comte’s conception of a future that belonged more to the social sciences than to religion was shared by Britain’s Spencer (1874), whose sales rivaled those of Dickens. Marx ([1844] 1963) envisioned a denarcotized future once the masses learned the real secret of their misery, substituted class consciousness for false consciousness, and exchanged otherworldly sighs for this-worldly action.

Weber and Durkheim continued the tradition in the first two decades of the twentieth century. Both provided key statements about the importance of religion: Weber’s “Protestant ethic” as a precondition of capitalism and Durkheim’s conception of religion as the latent worship of society. However, neither was personally religious, and both envisioned a secularized future without predicting it directly.

For Weber ([1905] 1993), secularization was an implication of the “rationalization” that was uniquely characteristic of the West. He was ambivalent about the results. On the one hand, he appreciated its cultural underpinnings of everything from capitalism and bureaucracy to architecture and music. On the other hand, he wrote in the tradition of German historiography and a concern for the spirit of every age. Weber lamented a dark side of rationality that would lead to secularized disenchantment. Toward the end of *The Protestant Ethic and the Spirit of Capitalism*, he commends the cynical sentiment:

Specialists without spirit, sensualists without heart; this nullity imagines that it has attained a level of civilization never before achieved.
([1905] 1993, p. 182)

Durkheim worked selectively within the tradition of Comte and French positivism and therefore was more positive about secularization. Durkheim (1961) was optimistic about a secular morality and an autonomous ethic for society. Although religious beliefs would be displaced by science, the sense of society as a sacred collectivity would remain. On the eve of World War I, he

described France as undergoing a period of “moral mediocrity,” but he was certain that it would soon be revitalized through a sense of “collective effervescence” and sacred renewal, possibly independently of conventional religion (Durkheim 1912).

By the middle of the twentieth century, secularization had become one of the master motifs of the social sciences. It was at least implicit in major transitional distinctions such as Durkheim’s “mechanical versus organic solidarity” Toennies’s ([1887] 1957) “Gemeinschaft” versus “Gesellschaft” societies, and Redfield’s (1953) “folk” versus “urban” cultures. At the same time, prophecies had given way to theories as sociology began to develop more nuanced versions of secularization. The 1960s produced a bumper crop of new works, among the most influential of which were Berger’s *The Sacred Canopy* (1967) and Wilson’s *Religion in Secular Society* (1966).

Berger dealt with both the rise and the decline of religion. Having described religion’s importance as a source of meaning for a cosmos that is often inchoate, he then noted factors involved in religion’s erosion. These included privatization, pluralism, and a new religious marketplace, all of which contributed to a secularization he defined as “the process by which sectors of society and culture are removed from the domination of religious institutions and symbols” (1967, p. 107). Berger did not place all the blame for the decline of religion on external factors. Liberal clergy and theologians were often ahead of the process in diluting religion to avoid conflicts with a secular society.

If Berger’s conception of secularization suggests society pulling away from a still-religious core, Wilson conveys a scenario in which religion recedes to the margins and suffers a diminution of influence. For Wilson, secularization is “the process whereby religious institutions, actions, and consciousness lose their social significance” (1966, p. xiv). However, Wilson was aware of a profound difference between the declining influence of the established churches and the surging growth of sectarian movements (Wilson 1998): As society becomes more complex, all its institutions become more differentiated from each other and have more autonomy but less influence. However, the process does not occur equally, and traditional institutions such as religion are more

affected by these changes. Often seen as part of a larger process of “modernization,” differentiation has been a prominent theme among functionalists such as Parsons (1977) and Luhmann (1982) and neofunctionalists such as Bell (1976) and Habermas (1988).

Differentiation takes different forms and exacts different tolls. The Belgian scholar Dobbelaere (1981) draws a parallel between secularization and the French term “laicization,” which Durkheim and others used to denote a loss of priestly control, with a consequent decanonization of religion. While developing the concept for European settings, Dobbelaere draws two sets of distinctions: between the processes of differentiation, decline, and change (1981) and between the levels of the individual, the organization, and the society (Dobbelaere 1985).

By this time, secularization had become a major priority for social scientists examining religion. In analyzing the United States, Fenn (1979) stresses that secularization involves a blurring rather than a sharpening of the boundaries between the sacred and the secular; more recently, Fenn refers to secularization as the “domestication of charisma” (1993). Meanwhile, the concept is at least a subtheme of Bellah et al. (1985) in a work that depicts the community’s losing struggle with individualism, perhaps the ultimate form of differentiation at the personal level.

Roof and McKinney (1987) describe a similar pattern as a “new voluntarism” that has displaced old denominational loyalties. Similarly, Wuthnow (1988) notes how other forces of differentiation have shifted religious action away from the denominations and congregations and in the direction of “special-purpose groups” whose single-issue agendas are often more a reflection of political morality than of religious doctrine or theology. Wuthnow also describes a differentiation between America’s liberal and conservative “civil religions” and the rise of a third national faith in the form of secular technology.

Finally, Chaves (1993) documents the emergence of differentiated “dual structures” within denominations. This duality represents a split between declining “religious” authority and increasing secular “agency” authority. This formulation is consistent with other traditions of organizational analysis in religion, including the classic

distinction between “sects” and “churches” and the process by which the purity of sects is compromised by their transformation into accommodating churches.

SECULARIZATION MYTHOLOGIZED

Originally, the detractors of secularization were defenders of the faith. More recently, they have portrayed themselves as critics of a very different faith, which they have played a large role in constructing. Recent years have seen the attribution of a full-blown “secularization thesis” that is not so much a series of questions for investigation as a definitive answer with all the qualities of an epochal narrative. Here the older eighteenth-century prophetic vision of secularization has been substituted for more recent and less sweeping versions. Secularization is presented as a tenuous article of faith that is suspended between two mythical points. The first point involves the fiction of a deeply and universally religious past; the second involves the conceit of a religionless present and future (Stark 1992). Thus, secularization has been recast as a sweeping saga that serves as a sort of antisacred doctrine, in its own right—though it is important to bear in mind that it is the critics of secularization who have both popularized this version and savaged it.

The British anthropologist Douglas (1982) was among the first to chastise proponents of secularization for imagining a mythical past against which the present inevitably comes up short. In her case, the past involved those simple, undifferentiated societies studied by anthropologists but used by others as convenient foils. Thus, even here religious piety and participation are not always deep or universal. If these societies are the beginnings of the neoevolutionary process of modernization, their religion has inconvenient similarities with the religion of complex societies toward the end of the process.

Stark (1998) elaborates this point for early Western societies. To the extent that a secularizing trend depends on a contrast with a pious ancient and medieval Europe, Stark cites evidence suggesting that this past is also mythical. Once one looks beyond the public displays of ecclesiastical officialdom, the masses appear to be antichurch, if not antireligious. Attitudes toward organized faith were conspicuous for their alienation, corruption, and

raucousness. Many “Christian” nations founded in the late middle ages were only inches deep as surface monopolies atop an impious base.

What of the myth of religious demise? Martin (1969) was among the first to find religion in the midst of putative nonreligion, in this case in “highly secularized” Great Britain. In fact, Martin called for dropping the term “secularization” because of the confusion it had elicited, though ten years later he adopted the semantic fashion by publishing *A General Theory of Secularization* (1978).

Stark has also been a relentless critic of the second myth, and he has had company. His book with Finke, *The Churching of America* (Finke and Stark 1992), uses actual and reconstructed church membership data to argue that the real “winners” over the past two centuries have been conservative churches while liberal (and more secular) churches have been the “losers.” Critics note that the work is not without problems; for example, its thesis refers to rates of growth and decline rather than absolute size, and it assumes that membership is a reliable measure of general religiosity over time (Demerath 1992).

Many other scholars have noted the continued vitality of religion in America. Warner’s “new paradigm” (1993) provides a systematic description of how the American case may differ from the European scene that spawned secularization theory. Meanwhile, Stark has taken his methods and “market” model of religion abroad. He and the economist Iannaccone (1994) developed a nonmonopolistic, “supply-side” interpretation of European religion, arguing that its death and secularization have been greatly exaggerated. This argument has had both supporters (Davie 1994; Swatos 1997) and detractors (Bruce 1995; Dobbelaere 1993; Wilson 1998).

Meanwhile, the dispute over secularization is not restricted to the West. In fact, the Western version of the debate is comparatively innocuous because it is confined largely to scholars removed from political conflicts and because the politics of religion has generally been laid to rest except in a few cases, such as the tragic violence in Northern Ireland and the anticlimactic decision of Sweden to sever state ties with the Lutheran Church as of 2000. Once one leaves the West, however (Demerath 2000), assessments of secularization and secularity have become volatile public issues exacerbated by

the ideological conflict between forthright pro- and antisecularists.

Moving from Poland and eastern Europe through the remains of the Soviet Union to Afghanistan, from the Balkans through Turkey and into Iran, from Algeria through Egypt to Israel, from Pakistan through India to Sri Lanka, and from Indonesia through China to Japan, one sees countries whose national identities are being defined by a prolonged conflict over secularization (Juergensmeyer 1993). In each case, the struggle involves less one religious group versus another than religion generally versus secular alternatives.

In addition to what might be termed a “bottom-up” process of seeping secularization, there are instances of a “top-down” coercive scenario, and the two are not mutually exclusive. The former Soviet Union, Turkey, and China illustrate the latter process through political systems headed by Lenin, Ataturk, and Mao Tse-Tung and their followers, respectively. This structurally imposed secularization had cultural effects as specifically defined state rituals became common alternatives to traditional religious ceremonies. However, in all these countries, traditional religion remains in evidence in the private sphere and occasionally bursts into the public arena.

Although there are examples of externally coerced secularization (e.g., the U.S. insistence on Japan’s abolishing “State Shinto” after World War II), secularization generally takes a far less direct form. Consider India as a case in point. Over the centuries, the south Asian subcontinent has given the world Hinduism, Buddhism, Jainism, and Sikhism, but from the early sixteenth century until the mid-twentieth century, it was dominated by outside rulers representing first Islam in the Moghul period and then Christianity under the British “raj.” When independence was won in 1947, the partitioning of Pakistan and India created two states, one Muslim and the other dominantly Hindu. The religious resorting involved a massive cross-migration as long-time residents of each area moved to the other so that they could live among their coreligionists. The violence that ensued is estimated to have left from 250,000 to 500,000 people dead.

Religious conflict has continued in both areas, but in each case, it is not simply one religion against another but also religion versus secularity.

After independence, India instituted a national government that followed the Western model of a secular and thus religiously neutral state. However, after a half century, a series of violent conflicts between Hindus, Muslims, and Sikhs have left a cloud over India's state secularity. In the 1990s, the dominant and secularist Congress Party lost its voting plurality to the Hindu nationalist Bharatiya Janata Party (BJP). Momentum is gathering on behalf of a Hindu state that would reflect the country's Hindu majority. Nor is the movement confined to right-wing religious zealots. A number of India's most prominent intellectuals have entered the fray and produced a series of strident exchanges (Nandy 1990; Madan 1998 Beteille 1994). For many people, the commitment to state secularity has ebbed; paradoxically, secularism has been secularized.

FINDING A MUDDLED GROUND

Today it is common to hear that secularization has been categorically "disproved" and that anyone who still uses the term is more of an ideological antediluvian than an *au courant* scholar. Yet one must be wary of throwing out the baby with a bathwater both drawn and drained by the critics themselves. And certainly one must always be suspicious of prophets who predict the vindication of their own ideology. Most of the early visionaries of secularization and a disproportionate number of the theorists who have followed have been personally nonreligious, if not necessarily antireligious. At the same time, the ranks of the antiseccularizationists have included a number of theorists with personal religious loyalties. Although a scholarly discipline should provide methods to avoid or transcend these biases, history indicates otherwise.

A full review of the empirical literature on the secularization debate is beyond the scope of this article, and it is not feasible to conduct an investigation that would constitute a critical test. However, this is not an issue that can be settled empirically. Statistical arguments will be irrelevant until a series of pressing ideological and conceptual issues are confronted.

One must decide what to test before deciding how to test it. Because the two great myths attributed to the secularizationists by their critics are

by their nature overblown, they are not hard to puncture. Debating the matter at such mythical levels lends an all-or-nothing quality to the dispute: Insofar as the thesis fails to document a shift from all to nothing, it is suspect. However, no recent secularization theorists stake their claim in those terms.

It is not difficult to refute the first myth of secular dynamics concerning a seamless and universal religiosity in tribal settings and in the historical past. However, for the past to be more religious, it is not necessary for it to be either consistently or totally so. For a society to have been dominated by religion as political power, it need not have been more religious at the level of the individual and *vice versa*. Even at that level, of the individual, the past may be more religious in terms of personal piety and belief without necessarily being more religious in terms of formal institutional participation. Also, to say that one group or society's past was more religious than its present is not necessarily to say that another's must be the same. Finally, there are multiple pasts, none of which need be linear in their linkages.

Meanwhile, the second myth of secular dynamics is even easier for critics of secularization to deflate. The notion of religion's actual death and disappearance has shifted from the sublime to the ridiculous, especially in the formulations of eighteenth- and nineteenth-century figures, some of whom foresaw the end in their own lifetimes (Stark 1998). Somehow religion survived the eighteenth and nineteenth centuries, not to mention the twentieth. Again, however, it is not clear that this is either necessary or sufficient to disprove a more nuanced conception of secularization. Today it is common to reject the concept of secularization simply because religion persists, but mere persistence masks a host of questions concerning religion's changing terms and circumstances.

The "secularization thesis" with a mythical beginning and a mythical end is erroneous, but it is a largely noninstructive error akin to "denying all climatology and the particular hypothesis of global warming because we have not yet been burned to a crisp and the nights do, after all, still get cooler" (Demerath 1998b, p. 9).

Clearly secularization as a textured social process remains a fruitful concept. In fact, once the focus shifts to a less extreme version, the consen-

sus widens considerably. Consider two recent remarks from arch critic Stark:

This refers to a decline in the social power of once-dominant religious institutions whereby other social institutions, especially political and educational institutions, have escaped from prior religious domination. If this were all that secularization means, there would be nothing to argue about. Everyone must agree that, in contemporary Europe, for example, Catholic bishops have less political power than they once possessed, and the same is true of Lutheran and Anglican bishops. . . . Nor are primary aspects of public life any longer suffused with religious symbols, rhetoric, or ritual. (1998, pp. 4–5)

Of course, religion changes. Of course, there is more religious participation and even greater belief in the supernatural at some times and places than in others, just as religious organizations have more secular power in some times and places than in others. Of course, doctrines change—Aquinas was not Augustine, and both would find heresy in the work of Avery Dulles. But change does not equate with decline. (1998, p. 29)

These statements greatly narrow the gap between secularization’s advocates and one key antagonist. For many of the former, Stark’s first passage suggests a battlefield conversion, though it is not a new position for him (Stark and Bainbridge 1985). While the second remark is correct in that change and declension are not identical, the implied invitation to deconstruct the two should be welcomed.

There is little question that secularization has come to connote decline. Whether in its long-range mythical or short-term process form, secularization posits some variant of religious erosion, if not extinction. However, all these versions represent a myopic and one-sided perspective compared to the alternative that follows.

PARADOXES OF SECULARIZATION AND SACRALIZATION

At a time when work on secularization might be expected to yield a consensually validated paradigm (Tschannen 1991), it is far closer to producing a new set of divisive paradoxes. Much of this

conflict results from the terms at issue. Both “secular” and “sacred” are mutually referential in that each makes a statement about the other. To be secular is to be nonsacred; to be sacred is to transcend and transform the secular. The same is true when one shifts from semantics to social processes. Just as an object must have been sacred for it be subsequently secularized, it must have been secular for it to be subsequently “sacralized.” Just as secularization marks a decline of the sacred, sacralization denotes an increase in the sacred in one form or another and at one level or another.

However, linking the processes of secularization and sacralization can have paradoxical results. The following eight propositions can serve as examples:

1. Religious revivals and “great awakenings” require previous eras of religious decline and secular “naps.” American religious history has been charted in terms of its eighteenth-, nineteenth-, and possibly twentieth-century awakenings (McLoughlin 1978), but an opposite focus has equal merit (May 1949; Erikson 1966; Turner 1985). It is the combination of the two that establishes the basic rhythm of a country’s religious history.
2. Modernization may lead to both secularization and sacralization. The grand narrative of the secularization thesis is that religion beats a steady and linear retreat in the face of mounting modernization. There is considerable truth to this but also some half-truth. This is what Berger referred to in recanting some of his earlier writing on secularization (Berger 1997). Modernization often leads to forms of secularization, but those often spark a sacralizing response—one that uses the means of modernity to protest the ends of modernity. This characterizes “fundamentalisms” everywhere, whether in the original Christian version in the United States or in the Islamic and Hindu variants around the global girdle of religious extremism. As was noted earlier, many countries demonstrate religion’s continuing presence, but these countries also bear witness to the incursions of secularity as a perceived threat to religious interests. If either religion or secularity

were fully dominant in these settings, the conflicts would be obviated.

3. The rise of a vital “religious marketplace” is evidence of both secularization and sacralization. An increase in religious competition often reflects the decline of religion’s structural monopolies and/or cultural hegemonies. Religious dominations once taken for granted are now subject to doubt and dismissal, yet the new consumer’s mentality may involve more stained-glass window shopping than long-term buying (actually joining a church). The debate over changing patterns of religiosity turns on this point, as does a current dispute over the significance of religious “switching” in the United States (Demerath and Yang 1998a).
4. Because movements that go against the societal grain often create more friction than do trends that go with it, one must be careful not to mistake the sacred exceptions for the secular rule. It is tempting to interpret the flames of a small religious movement as being more important than the smoking embers of its larger and more secularized context. In the same spirit, one must be wary of confusing growth rates with size. Both have their place, but even small, conservative religious movements with high growth rates may be marginal to the larger population and culture. As an example, see the “winners” and “losers” cited by Finke and Stark (1992).
5. Sacred manifestations may reflect secular forces, and vice versa. The relationship between any form of behavior and the motivations behind it is problematic. Standard indicators of religiosity such as civil religious loyalty, church membership, church attendance, and religious belief are all subject to myriad interpretations, not all of which are unambiguously sacred (Demerath 1998a; Haddaway et al. 1993). It may be more the case that the civil is religious than that the religious is civil: Church membership and attendance reflect a variety of sacred and secular meanings that vary across a population and across time, and affirming a religious belief may be less a matter of cognitive conviction than of cultural affiliation and continuity. Even the various “fundamentalist” movements may not be as uniformly or fanatically “religious” as they are often portrayed. Many of their members have a predominantly secular agenda that religion legitimizes (Demerath 2000). Similarly, a withdrawal from conventional religious frameworks may coexist with a more privatized faith (see the “little voice” of the pseudonymous Sheila Larson in Bellah et al. 1985, p. 221). Finally, there are any number of conventionally secular commitments that take on sacred valences for their devotees (see below).
6. Moderate secularization can be a prophylactic against ultimate secularization. Changing social conditions require changing forms of the sacred. Hence, some degree of secularization may serve as a form of sacred adaptation. This has been a tactical assumption in the trajectory of liberal Protestantism over the last century as pastors and theologians have made concessions to their secularizing adherents (Berger 1967; Demerath 1992). This tactic has been challenged by advocates of strict doctrine and strict churches (Kelley 1972; Iannaccone 1994), but cleaving to strictness may have cost the churches far more defections than has the alternative.
7. Secularization and sacralization are engaged in a dialectical oscillation in which each is contingent on and responsive to the other. The presence of one does not necessarily involve the absence of the other. As was noted above, a secularization that goes too far is likely to elicit a sacralizing reaction. Similarly, sacralizing may exceed the bounds of pertinence, propriety, credibility, or convenience in a complex social context. Thus, lapsing and laicization of various sorts result in a secularizing adjustment. Without suggesting that secularization is always balanced by a corresponding sacralization to create a religious equilibrium, one can say that this mutual responsiveness is an important

reason why secularization, like a sense of the sacred itself, will always be with us.

8. Focusing on the fate of old forms of religion may deflect attention from new forms of the sacred. An obsession with secularization in the past may preclude an analysis of sacralization in the present and future. Just as conventional religion may not necessarily be sacred, new sources of the sacred are not necessarily religious. Today one hears a good deal of talk about a growing distinction between religion and spirituality and about profound sacred commitments in everything from socialism to sex. Just because they have attained cliché status does not mean that these concepts should be jettisoned as possibilities for deeper investigation.

These eight propositions lead to a series of issues beyond the scope of this article: Does every individual need a sense of a sacred commitment and a regimen that is self-consciously maintained and ritually reinforced? Does every collectivity and society require something similar that is shared among its members? If the answers to these questions are affirmative, what is the relation between the sacredness required and conventional religion on the one hand and more secular sources on the other? To what extent can the sacred reside in high and low culture, moral and ethical convictions, and movements on behalf of political causes, personal identities, and nationalist ambitions? Is it possible to investigate these matters without falling into tautology and teleology? Precisely because these questions are so old, it is time for freshly conceptualized and newly researched answers.

The alternation of secularization and sacralization is a crucial historical dynamic not just for religion but for culture as a whole. Secularization without sacralization is a nearly defining characteristic of putative *postmodernity*, with its loss of grand narratives and collective bearings. At the other extreme, sacralization without secularization is a similarly defining characteristic of stereotypic *premodernity*, where the sacred is static and unchallenged. However, it is in historical *modernity* that secularization and sacralization play off each other in both producing and responding to change. Whether causes or effects, these are critical processes in the world of time as opposed to timelessness.

SUMMARY

The importance of any scholarly issue is revealed in the debates it engenders. By this standard, secularization qualifies as very important indeed. As a matter that seems to defy either empirical or ideological consensus, it has become a kind of Gordian knot for social scientific scholarship on religion.

Clearly, it is possible to construct versions of secularization that are either outrageous or reasonable. It matters greatly how the concept is deployed. For some, it is a prophecy of religious demise, whether a tragic jeremiad or a triumphant anticipation. For others, it is a set of historically and sociologically specified processes that move less linearly and with less certainty through time. For still others, secularization converges with sacralization to form a stream of constantly shifting conceptions and locations of the sacred. Whichever option is at issue, the stakes are high, and the sight of scholars impaled upon them is not uncommon.

SEGREGATION AND DESEGREGATION

In the early years of the American colonies and the new republic of the United States, segregation was not only impractical but undesirable. To benefit from slavery, slave masters had to manage and control slaves; therefore, they had to work with them. Not all slaves were field hands or agricultural workers; some were domestic servants, and so the slave master and mistress had to share their private quarters with slaves. Thus, many white Americans, especially Southerners in the pre-Civil War South, accepted daily, intimate, personal, primary face-to-face contact with slaves as a necessity. They insisted, however, that all such contacts reflect proper social distance: slaves were always to be subservient, behavioral assimilation was allowed only to a point, and slaves were supposed to know the dominant-group culture, use it appropriately, and always recognize that they were not the equals of their masters. Although structural assimilation occurred at a primary level, it was not among equals.

With the Emancipation Proclamation of 1863 and the ratification of the Thirteenth Amendment in 1865, some Americans seriously considered the idea of separating blacks and whites. As some blacks emigrated to poor urban areas in the South and as their numbers increased, some whites recognized that blacks were becoming a threat to the hard-won victories of higher-priced white labor

(Bonacich 1972). They recognized that the former mechanisms of deference and social distance would no longer allow whites to maintain the subordination of black men and women, and so they insisted on a system of separation. It was not enough to separate residentially; it was necessary to establish a caste system that would deny blacks equal access to most jobs, social and governmental services, schools and colleges, public accommodations, and the right to vote.

In both the South and the North, segregation was practiced long before it became embodied in law. It was a Supreme Court decision, however, that in 1896 established segregation as the law of the land. It was through the medium of statutes, therefore, that domination was ultimately exercised. In other words, it was the polity, not the economy, that suppressed the competition of black urban laborers and that established the shift from paternalistic to competitive race relations (Scott 1977; van den Berghe 1967).

Segregationist laws were passed as early as 1875 in Tennessee; they rapidly advanced throughout the South, and by the 1880s blacks were not only separated on all modes of transportation (Franklin 1947). However, the Civil Rights Act of 1875, which guaranteed black Americans all the privileges and rights of citizenship, was an impediment to the policy of segregation. Consequently, the impediment was removed in 1883, when the Supreme Court declared the Civil Rights Act of 1875 unconstitutional. Soon after that decision, black Americans were banned from most Southern venues, from hotels and other places of public accommodation—restaurants, theaters, and places of public amusement. The process of limiting opportunities for blacks continued, and by 1885 most Southern states had enacted laws requiring separate schools for blacks and whites. Finally, on May 18, 1896, the Supreme Court in the infamous *Plessy v. Ferguson* decision made segregation the law of the land (Kromkowski 1991). Although the North and the South were elated, the implication of the decision and the way it was to be implemented would be considerably different in the two regions. As a result, the consequences and effects of segregation in the South would be different from those in the North.

If segregation had not legitimated the rights of Southern whites to degrade and control blacks,

blacks might have seen opportunities for independent growth in segregation. Segregation in the South meant biracialism, and biracialism meant the creation of black institutions that were to some extent administered and controlled by blacks. Although most blacks in the South worked for whites, they did not have to depend on them for all their basic services: They had separate schools, hospitals, and churches. Most blacks in the South became sharecroppers, working rented land. The land meant debt for the sharecropper, but it also meant a certain amount of daily independence. It is conceivable, therefore, that under a more positive set of circumstances blacks could have focused on the "equal requirement" of the *Plessy* "separate but equal" decision. However, because segregation became the detested symbol of injustice, Southern blacks insisted on destroying it.

As blacks struggled against segregation, they were beaten and murdered. Law enforcement participated in those affronts either by refusing to protect black people or by becoming the perpetrators of violence. Such actions reinforced the view of Southern blacks that segregation was the symbol of black inferiority. As blacks struggled to defend themselves, they learned that sheriffs and law enforcement officials, mayors, governors, the FBI, the federal government, the attorney general of the United States, and even the president participated in one way or another in the maintenance of a system of segregation that declared black people inferior and denied them equal access to the labor market and to educational opportunity.

Although Southern blacks were eventually successful in destroying the system of segregation in the South, blacks in the North, where the *Plessy* decision had been implemented differently, often failed. Because the major problem in the North was not segregation, the strategies of Southern blacks were inappropriate for the problems of Northern blacks and those who moved north. Desegregationist strategies were designed for problems such as residential segregation but not for problems such as poverty and differential access to occupational opportunities. This is why the Southern Christian Leadership Conference left the urban slums of Chicago in 1965, where the real problems were, and attacked the issue of segregated housing in Cicero, Illinois, which for blacks at that time was insignificant.

Although Southern whites insisted on black inferiority, one should not assume that they therefore wanted to dispose of blacks. They needed blacks for at least two reasons: to establish their alleged superiority and to exploit black labor. Blacks had been their slaves, had worked their fields, had stabilized and maintained their households, and had been a source of wealth and sometimes pleasure. Many Southern whites had even developed a degree of affection for blacks.

Northern whites were quite different in this regard. Some knew the value of black Americans, but their major goal was to make certain that blacks and whites remained apart. A biracial system was not required because occupational and economic discrimination kept blacks and whites apart. When and where necessary, whites would use restrictive real estate practices to keep the races separate. Whites in the North wanted blacks to stay completely to themselves unless there was some need for their labor. With the exception of hiring black women, whites did not really want to make competitive use of black labor. It seems that Northern whites wanted blacks to disappear, and so they pretended that they did not exist.

In the South, segregationist policies eventually led to a biracial system that produced unanticipated consequences. It actually laid the groundwork for the development of a black middle class composed of clergy, college administrators and professors, medical doctors, journalists, schoolteachers, artisans, and skilled craftspeople, all of whom had learned to be independent in their respective institutional settings. They were the decision makers and leaders of their people. They would train the new teachers, the new professionals, and even a new business elite. Their protégés would become the new entrepreneurs and open businesses of various kinds—barbershops, beauty shops, grocery stores, restaurants, and nightclubs. They would establish black banks, publish black newspapers, and establish professional societies. Many of the college graduates would become ministers and establish their own churches. In time, all these professionals would combine their resources and expertise and, using their two institutional bases, the school and the church, lead a struggle against the very system that made their existence possible: the system of segregation. In the South segregation did not mean separation only. It meant the right of whites to degrade blacks and treat

blacks unjustly, but mostly it meant the right to keep blacks in an inferior position by denying them equal access and equal opportunity.

Eventually the black church, a product of segregation and discrimination, would become the institutional base for the fight against segregation and discrimination. Not only did the black church provide the leadership, it also provided the following. However, since black churches had existed for decades and their congregations had been ready for change for decades, why did the "movement" take until 1955 to start? A critical component is the size of the black middle and skilled-working classes. In the middle to late 1950s, those two classes constituted approximately 39 percent of the black community, a larger percentage than ever before. World War II had been a major period of opportunity for African Americans, and as a result, they garnered more resources and consequently expected more from the system. In short, they experienced a revolution of rising expectations. They had become intolerant of abuse, the various forms of discrimination they had experienced, and insults to their dignity. They were in need of a social movement.

DESEGREGATION: THE CIVIL-RIGHTS MOVEMENT

The impetus for the civil-rights movement, the movement to desegregate the South, actually began before Mrs. Rosa Parks's heroic refusal in 1955 to give up her bus seat to a white person. The initial stimulus was the May 17, 1954, decision of the Supreme Court in *Brown v. Board of Education* (1954) that the 1896 *Plessy* decision was unconstitutional. Black soldiers returning from World War II and the burgeoning black middle class praised the decision and proclaimed that the *Brown* decision must usher in a new social order.

No sooner had the decision been made, however, than the nation was shocked by the grisly murder of a young teenager, Emmett Till, in Sumner, Mississippi. That murder dramatized the fact that no change in the law would change the customs of Southern whites, and the case demonstrated how the circumstances of blacks in the South were radically different from those of blacks in the North. According to Emmett Till's uncle, Emmett had been bragging to some black youngsters outside a rural store. He claimed to have

white friends, even white girlfriends, in Chicago and showed photographs of his friends. Emmett had just arrived in Sumner and was trying to impress those young boys to gain their friendship. One of the boys apparently said to Emmett, "I bet you won't go into that store and say something to that white lady." Till accepted the challenge, went in, purchased some candy, and in leaving said, "Bye, baby." Late the same night, two or more white men knocked at the door of Emmett's grandfather, Mose Wright, and took the boy away in a car. When Emmett Till was found, he had been mutilated and beaten beyond recognition, with a bullet hole through his temple. The picture of Emmett Till's disfigured body was published in *Jet* magazine by Johnson Publications, a black publishing firm, and black people throughout the nation saw the picture. Till's mother insisted on an open casket. Two men were charged with the murder, but both were found not guilty. Black people recognized that a change in the law was not enough. More had to be done.

Emmett Till was a Northern urban kid who had grown up and apparently gone to school with some liberal whites, and although the commingling of whites and blacks in the North could lead to violence, in some circles it was tolerated. Because the issue in the North was residential separation, it was easy for a black person to find himself in a predominantly black school, though generally there were at least a few white students. More important, however, was the fact that the overwhelming majority of the teachers were white (Jones 1985, p. 180). Those teachers and other professionals usually lived outside the school districts in which they taught. Although they insisted that black schoolchildren obey them, they did not insist that blacks be subservient and inferior. As teachers, they were proud of their successful black students. Northern blacks thus developed self-esteem, a sense of "somebodyness," a belief that they were the equals of others. That attitude was reinforced in black urban enclaves. In the South, however, every contact a black person had with a white person required a demonstration of black inferiority and even fear. The idea of being equal to whites was generally unthinkable, that is, if the idea was to be put into action. Northern blacks were always warned by their relatives when they went to the South that the rules were different there, that not obeying them could place every-

body in jeopardy and could even lead to the loss of life.

Emmett Till was a tough urban kid, not unlike many of the gang members of the 1990s, and the fact that he was not afraid of his captors and refused to stop fighting back made them angrier. He obviously did not know that what he did in the North could get him killed in the South. He had not been warned, or he did not heed the warning.

Emmett Till's murder and the injustice of the final verdict produced mounting frustration. Thus, on December 1, 1955, Mrs. Rosa Parks told a bus driver who asked her to give her seat to a white person, which was the law, that she would not. This galvanized the entire black population of Montgomery, Alabama. The black community organized a bus boycott, and soon the buses were empty. The leadership was surprised (Raines 1977). Black people were fed up. They had always been angered by such demands and customs, but as Christians they had been taught to accept them and hope for change. Now, however, former soldiers and their families who had been patriotic and had sacrificed during World War II had become intolerant. Segregation did not mean biracialism to them. Instead it meant abuse and insult. A social movement had started.

Soon a brilliant young black Baptist minister would join the movement, and even though he was only twenty-six years of age, he would become the leader. That leader, Martin Luther King, Jr., defined the enemy as segregation. Segregation, King insisted, "scars the soul of the segregated. . . . It not only harms one physically, but injures one spiritually." It is a system, asserted King, that "forever stares the segregated in the face saying you are less than, you are not equal to." Segregation denies a human being the right to express his or her true essence; therefore, it must be destroyed. King declared that nonviolence would be the movement's strategy and philosophy. Nevertheless, violence erupted immediately. Whites were resisting, but the Montgomery Improvement Association won its victory when the Supreme Court declared segregated busing unconstitutional. King and his leadership cadre immediately set about the task of desegregating other public facilities in Montgomery. The movement had begun, and from that point on other struggles would erupt sponta-

neously across the South, all of them devoted to desegregation.

As African-American college students observed the activities of Dr. King and his organization, the Southern Christian Leadership Conference (SCLC), they agreed to continue the process of desegregation. Dr. King was desegregating downtown department stores in Montgomery; they would desegregate lunch counters. It was the custom in the South not to serve blacks at lunch counters in the various dime stores, especially the Woolworth's chain. On November 1, 1960, four students from the local black college took seats at the lunch counter in Greensboro, North Carolina. They asked to be served, and when the management refused, they resolved to stay. After a day or two, violence broke out. A group of young white toughs and some older adults began to pull them out of their seats and beat them. The police were called in, but they refused to arrest the perpetrators of the violence. Instead they arrested the victims, those who were involved peacefully in what became known as sit-ins. As a result of the police actions, Southern blacks noted again that not only were the citizens of the South opposed to their rights, so were public officials. Segregation had to be destroyed "lock, stock, and barrel, top to bottom, left to right" (Carmichael 1971) because it also corrupted public officials and officers of the law whose sworn duty it was to protect the citizenry. From this point on segregation was the enemy, and going to jail to end it became a badge of honor.

The issue of segregation on buses involving interstate travel remained a problem even after the Montgomery victory. Therefore, it was not long before groups of Freedom Riders were mobilized to test the Supreme Court decision's relevance to interstate travel. The Freedom Riders included blacks and whites, a fact that should not be forgotten. The Freedom Rides began in May 1961 and were immediately confronted with violence. Buses were bombed. Freedom Riders were beaten unmercifully at several destinations, and some were permanently disabled. The perpetrators were indiscriminate: they beat blacks and whites. Their hatred seemed greater for whites—"nigger lovers," they were called then. The Freedom Riders expected to be protected by the FBI, but J. Edgar Hoover, the director, made it clear that his agency had no intention of protecting those agitators. The failure of the federal govern-

ment to uphold the law in this instance finally communicated to black people and some whites that the existence of segregation had corrupted not just local public officials but even officials of the federal government. The fight had to begin at the top.

The next major chapter in the effort to desegregate the South took place in Albany, Georgia, in 1961. Failing in their desegregation efforts there, King and the SCLC launched a new project to protest segregated lunch counters in downtown Birmingham, Alabama. King was jailed. While in jail, he wrote his philosophically brilliant "Letter from a Birmingham Jail." Although Birmingham's white business leaders agreed on a desegregation plan, King's motel was still bombed. Medgar Evers was shot to death in neighboring Jackson, Mississippi, and four young children were murdered in the bombing of the Sixteenth Street Baptist Church in Birmingham. Blacks learned that even if they could get local public officials and businessmen to change segregationist policies, some Southern whites, perhaps even the majority, would not accept change. They also learned that among the majority there were those who were willing to use violence. Blacks had to have protection from another source.

In 1964, the Student Nonviolent Coordinating Committee (SNCC) began its Freedom Summers Project in Mississippi. Mississippi was considered by blacks the most dangerous state in the South, and it lived up to its reputation. On Sunday, August 4, 1964, Mississippi claimed the lives of James Chaney, Michael Swerner, and Andrew Goodman—the latter two were white. All three were members of SNCC's Freedom Summer Project. Their only offense was that they had volunteered to teach black youth, work with the rural poor, and register blacks to vote. If it was not apparent during the Freedom Rides, it was now apparent that Southern whites would kill anybody, whites included, who opposed their way of life.

Blacks now had a growing collection of concerned Northern whites. Swerner's wife commented that it was unfortunate, but apparently whites had to die before other, complacent whites would listen. The parents of the two young white students, Swerner and Goodman, talked about the martyrdom of their children. They were proud but grief-stricken. They insisted that the monstrous

evil of segregation must be destroyed. Black members of the Congress of Racial Equality (CORE) and SNCC were furious. Some of them had been personal friends of James Chaney, who was black. They blamed the governor of the state and the federal government for what happened in Philadelphia, Mississippi, during the summer of 1964.

As a result of those murders, SNCC and SCLC mobilized a march to Montgomery. Near the end of their march, however, they were attacked by mounted sheriff's officers wielding clubs. Men and women, as well as young adults and children, were beaten.

In summary, the central focus of black struggle in the South from 1955 to 1965 was desegregation. Blacks insisted on desegregating public transportation facilities, public eating establishments, public water fountains, public bathrooms, and public institutions of higher education. As a result of the violence they experienced, black Southerners learned that desegregation required more than protests, it required changes in the law at the national level. A civil-rights bill was required. Certainly a change in the law was required, but even that was not enough. In order for changes to be implemented, government officials had to demonstrate a willingness to protect and defend the rights of African Americans.

It was not long after Selma that Watts, an urban ethnic enclave near Los Angeles, exploded, beginning a series of race riots that developed spontaneously throughout the latter half of the 1960s. Stores were torched and looted. Surveying the destruction in Watts, Dr. King and SCLC decided that it was time to take their movement north. What they were not aware of was that their desegregation strategies would not solve the problems of Northern blacks, because the central problem for that group was *not* segregation. To understand this, it is necessary to contrast the evolution of the black middle class in the South with that in the North.

DESEGREGATION VERSUS INTEGRATION

A biracial system similar to that in the South never surfaced in the American North. As a result, blacks there depended almost completely on whites for employment. Northern whites, furthermore, had not come to depend on black labor, with the

possible exception of domestic labor. Domestic labor, however, did not produce wealth; it was a symbol of surplus wealth. In addition, Northern whites who wanted to remain physically (residentially) separated from blacks did not feel any need to employ them, with the exception of menial labor jobs. With the influx of European immigrants, Northern whites preferred to hire the sons and daughters of Europe rather than the emancipated slaves of the South (Blauner 1972; Jones 1985). Indeed, from the turn of the century to the beginning of World War II, Northern blacks never established a foothold in the manufacturing industries of the North (Jones 1985). According to Blauner, even in ancillary industries such as meatpacking where blacks initially gained a foothold because of the unhealthy working conditions they were actually displaced by European immigrants during the 1930s.

Given their background, the problem for the black middle class in the North was different from that for the black middle class in the South, and the leadership of the civil-rights movement knew it. At one point, Dr. King said that “the struggles of the past decade were not national in scope; they were Southern; they were specifically designed to change life in the South” (1968, p. 70). Northern blacks had only been segregated (de facto) residentially. Otherwise they could ride public transportation and eat at many of the major restaurants, although it was understood that some owners would discourage blacks from coming by being discourteous. The major concern of Northern middle-class blacks, therefore, was not formal desegregation but discrimination and unequal access. They insisted that they should get the same quality of goods or service for their money. Their major concern was reflected in their insistence on greater job opportunities. They rejected the idea of caste barriers in employment, and they insisted that promotions be tied fairly to evaluation, irrespective of race. They rejected job ceilings and the idea of determining job status on the basis of race. These kinds of problems could not be solved by civil rights marches. They could not be solved simply by desegregation or changing the law. Such changes would help, perhaps, but what was required was to get the federal government to establish civil-rights policies that would declare such acts as violations of the law and then, even more important, connect those policies to some kind of

enforcement device so that private corporations and governmental agencies would comply with the law. This is exactly what the Civil Rights Act of 1964 in combination with affirmative action, did.

THE FAILURE OF INTEGRATION: THE URBAN POOR

Soon after the Civil Rights Act was passed by Congress and signed by President Lyndon B. Johnson, Executive Orders 11246 and 11375 were issued. Those orders led to the policy of affirmative action (Black 1981). Affirmative action policies essentially required that all city, state, and federal agencies, as well as any private corporation that contracted with the federal government, make every reasonable attempt to increase the proportion of minority workers in their workforces. Affirmative action was to be a device to address the effects of past discrimination. It did not take long to realize, however, that mostly middle-class blacks were benefiting from affirmative-action policies (Wilson 1987). The reason for this was twofold. First, middle-class blacks were the only ones who had competitive resources (such as skills they had acquired from higher education), owned businesses, or had parents who as a result of their professional status (doctors, dentists, ministers, etc.) were able to provide a competitive advantage for their children. Second, the American economy underwent structural changes that created more opportunities for professional, technical, human service, and clerical staff. As these opportunities increased, affirmative-action policies increased the likelihood that some of those jobs would go to black Americans. It was not long, however, before it also became apparent that neither affirmative-action policies nor the structural shift in the economy would aid black Americans who were poor and unskilled. In fact, as the economy shifted from a majority of manufacturing industries to a majority of service industries, a segmented labor market developed. A segmented labor market generated differential rates of mobility for differing class segments of the same group (Wilson 1978; 1981; 1987).

It is not surprising that when Mayor Richard Daley of Chicago and Martin Luther King, Jr., met early in 1966 and King complained about the slum housing of poor blacks in that city, Daley responded, “How do you expect me to solve the problems of

poverty and joblessness overnight?" King had no answer. He would quickly leave Chicago and the North after unsuccessful attempts both to help the impoverished and to desegregate Cicero, Illinois. It is to Dr. King's credit, however, that he recognized that the problems of the poor had not been solved and that a Poor People's Campaign was required.

Oblivious to the needs of the poor in the black community, Northern blacks who had turned a desegregationist movement into an integrationist movement (those Sowell [1984] incorrectly labels as people with a civil-rights vision) pursued integration with a vengeance. When the Civil Rights Act of 1964 became the law of the land, affirmative action was to be its guiding policy and equal opportunity and equal access the measure of fairness. It was not long, however, before civil-rights advocates recognized that something was amiss not only for the Northern black poor but also for the middle class. For example, although data from the 1970 census showed that black male college graduates in 1969 received a slightly higher average income than did comparable whites, other data demonstrated that the majority of black college students did not graduate from college. In fact, when Fleming (1985) researched this issue and compared the performance of black colleges with limited resources to that of predominantly white urban universities with considerably more resources that attracted black students with higher SAT scores, she found that the black colleges produced more intellectual and psychosocial development among black students than did the white colleges. Further, she found that typically white colleges produced "academic deterioration" among black students and concluded that better facilities and more institutional resources do not necessarily translate into a higher-quality college or university education (Fleming 1985, p. 186). She added that similar findings were reported in desegregated or so-called integrated public schools (Knowles 1962).

The fact is that whether or not schools are integrated, the situation confronting black children in most Northern and Southern public schools is catastrophic. Indeed, for the most part integration has failed black children. Once they enter school, they fall quickly behind their white counterparts on most measures of intelligence and scholastic achievement (Coleman 1966; Denton

1981). In fact, the longer black children remain in school, the further they fall behind. Denton (1981) reports that compared to white children, black children are three times as likely to be labeled mentally retarded, twice as likely to be suspended for discipline and attendance problems, and twice as likely to drop out of high school (White 1984, pp. 102-103). Black students who remain in school on average are two to three years below grade level in the basics—reading, writing, and arithmetic.

Educational integration consequently has often led to less growth and, even worse, the actual deterioration of the academic potential of black students in institutions of higher education. In those situations where deterioration does not actually occur, stagnation does (Black 1981).

These kinds of problems compound in later life such that black students have only "half as much . . . chance as a white child of finishing college and becoming a professional person," twice as much chance of being unemployed, and a one in ten chance of getting in trouble with the law (and, if these students are young males, a one in four chance of involvement with the criminal justice system); finally, as they age, black students have a life expectancy that is five years shorter than that of white adults (White 1984, p. 103).

Without an adequate education, black males become less employable, less marriageable, and more criminal.

Wilson (1981, 1987) examined the combined indicators of unemployment rates, labor-force participation rates, employment-population ratios, and work experience and concluded that not only do these indicators reveal a disturbing picture of joblessness, they also indicate that a growing percentage of young black males are not marriageable, that is, cannot contribute to the support of a family. Examining rates of teenage pregnancy; crime and violence, especially homicide; and increases in substance abuse, Wilson argues that many of these young men are more likely to become predators than responsible workers.

Further, according to Wilson, poverty has compounded in black urban ethnic enclaves. He demonstrates that there has been a significant increase in what he refers to as extreme poverty areas (i.e., areas with a poverty rate of at least 40 percent) in the black urban ethnic enclave. Wilson contrasts

the growth of these areas with low-poverty areas (census tracts with a poverty rate of at least 20 percent) and high-poverty areas (with a poverty rate of at least 30 percent). The number of extreme poverty areas, he emphasizes, increased by a staggering 161 percent.

Wilson also demonstrates that the black community is losing its vertical class integration. Black middle-class and stable working-class families are choosing to live in the suburbs, and as they do, the institutions they used to staff, support, and nourish decline in number and importance.

The eventual demise of ethnic enclaves in urban areas has been experienced by all ethnic groups in America; for Europeans the process has taken from four to six generations. For blacks the process began in the late 1960s and early 1970s. Of course there was resistance to residential integration, as mirrored in the hostility that exploded in Cicero, Illinois, in the 1960s, and it continued in the 1990s. Although blacks residing in white suburbs are often racially harassed, residential integration is gaining momentum even as some whites move out of suburbia to exurbia or back to the city.

It should be noted, however, that the process of ethnic enclave decline for blacks is fundamentally different from that for European ethnics. Europeans settled in urban areas at a time when urban job opportunities were increasingly plentiful. Most of the jobs were in manufacturing and did not require skilled labor. And since Europeans were preferred over blacks, the sheer numbers of jobs allowed them to lift a whole mass of people out of squalor. As economic stability increased, European ethnics began the process of preparing themselves for increased mobility within the American occupational structure. To do this, education was critical—educational institutions are essentially preparatory institutions. In sum, the occupational and economic success of European ethnics required a stable economic base first, education second, and occupational success third (Greeley 1976). The circumstances of black Americans (a sizable segment of whom were denied stable employment opportunities in the North) were totally different, particularly in urban areas and especially in the North.

European ethnics were preferred over black laborers. Consequently, while European ethnics

were reaping the benefits of full employment, blacks were denied equal access to the labor market, undermining their ability to establish a stable economic base. And for those who would come later, after manufacturing jobs actually began to diminish because of the restructuring of the economy, there would be nothing but long-term unemployment. These groups would eventually form the black underclass as one generation of unemployed workers would quickly give rise to another. European ethnics were described by the sociologists of the 1920s and 1930s as socially disorganized (Thomas and Znaniecki 1927). Their communities were plagued by crime, delinquency, gangs, prostitution, and filth, but the availability of employment opportunities in the 1940s and 1950s allowed many to “lift themselves up by their own bootstraps.”

The jobs that are available to blacks now because of the growth in the service sector of the American economy are either jobs that do not pay enough for a person to support a family or require considerable education and training, and so black urban ethnic enclaves are likely to undergo a different kind of transformation than did the European ethnic enclaves of the early 1900s. The middle class will be increasingly siphoned off from such enclaves, leaving behind a large residue of the most despondent and dependent, the most impoverished, the most violent, and the most criminal elements. Without new institutions to play the role of surrogate parents, without some kind of mandatory civilian social service corps, blacks in those communities may become a permanent underclass. A residue was also left behind by European ethnics, but it was much smaller and therefore much less problematic. As the black middle class leaves, it leaves its ethnic community devoid of the leadership or resources needed to regain its health. And as the numbers of female-headed families increase, the middle class will eventually have left the majority of black people behind. Integration, then, has undermined the health and the integrity of the black community.

The counterposition is now being proffered by many people, organizations, and school systems throughout the United States. This can be seen in the proliferation of segregated black programs where black youngsters are being taught only by black teachers. In this context, race clearly

is the critical issue. Gender however, has also become an issue. In many of these schools, black males insist that only they can do the job. Since black women have had to bear the burden of rearing children alone for so long, there is no doubt that they can use some help. One critical problem remains for people of this persuasion, however, and that is the continuing trend of black middle-class and stable working-class flight. Can the black community stem the tide? It is not suggested here that the black middle class can solve the problem alone but rather that it must provide the leadership, as it did in the segregated black institutions of the South, and that government must pay for it. Can the exodus be diminished?

Possibly, the passage of anti-affirmative action legislation and the increased reliance on standardized testing in higher education may alert the black middle class that the opportunities for their children are diminishing. Already they are starting to send their children to historically black colleges and universities in record numbers. This is a major shift in black higher education, and the number of available admissions is limited. As their children's opportunities decrease, maybe they will come to see that in America the opportunities of black Americans will always be dependent upon the amount of pressure that blacks as a people can bring to bear on the system.

In the last few months of 1998, several anti-affirmative action programs were passed—Proposition 209 in California and Initiative 200 in Washington, for example. These initiatives were passed despite the demonstrated benefits of affirmative action for the broader society.

ALBERT WESLEY BLACK, JR.

SEGREGATION INDICES

Residential segregation has been a prominent topic in sociology since Burgess (1928) published his landmark study more than seventy years ago, and for almost as long, sociologists have argued about how to measure it. The debate has ebbed and flowed, and for a time the issue seemed to have been settled. In 1955, Duncan and Duncan published a landmark article (Duncan and Duncan 1955) demonstrating that there was little information in any of the prevailing indices that had not been captured already by the index of dissimilarity. For twenty years afterward, that measure was employed as the standard index of residential segregation.

This *Pax Duncanae* came to an abrupt end in 1976 with the publication of a critique of the dissimilarity index by Cortese and colleagues, ushering in a period of debate that has not ended (Cortese et al. 1976). Over the ensuing decade, a variety of old indices were reintroduced and new ones were invented, yielding a multiplicity of candidates. In an effort to bring some order to the field, Massey and Denton (1988) undertook a systematic analysis of twenty segregation indices they had identified from a review of the literature. They argued that segregation is not a unidimensional construct but encompasses five distinct dimensions of spatial variation. No single dimension is intrinsically more "correct" than any other; each reflects a different facet of the spatial distribution of social groups.

The five dimensions they identified are evenness, exposure, clustering, concentration, and cen-

tralization. To verify that conceptualization, Massey and Denton (1988) carried out a factor analysis of indices computed from 1980 census data for U.S. metropolitan areas. Their results showed that each index correlated with one of five factors corresponding to the dimensions they postulated. On theoretical, empirical, and practical grounds, they selected a single "best" indicator for each dimension of segregation. The dimensional structure of segregation and Massey and Denton's (1988) selection of indices have been reaffirmed using 1990 census data (Massey et al. 1996).

The first dimension of segregation is evenness, which refers to the unequal distribution of social groups across areal units of an urban area. A minority group is segregated if it is unevenly spread across neighborhoods. Evenness is not measured in an absolute sense but is scaled relative to another group. It is maximized when all areal units have the same relative number of minority and majority members as the city as a whole and is minimized when minority and majority members have no areas in common.

The index of dissimilarity quantifies the degree of departure from an even residential distribution. It computes the number of minority group members who would have to change neighborhoods to achieve an even distribution and expresses that quantity as a proportion of the number that would have to change areas under conditions of maximum unevenness. The index varies between zero and one, and for any two groups X and Y it is computed as:

$$D = .5 \sum_{i=1}^n \left| \frac{x_i}{X} - \frac{y_i}{Y} \right| \quad (1)$$

where x_i and y_i are the number of group X and group Y members in areal unit i and X and Y are the number of group X and group Y members in the city as a whole, which is subdivided into n areal units.

Among its properties, the index is inflated by random factors when the number of minority group members is small relative to the number of areal units (Cortese et al. 1976). It is also insensitive to the redistribution of minority group members among areal units with minority proportions above or below the city's minority proportion

(James and Taeuber 1985; White 1986). Only transfers of minority members from areas where they are overrepresented (above the city's minority proportion) to areas where they are underrepresented (below the minority proportion) affect the value of the index.

The property means that the dissimilarity index fails the "transfers principle," which requires that segregation be lowered whenever minority members move to areas where they constitute a smaller proportion of the population. This and other problems led James and Taeuber (1985) to recommend using another measure of evenness, the Atkinson index (Atkinson 1970). Massey and Denton (1988), however, pointed out that the Atkinson index and dissimilarity indices are highly correlated and generally yield the same substantive conclusions. Moreover, the Atkinson index is actually a family of indices, each of which gives a slightly different result, creating problems of comparability. Given that D has been the standard index for more than thirty years, that its use has led to a large body of findings, and that that index is easy to compute and interpret, Massey and Denton (1988) recommended using it to measure evenness in most cases.

White (1986) points out, however, that another index may be preferred in measuring segregation between multiple groups, since the dissimilarity index is cumbersome to compute and interpret when the number of groups exceeds two. Thus, if one wants to generate an overall measure of segregation between ten ethnic groups, separate dissimilarity indices will have to be computed between all possible pairs of groups and averaged to get a single measure. An alternative index is Theil's (1972) entropy index, which yields a single comprehensive measure of ethnic segregation. The entropy index also can be expanded to measure segregation across two or more variables simultaneously (e.g. ethnicity and income) and can be decomposed into portions attributable to each of the variables and their interaction (see White 1986).

The second dimension of segregation is exposure, which refers to the degree of potential contact between groups within the neighborhoods of a city. Exposure indices measure the extent to which groups must physically confront one another because they share a residential area. For

any city, the degree of minority exposure to the majority is defined as the likelihood of having a neighborhood in common. Rather than measuring segregation as a departure from an abstract ideal of "evenness," however, exposure indices get at the *experience* of segregation from the viewpoint of the average person.

Although indices of exposure and evenness are correlated empirically, they are conceptually distinct because the former depend on the relative size of the groups that are being compared, while the latter do not. Minority group members can be evenly distributed among the residential areas of a city but at the same time experience little exposure to majority group members if they constitute a relatively large share of the population of the city. Conversely, if they constitute a small proportion of the city's population, minority group members tend to experience high levels of exposure to the majority regardless of the level of evenness. Exposure indices take explicit account of such compositional effects in determining the degree of segregation between groups.

The importance of exposure was noted early by Bell (1954), who introduced several indices. However, with the establishment of the *Pax Duncanae* in 1955, sentiment coalesced around the dissimilarity index and exposure was largely forgotten until Lieberson reintroduced the P^* index in the early 1980s (Lieberson 1980, 1981). This index has two basic variants. The interaction index (${}_xP^*_y$) measures the probability that members of group X share a neighborhood with members of group Y, and the isolation index (${}_xP^*_x$) measures the probability that group X members share an area with each other.

The interaction index is computed as the minority-weighted average of each neighborhood's majority proportion:

$${}_xP^*_y = \sum_{i=1}^n \left[\frac{x_i}{X} \right] \left[\frac{y_i}{t_i} \right] \quad (2)$$

where x_i , y_i , and t_i are the numbers of group X members, group Y members, and the total population of unit i , respectively, and X represents the number of group X members citywide. The isolation index is computed as the minority-weighted average of each neighborhood's minority proportion:

$${}_xP^*_x = \sum_{i=1}^n \left[\frac{x_i}{X} \right] \left[\frac{x_i}{t_i} \right] \quad (3)$$

Both indices vary between zero and one and give the probability that a randomly drawn group X member shares a neighborhood with a member of group Y (in the case of ${}_xP^*_y$) or with another group X member (in the case of ${}_xP^*_x$). Values of ${}_yP^*_x$ and ${}_yP^*_y$ can be computed analogously from equations (2) and (3) by switching the x and y subscripts. When there are only two groups, the isolation and interaction indices sum to one, so that ${}_xP^*_y + {}_xP^*_x = 1.0$ and ${}_yP^*_x + {}_yP^*_y = 1.0$. The interaction indices are also asymmetrical; only when group X and group Y constitute the same proportion of the population does ${}_xP^*_y$ equal ${}_yP^*_x$.

P^* indices can be standardized to control for population composition and eliminate the asymmetry (Bell 1954; White 1986). Standardizing the isolation index yields the well-known correlation ratio, or η^2 (White 1986). Stearns and Logan (1986) argue that η^2 constitutes an independent dimension of segregation, but Massey and Denton (1988) hold that it straddles two dimensions. Since it is derived from P^* , η^2 displays some properties associated with an exposure measure, but standardization also gives it the qualities of an evenness index. Massey and Denton (1988) demonstrate this duality empirically and argue that it is better to use D and P^* as separate measures of evenness and exposure. Nonetheless, Jargowsky (1996) has shown that one version of η^2 yields a better and more concise measure of segregation when one wishes to measure segregation between multiple groups simultaneously (e.g., between income categories).

The third dimension of segregation is clustering, or the extent to which areas inhabited by minority group members adjoin one another in space. A high degree of clustering implies a residential structure in which minority areas are arranged contiguously, creating one large enclave, whereas a low level of clustering means that minority areas are widely scattered around the urban environment, like a checkerboard.

The index of clustering recommended by Massey and Denton (1988) is White's (1983) index of spatial proximity, SP. It is constructed by calculating the average distance between members of

the same group and the average distance between members of different groups and then computing a weighted average of those quantities. The average distance, or proximity, between group X members is

$$P_{xx} = \sum_{i=1}^n \sum_{j=1}^n \frac{x_i x_j c_{ij}}{X^2} \quad (4)$$

and the average proximity between members of group X and group Y is

$$P_{xy} = \sum_{i=1}^n \sum_{j=1}^n \frac{x_i y_j c_{ij}}{XY} \quad (5)$$

where Y is the number of group Y members city-wide, x_i and y_j are the numbers of group X and group Y members in units i and j , and c_{ij} is a distance function between these two areas, defined here as a negative exponential: $c_{ij} = \exp(-d_{ij})$. The term d_{ij} represents the linear distance between the centroids of units i and j , and d_{ij} is estimated as $(.6a_i)^{.5}$, where a_i is the area of the spatial unit. Use of the negative exponential implicitly assumes that the likelihood of interaction declines rapidly as the distance between people increases.

Average proximities also may be calculated among group Y members (P_{yy}) and among all members of the population (P_u) by analogy with equation (4). White's SP index (1983) represents the average of intragroup proximities, P_{xx}/P_u and P_{yy}/P_u , weighted by the fraction of each group in the population:

$$SP = \frac{XP_{xx} + YP_{yy}}{TP_u} \quad (6)$$

SP equals one when there is no differential clustering between group X and group Y and is greater than one when group X members live nearer to each other than they do to group Y members. In practice, SP can be converted to a zero-to-one scale by taking the quantity $SP-1$ (Massey and Denton 1988). White (1984) also has proposed a more complex standardization by taking $f(d_{ij})=d_{ij}^{-2}$, which yields a statistic equivalent to the proportion of spatial variance explained.

Jakubs (1981) and Morgan (1983a, 1983b) have proposed that D and P^* be adjusted to incorporate the effects of clustering. Massey and Denton

(1988) argue against this procedure because it confounds two different dimensions of segregation. They maintain that it is better to measure clustering directly as a separate dimension than to try to adjust other measures to reflect it.

The fourth dimension of segregation is centralization, or the degree to which a group is located near the center of an urban area. In the postwar period, African-Americans became increasingly isolated in older central cities as whites gravitated to the suburbs. Centralization is measured by an index that reflects the degree to which a group is spatially distributed close to or far away from the central business district (CBD). It compares a group's distribution around the CBD to the distribution of land area around the CBD by using a formula adapted from Duncan (1957):

$$CE = \left(\sum_{i=1}^n X_{i-1} A_i \right) - \left(\sum_{i=1}^n X_i A_{i-1} \right) \quad (7)$$

where the n areal units are ordered by increasing distance from the CBD and X_i and A_i are the respective cumulative proportions of group X members and land area in unit i .

In most circumstances, the centralization index varies between plus one and minus one, with positive values indicating a tendency for group X members to reside close to the city center and negative values indicating a tendency for them to live in outlying areas. A score of zero means that the group has a uniform distribution throughout the metropolitan area. The index states the proportion of group X members who would have to change their area of residence to achieve a uniform distribution around the CBD.

The last dimension of segregation is concentration, or the relative amount of physical space occupied by a minority group in the urban environment. Concentration is a relevant dimension of segregation because discrimination restricts minorities to a small set of neighborhoods that together account for a small share of the urban environment. The index of concentration takes the average amount of physical space occupied by group X relative to group Y and compares that quantity to the ratio that would obtain if group X were maximally concentrated and group Y were maximally dispersed:

$$CO = \frac{\sum_{i=1}^n \frac{x_i a_i}{X} \sum_{i=1}^n \frac{y_i a_i}{Y} - 1}{\sum_{i=1}^{n_1} \frac{t_i a_i}{T_1} \sum_{i=n_2}^n \frac{t_i a_i}{T_2} - 1} \quad (8)$$

where areal units are ordered by geographic size from smallest to largest, a_i is the land area of unit i , and the two numbers n_1 and n_2 refer to different points in the rank ordering of areal units from smallest to largest: n_1 is the rank of the unit where the cumulative total population of units equals the total minority population of the city, summing from the smallest unit up, and n_2 is the rank of the areal unit where the cumulative total population of units equals the majority population, totaling from the largest unit down. T_1 equals the total population of areal units from 1 to n_1 , and T_2 equals the total population of areal units from n_2 to n . As before, t_i refers to the total population of unit i and X is the number of group X members in the city.

In most circumstances, the resulting index varies from minus one to plus one; a score of zero means that the two groups are equally concentrated in urban space, and a score of minus one means that group Y's concentration exceeds group X's to the maximum extent possible; a score of positive one means the converse. In certain circumstances, however, Egan et al. (1998) demonstrate that whenever the number of group X members is very small and the areas in which they live are very large, the index becomes unbounded in the negative direction. Thus, caution should be used in measuring the concentration of groups with very few members.

Which of these five indices of segregation is chosen for a particular application depends on the purpose of the study. All are valid measures, and arguments about which one is "correct" or "best" are meaningless, since they measure different facets of segregation. D provides an overall measure of evenness that is highly comparable with prior work, widely understood, readily interpretable, and independent of population composition. P^* captures the degree of inter- and intragroup contact likely to be experienced by members of different groups and directly incorporates the effect of population composition. Most recent work has relied most heavily on these two segregation mea-

sures (Massey and Denton 1993; Frey and Farley 1994, 1996; Massey and Hajnal 1995; Peach 1998).

Neither D nor P^* is inherently spatial, however, and each may be applied to study nongeographic forms of segregation, such as segregation between men and women across occupations (see Jacobs 1989). The remaining three dimensions are relevant whenever it is important to know about the physical location of a group in space. If the extent to which group members cluster is important, SP should be computed; if it is important to know how close to the city center a group has settled, CE may be calculated; and if the amount of physical space occupied by a group is relevant, CO is the appropriate index.

The most comprehensive understanding of residential segregation is achieved, however, when all five indices are examined simultaneously. That multidimensional approach yields a fuller picture of segregation than can be achieved by using any single index alone. Thus, Massey and Denton (1989) found that blacks in certain U.S. cities were highly segregated on all five dimensions simultaneously, a pattern they called "hypersegregation." Denton (1994) has shown that this pattern not only persisted to 1990 but extended to other metropolitan areas. By relying primarily on the index of dissimilarity, prior work overlooked this unique aspect of black urban life and understated the severity of black segregation in U.S. cities.

SELF-CONCEPT

The self is the central concept used to represent the individual in sociological social psychology. The importance of the self reflects the influence of symbolic interactionism in sociology. In the last twenty years social psychologists trained in psychology also have developed a strong interest in the self as their emphasis has shifted from behaviorism to cognitive theories (Baumeister, 1998).

STABLE SELF-CONCEPTS

The social psychological conception of the self is based on the idea that people are reflexive, responding to themselves just as they respond to other "objects." Since reflexive thinking requires language, it is assumed that infants and nonhuman animals lack a self-concept. However, there is some evidence that chimpanzees are aware of what they look like, since they notice markings on their faces (Gallup 1977). This self-recognition suggests that some animals and prelinguistic humans have a rudimentary sense of self but that it lacks meaning or content.

Some sociologists, particularly those with a philosophical and qualitative orientation, view the

self as a process involving people's internal conversations. Those with a more positivistic and quantitative orientation emphasize more stable aspects of the self. From their point of view, the self-concept refers to all the ways in which people describe themselves. These linguistic descriptions refer to the way people think they are, not to their actual personal characteristics.

People describe themselves in many different ways. One way to find out about the content of the self-concept is to ask respondents to answer the question "Who am I?" Studies of responses to this question reveal that people often think of themselves in terms of their roles (or role identities). For example, people often describe themselves on the basis of their sex, age, race, and occupation. Stryker (1968) suggests that these and other roles are organized in a hierarchy according to their salience for a person. The salience of a role is based in part on the extent to which adequate performance of that role affects relationships with "significant others." Salience is also a function of how distinctive a role is (McGuire and Padawer-Singer 1976). For example, a female is more likely to mention her gender in describing herself if she is in a group of males.

People also describe themselves in terms of personal attributes, such as "lazy," "smart," and "attractive." In contrast to roles—which usually are described with nouns—these self-concepts are more likely to be defined by adjectives. They often reflect individuals' conceptions of their abilities or performance in different roles. For example, on a questionnaire children can be asked, "How smart in school do you think you are, among the smartest, above average, average, or below average?" Respondents sometimes try to be objective in answering this type of question and to place themselves according to the criteria they think the researcher is using. Sometimes they report more subjective feelings about where they stand in accordance with their own standards. For example, professional athletes may be dissatisfied with their level of play even if they think they are better than most people. Other personal attributes involve self-attributed traits such as "aggressive" or "nice." Also included here are the ways in which people characterize their beliefs and attitudes. For example, people may conceive of themselves as prejudiced or not independently of whether they are prejudiced by an objective standard.

While individuals think of themselves in terms of specific roles and specific evaluations of their personal attributes, they also have a more general opinion of themselves (Gecas and Burke, 1995). This global evaluation Brown, 1993 called *self-esteem* and is measured by statements such as "I feel I do not have much to be proud of" and "At times I think I am no good at all" (Rosenberg 1965). The global nature of self-esteem is indicated by the tendency of individuals to describe themselves as consistently positive or negative on different personal attributes. However, self-esteem also has different dimensions, such as self-efficacy and self-worth (Gecas 1982). Self-esteem, like depression and anxiety, usually is considered an aspect of mental health. Research using longitudinal data has shown that self-esteem affects and is affected by depression among adolescents (Rosenberg et al. 1989).

There is considerable evidence that people are motivated to enhance their self-esteem. For example, respondents tend to give inflated evaluations of themselves on anonymous questionnaires. In addition, subjects in experiments are more likely to explain their successes in terms of internal attributes, such as effort and ability, while attributing their failures to external factors, such as task difficulty (Bradley 1978).

SITUATIONAL SELF-IMAGES

Some self-statements are more temporary than those described above, involving the roles or personal attributes people use to describe themselves in particular situations. For example, a woman may think of herself as a "teacher" when she is talking to her students and as "foolish" when she has made a mistake. If repeated, these situational images may become stable as people come to believe them. Emotions also can be considered temporary self-concepts if one thinks of them as statements about how people say they feel rather than as a physiological process. Thinking about emotions in this way leads to the examination of how emotions are affected by social processes.

Some scholars focus on the presentation of situational self-images to others (Goffman 1959). Borrowing language from the theater, they view behavior as a performance displayed in front of an audience, a form of self-presentation or impression

management. This approach presents a challenge to those who attempt to measure self-concepts, since it suggests that responses on questionnaires reflect self-presentation rather than privately held beliefs. Researchers try to minimize this problem by using carefully worded questions and guaranteeing anonymity.

Situational self-images often are studied in laboratory experiments. For example, subjects may be asked to respond after receiving false feedback about themselves. To determine whether a self-description involves impression management, the privacy of subjects' responses may be manipulated. When behavior in front of an audience is different from behavior performed in private, this suggests that the behavior reflects impression management rather than privately held beliefs. This type of research also can tell researchers something about how behavior is affected by subjects' awareness that they are being studied. Some behaviors in experimental settings have been shown to result from subjects doing what they think is expected of them (Orne 1962).

Self-presentation behavior is particularly likely to occur when people have done something that is apt to gain disapproval from an audience. When people find themselves in these "predicaments," they are embarrassed and engage in various forms of "facework" to avoid a negative image. Frequently, people give excuses and justifications in an attempt to explain their behavior and avoid condemnation from others. Research shows that subjects are more likely to use self-presentation tactics when they are dependent on the audience for rewards. An important role of self-presentation in conformity, altruism, aggression, and other behaviors has been demonstrated. For example, self-presentation processes are important in explaining the behavior of bullies and the tendency for people to retaliate when attacked (Tedeschi and Felson 1994).

DEVELOPMENT OF SELF-APPRAISALS

Three processes have been used to explain why people have favorable or unfavorable opinions about themselves: (1) attribution, (2) comparison, and (3) reflected appraisal. The first two processes have been emphasized by psychological social psychologists, while the third has been the focus of

sociological social psychologists, particularly those sympathetic toward symbolic interactionism.

According to attribution theory, people learn about themselves and others in similar ways. Individuals base judgments about themselves on observations of their own behavior just as they base judgments about others on their observations of those people's behavior (Bem 1972). These judgments are socially influenced, since beliefs about the association of behaviors and personal attributes are learned from others. In judging their abilities, for example, people rely in part on observations of their performances on tasks they believe reflect those abilities. Thus, children who get high grades tend to attribute more ability to themselves. Individuals are likely to attribute a high level of ability to themselves when there is a consistent pattern of success (Kelley 1967).

When people view their behavior as being caused by external forces, they treat it as uninformative about themselves. However, when they view their behavior as being internally caused, there is likely to be some change in their self-appraisals. For example, research shows that external rewards sometimes can reduce the motivation of children to do things they have enjoyed in the past, such as playing with magic markers (Deci and Ryan 1980). If they are rewarded for playing with magic markers, they tend to lose interest when they are no longer rewarded because they attribute their behavior to the reward rather than to their intrinsic motivation. The external reward can decrease their interest in the behavior because it affects their judgments about why they did it. More generally, there is evidence that people's behaviors can affect their attitudes, just as their attitudes can affect their behaviors (Liska et al. 1984). For example, a person may decide that she likes an activity because she observes herself voluntarily engaging in that activity.

Comparison processes are also important factors in the development of self-appraisals. They affect the standards people use in evaluating their behavior. For example, students may think a B is a good grade or a poor grade depending on the standard they use. Standards are a function of two types of comparisons. A *temporal comparison* is a comparison of present performance and past performance. People are likely to judge their recent performances more harshly if they have been suc-

cessful in the past. A *social comparison* is a comparison of one's own behavior to the behavior of others. The more successful the others are, the higher the standard is and the more negative the self-appraisal is. Thus, subjects are more negative in describing themselves when there is another person with very positive qualities present than they are when that person has negative qualities (Morse and Gergen 1970). This implies that self-appraisals tend to be more favorable if one is a "big fish in a small pond." For example, research shows that high school students tend to have more negative self-appraisals of their academic ability if their schoolmates are bright (Felson and Reed 1986). However, sometimes the performance of others has a positive effect on self-appraisal. This occurs when people "borrow status" from successful others with whom they are associated and "bask in reflected glory" (Cialdini et al. 1976).

Festinger (1954) suggested that social comparison processes result from the desire to gain accurate appraisals of one's abilities and to find out whether one's opinions are correct. When objective information is not available, people compare themselves to others. Further, Festinger suggested that people usually choose similar others for comparison because the behavior of those persons provides the most information. Some research has examined the hypothesis that people evaluate their abilities by comparing themselves to others who are similar to themselves on attributes (other than ability) that are related to performance. For example, comparisons with people who have engaged in a similar effort will be the most informative. Similarly, if a boy believes that gender is related to athletic performance, he will compare himself to other boys in order to decide how much athletic ability he has.

According to the reflected appraisal process, people come to see themselves as others see them, or at least as they think others see them. This notion of the "looking-glass self" focuses on how individuals think they appear to others (Cooley 1902). According to Mead (1934), this helps explain the initial formation of self in young children. Mead suggested that when children role-play, they respond to themselves when they play the role of others. This role-taking process leads them to see themselves as objects. Later, the appraisals of significant others shape the specific content of people's self-concepts. The appraisals

of others are accurately perceived and then are incorporated into the self-concept. Significant others may have special expertise or may be parents or close friends, but those who influence one aspect of the self-concept do not necessarily influence other aspects.

Experimental research suggests that subjects' self-appraisals are affected by the false feedback they receive from others. Survey research—which examines correlations between self-appraisals, the appraisals of significant others, and a person's perception of those appraisals—suggests that the appraisals of significant others are not perceived very accurately (Schrauger and Schoeneman 1979). Apparently, rules of politeness limit the amount of open communication—particularly criticism—making it difficult for people to find out what others think of them (Felson 1980). When feedback is given, it tends to involve specific comments about behavior rather than global evaluations. When praise is given, it often is not believed. As a result, people usually have only vague, general impressions of what others think of them and self-appraisals tend to be idiosyncratic and idealized (Felson 1989). While others are in some agreement about a person, that person does not share in the consensus. In addition, ambiguous feedback allows people to think more favorably about themselves and thus protect their self-esteem.

This discussion also applies to global self-esteem. Educators and parents may overemphasize the importance of praise in the development of self-esteem in children. While there is evidence that parents' praise and other supportive behavior affects the self-esteem of children (Felson and Zielinski 1989), successful performance in activities that children value may be more important.

There are other processes that increase the correspondence between people's appraisals of themselves and the appraisals of others. First, in some instances, people have access to the same information others have. For example, children's self-appraisals of their ability and their friends' appraisals of them correspond, because both are affected by the children's grades. Second, some other people can influence self-concepts if they have control over formal evaluations. For example, evidence shows that teachers influence self-concepts because they assign grades, but that is usually the extent of their influence in this area.

The discussion above has focused on the interpersonal environment. Social-demographic characteristics also affect self-appraisal. Social class, for example, has been shown to affect the self-esteem of adults but not that of children (Rosenberg and Pearlin 1978). Blacks and whites, by contrast, have similar levels of self-esteem (Porter and Washington, 1993; Wylie, 1979). A key element here appears to be whether people associate with others who are like themselves. The self-esteem of minority group members is likely to be lower in more heterogeneous settings where invidious comparisons are made and where members of higher-status groups may act in prejudicial ways.

CONSEQUENCES OF SELF-CONCEPTS

The way individuals think of themselves has an important impact on how they behave. Thus, people who think of themselves in terms of particular role identities tend to act in ways that are consistent with those identities. For example, a man who identifies himself as a father will engage in the behaviors he associates with being a father. These roles provide links between the individual and society. Individuals are plugged into the social structure through the roles that are mapped onto selves. In other words, role performance reflects the way people think about themselves. Of course, people vary in terms of the importance they attach to different roles. When people must decide between roles, they tend to choose the role more salient to them (Stryker 1968). For example, the choice between doing work and playing with children on a Sunday afternoon may reflect the relative salience of family and occupational roles.

Success and failure frequently are attributed to variations in self-confidence. Self-appraisals and performance are certainly correlated, but this does not necessarily mean that the former causes the latter. Longitudinal studies, which attempt to disentangle these causal relationships, suggest that students' global self-esteem does not affect their academic performance. However, there is evidence that specific self-appraisals of ability affect performance. Longitudinal analyses of high school students suggest that self-appraisals of academic ability have an effect on grades (Felson 1984). Self-appraisals of ability affect performance through two processes: effort and test anxiety. Those who are self-confident about their ability are likely to

work harder because they think effort will bring success. In addition, they are less anxious when they are tested, and so nervousness does not interfere with their performance. However, the effect of self-appraisal on performance probably is not as strong as people think. The effect of grades on self-appraisal is much stronger, suggesting that success is more likely to lead to self-confidence than self-confidence is to lead to success.

Causal interpretation has been problematic in the study of the effects of self-concept on other behaviors as well. While self-esteem and various self-appraisals have been shown to correlate with behavior, it is difficult to show that the self-concepts cause the behaviors. Relatively few studies have attempted to sort out these relationships. Exceptions include longitudinal studies that suggest that low self-esteem increases delinquency among adolescents (e.g., Kaplan 1980; Rosenberg et al. 1989). In general, criminologists today are more likely to attribute criminal behavior to low self-control than to low self-esteem.

An interesting experimental method for examining the effects of self-concept on behavior has been suggested by Duval and Wicklund (1972). They suggest that since much human behavior is automatic or habitual, people do not always think about themselves before they engage in a behavior. These authors argue that self-concepts affect behavior when attention is directed toward the self rather than toward the environment, a condition they call "objective self-awareness." Objective self-awareness is likely to occur when people are in unfamiliar surroundings, when there are disruptions in social interaction, and when people find themselves in a minority. Mirrors are commonly used in experiments to create objective self-awareness. These studies show that subjects are more likely to engage in behavior that is consistent with their self-standards when they are facing a mirror (e.g., Beaman et al. 1979). In addition, there are individual differences: Some people are more chronically focused on themselves as objects. The behavior of such people is more likely to be consistent with their self-appraisals and internalized standards.

A number of researchers have examined the role of self-concepts in resisting change. For example, research suggests that people are motivated to

reaffirm self-concepts when they are challenged (Swann 1984). Markus (1977) considers the generalizations people make about themselves as "self-schemas" that affect the way they process information. Self-schemas usually refer to personality traits (e.g., "independent" and "generous") that people attribute to themselves on the basis of past actions. Once formed, they affect the information people attend to and remember and how quickly they process it. For example, people are more likely to learn and recall information that is associated with their self-schemas. In other words, self-schemas act like filters, guiding the processing of incoming information. Thus, self-schemas have a conservative function because they lead people to focus on information that is consistent with their views of themselves.

SUMMARY

The determinants and consequences of the self have become central concerns for both sociologically and psychologically trained social psychologists. Self-concepts depend on the way individuals think they are viewed by others, on individuals' observations of their behavior, and on the standards individuals use to judge that behavior. These judgments in turn depend on the performance (for comparison) and appraisals of others. Self-concepts have consequences in that they affect which roles are performed and how successfully they are performed. They also affect conformity and deviance and the management of impressions. Finally, they are important in their own right as indicators of mental health.

RICHARD B. FELSON

SELF-ESTEEM

Self-esteem is a concept that has been used to explain a vast array of emotional, motivational, and behavioral phenomena. Most Americans believe intuitively that low self-esteem is undesirable; indeed, the link between low self-esteem and depression, shyness, loneliness, and alienation supports the general idea that low self-esteem is an aversive state. The view that self-esteem is a vital component of mental health is also evident in the popular media and in educational policy. Low self-esteem has been viewed as the root cause of societal problems ranging from drug abuse to teenage pregnancy to poor school performance. A number of educational and therapeutic programs have been developed to solve these problems by increasing self-esteem. Self-esteem is one of the most frequently examined constructs in sociology and psychology, with more than 15,000 research articles referring to it over the past thirty years. This entry reviews the research that has focused on the conceptual and functional basis of self-esteem.

Self-esteem is defined as the evaluative component of the self-concept, the extent to which people view themselves as likable and worthy as opposed to unlikable and unworthy. As a self-reflexive attitude, self-esteem is composed of cognitive and affective components. Self-esteem is related to personal beliefs about skills, abilities, and future outcomes as well as the strategies people use to gain self-knowledge. However, the personal experience of self-esteem is more emotional than rational. Some people dislike themselves in spite of objective evidence suggesting that they should feel very good about themselves. Many successful doctors, lawyers, professors, and entrepreneurs are filled with self-loathing despite their objective career success.

The term "self-esteem" sometimes is used interchangeably with terms such as "self-confidence," "self-efficacy," and even "self-concept," but such usage is inaccurate and should be discouraged. Self-confidence and self-efficacy refer to the belief that one can attain specific outcomes. Although people with high self-esteem often are self-confident, evaluative reactions to personal outcomes vary greatly, and it is possible for people to be confident about attaining a goal without feeling good about themselves in the process. The term "self-concept" refers to the components of self-

knowledge and includes things such as name, race, ethnicity, gender, occupation, likes and dislikes, and personality traits. As such, self-concept refers to cognitive beliefs and other forms of self-relevant knowledge (Felson 1992). Although self-esteem clearly is influenced by the contents of the self-concept, they are not the same thing.

STRUCTURE AND MEASUREMENT OF SELF-ESTEEM

An important issue in the literature on self-esteem is whether self-esteem is best conceptualized as a unitary global trait or a multidimensional trait with independent subcomponents. An example of a multidimensional trait model is Tatarodi and Swann's (1995) differentiation between self-liking and self-competence. From this perspective, it is possible for people to like themselves generally but view themselves as not particularly efficacious at various tasks. Conversely, it is possible for people to view themselves as generally competent but not really like themselves. Mismatches between self-liking and self-competence lead to biases in the interpretation of social and performance feedback that confirm the level of self-liking. For instance, those who are high in self-liking but low in self-competence perceive negative feedback more positively than do those who are low in self-liking but high in self-competence.

Global self-esteem is best conceptualized as a hierarchical construct with three major components: *performance* self-esteem, *social* self-esteem, and *physical* self-esteem. Each component can be broken down into progressively smaller subcomponents. Performance self-esteem refers to one's sense of general competence and includes intellectual ability, school performance, self-regulatory capacities, self-confidence, efficacy, and agency. People who are high in performance self-esteem believe that they are smart and capable. As will be discussed below, personal beliefs about performance are poorly related to objective outcomes. Social self-esteem refers to how people believe they are perceived by others. It is perception rather than reality that is critical here. If people believe that others, especially significant others, value and respect them, they experience high social self-esteem even if others truly dislike them or hold them in contempt. The influence of these reflected appraisals on self-esteem is an integral part

of Cooley's (1902) "looking-glass self" and has been implicated in the development of self-esteem by sociological theorists such as George Herbert Mead and Stanley Rosenberg. People who are low in social self-esteem often experience social anxiety and are high in public self-consciousness. They are highly attentive to their public images and worry about how others view them. Physical self-esteem refers to how people view their physical bodies and includes things such as athletic skills, physical attractiveness, and body image as well as physical stigmas and feelings about race and ethnicity.

How are these subcomponents of self-esteem related to global self-esteem? James (1892) proposed that global self-esteem is the summation of specific components of self-esteem, each of which is weighted by its importance to the self-concept. In other words, people have high self-esteem to the extent that they feel good about the things that matter to them. Not being good at tennis is irrelevant to the self-concept of a nonathlete, and doing poorly in school may have little impact on inner-city youth who do not identify with mainstream values (Steele 1997). Pelham (1995) and Marsh (1995) debated the value of global versus specific component models. Pelham's research generally supports the Jamesian view that the centrality of self-views is an important predictor of the emotional response to the self (i.e., one's feelings of self-esteem), whereas Marsh claims that domain importance does not have a strong impact on self-esteem. Although the jury is still out on this issue, the concept of domain importance is a central feature of most theories of self-esteem.

In terms of measurement, most research uses global measures of self-esteem, since this is viewed as having the greatest theoretical importance (Baumeister 1998). The most widely used measure of global self-esteem is the Rosenberg (1965) scale, which consists of ten general statements such as "On the whole, I am satisfied with myself," "I certainly feel useless at times," and "I take a positive attitude toward myself." Unfortunately, scores on this scale tend to be tightly clustered around its mean, limiting its predictive value. A review of self-esteem measures conducted by Blascovich and Tomaka (1991) recommended the Revised Feelings of Inadequacy Scale (Fleming and Courtney 1984), which is a modified version of the Janis and Field (1959) scale. This scale has five factors: social

confidence, school abilities, self-regard, physical appearance, and physical ability. The total score on this scale is widely used as a measure of global self-esteem.

Another issue in the measurement and definition of self-esteem is whether it is best conceptualized as a stable personality *trait* or a context-specific *state*. Most theories of self-esteem view it as a relatively stable trait: If one has high self-esteem today, one probably will have high self-esteem tomorrow. Around this stable baseline, however, there are fluctuations; although people generally may feel good about themselves, there are times when they may experience self-doubt and even dislike themselves. In terms of research, the selection of trait or state measures of self-esteem depends on whether one is interested in predicting long-term outcomes or in the immediate effects associated with feelings about the self. Obviously, measures of state self-esteem are more useful for the latter group. The State Self-Esteem Scale (Heatherton and Polivy 1991) is a commonly used measure that has been shown to be sensitive to laboratory manipulations of self-esteem. This scale measures context-specific feelings related to performance, social, and physical self-esteem. Measures of trait and state self-esteem are highly correlated. However, frequent fluctuations in state self-esteem have been found to be associated with increased sensitivity to and reliance on social evaluations, increased concern about how one views the self, and even anger and hostility (Kernis 1993). In general, those with a fragile sense of self-esteem respond extremely favorably to positive feedback and extremely defensively to negative feedback.

SOURCES AND FUNCTIONS OF SELF-ESTEEM

A central issue in self-esteem pertains to its source. Research in psychology and sociology has focused on the role of early childhood experiences, especially in terms of parental treatment. Harter has incorporated the Jamesian and Cooley views of the development of self-esteem into a general model of self-esteem development (Harter 1993). Harter proposes that reflected appraisals about important dimensions affect the development of self-esteem but that specific domains are closely linked to potential audiences. According to her theory, parents are particularly concerned about behav-

ioral conduct and school performance, and therefore, children's beliefs about how their parents view them on these dimensions influence self-esteem. Children who do well scholastically and behave in accordance with parental expectations believe that their parents support and love them. However, parents have less impact than do peers on self-perceptions related to physical appearance, athletic ability, and peer likability. To obtain the support of one's peers, children believe they have to be attractive, athletic, and likable. Failure to obtain support from either parents or peers can lead to feelings of hopelessness, depression, and poor global self-esteem. Harter's model offers a significant advance over earlier developmental theories by integrating importance and social support from a domain-specific perspective.

Further evidence for socialization processes can be found when one considers the influence of gender differences. A number of studies suggest that boys and girls diverge in their primary sources of self-esteem, with girls being more influenced by relationships and boys being more influenced by objective success. Stein et al. (1992) examined participants in an eight-year longitudinal study of adolescent growth and development. During adolescence, an agentic orientation predicted heightened self-esteem for males but not for females, whereas a communal orientation predicted heightened self-esteem for females but not for males. The possibility that males and females differ in terms of what constitutes the self-concept was also addressed by Josephs et al. (1992). In a series of studies, men and women were given false feedback indicating that they had deficits either on a performance dimension (e.g., competition, individual thinking) or on a social dimension (e.g., nurturance, interpersonal integration). Consistent with predictions, men high in self-esteem enhanced their estimates of being able to engage successfully in future performance behaviors, whereas women high in self-esteem enhanced their estimates of being able to engage successfully in future social behaviors. The authors of this entry recently compared the experiences of boys and girls in a summer tennis camp designed to increase self-esteem (Hebl et al. 1999). Scores on a children's version of the state self-esteem scale showed that both boys and girls had increases in overall self-esteem during the tennis camp, but whereas boys gained self-esteem primarily in the performance self-esteem

domain, girls gained self-esteem primarily in the social self-esteem domain. In each case it can be seen that boys gain self-esteem from getting ahead whereas girls gain self-esteem from getting along.

From a completely different perspective, some researchers have begun to explore the possibility that self-esteem is determined more by biology than by socialization. Although direct evidence is minimal, there is circumstantial evidence that some components of self-esteem are based in biology. Twin studies have suggested that self-esteem is moderately heritable, with estimates ranging from 30 to 50 percent (Kendler et al. 1998). In addition, traits known to be associated with self-esteem, such as extraversion and neuroticism, have long been known to have a genetic component. Kramer (1993) argues that self-esteem is rooted in activity of the serotonergic neurotransmitter system. He notes that pharmacological treatments that increase the activity of serotonin are associated with an increased sense of self-confidence and self-esteem. However, there have not been any systematic or rigorous tests of this hypothesis. The possibility that self-esteem has a biological component remains an important empirical issue.

Some theorists have portrayed self-esteem as a mechanism that has evolved through adaptation to promote survival of the species. Accordingly, self-esteem is viewed as a force that promotes feelings of confidence and competence that may lead to superior performance across a broad range of activities. Interestingly, this perspective can be used to explain gender differences in the major sources of self-esteem. Throughout human evolutionary history, males were of value to the group primarily through their role as hunters and protectors whereas women gathered food and nurtured offspring. Hence, being good at tasks closely associated with ancestral sex roles may be associated with increased feelings of self-esteem. However, because theories of evolution and socialization predict the same gender pattern for self-esteem, it is impossible to clarify which perspective is correct or whether they are equally correct or incorrect. Baumeister (1998) has noted that simple evolutionary accounts of self-esteem are difficult to accept because of the rather negligible benefits associated with self-esteem and the possibility that high self-esteem may promote overconfidence and excessive risk taking.

A novel and important functional account of self-esteem has been proposed by Leary and his colleagues. Leary begins with the assumption that humans have a fundamental need to belong that is rooted in evolutionary history (Baumeister and Leary 1995). For most of human evolution, survival and reproduction depended on affiliation with a group. Those who belonged to social groups were more likely to survive and reproduce than were those who were excluded from groups and left to survive on their own. According to Leary, self-esteem functions as a monitor of the likelihood of social exclusion. When people behave in ways that increase the likelihood that they will be rejected, they experience a reduction in state self-esteem. Thus, self-esteem serves as a monitor, or sociometer, of social acceptance and/or rejection. At the trait level, those with high self-esteem have sociometers that indicate a low probability of rejection and therefore do not worry about how they are perceived by others. By contrast, those with low self-esteem have sociometers that indicate the imminent possibility of rejection and therefore are highly motivated to manage their public impressions.

CONSEQUENCES OF HAVING HIGH OR LOW SELF-ESTEEM

Self-esteem has both cognitive and affective components. Accordingly, a number of researchers have examined the cognitive and affective reactions of those with high and low self-esteem. The overall view suggests that people process information in a way that confirms and supports their chronic self-views. People with high self-esteem actively defend their positive self-views, whereas those with low self-esteem appear to be less able to do so. This section reviews research that has examined differences between individuals with high and low self-esteem.

Self-esteem differences have been reported for a wide range of intrapsychic phenomena, including emotional reactions, cognitive processes, and motivational states. There are obvious differences in how individuals with high and low self-esteem feel about themselves; the positivity and negativity of self-feelings are of course central to self-esteem. For instance, people with low self-esteem are more likely to report being depressed and anxious than are those with high self-esteem. These differences appear to be more subjective

than objective. Researchers have used diary studies to examine whether high and low self-esteem people differ in their daily moods and emotions (Campbell et al. 1991). Compared with individuals with high self-esteem, individuals with low self-esteem judged the events in their lives more negatively and as having a greater impact on their moods. However, when outside judges read participants' diaries, they could not distinguish between the events experienced by participants with high and low self-esteem. Thus, similar circumstances are perceived and experienced differently as a function of a person's self-esteem level. In terms of specific emotional states, there are no differences in how high and low self-esteem individuals experience impersonal emotions (e.g., happiness), but there are differences in how they experience self-relevant emotions (e.g., pride and shame). People with high self-esteem are more likely to report pride, whereas those with low self-esteem are more likely to report shame. Once again, this pattern is independent of actual events in the lives of people with high and low self-esteem.

A robust finding in social psychological research is that everyone feels good after receiving positive feedback regardless of one's self-esteem level. People with low self-esteem like to hear good things about themselves just as much as do people with high self-esteem, and both groups hope to be successful in life. However, people with high self-esteem are much more likely to believe positive feedback. People with low self-esteem are distrustful of overly positive feedback because it contradicts what they believe to be true about themselves. Swann (Swann et al. 1987) argues that people with low self-esteem are attracted to negative information because it validates and confirms their negative self-views. Swann likens the conflict between an emotional preference for positivity and a cognitive preference for negativity to being caught in the cross fire between two warring factions.

A consistent theme in the literature on self-esteem is that self-esteem involves a cognitive bias in processing evaluative and social information. In a world filled with ambiguities and uncertainties, people selectively construct their own reality through biased encoding, retrieval, and interpretation of life events. Research on information-processing styles shows that high self-esteem is associated with cognitive strategies aimed at en-

hancing self-appraisals and thinking of oneself in the most positive way. These objectives are accomplished by means of deeper encoding and more frequent retrieval of positive self-knowledge coupled with an avoidance of negative self-relevant information. That is, people with high self-esteem pay attention to information that says good things about them but ignore information that challenges a positive self-view. By contrast, the processing style associated with low self-esteem is one of self-consciousness and rumination. Individuals with low self-esteem focus on their own thoughts and feelings, often dwelling on negative life events. They are vigilant for information that confirms a negative self-view and ruminate on past failures, embarrassments, and setbacks in a nonproductive fashion.

Biased information processing helps people maintain their existing self-views. For example, an individual with high self-esteem may create a personal definition of what it means to be a "good student" that includes areas in which he or she excels while downplaying the importance of areas of personal deficiency. People with high self-esteem also believe that their talents are unique and special but that their weaknesses are common and trivial. As a result of their selective processing of evaluative information, people with high self-esteem are more adept at defending their self-esteem from external threats. Thus, people with high self-esteem discredit sources of negative feedback while readily accepting positive feedback. These people are also more likely to show a self-serving bias, which refers to the tendency of individuals to take personal credit for success but to blame failure on external circumstances. Some studies in fact find a reversal of the self-serving bias in individuals with low self-esteem such that they credit success to the environment (e.g., an easy task or luck) and blame themselves for failure. People with low self-esteem appear to be generally less able to put a positive spin on negative personal information. For instance, after receiving a negative evaluation, individuals with low self-esteem are more likely to dwell on their weaknesses while individuals with high self-esteem recruit thoughts about their strengths. Differential responses to feedback appear to be an automatic consequence of self-esteem that does not require effort or conscious initiation (Dodgson and Wood 1998).

Baumeister and Tice (Baumeister et al. 1989) have proposed that the basic distinction between

high self-esteem and low self-esteem is motivational. People with high self-esteem are concerned primarily with self-enhancement, whereas people with low self-esteem are concerned primarily with self-protection. The self-enhancement motive emphasizes feeling good about oneself with the aim of increasing one's self-esteem. Thus, people with high self-esteem look for areas in which they can excel and stand out. When they fail at a task, they set higher goals so that they can prove they possess exceptional skills. By contrast, people with low self-esteem are concerned with avoiding humiliation, embarrassment, and rejection. Low self-esteem individuals' self-protective orientation guards against feeling even worse about themselves. Thus, when they fail at a task, they set more modest goals so that they do not lose further esteem through failure.

Self-esteem is known to be relevant to interpersonal behavior. For instance, high and low self-esteem people differ in their perceptions of interpersonal acceptance or rejection. A study in which participants were told that they had been rejected or accepted by their peers (Nezlek et al. 1997) showed that individuals with low self-esteem perceived peer inclusion and exclusion accurately, corresponding to experimental feedback. High self-esteem individuals, however, always perceived inclusion, even when they had been told they had been personally rejected. In general, people with high self-esteem believe that others admire, like, and respect them, whereas people with low self-esteem do not feel that others provide them with adequate support. This pattern fits in well with the reflected appraisal model of self-esteem that was discussed earlier. Because they are concerned with how others view them and are uncertain about their own beliefs, people with low self-esteem are especially yielding; they change their minds and behaviors to conform to the beliefs and opinions of others. Conversely, people with high self-esteem are confident about their opinions and tend not to be influenced by others. Indeed, they often view their own ideas and beliefs as being superior to those of others.

The currently available evidence paints the cognitive, affective, and social worlds of those with high and low self-esteem to be quite different. But do people truly differ as a function of self-esteem? When people are interviewed, there appear to be great differences between those with high and low

self-esteem. When describing themselves, high self-esteem people say they are physically attractive, intelligent, socially skilled, outgoing, upbeat, optimistic, and satisfied with the state of their lives. Low self-esteem people depict themselves in a much less positive light and describe themselves by using more neutral and negative self-aspects than do those with high self-esteem. Unfortunately, the use of self-reports is problematic because they are confounded by one's level of self-esteem. High self-esteem people generally like and believe favorable things about themselves, and it is not surprising that they rate themselves highly on positive personality traits. However, the extent to which high self-esteem individuals actually possess and exhibit these positive traits—and the extent to which they do not possess or exhibit negative traits—is not well known.

The few studies that have compared claims by high and low self-esteem people to objective standards have not found differences between self-esteem groups. For instance, although people with high self-esteem think of themselves as more attractive than do people with low self-esteem, both groups are seen as equally attractive by others (Diener et al. 1995). Ratings of intelligence show the same pattern: High self-esteem people claim to be more intelligent, but intelligence tests show no differences as a function of self-esteem (Gabriel et al. 1994). Similarly, self-report data indicate that high self-esteem individuals are more likable than are low self-esteem individuals. However, likability ratings of high and low self-esteem people by interaction partners show no relation to self-esteem (Brockner and Lloyd 1986). Overall, most researchers have concluded that there are few differences in objective outcomes between those high and low in self-esteem (Baumeister 1998). A review of the literature by the California Task Force to Promote Self-Esteem and Personal and Social Responsibility (1990) conceded that “the associations between self-esteem and its expected consequences are mixed, insignificant, or absent” (Mecca et al. 1989, p. 15). Self-esteem appears to be related to *subjective* rather than *objective* life outcomes.

It is even possible that high self-esteem is associated with negative outcomes in some contexts. For instance, although high self-esteem typically is associated with superior self-regulation, some evidence suggests that high self-esteem may

interfere with self-regulation when self-esteem is threatened. Relative to when they succeed, failure elicits higher goals and increased persistence—even on unsolvable tasks—in those with high self-esteem (McFarlin et al. 1984). Baumeister et al. (1993) demonstrated that ego threats sabotage self-regulation among those with high self-esteem. In this research, high and low self-esteem participants chose performance contingencies in which greater payoffs were associated with loftier and riskier personal goals. In the control condition, those with high self-esteem set appropriate goals and showed superior self-regulation. However, after ego threat (being told to play it safe if they “didn't have what it takes”), high self-esteem participants set inappropriate, risky goals and ended up with smaller monetary rewards than did participants with low self-esteem. Under threat, participants with high self-esteem also were significantly more likely to choke under pressure (i.e., to show performance decrements under conditions where superior performance is important) than were participants with low self-esteem. These findings suggest that people with high self-esteem are prone to self-regulatory failure in certain situations.

Similarly, extremely positive self-appraisals have been linked to poor interpersonal outcomes, especially when such self-appraisals are challenged or discredited. Baumeister et al. (1996) examined the literature linking self-esteem to interpersonal violence. In contrast to widely held assumptions that low self-esteem is associated with violent actions, they found a consistent pattern in which those who thought highly of themselves but encountered a threat or challenge to their positive self-views were more likely to act in hostile and violent ways. Similarly, Kernis and colleagues (Kernis 1993) have demonstrated that when it is unstable, high self-esteem is associated with increased hostility and aggression. They found that those with unstable high self-esteem are likely to respond to ego threats with self-aggrandizement and defensiveness (Kernis et al. 1997).

Other evidence suggests that those with highly positive self-views may exhibit poor interpersonal skills. Colvin et al. (1995) examined individuals with apparently inflated self-views, as indicated by the difference between self and other ratings. They found that those individuals were viewed by others as hostile and unlikable. In addition, during a structured and highly charged debate, such indi-

viduals engaged in a variety of negatively evaluated interpersonal behaviors, such as bragging, interrupting their partners, and showing an overall lack of genuine concern for their partners. Once again, these patterns are most likely to occur when high self-esteem individuals feel personally challenged. Schlenker et al. (1990) exposed high and low self-esteem subjects to contexts in which they were motivated to make a positive impression on a critical or a supportive audience. They found that high self-esteem subjects became egotistical when the evaluative pressures were greatest. They concluded that "people with high self-esteem become more boastful as the social stakes increase" (p. 891). Similar findings have been reported by Schneider and Turkat (1975), who found that high self-esteem subjects who also expressed high needs for social approval presented themselves much more positively after negative feedback than they did after positive feedback. Perhaps ironically, high self-esteem subjects who receive negative feedback about their intellectual abilities claim to have especially good social skills. However, the available evidence does not support their claims.

SUMMARY

Having high self-esteem confers a number of benefits to those who possess it: Such people feel good about themselves, are able to cope effectively with challenges and negative feedback, and live in a social world in which they believe that people value and respect them. Although there may be some negative consequences associated with having extremely high self-esteem, most people with high self-esteem lead happy and productive lives. People with low self-esteem see the world through a more negative filter, and their general dislike for themselves influences their perceptions of everything around them. It is striking that the objective record does not validate the subjective experiences of those with high and low self-esteem. The interesting unanswered questions about self-esteem are related to what allows people to hold such positive or negative views of themselves in spite of objective evidence. For instance, it is possible that self-esteem is rooted in neurochemistry and therefore is not sensitive to contextual influence, but this has not been established. It is equally plausible that self-esteem is a cognitive style that develops through early socialization experiences, but this perspective also requires more conclusive

evidence. In any case, the subjective experience of having high or low self-esteem plays an important role in how people interpret the world around them.

SENTIMENTS

To define the affective state, four terms can be used: passion, state of mind, emotion, and sentiments. The term "passion" is linked with the philosophical and literary tradition and designates a violent tension that the individual sustains for a certain duration. States of mind or moods are affective states of low intensity that are durable and pervasive, lack an immediately perceptible cause, and can influence initially neutral events. The term "emotion" indicates an intense affective state of short duration with a precise external or inner cause, a clear cognitive content, and the

ability to reorient attention. Most scholars agree that emotion is a psychological construct with several components: (1) cognitive: finalized by the stimulus caused by emotion, (2) physiological: from the participation of the neurovegetative system, (3) expressive: linked with movement, (4) motivational: linked with intentions and the tendency to act or react, and (5) subjective: consisting of the sentiment felt by the individual.

Sentiments are more enduring than are emotions (e.g., hatred compared with a momentary explosion of anger) and are more cognitively structured. Sentiments may last seconds (embarrassment) or months (mourning) and may be more or less intense, conscious or unconscious, and controllable or outside one's control. When an individual names a sentiment by using a certain terms he or she refers to different elements: affection, cognitive contents or structures of evaluation, awareness of the level of readiness for action, and awareness of the body. Sentiments pervade daily life and are found in several artistic forms: music, poetry, literature, and painting.

In the philosophical tradition, the affective dimension appeared as a perturbation of human behavior that was considered the result of reasoning. Plato was the first to define passions as "diseases of the spirit." For the Stoics, passion was a disease that gets hold of the entire spirit at the expense of reason: Crisippo considered it an unbridled agitation, an unstoppable force that makes the ego leave the self. For Aristotle, passions act as a destabilizer of the rational powers of the individual. An ambivalent attitude toward passions developed at the beginning of the modern age. They were execrated during the age of illuminism, exalted during the romantic era, condemned during the period of critical rationalism and rehabilitated in the postmodern age.

THE INATTENTION OF THE FOUNDERS

For a long time sociology, evidently influenced by the hegemonic philosophical paradigm, excluded the study of the affective dimension from its theoretical concerns. Affects thus were relegated to anthropology and psychology. The founders of sociology saw the role of sentiments in social life as rather marginal. An interest in sentiments can be

found in Durkheim, who saw them as agents and factors of cohesion in the formation of solidarity and morality. In his view, sentiments are learned and internalized during rituals and collective ceremonies through the sharing of emotions.

In Pareto's terminology, *residui* are sentiments or the expressions of sentiments inscribed in human nature and *derivazioni* are the conceptual systems of justification with which individuals disguise their passions or give an appearance of rationality to propositions or behaviors that are not rational. People rarely behave in a logical way but always want to make their fellow people believe that their conduct is logical. The main characteristic of human nature is that it lets itself be guided by sentiments and puts forward pseudological justifications for sentimental attitudes. According to Pareto, nonlogical is not necessarily equivalent to illogical: Emotions follow some principles. The logic of sentiments Pareto identified can be summarized in five points. First, while reason is analytic, sentiment is synthetic. Second, sentiment follows justificational and persuasive principles. Third, sentiments are inaccurate, indefinite, and indeterminate. Fourth, sentiments may be ambivalent and conflicting. Fifth, sentiments can take on extreme, absolute characteristics that prevent learning from reality.

Weber begins by distinguishing four types of action: rational action in relation to an aim, rational action in relation to a value, affective or emotional action, and traditional action. The action Weber calls affective results from the state of mind or mood of an individual: the slap a mother gives to her unbearable child or the fist of a soccer player who loses his temper. Action, that is, is defined with reference not to an aim or system of values but to the emotional reaction of an agent who finds himself or herself in certain circumstances. The distinctive characteristic of the world in which people live is rationalization: a firm is rational, as is the bureaucratic management of a state, while scientific action is a combination of a rational action in relation to an aim and a rational action in relation to a value, which is truth.

The importance of the emotional factor in the formation of charisma and the religious spirit is mentioned explicitly by Weber. Perhaps the spirit of capitalism is seen by Weber as deriving from the

pressure of strong and pervasive emotions such as anxiety, desperation, and fear on which Calvinist doctrine was founded. Weber does not ignore affection, but he considers it a parasite of reason, a noise producer, a disturber in the ascent to rationality.

SOME PRECURSORS

Sentiments are central in the work of Simmel, who thoroughly analyzed their role and formation, especially in his essay on love and his reflections on sociability. For Simmel, emotional reality is the foundation of an individual's experience and social interactions. Individuals, he maintains, enter into relationships with one another through the sentiments. Social relations produce other sentiments that therefore are always connected to interactions. The Italian protosociologist Ferrero studied fear and tried to read the historical existence of civilizations in the light of such sentiments. For Ferrero, fear is the spirit of the universe. People, like all creatures, are molded by fear: To overcome fear, people arm themselves, but because they are armed, they cannot help fearing each other. Consequently, people become the most frightening and the most frightened beings because they are the only ones able to manufacture deadly and thus frightful instruments of offense. Moreover, fantasy creates imaginary dangers of all kinds. The human condition therefore is characterized by a permanent dialogue with fear. Even sacrificial rituals are interpreted as expedients to exorcise the fear that every person has of her or his fellow creatures, who are seen as potential bearers of death. Thus, the salute is a technique of mutual reassurance, a ceremony through which one manifests the absence of aggressive intentions toward others. The main instrument for defeating the original fear is power: the institutionalization of the monopoly of violence. This solution transforms people into subject by taking away their freedom. As a result of the monopoly of violence among those who exercise command, peace is guaranteed, but its price is very high. The fear of war of all against all is eliminated, but it is replaced by fear of power.

However, Ferrero emphasizes that those in power fear the subjects over whom they exercise command. No government is certain of the total

obedience of its citizens, and a revolt can break out among the most compliant subjects. In this way, feedback develops between the use of force and fear: The more those in power fear their subjects, the more they resort to instruments of repression, the more they are repressive, and the more they feel fear. For the usurper of power there is not only an external threat, as Plato, Senofonte, Machiavelli, and Montesquieu showed, but also an internal torment: fear of one's own illegitimacy. In *Community and Society*, Toennies, in theorizing about the fundamental category of "community," emphasized the sentiment of belonging. He recognized in sentiments a relative autonomy when he assumed that they were a guide for action and that the fundamental directions of human action depend largely on inner conditions (dispositions) and to a lesser extent on external conditions (circumstances). Veblen based his concept of the wealthy class on a complex mix of sentiments (superiority and inferiority, emulation and imitation) and showed their influence on collective behavior.

Scheler showed, through a phenomenology of resentment, the tight link between the sphere of individual sentiments and that of collective behavior. For Scheler, the forming of resentment and its mode of expression have an individual component tied to temperament and a social component: "The way and the measure in which resentment takes shape in entire groups and in individuals is linked in the first place to the disposition of the human material at issue, in the second place to the structure of society in which this lives." Therefore, there is constant interaction between individual attitudes and collective mentality. The manifestation of resentment is linked to social inequalities and the inability to heal an offense, true or presumed, through vengeance or rebellion. The spreading of resentment creates the psychological premises that become linked with the structural premises, leading to the explosion of mass movements.

For Scheler, "the formal structure of the expression of resentment is always the same: A is approved of, supported and praised not for his intrinsic qualities, but with the intention—that remains unsaid in words—to deny, devaluate and reprove B." The refusal of wealth is nothing but a repressed desire for wealth among the poor, who despise what they want but cannot have. Like

Tocqueville, Scheler sees in democracy the fuel of resentment. He maintains: "It will possess a maximum charge of resentment a society in which political rights and others of almost equal kind, jointly with a formal social parity publicly recognized, go together with great differences of power, of effective possession of assets and effective cultural formation."

In the 1960s, MacIver explored the sentiment of attachment to a community, referring to the complex of memories, traditions, customs, and institutions shared by the members of a community. This sentiment of community, which is acquired through the socialization process, has three main elements: (1) the sentiment of we, (2) the sentiment of role, and (3) the sentiment of dependence. The first leads to the identification of a person with the others; the second is associated with the functions individual members perform in the community and expresses the way in which the individual normally realizes his or her belonging to the entire community. The sentiment of dependence expresses the dependence of a person on the community, which is considered a necessary condition for his or her existence, lessening his or her isolation. In modern society, an individual belongs not only to a single community but also to specific associations, as social life is subject to the process of differentiation and specialization. Moreover, the sentiment of belonging to the community seems to persist only in rural areas; in urban areas, it is replaced by attachment to other, less inclusive and more sectorial groups. In rural areas, the sentiment of attachment to the community remains strong because of people's longer periods of residence. An enlarged sentiment of community is the sentiment of nationality, which is produced by historical circumstances and supported by common psychological factors.

Helen Lynd was the first to recognize the importance of shame in the complex dynamics of identity growth. According to Lynd, the values of a culture do not stimulate the experience and communication of emotions such as shame, joy, wonder, and love. However, once trust has been created—allowing one to reveal oneself and thus look for the ways in which to communicate shame—the risk of being exposed may become an experience of abandonment, self-revelation, and intimacy with others. Once accepted, shame leads a person to a

greater awareness and to an enrichment of his or her personality.

CONTEMPORARY APPROACHES

Sociologists' interest in emotions and sentiments can be traced to the mid-1970s. In that period, one of the foundations of sociology—the idea of a rational social actor guided in his or her conduct, motivation, and choices by a utilitarian and instrumental logic while sentiments play a residual and socially insignificant role—was questioned. This model started showing its abstractness and rigid partiality and its inadequacy in explaining the complexity of individual and collective action, which depends on how people feel and manage their emotions. Thus, emotions started losing their residual and even disturbing function and were recognized as integral parts of social action.

This crack in the rational actor construction went together with a new cultural climate characterized by attention to the self and to the world of private and interpersonal relations, a desire for authenticity, and the revaluation of sentiments. Emotions and sentiments became objects of knowledge, attention, and communication both in daily life and in sociological reflection. In women and youth subcultures especially, the expression of one's sentiments was encouraged. Advertising saw the positive value of the affective dimension and used it in its campaigns by linking it to products potentially able to stimulate emotions, such as sports, film, television, cars, and even food. The revaluation of the affective dimension also was stimulated by the increase in the number of magazines dealing with psychoanalytic issues and the growth of university courses on psychological subjects: In many textbooks, at least one chapter is devoted to the dynamics of sentiments and emotions. A widespread representation of emotions has resulted from cinematic and television fiction.

In the growing social sciences literature on sentiments and emotions, five approaches can be singled out: (1) sociohistorical, (2) positivist, (3) functionalist, (4) conflict, (5) interactionist, and (6) socialconstructivist.

The Sociohistorical Approach. According to Elias, the phenomenon of civilization is a matter of controlling emotions and natural impulses. From

the documents he collected, it can be inferred that anger, which now seems psychopathic, was in medieval times considered normal, and that the desire to destroy was openly confessed, while it now is admitted with shame or used to attract attention.

For Elias, emotions and their expressive forms are strongly correlated with the social contexts in which they manifest themselves. Every social structure, he maintains, corresponds to a structure of emotions and sentiments, and their inhibition, repression, or free expression depends on their being functional to different social systems.

According to Elias's theory of the process of civilization, daily life in the Middle Ages was characterized by abuse and violence. People, lived in a permanent state of insecurity and fear. The situation began to change when a stronger territorial power prevailed on the weaker ones and the monopoly of the state's legal violence gradually was established. Violence, reserved to specialized bodies, began to be excluded from other areas of life, and some calm, protected zones started to form. Within those areas, "good manners" developed and eventually replaced violence and abuse in interpersonal relations. Starting in the higher ranks, individuals began to abandon spontaneity and impetuosity and learned to dominate themselves, control their impulses and passions, and regulate aggressiveness.

For Elias, institutionalized sports channel and often divert people's natural emotions. Hunting, for example, often has been recognized as a substitute for war. In their free time, people can carry out activities that incite emotions closely tied to those of normal life.

The Positivist Approach. According to Kemper's positivist approach, people have phylogenetically inherited a set of primary emotions—fear, anger, joy, and depression—that serve evolutionary and adaptive needs and are sensitive to certain contingent environmental situations. For human beings, the main contingent environmental situations are of a social nature; therefore, social vicissitudes determine emotions unless society intervenes normatively with different demands.

Kemper states that emotions are universally elicited by two fundamental dimensions of social relationships: power and status. Possessing ade-

quate power produces feelings of security, possessing excessive power produces feelings of guilt, and possessing inadequate power produces anxiety. Fear develops when the power of two interacting individuals is uneven.

Anger emerges from interactions in which an expected, habitual status is denied or withdrawn by an actor considered responsible for the status reduction. Depression is tied to a loss of status, and the person considers himself or herself responsible for the loss. Individuals feel shame if they perceive that their status is too high; in the opposite case, they feel depression. Satisfaction results from interactions in which power is not felt as threatening and the status is expected and desired.

The positivist approach to the study of emotions attempts to (1) treat emotion as a variable, (2) undertake studies that embrace various cultures, (3) develop the history of particular emotions, and (4) examine the link between emotions and sociological variables such as social class, gender, and ethnicity.

The Functionalist Approach. In the functionalist perspective, innate emotional behavior may have developed in the course of evolution because of its value in being functional to adaptation. The purpose of emotions is to face emergency situations by estimating the importance of the events in order to organize appropriate action. First, emotions prepare the body to react to hostile or dangerous situations, predisposing the organism for the emergency and thus leading to rebalance and adaptation. As Darwin noted, fear is an emotion common to various species, as it is conducive to survival, aids in adaptation, and is linked to a safeguarding mechanism that is evident in the first phases of life.

Emotions also have the function of interpersonal signaling. That is, they produce the effect of communicating the state of the organism to the outside world. The variety and specificity of emotions reflect the flexibility of the forms of adaptation to the environment. Therefore, for example, fear helps avert danger, sadness is a call for help, and happiness is a phase of recovery after the attainment of a goal.

The Conflict Approach. The conflict theory of emotion can be found in the works of Coser and

Collins, according to whom the crucial determinant of emotion is membership in competing groups and classes. Emotion, Coser says, is a resource that can be mobilized, directed, and exploited in conflicts over power. Moreover, it can be used to create emotional loyalty and solidarity. Human biological nature supplies emotional energy, but the differentiation and management of emotion are achieved by competing groups that fight for control over the means of emotional reproduction, that is, the resources for assembling the ritualistic arousal of emotions in support of one's group. According to conflict theory, persons not only manage their own emotions but also to stimulate, suppress, or transform emotions in other people. This also happens at the collective level. For example, hostility perceived as coming from external groups increases in-group solidarity, and emotion is intensified by the presence of a large number of people in an expressive ritual.

For Collins, emotional energy is an essential part of the model of chain ritual interaction, and he maintains that the basis of every interaction is a minimum feeling of positivity toward others. Thus, a person accepted in a conversation receives from that experience not only an increase of positive emotional energy but also additional emotional resources (trust, warmth, enthusiasm) with which to negotiate in the next interaction.

The Interactionist Approach. In the interactionist approach, emotions essentially result from social interaction. They differ according to the social and cultural worlds one belongs to and thus continuously change.

Symbolic interactionists draw a distinction between biological emotions and social sentiments. An emotion is fixed in the human organism, is experienced concurrently with bodily change, and consists of a fixed configuration of bodily sensations and gestures in response to simple, standard stimuli. In contrast, a sentiment originates through cultural definition and social interaction and continues over time in enduring social relationships. The expressive gestures and internal sensations of a sentiment are culturally defined and can be altered according to the situation and on a broader cultural scale, since sentiments are not fixed in human biological nature. In the course of interaction, differences among sentiments are developed,

and sentiments are redefined continuously through encounters and relationships.

Goffman has examined the system of rules that dominate interaction and the efforts made by individuals to be in tune with the emotional states of a situation. This control of impressions essentially is a strategy for avoiding embarrassment or shame and is inspired by pride and the desire to make a positive impression.

According to Goffman, embarrassment is linked to the impression of people transmitted to others and is a phenomenon that blocks interactions among individuals and makes them unable to interact. The attitudes deriving from this process violate behavioral standards shared with others and cause inappropriate behaviors. Embarrassment, however, is a normal part of everyday life, since it is a manifestation of adaptation to social organization. One structures in several ways other people's perception of oneself according to the various roles one takes on. What creates embarrassment and uneasiness for an individual is the diversity of multiple interactive situations, which imply different and often discordant rules of behavior. Goffman also describes the process of emotion management: By managing the impressions others have of them, people facilitate their goals and attract the responses they need. Often, however, expression management involves inauthentic sentiments to avoid situationally inappropriate emotional gestures, such as laughter at a funeral or a forced smile on meeting an enemy. Emotion management is guided by implicit and shared social rules about appropriate or inappropriate displays of sentiment and emotion. These emotional rules constitute a normative framework of expectations that people take into account.

The Social Constructivist Approach. For constructionist theorists, emotions are not natural answers but experiential and expressive models determined by the sociocultural context; they are learned answers that have neither natural contents nor functions and are tied to the conservation of the individual and the species. From the constructionist point of view, emotions are complex syndromes whose meaning and function can be understood only by referring to the social system of which they are part.

According to constructionists, emotions are functional, as they are socially constructed and pre-

scribed to maintain and support a certain system of values. Therefore, a community will try to promote emotional manifestations that are functional to the maintenance of a socially founded moral order and will try to penalize and remove emotions that are in opposition to the moral order. Examples of how an emotion with a negative connotation, such as hatred, can be promoted and prescribed by a community include Nazi Germany and the Ku Klux Klan. In both cases, hatred became the accepted emotional behavior, as its negative side was socially nationalized. Does the ethics of success on which contemporary Western culture is founded not use in a functional way the emotion of envy as a motivational force for the individual?

SOCIAL IMPACT OF SENTIMENTS

Imagining a passionate individual in total isolation is impossible: Passions require sharing, participation, and a common horizon of values and rules. A person perceives his or her passions through those he or she is able to stimulate in other people and decodes them on the basis of their reactions. There is no passion without a mental or a real relational context.

“Others” are necessary interlocutors for the expression of sentiments that involve a mutual exchange: Often children wait to be in the presence of an obliging listener before venting their emotions. Moreover, some places are considered socially more suitable than others for expressing certain emotions. For example, aggressiveness is more often shown in a stadium than in a church.

Research on large social groups shows that the distribution of specific emotions (pain, jealousy, love) varies from one social group to another, while studies conducted at the micro level indicate that the experience and expression of an emotion, as well as attempts to control it, are influenced by socialization and the prevailing situational factors.

A society is certainly founded on some sociostructural presuppositions, but it cannot function if it does not also rest on sentiments, beliefs, and obligations. These factors act as a social glue, as an “a priori” that, without being the object of codification or knowledge from individuals is nonetheless necessary for society to function.

One of these psychosocial elements is trust, which represents a precontractual requirement of the fulfillment of social exchanges. As Simmel maintained, society would disintegrate in the absence of trust among men.

It is not trust alone that supports social order, but trust is one of the psychosocial elements that play a fundamental role in maintaining the social system, even if structural theories neglect it. Trust is a powerful cultural resource, a precondition for a full use of other resources, such as entrepreneurship, citizenship, and legality. It is an intangible resource, like the spirit of belonging or consent.

Different social objects can be invested with trust, and so there can be various types of trust:

1. Generalized trust gives people an ontological security about the system.
2. Segmental trust involves entire institutional segments of society, such as the economy and justice.
3. Technological trust involves the expert systems such as transportation and computer science networks.
4. Organizational trust refers to real organizations such as the army and the university.
5. Commercial trust refers to goods with a specific trademark or produced in certain countries.
6. Positional trust is invested in particular social roles, such as priests and doctors.
7. Personal trust can refer to virtues revealed by public or private persons.

The social objects in which trust is placed can be found in one’s own society or in foreign societies. From this fact arises the distinction between inner trust and outer trust. One speaks of focused trust when trust is placed in a particular category of objects; one speaks of diffuse trust when one metaphorically refers to the trustful or distrustful atmosphere that pervades the society. This climate can be incorporated in a culture as well as in a normative perspective. For example, a large part of Italian fiscal legislation appears to be based on distrust of the honesty of the contributors. Trust in a specific object can be justified in an indirect way,

when its reliability depends on the trust that is placed in bodies of supervision and control. In contrast, distrust feeds conflict and social atomization, therefore becoming a powerful destructive force.

Once distrust has been initiated, it soon becomes impossible to know if it was justified, since it has the ability to fulfill itself, to generate a reality that is coherent with it. Observing events that refute past fiduciary relations, for example, finding out that certain scientific data have been counterfeited so that one can publish spectacular results, can cause an unexpected loss of trust. The absence of trust involves an excessive increase in vigilance and the creation of more complex systems of control.

The slump in institutional trust is reflected in a generalized loss of trust in monetary means of exchange, the authorities' legitimacy, the credibility of the political system, and the effectiveness of specialized spheres such as scholastic and religious institutions. A similar collapse of institutional trust can lead to a loss of trust in individuals.

In the postcommunist societies of eastern Europe, there is a widespread lack of trust that leads to a spreading syndrome of diffidence. The Polish sociologist Sztompka has cited some indicators. The strongest behavioral indicator of generalized distrust in the society to which one belongs is choosing to emigrate. This is the obvious form of escape people choose when living conditions become unbearable and signs of improvement cannot be seen. Another form of escape is withdrawing from public life and taking refuge in primary groups. Here there is a horizontal trust that compensates for the lack of vertical trust in institutions. Another indicator of public distrust is the number of protest demonstrations. Yet another is reluctance to think about the long-term future. In the economic field, an indicator of distrust is neglecting investment forms and spending a lot on consumer goods, especially foreign-made goods. The opening and dissemination of casino chains are also important indicators of distrust. Finally, in the postcommunist societies of eastern Europe, trust is undermined because of normative disorganization and the high level of expectations after the "glorious" revolution of 1989.

Some sentiments may derive from the social order, such as loneliness and historical contingen-

cies that generate fear. Some demographic transformations, such as the lengthening of life, and other social changes, such as breaking the bond of marriage or choosing to remain single, amplify the sentiment of loneliness. Feeling lonely has two sides: It is a sad sentiment connected with loss, refusal, and isolation, but it is also a source of serenity, as it means staying with oneself. This develops the inner world and fosters creativity and the birth of the new.

A large amount of the research on loneliness has established only simple correlations between loneliness and other variables. On the whole, it seems that loneliness is more common among women than men, poor people than rich, and adolescents than elderly people. Data on attitudes and sentiments generally indicate that a person who feels lonely also feels distrust and hostility, is rarely attracted by other people, and expects to be rejected. A large number of studies have found positive correlations between loneliness and feelings of impotence and inadequacy, a tendency to self-devaluation, and self-deprecation. A gap can be found in research on loneliness concerning the etiology of the phenomenon. Sociologists are not in a position to establish which factors cause loneliness and which are facilitating conditions. Sociologists do not know, for example, the relationship between objective causes (mournings, transfers, separations) and subjective causes (introversion, shyness, low self-esteem).

In regard to fear, it is necessary to assume that in the past, some events connected to the adversities of nature generated emotional reactions that were stronger than those of today. The historian Delumeau showed how in past centuries, primary concrete fears (of war, scarcity, plague, tyranny, and earthquake) were grafted onto secondary fears that resulted from cultural processes and movements that singled out dangers and adversaries (the heretic, the Hebrew, the witch, the demon, the vampire, the plague spreader) on which it was easier to unload the anguish caused by real but frightening and unmanageable phenomena.

In modern society, fear of machines has sometimes developed. In England at the beginning of the nineteenth century, the Luddites were organized bands of laborers who destroyed textile machines, which caused layoffs of many craftsmen.

Fear of the dominion of the machine is found in many science fiction, utopian, and dystopian novels in this century. In *Erewhon* by Samuel Butler, there are no machines; in Spengler, the machine is devilish and is seen as the dissolver of Western civilization. In the *Brave New World* by Aldous Huxley and *1984* by George Orwell, pervasive technology supplants people's individuality. Similarly dark scenes are accompanying the current computer science phase that features the presence of apocalyptic Cassandras afraid of the effect of computers on the human brain.

In the second half of the 1980s, after the Chernobyl accident, a strong fear of nuclear energy developed, while the 1990s were characterized by the fear of ecological catastrophes tied to the greenhouse effect or the perforation of the ozone layer. The modern age has brought new threats in the form of drugs and the acquired immune deficiency syndrome (AIDS). Sometimes a social fear may be born, the perception, that is, of a "barbarization" of social life, of a progressive loss of freedom, the feeling of being a pawn in the mosaic of daily life, impotent before the great bureaucratic and occult powers. Another source of fear is food, which in Europe was manifested after the Chernobyl accident and during the mad cow crisis. Today a great fear is that of being killed by someone whom one does not know and who has no reason to direct his anger against an individual. Bodyguards represent a new defense against this fear, while the fear of burglars, especially in cities and urban areas, is causing a rush to purchase electronic systems for defense for the home. In Europe, the fear of a demographic decline accompanies the fear of immigration and of being submerged by other ethnic groups.

EMOTIONS AND CULTURE

A common question among those who study sentiments and emotions is whether these affective states are culturally universal or vary from culture to culture. There are two schools of thought. According to the universalistic school, emotions are always the same in all cultures, while for the relativistic school, they vary in time and among different cultures. Cross-cultural studies have shown differences among cultures concerning the language, the meaning, the objects, and the appraisal

of emotions: One therefore would have to speak of ethnotheories of emotions.

One of the distinctions made by anthropologists is based on the prevalence of sentiments of shame versus guilt. In regard to the fact that a certain culture attributes a preponderant importance to the former or the latter emotion, one speaks of "cultures of shame" and "cultures of guilt": cultures of shame regulate individual behavior through external sanctions, while cultures of guilt are based on interiorized sanctions; that is, guilt is caused by the knowledge of having transgressed important moral or social norms. The cultures of guilt would therefore be those of Western societies, characterized by the Judeo-Christian tradition or the Protestant ethic.

In cultures that systematically resort to humiliation as an educational method, the sentiment of shame is present in massive doses. This happens, for example, in the Japanese culture, which is defined by anthropologists as "the culture of shame." Anthropological data on some cultures of New Guinea show that shame may have a paralyzing effect. In New Guinea, people who have not made a good impression shelter under the porch of the house, cover their faces in chalk powder and wait for the others members to come and playfully reproach them. After a few days, such a person washes his or her face and reenters the group.

The geography of jealousy also shows some variation. In fact, anthropological research shows that jealousy is more widespread and accepted in cultures that are based on private property, authorize sex only within marriage, and grant the status of a responsible adult only to married persons.

In some cultures there are social classes in which a quarrel is unthinkable and an accusation of another person makes clear one's own victimized state. Examples are ritual sounds among the Australian aboriginals, accusing the object of one's anger of witchcraft, and the icy silence of the English bourgeois. In some cultures, such as the Korean, a person who offends is treated with intensified respectful manners, that is, with an increased formality of words and intonation. It is said that the Tasaday did not have in their language a word to express anger. Among the Ibo in Nigeria, anger also seems to be completely absent. A culture, such as the Tahitian, in which social life

is little differentiated, produces few emotions; in this case, one speaks of hypocognition or underidentification.

EMOTION NORMS

Emotion norms indicate the expected range, intensity, duration, and target of a specific emotion in specific situations. The principles that govern emotion are of four types:

1. Rules of appraisal that define how a situation is perceived and evaluated
2. Rules of behavior that establish how an emotion has to be expressed
3. Prognostic rules that indicate the correct duration of an emotion
4. Rules of attribution that legitimate an emotion in regard to the social system

The rules of expression defined by a given culture and subgroup influence how much the emotional state is expressed in self-description, behavior and bodily expression. Emotion rules prescribe the depth and duration of feelings and provide a measure of how much a certain feeling is unusual, crazy, unsuitable, or normal in a certain social context.

Feeling and expression rules are an integral part of what has been called "emotion culture." Moreover, emotion culture includes beliefs concerning sentiments as well as concepts regarding the way in which one should lend attention, codify, evaluate, control, and express feelings. Emotion culture is reflected in films, religion, psychiatric theories, and the law. Many systems of law mention, for example, two sentiments, widespread among the population, that are worth of being safeguarded: decency and honor.

Decency. The sentiment of decency concerns the intimate sphere of one's personality, the area a person thinks should be private and confidential. Analyses carried out in the social sciences reveal extreme variability in the sphere of decency: In different epochs and cultures, different actions and behaviors are considered as damaging this feeling, whereas in other contexts they appear totally legitimate. However, the sentiment of decency is present in all ages and cultures, and

through it, a peculiar relationship occurs between subjective perceptions and objective images of confidentiality, especially in the sexual sphere. Reflecting on the characteristics of the sentiment of decency in a society makes it possible to individuate the prevailing values of a social group concerning the protection of confidentiality but also to explore in depth the reasons for behaviors that do not fall within the sphere of the individual. For example, the meticulous and detailed Starr report on President Clinton disseminated by electronic mail all over the world is an example of the absence of decency in the American judicial system.

Honor. Honor is the pretension and the right to be proud, but it also means that society acknowledges this individual pretension. The sentiment of honor spurs honored behavior. Honor is the social acknowledgment of those who fulfill the duties of their status.

In contemporary society, there are a great number of ritual situations in which specific persons are given, while alive, special honors or special offices, degrees, or prizes. After death, these persons are honored with symbolic actions: A recent example was the garlands of flowers that were laid on Mother Teresa's coffin.

A call to honor is made when a citizen sees his or her name and respect wounded by his or her fellow citizens. Civil and penal laws protect honor legally. There are professional groups that supervise the observance of specific norms by means of a code of honor. In this epoch, honor brings to mind retrograde and fragmented elements. In past societies, honor was not only a particular type of sentiment linked to occasional events and one that operated as a cultural superstructure: The conceptions of honor were more than simple accessories of life; they went beyond abstract values one referred to only occasionally. For centuries, they determined the style of life of wide layers of people in premodern societies, orienting their social and private conduct.

Through honor, the individual identifies as member of a group, which in turn confers a status, that is, a dignity and a value in the social relations occurring within and outside the group to which one belongs. The functional cost an individual has to face consists of control of morals through endorsement mechanisms whose most qualifying phase is the formation and application of honor

codes. Acts of violence in defense of the honor of one's family were widely tolerated by the law until relatively recent times.

The Mediterranean culture of honor has been characterized as a phenomenon of archaic societies that have not reached a high level of civilization. With modernization, it was maintained, this dark phase would disappear. Instead, the culture of honor has succeeded in preserving its importance among immigrants in the industrialized metropolis.

The fact that the code of honor has not lost its valence, at least in the Mediterranean area, makes one question whether the linear concept of modernization is truly valid or whether a concept based on a permanent dialectic between persistence and change is more valid.

The regulation of emotion comes largely from social sources that consist partly in the interests that others have and in the norms of social interaction and partly in the expression and feelings rules of society: Boys should not cry, and mourning should not be shown too much, at least in the Nordic countries. Expression rules are specific to a given culture or social role: English people, for example, are little inclined to express how they feel, and the clergy behave with dignity. In some cultures, jealousy cannot be felt, while in others, it must be; in some cultures, an offense to honor is strongly felt, while in others, the honor concept is almost nonexistent. The rules are often explicit to the point of being codified in books of ethics and good manners. In the Western culture, the ethic of control of emotional impulses prevails.

Anger also is subject to social rules. For every class, there are prescriptive rules that indicate the choices that have to be made and proscriptive rules that indicate those to avoid. For example, one can show anger for a behavior that attacks one's honor, freedom, or property (prescriptive rule), but anger cannot exceed the limits of what is necessary to correct the situation (proscriptive rule).

SENTIMENTS IN THE POSTMODERN AGE

In the contemporary world, several indications seem to point to a situation in which the consumer society is increasingly inviting people to be passionate but people are distanced from passion. The threshold of emotional involvement has be-

come high to protect people from a useless daily mobilization: In post-modern culture, emotions and social action seem more and more separated.

The process of "blaiseization" that Simmel saw at the beginning of the century thus has accelerated. However, certain episodes occur, like Princess Diana's death, that are experienced with a sentiment of pain that is almost cosmic, so that Pareto's *residuo* of "displaying sentiments with exterior acts" seems still present, although only latently.

The relevance of the affective dimension also is evidenced within the religious and family domain. In religion, several scholars maintain that once people get rid of ritualistic and pretentious display and once reciprocal aggressiveness has disappeared, the prevalent function of religion is to provide affective support of people against the uncertainties of the world. The family which has lost some of its fundamental functions, such as economic and socialization, has maintained and perhaps strengthened its function of affective support both horizontal and vertical.

Within the job world concerns about feelings of alienation during the assembly line period, have been replaced by concerns about the burnout phenomenon, which is a feeling of powerlessness and indifference, which affects especially the health, helping, and education professions.

According to some management scholars, in the next decades a resource to contrast these negative phenomena could be the development of emotional intelligence, which is the ability to effectively perceive, realize, and apply the strength and perspicacity that emotions—meant as sources of energy, information, relations and influence—provide human beings with.

In the 1990s, different authors tried to individuate the prevalence of some sentiments in society or in parts of it. At the beginning of the twenty-first century a sentiment that seems widespread is narcissism, understood as self-complacency and desire to be admired. Some indicators of this feeling are the cult of the body, abandoning every emotional involvement, the proliferation of interpersonal relationships governed by appearance, and a flight from the social. Post-modern society thus seems to be pervaded with a dominant passion: love for the self, which is translated into

vanity and desire for power, wish to control anxiety over self-approval, self-interest, and egoism. Such syndrome, however, seems to co-exist with an altruistic dimension, normally rather latent but that grows in emergencies. The prevailing sentiments seem however to be linked to the spreading of post-materialistic values, such as love and friendship. Along the continuum localism—cosmopolitan, following Huntington, it seems that we are moving towards an attachment for intermediate cultural areas, essentially configured according to the religious tradition.

Contrary to the expectations raised by the fall of the Berlin wall, in various parts of the world (Burundi, Algeria, Bosnia, Kosovo) during the 90s there were carnages caused also by feelings of interethnic hatred.

Another sentiment, felt especially by younger generations, is a worry about the future that generates anxiety and is capable of determining behaviors that are aggressive and antisocial.

Lately mass media scholars complain about the spreading, especially in television and movies, of a certain provocative impudence, together with the weakening of feelings of shame. Moreover, some psychologists have noticed an increase in interpersonal aggressiveness that parallels the increase in the time devoted to city mobility.

In a time of increasing globalization of markets the McDonaldization of tastes, the process of conforming seems to proceed also in the affective sphere, with the consequent weakening of passions and the misting over of the ability to suffer but also to feel joy, indignation, and pity. All these worries had been expressed by the antiutopians, by Riesman, and by the supporters of the critical theory of society. Leading to the valorization of sentiments as bulwark against any attempt of hegemonic oppression. In postmodernity, it thus seems appropriate to place *Homo sentiens* near *Homo faber* and *Homo sapiens*.

SEX DIFFERENCES

"Sex differences" is the label used in describing variations between women and men. The term "sex" reflects the division of women and men into two groups on the basis of their unique biological features; the term "differences" derives from the tradition of differential psychology, in which distinct groups of people (defined by natural categories such as sex or constructed categories such as socioeconomic class) are compared in terms of an outcome.

Both terms have been criticized. To many people, references to sex differences imply a biological determinism that ignores the role of socialization and context. The more contemporary term "gender" directs attention to the social meanings assigned to the categories of male and female. With either term, however, it is not necessary to assume a particular causal factor for an observed pattern of variation. A problem with the term "differences" is that it suggests that *dissimilarities* are the norm and *similarities* are the exception. More appropriately, one makes comparisons between groups to see whether there are similarities or differences.

Regardless of the rubric used to characterize the investigation, comparisons between women and men pervade social science literature. Thousands of studies have analyzed sex-related patterns in physical performance, cognitive abilities, personality traits, moral reasoning, social interaction, occupational choice, sexual behavior, attitudes, aggression, depression, self-esteem, leadership, non-verbal behavior, self-disclosure, intelligence, life satisfaction, workplace achievement, and almost every other domain of human activity. To learn how these behaviors emerge, developmental psychologists explore the ways in which specific socialization practices contribute to observed differences between girls and boys and, by extension, women and men. Sociologists study structural features that shape the roles of women and men in organizational settings, family units, and labor markets. All these analyses contribute to the understanding of gender.

Not all of these topics can be discussed in this entry, and this review will not deal with sexual behavior or the biological basis of sex-related differences. Instead, this article will examine some of the main theoretical accounts of sex differences and then turn to 1) sex differences in four domains that were highlighted in early reviews (verbal, quantitative, and spatial ability and aggression), 2) differences in mathematics and science achievement, 3) other analyses of sex differences, and 4) contextual influences on sex-related patterns of behavior.

THEORETICAL ACCOUNTS OF SEX DIFFERENCES

Two predominant and contrasting theoretical accounts of sex differences are evolutionary approaches and a variety of social roles, expectations, and/or status perspectives (Eagly and Wood 1999). Evolutionary theory predicts that “the sexes will differ in precisely those domains in which women and men have faced different sorts of adaptive problems” in evolutionary history (Buss 1995, p. 164). These domains primarily are those relevant to reproduction, such as mate selection and sexual behavior (Feingold 1992), but also may include physical skills, the commission of violent crimes (Daly and Wilson 1988), and thresholds for physical risk taking (Wilson and Daly 1985). The evolutionary perspective suggests that in domains

irrelevant to sexual selection, the sexes should and do tend to be psychologically similar.

The social roles and/or expectations perspective focuses on the relationship between male gender and high status in American and other societies. Sex differences in behavior may emerge because men are expected to be more competent and authoritative than women, and many social situations are structured to support this outcome (Foschi 1998; Geis 1993; Ridgeway and Diekema 1992). Eagly’s (1987) social role theory further suggests that the unequal distribution of men and women in social roles (e.g., homemaker versus paid employee) contributes to both biased perceptions of the sexes and the development of skills and behavior that fit those roles.

The literature on self-fulfilling prophecy (Geis 1993; Rosenthal and Jacobson 1968) is consistent with this perspective. Expectations lead people to behave in ways that make the expected outcome more likely to occur. Gender-stereotyped beliefs of parents, for example, predict students’ performance in mathematics courses: Parents who believe that girls are inferior in mathematical ability are more likely to have daughters who do poorly in mathematics (Eccles 1985). Deaux and Major’s (1987) interactionist perspective further details how contextual factors determine whether and how gender-related expectations are translated into gendered behavior.

Other accounts of sex differences exist, including biological approaches (emphasizing hormones, brain structure, and genetics), developmental and/or learning approaches (e.g., social learning theory and gender schema theory) (Jacklin and Reynolds 1993), and constructionist perspectives (which describe “doing gender” rather than “having gender”) (West and Zimmerman 1987). The basic theme of “biology or environment” pervades these perspectives. As is discussed below, any theoretical account faces the challenge of accounting for the size and pattern of sex differences across domains and the susceptibility of those differences to contextual moderation.

WELL-ESTABLISHED SEX DIFFERENCES?

In discussing sex differences, one can begin with Maccoby and Jacklin’s (1974) landmark book *The Psychology of Sex Differences*. In this volume, the

authors review the literature on sex differences and highlight several that are “fairly well established” (p. 351): Females tend to have greater verbal ability than males, and males tend to surpass females in quantitative ability, spatial ability, and aggression.

After the appearance of this narrative review, the statistical technique of “meta-analysis” was developed, enabling researchers to quantitatively combine results across many studies. Rather than rely on subjective impressions of the literature or a “count” of significant and nonsignificant effects, meta-analysis is based on calculation of an effect size (d) that reflects the mean sex difference in pooled standard deviation units in a given study. D 's are combined across studies to compute an average effect size. As a rough guide, Cohen (1977) suggests that d 's of .20 are small, those of .50 are medium, and those of .80 are large in magnitude. (To take a familiar example of a physical sex difference, the effect size for U.S. male-female differences in height is very large at $d = 1.93$.)

Meta-analyses of the four “established” sex differences have reached somewhat different conclusions than did Maccoby and Jacklin's (1974) narrative review. For example, females and males appear to be comparable in verbal ability in general and in most specific types of verbal ability, such as vocabulary, verbal analogies, and reading comprehension (overall $d = .11$) (Hyde and Linn 1988); positive d 's indicate a relative female advantage. This effect was fairly stable across age despite Maccoby and Jacklin's (1974) conclusion that the onset of sex differences in verbal ability occurs at around age 11. A possible exception to the smallness of sex differences is verbal fluency (e.g., speed and accuracy of speech production and the production of sentences meeting meaning requirements), where females more clearly outperform males ($d = .33$) (Hyde and Linn 1988). It is also the case that males are more prevalent at the low end of the verbal abilities distribution. For example, there are three to four times as many male stutterers as female stutterers (Skinner and Shelton 1985), and severe dyslexia is about 10 times more common in males than in females (Sutaria 1985; see also Halpern 1992).

In regard to quantitative ability, some meta-analyses have reported modest differences between males and females in performance on tests of

mathematical skill ($d = -.36$ and $-.43$) (Feingold 1988; Hyde 1981). A more recent study, however, found a very small overall effect in the direction of female superiority ($d = .05$), although differences favoring men emerged in high school ($d = -.29$) and college samples ($d = -.32$) (Hyde et al. 1990). Sex differences also tend to be greater among selected samples of mathematically talented youth tested on the mathematics section of the Scholastic Aptitude Test (Benbow 1988). Overall, the average scores of 12- and 13-year-old boys are higher than those of girls of the same age in these samples; the variability in the boys' scores is also greater. As a result, in the upper 3 percent of the distribution defined as mathematically precocious, boys outnumber girls in ratios that sometimes are dramatic (Benbow and Lubinski 1993).

Spatial ability has a possible (though still unclear) link to mathematical aptitude and scientific and engineering achievement. Meta-analyses of sex differences in visual-spatial ability have shown a variety of effect sizes, depending on the specific type of task or skill assessed. For example, on tasks of mental rotation, in which one is asked to visualize the rotation of a three-dimensional object, large sex differences favoring males have been found on one specific type of test (the Shepard-Metzler test; $d = -.94$) but not on others ($d = -.26$) (Linn and Peterson 1986). Tasks involving spatial perception (e.g., determining the true vertical plane when one is seated in a tilted chair) also indicate relatively smaller sex effects ($d = -.44$), and those involving spatial visualization (e.g., finding a simple shape in a complex pattern of shapes) show virtually no sex difference ($d = -.13$) (Linn and Peterson 1986; see also Masters and Sanders 1993; Voyer et al. 1995). Thus, sex differences in this domain are quite task-specific.

The only social behavior highlighted in Maccoby and Jacklin (1974) was aggression. Two meta-analyses of sex differences in aggression that were published a decade apart produced comparable, small effect sizes that indicated less evidence of aggression among females than among males ($d = -.24$ and $d = -.29$ in Eagly and Steffen 1986 and Bettencourt and Miller 1996, respectively). Bettencourt and Miller (1996) also identified an important moderating condition of this sex effect: Unprovoked men tend to be more aggressive than are unprovoked women ($d = -.33$), but under conditions of provocation, this sex effect is much

smaller ($d = -.17$). A sense of the relatively small size of these effects can be gleaned by comparing them to the effect of provocation on aggression ($d = .76$). Although sex differences in aggression emerge, they do not seem to be as strong or straightforward as previously was thought.

MATHEMATICS AND SCIENCE ACHIEVEMENT

Although meta-analyses indicate relatively small sex differences in quantitative ability, an important related question is whether females and males differ in real-world achievements in quantitative domains such as mathematics, science, and engineering.

A report on women's representation in science and engineering by the National Science Foundation (1999) describes several significant findings. First, with regard to secondary education, male and female students are similar in their completion of high school mathematics and science courses (about 17 percent of both sexes have taken trigonometry, and about 25 percent have taken physics). Furthermore, average mathematics scores for females and males in the eighth and twelfth grades are not significantly different, although science scores among twelfth-graders are slightly higher for males than for females (based on the 1996 National Assessment of Educational Progress mathematics and science assessment).

On the mathematics portion of the Scholastic Assessment Test (SAT), men tend to score about 35 points higher than do women, a gap that remains even for students who reported having taken calculus and physics courses in high school. However, this difference appears to be due in part to the fact that a larger number of women than men who take the SAT are from lower-income families. Because parental income is related to SAT scores, the greater proportion of low-income women may reduce the overall female average (National Science Foundation 1999). It is unclear whether this income factor also accounts for findings regarding men's and women's performance on the 1996 College Board Advanced Placement (AP) tests. These data indicated a male advantage over females on AP tests in physics, computer science, chemistry, and calculus (d from $-.26$ to $-.52$) as well as an overrepresentation of males in the upper tail and an underrepresentation in the lower

tail of the distribution of test scores (Stumpf and Stanley 1998). Interestingly, across twenty-nine different AP tests, the size of the effect favoring males was highly correlated with the percentage of males taking a given test ($r = .71$). That is, the greater proportion of male to female high school students who choose to take a given AP test, the greater the male advantage in performance. Students taking AP tests are college-bound and self-select test subjects on the basis of their levels of preparation and expertise. Thus, this finding demonstrates that males feel more competent than females in the domains where they outperform females and that sex differences are apparent even among this highly self-selected group of "prepared" male and female students.

The National Science Foundation report (1999) details larger differences in female versus male achievement in regard to the attainment of advanced degrees and employment. Although women received 46 percent of science and engineering bachelor's degrees in 1995, they earned only 31 percent of the total science and engineering doctoral degrees in that year (up from 26 percent in 1985). The only science field in which women received the majority of doctoral degrees (64 percent) was psychology.

With regard to employment, women represent 46 percent of the total U.S. labor force but only 22 percent of scientists and engineers. Representation differs dramatically across fields: More than half of psychologists and 47 percent of sociologists are women, but women account for only 12 percent of physicists and 9 percent of engineers (National Science Foundation 1999). Among those with academic employment, women with science training are more likely than are men to work in elementary or secondary schools and two-year colleges. In four-year colleges, women are less likely than men to be tenured (35 percent versus 59 percent) or full professors (24 percent versus 49 percent). Men also are more likely than women to be managers, and across fields, full-time male scientists and engineers earn more than do females (overall median salary of \$52,000 versus \$42,000). Some, but not all, of these differences in employment placement may be due to differences in age, and women in science and engineering tend to be younger than men. Similarly, salary differences are due in part to age and field differences, since men are more likely than women to enter the high-

paying fields of computer science and engineering. Nonetheless, differences in academic rank remain after one controls for age, and with increasing age, the gap in salaries between female and male scientists and engineers widens (National Science Foundation 1999)

OTHER SEX DIFFERENCES AND SIMILARITIES

It is impossible to provide a thorough overview of other research on sex differences in this brief article. In addition to the thousands of original empirical studies, over 180 meta-analyses have been published since Hall's (1978) initial meta-analytic study of sex differences in the decoding of nonverbal cues (where $d = .40$).

In a review of the "science and politics of comparing women and men," Eagly (1995) summarizes meta-analytic research by suggesting that the sizes of sex differences vary considerably across domains. The largest differences ($d > .80$) tend to be found for (1) some physical abilities (e.g., throwing distance, speed, and accuracy), (2) the Shepard-Metzler mental rotation task described above, (3) social behaviors such as facial expressiveness, (4) sexual behaviors such as the frequency of masturbation and attitudes toward casual sex, and (5) nurturant personality traits (tender-mindedness) (Feingold 1994). Most other examined attributes, however, tend to support sex differences that are small to moderate (or negligible) in size. For example, the mean effect size is $-.14$ for studies of sex differences in self-esteem (Major et al. 1999), $.21$ for fine eye-motor coordination (Thomas and French 1985), $.02$ for perceived leadership effectiveness (Eagly et al. 1995), $.26$ for negative attitudes toward homosexuality (Whitley and Kite 1995), and $.07$ for competitiveness in negotiation (Walters et al. 1998). Ashmore (1990) summarizes his review of the meta-analytic sex differences literature by noting that "relatively large sex differences are demonstrated for physical abilities and for body use and positioning; more modest differences are shown in abilities and social behaviors; and many negligible sex differences are sprinkled across all domains" (p. 500).

Whether one views observed sex differences as "meaningful" depends on one's opinion and perspective. On the one hand, as Eagly (1995) points out, even a large effect size translates into

substantial overlap between the sexes: A d of around $.80$ indicates about a 53 percent overlap in female-male distributions. In this manner, findings of difference may mask substantial similarity between the sexes. Furthermore, many sex differences are quite small in magnitude compared with other important psychological phenomena (e.g., the provocation-aggression link of $.76$ described above and the effect of group pressure on conformity of $d = 1.06$) (Bond and Smith 1996).

On the other hand, a number of other sex differences are comparable in magnitude to psychological effects that typically are interpreted as both theoretically and socially meaningful. For example, the effect of exposure to media violence on aggression is $d = .27$ (Wood et al. 1991), and the effect of having a type A personality style on systolic blood pressure is $d = .33$ (Lyness 1993). It is also the case that sex differences based on general population samples may be smaller than the differences that appear when one looks at selected populations or those in the "tails" of frequency distributions. The greater representation of males among the mathematically precocious, the verbally challenged, and the most violently criminal, for example, suggests that for some highly salient important outcomes, sex differences may be more striking than one might assume based on observations of "average" people encountered in everyday experience.

Some have questioned the wisdom of overreliance on meta-analysis, as this quantitative approach cannot overcome the shortcomings or biases in the original set of studies on which the data summary is based. For example, in Eagly and Crowley's (1986) meta-analysis of sex differences in helping behavior, the authors note that their findings are based primarily on studies that involve short-term helping of strangers ("heroic helping"), a type of helping that is more consistent with the male role than the female role. Any finding of sex differences must be taken in light of this fact and not generalized across all helping situations.

Others have illustrated the limitations of meta-analysis for making causal inferences (Knight et al. 1996). For example, a number of meta-analyses of sex differences have indicated a "year of publication" effect: Studies published relatively recently suggest smaller sex differences in domains such as

aggression; verbal, cognitive, and mathematical abilities; helping behavior; influenceability; leadership; and sexuality. Although some have interpreted these findings to mean that sex differences are disappearing (an interpretation more supportive of an environmental than a biological account), changes in research methodology over time may provide an alternative explanation. Indeed, in revisiting a meta-analysis of sex differences in aggression, Knight et al. (1996) found that statistically controlling for method characteristics (e.g., experimental or not, observational or self-report measures, physical or verbal aggression) removed the year of publication effect; small sex differences in aggression appear to have remained stable over time.

The entire enterprise of studying sex differences has its critics, and a number of relevant issues have been questioned and debated in several recent venues (*American Psychologist* 1995; *Feminism and Psychology* 1994; *Journal of Social Issues* 1997). Criticisms center on the tendency in this work to treat females and males as belonging to polar, global categories that ignore the other social characteristics of individuals (race, class, age, sexual orientation), invoke unsophisticated nature versus nurture explanations, ignore social context, and imply that a difference means a deficit. Despite these criticisms, the research literature continues to grow, and there appears to be a trend “toward a more contextualized version of gender-related behavior” (Deaux and LaFrance 1998, p. 816).

CONTEXTUAL INFLUENCES ON SEX-RELATED PATTERNS

As is indicated in many of the patterns of sex difference described above, researchers often find important moderators of the sex differences that emerge. For example, experimental work has demonstrated that the way in which a task is framed can affect performance outcomes. Thus, when the “spatial nature” of a spatial reasoning task was emphasized, men outperformed women, but when this aspect of the task was ignored, no sex difference emerged (Sharps et al. 1993). Similar findings have appeared with regard to mathematics performance, as predicted by Steele’s (1997) theory of “stereotype threat.” This perspective suggests that women’s (and minorities) weaker mathe-

matics performance may be based in part on the threat of being judged consistently with negative group stereotypes. When that threat is lifted, performance differences should disappear. In one study, when a mathematics test was described as producing sex differences, women performed worse than did similarly qualified men; when the test was described as not producing sex differences, women and men did not differ in performance (Spencer et al. 1999). Other testing characteristics also may affect the size of sex differences. For example, structured tests that use a free-response format tend to produce smaller sex differences than do those which use a multiple-choice format (Kimball 1989).

The contextual setting also can play a role in the size of sex differences. A case in point is the analysis of leadership effectiveness, where military settings promote sex differences of moderate size ($d = -.42$) but other organizational contexts produce effect sizes of a much smaller magnitude or reversed direction, ranging from $-.07$ to $.15$ (Eagly et al. 1995). An analysis of gender and self-esteem indicated the importance of considering age and ethnicity in discussions of sex differences (Major et al. 1999). No sex difference in self-esteem was apparent before adolescence ($d = -.01$), but very modest differences began to emerge around ages 11 through 13 ($d = -.12$). Similarly, sex differences in self-esteem are apparent among whites ($d = -.20$) but virtually nonexistent among North American minority groups, especially African-Americans ($d = .03$). Finally, many abilities addressed in studies of sex differences are easily modified by experience. For example, spatial skills improve with exposure, and specific training programs designed to improve spatial skills are equally effective for women and men (Baenninger and Newcombe 1989).

Thus, task characteristics, familiarity, and social context can create sex differences or make them disappear. As Deaux and Major (1987) suggest, the basic behavioral repertoires of women and men are quite similar (e.g., both women and men know how to be aggressive, how to be helpful, how to smile). What men and women actually do is determined less by differential abilities than by the context in which they act. Norms, expectations, the actions of others, and the actor’s goals and objectives may all combine to produce sex differences in behavior in some circumstances.

No doubt people will continue to ask how or why women and men differ, but the answers will never be simple and the explanations will not fall squarely on the side of biology or that of environment. Evolutionary and social role models ultimately may complement each other in their relative emphases on distal (distant) versus proximal (immediate) causal factors. The causal direction of some reasoning may need to be examined further. For example, observed differences between the sexes cannot be used as a simple explanation for broader gender roles. Instead, accepted roles may channel men and women into different patterns of behavior. Whatever the patterns observed, most sex differences will continue to reflect a gendered environment and be subject to change as social factors shift over place and time.

SEXUAL BEHAVIOR IN MARRIAGE AND CLOSE RELATIONSHIPS

The scientific study of sexuality is not limited to a single discipline but involves scholars from a variety of fields, including sociology, psychology, and biology. The multidisciplinary nature of sexuality research lends itself to various and often contradictory theoretical interpretations of sexual phenomena. Furthermore, individuals have various perspectives on the purpose of sexual behavior and engage in a variety of sexual behaviors. For example, Reiss (1960) asserts that individuals take one of three general approaches to sexuality. Some individuals have a "procreational orientation," believing that the purpose of sexual intercourse is reproduction; others have what Reiss (1960) refers to as a "relational orientation," believing that sexual intercourse is for the purpose of expressing emotional attachment to a partner; and still others have a "recreational orientation," viewing the purpose of sexual behavior as enjoyment. Other researchers (e.g., Peplau et al. 1977) have constructed similar typologies. These perspectives or standards are likely to overlap; for example, couples who engage in sexual intercourse in order to reproduce also express their love and affection for each other and may enjoy themselves in the process. However, Reiss (1960) argues that individuals have one of these orientations as a primary explanation for engaging in sexual behavior. This article focuses on sexuality within close relationships. It begins by presenting some of the theoretical perspectives on sexuality and then discusses recent research findings on sexuality in close relationships.

THEORETICAL FRAMEWORKS

As was stated above, numerous theories have been developed to explain why certain individuals engage in sexual activities with certain other individuals and the context in which sexual behaviors occur. These theories generally fall on either side of an essentialist versus social constructionist dichotomy (DeLamater and Hyde 1998).

Essentialism. According to the essentialist perspective, certain behaviors are biologically driven and thus are natural and ubiquitous. An example of essentialist theories would be evolutionary theories such as sociobiology and sexual strategies theory (Buss 1998; DeLamater and Hyde 1998). According to those theories, which often are applied to gain an understanding of mate selection, certain contemporary sexual behaviors have emerged over time in response to environmental conditions. For example, both men and women are thought to strive to maximize their reproductive success (Oliver and Hyde 1993). Men are theorized to want to pass their genes to successive generations; therefore, they wish to impregnate as many women as possible to increase the likelihood that they will have offspring. Women also want to maximize their reproductive success, but they do so by striving to secure a long-term partner who will provide for their children financially (Chodorow 1978). Because men would not be passing along their genetic heritage by caring for another man's child, a woman's sexual exclusivity to one man has been socially desirable. These theories correspond to Freudian theories in psychology ("anatomy is destiny") and structural functionalist theories in sociology, which argue that traditional heterosexual marriage is the only appropriate forum in which sexual behaviors should occur, as the integrity of families and societies can be maintained only by that institution (see Parsons and Bales 1955).

Social Constructionism. Social constructionist theories minimize the influence of biological drives in explaining sexuality, instead focusing on how sexuality, like other phenomena, is socially constructed (DeLamater and Hyde 1998). For example, instead of arguing that men are biologically driven to be sexually promiscuous while women are biologically driven to be sexually exclusive, social constructionists argue that men and women engage in specific sexual behaviors as a result of the cultural messages they receive through socialization. Examples of theories within this framework are symbolic interactionism, social learning, social exchange, and conflict theories (Longmore 1998; Oliver and Hyde 1993; Sprecher 1998).

According to symbolic interactionism, individuals create meaning through their interactions with others; that is, they learn their sexual identities by communicating with others. Indeed, individuals learn and follow sexual scripts (Laumann

et al. 1994; Longmore 1998; Oliver and Hyde 1993) that are specific to their culture, gender, race, social class, and so forth. These scripts are fluid; individuals frequently modify them to adapt to their environments. According to network theory (Laumann et al. 1994), sexual relationships are embedded in larger social networks that influence intimate dyads (Sprecher et al. in press). More specifically, network members influence who pairs up with whom, what behaviors (sexual and otherwise) should be encouraged and/or tolerated in an intimate relationship, and whether dissolution should occur.

To explain sexual behavior, social exchange theories postulate that the members of a dyad exchange resources with each other in an attempt to maximize their rewards and minimize their costs (Sprecher 1998). Examples of social exchange theories are equity theory (individuals reward their partners or withhold rewards in an attempt to influence the balance of equity in the relationship; Sprecher 1998) and choice theory (individuals pursue goals on the basis of the resources available to them, such as energy, physical attractiveness, and money; Laumann et al. 1994).

In explaining sexuality, conflict theories emphasize the power struggle inherent in intimate relationships. According to this perspective, men sexually dominate and exploit women in order to achieve their own goals, while women, lacking power, service men's sexual needs (Weis 1998b). While men may be better positioned to dominate and exploit because of their greater average physical strength, the power struggle is social and is based on the system of patriarchy (see Richardson 1996 for a discussion of this issue).

Summary. Despite these theoretical perspectives, sexuality research has been accused of being atheoretical (Weis 1998a, 1998b). Weis argues that theories of sexuality are still in an early stage compared to the theoretical development of other scholarly fields because of a lack of sexuality research that tests hypotheses (below, it will be seen that much sexuality research is descriptive) and because few strong connections have been established between theory and research. Christopher and Sprecher (in press) concur; in their decadelong review of sexuality in close relationships, they note the limited progress made in theories of sexuality despite the considerable increase in research in-

terest in this topic. They call for more theoretical advancements in future research on sexuality.

The following sections present some of the research findings concerning sexuality in close relationships. Several large-scale studies have been conducted within the last decade (most notably the National Health and Social Life Survey in addition to the second wave of the National Survey of Families and Households and several waves of the General Social Survey, which include measures tapping sexual behavior) despite the politicized nature of conducting studies on sexual behavior. These studies have greatly increased sociological understanding of sexuality in committed relationships. The discussion here focuses on three main concerns: (1) descriptive information on sexual behavior in close relationships (e.g., frequency of intercourse, number of partners), (2) the character of extramarital/extradynamic sex, and (3) qualities of homosexual close relationships.

DESCRIPTIVE CHARACTERISTICS OF SEXUAL BEHAVIOR

As was stated above, much sexuality research is descriptive. Thus, there is considerable knowledge of how frequently individuals engage in sexual behaviors, the types of behaviors in which they engage, how many sexual partners individuals have had over the course of their lives, the prevalence and character of extramarital or extradynamic sex, and the extent of sexual and overall life satisfaction, in addition to numerous other behavioral and attitudinal characteristics. This section focuses on the frequency of sex, the number of partners, and sexual and overall life satisfaction.

The state of descriptive knowledge of sexual behavior has increased considerably over the last several years as a result of the implementation of large-scale national surveys that use rigorous sampling methods. In particular, the National Health and Social Life Survey, which is based on a national sample of the noninstitutionalized population between ages 18 and 59, has provided extensive information on the sex lives of U.S. citizens (Laumann et al. 1994). The design of this survey is much more rigorous than that of the famous Kinsey studies (Kinsey et al. 1948, 1953), which relied largely on volunteers, calling into question the extent to which their data represented the general population.

Frequency of Sex. Contrary to the popular opinion that married couples engage in sex less than anyone else does, Laumann et al. (1994) found that only 1.3 percent of married men and 3.0 percent of married women did not engage in sex in the past year (respondents defined the meaning of engaging in sex, which may or may not have included vaginal intercourse). Twenty-two percent of the never-married/noncohabiting men and 30.2 percent of the never-married/noncohabiting women did not engage in sex in the past year. These figures are similar to those for divorced, separated, or widowed individuals who were not cohabiting (23.8 percent of the men and 34.3 percent of the women, respectively). However, all the cohabiting men and all the divorced/separated/widowed cohabiting women had engaged in sex at least a few times in the past year (1.4 percent of the never-married cohabiting women reported not engaging in sexual activity in the past year). According to Laumann et al. (1994), then, while cohabitators on average are more likely to engage in sex than are respondents in any other heterosexual category, sexual activity occurs in nearly all marriages.

According to Laumann et al. (1994), cohabitators are also more likely than are other heterosexuals to engage in frequent sex. More specifically, 18.6 percent of never-married cohabiting men (11.1 percent of divorced/separated/widowed cohabiting men) and 16.7 percent of never-married cohabiting women (11.3% of divorced/separated/widowed cohabiting women) engaged in sex at least four times a week, compared with 7.3 percent of married men and 6.6 percent of married women. Blumstein and Schwartz (1983), who conducted face-to-face interviews and collected questionnaire data from a convenience sample of heterosexual married couples, heterosexual cohabiting couples, and gay and lesbian cohabiting couples, found more substantial differences. They report that while 45 percent of couples in short marriages (two years or less) engage in sex at least three times a week or more, the corresponding figure for short-term cohabitators is 61 percent. This pattern persists when one compares marital and cohabiting unions of two to ten years (27 percent of the marrieds and 38 percent of the cohabitators engage in sex at least three times a week) (Blumstein and Schwartz 1983). Similarly, Rao and DeMaris (1995), using National Survey of Families and Households

data, found that the mean monthly frequency of sexual intercourse among cohabitators was approximately 1.3 times the mean frequency of the legally married.

As was noted above, those who are not currently married and are not cohabiting are more likely than anyone else not to have engaged in sex in the last year (Laumann et al. 1994). However, never-married/noncohabiting men and women who do engage in sex are slightly more likely than are married men and women, respectively, to have sex four or more times a week (7.6 percent of the noncohabiting men versus 7.3 percent of the married men and 7.0 percent of the noncohabiting women versus 6.6 percent of the married women). The divorced/separated/widowed respondents who are not cohabiting are less likely than are married couples to engage in sex at least four times a week (4.6 percent of the noncohabiting men and 3.7 percent of the noncohabiting women engage in sex this frequently).

Blumstein and Schwartz (1983) also found that gay men engaged in sexual behaviors more frequently than did anyone else in their sample (67 percent of gay men in short-term relationships of less than two years reported engaging in sex three or more times a week, compared with 32 percent of gay men in unions of two to ten years). Lesbians engaged in sex less frequently than did anyone else in the sample (33 percent of lesbians in relationships of less than two years engaged in sex at least three times a week; only 7 percent of lesbians in unions of two to ten years engaged in sex that frequently). However, Laumann et al. (1994) found no statistically significant difference in the frequency of sex among gay men versus all men. Statistically significant differences also did not appear among the women (however, the sample size of lesbians was very small).

In summary, cohabitators engage in more sex than do other heterosexuals, but marital sex is not the anomaly that popular opinion asserts (in other words, that sex rarely occurs in marriage; see Blumstein and Schwartz [1983] for a discussion of this issue). However, sexual frequency does decline with increasing age and duration of marriage (see Donnelly 1993; Marsiglio and Donnelly 1991; Call et al. 1995). Findings concerning the frequency of sex among homosexual men and women

compared with their heterosexual counterparts are mixed.

Number of Sexual Partners. Individuals vary in terms of their number of lifetime (since age 18) sexual partners as a function of gender and relationship status. First, women are much more likely than men to have had only one sex partner since age 18 (31.5 percent of women report one partner compared with 19.5 percent of men) (Laumann et al. 1994). Men are more likely to report having had at least eleven sexual partners since age 18 (32.9 percent of men and 9.2 percent of women reporting having had at least eleven sexual partners).

Married individuals are less likely than are individuals in any other relationship status to have had numerous sex partners since age 18 (Laumann et al. 1994). More specifically, 37.1 percent of married respondents have had only one sex partner since age 18, compared with 24.6 percent of the never-married cohabitators and none of the divorced/widowed/separated cohabitators (who have all had more than one sexual partner). Nearly 15 percent of the never-married/noncohabitators have had only one sex partner (12.3 percent have had no sex partners), and 11.1 percent of the divorced/widowed/separated noncohabitators have had only one sex partner (0.2 percent have had no sex partners). The percentage of respondents who have had two to four sex partners since age 18 is quite similar across all relationship statuses. However, married respondents are consistently less likely than are respondents in all other relationship statuses (with the exception of never-married cohabitators) to have at least five or more sex partners since age 18. Those in other relationship statuses are quite similar in terms of the percentages who have had at least twenty-one sex partners. Thus, while cohabitators are more likely to engage in sexual behaviors and do so more frequently than other heterosexuals do, they do not differ appreciably from heterosexuals in all other nonmarital relationship statuses in the likelihood of having a high number of sexual partners.

Sexual Satisfaction. Sexual frequency is associated with overall perceptions of the quality of one's sex life (Blumstein and Schwartz 1983). Among those who engage in sex at least three times a week, the vast majority are satisfied with the quality of their sex lives (89 percent of both husbands and wives, 87 percent of male cohabitators,

88 percent of female cohabitators, 85 percent of gay men, and 95 percent of lesbians report satisfaction). The percentages of respondents who are satisfied with the quality of their sex lives decreases linearly with decreasing sexual frequency in all types of unions. For example, among those engaging in sex once a month or less, only 32 percent of husbands and wives are satisfied with the quality of their sex lives, compared with 4 percent of male cohabitators, 30 percent of female cohabitators, 26 percent of gay men, and 37 percent of lesbians. Other research has confirmed these findings (e.g., Call et al. 1995; Donnelly 1993).

The number of sexual partners a respondent has within the last year also influences physical pleasure and emotional satisfaction (Laumann et al. 1994). Married and cohabiting respondents who have had only one sexual partner in the last year are identical in terms of the the percentage reporting that they are extremely or very physically pleased with their relationships (87.4 percent and 84.4 percent, respectively). However, married and cohabiting respondents with more than one partner in the last year are less physically pleased by their primary partners (61.2 percent and 74.5 percent, respectively). The majority of those who are neither spouses nor cohabitators are also extremely or very physically pleased with their primary relationships regardless of whether they have one or more partners (78.2 percent with one partner are extremely or very physically pleased, compared with 77.9 percent of those with more than one partner).

Spouses with only one sexual partner in the last year are more likely than are respondents in the other union types to report that they are extremely or very emotionally satisfied with their relationships (84.8 percent; 75.6 percent of the cohabitators and 71.0 percent of those who are neither married nor cohabiting report that they are extremely or very emotionally satisfied). However, only 56.7 percent of marrieds with more than one partner report being extremely or very emotionally satisfied with their primary partners (the corresponding figures for cohabitators and those who are neither married nor cohabiting are 57.9 percent and 61.7 percent, respectively). In short, these numbers indicate that most individuals with one partner are quite physically pleased and emotionally satisfied with their relationships. Unfortu-

nately, statistics are not provided comparing homosexual relationships to heterosexual relationships.

Overall Satisfaction with Life. As previous researchers have argued (e.g., Cupach and Comstock 1990; Edwards and Booth 1994; Greeley 1991; Lawrance and Byers 1995), sexual satisfaction is associated with overall relationship satisfaction, which is associated with overall satisfaction with life. Men and women are very similar in terms of their self-reports of overall life satisfaction (Laumann et al. 1994). There are, however, differences by marital status, sexual frequency, and number of partners. First, married respondents are more likely than are the never married, the divorced, the widowed, and the separated to state that they are extremely or very happy overall (67.5 percent, compared with 51.9 percent of never-marrieds, the next highest percentage) (Laumann et al. 1994). Similarly, they are less likely than are those in other statuses to report that they are fairly unhappy or unhappy with life most times (8.7 percent versus 15.2 percent of the never-married, the next lowest percentage in the sample). Unfortunately, Laumann et al. (1994) did not compare cohabitators, nonmarried/noncohabitators, or gays and lesbians to the legally married on this measure. However, they report that 62.5 percent of heterosexual men and 59.2 percent of heterosexual women are extremely or very happy, compared with only 47.1 percent of homosexual men and 45.6 percent of lesbians.

Respondents with only one sexual partner in the last year are happier overall (63.4 percent report being extremely or very happy) than are those with no sexual partners in the last year (40.7 percent) and those with more than one sexual partner (44.9 percent of those with two to four sexual partners and 47.2 percent of those with five or more sexual partners) (Laumann et al. 1994). Furthermore, the frequency of sex is associated with overall happiness in a generally linear fashion: The proportion of respondents stating that they are extremely or very happy increases with increasing frequency of sex in the past year unless the respondents engage in sex at least four times a week; the proportion reporting that they are extremely or very happy decreases slightly at this point. Again, Laumann et al. (1994) do not report distinctions among the respondents based on union status (married, cohabiting, homosexual, etc.).

Summary. These results clearly indicate that sex in marriage is not boring or non-existent for most couples and that unattached (not married and not cohabiting) individuals are not having all the fun. Indeed, because frequency of sex is associated with satisfaction with one's sex life and with overall feelings of happiness, one would expect married individuals to exhibit high levels of well-being in this regard, since most have steady access to a sexual partner. Also, variety of sexual experience as a function of having numerous partners is not associated with increasing feelings of happiness; instead, exclusive attachment to one sexual partner is associated with high levels of well-being for most respondents. These results raise the question: Why do some individuals engage in extramarital/extradyadic sex?

EXTRAMARITAL/EXTRADYADIC SEX

Behavioral Incidence. Kinsey et al. (1948, 1953) estimated that approximately half of married men have engaged in extramarital intercourse; the corresponding proportion for married women is approximately one-fourth. More recent figures that are based on more rigorous sampling methods indicate that on average, approximately 25 percent of men and 15 percent of women have experienced extramarital sex (Laumann et al. 1994). In additional analyses conducted by Laumann et al. using 1991 General Social Survey data, 21.7 percent of men and 13.4 percent of women (both between the ages of 18 to 59, consistent with their own sample) reported having extramarital sexual experience. These figures are consistent with those of Wiederman (1997), who, using data from the General Social Survey, found that 22.7 percent of men and 11.6 percent of women have engaged in extramarital sex. In their analysis of the National AIDS Behavioral Survey, Choi et al. (1994) found that 2.9 percent of men in the national sample (4.1 percent of men in the urban sample) and 1.5 percent of women in the national sample (1.0 percent of women in the urban sample) had engaged in extramarital sexual activity within the last twelve months (these percentages would increase with longer periods of exposure to opportunities for extramarital sex). Laumann et al. (1994) found that 3.8 percent of the married respondents had engaged in extramarital sex within the last twelve months (they did not differentiate between men and women among marrieds).

Blumstein and Schwartz (1983) found that 26 percent of husbands and 21 percent of wives had been nonmonogamous in their current relationships. According to those authors, 29 percent of nonmonogamous husbands had only one extramarital partner, while 42 percent reported having two to five extramarital partners. The corresponding figures for wives are 43 percent and 40 percent, respectively. Blumstein and Schwartz (1983) also found that 33 percent of male cohabitators and 30 percent of female cohabitators had engaged in extradyadic sex. Thirty-six percent of nonmonogamous male cohabitators had only one extradyadic partner (49 percent reported having had two to five partners). Forty-four percent of nonmonogamous female cohabitators reported having had only one extradyadic partner (41 percent reported having had two to five partners). Furthermore, 82 percent of gay men have engaged in extradyadic sex; among them, only 7 percent reported having had only one extradyadic partner (43 percent reported having had at least twenty). Blumstein and Schwartz (1983) report that 28 percent of lesbians were nonmonogamous; 53 percent had only one extradyadic partner, while 42 percent had two to five.

Unfortunately, Laumann et al. (1994) did not present the percentages of those in nonmarital/noncohabiting relationships who are sexually nonexclusive. However, Forste and Tanfer (1996) found that 18 percent of dating women between ages 20 and 37 had engaged in a least one instance of extradyadic sex.

As these results indicate, when respondents are asked if they have engaged in extramarital/extradyadic sex, the majority (with the exception of gay men) report sexual exclusivity with their spouses/partners. Also, at young ages (those under age 40), there does not appear to be a gender difference in sexual nonexclusivity among married respondents (Wiederman 1997). Over the age of 40, however, men are more likely to have engaged in extramarital sex. For example, 29.3 percent of men in their forties have engaged in extramarital sex, compared with 19.3 percent of women in their forties (Wiederman 1997). The greatest gender difference was found among respondents in their sixties, among whom 34 percent of men but only 7.6 percent of women reported having engaged in extramarital sex. It appears that the extramarital sexual behavior of women is becom-

ing more similar to that of men as younger cohorts age.

Attitudes. According to Sprecher and McKinney (1993), much research has been conducted on attitudes toward extramarital sex. Generally, the measures employed in these studies assess either normative attitudes (those concerning the acceptability of extramarital sex in general) or personal standards (those assessing the acceptability of extramarital sex for oneself). Most research on normative standards has found that the majority of Americans disapprove of sexual relations with someone other than a person's spouse (Davis 1980; Greeley 1991). For example, Laumann et al. (1994) found that 77.2 percent of their (unweighted) sample believe that extramarital sex is "always wrong." Similarly, using General Social Survey data and restricting the sample to those between the ages of 18 and 59, they found that 74.3 percent believe that extramarital sex is "always wrong." However, other studies measuring personal standards have found that among younger men (under age 40), 70 percent envision themselves as having extramarital affairs at some point (Pietropinto and Simenaur 1977). Furthermore, Atwater (1982) reports that current predictions assert that as young married women age, approximately 50 percent will engage in extramarital sex. Of course, there is considerable difference between actual behavior, attitudes toward behavior for oneself versus others, and predictions concerning the future, as these numbers indicate. It may be expected that statistics on actual behavior are the most accurate in determining the prevalence of extramarital sex.

Explanations for Extramarital/Extradyadic Sex. Why do individuals engage in extramarital/extradyadic sex? It appears that the answer to this question depends in part on one's gender and relationship status. Extradyadic sex appears to be part of the culture of male homosexuality (Blumstein and Schwartz 1983). Indeed, it may be part of the socialization experience of most young men, who may enjoy high status among their peers for being sexually nonexclusive, while women are encouraged to be sexually exclusive (Peplau et al. 1977; Rubin 1990). Also, cohabitators in general (both men and women) tend to be much more liberal than are married couples on a variety of measures, such as premarital sex, abortion, and divorce (Blair 1994; Denmark et al. 1985; Macklin 1983a, 1983b). These liberal attitudes may correspond with more

liberal attitudes and behaviors regarding sexuality, including extradyadic sexual behaviors.

Atwater (1982) conducted an in-depth study of married women who engaged in extramarital affairs with single men. She argues that married men and women engage in extramarital affairs for different reasons. Married women who have such affairs report that their self-esteem and confidence increase as a result of an affair; they report feeling more powerful, independent, and resourceful. Married men, in contrast, typically become involved in extramarital affairs in response to unsatisfying marital sex or the belief that their wives (or any one woman, for that matter) could not possibly satisfy all their sexual needs (Meyers and Leggitt 1975; Yablonsky 1979).

In a study of justifications for extramarital sex, Glass and Wright (1992), found that men and women differ in their approval of specific justifications. They found that men are more likely to support sexual justifications for extramarital sex, including engaging in extramarital sex for the purposes of enjoyment, curiosity, excitement, and novelty. Women, in comparison, are more likely to support love justifications (getting love and affection and falling in love) and emotional justifications (intellectual sharing, understanding, companionship, enhanced self-esteem, and respect for extramarital sex). The data collection methods employed in this study were not rigorous (questionnaires were handed out on the street to be completed and mailed back, with a response rate of 36 percent), and only respondents' attitudes were assessed, not actual justifications for their own extramarital sexual experience. However, this research suggests that men and women think differently about extramarital/extradyadic sex (as they do about other forms of sexuality, as evidenced by the sexual double standard; see Sprecher and McKinney 1993). Future research should continue to explore the use of justifications by men and women for engaging in extramarital/extradyadic sex.

The Character of Extramarital/Extradyadic Relationships. What are extramarital/extradyadic relationships like? The perspectives of those involved probably differ. Such relationships have been explored in depth only among legally married spouses involved with single individuals. Thus, the discussion here applies only to married cou-

ples, although the findings presented may apply to cohabitators as well.

In an extensive analysis of the relationships between married men and single women, Richardson (1985, 1988) discusses the power play inherent in an extramarital (and, by extension, an extradyadic) relationship. Popular opinion would suggest that the unmarried partner is the one with the power because at any moment she could reveal the affair to her married lover's wife. However, the partner who is married typically holds most of the power. Being married typically requires that the extramarital relationship be maintained in secret and thus in privacy. Often the home of the unmarried partner becomes "their" home because it provides the only safe setting in which the partners can come together. Furthermore, the married partner decides when and how much time the couple will spend together. The man is more likely to have competing obligations (notably a spouse and children), and so the unmarried partner often makes herself constantly available to her married lover whenever he can find time to spend with her. As a result, the single woman often constructs her entire life around her married lover, as she cannot obtain social support for her relationship from other family members and friends (because the relationship is maintained in secret). By being so dependent on her married lover, the single woman empowers him while giving up any control she formerly had.

Also, the unmarried partner has much to lose by revealing the affair to her married lover's wife (Richardson 1985). She may lose the relationship altogether, since the married partner's spouse would in most situations call for an immediate end to the relationship. Also, the betrayed spouse could destroy the reputation of the other woman by accusing her of being a home wrecker, causing emotional distress to the betrayed spouse and her children, causing financial problems, and so on. Furthermore, if the other woman works with her married lover, she may be labeled as "sleeping her way to the top," which could mean career and financial problems. This does not mean, however, that the single woman never reveals to the wife that her husband is having an extramarital affair. Block (1978) reports that some of these women (and men, in addition to the married lovers) intentionally plant evidence of an affair in an attempt to force a marital separation. However, it is not the

case that the single woman could only benefit from such a revelation.

Popular opinion also states that the “wife is always the last to know” about her husband’s extramarital liaisons, but it is more accurate to say that the wife is always the last to acknowledge an affair. Indeed, numerous researchers (e.g., Atwater 1982; Block 1978; Framo et al., 1975; Richardson 1985; Yablonsky 1979) have discussed the lengths to which a monogamous spouse will go to pretend that the affair does not exist, some bordering on the absurd. Atwater (1982) refers to such feigned ignorance of an affair as a “‘pretense’ context” (p. 86). Most wives pretend not to know about the affair because admitting knowledge of it would force them to feel compelled to respond to such a transgression (Framo et al. 1975). These women appear to have been lulled into a sense of complacency. They do not want to believe that their comfortable (although possibly dull) marriages may be in danger. Therefore, feigning ignorance may be a strategy to maintain the marriage (Richardson 1985). This may be especially important to wives who feel they have few alternatives to the marriage. Women in midlife, who have minimal chances of successfully competing with other women to find a long-term heterosexual relationship, and women who have been financially dependent on their husbands for many years may feel they have no choice but to stay with their husbands.

Similarly, a single woman interested in a permanent relationship with a married man (not all of these women are interested in permanent relationships, as that typically would entail performing housework and other services for the man, something their wives do instead; Richardson 1985) often denies the existence of the wife in order to more easily engage in her fantasies of permanence (Richardson 1985; Yablonsky 1979). Thus, feigned ignorance allows both women to indulge in their preferred fictions. The result, of course, is that the married man has the implicit permission of his wife to engage in the extramarital affair, while the single woman does not place undue pressure on him to divorce his wife.

Sometimes the evidence of an extramarital affair cannot be ignored. In these cases, there are several possible outcomes. One may be the immediate end of the extramarital affair (Framo et al.

1975). Another may be the eventual end of the marriage. Even if the marriage ends, however, it is unlikely that the newly divorced husband will marry the other woman even if he leaves his wife for her (Richardson 1985). A third possible outcome is that the married couple will arrive at an understanding of the husband’s infidelity. For example, upon the discovery of the husband’s extramarital liaison, the couple may engage in a tremendous and ugly conflict, followed by the husband promising to never stray again and the couple maintaining their relationship. However, few wives place much faith in a husband’s new claims to fidelity (Ziskin and Ziskin 1973). Other couples construct an arrangement in which husbands are permitted to engage in extramarital sex, presumably because of their greater sexual need (Yablonsky 1979), but wives are expected to remain monogamous (Ziskin and Ziskin 1973). The wives typically accept this arrangement with resignation: They believe that they will not be able to stop their husbands from engaging in extramarital sex, and as long as the husband continues to remain married to the wife, does not allow himself to develop a deep emotional attachment to any of the other women with whom he is involved, and does not bring home a sexually transmitted disease, the stability of the marriage is not threatened (Block 1978; Yablonsky 1979; Ziskin and Ziskin 1973). A few wives may believe that they benefit from this situation, as they are granted the ability to pursue their own interests (rather than responding to the husband’s needs), while the husband has some of his needs met by other women (Moultrup 1990). Finally, some spouses construct a new agreement in which both spouses are permitted to engage in extramarital sex (Myers and Leggitt 1975; Yablonsky 1979).

Summary. These results indicate that extramarital/extradyadic sex is not a majority experience. Indeed, with the exception of gay men, most individuals in committed relationships are sexually monogamous. These results also indicate that single women involved in extramarital affairs are not necessarily home wreckers or are looking to “steal away” another woman’s husband. Furthermore, the married men involved in these affairs are not the hapless victims of single women’s feminine wiles, powerless to reject any and all sexual advances. Finally, the monogamous husbands and wives left at home while their spouses rendezvous with single lovers are not necessarily

the fools that others make them out to be but are often making a conscious choice to ignore a spouse's infidelity because of a lack of attractive alternatives to the current relationship.

As this discussion illustrates, little research has been conducted on extradyadic affairs among cohabitators, gay men, and lesbians, with the exception being the collection of statistics on the incidence of such experiences, as was discussed above. While heterosexual cohabitators may experience the same conditions and responses to their own or their partners' infidelity as do the legally married, future research should specifically address the experience of extradyadic sex among them in addition to infidelity among homosexual couples.

As has been suggested throughout this article, the relationships of homosexuals may be both similar to and different from those of heterosexuals in important respects (as an example, recall the very high relative rates of nonmonogamy among gay men, while the rates of nonmonogamy are similar among lesbians and heterosexual wives). Indeed, the relationships of gay men and lesbians are similar to and different from each other in important ways as well. The following section presents the results of research indicating the incidence and prevalence of homosexuality for both men and women as well as how those relationships may be similar to and different from the relationships of heterosexuals.

HOMOSEXUALITY

Behavioral Incidence. In discussing statistics on the prevalence of homosexual experience among men and women, one must be extremely cautious. Even at the end of the twentieth century, homosexuality was still a decidedly stigmatized status. This can be seen in attitudes toward homosexuality: In their analysis of General Social Survey data, Davis and Smith (1987) found that 75 percent of adults in the United States believe that sexual relations between two adults of the same sex are "always wrong." Only 12 percent of adults believe that sexual relations between two same-sex partners are "not wrong at all." This stigma probably results in some individuals claiming no homosexual experience when such experience has occurred or continues to occur for those individuals. Thus, one may suspect that reported statistics on the

incidence and prevalence of homosexuality are inaccurately low.

Furthermore, homosexuality may be measured in a number of ways. For example, homosexuality may be defined as having same-gender sex partners, as expressing homosexual desires, or defining oneself as homosexual, bisexual, heterosexual, and so on (Laumann et al. 1994). Such variability leads Laumann et al. to conclude that there is "unambiguous evidence that no single number can be used to provide an accurate and valid characterization of the incidence and prevalence of homosexuality in the population at large" (1994, p. 301).

Laumann et al. (1994) report different percentages of the incidence and prevalence of homosexuality depending on how homosexual experience is defined. For example, they found that 0.6 percent of men and 0.2 percent of women have exclusive homosexual experience; that is, these men and women have never engaged in sexual activity with a person of the opposite sex. However, when respondents were asked if they had had any same-gender sex partners since the age of 18, 4.9 percent of the men and 4.1 percent of the women reported having had same-gender sex partners. Furthermore, 9.1 percent of men and 4.3 percent of women reported having engaged in at least one sexual practice with a same-gender partner since puberty (these practices include oral and anal sex). Also, 2.0 percent of men and 0.9 percent of women define themselves as homosexual (0.8 percent of men and 0.5 percent of women define themselves as bisexual; the remainder define themselves as heterosexual). In short, as these statistics illustrate, accurately determining the incidence and prevalence of homosexuality is both a political issue and a methodological issue.

The Character of Homosexual Relationships.

Today most individuals maintain their intimate relationships in ways that differ from the traditional model (i.e., a breadwinning father and a stay-at-home mother). These various methods of maintaining relationships typically are referred to by social scientists and the larger public as "alternatives" rather than as legitimate family relationships (Boswell 1994; Scanzoni et al. 1989). Defining these relationships as alternatives to the standard (the traditional nuclear family) implies that such

relationships are somehow not as legitimate or valid as the standard (Scanzoni et al. 1989).

A closer examination of these relationships, however, indicates that dyads that do not conform to the traditional standard are similar in certain important respects to traditional heterosexual relationships, particularly in the dyads' search for emotional intimacy and permanence (Scanzoni et al. 1989). More specifically, both heterosexual and homosexual individuals often seek potential partners who are similar to themselves in important ways (Murray 1996). For example, in her analysis of the relationships of homosexual dyads, Sherman (1992) interviewed numerous couples who specifically stated that they chose their current partners on the basis of shared behaviors or interests. For example, John and Reid, a couple that had been together for seventeen years, discussed how

when we first got together, we talked a great deal about life goals and how we felt about relationships. . . . We decided early on that we wouldn't allow anything to come between us. We've really worked at that. We've made sacrifices about where we wanted to live and what we did professionally to help the other out at different points (p. 60).

However, both men agreed that while their relationship comes before the pursuit of individual interests, "we both sense the importance of being individuals and helping the other toward self-actualization" (p. 60). Thus, this couple struck a balance between pursuing their individual autonomy and maintaining their relationship on the basis of their similar values.

Similarly, in a study of eighty-four lesbian couples, Weber (1998) interviewed numerous couples who emphasized the importance of shared interests in forming and maintaining their relationships. A 46-year-old educator and a 43-year-old registered nurse who had been cohabiting for two years reminisced about how they came together: "We met at a Democratic fund-raiser, so through our work there we gained respect for each other overall and realized that we are intellectual and political equals. We also noted that we are peers on an educational and vocational level" (p. 57).

It appears that similarity in relevant characteristics attracts potential long-term partners to each other regardless of whether the couple consists of

heterosexual partners, gay men, or lesbians. These long-term couples share a strong sense of commitment and the expectation of permanence based on similar values, making their relationships similar.

However, the relationships of both gay men and lesbians differ in some important respects from those of heterosexual couples, mainly because of the lack of social support homosexual couples experience as a result of their stigmatized status. More specifically, legal and religious institutions for the most part do not acknowledge the legitimacy of homosexual relationships. While in some cities homosexual couples may obtain domestic partnership certificates that publicly acknowledge their relationships, they still may not legally marry in the United States (Wisensale and Heckart 1993; Worsnop 1992). Also, while some representatives of mainstream religious organizations are willing to perform commitment ceremonies (see Sherman 1992 for a discussion of couples who engaged in these ceremonies), the official position of Catholicism, Judaism, and mainstream Protestantism is not to acknowledge such relationships in a religious sense.

Homosexuals confront numerous issues that do not affect heterosexuals. For example, homosexuals often must come to terms with a sexual identity that is stigmatized by the society in which they live. They also must decide whether they will "come out" to family members, friends, and coworkers, recognizing that doing so may jeopardize their relationships and employment. Heterosexuals do not "come out" with their sexual identity, as it is assumed that they are straight, and such an identity is encouraged and valued. Also, heterosexuals are rarely concerned that their sexual identity may result in social ostracism. One may expect that such concerns have an impact on the relationships of homosexual couples, something that is not experienced by heterosexual couples.

Homosexual couples often are shunned by family members and heterosexual friends when they reveal their sexual identity and introduce their partners to others. As a result, friends who do support the couple become defined by that couple as family (Nardi 1992). Those friends may be more important to the support of homosexual relationships than are the friends and family members of heterosexual couples, who also enjoy societywide support for their relationships, as was noted above.

Homosexuals are clearly aware of their second-class status in U.S. society. As a 35-year-old Department of Defense worker explained (Weber 1998, p. 50): "I am a valid and vital human being. I am a taxpayer, a property owner, a veteran, a professional, and also happen to be a lesbian. It is one aspect of who I am, yet it is the only aspect by which I am judged." A 36-year-old school counselor shared her experiences with the pressure associated with her socially ascribed second-class status (Weber 1998, pp. 51-52):

I love my child. I work. I pay taxes. I follow the Ten Commandments. I have friends and relatives that love me and I love them. I would help anyone in their time of need. I live next door to you in a clean house with a manicured yard. I live with my spouse, my child, and two dogs. I'm so normal that I'm boring. Yet, while I call her my spouse, I cannot legally marry the love of my life. While I love and support and care for my child, she could be taken away from me at the drop of a hat. While I have a responsible job at which I am very good, I could get fired without recourse. While I pay taxes, I cannot claim "head of household" or file jointly with my partner. While I follow the Ten Commandments, many churches will not allow me to attend their services.

My family and friends are the most important things in my life, yet if many of my friends knew what my family included, they would cease to be my friends. How can this be? Because I am a lesbian, and according to the laws of this country and the moral judgments of most of you, I am a pervert that should not be allowed to exist.

In discussing both lesbian and gay male relationships together and comparing them to heterosexual relationships, it should not be assumed that homosexual relationships are similar regardless of the gender of the partners (indeed, it should not be assumed that all heterosexual relationships, all lesbian relationships, or all gay male relationships are similar). As was noted above, gay men and lesbians differ significantly with regard to sexual frequency, number of partners, and other characteristics. However, lesbians and gay men suffer from the same stigmatized status as homosexuals. Future research should continue to explore the various coping mechanisms employed by homosexual couples in dealing with this stigma as well as

the ways in which their relationships are affected by it.

Summary. As this discussion illustrates, homosexual relationships are similar in a variety of ways to heterosexual relationships, particularly with regard to the degree of commitment in long-term relationships and the expectation for permanence. Although, as was noted earlier, the majority of gay men are sexually nonexclusive, one should not interpret this to mean that among gay men involved in long-term unions, few are committed to their partners as evidenced by sexual nonexclusivity. Indeed, there are heterosexual couples who engage in nonmonogamy yet remain committed to their primary unions (see the above discussion of extramarital sex). Monogamy should not be confused with commitment to one's relationship, and nonmonogamy should not be considered an indication of a lack of commitment.

Homosexual relationships do, however, differ in important respects from heterosexual relationships as a result of the second-class status of their unions. One may suspect that this stigma has an impact on the relationship dynamics of homosexual unions. Future research is needed to understand more fully how societal conditions affect these intimate relationships.

CONCLUSIONS

This article has demonstrated that even in examining only close, committed relationships, knowledge of sexual behavior is largely descriptive. Researchers need to explore in much greater depth the sexual dynamics of these relationships. More specifically, there is a need for a better understanding of how couples negotiate their sexual behaviors. Who decides how frequently a couple will engage in sexual activity and in what behaviors they will engage in and when? What is the negotiation process? Also, there is virtually no understanding of how the larger society affects the sex lives of individuals and couples, with the exception of theories of gender socialization in explaining differences between men and women. Of course, asking these questions is a political as well as a methodological endeavor that requires a strong financial and philosophical commitment on a societal basis. While the knowledge of sexual behavior in close relationships has progressed considerably the last few years, a greater understanding is

needed of how individuals negotiate and manage their sex lives in the context of committed relationships rather than simply understanding what individuals *do* sexually. (Note: The authors wish to thank Susan Sprecher for her assistance on this article.)

SEXUAL BEHAVIOR PATTERNS

In the face of significant political and methodological obstacles, social science researchers have continued to advance the understanding of human sexuality. Clearly, the political climate surrounding sex research has improved since Kinsey and his colleagues conducted their pioneering studies on male and female sexuality in the late 1940s and early 1950s (Kinsey et al. 1948, 1953), but the politics of sex research continue to impede progress in this area. One prominent research team, for example, was forced to abandon its efforts to secure federal funding and turn to private foundations to support a landmark study on human sexuality in the general population (Laumann et al. 1994b).

Despite the efforts of some conservative politicians, policymakers have become more willing to fund research on sexuality and related issues. This funding pattern is documented by the numerous large-scale national surveys that were supported by federal monies during the late 1980s and 1990s. These studies dealt extensively with sex and re-

lated issues (e.g., National AIDS Behavioral Survey, National Surveys of Adolescent Males, National Surveys of Men) or included a small battery of sex-related questions in surveys dealing primarily with other topics (e.g., ADD Health Surveys, National Household Survey of Drug Use, National Surveys of Families and Households, National Survey of Labor Market Experience–Youth, Youth Risk Behavior Survey). Funding agencies such as the Social Science Research Council Sexuality Research Fellowship Program are expanding studies of sexuality by offering crucial support for both quantitative and qualitative research projects about sexuality (Di Mauro 1997). Efforts also are being made to expand international studies of sexual behavior (Parker 1997). Most observers agree that the human immunodeficiency virus/acquired immune deficiency syndrome (HIV/AIDS) epidemic has provided the major impetus for this turnaround.

While a great deal has been learned about sexual behavior in recent years, especially among adolescent and young adult men, much of this research has focused on sexuality within a “social problems” context. This research typically has dealt with issues associated with teenage sexuality and pregnancy, HIV/AIDS, coercive sexuality, or another form of sexuality that has attracted a “deviant” label. As a result, relatively little attention has been devoted to studying the expression of sexuality in noncontroversial, everyday life circumstances.

Sex research took an impressive step forward with the publication of *The Social Organization of Sexuality: Sexual Practices in the United States* (Laumann et al. 1994a) and *Sex in America* (Michael et al. 1994), the less technical version of this study prepared for the general public. These publications were based on data drawn from the National Health and Social Life Survey (NHSL) that included face-to-face interviews and supplemental self-administered questionnaires given to 3,432 respondents aged 18–59 who were selected randomly from the noninstitutionalized population. The NHSL represents the most comprehensive sex survey to date that uses a probability sample of the general noninstitutionalized U.S. population.

Conducting sex surveys or other types of research in this area continues to be difficult because sex researchers, compared with researchers in

most other areas, deal with particularly sensitive and personal topics and therefore face serious difficulties with issues related to response bias, sample representativeness, measurement, and ethics. With these methodological issues in mind (Bancroft 1997; Bentler and Abramson 1980; Jayne 1986; Kelley 1986) and given this article’s space limitations, this review assesses the available research on sexual *behavior* in the United States. The brevity of this article precludes a review of all the literature on individuals’ subjective perceptions of sexuality. Notably, much of the research on gay, lesbian, and bisexual experiences has revolved around identity, etiology, community, and AIDS (Risman and Schwartz 1988). While this entry discusses same-sex sexual behavior patterns, the reader should consult “Sexual Orientation” in this encyclopedia for a summary of literature about gay, lesbian, bisexual, and transsexual/transvestite identities and experiences. Since much of the literature on sexuality subsumes behavior under identity, this discussion uses the terms “heterosexual,” “homosexual,” and “bisexual” as adjectives rather than nouns and uses the terms “gay,” “lesbian,” and “bisexual” to refer to self-identity as reported in research studies (Risman and Schwartz 1988).

This discussion takes into account five basic and interrelated features of sexuality: (1) patterns of behavior, emphasizing gender, race, and sexual orientation, (2) the varied meaning of sexuality at distinctive periods throughout the life course, (3) social control aspects, particularly as they relate to prostitution, (4) the consensual and coercive contexts within which sex occurs, and (5) the relationship between the HIV epidemic and sexual behavior. While this entry reviews primarily social science literature, a number of studies have been published in the popular press, some of which have received considerable attention from the lay population, that are based on self-selected samples of persons who returned magazine surveys (Kelley 1986 provides a review of these works) or volunteered for qualitative interview studies (Rubin 1990).

SEXUALITY IN THE LIFE COURSE

Childhood Sexual Behavior. Given the Western view of children as asexual beings, little social science research has been conducted on childhood sexuality in the United States; most of the

limited research has occurred within northern Europe. Data that are available typically rely on adults' recollections of their childhood experiences or the reports of parents about their children. While this research is methodologically limited, it does offer a glimpse of children's sexual behavior and play.

Anthropological research has shown clearly that while individuals in Western cultures tend to view children as asexual, children are seen as being capable of sexual activity in many nonindustrialized, non-Western countries (Ford and Beach 1951). Parents in non-Western countries sometimes tolerate and even encourage their children to pursue heterosexual behaviors (including intercourse), homosexual behaviors (e.g., fellatio), or both. In some societies mothers masturbate their children to soothe them.

The available research indicates that prepubertal boys are much more likely to experience intense sexual interest and masturbate and to do so at younger ages than their female counterparts. Boys also appear to participate more frequently throughout childhood in both heterosexual and homosexual play activities that have sexual overtones (e.g., "doctor and nurse"). These activities typically include an element of exhibition, exploration, and experimentation. In a unique longitudinal study of children in California, researchers found that about 48 percent of mothers reported that their children had engaged in interactive sex play (77 percent when masturbation was included) before age 6 and that exposure to such sex play was not related to children's long-term adjustment at ages 17 to 18 (Okami et al. 1997).

Other researchers focusing on heterosexual and lesbian women in Brazil, Peru, the Philippines, and the United States found similarities across cultures in regard to memories of childhood sexual behavior. Self-identified lesbians were found to be more sexually active as children and reported earlier contact than did heterosexual women. Lesbians also were more interested in girls than heterosexual women were in boys, even though lesbians reported more early attractions to men than did heterosexual women (Whitam et al. 1998). Another study of gay and bisexual male youth ranging in age from 17 to 23 also depends on memories of childhood to understand early childhood same-sex attractions. The results of this

study show that in most cases, same-sex attractions began in childhood and were given sexual meaning at the onset of puberty (Savin-Williams et al. 1996). Both studies suggest that same-sex attractions are felt in childhood and are acted on in adolescence.

Adolescent and Young Adult Sexual Behavior. In contrast to childhood sexuality, an expansive body of literature on adolescent heterosexual behavior has emerged during the past two decades, and much more extensive data are now available on young males (Moore et al. 1995, 1998; Sonenstein et al. 1997). Much of this research has used one of several national data sets to document and examine rates and trends for age at first intercourse and sexual activity patterns, with particular attention given to racial patterns.

The bulk of the evidence suggests that there was a sizable increase in the rate of sexual activity among teenage females in the 1970s and 1980s, although that increase appears to have leveled off in the 1990s. In fact, among 15- to 19-year-old females, while the proportion that had ever had intercourse increased from 29 percent in 1970 to 55 percent in 1990, it declined slightly to 50 percent in 1995. About 77 percent of 19-year-old females have had sex at least once. The main reason teenage females remain virgins is that having sex would violate their religious or moral values. While rates among African-American and white females have converged over the past two decades, black females are still more likely to report being sexually active than are their white counterparts. Whereas 90 percent of black females have had intercourse by age 19, about 75 percent of whites and Hispanics have had coitus.

Sexual activity rates among comparably aged males have increased since the 1970s and have always been higher than those of females. A 1998 study compared three separate national samples of males aged 17-19 living in metropolitan areas in 1979, 1988, and 1995 and found that the percentage of respondents who had ever had heterosexual intercourse shifted from 66 percent, to 76 percent, to 68 percent (Ku et al. 1998). However, these changes were restricted to nonblack males because the rates for blacks increased from 1979 to 1988 and then remained basically constant between 1988 and 1995. A similar curvilinear pattern

for the overall sample (but not for blacks) was observed when researchers examined the proportion of teenage males who had had intercourse in the four-week period before the interview. Meanwhile, the average number of times young males engaged in sexual intercourse during the previous twelve-month period increased from fourteen in 1979 to seventeen in 1988 to twenty-one in 1995. While black males did not experience a change in frequency between 1979 and 1988, they reported a significant increase from 1988 to 1995 (thirteen versus twenty-four acts per year).

Attempts to explain why youth initiate sex have focused primarily on the direct and indirect influence of sociodemographic, social psychological, and biological factors. Most of the research designs, especially those used in studying females, are not ideal for concluding a causal relationship between beliefs, attitudes, or values and sexual behavior because these variables tend to be measured simultaneously. Despite this methodological shortcoming, a number of factors appear to be related positively (when controlling for numerous variables) to the probability of individuals engaging in heterosexual intercourse at a young age: being black, living in a poverty area, having weak religious beliefs, attending a segregated school (for blacks), attending an integrated school (for whites), lower parental education, having a mother who was sexually active at a young age, living in a single-parent household, having more siblings, and having a low level of academic achievement.

In addition to these social variables, a small number of researchers have used cross-sectional and longitudinal designs to study the relationship between adolescent hormones and heterosexual behavior (Udry 1988). While this research has produced mixed results, hormones and biological markers associated with puberty appear to be related to adolescents' sexuality (both attitudes and behavior). Consequently, a growing number of social scientists are advocating the development of biosocial models that take into account the complex interrelationship among the pubertal process, sexual identity development, sexual behavior, and societal norms. Collecting saliva and blood samples has become an acceptable, and increasingly expected, component of national data collection efforts that target adolescent sexuality and fertility.

The discussion of social and biological factors leading toward the initiation of sexual behavior is also present in studies of same-sex attractions, desires, and behaviors. Similar to heterosexual onset of active sexuality, gay, lesbian, and bisexual youth report the development of sexual interest during puberty. Gagnon (1977) explains that young men typically self-identify as gay and have homosexual experiences at an earlier age than do young women. Jay and Young (1979) report awareness of same-sex attraction for young men developing at the median age of 13 or 14 and for young women at age 18. Cohen and Savin-Williams (1996, pp. 120-121) summarize the results of ten different studies of the initiation of sexual behavior (mostly among young men) and find that the average age of reported first experience of homosexual sex is 15 for young men, with young women reporting an average age of 16. Importantly, same-sex sexual behavior is not always correlated with the development of a gay, lesbian, or bisexual identity. Studies show that youth will participate in homosexual activities without later "coming out" as gay, lesbian, or bisexual. In particular, as a result of cultural understandings of gender and sexuality, Chicano men who participate in same-sex anal intercourse do not consider it "gay sex" unless one is in the subordinant (receptor) role (Almaguer 1993; Alonso and Koreck 1993; Carrier 1989). Research in this area supports the supposition that social and cultural factors are important in the initiation of same-sex sexual behavior and its attendant meaning.

Research on adolescent homosexual and bisexual behavior is complicated by the stigma associated with a gay, lesbian, or bisexual identity, and so many youths do not self-report same-sex activities (Savin-Williams et al. 1996). While many self-identified gay, lesbian, and bisexual adolescents report desiring steady, loving same-sex relationships, many maintain heterosexual relationships and fear revealing close same-sex friendship because of the stigma associated with being "gay" (Hetrick and Martin 1987). Thus, studies of sexual behavior among gay, lesbian, and bisexual adolescents have documented heterosexual behavior, although with a lesser frequency than is the case with heterosexual counterparts. Interestingly, lesbian and bisexual female adolescents tend to report more heterosexual experiences than do gay and bisexual male adolescents (Herdt and Boxer

1993). Research on the frequency of sexual activity among gay, lesbian, and bisexual young adults indicates that for some populations, entry into college allows an increase in the frequency of sexual experiences (Evans and D'Augelli 1996).

While most research has focused on heterosexual intercourse, a number of studies of adolescent and young adult populations have examined issues related to the number of sexual partners, frequency of sexual intercourse, other types of sex acts, and the sequencing of petting behaviors (Laumann et al. 1994a; Moore et al. 1995; Warren et al. 1998). The majority of teenagers and those in their twenties tend to have one sexual partner at a time, a form of serial monogamy. One study found that 72 percent of women aged 18–29 reported having only one partner in the previous year, and another found that only about 10 percent of females have two or more partners in a three-month period. Among the sexually experienced, about 77 percent of 15- to 19-year-old females and 85 percent of those aged 20–24 report having sex more than once a month. Among sexually experienced teenage males aged 15–19, 54 percent report having had no more than one partner in the previous year, 80 percent report having had two partners, and 6 percent report having had five or more.

Researchers also have shown that the prevalence of oral sex has grown tremendously in this century. Kinsey's data revealed that very few college women born between 1910 and 1935 performed fellatio (11 percent) or received cunnilingus (12 percent). More recent studies in California and North Carolina suggest that between one-third and one-half of adolescents aged 15–18 have engaged in oral sex (Hass 1979; Newcomer and Udry 1985), while nonrepresentative studies of college students in the United States and Canada indicate that between 32 and 86 percent of females have administered oral sex and between 44 and 68 percent say they have received it (Herold and Way 1983; Young 1980). Furthermore, Kinsey's data suggested that oral sex was primarily experienced only among those who also had experienced coitus (only 5 percent of male and female virgins reported performing it), but more recent research indicates that a sizable minority of youth are experiencing oral sex while they are technically virgins.

Single-Adult Sexual Behavior. Because researchers have not clearly and consistently distin-

guished between young adult (18- to 24-year-olds) and adult sexual behavior in presenting their findings, it is difficult to present a clear-cut review of "adult" sexual behavior among single persons. Research has shown that rising divorce rates and postponement of marriage for heterosexual men and women have increased the population of single adults (Blumstein and Schwartz 1983). The inability of gay and lesbian partners to marry legally also contributes to the growing population of "single adults" because some persons in committed relationships are categorized as single. This growing population of single adults and the typical transition from experimentation and dating to long-term, committed relationships bring into focus a significant type of adult sexual behavior. While these demographic patterns are noteworthy, a large proportion of individuals still experience a significant proportion of their adult sexual histories within committed relationships or marriage.

For single adults, it is known that individuals today move through the sequence from first kiss to first intercourse much more quickly than did older cohorts of a similar age. Many of these first sexual experiences with a new partner occur within an arrangement that is perceived in some ways to be a relationship. Although men are more likely to find recreational sex outside a relationship acceptable, both men and women prefer to have sex within an ongoing romantic relationship. Thus, contrary to stereotypical images, most adults have sex infrequently when they are not in a relationship. Indeed, national data based on a sample of 18- to 59-year-olds who report being sexually active in the past year indicate that without controlling for age, 48 percent of men and 54 percent of women who have never been married and are not currently cohabiting have had sex only a few times or not at all in the past year. These figures varied only slightly for men (46 percent) and women (58 percent) who were divorced, separated, or widowed but were not married or cohabiting. The mean monthly frequency of sex (vaginal, oral, or anal) was 5.6 and 5.3 for men and women who never married and were not currently cohabiting and 5.4 and 5.1 for men and women who were divorced, separated, or widowed. Only 8 to 9 percent of men and women who had never married but were currently cohabiting—persons who could be perceived technically as being single—reported similarly low levels of sexual activity: a

few times a year or not at all. Meanwhile, among never married, noncohabiting persons, 29 percent of men and 21 percent of women reported giving oral sex to their partners during the most recent sexual experience. Among the entire sample, regardless of whether the respondents had sex in the past year, 67 percent of men and 70 percent of women reported that they had engaged in active oral sex at some point during their lives.

One of the revelations of Kinsey's early research was the extent to which people had same-sex sexual experiences without identifying themselves as gay, lesbian or bisexual. Since Kinsey's research, this finding has been reproduced in a variety of different contexts. Laumann et al.'s comprehensive sex study (1994a) illustrates how the interaction of behavior, attraction, and sexual identity complicates the measurement of the number of people who could be understood to be gay, lesbian, or bisexual. Ultimately, Laumann et al. (1994a) conclude that there is a core group of people who define themselves as "homosexual or bisexual," have same-gender partners, *and* express homosexual desires. Yet there are also a number of men and women who have adult same-sex sexual experiences or desires but do not identify themselves as "homosexual or bisexual." Additionally, variables (e.g., place of residence and level of education) are found to influence the number of homosexual experiences. Because of the complexity of measurement, Laumann et al. (1994a) conclude that there is no single answer to the prevalence of homosexuality. Studies of adult sexual experiences among men of color in the United States and men of color in other cultures also have illustrated the extent to which heterosexual adults engage in same-sex sexual behavior: Research has identified a large population of men who have sex with men (MSM) yet do not self-identify as gay or bisexual (Manalansan 1996). Research since Kinsey's original attempt to develop a comprehensive (although nonrepresentative) understanding of sexual behavior in the United States has shown that some adults participate in homosexual behavior without self-identifying as such.

Despite the complexity of sexual identity and behavior, a great deal of research on same-sex adult behavior patterns has been comparative, creating a binary heterosexual-homosexual comparison. This dualistic approach is so prevalent that many sexual activities are understood as being

in the domain of only heterosexual behavior or only homosexual behavior. For example, tranvestitism (cross-dressing) has been defined in the psychological literature as primarily the domain of heterosexual men, yet more recent research suggests that men with cross-dressing habits behave as homosexual, bisexual, and asexual as well as heterosexual, suggesting a complexity to adult sexual behavior patterns that is not fully understood (Bullough and Bullough 1997). In a significant study comparing same-sex sexual behavior patterns with opposite-sex behavior patterns, Masters and Johnson (1979) found some general trends of similarity for adult "heterosexuals" and "homosexuals" (both men and women). Overall, their research shows that "heterosexuals" and "homosexuals" have similar fantasy patterns and physiological responses to sexual stimuli. In other words, response to sexual stimuli is not conditioned by a particular sexual identity. Some differences between heterosexuals and nonheterosexuals emerge when women's experiences are highlighted. A study of 70 self-categorized heterosexual, bisexual, or homosexual women showed that bisexual and lesbian women were significantly more likely than were heterosexual women to describe their orgasms as "strong." In addition, bisexual and lesbian women put more emphasis on oral and manual sexuality, while heterosexual women put more emphasis on intercourse as a source of sexual response (Bressler and Lavender 1986). Overall, comparative studies suggest a similarity of sexual response and fantasy for both heterosexual and homosexual behaviors but some distinctions in terms of actual sexual activities participated in by self-identified gay, lesbian, or bisexual individuals.

Another arena of research that compares heterosexual behavior to gay and lesbian behavior is the study of committed relationships. A great deal of research illustrates the prevalence of stereotypes about gay, lesbian, and bisexual people being promiscuous and not involved in long-term, committed relationships. However, in one of the few large-scale studies of relationships (including heterosexual, gay, and lesbian couples), Blumstein and Schwartz (1983) found that many lesbians and gay men establish lifelong partnerships. Research also shows that in established couples, gay men and lesbians report as much satisfaction (measured in numerous ways) as heterosexuals do (Peplau 1982). Specific research about sexual be-

havior among gay and lesbian couples has shown some interesting trends. A notable finding in Blumstein and Schwartz's (1983) research is that the frequency of sex in lesbian couples is low compared to that in other couples. Among lesbian couples who had been together two to ten years, more than 25 percent reported having sex once a month or less. This finding has been explained in terms of women's sexual socialization, different definitions of sexuality, and age of couples (Blumstein and Schwartz 1983; Johnson 1990). By contrast, Blumstein and Schwarz (1983) report that gay male couples report higher sexual frequency than do married couples (of one to ten years). This often is explained in terms of men's socialization to value sexuality. Research on sexual frequency in committed couples illustrates the significance of gender and thus the diversity of relationships and attendant sexual behavior among self-identified gay men and lesbians.

Research about the diversity of sexual behaviors among gay, lesbian, and bisexual adults expanded in the 1990s. In general, gender is understood to account for variation of sexual behavior in the gay, lesbian, and bisexual population: Men having sex with men are understood to do so differently (in terms of frequency and activities) than women having sex with women. Variation also has been found within sexual identity categories. For example, it has been found that individuals involved in bisexual behavior have a variety of relationship types (Blumstein and Schwartz 1976). Meanwhile, distinctions in regard to adult same-sex sexual behavior in terms of race are not well understood. In a national-level study of more than 700 coupled, homosexually active African-American men and women, most of the respondents reported satisfying sex lives with their current partners and variation of sexual frequency among couples but no systematic difference between women and men (Peplau et al. 1997). The varieties of sexual behavior within gay, lesbian, and bisexual categories and couples are just being discovered.

The politics of sexuality research in the era of HIV/AIDS has expanded the understanding of sexual behavior among adults, but only in particular arenas. For example, national-level research on sexual behaviors among bisexual men and women and lesbians remains limited (Doll 1997). In addition, the way in which studies of male homosexuality have been conducted differentially operationalizes

"homosexual" as an identity, so that populations of men who have sex with men (MSM) sometimes are included and at other times are excluded (Carballo-Diequez 1997; Sandfort 1997). Clearly, studies of sexuality expanded dramatically in the 1990s, yet this growth pattern has been shaped by concerns associated with an era of HIV/AIDS.

Sexual Behavior among Elderly Persons. Although the proportion of the U.S. population over age 50 continues to grow, research addressing the relationship between aging and sexuality, in particular the sexual behavior of the elderly population (65 and older) is quite limited because of its frequent use of small nonrepresentative samples, its cross-sectional research designs, and its narrow, youth-oriented definition of sexuality as coitus. Consequently, generalizations are difficult to make, and most research on elderly persons' sexual behavior deals with the physiological and psychological aspects of this phenomenon. The Viagra revolution undoubtedly will prompt researchers to devote more attention to older persons' sexuality (Butler 1998).

Two of the more frequently cited, though perhaps dated, studies of aging and sexuality issues are the Starr-Weiner Report (1981) and the second Duke Longitudinal Study (George and Weiler 1981), neither of which was based on random sampling techniques. The former study included 800 sociodemographically diverse participants in senior centers, while the latter included a panel design of men and women health insurance program participants who were 46 to 71 years of age at the first observation period in 1969 and were followed for six years ($n = 348$ for those enrolled in all four data collection points). Seventy-five percent of the respondents in the first study reported that sex felt as good as or better than it did when they were younger. The results from an analysis restricted to the 278 married respondents who had been retained throughout the Duke study revealed that patterns of sexual interest and activity remained fairly stable over time, men reported higher levels of sexual interest and activity than did their female age peers, and younger cohorts of respondents reported higher levels of sexual interest and activity.

Compared to earlier studies (e.g., the Kinsey reports), the Starr-Weider and Duke studies as well as more recent ones have found higher levels

of sexual activity among older persons. Accordingly, Riporetelia-Muller (1989, p. 214) concluded that "for those elderly who remain sexually active and have a regular partner, the rate of decline is not as great as formerly believed." However, many older persons do not remain sexually active. Using data from the second Duke study, George and Weiler (1981) found that among those who were at least 56 years of age at the first observation date, 21 percent of men and 39 percent of women reported six years later that they had abstained from sexual relations throughout the study or were currently inactive.

In a study using data from a nationally representative household sample (Marsiglio and Donnelly 1991), about 53 percent of all married persons 60 years of age and older reported having sex in the past month, with 65 percent of those 60 to 65 years old being sexually active compared to 44 percent of those 66 or older. Among those who had been sexually active during the past month, the overall mean frequency for sexual relations was 4.3 times. In a multivariate context, persons were most likely to have had sex during the past month if they were younger, had a higher sense of self-worth and competency, and were married to a spouse who self-reported his or her health status as favorable. Surprisingly, when an interaction term was used to compare husbands and wives, no significant differences were observed in the way the partner's health status was related to sexual behavior, although other research has found that both husbands and wives report that males' attitude or physical condition tends to be the principal reason why they have curtailed or ceased to have sexual relations. Meanwhile, other research indicates that being widowed is the most frequently cited reason for not being sexually active among older women overall. While data on persons who are institutionalized are scarce, it appears that their sexual activity levels are low.

Being without a spouse does not necessarily mean that older persons are sexually inactive. Brecher (1984) reported, for example, that among unmarried persons 60 years of age and older, about 75 percent of men and 50 percent of women were sexually active. This is reinforced by Starr and Weiner's (1981) finding that 70 percent of their respondents over 60 were sexually active, although only 47 percent were married. Finally, masturbation is an option used by some elderly

persons to express their sexuality, presumably in a nonsocial setting. In a few studies, about one-third of women and slightly less than one-half of men over 70 report masturbating.

Just as stereotypes about elderly people and sexuality abound, so do stereotypes about the sexuality of gay, lesbian, and bisexual elders. However, research suggests that gays and lesbians offer a model of successful aging (Berger 1996). In terms of actual sexual behaviors, many of the gay men interviewed for this study reported that their frequency of sex had changed as they aged, supporting the idea that age is associated with a lower frequency of sexual relations (Berger 1996). Similarly, another study based on self-report data obtained from men between 40 and 77 years old found that the majority of these self-identified gay men were currently sexually active, although sexual interest declined somewhat with age. The majority reported no change in their enjoyment of sex from their younger years to the present (Pope and Schulz 1990). The myth of sexual and emotional isolation for lesbians is also challenged by a series of in-depth interviews with 20 women over age 50 who self-identified as lesbian. This research found that lesbians continue to be sexually active and tend to seek out other older women as partners (Raphael and Robinson 1992). Like other research on aging and sexuality, research on self-identified gay and lesbian elders shows that they have continued interest in expressing themselves sexually.

CONSENT AND COERCION

In recent decades, researchers have increasingly focused on "rape and other forms of sexual coercion" (Muehlenhard 1994, p. 143). A few observers have reacted by asserting that the data assessing sexual coerciveness among adults who are known to one another are seriously flawed and thus exaggerate their substantive and policy significance (Roiphe 1993; Muehlenhard et al. 1994). However, most social scientists and clinicians consider sexual coerciveness to be both serious and significant and have begun to scrutinize the conceptual and measurement problems that underlie its use.

Perhaps the most significant historical distinction in this realm was between stranger versus nonstranger, or unknown versus known. Rape

occurred most convincingly—to the minds of jurors, for example—when a man who was totally unknown to a woman executed penile penetration. If the man had been known to the woman in any way, her charge of forcible sex could be undermined, depending on how well she knew the man. If, for example, the man was her husband, she could not claim rape at all because consenting to be married carried the obligation to give her body to him unreservedly.

Koss and her colleagues were among the first to expand the discourse on sexual coercion beyond its conventional historical understanding. Using a national survey of college students, they reported that 38 percent of female college students reported sexual victimization that met the legal criterion for rape or attempted rape and almost 8 percent of males admitted to behaviors that could be classified as raped or attempted rape with at least one woman since the fourteenth birthday (Koss et al. 1985, 1988). Their conclusions were supported by other studies (Mosher and Anderson 1986; Rapaport and Burkhart 1984). Using data from the 1987 wave of the National Survey of Children, Moore et al. (1989) found that about 7 percent of U.S. adults aged 18–22 (females being more likely than males) confirmed that they had sex against their will or had been raped on at least one occasion. Other researchers have reported that between 10 and 12 percent of women report having been raped by dates and between 8 and 14 percent of wives report that their husbands have sexually assaulted or raped them (Finkelhor and Yilo 1985; Russell and Howell 1982).

Estimating the prevalence of the various forms of coercive sexuality is exceedingly difficult because the Uniform Crime Reports are widely believed to underreport the true rate of sex crimes and anonymous, self-report surveys vary widely in sampling techniques and findings. Nevertheless, Grauerholz and Solomon's (1989) review of research in this area suggests that a large proportion of the U.S. population has experienced or will experience coercive sexual relations as a victim, a perpetrator, or both. A comparison of sexual coercion among university students in the United States and Sweden found higher rates in the United States (Lottes and Weinberg 1996). Researchers' estimates of the pervasiveness of incest in the United States may vary the most. Whereas some researchers have observed that about 1 percent of

U.S. females have been incest victims (Kempe and Kempe 1984), others have reported much higher figures. For example, Russell (1984) found that 16 percent of her large household sample of women 18 years of age and older in San Francisco had experienced incest before age 18, and 20 percent of Finkelhor's (1979) predominantly white, middle-class New England college student sample who were raised primarily in nonmetropolitan areas reported having been an incest victim. The 1998 National Violence Against Women survey of 8,000 women estimated that some 17.7 million women in the United States, nearly 18 percent, have been raped or have been the victim of attempted rape. Nearly half the victims were assaulted before their seventeenth birthday. Some three-quarters of those saying they had been raped or assaulted as adults reported that the perpetrator was a current or former husband, a cohabiting partner, or a date.

Not only is sexual coercion an issue for many women, there is evidence to suggest that it is pertinent for some boys and men as well (Finkelhor 1979; Moore et al. 1989). A study of 115 sexually assaulted men found that the majority were assaulted at age 15 or younger, about half were assaulted more than once, and a majority knew their assailants. Among the 115 surveyed, 100 were assaulted by at least one man, 7 by a man and a woman, and 8 by women (King and Wollett 1997). Further, much of the research about sexual assault on men assumes that it is primarily heterosexual men who are the perpetrators of sexual assault on other men, doing so to express power and control. However, in a study of 930 "homosexually-active males" in England and Wales, about 28 percent reported having been sexually assaulted or having had sex against their will at some point in their lives. Moreover, 33 percent of the respondents reported being forced into sexual activity by men with whom they had previously had or were currently having consensual sexual activity. This research suggests that sexual assault in the gay, lesbian, and bisexual community needs to be researched further (Hickson et al. 1994). Some studies (Struckman-Johnson and Struckman-Johnson 1994) indicate that some men report that they were pressured or coerced by women into a sexual experience. Other studies focus on men both in and outside of prison who coerce and/or physically force other men into having sex (King and Wollett 1997; Struckman-Johnson et al. 1996).

In an effort to clarify matters of coercion and consent in the case of both sexes, O'Sullivan and Allgeier (1998) proposed a series of points along a continuum. First, there is sexual activity among persons known to each other that is the result of actual or threatened restraint, aggression, or force. It can be done by men against women and by men against men. Logically, it could involve women against women, but empirically that appears to be quite rare even in a prison situation (Struckman-Johnson et al. 1996), although Renzetti's (1992) research on partner abuse among lesbian couples suggests that lesbian couples experience a cycle of violence that can include sexual assault. Nevertheless, the general lack of empirical evidence about coercive sex between women could indicate either lower rates of occurrence or gaps in the research. Coercive sex also could be initiated by women against men, but again, this seems to be rare and is associated with the male having become intoxicated (Struckman-Johnson and Struckman-Johnson 1994). O'Sullivan and Allgeier (1998, p. 234) summarize the first category as "coercive interactions in which a person [submits] to . . . sexual activity but does so under duress."

Their second category of sexual activity occurs as the result of "seduction interactions in which one partner is clearly resistant," [and a third is] "'token resistance' interactions in which a person expresses nonconsent but is willing and intends to engage in the sexual activity." Their final category is "willing participation in an unwanted sexual activity." This refers to "situations in which a person freely consents to sexual activity . . . without experiencing a concomitant desire for the initiated sexual activity." They review literature suggesting the validity of these four categories and present their own research in support of the last one. Future research, they imply, should utilize these and/or other constructs to sort out differences along the consent-coercion continuum.

With evidence that coercive sexuality is prevalent, the question remains: Why do many men and some women coerce others to have sex with them? Some theorists argue that males are more likely to engage in various forms of coercive sexuality if they have strong ties to a peer group that supports sexually aggressive behavior. Compared to their less stereotypically masculine counterparts, men studied in the research noted above who possess traditionally masculine personality characteristics

and hold rigid views of gender stereotypes are more likely to report that they have used physical force and threats to have sex and probably would use physical force to obtain sex if they could be assured that they would not be prosecuted. Other theorists have argued that a small percentage of women may facilitate different forms of coercive sexuality by playing sexually receptive or seductive roles. Not surprisingly, it is common for sexual assailants to believe, or at least report, that their victims were willing participants who enjoyed themselves while being sexually assaulted, even though these perceptions are clearly inconsistent with the victims' accounts (Scully and Marolla 1984).

While the several forms of coercive sexuality share a number of themes, such as the objectification of women, individual factors and circumstances may be significant in accounting for why particular types of coercive sexuality occur. One of the important factors that seem to distinguish the typical stranger or acquaintance rapist from the "average" date rapist is the former's greater tendency to have been sexually or physically abused by his parents or others. Date rapes tend to involve partners who knew one another and had established at least a modicum of interpersonal trust by making a commitment to spend time together. The dynamic nature of the interaction episodes that typify date rapes and the fact that at least one of the persons often has been influenced by drugs, alcohol, or both can obscure the participants' intentions and behavior. Furthermore, the more individuals' sexual scripting is influenced by traditional gender socialization, the more likely it is that coercive sexuality will occur because of sexual miscommunication and males' reliance on coping strategies that emphasize dominance and aggression. Many men assume that women will offer token resistance to their sexual advances to create an impression that they are not sexually "promiscuous" (Check and Malamuth 1985). One study of 610 female undergraduates revealed that almost 40 percent had engaged in this type of token resistance at least once (Muehlenhard and Hollabaugh 1988). While these patterns should not be used to justify date rape, it is not surprising that some men distort the consensual petting that generally precedes date rape as a woman's way of acknowledging her willingness to engage in more intimate forms of sexual interaction, even if this means that in some cases men will be required to pursue it

forcefully. Finally, while there are many factors related to fathers' incestuous behavior, one of the more frequently noted arguments underscores the common pattern in which a father pursues sexual and emotional intimacy with his female children (usually a series of episodes over time with the oldest female child) to compensate for his unfulfilling relationship with the adult female, who generally has withdrawn from her roles as mother and wife (partner).

SEXUAL RISK-TAKING BEHAVIOR

Despite the well-documented overall increase in condom use in the 1990s, most research on risk-taking behavior indicates that a high percentage of people still regularly place themselves at risk of getting pregnant and/or contracting a sexually transmitted disease (STD) and/or HIV/AIDS. These patterns persist despite increased efforts at safe-sex education programs and services. Some trends are becoming increasingly evident. Data from face-to-face interviews with adult men and women aged 18–59 in the 1996 National Household Survey on Drug Abuse showed that 19 percent of the respondents used a condom during their last sexual experience (vaginal, oral, or anal sex, with no distinction being made in terms of the gender of the partner) when the event occurred within a relationship, while 62 percent did so when sex occurred outside an ongoing relationship (Anderson et al. 1999). Ninety-five percent of the respondents indicated that their last sexual experience occurred within a relationship. These data also showed that once relationship status was statistically controlled, individuals with high-risk sex and drug use profiles did not use condoms at a higher rate than did their counterparts who were not classified as being at an increased risk for HIV infection. Only about 22 percent of high-risk individuals used a condom at last intercourse within an ongoing relationship. Thus, both the casual and steady partners of high-risk individuals continue to place themselves at risk.

Meanwhile, a study of college students highlights gender differences in which men are found to be engaged in more risk-taking behaviors relevant to partner choice and sexual practices (Poppen 1995). Another study indicates that college women tend to put themselves at risk for sexually transmitted diseases by rarely using condoms and only

minimally discussing sexual history with a partner (Sheahan et al. 1994). Further, differences in behavior based on sexual identity are empirically supported. Interview data from gay and bisexual men suggest different behavior patterns in regard to "safe sex." These data suggest that gay men were more likely to have had a steady male partner and to have engaged in unprotected anal sex than were bisexual men (Stokes et al. 1997). Other studies indicate that young gay men's reports of having unprotected anal intercourse were more common when they knew their partners. Also, increased involvement in the gay community was related to higher levels of risk-taking behavior (Meyer and Dean 1995). Bisexual men use condoms inconsistently with male and female partners, seldom disclose their bisexuality to female partners, and are more likely than men who participate exclusively in same-sex sexual relations to report risk behaviors associated with HIV. The four factors found to raise HIV risk for bisexual men were (1) male prostitution, (2) injection drug use, (3) sexual identity exploration, and (4) culturally specific gender roles and norms such as those characterizing some African-American and Hispanic communities (Doll and Beeker 1996).

PROSTITUTION

Sociological research on prostitution emerged from studies of crime and delinquency, with an emphasis on theories of innate criminal drives. Contemporary sociological research on prostitution more often focuses on actual behaviors. In fact, the commercial sex industry has become a renewed area of research interest and funding as it has been identified as a site of potentially high transmission of HIV. Most research on prostitution still typically relies on self-report data with small-scale, situationally specific convenience samples. Thus, Kinsey's nonrepresentative data, which are more than forty-five years old, remain the best available comprehensive data on commercial sexual behavior. The available data on commercial sexual behavior identifies a variety of types: heterosexual prostitution of women (street prostitutes, brothels, etc.), heterosexual prostitution of men (e.g., escort services), homosexual prostitution of men (hustlers), homosexual prostitution of women, transvestite/transsexual prostitution, and the global/tourist sex industry (Brock and Thistlethwaite 1996; Perkins and Bennett 1985). Among these

types of prostitution, some trends are increasingly visible.

The most historically well known form of prostitution is the heterosexual prostitution of women. Feminists offer a variety of interpretations for why women enter into prostitution, ranging from exploitation to legitimate work (Jenness 1990). Gagnon (1977) suggests that the six most common reasons men visit prostitutes are (1) sex without negotiation, (2) sexual involvement without commitment, (3) sex for eroticism and variety, (4) a form of socializing, (5) sex away from home, and (6) sex without rejection. Some sociologists believe that prostitution serves a useful societal function by providing men with a convenient sexual outlet, which in turn minimizes the numbers of sexual transgressions against "respectable" women. Other sociologists view female prostitution as an extreme form of sexism.

Rather than addressing this debate, let us note some empirical trends. Kinsey reported that before World War II, between 60 and 70 percent of adult men had visited a prostitute and about 15 to 20 percent used them regularly. However, many commentators have indicated that rates of prostitution, a form of commercialized sex that in the past provided men with sexual opportunities in a less sexually open society, have decreased drastically since World War II. Notably, current research on sexual behavior in the context of prostitution shows the preponderance of incidents of sexual violence and the increased use of condoms. For example, Miller's (1993) study of 16 women incarcerated for prostitution found that almost all had experienced some form of sexual assault and other violent crimes. Benson and Mathews (1995) surveyed vice squads, women working as prostitutes on the streets and in brothels, and clients and resident groups in England, finding that most street prostitutes began working in their teens and have been victims of repeated sexual and physical attacks, while the majority of clients have regular partners or are married and tend to be middle-class and middle-aged. A study in the Netherlands of 559 male clients of female prostitutes found that 14 percent of the clients do not use condoms (De Graaf et al. 1997). Typically, men who are less educated, have more commercial sex contacts, and have more contacts with prostitutes are the least likely to use condoms. It is not known if similar trends are characteristic of the heterosex-

ual prostitution of men or the homosexual prostitution of women because there is little empirical research. Thus, it is difficult to determine whether similar patterns of sexual violence and safe sex are present across gender and sexuality lines.

The concern about the transmission of HIV/AIDS has, however, stimulated new and more comprehensive research about the homosexual prostitution of men and transvestite/transsexual prostitution. For example, Browne and Minichiello (1996) illustrate that many early studies of homosexual prostitution of men (from the 1960s to the 1980s) focused on biopsychological concerns, creating the need for future studies to focus on the behaviors and attendant risk for HIV infection of both the prostitute and the client. A study of 211 male street prostitutes and 15 male customers further makes this point (Morse et al. 1992). Morse et al. (1992) found that despite knowledge of HIV infection and its transmission, customers engage in high-risk sexual and drug use behaviors with prostitutes. However, another study contradicts these findings. Waldorf and Lauderback (1992) interviewed 552 men who solicit clients in public places (hustlers) and men who solicit by telephone and advertisements (call men) and found that 90 percent of the respondents used condoms in the past year and 75 percent used them in the past week. Similar studies of risk behavior are emerging for the transvestite/transsexual prostitution population. For example, Boles and Elifson (1994) interviewed 52 transvestite prostitutes and found that those who are socially isolated tend to be at more risk of HIV infection and those networked with nontransvestite male prostitutes tend to have a lower risk of HIV infection. Sociological research on men involved in homosexual prostitution and transvestites involved in prostitution suggests that sexual behaviors have been altered in an era of HIV/AIDS. However, little research about sexual behavior patterns outside the context of risk behaviors has been reported.

Another area of research in prostitution concerns the growing global sex industry. Sex tourism has long existed, but increasing globalization of travel and Internet advertising have sparked research in this area. Sociologists often explain the global sex industry as an outgrowth of "third world" poverty and the inequity of a global economy. Sex tourism does not involve only heterosex-

ual prostitution of women; homosexual prostitution of men is also prevalent. Empirical studies of sexual behavior in the global sex industry remain minimal as it is illegal in many countries and most research is still done on European or American prostitution (Brock and Thistlewaite 1996).

Sociological studies of the varieties of prostitution in the United States and around the world point to a more general trend of contemporary empirical research focusing on sexual risk behaviors. Many of these studies indicate that the study of sexuality is complicated by both politics and the complexities of research methodology. However, the emergence of HIV/AIDS also reminds the sociological community of the importance of studies of sexual behavior and patterns.

CONCLUSION

This review has documented the extensive efforts of social scientists in recent decades to enhance the understanding of human sexual behavior. Indeed knowledge of sexual behavior has increased dramatically since the days of Kinsey's early studies. This review also serves as a reminder, however, that knowledge about human sexual behavior, in some areas more than in others, remains limited because sex research is a function of both political and ethical decisions. For example, knowledge about homosexual experiences will continue to be less reliable and complete than it is for heterosexual behavior because the political commitment and considerable resources needed to secure nationally representative samples of gays, lesbians, and bisexuals are missing. Thus, just as social scientists can be held accountable for any shortcomings associated with the prevailing theoretical approaches to sexuality issues, the larger society and its institutionalized, politicized mechanisms for providing research support are responsible for impeding the research community's efforts to understand sexual behavior. Because sexual activity tends to be a highly private social experience, social scientists' incremental advances in documenting and explaining it are linked to the lay population's commitment to this type of research endeavor.

SEXUAL ORIENTATION

As Nietzsche noted, "[O]nly that which has no history is definable" ([1887] 1968, p. 516). This observation is clearly supported by the dramatic changes in the ways in which sexual orientation has been conceptualized over the last quarter century and, in particular, the last decade. As a result, the concept of sexual orientation may be difficult to define with any assurance of general agree-

ment. It is currently mired, and surely will continue to be mired, in conflicting interpretations of the history of the behaviors that are assumed to be the expression of specific sexual orientations. The question of sexual orientation remains a conceptual battleground where many of the most critical issues regarding the nature of human sexuality, if not the human condition itself, are debated.

Sexual orientation generally can be described as the integration of the ways in which individuals experience the intersection of sexual desires and available sexual social roles. For some people, this intersection is experienced happily as an unproblematic confluence of personal and social expectations. For others, it is experienced as a persistent conflict. For still others, issues of sexual orientation are experienced as an occasion for experimentation, compromise, and sometimes change in how they see themselves, how they present themselves to others, and how different segments of social life respond to such outcomes.

Sexual orientation is also part of the conceptual apparatus of contemporary scientific and popular discourse; it has become a way in which people recognize and “explain” sexual behavior. It is as if establishing an individual’s sexual orientation, however inaccurately, were enough to explain most of what has to be known about that individual’s sexuality. As a result, the discourses of sexual orientation often become a point of contact with the discourses of age, gender, morality, and law.

SEXUAL ORIENTATION AND GENDER

Following Freud’s distinction between the “object” (the “who”) and the “aim” (the “what”) of sexual desire ([1905] 1953), current conceptions of sexual orientation can be said to focus primarily on the nature of the object defined in narrow terms of gender. This almost exclusive distinction derives from the dimorphic nature of the human species, that is, two genders giving rise to three possible categories—homosexual, heterosexual, and bisexual—although within each of these categories there is a wide range of variations in both sexual and nonsexual attributes of individuals and there are many aspects of sexual preference that are shared across these categories. Among such aspects of desire would be the other’s age, race, social class, and ethnic status; the nature of the emotional bond; and the conventions of physical

beauty. Important differences regarding sexual aims, such as sadomasochism, pedophilia, hebophilia (sexual attraction to postpubescent minors), and transvestism, are most often subsumed within each of these gender-based categories. Most often, they become adjectives modifying the label “homosexual” or “heterosexual.”

The continuing significance of gender may reflect the fact that within modern Western societies, gender is possibly the last fully pervasive aspect of identity that provides cohesion among the increasingly complex components of multiple social roles. Gender serves this role in a social context of continuing change because of its seeming permanence and seemingly *ascriptive* character. As a result, the gender of the object of one’s desires continues to dominate the meaning of sexual orientation almost to the exclusion of all the other attributes of potential partners that contribute to or preclude sexual interest or excitement.

This emphasis on the gender of the object of desire may be a culturally specific development. Some, for example, have argued that in other cultural or historical contexts, gender may be less significant in defining categories of legitimate sexual access than are other social distinctions. Thus, the acceptability of same-gender sexual contacts among males in ancient Greece was contingent on differences in age (mature adult versus youth) and social status (free citizen versus slave). Respect for those distinctions in social status required that there be no direct reciprocity, that the “active” role (the seeking of sexual pleasure) and the “passive” role (the providing of sexual pleasure) remain respectful of social status (Halperin 1989). Men engaging in such behavior were viewed as conventional so long as those rules were maintained. Such examples indicate that not all persons engaging in sexual acts experience their participation as erotic or experience those activities in the context of what might be termed sexual excitement. By the same token, they also indicate that not all motives for engaging in specific sexual acts derive from intrinsically sexual motives.

Through much of the twentieth century, the question of sexual orientation would not have appeared problematic. In a range of theoretical positions, from Freud’s assumption of an inherent bisexuality ([1905] 1953) to those postulating an exclusive heterosexuality, sexual orientation was

taken as being so firmly rooted in the “natural” process of human psychosexual development that it was treated as a transcultural phenomenon (Simon 1996). This was true for heterosexuality, which often was, and for many people still is, viewed as being phylogenetically programmed as a requirement of species survival (Symons 1979; Wilson 1978). Homosexuality and bisexuality were viewed as a disturbance of “normal” development (Freud [1905] 1953), an inherited decadence (Ellis 1937), a gender-discordant development (Krafft-Ebing [1896] 1965), later as a normal but minor genetic variant (Kinsey et al. 1948), and more recently as a sociocultural construction (see below). This social constructionist position has been extended to the treatment of heterosexuality as well (Katz 1995; Richardson 1996).

Explanations of sexual orientation currently might be described as a continuum anchored at one polar position by the assumption of an entirely biological or phylogenetic source (essentialism) and at the other polar position by sources reflecting the adaptation of specific individuals within given sociocultural settings (constructionism) and still more recently as the reflection of the sociocultural construction of gender as a binary phenomenon (queer theory).

Essentialist Perspectives. The extreme essentialist position leads to a view of sexual orientation (as gender preference) that is potentially present in all human populations, varying only in its manifest expression as a result of differing qualities of encouragement or repression (Gladue 1987; Boswell 1983; Whitam 1983; LaVay 1996). Other biologically oriented explanations link biological developments with experiential adaptations. Typically, those approaches link variations in phenomena such as prenatal hormonal chemistry with critical but often unpredictable postnatal experiences in the shaping of sexual orientation (Money 1988).

The essentialist end of the conceptual continuum assumes that at some basic level of character or personality, there are objective, constitutional sources of sexual orientation (Green 1988). It is almost as if such approaches viewed different categories of sexual orientation as different species or subspecies, as if all those included within a specific category of sexual interactions shared a common origin. A commitment to such permanent distinctions is often evident in the use of a concept such

as *latent homosexuality*, which implies that even when such differences fail to be manifested or are manifested late in life, this orientation is viewed as the “real” one.

Constructionist Perspectives. At the other end of this continuum are constructionists, who view sexual orientation as the product of specific historical contingencies, as something to be acquired or perhaps even “an accomplishment” (Stoller 1985a). Most of those holding this position reject the idea of a sexual drive or at best see such a drive as an unformed potential that is largely dependent on experience to give it power and directionality. “Every culture has a distinctive cultural configuration with its own ‘anthropological’ assumptions in the sexual area. The empirical relativity of these configurations, their immense variety, and luxurious inventiveness, indicate that they are products of man’s own socio-cultural formations rather than a biologically fixed human nature” (Berger and Luckman 1966, p. 49).

For most constructionists, sexual orientation is a reflection of the more general practices of a time and place and is expressive of social power (Foucault 1978; Weeks 1985; Padgug 1979; Greenberg 1988; Halperin 1989). Others would add concern for the specific contexts of interaction and the management of identities and social roles (Simon and Gagnon 1967; McIntosh 1976; Plummer 1975; Ponse 1968; Weinberg 1983), and still others would add concern for the experiences that constitute primary socialization (Gagnon and Simon 1973; Stoller 1985b; Simon and Gagnon 1986; Mitchell 1988).

From a constructionist perspective, the concept of sexual orientation itself is viewed as an aspect of the very cultural practices that sustain the differential evaluations of the sexual behaviors the concept purports to explain. The focusing of attention on something that can be called sexual orientation is seen as signifying an importance to be assigned to the sexual that may not be intrinsic to it but may derive from the evolved meanings and uses that constitute the sexual in specific sociohistorical contexts.

Whereas essentialists tend to view the sexual as a biological constant that presses on evolving social conventions, constructionists view the sexual as the product of the individual’s contingent response to the experiencing of social conven-

tions. For essentialists, the sexual might be said to develop from the inside out, whereas for constructionists, the sexual, like most other social practices, is learned from the outside in. A middle ground is taken by many who view sexual behavior as the outcome of a dialectical relationship between biology and culture (Erikson 1950).

CURRENT CONCEPTS

If only in recognition of the enormous diversity of sexual practices in different cultural and historical settings despite the relative stability of human physiology, almost everyone who has approached the study of human sexuality admits the need for some degree of sociological explanation of specific patterns of sexual interaction and the significance accorded to them (Gregersen 1983). The question of homosexuality was the dominant issue in most discussions of sexual orientation until relatively recently. Heterosexuality, insofar as it was viewed as doing what came naturally, seemingly required no "explanation" unless it was expressed in unconventional ways. Instead, it was homosexuality that was viewed as problematic, if not pathological, and whose explanation was more urgent. The medicalization of same-gender sexual preference, which preceded the initial public use of terms such as "homosexuality" and "heterosexuality" in 1880 (Herzer 1985), involved the "disease" model of seeking a specific cause as well as a mode of prevention and possible cure. This implicitly homophobic commitment persists in some of the scientific community's considerations of homosexuality (Irving 1990).

The acceptance of homosexuality as an alternative life-style, however, did not necessarily require the abandonment of a concern for explaining its appearance; it merely made it more obvious that heterosexuality cannot be taken for granted but requires explanation (Katz 1990). One characteristic of the modern Western condition is that it has made sexual orientation and the closely related issue of sexual identity problematic. The question, What will I be when I grow up? is asked of an ever-growing number of dimensions of life, including the sexual, and is asked with increasing uncertainty regarding the possible answers.

Heterosexuality. Heterosexuality, defined as *cross-gender sexual intercourse*, has been a preference in all societies, though not necessarily an exclusive

preference in all societies. Nor does the universality of this preference establish the full range of definitions of with whom, when, where, or in what manner it should occur. Thus, outside of incest taboos involving immediate family members and a variable list of other close relatives, different cultures and periods of history have defined legitimate and illegitimate sexual contacts in dramatically contrasting ways (Bullough [1978] 1980). These differences involve not only what might be called the mechanics of sexual acts, that is, matters of relationship, time, place, costume, sequence of gestures, and positions, but also the determinants of their relative significance.

The potential reproductive consequences of heterosexual genital intercourse inevitably led to a linking of the desire for sex with a conscious or unconscious desire for reproduction. This view has been criticized as resting on the questionable assumption of a biologically rooted commitment to species survival (Beach 1956). Valid or not, such views constitute a cultural legacy that gives credence to many current norms regarding sexual acts, norms that enhance the social regulation of reproduction in the name of an assumed natural mandate.

More specifically, expectations regarding gender and family, influenced by many aspects of social life, generally have shaped the social meaning of sexual acts. Current language for describing cross-gender sexual contacts explicitly assumes a relationship to the family—marital, premarital, postmarital, and extramarital sex—and implicitly evaluates behaviors in terms of their "distance" from location within the family.

Similarly, genital intercourse still is viewed commonly as the ultimate or purest form of sexual exchange, as the "fulfillment of nature's intent." As a result, it continues to serve as the measure of the "normality" of alternative forms of sexual contact. This was reflected in the historical, but declining, practice of criminalizing not only sexual acts occurring outside of marriage but also those involving oral or anal contact or in viewing masturbation as pathogenic when practiced by the young and symptomatic when practiced by adults, although recent research (Lauman et al. 1994) indicates that masturbation occurs in North America among significant segments of postpubertal individuals at all stages of the life course.

Many of the conventions surrounding gender expectations also directly reinforced the “scripting,” or construction, of heterosexuality. This involves presenting images of the sexual that both naturalize and normalize evolved Western heterosexual practices, making them appear unquestionably proper. The labels “active” and “passive,” terms that had applications in many domains of social life, virtually became synonymous with “masculine” and “feminine,” respectively. Even physical positions in sexual intercourse—“Who is on top?”—have often had to pay homage to prevailing patterns of social domination.

The nineteenth century witnessed the elaboration of images of the female as fragile, domestic, nurturant, receptive, and either only minimally sexual or capable of insatiable lusts. These images of femininity were complemented by images of the male as strong, given to exploratory curiosity, possessively protective, and aggressively lustful. Although applied diffusely, these implicit norms were not always applied equally. The restraint and fragility of the female found a common application in the parlors and bedrooms of the urban middle class and rural gentry but was applied far less in the fields, factories, servants’ quarters, and brothels of the day.

While the images of heterosexuality reinforced patterns of family life and gender differentiation, it is equally appropriate to speak of the ways in which patterns of family life and gender differentiation reinforced prevailing concepts of the “naturalness” of heterosexuality. This same gender-based division of labor within the family was taken for granted by mid-twentieth century sociological theorists (Parsons and Bales 1955), as it was inscribed in the most widely held views regarding “normal” human development (Erikson 1950).

From the late nineteenth century on, concepts of the family became substantially more voluntary and egalitarian. However, those modifications further empowered the heterosexual scenario, which now plays an even more important role in the creation of marital bonding and the preservation of the nuclear family. Heterosexuality, given the assumption of its powers as a basic drive, simultaneously became a nearly constant threat to and vital aspect of family life. This in turn gave rise to various methods, both formal and informal, of restricting nonmarital expressions of sexual activity.

The emphasis placed on the heterosexual scenario led in turn to a greater emphasis on the subjective aspects of one’s sexual orientation. Faith in the mute logic of “nature’s” intent gave way to concern for the fashioning and maintenance of individual desire. Women increasingly were expected not only to be receptive but to desire as well as to be desirable. Men increasingly were expected to use the sexual to affirm their masculinity not only by their ability to find sexual pleasure but also by their ability to provide pleasure to their partners. Heterosexual preference continued to be taken for granted while heterosexual competence was being placed on the agenda in new and unanticipated ways.

In recent years, evident trends have called into question many of these practices, challenging many earlier basic expectations regarding family and gender. The conjugal family is no longer the exclusive social address for heterosexuality. Premarital sex has become *statistically* normal at all social levels, and it approaches becoming *attitudinally* normative. Moreover, the age at which sexual intercourse first occurs has declined, particularly for females. By age 18, over half are no longer virgins, which is more than double the proportion of nonvirgins reported two generations ago. This suggests that most of what occurs by way of sexual activity among adolescents and young adults can be described as pre-premarital, as much of this early sexual behavior occurs outside the context of family-forming courtship, where much of the premarital experience of older generations took place.

Similarly, at the premarital and postmarital stages, there has been increasing acceptance of nonmarital cohabitation in the sense that it tends to be more openly acknowledged with little anticipation of social rejection or stigmatization. While the number of middle- to upper-middle-class females who have deliberately borne children without marriage or an acknowledged male partner is not great, the fact that this practice has achieved considerable visibility and implicit legitimacy is significant.

Reflecting the diffusion of feminist values, support for women with regard to sexual interest, sexual activity, and especially sexual competence, with the latter measured by the capacity to achieve orgasm, has visibly increased (Ehrenreich et al. 1986). As a result, gender stereotypes with regard

to sexual behavior have experienced changes that for the most part have served to blur many of the gender distinctions that previously appeared to give heterosexuality its distinctive complementarity.

Specific behaviors, such as oral sex, that once were associated with devalued sexual actors, homosexuals, and prostitutes in recent years have become a conventional part of the heterosexual script. This is particularly true at higher social class levels, where oral sex tends to occur regularly, often substituting for genital intercourse (Gagnon and Simon 1987; Blumstein and Schwartz 1983; Simon et al. 1990).

Heterosexuality remains the dominant erotic imagery of Western societies. However, changing concerns for reproduction, continuing changes in the organization of family life, and the constraints describing gender presentations indicate that present trends toward a pluralization of the ways in which heterosexuality is experienced and the contexts within which it is expressed will continue into the imaginable future.

Homosexuality. Same-gender sexual interactions have been reported in a sufficient number of social settings to suggest that they fall within the normal range of human behaviors (Ford and Beach 1951; Gregersen 1983). As Kinsey and associates (1948) observed, "The homosexual has been a significant part of human sexual activity ever since the dawn of history, primarily because it is an expression of capacities that are basic in the human animal" (p. 666). This essentialist view implies that a predisposition to same-gender sexual acts is an immutable fact of nature like gender and race and as such is totally independent of personal preference and societal values (Green 1988).

The fact that same-gender sexual involvements fail to be reported or occur as atypical behaviors in sufficient numbers suggests that there is little about them on which to predicate a universal or singular explanation. Where homosexual behavior occurs, the specific forms it takes, and the kinds of sexual acts and the relations within which they occur, as with most aspects of heterosexuality, vary so much that a full understanding must be sought in terms of the contingent features of specific social contexts. In other words, apparent uniformity of acts, such as members of the same gender engaging in sexual acts, allows one to assume very little, if any, uniformity of actors, their development, their mo-

tives, or the social and personal meanings of their behavior. When constructionists assert that the homosexual is an invention of the modern world, they are not suggesting that same-gender contacts were unknown in earlier periods of Western history or in other cultural settings. What they do suggest is that the processes that constitute the behavior, that give it meaning, and that transform otherwise identical forms of "behavior" into different forms of evaluated "conduct" may be of a fundamentally different character.

The variety of meanings given to same-gender "sexual" contacts is as wide as that given to cross-gender contacts. "Sexual" is placed in quotation marks as a reminder that while genital contact and orgasm may be present, in many instances the behavior is not necessarily experienced as sexual in the contemporary Western sense of that word. Such same-gender contacts range from those which are incidental to religious rites or rites of puberty, to those specific to certain statuses that may be temporary and that are not in themselves significant aspects of the individual's social identity, to those in which same-gender contacts are defined as permanent features of the individual's character.

An example of age-specific sexual contact can be found among the Sambians of New Guinea. Male children at about age 6 are removed to the men's hut, where they ingest semen, a practice that is viewed as necessary for full masculine development, by engaging in fellation with older, unmarried fellow villagers. At puberty, such males enter the role of semen donor by making their penises available to their younger fellow villagers. During early adulthood, they enter arranged marriages and are expected to practice heterosexual sex exclusively for the remainder of their lives. Observers report a nearly universal absence of fixation with regard to the activities of earlier stages or a reversal of age roles (Herdt 1981; Stoller 1985a).

This of course stands in dramatic contrast with the modern Western experience, in which the imagery of the behavior is associated with powerful meanings whose very invocation is often capable of exciting intense emotional responses of all kinds. Thus, negative images promote strong feelings of homophobia and at times cause "homosexual panic" in which the fear of being or becoming homosexual generates highly charged nonrational responses. At the same time, the possibility of

same-gender sexual contacts often generates responses sufficiently strong to allow many individuals to experience and accept themselves as being homosexual despite the homophobic character of their immediate social settings (Bell and Weinberg 1978; Weinberg 1983).

In the examples of both the Sambians and the contemporary Western experience, the biological processes associated with arousal and orgasm are undoubtedly the same. What vary are the meanings and the representations that occasion arousal. As Beach noted, "Human sexual arousal is subject to extensive modification as a result of experience. Sexual values may become attached to a wide variety of biologically inappropriate stimulus objects or partners" (1956, p. 27).

Patterns of homosexual behavior, like those of heterosexual behavior, have manifested persistent change. While same-gender sexual contact was known in premodern Europe and was severely sanctioned, often treated as a capital offense, it was not viewed as being the behavior of a different kind of person but as a moral failing, a sin, to which all might be vulnerable (Bray 1982). Some have argued that a conception of homosexuality as a sexual orientation involving a distinct kind of person was a correlate of many of the changing patterns and values associated with the emergence of urban, industrial capitalism (Adam 1978; Hocquenghem 1978; Foucault 1978).

Within the category of male homosexuality, different styles of homosexual activity predominated in different periods of history and different social settings. If the concept of homosexuality is to have any meaning, such variations suggest that modern forms of homosexuality reflect an eroticization of gender, not a fixation on a specific form of sexual activity. In other words, it is the gender of the participants that generates and sustains sexual interest and only secondarily the specific form of sexual activity (Gagnon 1990; Simon et al. 1990).

The significance of gender in considerations of homosexuality has marked much of its recent history. Initial nineteenth-century views defined and implicitly explained homosexuality as an inversion of gender. Lesbians often were viewed as "men trapped in women's bodies," and gay men the reverse. Consistent with this, a common designation was "invert." Despite this early view, more

recent research indicates that in many respects lesbians and gay men tend in their sexual development and subsequent behavior to approximate their genders. This suggests that sexual development tends to follow gender socialization: Gender roles and gender role expectations influence sexuality more often than sexuality prompts changes in gender identity (Gagnon and Simon 1973; Blumstein and Schwartz 1983).

Change in sexual patterns has been a critical aspect of recent social history. Whereas heterosexual practice might be described as being increasingly privatized and dissociated from the major institutions of society, homosexual practice has moved from the margins of society to sharing the central stage. Whereas the family becomes less and less the exclusive legitimate context for heterosexual activities, the appearance and survival of bonded relationships among homosexuals, particularly gay men, has visibly increased. Whereas the larger community appears increasingly anomic, gay communities (which once were limited to bars, discreet networks of friends, and, for gay men, locations for anonymous sexual contacts) now rival even the most solidary of ethnic groups. There is a flowering of recreational, religious, welfare, political, and other affinity groups and organizations as well as of areas of residential dominance (Epstein 1987; Escoffier 1998; Levine 1998).

Homosexuality remains negatively valued, remains stigmatized. Discrimination in employment and housing, instances of "gay bashing," and criminalization of same-gender sexual activity in some jurisdictions speak directly to continued homophobic practices and fears. However, on the whole, the 1960s, 1970s, and 1980s witnessed increasing acceptance of both homosexuality and the homosexual. Even the identification of gay men with transmission of the HIV virus, which initially was associated with an incipient moral panic and occasioned expressions of antihomosexual attitudes, became an occasion for sympathetic representation in the major public media and broadened understanding of gay men, their life-styles, and the many roles they play in and contributions they make to the larger society.

Currently, possibly owing to the heightened visibility of lesbians and gay men, the homogenizing of identities has been called into question. What once was viewed as a singular phenome-

non is now more generally seen as pluralized. It now encompasses different developmental histories, affording different ways of incorporating a homoerotic commitment within a specific life history. The same is true for the development of a heterosexual orientation (Murray 1984; Stoller 1985a). As a consequence, the major questions that previously dominated issues of homosexuality (What is *the* cause? How many are there?) have become incurably cloudy as claims for a “biology of identity” conflict with what has been called the “politics of identity.” Same-gender sexual interactions remain a characteristic of a minority of persons (Lauman et al. 1994), but the actual number cannot be established without resolving the question of what a homosexual is. Reflecting the complexity of these questions, Lauman et al. (1994) distinguish between three critical dimensions: same-gender sexual *behavior*, same-gender sexual *attraction* or *desire*, and *identity* as a homosexual. They found that among the 10.1 percent of the men in their survey who reported *any* adult same-gender sexuality, only 24 percent reported positive responses on all three dimensions and among the 8.6 percent of the women reporting *any* adult same-gender sexuality, only 15 percent were positive on all three dimensions. (p. 298)

What is clear is that there may be many more reasons for developing a homosexual orientation than there are ways of giving it expression. Aspects of development such as variations in the development of a gender identity may be significant in the development of homosexual orientations for some individuals (Harry 1982; Green 1987), but these aspects may have to be reconsidered as society modifies its more general beliefs and practices regarding gender identity. For example, the question must be asked, On what basis should “effeminacy” in male children be treated as symptomatic of some pathology any more than comparable displays of “effeminacy” in female children? Or the reverse, regarding what is commonly referred to as “tomboyishness” among young females?

Individuals with a marked homosexual preference appear in virtually all social contexts: different types of community settings; at different class levels; in all racial, ethnic, and religious categories; and from all manner of family backgrounds (Gebhard and Johnson 1979; Bell et al. 1981). There are differences between such categories, but in the absence of unbiased and comprehensive data, it is

difficult to determine with any confidence whether significant effects are associated with possible differentials. There is reason to suspect that such statistics can provide only an approximation of current populations and a poor guide to future developments, developments that depend more on society’s conceptions and uses of sex and gender, which appear to be in continuing transition.

Whether rooted in biology, social experience, or some combination of these elements, homosexuality as a concept, as a class of persons, and as social groups will persist into the twenty-first century. However, factors such as the greater visibility of representations in the media that challenge prior negative stereotypes and folk psychologies, the depathologizing of homosexuality by medical and social science communities, and its greater acceptance by conventional major institutions may be in the process of transforming what was once a closeted, isolated group into one that is different but is seen as neither abnormal nor threatening. Indeed, one may be observing a process of the *normalization* of homosexuality. Some, in effect, have raised the question of the disappearance of homosexuality through its assimilation into mainstream social life as minor variant. (Bech 1997; Seidman et al. 1999). Alternative arguments suggest that this ultimate assimilation is an unrealistic and undesirable possibility based on conceptions of gender (queer theory) that are ethnocentrically biased in their narrow emphasis on the North American and Western European experiences (Murray 1996).

Bisexuality. Bisexuality is a complex concept and, like homosexuality and heterosexuality, has become more complex in recent years as the framing concepts of gender have become less arbitrarily complementary and distinct (Butler 1993; Weinberg et al. 1994). Bisexuality can refer to behavior (those who have had both homosexual and heterosexual experience), psychic response (those capable of being erotically aroused by both homosexual and heterosexual imagery), and either social labeling or self-labeling. Substantial numbers of people have had, if only incidentally, both homosexual and heterosexual experiences while retaining a firm self-identity as being one or the other (Lauman et al. 1994). Even larger numbers have or can be assumed to have experienced sexual arousal in association with both heteroerotic and homoerotic imagery (Kinsey et al. 1948, 1953;

Bell and Weinberg 1978; Bell et al. 1981). The mere experience of having sex with members of both genders may not be sufficient to justify the application of the term "bisexual." What can be called "situational same-gender, sexual contacts," such as those which occur in single-gender penal institutions, may represent little more than conventionally styled heterosexual orientations expressed in restrictive circumstances (Gagnon and Simon 1973).

Relatively few people conceive of themselves as bisexual or can be labeled as such, particularly if the concept is defined as an attraction to both genders and an attraction for the sexual behaviors commonly attributed to both genders. However, bisexual identification probably has increased as an expression of an increase among younger cohorts of "open gender schemas" (Weinberg et al. 1994).

Many people whose sexual histories involve interaction with both genders still see themselves as being either homosexual or heterosexual in orientation. This may be a reflection of the fact that outside of relatively few "bisexual support groups," until recently neither heterosexual nor homosexual social worlds appeared to accept or validate such an identity. The very concept of bisexuality, when used to refer to a specific type of person, was viewed with skepticism (Tripp 1987). Having bisexual interests often was viewed as a mask or apology for an underlying orientation. Undoubtedly, for some people the bisexual label served as a transitional phase in the complicated task of identity transformation. Although a large number of the psychotherapeutic communities accept bisexuality as a distinct type of psychosexual development (Hill 1989), even among those who identify themselves as bisexual there are some who tend to have patterns of sexual behavior that are "amazingly diverse and that [their] day to day life roles are greatly different from one another . . . [and] it is clear that people come to bisexuality in an incredibly diverse number of ways" (Blumstein and Schwartz 1976, p. 180).

Bisexuality as denoting a special orientation tends to be a recent conceptualization, that reflects the increased recognition of gender as a crystallization of erotic responses that are not necessarily coded by the logic of an excluding complementarity. Prior images of bisexuality re-

flected the assumed differences of masculinity and femininity such as the persistently masculinized dominant sexual actor and the individual who could switch between stereotypical presentations of gender. Increased recognition of a bisexual possibility follows the recognition of the possible absence of complementarity, that is, with each participant providing what is absent in and desired by the other, within many heterosexual and homosexual relationships and the calling into question an implicit complementarity within existing conceptions of gender (Garber 1995).

Transvestism and Transsexuality. These two concepts do not represent discrete categories so much as a continuum describing the degree to which an individual biologically of one gender desires and enacts the identities or aspects of the identities of the other (Feinbloom 1976). For an unknown number of people this is limited to using the clothing of the other gender to elicit sexual excitement, with little more being directly involved. For most, however, more is involved; for most it involves adopting and enacting, if only for an audience of oneself, aspects of the identity and selected roles of the other gender, not merely cross-dressing but cross-gendering. However, for transvestites, cross-dressing is temporary, and they do not abandon their primary gender identity; they play at being the other (Newton 1979).

At the other end of the continuum is the transsexual who ideally seeks to adopt permanently the gender, costumes, and roles of the other gender (Green 1974). While an absolute realization of this aspiration is impossible, combined modern surgical and pharmacological techniques and permissive bureaucracies (the former cosmetically "redesigning" the body, while the latter allow for a redesigning of one's identifying credentials) have brought about the possibility of coming close to allowing some people to more fully realize their aspiration to live their lives, as fully as possible, in the costumes and roles of the other gender (Bolin 1988; Lothstein 1983).

The desirability of supporting transsexuality remains a matter of continuing contention that involves issues of mental health and gender. Several medical centers that once maintained programs of "surgical gender reassignment" have suspended those programs after reporting results

that were too mixed to justify their continuation. Additionally, feminists have criticized such programs as catering to the desire to enact some of the most extreme forms of gender stereotypes (Irving 1990).

Midway between these extremes, between the erotic fetishizing of the clothing of the opposite gender and the desire to become the opposite gender, are those who prefer the costumes and behavior roles of the opposite gender without wanting to or needing to abandon their own initial gender or genitalia. This ranges from those who deliberately blur costumes and the coding or semiotics of gestures to obscure distinctions—women who have masculinized or men who have feminized their presentation of self—to those who experience a continuing conflict between a “masculine self” and a “feminine self,” feeling that each of these components of a divided self requires its own costumes, vocabulary of gestures, and social space. (Bullough et al. 1997)

Again, as is true for most forms of stigmatized behavior, estimates of how many individuals are involved in such practices are virtually impossible to determine with any accuracy. Across this continuum of cross-gendering, both males and females can be observed. Most researchers speculate that more males than females are involved, generalizing the apparent tendency for significantly more males than females to be involved in various kinds of sexual deviance.

This speculation is made additionally plausible by the manifest tendency for violations of gender by men to generate more nervousness and be more heavily sanctioned than are comparable violations by females. It is possible for many females to mask their transvestic desires through the broader range of fashion available to women. For example, female cross-dressing in film and literature often involves the beginnings of romantic investment, while male cross-dressing is almost entirely restricted to the comic mode.

These two concepts, transvestism and transsexuality, perhaps more than any other, speak to the powers of gender and its multiple correlates. They speak as well to the complex relationship between gender and sexuality. For relatively few people are gender presentations altered to facilitate a specific sexual aim; more often the sexual is

organized to facilitate desired gender effects. Little that is manifestly sexual appears in the cross-gendering of some people, as in the case of many male heterosexual transvestites. In the case of the transsexual, surgical procedures often diminish orgasmic capacity. However, confirmation is often one of the major motives for engaging in sexual behavior and a major source of its capacity to gratify, a capacity that may go well beyond the narrow physicalist emphasis on orgasm.

However, conflict between the sexual as genital involvement and the sexual as gender confirmation has been seen by some as an expression of the application of a socially constructed arbitrary binary system that coercively mutes existing heterogeneities of desires and identity themes. This recently articulated perspective views *transgendering* as a moment of potential liberation from an arbitrary binary gender system, allowing individuals to give fuller expression to the totality of their eroticized and noneroticized desires (Stone 1991).

CONCLUSIONS

Sexual orientation is a complex construct rather than a simple thing. While it tends to identify individuals in terms of commitment to similar sexual preferences, it also has the capacity to mask differences among those who appear to otherwise share identical orientations. This is not surprising. Sexual behaviors, like many other aspects of human experience that are linked in critical ways to biology, are also historical and subject to change and as such reflect the very connections of the sexual ultimately to the total fabric of social life.

At the same time, concepts of sexual orientation are aspects of the cultural apparatus of a time and place and are used to explain the behaviors of others as well as one's own behavior. As such, they have the capacity to influence the very behaviors they appear merely to describe. Thus, to view the sexual in isolation from the continuing dynamic of social life, which until recently has largely been its fate, is to run the risk of unself-consciously transforming the science of social life into an oppressive disciplinary instrument of social life.

SEXUAL VIOLENCE AND EXPLOITATION

Sexual violence and exploitation are social problems that were relatively neglected as research topics until the late 1960s. This article focuses primarily on the different categories of rape, sexual harassment, child sexual abuse, and related issues.

RAPE AS A FORM OF SEXUAL VIOLENCE

Rape was not conceptualized as a major problem in the United States until the late 1960s; this awareness accompanied the resurrected women's movement and the establishment of the National Center for the Prevention and Control of Rape. After this awakening of interest, enough information was generated to document the fact that there were explanations for rape that went beyond the biological and psychological. Society and its institutions, laws, and attitudes were seen as contributing greatly to the problem. In the 1970s, rape was clearly defined as a social problem.

The works of three feminists contributed to advancing awareness of rape or sexual violence against women: Millet's *Sexual Politics* (1972), Griffin's "Rape: The All American Crime" (1971), and Brownmiller's *Against Our Will: Men, Women, and Rape* (1975). Millet argued that rape is linked to the concept of patriarchy, in which men use power and coercion to control women's sexuality. Nowhere is this better articulated than in the "crimes of honor" concept or social norm still evident in many Middle Eastern countries. Griffin's article focused on the nature of rape. She argued that rape is not a sexual act but a violent political act and that the threat of being raped controls women socially. This social control is present even among very young females. In response to the survey questions, "Would you rather be a man or woman?" and "Why?" a 10-year old girl replied that she would rather be a man, because women get killed and raped (Renzetti and Curran 1995, p. 338). Research indicates that rape is the crime women fear most, and this fear is compounded by the possibility of getting pregnant and contracting AIDS. Brownmiller's book is a historical account of rape that expands on the ideas of Millet and Griffin. The writings of these women clearly demonstrated that rape is more a sociological than a psychological phenomenon.

The definition of rape that served as the basis for most rape laws is grounded in English common law: "the unlawful carnal knowledge of a woman by force and against her will." Implicit in this idea is the assumption that the assailant is a man. In the 1970s, many states redefined rape laws to more comprehensively describe the behaviors that constituted rape and define the age of consent. By the end of the decade, forty-one states had passed some form of rape shield laws that limited the use in court of victims' prior sexual conduct with persons other than the offender (Green 1988, pp. 16-40). Many states have abandoned the concept of rape in favor of the more gender-neutral concept of sexual assault.

The Federal Bureau of Investigation (FBI) indicates that a rape happens every five minutes in the United States. American women are eight times more likely to be raped than are European women and twenty-six times more likely than Japanese women. In the 1980s, the rate of rape in the United States rose four times faster than did the total crime rate. While the number of rapes appears to have fallen over the last few years, rape is still the most frequently committed and least reported violent crime. A total of 97,464 forcible rapes were reported to law enforcement bodies in 1995, the lowest number since 1989. Based on this statistic, it is estimated that in 1995, 72 of every 100,000 females were reported rape victims (U.S. Department of Justice 1995). However, a study funded by the U.S. Department of Health and Human Services found that 683,000 women had been raped in 1990, a figure more than five times as high as the 130,260 reported to the police in that year (Johnston 1992).

Victimization studies such as the National Crime Survey (NCS) and other research projects were initiated to get better estimates of the prevalence of rape. These studies show that the amount of rape is greatly underestimated, although prevalence rates vary from study to study and are hard to reconcile because of variations in research design, sampling, and geographic location.

Rape is described in a number of ways. Sometimes it is discussed in terms of the number of

offenders per victim: the single-offender, two-offender, or multiple, group, or gang rape. Victimization statistics for these forms of rape are, respectively, 81 percent, 10 percent, and 8 percent (Koss and Harvey 1987, p. 10). Rape also is classified as stranger rape, in which the victim and offender have no relationship to one another, or acquaintance rape, which includes date rape and rape between individuals who knew each other before the assault. According to the U.S. Department of Justice, about 55 percent of rapes are acquaintance rapes; the younger the victim is, the more likely it is that she knew the rapist. Acquaintance rapes are especially common on college campuses. Warshaw (1988, chap. 1), citing statistics from the *Ms.* magazine Project on Campus Assault, reports fewer stranger (16 percent) and group rapes (15 percent), with the vast majority of incidents (95 percent) being individual assaults that involve acquaintances or dates (84 percent). The NCS's rape statistics indicate that 27 percent of rapes involve multiple offenders. While acquaintance rapes are more common, women raped by strangers are ten times more likely to report the incident (Renzetti and Curran 1995, p. 341).

Many researchers have attempted to classify rapists into types. Some typologies suggest as few as two or three types (e.g., Groth 1979), while others describe five (e.g., Rada 1978). A review of this literature leads to the conclusion that the typologies are tied closely to the developer's theoretical orientation and educational background.

Rape legally occurs when a person uses force or the threat of force to engage in sexual intercourse (vaginal, oral, or anal) with another person. This seems like a straightforward definition that may lead to the conclusion that rape cases are easy to prosecute. However, one of the most common defenses in rape cases involves the issue of consent. For example, if the victim was drinking, how can she be sure she did not consent? Many rapists have learned that the "alcohol excuse" can help them escape rape charges. A more insidious drug, rohypnol, is being used on college campuses and in bars and nightclubs to facilitate raping and getting away with it. It is dropped into a potential victim's drink. The symptoms are dizziness,

disorientation, lack of coordination, and passing out. The victim is then raped but has no memory of the sexual assault. The question again is posed, If she cannot remember, how does she know she did not consent?

According to the Center for Women Policy Studies (1991, pp. 3-4), fewer than 40 percent of reported rapes result in charges against the offenders and only 3 percent result in convictions. Many researchers have commented on the comparatively light sentences associated with rape convictions. There appear to be several reasons for this, including the tendency to blame the victim rather than the perpetrator: "She should have been more cautious or more sensible or not been walking alone at night." Closely associated with blaming the victim is the notion of "victim precipitation," or the idea that the victim did something to provoke the rape. This can be tied to how the victim was dressed, her profession (e.g., a prostitute), or where she was when the rape happened (e.g., in a fraternity member's room or a male's hotel room, as in the Mike Tyson rape case). Many researchers who have studied rape and the criminal justice system argue that women who are rape victims are "double victims." They are victimized by both the rapist and the criminal justice system.

OTHER TYPES OF RAPE AS SEXUAL VIOLENCE

Marital Rape. Most discussions of rape focus on date rape or acquaintance rape and stranger rape. A third type of rape among intimates that has received increased attention since the 1980s is marital rape. This type of rape occurs when the victim and offender are spouses or are living in a spouselike arrangement. Although this was thought to be rare, Russell (1984, p. 59) found that 8 percent of ever-married women reported being raped by their husbands. Some researchers believe that marital rape is more common than all other types combined. The 1980s brought about many changes, as spousal immunity laws, which historically prevented husbands from being charged with raping their wives because a wife was viewed as a husband's property, were challenged.

In 1977, Oregon repealed the marital exemption to its rape statute, and in 1979, James K. Chretien became the first person in the United States to be convicted of marital rape. Currently all states prohibit forced sex between a husband and a wife, although most include numerous spousal exemptions. As of 1990, seventeen states and the District of Columbia allowed the prosecution of husbands for raping their wives without exemptions. In twenty-six states, husbands are exempt from prosecution in certain circumstances, such as if only force is employed (Wallace 1999, p. 509) but there is no additional violence such as the threat of using a weapon. In eight states (Kentucky, Missouri, New Mexico, North Carolina, Oklahoma, South Carolina, South Dakota, and Utah), a husband cannot be prosecuted for raping his wife unless they are living apart, are legally separated, or have filed for divorce. In five states, exemptions are extended to unmarried cohabiting couples, and there is an exemption for dating relationships in Delaware.

Males as Victims of Sexual Violence. Males appear to be victimized both in and out of prison by heterosexual and homosexual males and by females. Currently, men are thought to make up less than 10 percent of all rape victims (Renzetti and Curran 1995, p. 39.) In *Rape in Prison* (1975), Scacco emphasized that rape in prisons is not an act of homosexuality. Rather, it is an extension of the traditional male sex role and the patriarchal culture in which a single male or group of males seeks to dominate another person through a violent act. In the absence of females, those who are powerful, dominant conquerors are viewed as the “real” or “masculine” men and those who are raped are relegated to a lower status. As Scacco puts it, the victims of rape become “a punk, a queen, or a female.” They have, in the words of the rapists, “had their manhood taken” (1975, p. 52). Scacco’s interpretation of male rape in prison fits into most feminist theories of rape: Rape is an act of power and control rather than a sexual act. While the prevalence rates for the rape of males in prisons appear to vary from one institution to another, it seems safe to conclude that these rates are higher in prisons than outside prisons, where women are available targets.

Rape Outside Prisons. Outside the prison environment, most people think rape happens only to women. Scacco (1975) argues, however, that rape would not exist in prison if it did not exist first on the streets. A survey of literature on males raping males indicates that the overwhelming majority of rapists are heterosexual both in and out of prison. However, as more is learned about sexual assaults of males, rape is found to be part of gay men’s relationships as well as involving gay men raping women and other men. If, as most rape theorists agree, rape is a crime of power and not sex, there is no reason to believe that some homosexual males do not commit rape. Russell (1984, p. 74) argues that the insignificant number of females raping males (less than 1 percent) has received more attention than has rape by homosexual men. She notes that this politically controversial issue has resulted in an avoidance of even discussing the issue (1984, p. 74).

While there is no agreement about the prevalence of males being raped, there is a consensus that men get raped by other men and women, that homosexual and heterosexual males are rape victims and offenders, that rape happens in all parts of society and not just in prisons, and that men are less likely than women to report rape. It is known that male victims share some of the traumas of female victims as well as having special concerns. Those added concerns include issues of masculinity and/or sexuality, medical procedures, reporting to the police, telling others, and finding resources and support.

Rape and War. Brownmiller’s (1975, chap. 3) historical account of rape provides evidence that rape has always been a part of war. This applies whether one analyzes biblical accounts or the raping of women by American soldiers during the Vietnam War.

There is much documentation that the rape of women and even children is not, as some military and government officials argue, an unfortunate but inevitable part of war. Instead, Brownmiller argues, it is a planned part of war strategy that has included not only rape during the conquest of a village, town, or city but women being captured

and used as sexual slaves. She contends that it is the winning side or the conquerors in battle who do the raping. Rape is not only a way of measuring victory but also the way males assert their masculinity. Consistent with the idea that women are property, women are seen as tangible rewards of war.

Rape during war is considered a criminal act under international law, punishable by imprisonment or death, but wartime rape continues. This violence against women generated public attention as a human rights issue when, in 1993, the U.S. and European media reported the systematic rape, sexual enslavement, torture, and murder of Bosnian Muslim women and children by Serbian military forces in the former Yugoslavia. The estimate of the number of rapes in 1993 was 20,000 (Riding 1993). In 1999, the rape of women and children by the Serb military continued. Investigations of these atrocities conclude, as did Brownmiller, that rape is used as a weapon of war. They argue that it is a central part of the Serbian ethnic cleansing campaign. Bosnian and Kosovar men are murdered, while the women are raped with the objective of impregnating them to produce offspring with Serbian genetic characteristics. It is also psychological warfare, with the intent to demoralize and terrorize Muslims and drive them from their homes. European investigators reported that many women and children died during sadistic and brutal rapes. Brownmiller's historical account of rape and war indicates that an additional consequence of rape and impregnation is suicide and infanticide.

Rape during war often takes the form of group or gang rape. There are documented cases of gang rape by police and military personnel in numerous countries, including Haiti, Honduras, El Salvador, and Iran (Sontag 1993). There are also recent accounts of Algerian women being raped by Islamic radicals. Muslim women in Bosnia, Kosovo, and Algeria who survive rape face psychological problems associated not only with rape but with living in a culture that values sexual purity, by which the male's honor as well as the family's honor is defined.

The motivations for rape and violence against women in war are similar to those for rape be-

tween strangers, acquaintances, and intimates in everyday society and prisons. It is an attempt to socially control and harm individuals who are viewed as having lower or undesirable statuses or are viewed as the enemy. In war, the rapes occur on a larger scale.

In the 1990s, the United Nations attempted to develop policies to eliminate all forms of discrimination against women. However, as long as rape of women and children remains an open or hidden part of war strategy, this violent act will continue.

EXPLANATIONS FOR RAPE

Explanations for rape come from a variety of disciplines, although many explanations have been dominated by the psychiatric perspective and the medical model (Koss and Leonard 1984, pp. 213–232). The basic assumption underlying this thinking is that rapists are psychologically sick and that rape is sexually motivated. Hence, many explanations focus on developing profiles of rapists (e.g., Groth 1975), leading to a body of research whose validity is questioned because it is based primarily on nonrepresentative clinical or prison populations.

Sociological explanations of rape focus on the social dynamics of society that promote, treat, or proscribe such behaviors and include sociocultural, sociohistorical, and sociopsychological analyses. While these types of explanations lagged behind those of psychology and biology, they offer an alternative to individual-based theories.

Sociocultural explanations of rape are supported by large cross-cultural studies of tribal societies (Sanday 1981) and large studies in nonindustrialized nations. All these studies draw similar conclusions. Rape-prone societies endorse the macho personality and a fundamental belief in the inferiority of females, a belief system that incorporates an acceptance of physical aggression, a high amount of risk taking, and a casual attitude toward sex. Rape also is related to a culture's socioeconomic structure.

Among industrialized societies, the United States has high rape rates. Baron and Straus's

(1989, p. 180) state-level analyses show that rape rates vary by region and state within the United States and that those rates are positively related to the amount of social disorganization, sex magazine circulation (pornography), and gender inequality in a state or region. This adds weight to earlier research that ties rape-specific myths and attitudes to a larger attitudinal construct supportive of sex role stereotyping, violence against women, and adversarial sexual beliefs.

Sociocultural and sociopsychological explanations of rape support the sociohistorical analysis of Brownmiller (1975). While Brownmiller has been criticized for exaggerating the notion of male intimidation, sociological and anthropological research indicates that rape is a socially created phenomenon that is much more likely to occur in cultures that support patriarchy and violence. Sociocultural explanations also may explain why the majority of offenders are male irrespective of whether the victims are male or female, adult or child.

Regardless of the varied theoretical perspectives, most researchers agree that multifactorial (psychological and sociological factors), compared with single-factor, explanations are better predictors of rape. Russell (1984, p. 111) notes that most rape theories could fit into Finkelhor's (1984) four-factor explanation of child sexual abuse, which is discussed in a later section.

SEXUAL HARASSMENT

Sexual harassment is a form of violence against both males and females, but the overwhelming majority of victims are women and most of the perpetrators are men. While the exact prevalence seems to vary from one study to another, it is safe to conclude that sexual harassment in the workplace is widespread. While sexual harassment can occur in other social institutions, such as colleges and schools where professors and teachers use their positions of power to obtain sexual favors from students, most sexual harassment research has focused on the workplace.

Sexual harassment policies, laws, and rulings generally have relied on Title VII of the Civil

Rights Act of 1964, which prohibits employment discrimination on the basis of race, color, religion, sex, pregnancy, or national origin. In 1980, the Equal Employment Opportunity Commission (EEOC) adopted guidelines that specifically address discrimination on the basis of sex. While these guidelines were not binding, they were used by courts in making decisions in sexual harassment cases. In 1993, the Supreme Court further articulated the meaning of sexual harassment in *Harris v. Forklift Systems, Inc.* Basically, the case focused on the "nature" of sexual harassment and ruled that there was no requirement that the severity of the harassing conduct cause the victim psychological or physical harm. The Court held that victims alleging sexual harassment met their burden of proof if they proved that the environment was *perceived* as hostile or abusive. The circumstances for making such a judgment could include the frequency of the alleged harassment, whether it was physically threatening or humiliating, and the extent to which it interfered with an employee's work performance.

Sexual harassment may take two forms that are not mutually exclusive: quid pro quo harassment and hostile environment harassment. The former type occurs when the victim is placed in a situation where an employer or supervisor uses his or her position to request sexual favors as a basis for continued employment or job benefits. The victim is put in the position of choosing between providing sex and losing employment or benefits. Hostile environment harassment happens when victims are exposed to a series of unwelcome sexual acts that result in psychological harm or humiliation. The difference between the two types of harassment is that the quid pro quo form focuses on harassment that is tied to economic disadvantage, while the hostile environment type focuses on psychological harm.

Tangri et al. (1982) offer several models to explain sexual harassment: the biological, organizational, and sociocultural models. The biological model assumes that sexual behavior in the workplace is an extension of human sexuality or strong sex drives. The organizational model focuses on the situation in which the workplace offers oppor-

tunities for sexual aggression. This model focuses on power that derives from formal roles in an organization. The sociocultural model is derived from theories of patriarchy in which men are viewed as dominant in Western culture and are the gatekeepers of political and economic power. This explanation is the most congruent with a feminist view of sexual harassment.

Two prominent sexual harassment cases have captured the public's attention. The first involved Anita Hill and Clarence Thomas. Hill, a law professor, testified to the U.S. Congress that Thomas, who had been nominated to the Supreme Court, had sexually harassed her. The second was the case of *Paula Jones v. William J. Clinton*. Jones brought charges against President Clinton, alleging that when he was governor of Arkansas and she was an employee of that state, he asked her to engage in sexual activities. Her reluctance, she argued, led to the loss of job benefits. Both cases demonstrated the difficulties of proving sexual harassment cases. They also sent messages that bringing charges against very powerful males can lead to additional reputational, economic, and psychological victimization.

Simply having agencies and courts establish procedures and policies to process sexual harassment will not terminate this behavior. The public must send a clear message that it stands behind sexual harassment laws and that everyone, regardless of social status, must be held accountable. Accounts of sexual harassment, rape, or sexual exploitation by President Clinton of Gennifer Flowers, Paula Jones, Monica Lewinsky, Kathleen Willey, Juanita Broaddrick, and others raise questions about the public's concern about these issues as well as the issue of a double standard. The public seems willing to support or excuse some offenders, such as President Clinton, while punishing others.

CHILD SEXUAL ABUSE

Since the mid-1970s, there has been increased interest in understanding child sexual abuse. This concern led to the founding of the National Cen-

ter on Child Abuse and Neglect and the passage of the 1977 Protection of Children against Sexual Exploitation Act. A review of the child sex abuse research (Finkelhor et al. 1986) demonstrates many similarities with what is known about rape. Paralleling Brownmiller's (1975) historical analysis of rape, for example, is Rush's (1980) analysis of child sexual abuse. Like Brownmiller, Rush elevates child sexual abuse to the level of a social problem by tracing its roots to patriarchal societies and their social institutions, belief systems, and myths. However, there are groups that do not view child-adult sex as a problem, such as the North American Man Boy Love Association; in fact, they advocate it.

In general, child sexual abuse can be defined as sexual exploitation of or sexual activities with a child by an adult, in which the child's health or welfare may be harmed or threatened. While all states consider child sexual abuse a crime, definitions vary from state to state and some states leave the interpretation to the courts. There is no real agreement among social scientists about the true extent of child sexual abuse, but all concede that the number of reported cases is increasing and that the actual numbers are underestimated, particularly for males. A comparison of national findings with less comprehensive research studies reveals conflicting estimates of the incidence of child sexual abuse. Commonly cited estimates suggest that one in four girls and one in six to seven boys will be sexually abused by the time they reach age 18.

Studies do not support a general social characteristics profile of the victims or offenders, although females tend to be at somewhat greater risk of victimization than males and males are overwhelmingly the offenders. The ages of greatest risk for victimization appear to be between 4 and 9. Most offenders are either known by or related to their victims and are not old. Only about 10 percent of child sexual abusers are strangers, although the Internet could change this statistic.

The impact of being a victim of child sexual abuse has been widely studied. It generally is agreed that the amount of trauma experienced varies with the type of abuse, how the offender is related to

the child, how long the abuse lasted, how sexually intrusive the abuse was, the age when the abuse began, the reactions of others to the disclosure of the abuse, and the child's personality.

As an ever-increasing number of child sexual abuse cases have moved into the courts, particularly in cases involving divorce and custody, concern for balancing the needs of the legal system against those of children has arisen. Placing children in the courtroom subjects them to many of the same problems faced by rape victims: victim blaming and other courtroom-produced traumas. Although still in the early stages, reforms are being implemented and suggested, with one area of legislative reform focusing on increasing convictions and community notification once sex offenders are released. The latter was largely an outgrowth of Megan's Law, which was named after Megan Kanka, a 7-year-old who was molested and killed in 1994 by a released sex offender who was living in her neighborhood without residents' knowledge of his history of sexually abusing children. By 1995, forty-three states had adopted laws requiring offenders to register with a law enforcement agency when they were released.

The late 1980s and early 1990s ushered in a new area of child sexual abuse. Children 12 years of age and younger have sexually abused other children. These young offenders have predatory patterns that are very similar to those of adult and adolescent molesters. Some, but not all, are reacting to their own victimization. An interesting finding from this research is that females tend to be about as likely to be perpetrators as are males and are equally aggressive in their sexual acts. Questions have been raised about why females are not found in larger numbers among the adolescent and adult sex offender populations. The family system appears to be the learning and training ground for these youthful (some as young as 2 years old) perpetrators (Araji 1997).

Studies of child sexual abuse do not offer a consistent link between social class, race, and ethnic group, although the lower socioeconomic classes tend to be overrepresented, as are, in the case of young perpetrators, single-parent families. It is too

early to make accurate cross-national comparisons of the extent of child sexual abuse. Some research has been conducted in other countries and Finkelhor (1994) suggests that, as in the United States, the problem is widespread. There have been no cross-cultural studies of children who sexually abuse other children.

EXPLANATIONS OF CHILD SEXUAL ABUSE

The development of child sexual abuse explanations has been similar to that of explanations for rape, as most early studies focused on offenders' psychopathological or biological motivations or attempted to develop profiles of child molesters, victims, and families. As with rape, most explanations offered only single-factor explanations, an approach criticized by Araji Finkelhor (1986, chap. 34). As an alternative, those authors proposed a four-factor explanation of child sexual abuse that includes the categories of emotional congruence, sexual arousal, blockage, and disinhibition. Respectively, these factors incorporate explanations of why an adult would have an emotional need to relate to a child, could be sexually aroused by a child, would not have alternative sources of gratification, and would not be deterred from such an interest by normal prohibitions (Araji and Finkelhor 1986, p. 117). The model includes both individual (e.g., arrested emotional development) and socio-cultural (pornography) factors. As was noted above, Russell (1984) believes that this model could be adapted to explain rape.

With respect to explaining youthful perpetrators' sexual aggression, Araji (1997) found much of the same theoretical history noted above. She proposes systems theory as a necessary explanatory and remedial guide.

INCEST

Most researchers and practitioners consider incest different from child sexual abuse, with incest viewed as intrafamilial and child sexual abuse viewed as extrafamilial sexual relations. While some argue that the two types of abuse have much in common,

one of the most significant differences is that the victims of incest are always betrayed by someone who has been charged with loving and protecting them. Much of the sexual abuse committed by children 12 years of age and younger is intrafamilial. Such experiences can have extremely destructive results, but this varies with the factors discussed above.

The most common type of incest researched and written about is between father and daughter (Herman and Hirschman 1981), although the most common type may be brother-sister. As stepfamilies are formed, the probability for incestuous relationships involving stepfathers increases. Estimates of incest range from a high of 38 percent of females in Russell's (1984) study to about 25 percent in several other survey studies (e.g., Finkelhor 1979). However, the same research problems surrounding rape and child sexual abuse apply to incest literature: underestimating the extent of the crime, not accurately defining it, and theory and sampling problems.

TREATMENT AND PREVENTION

A considerable body of literature on the prevention and treatment of sexual violence and abuse has emerged from applied disciplines such as social work and clinical psychology as well as from community and feminist organizations. An extensive discussion is beyond the scope of this article, and so only a few generalizations are noted. First, as treatment programs are informed by a variety of theories of rape and sexual abuse, it is not surprising that there is an array of treatment programs. With respect to offenders, most programs focus on punishment and/or rehabilitation (Groth 1979; Conte and Berliner 1981), and many are based on the psychiatric or medical model. In cases of child sexual abuse and incest, programs typically focus on helping the victims and their families get through the crisis. In the area of rape, programs have been aimed primarily at treating victims and families for the rape trauma syndrome and have been directed at females. Treatment programs have also been developed to deal with the short- and long-term effects of abuse (Brown and Finkelhor 1986) and can be either clinical or community-based. Some

are beginning to focus on sexual and ethnic differences. At present, however, there remain debates among professionals and practitioners about what the appropriate treatments are, which ones work, and how well.

Stemming from myths and callous societal attitudes toward sexual aggression and the extensive involvement of feminists, prevention programs have followed a victim advocacy model (Araji 1989, chap. 17). Under this concept, potential victims are taught in various ways how to protect themselves from becoming victims. Some newer programs are aimed at men and promote the development of a nurturant rather than a macho male image.

SUMMARY AND CONCLUSIONS

Extensive public and professional attention to sexual violence and exploitation has come about only since 1960 and has been primarily a grassroots movement. As a result, a large body of cross-disciplinary literature has developed and various reforms have taken place. While no consensus exists about the scope of these problems, the rates at which they are increasing or decreasing, definitions, explanations, social policies, and solutions, sociologists, particularly feminists, have concluded that sexual violence and exploitation will not be reduced or eliminated until societies stop supporting and/or promoting aggression, violence, exploitation, and inequality.

However, the prognosis that sexual violence and exploitation involving women and children will soon end is not convincing. As long as societal members, many of them women, are willing to turn a blind eye to predatory behaviors toward women on the part of the president of the United States and surveys of college, high school, and elementary students report large percentages (31 to 87 percent) of students believing that it is acceptable for males to engage in forced sex or rape of females under certain circumstances (White and Humphrey 1991) or if they do not get caught (Malamuth 1981), one must conclude that the fight against sexual violence and exploitation of women and children is still in the beginning stages.

SEXUALLY TRANSMITTED DISEASES

Until the 1980s, social science research on sexually transmitted diseases (STDs) focused primarily on the history of various pestilences, the epidemiology of those diseases, and the description of mass disasters (Brandt 1985; Aral and Holmes 1999). The disease that was most commonly researched was syphilis, long the best identified and most feared STD. Historians and anthropologists wrote numerous treatises on its origin and the social consequences of its introduction into isolated, tribal, or third world societies (Wood 1978; Hart 1978). In the early 1980s, the consequences of other STDs were studied, especially as sequelae of prostitution (Kalm 1985; Poherat et al. 1981).

When awareness of the “sexual revolution” finally induced social scientists and epidemiologists to think about the effects of STDs on less sexually active populations than prostitutes and their clients, the literature turned to the newly sexually active: vulnerable teenagers (Washington et al. 1985) and other young people who engaged in premarital sex (O’Reilly and Aral 1985). The exponential intensification of the discussion of and social science research on STDs, however, came only after the medical community’s horrified acknowledgment that the newest STD to become epidemiologically important, the acquired immune deficiency syndrome (AIDS), was also the deadliest and that social, not just biological, information was essential in order to combat it.

When AIDS first began to be discussed in 1981, the medical community was already alarmed at its mystery and virulence (Aral and Holmes 1999). Unhappily, it took years before more focused measures, such as those taken by fundraising organizations and institutes devoted to AIDS research, were initiated. Journalists, most notably Randy Shilts (1987), have persuasively ar-

gued that the lack of a strong reaction from the start was due to the fact that the early victims were gay men, not American Legionnaires or Girl Scouts. Today the basic facts of AIDS have been well disseminated. Almost everyone knows, for example, that in the United States gay men are disproportionately affected, as are people who mix blood while exchanging hypodermic needles. However, in the early 1980s, information was abysmally inadequate and myth and rumor educated more people than did social or medical research.

With the accuracy of hindsight, it is evident that sociologists should have looked at sociocultural histories of recent sexual behavior and used that information to help study disease transmission. But no one was proactive, and it took years for a pertinent literature to emerge. The exceptions were a small group of social researchers at the Centers for Disease Control (CDC), whose work was restricted to STD-related topics, and a few epidemiologists studying the social location of this disease among gay American men (Aral and Holmes 1999) and among heterosexuals in Africa. Otherwise, the analysis of AIDS remained mostly ghettoized in the medical literature until the mid-1980s. Until the publication in 1994 of the results from a large national survey of adult sexuality in the United States (Laumann et al. 1994), the best available data on sexual behavior were the Kinsey studies from the 1940s and early 1950s.

Finally, the combination of organized gay activism and public alarm created the kind of political pressure that made more money available and launched a flood of AIDS research. Indeed, interest in sex research in general, previously an area treated like a poor relation, received more credibility, though not enough to allow the funding of a nationally representative study of sexual behaviors. A large national study slated to be funded by the National Institutes of Health was stopped in 1990 after Senator Jesse Helms helped persuade the U.S. Senate that Americans should not be exposed to such questions. Nonetheless, research on sexuality, especially on STDs, found funds and larger and more diverse professional audiences. Even before the prevalence of AIDS among gay men was understood or publicized, some research

described how great numbers of anonymous sexual contacts in gay bars, baths, and parks happened and how such activity set the stage for infection (Darrow 1979; Ross 1984; Klovdahl 1985). By the 1990s research attention had become focused on how sexual cultures, such as a "gay lifestyle," increased exposure to the human immunodeficiency virus (HIV). Later, the issue was reframed to focus on behaviors that place people at risk (rather than on the groups to which they belong) and the social and psychological factors that influence sexual decision making. This avenue of research affirms that sex is a social behavior that must be studied in its social context.

Current AIDS literature centers on two main issues: (1) who is at risk and why and (2) risk-reduction factors, including education.

WHO IN THE UNITED STATES IS AT RISK AND WHY

Most researchers include in their lists of risk factors number of partners, sex of partners, intravenous (IV) drug use or an IV-drug-using partner (Ehrhardt et al. 1995), frequency of intercourse (Aral and Cates 1989), use of condoms (Morrison et al. 1995), contact with commercial sex workers (Plummer et al. 1999), and sex with bisexual men (Doll and Ostrow 1999). The last factor has been of increasing interest, since there seems to be more bisexuality than mainstream research acknowledged previously and because this is an obvious bridge between high- and low-HIV-rate populations. Information about bisexuality has become important in efforts to understand AIDS transmission. For example, a study of lesbian women, a group usually thought of as low-risk, showed that not only had 81 percent of these women had sex with men, at least one-third of their male partners had had sex with other men. Women with bisexual male partners were also more likely to have had anal sex, an activity thought to be an especially efficient mode of HIV transmission (Padian et al. 1987). Bisexuality among men constitutes a greater risk factor than was previously recognized because these men may make regular forays into the gay male world unknown to their female partners.

This may be more likely to occur among married couples or in some minority communities, where the behavior itself may necessitate the utmost secrecy and may even be defined by the participants as "not homosexual" and therefore not risky (Carrier 1985; Blumstein and Schwartz 1977; Humphreys, 1975).

Other, less obvious risks include the possibility of deviousness or outright lies from a partner. In a poll conducted by Cochran and Mays (1990), 196 men and 226 women aged 18–25 completed an anonymous questionnaire on sexual strategies. The findings indicated that a significant number of both men and women had told a lie in order to have sex. Men lied more frequently than did women, but both sexes were actively and passively willing to deceive a date.

Sociodemographic characteristics also have been studied as risk factors. Age is one such factor. Among U.S. teenagers the rate of AIDS is low overall (less than 1 percent of AIDS cases); however, such data underestimate the risk because of the long incubation period from HIV infection to the development of AIDS (ten or more years). Moreover, AIDS rates are higher among more vulnerable subpopulations of adolescents, such as runaway and homeless youth, STD clinic populations, and young people in the juvenile justice system. Such youths are more likely to engage in activities, such as drug use and "survival sex," that put them at high risk of HIV infection. Particularly worrisome is the high rate of other STDs among teenagers, especially young women, because having an STD is thought to enhance the probability of becoming infected with HIV after exposure. Unfortunately, although condom use has increased among teenagers, adolescents still do not use condoms consistently (Sonenstein et al. 1998.). Teenagers in the United States have higher rates of nonmarital pregnancies than do their counterparts in any other industrialized nation despite the fact that they are no more sexually active than are teens in other countries. These facts suggest that teenagers in the United States are not adequately protecting themselves against the outcomes of their sexuality. This may be the result of a lack of comfort with the idea of teenage sexuality in a nation that sends mixed messages to its youth.

In general, better-educated persons are more likely to use condoms. College students, however, are surprisingly casual about condom use. In a study by Reinish et al. (1990), less than two-thirds of the students studied had used a condom in the previous year, less than one-third had used a condom the last time they had had vaginal or anal intercourse, and only half had ever used contraceptive methods that also prevent STD transmission. Those in exclusive sexual relationships reported the highest levels of intercourse. This finding prompted concern among the researchers that while it seems that being in a committed sexual relationship lowers the overall risk of HIV infection by reducing the number of partners, risk may be increased because of frequency of relations unless partners use condoms or have accurate information about each other's sexual and drug use histories. Even well-educated college students tend to use criteria irrelevant to AIDS transmission, such as "just knowing" a partner is safe, as a means of determining when condom use is necessary (Civic, in press). A set of qualitative research notes indicates that condom use may decrease, even among populations that most need to use them, for socioemotional reasons. Kane's (1990) population of women with HIV-probable partners in the drug culture refused, as an act of solidarity, to use condoms. These women felt that using a condom would indicate their awareness and condemnation of the partner's addiction, alienating him and harming the relationship.

In the United States, not all racial and ethnic groups have been equally affected by the AIDS epidemic. Although European-Americans initially were the group with the highest rate of AIDs, this is no longer true: AIDS rates among racial and ethnic minority groups have increased substantially since the beginning of the epidemic. Data from the CDC show that in 1990 whites accounted for over half the AIDS cases (56 percent in January 1990), but they now account for fewer than half the cases (46 percent in January 1998). African-Americans in impoverished inner cities have been especially hard hit. In January 1990, 27 percent of AIDS cases occurred among African-Americans, but by January 1998, this figure had increased to 35 percent.

The infection rate also has been increasing among Americans of Hispanic origin (18 percent of cases in January 1998).

One of the newest groups in the United States to receive research attention is women. Since AIDS surfaced in this country among gay men, the lack of attention to women might seem reasonable until one remembers that as partners of bisexual men or drug users, as drug users themselves, or as inhabitants of countries where AIDS is not a "gay disease," women always were at risk. AIDS has been increasing steadily among women in the United States. CDC figures show that in January 1989 women represented only 9 percent of AIDS cases, but by January of 1998 this figure rose to 16 percent, a 44 percent increase in less than a decade. Women also have substantially higher rates of chlamydia—the most prevalent bacterial STD—as well as genital herpes. Unfortunately, STDs are more likely to be asymptomatic in women, thus causing delayed treatment, increased complications such as infertility, and increased vulnerability to HIV infection.

Initially, IV drug use was the primary mode of AIDS transmission among U.S. women, but today, heterosexual intercourse is the primary mode. In late 1989, 52 percent of AIDS cases among women were attributable to IV drug use, whereas in June 1998, only 23 percent of cases were thought to be IV drug use-related. Most women with AIDS are of childbearing age. This increases the chances of transmission from an infected pregnant woman to her unborn baby as well as increasing the number of children, often in single-parent families, who are forced to cope with the prolonged illness and then loss of a mother. The effects of AIDS on children have only recently begun to be studied. Studies show that between 13 and 35 percent of babies born to HIV-positive women are HIV-infected, a figure that has been rapidly declining since the beginning of the AIDS epidemic, largely as a result of the advent of newer antiviral drugs. Many pregnant HIV-infected women, even with knowledge of the risk, choose not to abort (*Proceedings NIMH/NIDA Conference on Women and AIDS* 1989). AIDS concerns attend other reproductive issues as well, such as the safety of artificial insemi-

nation. While the American Fertility Association has guidelines that exclude high-risk men from donating sperm, methods for testing for HIV seem to be inconsistent, and private physicians may not test at all (Campbell 1990).

The use of alcohol and drugs has been shown to be related to unsafe sex practices, although there have been contradictory findings (Leigh and Stall 1993 provide for a review). Fullilove and Fullilove (1989), for example, found that 62 percent of the 222 black inner-city teenagers they studied used crack, and 51 percent of the users said they combined crack use with sex. Forty-one percent of the teenagers surveyed had had at least one STD; those who used crack with sex had a significantly higher rate of STD infection. The correlation between crack use, sex, and STD transmission has been found by many other investigators (Aral and Holmes 1999). Although crack use has declined substantially since the late 1980s, the use of other drugs (e.g., methamphetamines) that also appear to be related to unsafe sex has risen. Leigh (1990) found that patterns of drug use and the effects of drugs on behavior differ among groups: Gay men were less affected by drinking and engaged in more risk taking when using cocaine, whereas heterosexual risk taking was predicted largely by total frequency of sex, with only a small amount of the variance explained by having partners who used drugs or alcohol. A note of caution is warranted in interpreting the findings of studies of the relationship between sexual practices and substance use. Most of this research that shows a relationship between substance use and risky sex has not demonstrated that substance use *causes* risky sex, because researchers rarely have information on which came first. Moreover, it is conceivable that a third factor, such as a propensity to take risks, is responsible for both substance use and sexual risk taking (Leigh and Stall 1993). Clearly, more research is needed.

Research has increasingly concentrated on infection resulting from exchange of blood caused by mutual use of needles during intravenous drug use. In a paper by Freeman et al. (1987), a comparison of gay males and IV drug users showed that peer support helped create safer sexual practices

for gays while lack of social organization reduced IV drug users' chance of self-protection. Among the drug users, 95 percent were well aware of their exposure and 68 percent knew that needle sharing could transmit AIDS. Some individual attempts at decreasing the use of potentially contaminated needles had been made, but the authors felt that the only way to reduce risk in this population was to create organizations for needle dispensation that eventually could create a culture of mutual protection. Opinion has changed from considering IV drug users uneducable to recognizing substantial successes in changing their drug-taking practices to include more self-protective habits. Still, ethnography shows that needle sharing between addicted partners is seen as an intimate and bonding behavior, and this makes change more difficult. Moreover, despite their demonstrated effectiveness, needle-exchange programs are under attack by conservatives who claim that they encourage drug use, even though there is no evidence to support that contention.

Although sexual behavior certainly has biological underpinning, it is clear from the research that sexual behavior and the spread of STDs are socially driven. Sociocultural factors, not biology, determine not only with whom one has sex, whether and when one is likely to have sex, and the specific forms of sexual expression in which one engages but even which persons, activities, and things are experienced as erotic. This fact is eminently evident in the early studies of the Kinsey group, Ford and Beach's (1951) cross-cultural studies, and more recent research (e.g., Laumann et al. 1994).

RISK REDUCTION AND EDUCATION IN THE UNITED STATES

It is difficult to discuss risk without touching on risk reduction. Indeed, a growing body of research literature reports the results of studies investigating specific risk-reduction strategies, curricula, and behavior modification that targets specific populations—such as gay men, minority group members, teenagers, mothers, and drug users—with what is hoped to be a useful approach.

The most encouraging findings indicate that it is possible to change risky sexual behavior. This is

a significant discovery, since many personal habits, such as drinking and overeating, are notoriously resistant to sustained modification. In the 1980s, researchers in San Francisco found that gay men there had reduced their numbers of partners and frequency of sex and increased their use of safer sex practices (McKusick et al. 1985). However, since much of this change was attributed to the extraordinary social power of organized gay groups in that city, the question arose whether such dramatic changes could occur among gay men who are less embedded in gay communities (Fisher 1988). However, change has occurred across the United States, indicating both the strength of educational and social control efforts among gay activists and, perhaps, the great motivation for change that exists when suffering and death are not only possible but probable (Martin 1987; Siegal and Glassman 1989; Roffman et al. 1998).

This conclusion is not self-evident because change in gay male circles has not been complete. Changes in behavior are associated with proximity to populations with high incidences of the disease: The more distance, the less change in behavior (Fox et al. 1987). Furthermore, even in densely infected areas, a significant minority of HIV-infected persons seem to continue engaging in risky sexual practices (Kelly et al. 1998). There is even evidence that for some men, fear wears off and unprotected sex practices increase (Martin 1987), whereas for others, initial changes toward safer sex are difficult to maintain in the long run (Kelly et al. 1998).

Naturally, there is a great deal of pressure on researchers to find out what helps all kinds of people protect themselves from AIDS. Depressingly but predictably, it has been found education alone is inadequate to induce behavior change. For example, Calabrese et al. (1987) reported that for gay men outside big cities, attendance at a safe-sex lecture, reading a safe-sex brochure, HIV antibody testing, advice from a physician, and counseling were all inadequate. Other sex education efforts have had a limited effect, often for a limited period. For example, researchers assessed the impact of a ten-week university course on human sexuality and AIDS-related behavior. While stu-

dents who had taken the course possessed more information about actual risk, worried about AIDS more, and asked sexual partners more questions relating to AIDS than did a control group, they did not increase their use of condoms or other contraceptives, decrease the number of sexual partners, or spend a longer time getting to know a prospective partner (Baldwin et al. 1990). Studies have consistently shown that sex education for adolescents is necessary but not sufficient to produce behavioral changes (Kirby and Coyle 1997).

The disappointing results of sex education have led researchers to search for more viable strategies. Because self-esteem, confidence, and ego strength have been hypothesized to help individuals protect themselves from others' as well as their own desires, a number of researchers have looked for ways to bolster these characteristics (Becher 1988). To date, the most promising programs appear to be ones that are conceptually based and provide information and skill building, enhance motivation and normative support for change, and are ethnically and culturally sensitive (Fisher and Fisher 1992 provide a review).

No one believes that any single approach is appropriate for all audiences. Increasingly, this literature has been investigating separate strategies for different groups. Students of race, ethnicity, and gender understand not only that various groups use language differently but also that reality is filtered through culture. This sociological truism has benefited research and education among at-risk populations. An example is understanding how gender differences affect health behavior. Campbell (1990) noted the limitations of educational programs aimed at women, especially non-IV drug users, who resist feeling at risk. She found that the partners of IV drug users are unlikely to be assertive and to insist on safer sex. Most of these women are already in subordinate, if not abusive, situations, and their vulnerability and passivity have to be addressed before progress can be made. This fact is underscored by findings from a study in which Beadnell et al. (in press) report that a strong predictor of the extent of at-risk women's attendance at a multi session AIDS prevention intervention is whether they are in an abusive

relationship. Campbell (1990) warns that there are special considerations about condom use among minority group women, since minority group men may reject condoms more resolutely than do white men. Campbell also reminds the reader that in educating commercial sex workers both for their own safety and for that of others, one needs to take into account the dual issues of their gender and their profession. She argues against overreliance on women as the safety net in sexual relations. To date, little AIDS research has focused on heterosexual men.

Among working and lower-income African-American women, gender issues often make safe-sex guidelines seem impossibly theoretical. Unemployment has put African-American men in transient relations with African-American women, and partners are unlikely to engage in the kind of cooperative communication many safe-sex guidelines assume (Fullilove, et al. 1994). Fullilove et al. also highlight black women's and teenagers' increased vulnerability to disease because of relatively high rates of nonmonogamy among potential partners. Those authors feel that individual strategies are unlikely to be as powerful as a "reknitting of community connections" for the evolution of protective norms. Social disorganization further complicates the problem by giving less and less accurate information to African-American and Hispanic populations.

Even designing messages for minorities or finding community outlets for their dissemination does not begin to handle the difficulty of reaching and influencing at-risk persons. Target audiences for prevention are not necessarily self-identified. For example, almost no AIDS-prevention research has been conducted with lesbian women who may have occasional intercourse with bisexual partners and do not consider themselves at risk. Latino men who occasionally visit gay bars and have anal intercourse often do not use condoms with their wives in part because, as the "*activo*," they do not see themselves as homosexual or as having participated in a homosexual act and therefore do not perceive themselves as being at risk (Magana 1990). Similarly, because virginity before marriage is highly valued in Latino culture, young unmarried Latinas

may engage in higher-risk anal sex in order to remain "technical virgins." Given the high value placed on motherhood among Latinas, using condoms during vaginal sex can imply that a man's intentions are less than honorable by eliminating the possibility of motherhood. Almost nothing is known about the sexual practices of Asian-Americans, perhaps because they have been depicted as the "model" minority. However, some data suggest that Asian-American youths are less knowledgeable about AIDS than are other groups (Wells et al. 1995), and a substantial minority of Asian-American adolescents have been shown to engage in unprotected sex (Schuster et al. 1998). Issues of identification, culture, and gender relations bedevil both researchers and health workers.

Despite the optimism of biomedical researchers, there is still no cure for AIDS or an effective vaccine against contracting HIV. Therefore, behavioral change remains the best hope for controlling the epidemic. Sociological and psychological theories have generated a number of programs that appear to be effective in reducing an individual's risk of contracting HIV. Most of these programs have focused on changing individuals' skills, knowledge, attitudes, and behaviors. However, sexual intercourse is inherently dyadic, and partner issues will need greater attention for such programs to achieve maximum effect, especially for women, who often do not have control over their sexuality. Moreover, the advent of new antiviral drugs and protease inhibitors has transformed the character of the AIDS epidemic to the public at large and the researchers as well as to those with HIV infection. Many people in the United States now view AIDS as a manageable chronic illness rather than a death sentence. Persons with AIDS are living longer, mortality rates have decreased, and those infected with HIV do not appear to be developing AIDS at the same rate as was the case before the use of these new drugs. In response to this change, the focus of AIDS research has changed: Researchers are increasingly studying how to prevent or reduce adverse outcomes, such as depression and relapse to unsafe behaviors, and enhance the quality of life among those living with HIV and AIDS (Kelly et al. 1998 provide a cogent discus-

sion). However, the new drugs are not a panacea. For some, they do not work at all; for others, they appear to work initially but then gradually become ineffective; and for far too many, the enormous cost of the drugs is beyond their means. The latter fact is even more tragic when one considers that in the United States most new cases of HIV infection are occurring among society's most vulnerable populations.

THE INTERNATIONAL SCENE

Data on STDs, including AIDS, from other countries are inadequate because many countries, especially third world nations, do not have sophisticated systems to monitor these diseases. The World Health Organization (WHO) estimates that the current annual prevalence of STDs is about 333 million cases worldwide, with about 5.8 million persons being newly infected with HIV in 1997. In 1999 there were nearly 31 million persons living with HIV or AIDS worldwide. If the current trend continues, WHO estimates that more than 40 million persons will be infected with HIV by the year 2000. To date, over eleven million people worldwide have died of AIDS, and in 1998 alone, about 2.3 million deaths were attributable to AIDS, 46 percent of which occurred among women. The vast majority of cases of STDs worldwide, including AIDS, have occurred in developing countries, and the growth of the AIDS epidemic has been fastest in sub-Saharan Africa, which is thought to have two-thirds of the world's population of persons infected with HIV. Although rates of infection are lower in Asia, where the epidemic started later, the number infected there is estimated to be quite large. In North America, western Europe, Australia and New Zealand, and a few third world countries that have sound economies (e.g., Costa Rica, Thailand), rates of several STDs (e.g., syphilis and gonorrhea) have been declining steadily over the past decade, but they have been skyrocketing (or being reported better) in regions such as China and Russia and remain high in Africa and Asia.

Why is the AIDS epidemic so heavily concentrated in the developing world? Decosas (1996) argues that differences in sexual behaviors alone

cannot explain this fact. He argues that the high incidence of untreated STDs that increase vulnerability to HIV infection, cultural factors such as age differences between male and female sexual partners (older persons typically have more sexual partners and therefore an increased likelihood of exposure to HIV), and demographic factors such as large-scale labor migration and refugee movements have all contributed to the difference. All these factors are related directly or indirectly to poverty and gender inequality. Young women in third world countries, for example, often have limited access to education or vocational training and may have few alternatives for economic survival other than having sex with men. Studies in Africa suggest that women in traditional relationships typically do not engage in risky sexual practices, yet they are increasingly being infected with HIV (Way et al. 1999). Even women who report having only one sexual partner in their lives and who believe that they are in monogamous relationships are found to be infected with HIV. In many regions of Africa, however, men not infrequently engage in extramarital sexual relations, often with higher-risk partners such as commercial sex workers (Way et al. 1999).

Today, the AIDS epidemic worldwide is spread primarily through heterosexual contact. As more women of childbearing age become infected, perinatal transmission from mother to infant is increasing. In urban areas of Uganda, Zambia, Malawi, and parts of Southern Africa, for example, HIV infection among pregnant women has been increasing rapidly; more than one-fifth, and in some areas up to 40 percent, of these women have been found to be HIV-positive (Way et al. 1999). There are important differences across the globe in the main mode of AIDS transmission and who has been infected as well as substantial differences in these factors within regions. In China, for example, there appears to be two epidemics: one among IV drug users in the mountainous regions and the southwestern areas and the other in the more prosperous eastern coastal areas, where commercial sex is reemerging in response to the growing gap between rich and poor. Ironically, AIDS was virtually unknown in China before that country it

opened its borders. In Africa, the highest HIV prevalence rates occur in urban as opposed to rural areas. In Mexico and Latin America, the epidemic is concentrated among the poorest and most marginalized members of society, as is becoming increasingly true of the United States. In eastern Europe, IV drug use accounts for the majority of new infections. Not only are there important differences in the major modes of AIDS transmission worldwide, the modes of transmission within regions have changed over time (Way et al. 1999). This is evident in the United States, where the AIDS epidemic first appeared among gay men, then among IV drug users, and now among racial and ethnic minorities and women. In Latin America, AIDS was first concentrated among IV drug users and gay men, but heterosexual sex is playing an increasing role in its transmission. The epidemic in Asia is moving rapidly from high-risk populations to the general population, largely as a result of heterosexual transmission. In developing nations particularly, new AIDS cases are occurring among younger persons.

The rate of STDs worldwide is alarming because although the most common nonviral STDs (syphilis, gonorrhea, chlamydia, and trichomoniasis) are curable, they are often initially asymptomatic. This is especially so for women, who also are more likely than men to become infected if exposed. Moreover, the increased mobility of populations, accompanied by urbanization, poverty, sexual exploitation of women, and changes in sexual behaviors, places an increasing proportion of the world's population at risk. Because younger people make up a much larger proportion of the population in developing nations than they do in industrialized ones and because younger persons today have more sexual partners than was previously the case, one can expect to see a steeper rise in the rate of AIDS in these countries.

Uganda was among the first nations to respond to the AIDS epidemic, making a strong effort to prevent the spread of the disease that appears to be having an effect, as is evident in the declining proportion of persons infected with HIV (Asiimwe-Okiror et al. 1997). This decline is consistent with behavioral studies that show increased

condom use, delay in sexual initiation, and a decline in the number of sex partners. Similarly, in Zaire, condom use among commercial sex workers dramatically increased from zero to 68 percent after a three-year condom promotion program (Adler 1998). The result was a marked decline in STDs. In Thailand, which is believed to have the best documented AIDS epidemic among developing countries, an aggressive and sustained national campaign to reduce HIV infection rates was instigated once authorities recognized that there was an epidemic. The campaign focused on increasing condom use, promoting respect for women, discouraging men from having sex with commercial sex workers, and increasing opportunities for education and employment to keep younger women from becoming commercial sex workers. The effects of this campaign have demonstrated the success of a concerted national effort. The use of condoms among commercial sex workers rose from 14 percent in 1989 to over 90% by 1994, rates of STDs declined, and the rate of new HIV infections has been declining, especially among commercial sex workers and their clients (Rojanapithayakorn and Hanenberg 1996). The success of this campaign has been attributed to several factors, including use of the existing infrastructure, a focus on a limited goal (improving condom use among commercial sex workers rather than trying to eliminate prostitution), widespread advertising, and a systematic means of monitoring the epidemic. Although less dramatic, local programs in other third world countries appear to be having some impact, as they have had in the United States. In Uganda, for example, a longitudinal study in an urban area showed a substantial increase in condom use, delay of sexual initiation, and a decrease in casual sex among adolescents over a period of two years. These changes were accompanied by a 40 percent decline in HIV seroprevalence among pregnant women who attended antenatal clinics (Asiimwe-Okiror et al. 1997). Similarly, a study of urban factory workers in Tanzania showed a decline over a two-year period in the number of sexual partners and casual sex, although condom use did not increase substantially (Ng'weshemi et al. 1996). A behavioral risk reduction program targeting truck-

ers in Kenya has shown significant declines in extramarital sex and sex with commercial sex workers, although condom use has not changed. These behavioral changes were accompanied by significant declines in STDs such as gonorrhea. In Bolivia, an HIV prevention intervention aimed at commercial sex workers appears to have increased condom use and resulted in lower STD rates in this high-risk group (Levine et al. 1998). In Jamaica, researchers have concluded that a comprehensive HIV/STD control program has resulted in reduced rates of STDs and increased condom use, although a significant minority continue to have unprotected sex in high-risk situations (Figueroa et al. 1998). Officials in some countries, such as India, deny that AIDS is a problem in their regions, and few efforts have been launched to stem the possibility of a widespread AIDS epidemic in those areas.

CONCLUSIONS

Studies have demonstrated that the psychosocial and economic impact of AIDS extends far beyond the persons infected (Craiel et al. 1998). Families have been shown to suffer from stress, economic hardship, stigma, and discrimination when one of their members has AIDS. Women, especially in third world countries, are in structurally less powerful positions than men and often have little or no control over their own sexual safety. These socioeconomic effects of AIDS, along with increasing mortality from AIDS among those in the most productive years of their lives, are expected to increase the gap between rich and poor and contribute to the feminization of poverty (Decosas 1996). Moreover, an infrequently mentioned consequence of AIDS in developing nations is its effect on children, who are being orphaned at alarming rates; WHO estimates that over eight million children in the world have been orphaned because of AIDS. In some areas of the world, AIDS may be changing the demography. It has been estimated that in areas hardest hit by the epidemic, life expectancy has declined by as much as seventeen years and mortality rates for children under age 5 have increased by 74 percent (Stover and Way 1998). Demographers project that by the year

2005, there will be 13 to 59 million fewer people and a 27 percent reduction in life expectancy in countries with the most severe epidemic compared with what have been the case if AIDS had not hit those regions (Stover and Way 1998). Mortality rates from AIDS are expected to continue to increase, and the gap in the death rates from AIDS in developing and developed countries is expected to grow wider. Finally, most people in third world countries cannot afford or do not have access to the new drugs that have prolonged lives of persons living with HIV or AIDS in the United States; thus, mortality rates there are not likely to drop. This may mean, as Way et al. (1999, p. 90) predict, that "the worst is yet to come."

The emergence of AIDS as a social issue not only has revitalized interest in the social context and consequences of STDs, it has caused medical research to understand more fully how disease can never be studied effectively apart from social conditions or without adequate information about relevant social actors. Still in its infancy is a fuller consideration of institutional and public responses to STDs, for example, how public policy gets made and by whom (Volinn 1989) or why some communities respond with compassion, others with fear, and others not at all. The social construction of disease, and that of STDs in particular, is an important and understudied area of social science research.

SLAVERY AND INVOLUNTARY SERVITUDE

Many observers view slavery and freedom as polar opposites, but both slave and free wage labor systems rely on compulsion. Slave systems depend ultimately on physical coercion to force slaves to work for masters, although cultural, ideological, and economic pressures typically augment physical force. Wage labor systems, by contrast, depend on workers being free "in the double sense" (Marx [1867] 1967, pp. 168-169): Not only must workers be free to seek employment and choose among potential employers, they also must be free of all other means of subsistence that would allow voluntary withdrawal from the labor market. In the absence of subsistence alternatives, economic necessity compels "free" workers to exchange labor services for wages. Although wage labor systems depend primarily on labor-market processes to supply employers with workers, physical coercion often supplements those processes, especially during periods of economic decline. Cultural expectations and ideological appeals also reinforce market mechanisms. Nevertheless, large-scale labor systems are maintained primarily by a mixture of physical and economic coercion that varies with the availability of subsistence alternatives.

The way in which the constellation of physical and economic coercion and subsistence alternatives is determined by the power of contending groups as well as historically specific cultural and ideological factors has been of great interest to social scientists. Perhaps the simplest and most durable statement of the causes of slavery is a conjecture known as the Nieboer-Domar hypothesis (Nieboer 1900; Domar 1970; Engerman 1986a; see Patterson 1977b for a critique), which links slavery to an abundance of arable land combined with a shortage of labor. The way in which slavery differs from other forms of involuntary servitude is explained in the next section. The Nieboer-Domar hypothesis is then amended to provide a provisional explanation for the worldwide trend away from slavery and toward freedom in large-scale labor systems over the last several hundred years. Finally, the Nieboer-Domar hypothesis is reevaluated in light of current patterns of slavery and involuntary servitude around the world.

SLAVERY AND OTHER FORMS OF INVOLUNTARY SERVITUDE

Patterson (1982, p. 13) argues that slavery is defined by three conditions. First, slaves suffer perpetual domination that ultimately is enforced by violence. The permanent subjugation of slaves is predicated on the capacity of masters to coerce them physically. Second, slaves suffer natal alienation, or the severance of all family ties and the nullification of all claims of birth. They inherit no protection or privilege from their ancestors, and they cannot convey protection or privilege to their descendants. Third, slaves are denied honor, whereas masters are socially exalted. This condition appears to be derivative rather than definitive of slavery because all hierarchical social systems develop legitimating ideologies that elevate elites and denigrate those at lower levels. The first two conditions, which distinguish slavery from other forms of involuntary servitude, constitute the working definition used in this article.

In chattel slave systems, slaves are movable property owned by masters and exchanged through market processes. Because some societies con-

structed elaborate slave systems without well-developed notions of property and property rights, property relationships cannot be an essential defining element of slavery (Patterson 1982; 1977a). Nevertheless, property relations and economic processes had important effects on slavery and other forms of unfree labor in the Americas, Europe, and Africa in the period after the fifteenth century, which is the major focus of this analysis.

An unfree laborer cannot voluntarily terminate service to a master once the servile relationship has been established. Slavery maximizes the subordination of servant to master. Other servile workers, such as indentured and contract laborers, debt servants, peons, and pawns, are less dominated than slaves are and do not suffer natal alienation. Pawns, for example, were offered by their families in return for loans. Pawns maintained kinship ties to their original families, a situation which gave them some protection, and were freed once the loans were repaid. Indentured servants agreed to be bound to a master for a specific term, such as seven years, in exchange for a benefit such as passage to America or release from prison (Morris 1946; Smith 1947; Morgan 1975). Contract laborers also were bound for specified terms but could not be sold against their will to other masters, as was the case with indentured servants. Debt servitude consists of labor service obligations that are not reduced by the amount of work performed (Morris 1946; Sawyer 1986). Peons are tied to land as debt servants and owe labor services to a landlord. Serfs are not debt servants, but they are tied to land and perform labor services on their lords' estates. The right to labor services enjoyed by European feudal lords was vested in their political authority rather than in land ownership, although serfs were reduced to slaves in all but name in some instances (e.g., Russia in the nineteenth century) (Kolchin 1987).

Indentured servants and contract laborers may agree to the initial terms of their servitude, but they cannot willingly end it during its term once it begins. Usually some form of coercion, such as poverty, debt, or impending imprisonment, was necessary to force people to agree to terms of contractual servitude or pawnship. By contrast,

the status of the slave, serf, peon, and debt servant typically was inherited or imposed on workers against their will.

SLAVERY, THE LAND-LABOR RATIO, AND THE STATE

In its simplest form, the Nieboer-Domar hypothesis states that abundant free land makes it impossible for free workers and nonworking landowners to coexist. If free land is available and laborers can desert landowners whenever they choose, landowners will be unable to keep enough workers to maintain their status as nonworkers. If landlords can compel workers to perform labor services despite the availability of free land, landlords become labor lords and workers are not free. By contrast, scarce land combined with an abundant labor supply drives wages down, making wage laborers less expensive than slaves and other servile workers. When they are denied access to land, hunger forces workers to labor for wages and wage labor systems displace slave labor systems.

This model appears to be deficient in at least four ways. First, as Domar recognized, political factors determine the degree of freedom enjoyed by workers. Chief among those factors is the extent to which the state protects the interests of landowners when they conflict with those of laborers. Large-scale slave labor systems cannot exist without states that defend the power of slave masters to control and utilize the labor of slaves. A powerful state is essential for protecting slave masters against slave rebellions, capturing runaways, and enforcing slave discipline. State power is required for the enslavement of new supplies of slaves. If the state is responsive to the demands of workers or if workers can voluntarily withdraw their labor services, unfree labor systems cannot be maintained.

Second, the model presumes that slave masters exploit slaves in response to economic incentives, but slaves and other unfree laborers often provided military, administrative, domestic, and sexual services largely unrelated to economic activities (Roberts and Miers 1988; Patterson 1982).

The Nieboer–Domar hypothesis therefore does not apply to societies that employ slaves and other servile workers in noncommercial or minor economic roles (Lovejoy 1983; Finley 1968). It also does not apply to states that use race, religion, gender, or other status criteria to restrict the freedom of workers for noneconomic reasons (James 1988).

Third, the key issue from an employer’s perspective is not simply the ratio of land to labor but the relative costs and benefits of different forms of labor that can be profitably employed using existing capital (including land). A more general version of the Nieboer–Domar model compares the stock of available capital to the availability of different forms of labor at prevailing prices. Thus, labor scarcity means the scarcity of labor at prices that allow it to be employed profitably.

Fourth, the simple version of the Nieboer–Domar hypothesis ignores the organizational capacities of workers and capitalists’ ability to adopt labor-saving innovations. If workers demand concessions that threaten profits or engage in strikes and other production disruptions, capitalists experience “labor shortages” that stem not from insufficient numbers but from the organized resistance of the workers who are present (Miles 1987). Faced with such disruptions, capitalists with sufficient capital may adopt labor-saving innovations if they are available. When capitalists are unable to adopt those innovations, they may resort to coercive strategies to curb workers’ market-based demands (Paige 1975). This case contradicts the Nieboer–Domar hypothesis, which assumes that high ratios of labor to capital (or land) make coercive labor control strategies unnecessary.

UNFREE LABOR IN THE AMERICAS

From the fifteenth through the nineteenth centuries, Europe, Africa, and the Americas were closely linked by flows of people and commodities (Lovejoy 1983; Eltis 1987). The colonization of the Americas by strong European states provided vast, lightly populated lands for commercial exploitation. Expanding markets in Europe for sugar, cotton,

tobacco, coffee, and other commodities stimulated the demand for greater supplies of servile labor to work the plantations and mines of the Americas. Weak states in large areas of sub-Saharan Africa left large populations vulnerable to armed predation by stronger states that supplied the expanding markets for slaves.

Estimates of the numbers of bondsmen and slaves transported to the Americas are subject to sizable errors because of the paucity and unreliability of existing records, but relative magnitudes are thought to be reasonable (see Table 1). Differences in the sources of servile labor produced different racial compositions across American regions. Slaves from Africa outnumbered arrivals from Europe nearly four to one before 1820, and most were bound for sugarcane plantations in Brazil and the West Indies. British North America was atypical because its early immigrants were predominantly white indentured servants from Britain, Ireland, and Germany; perhaps two-thirds of the white immigrants who arrived before the American Revolution were bonded servants (Smith 1947, p. 336). Before being displaced by African slaves, white bondsmen were the principal source of labor in the plantation regions of all British colonies, including those in the Caribbean (Engerman 1986a; Galenson 1981).

Indentured servitude was the principal method of defraying the costs of supplying the colonies with workers. British laws and customs regulating master–servant relationships were modified significantly to fit American circumstances (Galenson 1981). Because of the high costs of transatlantic passage, longer periods of service were required, typically four to seven years rather than one year or less in England. English servants could not be sold against their will to another master, but that practice was sanctioned in colonial laws and customs because European servants could not negotiate terms with prospective masters before immigrating to America. Finally, opportunities for escape were much greater in America. Consequently, elaborate state enforcement mechanisms were implemented to discourage runaways and to catch, punish, and return those who did. Most indentured servants were transported to plantation re-

gions because plantation labor produced greater returns than did any other economic activity in the Americas (Galenson 1981). Employers in areas such as New England could afford few or no servants because they specialized in trades with lower labor productivity and lower profit margins.

White servile labor was replaced by black slavery throughout the Americas between 1600 and 1800. Racial prejudice encouraged the shift but probably was not decisive (Morgan 1975). First, the limited supply of indentured servants could not satisfy the demand for servile labor, whereas the supply of African slaves was almost completely elastic. Improving economic conditions in Britain and state restrictions on the emigration of British

servants reduced the numbers seeking passage to America, causing the price of servants to increase. As the price of servants exceeded the price of slaves, first for unskilled and later for skilled workers, slaves came to be preferred to bonded servants (Galenson 1981). Second, Africans were more resistant to the diseases of the tropics, where the most important export crops were grown (Eltis 1983).

Third, slaves could be compelled to comply with the labor-intensive plantation work regime that developed (Fogel 1989). Slaves were more efficient and profitable than free or indentured workers in sugar, cotton, coffee, rice, and tobacco agriculture because the work required by those crops could be performed efficiently by slave work

gangs. Work gangs were organized according to specialized tasks, and slaves were assigned to particular gangs according to their skills and capacities. The work was performed under close supervision to maintain work intensity and quality. Slave masters often used brutal violence to enforce discipline, but naked force might have been used less than once was thought. Slave masters experimented with different mixtures of positive and negative incentives, to encourage slaves to maximize their output (Fogel 1989). Thus, slave plantations anticipated the discipline of workers in the great factories of industrial capitalism, where assembly lines regulate the rhythms and intensity of work.

Forced migration from Africa greatly exceeded all migration from Europe as sugar production became the greatest consumer of servile labor in the Americas. High death rates and a preference for male slaves in the sugar-producing regions led to net population declines among blacks and mulattoes (compare immigration numbers to population sizes in Table 1), but the proportion of blacks in the British West Indies increased from 25 to 91 percent between 1650 and 1770 (Fogel 1989, p. 30). By the 1820s, the proportion of blacks and mulattoes in Brazil, the Guyanas, and the West Indies reached 75 percent (Table 1).

British North America was an exception to this pattern as both black and white populations had high rates of natural increase. Almost all major slave societies were unable to maintain the size of slave populations without continuous replenishment from outside sources. By contrast, the slave population in the United States multiplied because of unusually high fertility rates and low mortality rates (see Table 1 and Fogel 1989).

Political factors also encouraged the transition from white servitude to black slavery (Engerman 1986b; Galenson 1981). As British citizens, indentured servants retained state-protected natal rights that their masters were obliged to respect. For example, masters could beat servants and slaves to enforce work discipline, but colonial courts protected servants against unfair punishment (Smith 1947). Importantly, Europeans could choose the place of their servitude, and most refused trans-

portation to the plantation regions from the eighteenth century on. African slaves could not avoid the plantation regions and were citizens of no state in Africa or America that could or would defend their interests.

Because Spain conquered the continental regions with the largest Native American populations (Table 1), it had less need of African slaves. Instead, Spanish colonists installed a coercive labor system patterned on Spanish feudalism that forced natives to work part-time on colonial estates although slavery was still preferred in the mines (Slicher Van Bath 1986; Kloosterboer 1960). Unfree labor markets and compulsory labor endured for 400 years, eventually evolving into debt servitude in the nineteenth century. Native Americans and mestizos accounted for nearly 80 percent of the population of continental Spanish America by 1825 but were almost annihilated in the West Indies (Table 1).

Nowhere in the Americas was slavery in danger of withering away economically at the time when it was abolished (Eltis 1987). Furthermore, with the principal exception of Haiti in 1804, slave rebellions were not successful in conquering slave masters and transforming a slave system into a wage labor system. Paradoxically, Britain played the dominant role in abolishing slavery and the transatlantic slave trade even though it controlled half the transatlantic commerce in slaves and half of the world's exports in sugar and coffee, which were produced primarily on slave plantations (Eltis 1987). Britain outlawed the slave trade in 1808 and freed the slaves in its West Indian colonies in 1833 over the strenuous objections of slave owners. The United States prohibited the importation of slaves after 1808, and civil war led to abolition in 1865. By the 1870s, all the major European and American maritime and commercial powers had acquiesced to British pressure and outlawed the slave trade. Brazil, the last state in the Americas to abolish slavery, did so in 1888.

The land-labor ratio strongly affected planters' responses to abolition. In places where ex-slaves could find no alternative to plantation work, such as Barbados and Antigua, the transition to

free labor was rapid, and plantation production did not decline appreciably (Boogaart and Emmer 1986). In places where land or alternative employment was available, such as Jamaica and Trinidad, the ex-slaves abandoned the plantations, and plantation productivity declined (Engerman 1985). In response, planters implemented a variety of servile labor systems with mixed results. A second wave of indentured servants was imported chiefly from Asia, especially China and India, which more than compensated for the labor shortages induced by abolition in some cases, such as Mauritius and British Guiana (Engerman 1985, 1986b). China and colonial India eventually banned the recruitment of servants because of objections to employers' poor treatment of servants, and Brazil was never able to gain access to Asian indentured laborers (Boogaart and Emmer 1986).

In areas where planters retained a degree of political power, such as the West Indies and Brazil, vagrancy statutes and other compulsory labor schemes forced workers to accept wages below free market levels (Kloosterboer 1960; Huggins 1985). Indentured labor and other forms of involuntary servitude were banned in the United States in 1865 by the Thirteenth Amendment to the U.S. Constitution, but planters regained substantial influence over black workers through their control of racially discriminatory state and local governmental institutions (James 1988). Blacks were disfranchised by 1900, making them vulnerable to racial segregation, physical coercion, and economic discrimination. The extent to which racial discrimination interfered with free labor markets in the South is controversial (Wright 1986). Nevertheless, the most determined resistance to the civil rights movement of the 1960s occurred in the plantation regions (James 1988). The success of that movement led to increased protection of the citizenship rights of blacks and doomed widespread coercive labor control practices. The transition to capital-intensive agricultural practices was rapid during that period.

UNFREE LABOR IN AFRICA AND ASIA

Slavery was an indigenous institution in Africa and Arabia for centuries before Europeans entered

the African slave trade (Thornton 1998). While approximately 9.9 million Africans were transported to the Americas before the Atlantic slave trade was suppressed (Fogel 1989), an additional 5.2 million African slaves were transported across the Sahara, the Red Sea, and the Indian Ocean into the Islamic world between 1500 and 1900. Moreover, perhaps 6.4 million more were exported to Islamic societies between A.D. 650 and 1500 ("a rough approximation," Lovejoy 1983, p. 24). Many thousands more were enslaved in African societies in that period (Thornton 1998).

Whereas chattel slavery in the Americas was predicated on profit making, African slavery typically did not have a narrowly economic basis. African slaves were menial servants and field workers, but they also were concubines, surrogate kin, soldiers, commercial agents, and candidates for human sacrifice (Roberts and Miers 1988, p. 5). Female slaves were especially valued because women performed most agricultural and domestic work. African societies were based on kinship relations in which all individuals were linked in a complex network of dependency. Because power in kinship systems depends on the size of social groups, slave masters could increase their power by obtaining more slaves. Furthermore, slaves were immune to the appeals of their masters' rivals within kin groups because they had no kinship ties that mediated their subordination to their masters. Large numbers of persons were enslaved as a result of military victories in wars between African kingdoms and societies.

African slave masters also responded to economic incentives. An increasing number of slaves were provided to the Atlantic slave trade as the demand for slaves in the Americas increased. Thornton (1998, p. 125) concludes that African participation in the slave trade was voluntary because European slavers did not have the economic or political power to force African leaders to sell slaves. The established African practices of holding and trading slaves made it possible for African states to respond to the increasing European demand so long as the prices paid were attractive.

Islamic slavery also differed from chattel slavery in important ways. Islamic law prohibited the

enslavement of Muslims but permitted the enslavement of people born to slave parents or captured for the purpose of conversion to Islam (Gordon 1989). Concubines could not be sold if they bore a child to a master, and the child could not be enslaved. Allowing slaves to purchase their freedom brought honor to former masters. Manumitting slaves was also meritorious and could atone for certain sins and offenses.

Islamic slaves typically were employed as household servants, domestic workers, concubines, and to a lesser extent soldiers. Female slaves typically brought higher prices than did males because the heads of patriarchal Muslim families prized female slaves for assignment to sexual and domestic roles in their households. Slave eunuchs performed special tasks in large households and usually brought higher prices than did female slaves. Consequently, pre-twentieth-century slave traders castrated large numbers of African slave boys in crude operations that killed up to 90 percent of them (Gordon 1989, pp. 91–97). However, Islamic slave masters also responded to economic incentives as did their American counterparts when market opportunities arose. During the nineteenth century, over 750,000 slaves were transported to the clove plantations on Zanzibar and other locations on the east coast of Africa, for example (Cooper 1977; Lovejoy 1983, p. 151).

British diplomatic and military pressure finally led to the suppression of the Islamic and African slave trades as it did with the transatlantic traffic. In 1890, all the European powers agreed to suppress slave trading and slave raiding and to assist ex-slaves, a commitment that legitimated the conquest of Africa in the eyes of European citizens. However, European colonial administrators were reluctant abolitionists (Roberts and Miers 1988). Inadequate military and administrative power, fear of economic and political disruptions, and unfamiliarity with African customs delayed the process.

Colonial governments outlawed slavery almost everywhere in sub-Saharan Africa by the 1930s, but involuntary servitude persisted. Roberts and Miers (1989, pp. 42–47) identify three factors that

retarded the emergence of free labor markets in Africa. The first two were responses to abundant land and scarce labor. First, colonial states conscripted natives, imposed labor levies that local chiefs had to fill, and implemented other compulsory labor mechanisms to maintain a supply of cheap labor for European employers and administrators. Second, many Africans had access to land or livestock and were unwilling to work for wages. Colonial states tried to reduce the attractiveness of nonwage occupations by, for example, raising taxes above what peasant agriculturalists and pastoralists could pay and prohibiting Africans from growing lucrative cash crops. In settler colonies such as South Africa, native Africans were pushed off the land and confined to strictly regulated labor markets by pass laws. Third, Africans resorted widely to pawnship after abolition.

The reluctance of colonial administrators and the power of postcolonial states allowed slavery to survive in some nations in north Africa and the Arabian peninsula well into the twentieth century. In 1926, the League of Nations codified its opposition to slavery by adopting the Convention to Suppress the Slave Trade and Slavery, which defined slavery as the ownership of another person. Gradually, the remaining slave states abolished slavery officially: Ethiopia in 1942, Saudi Arabia in 1962, Muscat and Oman in 1970, and Mauritania for the third time in 1980. Nevertheless, reports of slavery persisted. Saudi Arabia allegedly failed to free some 250,000 slaves in the late 1960s; an estimated 100,000 chattel slaves existed in Saharan regions of Mauritania in 1980, although many were freed by 1984; and nomadic tribesmen allegedly held 250,000 slaves in the Sahelian districts of Mali in 1984 (Gordon 1989, pp. 232–234; United Nations 1984, pp. 18–19; United Nations 1988, p. 197; Sawyer 1986, p. 14).

In 1956, the United Nations increased the international attack on slavery and involuntary servitude by adopting the Supplementary Convention on the Abolition of Slavery, the Slave Trade, and Institutions and Practices Similar to Slavery. In addition to outlawing slavery, the Supplementary Convention pledged signatory nations to suppress debt bondage, serfdom, the pawning of chil-

dren, and servile marriage (forcing women to marry in exchange for payments to their family members or assigning wives, after the death of their husbands, to others as an inheritance). Progress has been slow. For example, India outlawed bondage in 1976, but a survey found more than 2.5 million bonded workers in 1978; only 163,000 had been freed by 1985 (Sawyer 1986, pp. 124–134). Debt servitude has been reported since 1970 among landless peasants in India and Nepal and among Native American rubber collectors in the Peruvian Amazon. As late as 1986, the Dominican Republic used its army to round up Haitian immigrants for forced work on sugar plantations during the harvest season (Plant 1987).

PATTERNS OF SLAVERY AND UNFREE LABOR SINCE 1990

Large-scale systems of slavery and involuntary servitude can be maintained only if slave owners and labor lords can use physical coercion to maintain labor discipline. Hence, large-scale systems of unfree labor depend on state institutions that deny citizenship rights to unfree workers and augment the power of dominant classes to coerce their workers physically. Today no nation officially protects the rights of employers to reduce their workers to slavery or involuntary servitude. Virtually all members of the United Nations have ratified the Supplementary Convention on the Abolition of Slavery, the Slave Trade, and Institutions and Practices Similar to Slavery (see United Nations [1957] 1999 for the current list of ratifying nations). Ratification of the Supplementary Convention officially commits a nation to the elimination of slavery and involuntary servitude within its borders and obligates it to cooperate with other nations in suppressing those practices. Although it took 200 years, the international antislavery campaigns led by politically powerful nations with wage labor markets were successful. Large-scale systems of slavery and involuntary servitude supported and protected by complementary state institutions no longer exist.

The expansion of capitalism and increasing world population displaced large numbers of peo-

ple from subsistence agriculture and other means of support in many regions. Great disparities between rich and poor nations drive people across state boundaries in search of jobs and improved living conditions. State power plays a crucial role in shaping migration and molding the relationship between capital and labor, but states with expanding economies now prevent the entrance of many willing workers rather than compelling the entrance of the unwilling. The whip of unemployment and poverty replaces the slave master's lash as free labor replaces slave labor.

However, slavery and forced labor persist and are widespread in some areas. Anti-Slavery International, the world's oldest human rights organization, estimates that over 200 million people, about 3 percent of the world's population, labor in some form of bondage. Table 2 provides examples of some existing systems of unfree labor. Because reliable information is difficult or impossible to obtain in some cases, the examples in Table 2 should not be considered exhaustive or the most egregious. The best available information suggests that slavery and involuntary servitude occur with the greatest frequency in nations that are ravaged by civil war or have weak states that are unwilling or unable to suppress coercive labor practices.

Somalia, Sudan, and Uganda provide examples of how civil war places defenseless people at the mercy of powerful military groups. A United Nations special rapporteur confirmed that armed militia groups abducted people in southern Sudan for use as forced laborers or for sale as slaves. Prisoners were subjected to beatings, electric shock, exposure to the sun for long periods, pouring of cold water on the naked body, rape and the threat of rape, sleep deprivation, and the refusal of food and medical treatment. Sudanese government security forces and allied militias as well as insurgent groups were guilty of conscripting children and forcing them to fight as soldiers (United Nations 1997). The civil war in Sudan has disrupted agricultural production to the extent that some impoverished parents give or sell their children to others to prevent their starvation (Finnigan 1999).

A large and active chattel slavery market is in operation in Sudan. Its magnitude is not known,

Examples of Slavery and Involuntary Servitude in 1998

COUNTRY	Servitude Type	Sector of Employment	Legal Status of the Servitude	Estimates of the Scope of Involuntary Servitude
Bangladesh	Bonded labor; forced labor; forced child labor; forced prostitution	Garment industry; forced prostitution	Prohibited by constitution	10,000 to 29,000 child prostitutes; bonded labor is not widespread; trafficking in women and children is widespread
Benin	Bonded labor; forced child labor	Agriculture; domestic service	Prohibited by labor codes	Some poor parents indenture their children
Brazil	Forced labor; bonded labor; forced child labor	Agriculture; sugar industry; mining industries	Prohibited by constitution	The government conducted more than 400 raids between 1995 and 1997 that freed more than 130,000 forced laborers; forced workers numbered 1.3 million in 1992 (Sutton 1994)
Burma	Forced labor; forced child labor;	Irrigation, transportation, and tourism services, and military service	No law prohibits forced or bonded labor by children	Government use of forced labor is widespread; bonded labor is not practiced
Cambodia	Forced and bonded labor; child prostitution	Military; wood-processing, rubber, and brick industries; prostitution	Labor law prohibits forced or bonded labor, including children	Prostitution and trafficking in children is widespread; bonded labor occurs but is not widespread
Cameroon	Slavery; forced and bonded child labor; contracting prison labor to private employers	Agriculture	Labor code does not protect children	The slavery still practiced in northern Cameroon is primarily enslavement of Kirdi by Fulani, a Muslim group that conquered the Kirdi 200 years ago
China	Contracting prison labor to private employers; forced prostitution	Manufacturing; agriculture; mines	Government prohibits export of goods made by prisoners and prohibits forced labor by children	Kidnapping and sale of women and children for prostitution is a problem recognized by the government; prohibitions against private use of prison labor have not been enforced effectively
Ethiopia	Sexual bondage	Children, especially girls, used as prostitutes	Prohibited by constitution and criminal code	Large-scale use of children as prostitutes; children are kidnapped and sold for about \$36; some poor parents sell their children

but international human rights groups estimate that chattel slaves number in the tens of thousands and that the market may extend as far as Saudi Arabia and the Gulf states (Finnigan 1999, p. 71). Anti-Slavery International (1999a) reports that more than 2,700 slaves were freed during the first four months of 1999 in return for over \$100,000 in payments. Finnigan (1999) photographed a Sudanese Arab slaver who hoped to sell over 130 indi-

viduals to a Christian antislavery organization for \$50 each. If that plan failed, he decided that he might return the former slaves to their families for a much lower price. Many others were not so fortunate. Slaves in Sudan are subject to severe punishment; are stripped of their cultural, religious, and personal identities; and can become the property of another person for life, traded and inherited, branded and bred.

COUNTRY	Servitude Type	Sector of Employment	Legal Status of the Servitude	Estimates of the Scope of Involuntary Servitude
India	Bonded labor; forced labor; indentured and bonded child labor; forced prostitution; contracting prison labor to private employers and brothels	Carpet industry; prostitution; domestic servants; gemstone, glass, footwear, textiles, silk, and fireworks industries	Prohibited by constitution and criminal code	5 million bonded laborers; 300,000 forced child laborers in the carpet industry alone; frequent reports of sale of children and women for forced domestic service and prostitution; some poor parents sell their children
Indonesia	Bonded labor; bonded child labor; forced prostitution	Fishing industry; prostitution	Law prohibits forced labor	Several thousand bonded child laborers; hundreds of bonded adults; widespread forced prostitution; 1,500 child prostitutes in one province
Mauritania	Slavery and vestiges of slavery; unpaid labor; forced child labor	Agriculture; shepherds and herdsmen	Slavery officially abolished several times, most recently in 1980	Slavery in the form of forced and involuntary servitude reportedly persists in some isolated areas; psychological, tribal, and religious bonds continue to tie former slaves to their prior masters; forced child labor is now rare
Morocco	Adoptive servitude of children	Domestic servants	Forced and compulsory labor prohibited by statute in 1957	The adoption of young girls for domestic service is socially accepted, and the government does little to discourage the practice
Nepal	Bonded labor; child labor; trafficking in women and children for sex work	Agriculture; forced prostitution; carpet industry	Prohibited by constitution	100,000 bonded labors in one region; 40,000 bonded child laborers; 5,000 to 7,000 girls forcibly transported to India as prostitutes annually; forced prostitution is widespread; forced child labor in carpet industry has been greatly reduced to international pressure
Nigeria	Child sexual slavery; forced labor	Domestic servants; prostitution	Prohibited by constitution but children are not protected	Child slavery rings operated between Nigeria and neighboring countries; also see Effah (1996); forced labor is now rare

Some slavery and slavery-like practices in India, Benin, Mauritania, Morocco, and Pakistan are supported by local customs and traditions that have long histories (Table 2). Mauritania and India have attempted to eliminate these practices, whereas other states are more reluctant or unable to act decisively. Debt bondage is widespread in the rural areas of India, but involuntary servitude has been adapted to the economic opportunities provided

by the operation of global markets. Just as European demand for sugar and coffee drove the Atlantic slave trade in the seventeenth and eighteenth centuries, employers of servile labor in poor countries find opportunities to supply consumer demands for cheap goods in economically advanced countries. For example, India, Pakistan, and Nepal employed as many as one million servile child workers in the hand-knotted carpet industry

SLAVERY AND INVOLUNTARY SERVITUDE

COUNTRY	Servitude Type	Sector of Employment	Legal Status of the Servitude	Estimates of the Scope of Involuntary Servitude
Pakistan	Bonded labor; bonded child labor; forced prostitution of children	Carpet, fish, glass and brick industries; agriculture; construction industry; prostitution	Forced labor is specifically prohibited by law	Bonded labor is widespread; landlords held 4,500 bonded laborers in one region; poor parents traditionally sell children to rich landlords as permanent bond servants in exchange for money or land; significant numbers of women and children are forced to work as prostitutes.
Somalia	Forced labor; child labor	Agriculture; military service	Civil war has eliminated any effective governmental system for the protection of human rights	Widespread vulnerability to forced labor in the service of warlords; in contrast to previous years, there were no reports of the use of forced labor by multinational fruit export firms
Sudan	Slavery including enslavement of prisoners of war, forced labor, and child labor	Agriculture; domestic service; concubines; trafficking in slaves; military service	Law prohibits forced or compulsory labor, but civil war has eliminated effective protection of human rights in many areas	Widespread use of slavery and forced labor by government troops and their allies; government forces and insurgents forcibly conscript children; international religious organizations paid \$50 each to purchase the freedom of slaves captured by raiding parties (Finnigan 1999)
Thailand	Trafficking of women and children for sex work; bonded child laborers	Prostitution, especially in response to tourists' demand; agriculture	Constitution prohibits forced labor but does not protect children	Forced prostitution is often protected by government officials who profit from it; child prostitutes number 20,000 to 40,000.
Togo	Forced labor; indentured servitude	Domestic servants	No law addresses forced or compulsory labor by adults or children	International trafficking in children, especially girls, for use as indentured servants or slaves; the government attempts to suppress the practice.
Uganda	Bonded labor; forced child labor; contracting prison labor to private employers	Agriculture; domestic service; concubines; soldiers	Prohibited by law	Government forces were too weak to defend rights of citizens; an insurgent militia group abducted 3000 Ugandan children and forced them to become soldiers or sexual slaves

in 1994 (United States Department of Labor 1995). The United States imported \$329 million worth of hand-knotted carpets in 1996, a large proportion of which were produced in those countries (United States Department of Labor 1997). Children in India have been kidnapped and transported from their villages to face years of forced labor in the

carpet industry. Forced child labor is characterized by long hours, threats of violence, dangerous conditions, little or no pay, and poor or nonexistent health care (United States Department of Labor 1994, 1998; Anti-Slavery International 1999b). Other commercial products produced by bonded and forced child workers for export are brassware,

silk cloth and silk garments, and stone and glass products (United States Department of Labor 1997).

Thailand, Nepal, Indonesia, and Cambodia are examples of weak states or states crippled by corruption that facilitate the persistence of forced labor and forced sexual prostitution. The flourishing Asian sex trade involves the transport of women and children across borders to work in brothels for foreign and domestic customers. Victims are lured by false promises of decent employment, kidnapped or sold by family members, or reduced to debt bondage by poverty. In Thailand, debt bondage sometimes continues from generation to generation as a result of very low wages, high interest charges, and fraudulent debts that cannot be repaid (U.S. Department of Labor 1994, 1996, 1998). Because of the spread of AIDS, brothel customers increasingly prefer very young girls who are supposedly disease-free. Consequently, brothel owners purchase or kidnap young girls from the surrounding countries to supply the demand. Girls from Burma, Cambodia, China, Laos, and Vietnam can be found in the brothels of Thailand (United States Department of Labor 1995).

The Asian sex trade is huge. UNICEF estimates that 100,000 child prostitutes are employed in Thailand alone, but the number could be more than 200,000 (U.S. Department of Labor 1995). Patterns vary from country to country, but the brothels typically are patronized by local customers and to a lesser extent by foreigners, including tourists, businessmen, and military personnel from the United States and Europe. Travel agencies arrange sex tours that include accommodations and a choice of escorts (United States Department of Labor 1995, 1996). As is the case with many handmade and manufactured products, the Asian sex trade and the exploitation of servile workers are intimately connected to the global economy.

In contrast to Britain's use of the navy to suppress the Atlantic slave trade in the nineteenth century, current international efforts to suppress slavery and involuntary servitude are weak. One enforcement tactic is to expose governments that do not suppress servile labor practices to the condemnation of world opinion. For example, the United Nations Commission on Human Rights investigates patterns of human rights violations within countries, including slavery and servitude, and disseminates its reports widely. The Interna-

tional Labor Organization, a special agency of the United Nations, formulates international labor standards and monitors the compliance efforts of governments (United Nations 1991). A wide variety of nongovernmental organizations are involved in the publicity campaigns against human bondage. Perhaps the most famous is Anti-Slavery International, which promotes the eradication of slavery and slavery-like practices by supporting the victims of those practices and through the collection and dissemination of information on specific cases. The negative publicity created by the public exposure of servile labor practices can diminish servile labor practices, but governments often do not cooperate because negative publicity alone is a feeble enforcement tool.

Economic pressure may be more effective than the investigative reporting and publicity efforts of the United Nations and other governmental and nongovernmental organizations. For example, the annual reports of the U.S. Department of State on Human Rights Practices are provided to the U.S. Congress to assist it in formulating foreign aid policies (Table 2 is based on the 1999 report). Countries are encouraged to suppress slavery and unfree labor practices to continue receiving aid from the United States and international organizations. Pressure from consumer organizations is effective in some cases. For example, a number of product-labeling programs were created to reassure buyers that products imported into affluent countries were not made by children. A nongovernmental organization in India initiated the RUGMARK program in 1994, which encourages carpet manufactures to stop using child labor by providing a labeling service that certifies that products are not made by children (United States Department of Labor 1997). By mid-1997, RUGMARK inspections had found over 1,000 illegal child workers in the carpet industry. Other labeling programs cover leather footwear, soccer balls, and the tea industry (United States Department of Labor 1997).

The historical decline in the land-labor ratio did not produce the abolition of slavery and involuntary servitude. The simple version of the Nieboer-Domar hypothesis is inadequate. From the middle of the nineteenth century until the present, political factors have played a decisive role in breaking the link between the availability of land and unfree labor. Rather than defending slavery when land

was plentiful, Britain used its political power to abolish slavery and suppress the slave trade even though it was not in its economic interest to do so.

By the late twentieth century, most nations had officially prohibited slavery and slavery-like practices, but both persist. As the modified Niebor-Domar hypothesis predicts, some employers will use physical coercion to drive down the cost of labor when opportunities arise. Weak or corrupt state institutions cannot or will not defend the rights of those who are most vulnerable to coercion. Civil wars destroy the ability of states to maintain order and subject citizens to the deprivations of warring militias. In some areas of the world, cultural support for servile labor and grinding poverty combine to make it difficult to eliminate some forms of slavery and forced labor. In all cases, the typical victims of these practices are the weakest and most vulnerable groups: women, children, migrant workers, low-status class or caste groups, and racial, ethnic, and religious minorities (Table 2).

All nations regulate the passage of individuals across their borders and assign superior rights and privileges to citizens compared to noncitizens. In advanced capitalist democracies with ostensibly free labor markets, the state-enforced distinction between citizen and noncitizen is a key mechanism in maintaining dual labor markets that disproportionately relegate noncitizens to the lowest-paying jobs (e.g., Thomas 1985; Miles 1987; Cohen 1987). Typically, noncitizen "guest workers" are less likely to enjoy state protection and more vulnerable to discrimination. Because the demand for cheap labor often can be satisfied by choosing among citizens and noncitizens who have no other labor market alternatives, democratic states can regulate noncitizens' access to domestic labor markets rather than forcibly import unfree workers from foreign lands.

However, many states are not liberal democracies. Thousands were confined for political reasons in forced labor camps during the Stalin era in the Soviet Union. Nazi Germany forced Jews and other minorities into slavery where they were to be "worked to death" (Sawyer 1986). Blacks were disfranchised and rigidly segregated in the southern United States for much of the twentieth century, making them vulnerable to coercive labor practices. The Republic of South Africa's now

abolished policy of apartheid denied citizenship status to indigenous blacks and exposed them to forced labor practices. Since 1988, the military government of Burma has engaged in systematic human rights abuses, including the imposition of forced labor on large segments of the population for military purposes and for the construction and development of infrastructure (Bureau of International Labor Affairs 1998).

The international condemnation of slavery and involuntary servitude represents a great victory for those who support and defend human rights. The use of forced and other forms of servile labor has not been eliminated, but it has been widely branded as criminal activity. As a consequence, those who would employ servile labor must risk prosecution or search for opportunities in countries with weak or corrupt political institutions that cannot or will not suppress slavery and involuntary servitude. Although the struggle to eradicate servile labor practices has not been won, nations and international human rights organizations appear to be more concerned about the loss of life and other human rights violations that accompany civil wars and international conflicts. For example, NATO recently intervened to stop the murder and forced displacement of thousands of ethnic Albanians in Kosovo. A similar intervention into the affairs of another nation to eliminate slavery or involuntary servitude is unlikely.

SMALL GROUPS

In sociology, the concept “group” implies more than simply an aggregate of individuals. Additional elements involved are (1) structure—interaction patterned in terms of statuses and roles, (2) history—some frequency and regularity of interaction over time, (3) interdependence—some degree of members’ mutual reliance on each other for needed or valued material and nonmaterial resources, and (4) common identity—grounded in shared meanings, values, experiences, and goals. Frequently there is a group product, not necessar-

ily of a material nature, which is the outcome or consequence of collective effort and interaction.

These elements are dimensional in that groups possess and manifest them to a greater or lesser degree. At one extreme, family groups typically have well-established and enduring structures, share extensive histories, encompass a wide range of activities, exert a broad scope of influence, and provide the basis of individual identity. At the other extreme, ad hoc work groups (and groups studied in laboratory experiments) may be assembled to perform specific tasks of very limited duration with little or no relevance for or influence on the members outside a clearly defined situation and range of activity. McGrath (1984) developed a comprehensive typology of groups in terms of origin, scope of activity, task, duration, and interaction.

Groups are regarded as small if meaningful and direct face-to-face interaction can take place among all members. The number of members usually is thought of as ranging from two to twenty, with three to seven common in many laboratory studies of groups.

PRIMARY AND SECONDARY GROUPS

Cooley (1909) identified a fundamental type of small group that is characterized by intimate association and cooperation, which he regarded as the basic building block of society. Cooley called groups of this sort “primary groups” and held them to be forms of association found everywhere. Primary groups work on the individual to form and develop the social nature of the person. “This nature consists of certain primary social sentiments and attitudes, such as consciousness of one’s self in relation to others, love of approbation, resentment of censure, emulation, and a sense of social right and wrong formed by the standards of a group” (1909, p. 32).

Membership and participation in primary groups are valued and rewarding for their own sake. The groups typically are long-lasting. Members interact as “whole persons” rather than merely in terms of specialized, partial roles. Primary groups are basic sources of socioemotional support and gratification, and participation in them is considered essential for a person’s psychological and emotional well-being. Some (the family, the neigh-

borhood peer group) are also primary in the sense that they are settings for early childhood socialization and personality development.

In contrast are groups formed and maintained to accomplish a task, to which people belong for extrinsic purposes (because they are paid or to achieve an external goal). These “secondary groups” are characterized by limited, instrumental relationships. They may be relatively short-term, and their range of activity is restricted. Affective ties and other “irrational” personal influences are intended to be minimized or eliminated.

It has been widely observed, however, that primary relationships develop pervasively within secondary groups and organizations. In a synthesis of observations and research findings, Homans (1950) attempted to identify universal variables of group behavior. He sought to develop a general theoretical scheme that would permit an understanding of groups as diverse as an industrial work unit, a street-corner gang, and a Polynesian family. Homans approached the small group as a system in which activity, interaction, and sentiment are interrelated. He concluded that interaction among group members increases their liking for one another and that they tend to express their friendship in an increasing range of activities and to interact more frequently. Affective elements emerge in virtually all ongoing groups and may enhance or interfere with the purposes for which a group was established. Soldiers are motivated to fight and workers are motivated to increase or restrict work output by loyalty to their friends and the norms of the immediate group.

BASES AND DEVELOPMENT OF SMALL GROUP RESEARCH

Sociological interest in small groups has several bases, including (1) the perception of small groups as fundamental, universal social units on which all larger organizational structures depend, (2) a concern with the description and understanding of particular small groups both for their own importance and as a source of observations from which hypotheses and general theories can be developed, and (3) the usefulness of the laboratory group as a research context in which to study the characteristics of the group as the unit of interest and as a setting for the investigation of social influence on individual cognition and behavior.

Foundations for small group research may be seen in nineteenth-century sociological thought, such as Emile Durkheim’s analyses of the development of social structures, specialization and task differentiation, and the bases of social cohesion and Georg Simmel’s work on the importance of group size and coalition formation. Early in the twentieth century Charles H. Cooley and George Herbert Mead stressed the social construction of the self through interaction within immediate group settings.

In the 1930s and 1940s, Jacob L. Moreno developed a systematic approach to the understanding and charting of group structure and Muzafer Sherif conducted key studies of group influence and conformity. William Foote Whyte’s field study of a street-corner gang demonstrated the existence and importance of group norms and structure in an urban milieu generally thought to lack social organization. Of major importance was Kurt Lewin’s work, which provided direction and inspiration for the postwar generation of social psychologists. Lewin combined principles of Gestalt psychology and concepts from the physical sciences to develop field theory in social psychology as a basis for the study of group dynamics. Interested in both theoretical and applied aspects of group interaction, in 1945 he established the first organization devoted to research on group dynamics. The widely utilized sensitivity-training group method originated serendipitously in sessions Lewin organized in 1946.

The period from the end of World War II to the early 1960s produced burgeoning activity in small group research (Hare et al. 1965). The pervasiveness of Lewin’s ideas was evident in the growth of group dynamics as an area of research and theoretical development. Cartwright and Zander’s important compilation, *Group Dynamics* (1968), first published in 1953, presented a theoretical overview and numerous influential studies of cohesiveness, group pressures and standards, individual motives and group goals, leadership and group performance, and the structural properties of groups.

Substantial work with a different orientation reflected concerns with functional needs that groups must meet in order to survive and with the relationship of those functions to dimensions of interpersonal behavior and personality traits. At

the same time, influences from anthropology, economics, and behavioral psychology were being melded in a view of social interaction as an exchange of resources, a perspective applied to the analysis of interdependence, cooperation and competition, and interpersonal relationship (Homans 1950, 1974; Thibaut and Kelley 1959). During those years small group research shared the methodological advances that were occurring throughout the social sciences, developing an increasing sophistication in research design, measurement, and analysis. The excitement, optimism, and productivity of the field led some to define social psychology as the study of small groups.

Small group research since the 1960s has not been as prominent, prolific, or influential as it was during the immediate postwar years, when social psychology was virtually dominated by the small groups "movement" (Borgatta 1981). The production of studies is steady, if moderate compared to the enthusiasm of the peak period, and some significant attempts have been made to organize and integrate the diverse body of work and theory that has accumulated (Hare 1982; McGrath 1984; Foschi and Lawler 1994). There is renewed interest in conceptualizing groups as entities with distinctive properties that cannot be understood in terms of reductionist individual psychology (Turner 1987). Many aspects and procedures of group process and dynamics are commonly utilized in applied settings, while practical concerns with group productivity, efficiency, and success are widespread (Hare et al. 1992; Forsyth 1999).

APPROACHES TO SMALL GROUP RESEARCH

Small group studies are characterized by a wide variety of research techniques and theoretical and practical concerns. Research methods vary in regard to the types of groups and circumstances studied—whether "natural" or contrived for research purposes—and in the intrusiveness of research procedures. Some investigators are concerned with properties of the group itself as the unit of interest, while others use the small group setting as context for exploring individual behavior. Although laboratory studies have predominated, the research techniques employed include direct observation of groups in natural as well as controlled settings; the use of structured observa-

tional systems to code communication or other aspects of behavior; the use of checklists, questionnaires, or interviews to elicit ratings, choices, opinions, or attitudes from group members; and field experimentation.

Laboratory studies have marked advantages in terms of the control and manipulation of variables in the precision of observation and measurement. The procedures employed normally permit replication of observation under controlled conditions. The experimental method is regarded as superior to others for rigorously testing causal hypotheses. Fundamental technical issues are whether relevant variables can be brought into laboratory situations and whether a meaningful range of variation can be achieved.

Criticisms of laboratory research center on the artificiality of the setting and the short-term nature of most studies. Representativeness of subject groups and thus the generalization of the findings also are questioned. Concerns for protecting the rights and well-being of human subjects have led to procedural safeguards that now inhibit or prevent practices that were typical of some well-known earlier studies.

The technical advantages of laboratory procedures, the desire to emulate the natural sciences in developing theory based on experimental evidence, and the compatibility of laboratory methods with the academic environment within which most researchers work all have contributed to the proliferation of laboratory studies that constitute much of small group research.

Direct observation of group behavior under basically uncontrolled ("natural") conditions may be coupled with the investigator's more or less active participation in the affairs of the group. Such research can employ structured systems for coding behavior and interaction patterns that are used by uninvolved "objective" observers, as when a children's play group is studied by adults. A more informal ethnographic approach was employed by Goffman (1964) in collecting the information that illustrated his characterization of human interaction as an elaborate sequence of symbolic presentations of self and groups as collaborating teams of performers.

Participant observation is a procedure in which the researcher acts as part of a (usually natural)

group to understand a situation from within, as members of the group define and experience it. Group members may know that the observer is an outsider who is there for his or her own purposes or may be led or allowed to believe that the observer is simply another “genuine” group member. In either case the observer’s status influences and constrains both the kinds and amount of information available and the opportunities for recording information. The observer also has some influence on the situations and processes being studied, thus producing outcomes different from those which would have occurred in his or her absence. The use of multiple observers increases opportunities for observation while also increasing the effect of the research on the group’s behavior (Festinger et al. 1964). For these reasons, reliability and validity are particularly problematic issues in using this technique.

Participant observation is regarded as useful primarily for descriptive and exploratory research and for generating or illustrating, as opposed to testing, theory. It is favored by those who want to understand the meanings of situations and actions generated and maintained by groups in their natural, everyday environments.

An important naturalistic study was conducted in the late 1930s by Whyte (1955), who studied a street-corner gang as a participant observer over a period of three and a half years. (The appendix to his monograph provides an informative discussion of practical and ethical issues in participant observation.) Whyte gained access to the gang through his association with its leader, and his view is from the top of the social structure. He described the recurrent patterns of relationships among members, group values and codes of behavior, the existence of implicit exchange relationships, territorial behavior, and the nature and functions of gang leadership. His observations of the ways in which members’ social rankings in the group affected their performance in athletic competition suggested a program of experimental studies of diffuse status characteristics: an exploration of the manner in which “logically” irrelevant social rank affects the amount of influence an individual has on others in activities ranging from pedestrian behavior to the making of perceptual judgments.

Sociometry, a seminal form of network analysis developed by Moreno (1953), is a technique for

eliciting and representing the patterns and structure of choices and liking among group members. While the most common procedure is for researchers to ask group members who they like, dislike, would prefer to work with, or would like to “be like,” ratings also can be based on direct observations of members’ behavior. The information can be represented as a sociogram showing individuals as circles and choices as arrows between the circles: The diagram depicts group structure in terms of affective relations. Indices of liking or disliking can be computed for each member, and ratings can be organized in a matrix format. The density and patterning of choices may be taken as indicators of group cohesiveness. In practical applications, sociometric data are used to restructure groups on the basis of members’ mutual choices.

Interaction Process Research. A prominent research concern has been the description and analysis of group interaction processes, focusing primarily on communication. The approaches employed have ranged from purely formal examination of the amount of communication sent and received by each member of the group to extremely detailed analyses of linguistic and paralinguistic material, including posture, gestures, and inflection.

The widely used system for Interaction Process Analysis (IPA) developed by Bales (1950, 1970) involves a set of twelve categories for coding units (acts) of communication. The categories reflect Bales’s conclusion that all groups confront two domains of concerns: instrumental concerns related to the task the group must accomplish and expressive concerns associated with the socioemotional needs and interrelationships of the group members. Both sets of concerns operate continuously and must be dealt with if a group is to succeed and survive, and there is a virtually constant conflict between them. The set of categories is used by observers to code types of active and passive task-related acts and positive and negative socioemotional acts, as they are generated by group members in the course of interaction.

Numerous studies using the IPA system have sought to document the patterns or “phase movements” of instrumental and expressive communication as groups try to establish the equilibrium necessary to operate. Interaction process scores

have been related to personality characteristics and to peer assessments and self-assessments (Borgatta 1962). Attention also has been paid to the roles of particular group members in exercising task leadership or socioemotional leadership.

The division of group leadership into instrumental and expressive functions proved compatible with accepted notions of "typical" male and female personal attributes and with a conceptualization of the family (at least in the Western world) as a small group with the father as task leader and the mother as socioemotional specialist. However, recent research comparing "natural" families with ad hoc laboratory groups indicates that the instrumental versus expressive specialization found in the laboratory seldom holds for groups in natural settings. There is greater diversity of behavior and less gender-linked stereotypical conduct in longer-lasting groups that cover a greater scope of activities (McGrath 1984).

The IPA system has been criticized on both theoretical and operational grounds, and numerous revisions and alternatives have been proposed. Bales and his colleagues developed an elaborated observational system, SYMLOG (Bales and Cohen 1979), that models personal space in three dimensions: dominant-submissive, friendly-unfriendly, and instrumentally controlled-emotionally expressive. Group interaction is observed and members' behaviors are coded on each dimension by outside observers or by the group members themselves. On the basis of combinations of multiple observations, each individual is located within the three-dimensional space and the positions of all group members are charted. The resulting diagram and indices based on the scores indicate the degree to which members are perceived as acting in a similar fashion. Interest in the SYMLOG technique is substantial, and it is utilized in many studies of group structure and performance.

GROUP COHESIVENESS

The understanding of what holds a social unit together, a central issue in sociology, also has been central in small group analysis. Cohesion—the sum of the forces that bind members to the group—was viewed by Lewin and other Gestaltists as a property or characteristic of the group itself, a sort of force field analogous to a magnetic or gravitational field. However, the assessment of cohesion

usually depends on observations of the attitudes and behaviors of the individual group members: their self-reported attraction to the group, their feeling of being accepted by the group, similarity in expressions of sentiment, how regularly they attend group meetings, how prompt or tardy they are, or how responsible they are in performing actions that benefit the group. Members also may be asked to describe the unity of the group (Evans and Jarvis 1986; Bollen and Hoyle 1990). Although Steiner (1972) suggested that "A true test of a group's cohesion would entail observation of its members' reaction to disruptive influences," he rejected this procedure on technical and ethical grounds (1972, p. 161).

The bases of cohesion include (1) rewards available within and through the group, (2) the congruence between individual goals and group goals, (3) the attraction and/or liking of members for each other, (4) the importance of the group as a source or ground of the individual's identity and self-perception and his or her internalization of group culture and values, and (5) in psychoanalytic group theory, the members' identification with and attraction to the group leader and "the alignment between particular individual superego formation and its corresponding punitive group structure" (Kellerman 1981, p. 11).

Although high cohesiveness often is taken as indicating a "healthy" group, its effect is to heighten members' susceptibility to influences in the group. Thus, group productivity, for example, may be increased or decreased depending on the nature of the predominant influences. A positive association between group cohesion and performance was found by Evans and Dion (1991) in a review of previous studies, but the relationship was modest.

Major importance in the study of cohesiveness has been placed on interpersonal attraction and interdependence, emphasizing the exchange of emotional and affective resources. Work by Tajfel (1981) and Turner (1987) supports, alternatively, an emphasis on social identity and self-categorization. A concept of cohesion based on interpersonal liking that is not mediated by shared group membership and depersonalized attraction to the group is held to be inadequate. Group membership and the resultant self-categorization occur prior to interaction and the emergence of interdependence, cooperation, influence, and cohesion.

Hogg (1987, 1992) advocates research that will produce answers about group solidarity and social identity rather than about interpersonal relationships.

Self-categorization in a most elemental form has been demonstrated in “minimal group” experiments (Tajfel 1981). Subjects are divided into two groups, sometimes presumably on the basis of an arbitrary and unimportant criterion and sometimes in an obviously random manner. The participants do not interact within or between groups during the experiment. Given the task of dividing a sum of money between two persons about whom they know nothing except their group membership, subjects show a marked bias in favor of members of their own group.

Interdependence in a most elemental form has been realized in experiments with the “minimal social situation” (Sidowski 1957). Two subjects, each of whom controls resources that may reward or punish the other and each of whom depends primarily on the other’s behavior as a source of reward or punishment, learn to exchange rewards despite being completely unaware of the nature of the situation.

Thibaut and Kelley (1959) identified two criteria individuals use in evaluating the rewards available within a particular situation: a usual, expected level of reward to which the person feels entitled, called the “comparison level,” and the person’s perceived best level of reward available outside the situation, called the “comparison level for alternatives.” An individual’s satisfaction with his or her group membership and participation depends on the relationship of rewards available within the group to his or her comparison level, while the likelihood that one will stay in or leave a group depends on the comparison level for alternatives.

Although the value and availability of rewards are usually emphasized in assessing the attractiveness of a group, Leon Festinger has pointed out the persistence of loyalty to “lost causes” and the effect that insufficient reward, or even aversive experiences, can have in strengthening members’ positive attitudes. In one experiment (Aronson and Mills 1959), potential group members who were subjected to a severe initiation expressed greater liking for the group than did those who had a mild initiation. And while an equitable and balanced exchange of rewarding outcomes is considered important in sustaining interpersonal rela-

tionships and participants’ satisfaction with them, Kelley and Thibaut (1978) noted that problematic situations provide particular opportunities. Attributions about a partner’s personality and motivations and self-presentations that encode messages of commitment and concern for the other person are facilitated when behavior cannot be explained simply in terms of “rational” self-interest. Such attributions and encodings strengthen affective ties and promote interdependence of the characteristics and attitudes displayed in the relationship.

GROUP INFLUENCE

Social Facilitation and Inhibition. In a study credited as the first social psychological experiment (1897), Triplett measured the average time his subjects took to wind 150 turns on a fishing reel, working both alone and in competition with one another. Subjects working in competition wound the reels faster than did those working alone. Numerous subsequent experiments (including some with nonhuman subjects) have supported and modified these results. It was found that the mere presence of other persons (as observers or coactors, whether or not they were competitors) facilitated well-learned responses but that the presence of others interfered with the acquisition of new responses. This “audience effect” thus facilitates performance but inhibits learning. Various explanations of social facilitation and inhibition have been proposed, generally incorporating the idea that the presence of others increases motivational arousal. Such arousal is a basic feature of the group environment (Zajonc 1966).

Conformity. Similarities of values, attitudes, beliefs, perceptions, and behavior are a ubiquitous and virtually defining feature of group existence. These similarities can facilitate coordination of goal-directed activity, motivate the members, provide sources of psychological security and emotional reward, reinforce members’ identification with the group, and increase cohesiveness. They also may prevent reasoned consideration of alternatives to group decisions and the potential consequences of group actions, reduce flexibility in adapting to new circumstances, and inhibit change in general. Closed circles of conformity in cohesive groups that are isolated from dissenting view-

points, producing “groupthink” (Janis 1982), have been implicated in producing military blunders, fascist atrocities, government scandals, and space shuttle disasters. Conformity (to modeled indifference or uncertainty) is a factor in the failure of bystanders to help others in emergencies.

The amount of conformity in a group may be seen as a characteristic of the collectivity. Experimental studies, however, usually have been concerned with effects on the individual. Considered from this viewpoint, conformity is defined as a change in an individual’s attitudes, beliefs, or behavior in the direction of a group norm. It is an example of social control resulting from peer influence (as distinct from, for example, obedience to a constituted authority) (Milgram 1974). Two types of conformity have been identified: belief (or informational) conformity and behavioral (or normative) conformity. Both types are increased by strong group cohesiveness.

Belief conformity involves an internalized and lasting change grounded in an individual’s dependence on social sources of information and guidance. Once they are internalized, the group’s standards and perceptions are constantly carried with the individual and constitute an ongoing element of social control.

Sherif (1935) asked individual subjects to judge the apparent movement of a pinpoint of light in an otherwise totally dark room. Under these conditions the light, which in fact was stationary, appeared to most people to move. Different individuals perceived different amounts of movement. Assembled in small groups viewing the light together, the subjects began to agree on the amount of movement they perceived: A group norm emerged in an ambiguous situation. After the group interaction, subjects were asked to view the light, again in isolation. They continued to see the amount of movement agreed on by the group rather than the amount they originally perceived individually. The group’s perceptions apparently had been internalized.

The strength of belief conformity varies with the ambiguity and unfamiliarity of the situation, the individual’s trust in the credibility of the group, the individual’s attraction to and identification with the group, and the individual’s prior experience and confidence.

Behavioral conformity is grounded in the potential rewards and punishments dispensed by the group and in the individual’s previous experience with the consequences of conformity and nonconformity. The consequences of agreeing with others’ judgments and opinions, emulating others’ behaviors, and following the customs of a group are usually pleasant, while disagreement and deviancy generally lead to unpleasant effects. Group members who hold deviant opinions typically receive, at first, greater than normal amounts of communication in an attempt to influence them to conform. If these efforts fail, they are likely to be isolated or rejected, depending on the severity of the deviance. Monitoring of behavior is necessary if reward or punishment is to depend on its occurrence; thus this type of influence is effective only if and when an individual’s actions are known to the group.

Experiments conducted by Asch (1951) demonstrated behavioral conformity. The subjects engaged in a perceptual estimation task that required them to pick out lines of the same length printed on boards that were presented side by side. The boards were presented in pairs, and the judgment of each pair constituted one experimental trial. In a typical experiment there was only one genuine subject; the other participants were employed by Asch, and their judgments were prearranged. After a number of trials in which correct judgments were given, the confederate “subjects” began stating unanimous wrong judgments. The genuine subjects conformed to a substantial extent by expressing judgments that agreed with those of the group. When removed from the group or allowed to state judgments in private, the real subjects did not persist in making these errors. Their conformity occurred only when it was witnessed by the other group members.

The strength of behavioral conformity varies with the size and unanimity of the group, the importance of the group to the individual, and the disclosure of relevant judgments or behaviors to the group.

Belief and behavioral conformity can be distinguished analytically (and empirically under some laboratory conditions), but in natural situations they operate in conjunction. The group member not only is rewarded for conforming but also depends on others as models for behavior and

guides for judgments and opinions. While it is common to think of beliefs and attitudes as existing before the behaviors that reflect them, a large body of research indicates that people come to believe the opinions they express. "Mere" behavioral conformity can lead to internalization.

Conformity effects usually are thought to reflect the majority influence in a group, but evidence shows that a determined minority can prevail. Minority influence seems especially relevant in regard to internalization (Moscovici 1980).

Group Polarization. Early theories of "group contagion" and the madness of crowds notwithstanding, a general assumption has been that conformity processes within a group operate to bring extreme opinions and judgments in toward the center of the range of opinions and judgments. However, a body of research has contradicted the notion that group actions are more moderate than those of individuals.

The experimental procedure called for individual subjects to evaluate each of twelve "choice dilemmas," situations in which a person was asked to choose between a highly desirable risky alternative and a less desirable but certain alternative. The subjects were instructed to indicate for each dilemma, the lowest probability of success they would accept in recommending that the desirable risky alternative be chosen. Probabilities were averaged for each subject over all dilemmas to generate a "riskiness" score for that person. Small groups of subjects were then formed and instructed to discuss each situation, reach a group decision, and indicate the group riskiness score for the dilemma. A group's scores were averaged over the twelve situations, and that value was compared to the mean of the individual scores of the group members.

Initial research that employed the choice dilemmas procedure found a significant "risky shift" in the group decisions compared to the mean of the individual scores. Numerous experiments and further analyses followed that extended and qualified those findings (Cartwright 1973). Certain kinds of choice dilemma scenarios produced risky shifts, while others produced conservative shifts or showed no significant difference. Shifts tended to move in the direction of the initial inclinations of the group: The interaction resulted in a collective outcome more extreme than might have been predicted on

the basis of the individual positions, but the individual positions forecast the nature of the shift.

Group polarization, as the effect is now called, has been theoretically interpreted in terms of risk as a cultural value, the persuasive influence of "risky" individuals, and the diffusion of responsibility in group action. However, the effect can be explained as being due to the normative and informational influences involved in conformity processes (McGrath 1984).

GROUP INTERACTION AND PERFORMANCE

Group performance in terms of problem solving, productivity, or effectiveness is a subject of both practical and theoretical concern that has generated numerous studies and a large body of theory. Productivity may refer to the quality of a group product, the efficiency of output per unit time or progress toward a group goal, or the realization of group potential. The establishment of an appropriate basis of evaluation is often problematic, and expected outcomes depend heavily on the type of task undertaken. When groups fall short of what (from some standpoint) it is felt they should accomplish, the failure often is attributed to "process losses" resulting from problems in interaction.

Steiner (1972) distinguished between tasks that require a coordinated division of effort, which he labeled "divisible," and those with a single outcome or product, which he called "unitary." Disjunctive unitary tasks are those which can be accomplished successfully by one individual alone. In such cases the group should be as "good" as the best member. Conjunctive unitary tasks require all the members to contribute successfully; in these tasks, the group can be only as good as the worst member. Tasks in which members' contributions are simply summed to produce the group outcome are called additive, and group performance should depend on the "average" member. Numerous laboratory studies of ad hoc groups performing a wide range of judgment tasks have been conducted. Overall, the results indicate that groups seldom do as well as the best member but usually do better than the average member.

Field studies of industrial workers in natural settings illustrate how influence processes in the group can regulate behavior. Work groups de-

velop norms with respect to what they, not the company, regard as an appropriate day's output. While pay, potential promotion, and retention or termination may be controlled by the employer, the immediate group controls powerful social rewards and sanctions that are brought to bear on a day-to-day basis. Those who exceed the group's production norm ("rate busters") and those who fail to produce an acceptable amount or attain an acceptable standard of quality are subjected to group pressure ranging from "kidding" and mild criticism to serious harassment. Since group cohesiveness increases conformity, some companies find it desirable to move workers frequently and attempt in other ways to inhibit the formation of interpersonal ties and identification with the group. Other organizations attempt to mobilize small group processes to support their goals.

Successful performance requires that a group have the necessary resources (material resources and members' skills, knowledge, and competencies) and time needed to accomplish its tasks. In addition, issues of coordination and motivation arise. When it confronts a disjunctive unitary task, the group simply must assure that the "best" member has the opportunity, recognition, and authorization to function and is motivated to do so. The only coordination needed may be to prevent interference from other members. For other types of tasks the quality, sequence, and articulation of many or all members' contributions are important (Miller and Hamblin 1963).

Allocation of opportunity to participate and evaluation of members' actions constitute elements of the status structures of groups. The explanation of how interaction inequalities in task groups are developed and maintained is the concern of expectation states theory (Foschi 1997; Foschi and Lawler 1994).

Group members hold expectations about the nature, quality, and value of each other's performances. Their expectations influence the quality of those performances and affect the evaluation of performances after they occur; they are in this sense self-fulfilling prophecies.

Though expectations may derive from firsthand task experience within the group, they also are based on "external" status characteristics of the members. Diffuse status characteristics such as age, race, gender, or perceived social rank may

influence expectations whether or not they are objectively relevant to the group's task and goals. Inequalities in participation, evaluation of performance outputs, and influence over the group's decisions reflect inequalities in status characteristics that members bring to the group. These inequalities tend to be maintained within the group regardless of their pertinence. Evaluations of performance output depend on previous evaluations, and expectations that arise out of group interaction influence subsequent interaction to produce their own confirmation (Berger et al. 1972, 1980). Thus the degree of influence exerted by group members and the impact of their contributions to the group's effort may not be highly correlated with their task-related competence and abilities.

Processes of influence and conformity may degrade performance quality. Majorities generate social pressure whether or not they are competent. Techniques have been devised to control these effects by regulating the kind of interaction that can take place. Some procedures, such as Multi-Attribute Utility Analysis, require the clear identification of task elements and their accomplishment in specified sequences. Group members can interact freely but must adhere to the task stages. Other approaches impose rules for communication in decision-making processes.

Many studies have been concerned with evaluating the effects of different patterns of interaction, primarily communication, on performance. "Brainstorming," a group interaction technique in which members generate as many ideas as possible within a given time period without evaluation or criticism, is intended to overcome inhibiting social influence processes while taking advantage of those which stimulate creativity. However, research indicates that a brainstorming group is generally less effective in producing ideas than are the same number of individuals working alone. The Delphi Method and the Nominal Group Technique are two approaches to regulating the combination of individual effort with group feedback or interaction to reduce the deleterious effects of social relations within the group, conformity, and personalized conflict. In the Delphi Method individuals, without communicating with each other, make judgments that are combined into a group "product." The results are made known to the participants, who then make another round of judgments. This procedure is repeated until a final

group judgment is attained. The Nominal Group Technique, which is used for developing plans or ideas or for choosing a correct or best solution, begins by having individuals work separately to generate plans, ideas, or judgments. The group then collectively lists and evaluates the material that was produced individually. These methods have advocates, but the desirability of some of their results is questionable and the time and cost involved in their utilization may be significant (McGrath 1984).

A substantial body of research has compared the relative effectiveness of structured networks of communication available to members of problem-solving groups. Typically, groups of three to five persons were required to combine information distributed across the individual members, communicating only through channels provided by the experimenters. Various networks of communication channels have been investigated to see how they affect a group's efficiency and the members' satisfaction. The networks differ in terms of how centralized or open they are. The most centralized network compels all messages to flow through one position, while the most open permits direct communication among all the members.

The conclusions from this research are that centralized networks are most efficient in dealing with simple tasks but that group members tend to be dissatisfied, except for the person occupying the central position. In more complex tasks the advantages of centralization are lost. Burgess (1969) suggested that the network experiments were basically flawed in failing to provide meaningful consequences for group performance and in studying groups only for brief periods, while they were learning to use the networks. His research demonstrated that when subjects had enough time to learn to use the channels provided, and received rewards based on performance, the type of network made no difference. Given time and motivation, groups adapted efficiently to overcome the structural constraints.

A type of process loss observed in both physical and cognitive tasks is the reduction in effort people put into group performance compared with the effort they make when working individually. This effect, called social loafing, has been observed in numerous cultures and is related to group size: As groups get larger, individual effort

tends to diminish. Social impact theory explains social loafing in terms of a conflict between a person's sense of responsibility and his or her feeling that inaction is the safest or least costly course of behavior. Diffusion of personal responsibility occurs in group situations and reduces the blame for inaction. Also, a lack of individual identification and the absence of evaluation by others become more likely as group size increases. Thus both rewards for effort and punishment for lack of effort become less certain and less consistent. While laziness and "goldbricking" often occur in individual situations, those behaviors can be concealed more easily in a crowd. Nonetheless, members who identify with and value a group and hold strongly to its norms will exert effort on behalf of the group (Hogg 1992). As was noted above, there is a positive association between group cohesion and productivity in groups with norms that support good performance. This relationship is reciprocal: Group success tends to increase cohesion.

The social loafing effect is confounded with problems of coordination, since both increase as the number of persons involved in a task gets larger. In addition, members' impatience and/or frustration with coordination problems can undermine their motivation and sense of responsibility, exacerbating social loafing.

Although researchers have paid much attention to process loss, there also are many significant process gains in group interaction. Social facilitation, stimulation, learning, socioemotional support, development and reinforcement of identity, and even conformity processes can enhance creativity, productivity, and effectiveness. While questions of individual versus group superiority may be provocative, most human endeavor occurs in group contexts and requires group effort.

The recognition that productivity can be affected substantially by the functions and quality of leadership in a group has stimulated much research and theorizing about leadership styles and effectiveness. An early experimental program conducted by Lewin et al. (1939) systematically varied the behavior of adult leaders of clubs of 11-year-old boys engaged in craft work and recreational activity. The leaders were trained to enact democratic, authoritarian (autocratic), and laissez-faire styles of leadership, and those styles were experienced by each club for several weeks. The resulting

changes in the boys' task performance, social relationships and interaction, and motivation as well as some aspects of group "climate" were intensively documented and analyzed. The results of the study, while complex, generally favored the democratic leadership style both for producing increased motivation and originality and for fostering more mutual friendliness and group-mindedness among the boys. Group members preferred the democratic leader to either the autocratic or the laissez-faire leader.

A contingency model of leadership effectiveness has been developed by Fiedler (1981), whose concepts of task-motivated versus relationship-motivated style recall Bales's identification of instrumental and socioemotional leadership functions. A leader's effectiveness results from the combination of style and situation: Task leaders are most effective in situations that are either highly favorable or unfavorable, while relationship leaders are most effective in middle-range situations. The contingency model, though supported by a large body of research, is questioned by some who feel that effective leaders are those who deal with both task and relationship elements of group situations.

COOPERATION AND COMPETITION IN GROUPS

Two different orientations are evident in research on competition and cooperation within groups. In one approach cooperation and competition are treated as imposed external conditions that influence the quality of group interaction and task performance. Alternatively, cooperation and competition have been studied as dependent behaviors that are affected by reward and risk contingencies, the availability of communication, and other situational factors.

Numerous studies have compared the productivity and efficiency of groups working under cooperative conditions (defined as working for group goals) and competitive conditions (defined as working for individual goals). The concept of cooperation in early research usually specified only mutual dependency of outcomes, with little attention paid to the interdependency of the members' task activities. The findings indicated that the efficiency of work under competition was greater than that under cooperation for tasks that did not require coordination of effort. Some research indicated

that cooperative groups worked together more frequently and were more highly coordinated.

Analysis of research focusing on the nature of tasks used as criteria in comparing cooperative and competitive reward structures points to the importance of "means interdependence," the degree to which group members are reliant on one another (Schmitt 1981, 1998). When tasks are simple, requiring no division of labor or sharing of information or resources, the advantage of cooperative contingencies seems to hold. However, cooperative contingencies are typically superior for tasks high in means interdependence involving distribution of effort, coordination of responses, or information sharing. Also, the long-term consequences of different reward structures may be substantial in natural groups, involving issues of morale and sustained member motivation that seldom arise in relatively brief laboratory studies. Such consequences can depend on the way in which competitive payoffs are determined; the possibility that some group members may become perpetual "losers" while others are constant winners will affect the efforts of all the members.

In a number of cases an additional element of competition between groups has been found to increase the productivity of internally cooperative groups. Turner (1987) observed that competition (for mutual distinctiveness) can develop between groups even in the absence of conflicts of interest. This striving to enhance positive social identity increases group cohesiveness and solidarity, making cooperation more likely.

Laboratory research treating cooperation as a dependent effect has focused on the participants' choice of cooperative rather than competitive behaviors and the distribution and coordination of responses. The effects of threat and communication were investigated in a well-known "trucking game" study (Deutsch and Krauss 1962). Two subjects could cooperate by taking turns using a "short route" to reach a destination and thus make money. Cooperation was reduced when one subject could block the route with a gate ("unilateral threat") and was extremely rare when both subjects had gates ("bilateral threat"). Communication between subjects did not increase cooperation under the threat conditions.

Communication sometimes has been found to increase cooperation in some of the many studies

using the "Prisoner's Dilemma." In this situation, two participants benefit moderately if both choose to cooperate and lose substantially if both "defect." If either one chooses to cooperate while the other defects, the cooperator suffers a very large loss and the defector's outcome is highly favorable. Thus, cooperation involves risk while defection implies motives of self-protection, exploitation, or both. The structure of outcomes is paradoxical: The rational choices of each individual lead to poor collective consequences.

The rates of cooperation observed in these studies are low. The Prisoner's Dilemma epitomizes the class of situations called social traps, in which individual (usually short-term) "rational" self-interest conflicts with the (usually longer-term) well-being of the group, leading to collective irrationality (Kollock 1998).

Inequity of outcomes and the presence of risk have been found to reduce cooperation across a wide range of experimental research (Marwell and Schmitt 1975). Beneficial effects of communication were dependent on the timing of its availability and the pattern of behavior that had occurred before communication took place.

Studies of cooperation and competition have addressed problems of motivation and coordination, issues of equity, the effects of short-term and long-term consequences, and the relationship of individual outcomes to collective outcomes. The analysis of these topics is a notable feature of recent small group research, particularly as concern with social traps and dilemmas resonates with the environmental and social issues facing contemporary society.

ROBERT W. SHOTOLA

SOCIAL AND POLITICAL ELITES

At one level, elites can be defined simply as persons who hold dominant positions in major institutions or are recognized leaders in art, education, business, and other fields of achievement. Such individuals exist in all societies, but beyond this mundane observation, social scientists are interested in why particular individuals attain positions of status and power. Does achievement reflect superior talent, or is it a product of social or

cultural advantage? Why are some achievements valued over others? How does the distribution of elite positions in society reflect the particular social structures in which they exist? These questions are the focus of much research on stratification and social inequality.

In the social sciences, the concept of elites refers to a more specific issue as well: the concentration of societal power—especially political power—in the hands of a few. At the heart of theoretical debates and empirical research on elites is the famous assertion of Mosca (1939, p. 50): “In all societies . . . two classes of people appear—a class that rules and a class that is ruled.” One can distinguish the conception of “functional elites” in a variety of institutional contexts from that of a “ruling” or “political” elite that in some sense wields societal-level power. Then the key questions concern the existence and nature of this dominant group. Is power over the major institutions of society highly concentrated, or is it broadly dispersed as “pluralists” claim? If a cohesive ruling elite exists, then who is in it and what is the basis of its power? What is the extent of its power in relation to the nonelite “masses”? Does this societal elite exercise power responsibly in the interests of society as a whole, or do elites maximize their own interests against those of subordinate groups?

CLASSICAL ELITE THEORY

Social thought on elites goes back at least to Plato and Aristotle, but contemporary debates usually begin with the “neo-Machiavellians” Pareto (1935), Mosca (1939), and Michels ([1915] 1959). Reacting to the turmoil of European society in the early twentieth century, each developed arguments supporting the inevitability of elite rule in opposition to classical democratic theory, Marxian class analysis, and socialist political movements. For Pareto, elites in general were those holding leadership positions in business, politics, education, and other areas of accomplishment. Those individuals could be distinguished from the rest of “nonelite” society. He further distinguished between the “governing elite”—the segment of the elite with broad political power—and the nongoverning elite. His best known statements concerned the former group. Though famous for his work in mathematical economics, Pareto believed that most human behavior was nonrational, the expression of

deep-seated “sentiments” and their observable manifestations, or “residues.” These motivational orientations led to behaviors that were then “explained” through our post hoc rationalizations, or “derivations” (1935, chap. IX). For Pareto, the governing elites were those with dominant talents or leadership skills derived primarily from superior individual attributes. Borrowing from Machiavelli, he distinguished two ideal types of political leaders on the basis of their dominant personal qualities and motivations (“residues”). “Lions” appealed to the conservative instincts that were most common in the masses, relying on tradition, strength, and coercion to rule. “Foxes” were more innovative leaders who relied on cunning, new ideas, and manipulation. Both types were necessary, but Pareto tended to see a cyclical pattern of rule in societies in which “foxes” dominated in periods of upheaval and transition, only to be displaced by “lions” after the restoration of social order (1935, chap. XII).

Pareto also noted that individuals in positions of power often attempt to maintain their privileged positions by closing off access for others. This risks social disruption by shutting off avenues of achievement and power to other talented individuals, who then mobilize to affect change. The “circulation of elites” refers to the process by which the ruling class is renewed periodically by superior individuals from other ranks. For Pareto, obstacles to elite circulation often resulted in the stagnation of the ruling class. Closed aristocracies and caste-like systems fostered tension, conflict, and eventually social change.

Like Pareto, Mosca began with the assertion that elite rule is an empirical fact in all societies. Although he also noted the superior individual attributes of the “ruling class,” his analysis was considerably more sociological than that of Pareto. Mosca emphasized the organizational advantages of the ruling elite in that they represented a relatively cohesive and easily organized minority against the disorganized masses (Mosca 1939, p. 53). He also discussed the role of the “subelite,” a technocratic stratum of managers, intellectuals, and bureaucrats that was increasingly important for elite rule in modern societies (1939, pp. 404–409; see also Marger 1987, p. 54). Mosca’s conception of social change and the circulation of elites was also more sociological. Social, economic, and technological

changes often generated new opportunities and called forth new talents, bringing new elites into prominence. Mosca agreed with Pareto that closed systems of rule threatened social stability, since a stagnant elite impeded adaptation to change.

In *Political Parties* ([1915] 1959), Michels traced the necessity of elite rule in modern societies to the imperatives of complex organization. His classic study analyzed the German Social Democratic Party, but his arguments have been applied to a variety of organizational contexts. Influenced by Weber's ([1921] 1968) work on politics and bureaucracy, Michels's most famous conclusion is summarized in his "Iron Law of Oligarchy," the argument that large-scale organizations necessarily concentrate power in the hands of a few at the top. Once in power, leaders in organizations such as labor unions and political parties act to preserve their positions. Those who rise from lower levels in the organization are co-opted in a process that preserves the structure of power. The resources available to institutional leaders and their relative unity of interest and perspective give them numerous advantages in maintaining their power over the unorganized rank and file. Over time, leaders develop similar interests and intralite attachments that reflect their elevated position and separate them from the masses. For their part, Michels saw the masses contributing to elite rule through their general apathy and acquiescence. With his focus on organizational factors, Michels has been very influential in the development of contemporary elite approaches to power (see Marger 1987, pp. 56–58; Burton and Higley 1987).

C. WRIGHT MILLS AND THE ELITE-PLURALIST DEBATE

Among elite theorists there is an important distinction between those who see the concentration of power as inevitable or desirable and those who do not. The former group includes the classical elite theorists and those who have extended their ideas (see Field and Higley 1980; Burton and Higley 1987). In contrast, "critical" or "radical" elite theorists recognize the concentration of power in society but argue that this condition is neither inevitable nor desirable. Unlike the classical theorists who emphasized mass apathy or incompetence, critical elite theorists argue that elite domination

is maintained through the manipulation and exploitation of nonelites.

The most influential representative of the critical elite perspective is Mills (1956). Mills, Hunter (1953), and other critical elite theorists developed their work in response to the dominance of "pluralist" studies of political power in the United States. Pluralism, as represented in the work of Dahl (1956), Truman (1951), Riesman (1950), and others, held that power in modern democratic societies was widely dispersed and that those in decision-making positions were subject to significant mass pressures (through electoral or other processes) or the countervailing power of other institutional elites or organized interest groups. For Mills, the notion of a pluralist balance of power between competing interest groups was a romantic ideal rather than a description of political reality in the United States. He acknowledged the activities of labor unions, farm groups, professional associations, and other organized interest groups but argued that those groups operated mainly at the secondary, local, and "middle levels" of power. The power to make decisions of national and international scope rested with a "power elite" of individuals in top positions of authority in major corporations, the executive branch of government, and the military. Congress was consigned to the middle levels of power, along with most of the interest groups studied by pluralist social scientists. Mills traced the historical consolidation of the power elite to the growth of the federal government in the 1930s and especially during World War II, as industrial production was coordinated with military needs through the government. That institutional alignment was strengthened in the Cold War years as the state expanded its commitment to national security, social welfare, and the direction of economic policy. By the 1950s there was a significant shift in power from Congress to the executive branch, reflecting an expansion of government that required a complex information-gathering and administrative capacity. Congress lacked the resources and coherence required for modern state administration.

Mills argued that most of the members of the power elite had similar values and interests, which reflected their similar backgrounds, common schools, shared membership in elite social clubs, and informal social interaction. He also empha-

sized the continuous professional interaction between these institutional leaders and the frequent exchange of top personnel between major corporations, the military, and the executive branch of government. Another factor contributing to the relative homogeneity of the power elite was their common experience at the apex of bureaucratic institutions. The skills, status, and even personality type required for success were similar in each sphere, reflecting their similarity of organizational structure (Mills 1956, p. 15).

The other side of Mills's conception of the power elite was that of mass society. The same social processes that had concentrated political power had created a society of increasingly fragmented individuals whose lives and interests were shaped for them from above. Information filtered selectively through bureaucratized institutions of mass education and the mass media, which became more susceptible to elite manipulation as they became more centralized. The media emphasized entertainment and consumption over information and critique. Educational institutions had developed into sites of large-scale vocational training rather than havens for the development of critical thought and an informed citizenry necessary for democratic politics (Mills 1956, chap. 13).

Mills's work became the touchstone for debates about the structure of power in the United States that have continued to this day. Pluralists argue that he exaggerated the unity of functional elites and neglected the influence of the electoral process and interest group competition. From the other direction, neo-Marxist and other class-theoretical analysts have been critical of the Millsian model for not acknowledging the extent to which political power is shaped by dominant economic interests (see the debates collected in Domhoff and Ballard 1968). A key question in these disputes concerns the degree of elite cohesion. How much consensus (or competition) between elites is required to support an elite (or pluralist) model? What is the extent of elite competition? Is there a hierarchy of elites, with a ruling class or "power elite" on top, or a "polyarchy" (Dahl 1971) of diverse institutional powers? Elite theorists acknowledge that individuals with different skills and constituencies hold leadership positions in a variety of institutions such as prestigious universities, private foundations, major civic organizations,

and the media (see Dye 1995). Pluralists view these institutions as relatively autonomous sources of societal influence. Although one may identify "strategic elites," or influential leaders, in a variety of fields (Keller 1963), they see no overall cohesion or uniform coordination of policy within a single ruling group. However, those defending an elite perspective argue that disagreements over particular interests occur within a general elite consensus on basic ideology and acceptable policy. Developing Mills's arguments, elite theorists have studied a variety of coordinating mechanisms that foster elite cohesion, such as private school ties, social networks, shared membership in policy planning organizations, and the general recruitment process in which future leaders are instilled with attitudes conducive to maintaining the existing structure of power (see Prewitt and Stone 1973; Marger 1987; Bottomore 1993; Dye 1995; Domhoff 1998). Some who work in this tradition go further than Mills in emphasizing the prominence of *class* interests and corporate power over the political process and other institutions in capitalist societies (Miliband 1969; Useem 1983; Domhoff 1990, 1998). Indeed, the distinction between "elite" and "class" analysis disappears in many such works (on the similarities and differences, see Marger 1987). From this perspective, prestigious Ivy League universities may harbor intellectuals critical of the existing power structure, that but only those academics with "acceptable" views are selected as advisers to political elites in turn must maintain acceptable levels of business confidence and campaign finance to remain in power.

In a similar vein, all parties agree that in a modern democratic system, the "elite," however defined, must pay some attention to the "masses." The question is, How much attention must be paid, and how do public preferences impose themselves on elites? Pluralists hold that the public has a significant influence on elite decision making through voting, public opinion, and the threat of social protest. From a different starting point, some class-based analysts note the role of working class mobilization or the effects of other nonelite social movements, such as the civil rights movement, that force changes in the polity and society (Piven and Cloward 1977). By contrast, those who emphasize elite power tend to leave little room for the influence of nonelites in promoting major social change. Change is viewed as the result of

elite mobilization, intraelite conflict, or the circulation of elites. Mills, for example, viewed the major societal decisions in the United States as the product of elite decision making, while more specific, localized issues were more likely to be negotiated at the “middle levels” of power. Domhoff (1998) considers major policy formation processes by looking at the “agenda-setting” power of elites, noting that while pluralistic interest group competition does occur on specific issues, the general parameters of public discourse and public policy are set in advance and behind the scenes through organizations such as policy planning groups and presidential task forces that bring elites together to build a consensus on major policy issues before specific proposals enter the formal legislative process. Other elite theorists point out that even in periods of mass mobilization over policy issues, the power of elites over the public agenda allows public sentiment to be deflected or diffused by temporary measures or by redirecting public attention to peripheral issues (Prewitt and Stone 1973, pp. 107–108).

MODERNIZATION, MERITOCRACY, AND ELITE RECRUITMENT

The dominant view of elites in the 1950s developed out of the structural functionalism of Parsons (1940; 1951) and the “end-of-ideology” arguments that appeared around that time (see Waxman 1968). This perspective, which is popular again today, holds that with the emergence of modern industrial societies and liberal democracy, elites increasingly represent a stratum of talented individuals filling important positions of leadership in dominant institutions (see especially Keller 1963; see also Mannheim 1940; Aron 1950). Variations on this theme point to a “New Class” of “knowledge” workers in “postindustrial” managerial and information-based professions and a proliferation of new institutional elites that transcend the old hierarchies of caste and class (Keller 1963; Bell 1974). From this perspective, modern elites are functionally necessary in a society of complex organizations and increasingly specialized occupations. Echoing Davis and Moore’s (1945) functionalist theory of stratification, status and material rewards are seen to reflect the high skill and social responsibility required for those positions. The legitimacy of functional elites is supported to the

extent that relatively equal opportunities to attain those positions are available to all talented and motivated individuals.

The validity of this “meritocracy” model of power is directly related to the issue of elite recruitment and the extent to which positions of power are open to nonelites. Once again, at one level there is general agreement among all parties on the relative openness of modern societies in comparison to traditional systems in which elite “recruitment” often was based on birth. In contemporary societies, differentiation fostered a proliferation of institutional elites requiring specific talents and skills in a variety of fields (see Keller 1963). However, beyond this empirical fact, the questions of contention are: (1) How much openness is there? and (2) Does it matter?

The first question has been the subject of much research in stratification and will be dealt with only briefly here. The meritocracy model assumes equal opportunity for individuals, but considerable research has challenged this assumption. For example, if elite positions are based on merit, educational institutions must provide avenues for mobility and equal opportunity for talented individuals from nonelite backgrounds, but a basic criticism of functionalist theories of stratification is that existing structures of inequality create barriers to nonelite achievement (see Tumin 1953). Beyond the obvious inequality of economic resources and formal educational institutions, the work of Bourdieu and others (Bourdieu 1984; Bourdieu and Passeron 1977; DiMaggio and Mohr 1985) has shown how the unequal distribution of “cultural capital” among groups in different locations in the class structure contributes to the reproduction of inequality in a variety of subtle ways. This research also points to the difficulty in assessing differences in “talent” among individuals or groups, since indicators such as “intelligence,” cultural appreciation, and political knowledge may reflect a preexisting distribution of cultural resources.

A more fundamental question regarding the openness of elite recruitment is: Does it matter? First, if the concern is the overall structure of power, as it was for Mills and most elite theorists, the success of a few upwardly mobile individuals from the lower strata does not affect the analysis: Power still may be concentrated in a few in key

positions. Second, elite recruitment from the lower ranks does not necessarily affect the *content* of elite decision making, given the selection process involved in the rise of “talented” individuals into elite positions. Most analysts agree that in modern societies, attainment of elite positions often requires a degree of talent, effort, and achievement, but elite theorists argue that those who make it to the top are selected for specific orientations that are compatible with existing structures of power. Those from privileged backgrounds, with access to economic, social, or cultural capital, have a definite advantage, but it is possible for nonelites people who possess the right attitudes and skills to rise into positions of power. This maintains the existing structure of power while providing legitimating examples of individual success. Limited avenues for mobility also provide a mechanism for the co-optation of promising leaders from below, as Pareto and Mosca would recognize (see the discussions of elite recruitment in Prewitt and Stone 1973; Marger 1987; Bottomore 1993; Dye 1995; Domhoff 1998).

ELITES AND DEMOCRACY

There have been a number of modifications of both “elite” and “pluralist” theory that have brought the two closer together. The work of Weber, Michels, and others influenced later theorists who viewed the concentration of power in modern institutions as necessary. From this vantage point, the issue was not whether broad “democratic” participation in political, economic, and other institutions was possible (it was not) but whether the interests of nonelites could be preserved in the face of modern bureaucratic organization. *Democratic elitism* represented a refinement of pluralist assumptions that redefined democracy in a manner congruent with elite rule. Given the inevitable concentration of power in modern societies, the central problem became: What legitimates elite rule or preserves elite “accountability”? The traditional answer of conservative elitists had been the “virtue,” “character,” or inward convictions of elite leaders in comparison to the selfish and undisciplined masses. In this tradition, with adherents from Plato to Pareto, elites have a stronger commitment to the “public interest” than do the “people” (Prewitt and Stone 1973, pp. 188–196). The meritocracy model represents a contempo-

rary variation of this viewpoint: Modern institutions require skilled leadership, and this means that institutional elites are increasingly likely to be selected on the basis of superior talent.

Another source of public accountability important for “democratic elitists” is elite competition for electoral support. Political elites must compete for votes in formal democracies, and this acts as a broad restraint on their actions. However, once in office, elite decision makers are relatively free to act as they see fit as long as their actions remain within acceptable limits. In a well-known formulation by Schumpeter (1942), elite rule is preserved both by superior talent and by the general mass apathy that he saw as functional for political rule. For Schumpeter (1942, pp. 269–296) and other conservative advocates of democratic elitism, the efficiency of modern representative governments depends on the “people” selecting their leaders and then leaving them alone. Note that the definition of “democracy” has been transformed from an emphasis on maximum public participation in political life to an assertion of the functional necessity of *non*participation. Far from government “by the people,” democracy is now defined as a procedure for the selection of political elites. This underscores the difficulty in weighing empirical claims concerning “democratic” representation made by competing theories, given the radically divergent definitions of the key concept. Classical theories of democracy emphasized the importance of political participation as an end in itself, one that was necessary for the *creation* of political citizens capable of democratic self-rule (Pateman 1970). Critics of conservative elitism such as Bottomore (1993, p. 95) wonder if “a person can live in a condition of complete and unalterable subordination for much of the time, and yet acquire the habits of responsible choice and self government which political democracy calls for.” This issue is muddier for the fact that many *critical* elite theorists are ambivalent about the possibilities for participatory democracy in modern society. If elite rule is undesirable, it would seem necessary to provide an alternative. Mills held up participatory democracy as an ideal from which to judge the contemporary United States in his concept of “publics” (1956, pp. 302–304), but he was not very clear about how that ideal could be implemented in modern “mass society.” Other critical elite theorists seem to have accepted

the classical argument for the inevitability of elite rule in modern, bureaucratically organized societies (see Prewitt and Stone 1973; Marger 1987; Burton and Higley 1987). For these critics, the only option to a “democracy” of mass apathy is one in which political institutions and decision-making elites are as open as possible to public scrutiny by a truly informed electorate.

LIMITATIONS OF THE ELITE PARADIGM

The elite paradigm—and by extension the “elitism-pluralism” debate as it usually is formulated—focuses on the leaders of large-scale organizations and organized institutions. Power is based on command over organizational resources; the elites are those in positions of organized power. While there are other ways to conceptualize elites, this is the dominant model in the social sciences today (see Marger 1987; Burton and Higley 1987; Dye 1995). Most scholars agree that power is concentrated in such organizations. The disagreements occur over whether there is a unified “ruling elite” above and beyond these multiple institutional elites that characterize all modern societies.

This controversy has led to much fruitful research and theoretical debate, but the “elitist-pluralist” framework is less adequate for dealing with other dimensions of societal power. For example, many of the social and cultural processes involved in the reproduction of class, gender, and racial inequality cannot be encompassed within an organizational paradigm. This includes socialization processes and everyday practices within the family, school, and workplace that reproduce the hegemony of a dominant culture. Further, it is possible to map the formal leadership structure of educational institutions, research foundations, and media organizations without explaining the *content* of their decisions. One might ask: Elite power, yes, but power for what? With its emphasis on the power of individuals within organizations, the elite paradigm neglects many structural and cultural forces that constrain those organizations and the elites within them. For example, how do global economic conditions and the imperative of “business confidence” constrain the decisions of political and economic elites? How are the ideologies and cultural practices that govern gender relations reproduced in the boardroom or the executive

mansion? These questions are significant, because without them it is difficult to explain why elites make the decisions they do or why some societal interests are better represented than others are in the decision-making process. It is necessary to consider elites and the organizations they command in their larger social and cultural context.

This issue was highlighted many years ago in debates over the “managerial revolution thesis.” This was an argument that modern corporations are different from traditional capitalist enterprises because of their separation of ownership from management. Managers were seen to have aims different from those of capitalists, reflecting their organizational position. They were more interested in long-term growth, stability, labor peace, and good community relations—good management—and less concerned with profit maximization (Berle and Means 1932; Burnham 1941). The simple but fundamental weakness in such an argument was that managers—the “elites” who wield organizational power in modern corporations—were still constrained by the imperatives of the market and capital accumulation. Time has shown that their ability to act “managerially” reflected a brief postwar period of U.S. dominance in the world economy. Global competition has since required that corporate elites act more like representatives of capital.

The same might be said about political elites as well, which brings one back to the issue of the relationship between political power and class interest. Recent debates in political sociology over the degree to which state institutions, governing officials, and policy intellectuals are “relatively autonomous” from the constraints of class interest or other societal pressures have again brought into focus the relationship between political power and economic interest (see Skocpol 1985; Jessop 1990). Class theorists have argued that the decisions of political elites are shaped not only by the superior resources of a dominant class but also by the structural constraints on the state in a market economy (see Block 1977; Lindbloom 1977). Others have traced a clear class bias and pro-capital selectivity inherent in the very institutions of modern states and the dominant political discourse (Jessop 1990). Parallel arguments have been made by feminists who hold that patriarchal domination is embedded in the very structure of the state (e.g.,

MacKinnon 1989). These lines of inquiry do not negate the importance of research on elites, but they lead one to ask questions about the larger social forces that shape their decisions.

SOCIAL BELONGING

THE DIMENSIONS OF HUMAN INVOLVEMENT

It is necessary to distinguish four different dimensions or states in the involvement of individuals in the context of human relations: territorial location, ecological participation, social belonging, and cultural conformity (Pollini 1990) (Figure 1). *Territorial location*, as Weber showed in his famous sociological analysis of the medieval European city (Weber 1921) does not involve any form of social relation among the individuals of a population in a particular territorial area. This dimension was subsequently defined by Parsons as one of the three primary relational criteria, with the other two being biological position and temporal location (Parsons 1959, pp. 89–96).

Unlike territorial location, *ecological participation* involves some sort of reciprocal relationality among the individual members of a human population, whether settled in the same territorial area or not. To use the terminology of human and social ecology in reference to nonsymbolic social relations, recalling Mead's well-known distinction (Mead 1934), ecological participation involves a specific form of interdependence among individuals ("symbiosis") (Park 1936, 1939) that is distinctly different from social interaction (Quinn 1939). For Parsons, the ecological system is "a state of mutually oriented interdependence of a plurality of actors who are not integrated by bonds of solidarity to form a collectivity but who are objects to one another" (1959, p. 93). Thus, instrumentally, the customers of a commercial firm, the participants in a market, and the antagonists in a struggle, and expressively, a network of purely personal friendships and the inhabitants of a neighborhood or district in a modern metropolis are paradigmatic examples of the dimension of participation in networks of ecological interaction or

in purely ecological systems. Parsons defined the state of ecological participation as a secondary relational criterion.

Social belonging refers to the state in which an individual, by assuming a role, is characterized by inclusion in the social collectivity, which is exclusively a *Gemeinschaft*, according to Weber (Weber 1922, 136), and which is a *Gemeinschaft* (an organization or association), according to Parsons (Parsons 1959, p. 100). In this frame of reference, the dimension of social belonging relates to any form of social collectivity, whether predominantly expressive (nonrational in Weber's terms) or predominantly instrumental. Strictly speaking, the status of belonging concerns only the *symbolic* dimension of human and social relations and interactions (Durkheim 1912; Pareto 1916; Weber 1921, 1922; Mead 1934; Park 1939; Parsons 1959; Merton 1963; Shils 1975). Parsons defines it as a secondary relational criterion.

Cultural conformity is symbolic in character. This dimension differs from social belonging in that it involves the sharing by individuals of value systems and therefore of attitudes of "consensus" as defined by Weber (Weber 1913) as well as, though not necessarily, conformism (Parsons 1959). The distinction between social belonging and cultural conformity demonstrates that belonging to a collectivity can be compatible with the exercise of internal opposition; thus, social membership does not exclude the possibility of disagreement, especially in regard to value orientations.

The distinction between social belonging and cultural conformity also has been drawn by Robert K. Merton, who expressly asserts the noncoincidence between membership groups and reference groups. The latter groups constitute a focus of reference toward which a certain degree of positive orientation is shown rather than being an already-established social bond that is manifest in the interactions among the individual members of a group (the membership group).

On the basis of the distinction between ecological participation and social belonging—both of which are secondary relational criteria, according to Parsons—it is possible to use the findings of human ecology and sociological analysis to differentiate between attachment to the community and belonging to the *Gemeinschaft*. Whereas attach-

ment to the community involves the ecological concept of community defined as “a) a population, territorially organized; b) more or less completely rooted in the soil it occupies; c) its individual units living in a relationship of mutual interdependence that is symbiotic rather than societal” (Park 1936, p. 148), the belonging to the *Gemeinschaft* concerns that sociological concept of *Gemeinschaft* as defined by Toennies (1887), Weber (*Vergemeinschaftung*) (1922), and Parsons (1959), although for Parsons as well as for some others, social belonging concerns not *Gemeinschaft* alone but any social collectivity and the social collectivity *qua talis*.

THE STRUCTURE OF SOCIAL BELONGING

The distinction between attachment to the ecological community and belonging to the social collectivity (particularly the *Gemeinschaft*) introduces the fundamental question of the structure of social belonging and the relations among its main components, which from an analytic and multidimensional perspective include attachment. Using Parsons’s scheme of reference, together with the contributions of other sociologists, the structure of social belonging can be described by

starting from the relations among the four chief components that define it as such: *attachment*, *loyalty*, *solidarity*, and the *sense of affinity* or *we-feeling* (Figure 2).

Attachment is a form of investment or “cathexis” (from the Freudian term *Besetzung*, denoting the relationship between emotional energy and an object) in a social object (the collectivity in this case), where “cathexis” refers to “the significance of ego’s relation to the object or objects in question for the gratification-deprivation balance of his personality” (Parsons 1959, p. 17). Attachment involves an “orientation to alter in which the paramount focus of cathective-evaluative significance is in alter’s attitudes” (Parsons 1959, p. 213), where “the relation to alter is the source, not merely of discrete, unorganized, ad hoc gratifications for ego, but of an organized *system* of gratifications which include expectations of the future continuance and development of alter’s gratificatory significance” (Parsons 1959, p. 77).

When attachment is organized into a symbolic pattern, particularly a pattern of expressive symbols whose meaning’s shared between ego and alter, become values—in other words, when they serve as a criterion or standard for selection (or an

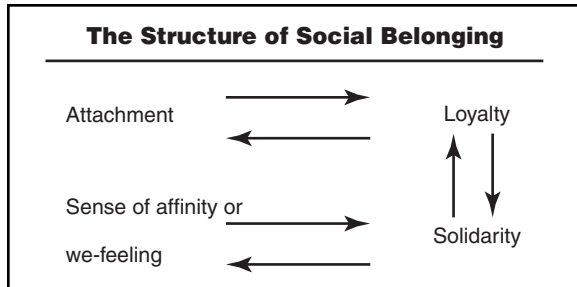

Figure 2

appreciative criterion in this case, which concerns expressive symbolism) among the alternatives of orientation that are intrinsically available in the situation—*loyalty* arises (Parsons 1959, p. 77). In the case of social belonging, loyalty defines the relation between ego as a subject and the collectivity as social object of which the ego is a member. Besides being the social object of attachment, the social collectivity thus becomes the object of loyalty as well. This raises the question of the trust the collectivity requires and the individual grants.

Along with attachment and loyalty, social belonging involves the *solidarity* of the collectivity. Solidarity, which “involves going a step beyond ‘loyalty,’” is defined by Parsons as “the institutionalized integration of collectivity,” and it is distinguished from loyalty because it entails that “collectivity-orientation converts this ‘propensity’ into an institutionalized obligation of the role-expectation. Then whether the actor ‘feels like it’ or not, he is obligated to act in certain ways and risks the application of negative sanctions if he does not” (Parsons 1959, p. 98).

The final component that defines the structure of social belonging is what has been called the “sense of affinity” (Shils 1975) or the “we-feeling” (MacIver and page 1949, p. 5ff). (Weber treated belonging in terms of *Zusammengehörigkeit*, or “subjective feeling of the parties, whether affectual or traditional, that they belong together”) (Weber 1922, p. 136). Although this component can be considered the final outcome of attachment, loyalty and solidarity, it also can be viewed as the component that controls and legitimates the others and therefore performs the function of pattern maintenance in the system of social belonging. It may include, at least in part, two of the factors that

Merton states constitute a collectivity as a social group: people’s definition of themselves as “members” of the group and definition by others as “belonging to the group,” with the others, including fellow members and nonmembers (Merton 1963).

In short, social belonging is constituted by the relations of interdependence among the dimensions of attachment, loyalty, solidarity, and sense of affinity, according to paths that extend from attachment to a sense of affinity or we-feeling and back, passing through the intermediate components of loyalty and solidarity.

From the point of view of the collectivity as a social system, belonging is the dimension that can be called a “residue,” to use Pareto’s term. A residue is the relatively constant symbolic-social element that can be deduced from the symbolic-linguistic expressions (or nonlogicoexperimental theories) associated with the nonlogical actions of associated individuals and that performs a function of “persistence of aggregates” maintain the equilibrium of the system. This equilibrium is characterized by the interdependence relations among the residues of various classes, genera, and specie, and between these and the system’s other “internal’ elements,” such as derivations, interests and social heterogeneity, and which is the circulation among the parts (Pareto 1916; Pollini 1987).

In regards to attachment, Shils, adopting a concrete rather than an analytic perspective, has drawn up a typology of four kinds of attachment that can be compared with the notions presented here. Shils’s first type of attachment is the *primordial attachment* that arises among individuals by virtue of “particularist existential connections” (such as the biological bond of kinship) and stable sexual relations or the sharing of a territorial area. It can be compared with the community attachment of human ecology and, more generally, the cathexis in a broad sense involved in ecological participation.

Personal attachment and *civil attachment* operate at different levels of the process of social structuring. They are distinctive of the social belonging defined by the “emerging” components of loyalty, solidarity, and the we-feeling.

Sacred attachment is grounded in beliefs and therefore also in notions of truth, justice, good-

ness, and beauty. It mainly but not exclusively includes cultural conformity and a consensus on beliefs, although it gives rise to a social community that Shils views as a community of *believers* (Shils 1961).

SOCIAL BELONGING AND ITS RELATIONS WITH OTHER COMPONENTS OF HUMAN ACTION

This discussion of the structure of social belonging and its main components has identified a number of elements by which it is constituted and conditioned. By adding further elements of fundamental importance, we may outline a complete frame of reference which social belonging involves interrelations among the following subsystems or “complexes”: the ecological complex of *territorial location* and *ecological interaction*, the mental complex of the *identity* of the personality, the social complex of the *solidarity* of the collectivity, and the cultural complex of *expressive and evaluative symbolism* (Figure 3).

Starting from territorial location and ecological interaction, central importance is assumed by the relationship between the *identity* of the personality and the *solidarity* of the collectivity, both of which stand in relation to the complex of *expressive and evaluative symbolism*. It is the latter factor in particular that, through internalization and institutionalization, characterizes personal identity and collective solidarity (Durkheim 1912), of which the personal identity involves the process by which the symbolic complex is acknowledged and the collective solidarity later involves the process by which it is represented.

The process by which the social collectivity relates to the individual person can be called the process of *inclusion*, while the mental process by which a person comes to be inducted in a collectivity may be called the mechanism of *identification*, or the mechanism by which a person learns “to play a role complementary to those of other members in accord with the pattern of values governing the collectivity” (Parsons 1958, p. 91). In other words, identification is “motivational ‘acceptance’—at levels of ‘deep’ motivational ‘commitment’—of membership in collective systems” (Parsons 1970, p. 356).

From the point of view of the personality, the multiple social belongings or even belonging to

multiple collectivities or social circles so distinctive of the individual condition today are inevitable components of an identity (Parsons 1968, p. 21), to the point where the perception of personal individuality is determined by membership in a collectivity or social circle (first sociological *a priori*) (Simmel 1890, 1908). However, just as the individual as a member of society (a social person) is determined not wholly by the fact that she/he is a member of society but also by the fact that she or he is “not socialized” (second sociological *a priori*) (Simmel 1890, 1908), identity marks out “the individual autonomy relative to *any* role and collectivity membership” (Parsons 1968, p. 20).

Simmel defined the relations between individual identity and belonging to social circles on the basis of the following principles:

1. A positive correlation exists between the development of personal identity and the widening of the social circle of belonging.
2. There is a positive correlation between the increased extension of the social circle and the centrifugal tendency of the individual toward other circles.
3. The individual belongs to an intermediate social circle that fosters the individualization of identity even in very large communities.
4. The determinacy of personal identity increases in direct proportion to belonging to other social circles.
5. The determinacy of individual identity is positively correlated with the dispersion and diffusion of the multiple social circles of belonging rather than with their overlapping, concentration and coincidence.
6. The shared belonging of several individuals to the same social circle may not be incompatible with their single and distinct belonging to other competing and conflicting circles.
7. The modern form of belonging displays voluntary and autonomous, rather than coercive and heteronomous, belonging to a social circle or circles.
8. In the modern age, the totalizing and globalizing nature of belonging to a single and all-encompassing social circle tends

Figure 3

to give way to the functional feature of belonging to multiple social circles (Simmel 1890, 1908).

A person's role as member of the collectivity, which is acquired by means of the mechanism of identification by which social belongings come to constitute inevitable components of personal identity, entails acknowledgment and internalization by the individual personality of the symbolic complex. This is both the foundation of the social collectivity and its representation. According to Durkheim, for whom the social group is defined by the symbolic complex and especially by the totemic symbol (Durkheim 1912), and according to Parsons, for whom expressive symbolism involves not only individual members or units (in that it is shared by each of them) but the entire collectivity constituted as a social object by symbolic social interaction, membership in the social collectivity is not expressed and represented only by the symbolic complex and by distinct symbols and emblems. More important, it is reinforced, developed, and augmented by them, in particular by participation in specific symbolic actions and rituals such as ceremonies, celebrations, gatherings, and meetings and by the projection of shared

value sentiments into individual members, especially those who assume the role of chief or leader and thus symbolically embody shared value patterns (Parsons 1959, pp. 395–399). Thus, ritual participation does not only express and manifest belonging to the collectivity and group; it also strengthens and develops this belonging, in particular the component of it denominated we-feeling or sense of affinity.

MEMBERSHIP AND NONMEMBERSHIP GROUPS

On the basis of the theory of the reference group, Merton has examined the limiting condition of nonmembership, which he defines as a positive orientation toward groups that, although not belonged to, are nevertheless reference groups. It is thus possible to identify a diversified set of nonmembership features that depend on the one hand on the nonmember's attitudes toward membership and on the other hand on possession of the qualities necessary for membership established by the group. Merton uses these two distinct dimensions to draw up a typology of a nonmembership group that includes a variety of forms and condi-

tions of nonmembership that may or may not eventually give rise to membership. These forms range from the “antagonistic nonmember” (out-group) to the “candidate for membership” through the intermediate types “potential member,” “autonomous nonmember,” “marginal man,” and “detached nonmember.” Merton thus overcomes the membership-nonmembership dichotomy by proposing gradations of nonmembership and investigating the various types of membership that cannot be defined by lack of membership.

A brief discussion is required of the type of nonmembership Merton calls “marginal man,” following Stonequist (1937) and Park (1928). This is the individual who, although he or she aspires to join a particular group, does not fulfil the requirements established by the group to do so. In other words, the marginal man is a person who, by simultaneously participating in two cultures, tends to occupy not the center but the margins of both. As a consequence, he is not fully accepted by either culture. More precisely, the “marginal man” is the individual who seeks to abandon his membership group, leaving its institutionalized value patterns and norms behind, but is unable to belong to the new group to which he aspires even though he has already absorbed its values and norms to some extent. This process by which the “marginal man” absorbs the values and groups of the group to which he aspires but does not yet belong is called “anticipatory socialization” by Merton (1963).

The “marginal man” also may be likened to the “stranger” described by Simmel (1908, 1964) and Schutz (1944).

BELONGING: INCLUSION AND PARTICIPATION

Belonging to a collectivity or social group characterized by solidarity through the assumption of some sort of role within it by an individual is brought about by two concomitant processes: *inclusion* and *participation*. By means of the process of inclusion, the social collectivity constantly retains or acquires individuals within its relational ambit, thus responding to the problem of integration by eliminating possible exclusion. The intensity of the inclusion process by which individuals

become full-fledged members of the collectivity may vary greatly with the features of the collectivity, primarily according to the criteria that must be fulfilled to join it. These criteria are defined by the collectivity itself and can be characterized as universalism or particularism (Levy 1952).

At the micro level it is possible to identify a number of ways in which the inclusion process comes about: physical and mental coercion, monetary and symbolic remuneration, persuasion, and co-option. At the macro-sociological level, the ways in which individuals are included in collectivities have been variously defined, mainly in the context of membership in the national community (i.e., citizenship) (Turner 1993; van Steenberg 1994) and in relation to immigration (Alexander 1980; Bauböck 1994; Miles and Thränhardt 1995). With no claim to exhaustiveness, one can point out some of these forms of inclusion: adjustment (Eisenstadt 1954), incorporation (Smith 1974; Horowitz 1975; Portes and Boeroc 1989; Schmitter Heisler 1992), absorption (Eisenstadt 1954), and assimilation (Park 1913; Gordon 1964; Horowitz 1975; Geazer 1993).

While inclusion is the process that moves from the collectivity to the individual as object, participation is the process that moves from the individual as subject to the collectivity.

The etymology of the term “participation” has a twofold meaning by which it can denote either “taking part in” something or “being part of” something. It is therefore advisable to distinguish the concept of participation from that of belonging by defining “participation” only in the former sense, in other words, on the basis of the action of “taking part in,” and defining “belonging” as “being part of.” However, it is possible to identify a relationship between belonging and participation, since participation denotes the action of “taking part in” the collectivity, of which one “becomes part” by virtue of the process of inclusion activated by the collectivity.

Besides operating “transitively”—through the relationship a person establishes with the collectivity as a symbolic-social object of attachment and loyalty—participation operates “intransitively” through the relationship the person establishes with himself or herself while participating. By undertaking the action of “taking part in” the

collectivity, a person exerts effects on himself or herself, generally in the direction of change in the elements, aspects, and traits of the psychic structure of his or her personality. Participation thus not only helps reinforce belonging but changes and develops the various components of the individual unit.

From the transitive point of view or from that of the individual vis-à-vis the collectivity, Smelser's theory of collective behaviour (Smelser 1963) and Merton's modes of individual adaptation (Merton 1963) provide the basis for the identification of at least four dimensions of participation: *diffuse* participation, *technical decision-making* participation, *reformatory* participation, and *revolutionary* participation.

Diffuse participation is the dimension of participation, of adaptive character, that accepts the institutionalized means and ends established by the collectivity and attempts to ensure its continued functioning. Technical decision-making participation is the dimension of participation that, while accepting the ends of the collectivity of membership, attempts to change its institutionalized means, which are deemed unable to achieve the goals established. Innovative-reformatory participation accepts the collectivity's means or at any rate is unconcerned by them and attempts instead to change its ends and goals. Revolutionary participation endeavours to change the institutionalized means and ends of the collectivity with a view to creating a "collectivity of the future" that differs from the "collectivity of the present."

GABRIELE POLLINI

SOCIAL CAPITAL

Social capital is a form of capital that exists within relationships among individuals. According to Bourdieu (1986), capital is accumulated labor that can be appropriated by individuals or groups for their exclusive use to further their interests and increase their capital holdings. By drawing on the social capital resources in their relationships, individuals can further their own goals. For example, the larger the social network an individual has while looking for a job, the more resources—through company contacts, information, and higher-status references—that individual can draw on. Greater availability of resources increases the likelihood that the individual will find a job better than will an individual with fewer social network resources. It is also likely that a well-connected individual will find employment sooner. Simply put, social capital is “an elegant term to call attention to the possible individual and family benefits of sociability” (Portes and Landolt 1996, p. 94).

Some scholars have remarked on the “plethora of capitals” recently appearing in social and economic theories that refer to virtually all aspects of social life as a form of capital (Baron and Hannan 1994). The notion of physical capital, as embodied in machines, tools, and equipment, has been extended by economists to include human capital. Just as investments can be made to improve physical capital—newer and better tools—human capital can be increased by enlarging an individual's skills or knowledge base. Social capital, then, is created when relationships are used to enable actions by individuals to further their own interests. According to Coleman (1988), each actor has control over and interests in certain resources and events. Social capital constitutes a specific kind of resource that is available to an actor. Unlike other resources, social capital is based on reciprocity and thus comes with the expectation that obligations will be repaid as requested by other individuals in the network. Social capital

does not have a set rate of exchange, and payments often are made according to need rather than in standard purchase terms as is done with equipment and education.

The theoretical foundation of the concept of social capital is still in a nascent phase, and there is much debate about its definition, creation, and utility as well as its role in public policy and modernization strategies. Advanced most notably in the work of the French sociologist Bourdieu and further developed by Coleman, the notion of social capital has been put forth as a conceptual tool to bridge two divergent theories of social action: economism and semiologism (Bourdieu 1986). Economism reduces all social exchanges to economic transactions in which independent social actors pursue their own self-interest with little attention to social context. In this view, social action is based on the principle of maximizing utility. In contrast, semiologism reduces social exchanges to communicative acts by socialized actors and downplays the impact of economic factors. In this theoretical orientation, social action is governed by social norms, rules, and obligations. The notion of social capital mediates these divergent orientations by acknowledging both the self-interest of actors and the influence of the social and economic context.

As social capital refers to the aspects of the social structure that are of value to social actors as resources that can be mobilized in pursuit of their interests, it is defined by its function. Social capital is not located in the actors themselves (as with human capital) or in any physical implements of production (as with physical capital). Instead, it is located in the relationships and personal networks between and among social actors. Social capital, then, appears in a variety of forms that have two common elements: (1) Social capital appears as an aspect of social structures, and (2) actors are able to use social capital as a resource to achieve their goals within the social structure.

Coleman (1988, 1990) conceives of social capital as a social structural resource that is a capital asset for the individual. It is productive, making it possible to achieve certain goals that cannot be achieved in its absence, and it is constituted within social organizations often as a by-product of activities undertaken for other purposes. For Coleman,

the value of the concept lies primarily in accounting for different outcomes of individual efforts and illuminating how resources can be combined with other resources to create system-level differences. The concept of social capital is most useful in qualitative analyses of social systems and studies relying on qualitative indicators.

FORMS OF SOCIAL CAPITAL

Coleman (1990) identifies six forms of social capital: obligations and expectations, information potential, norms and effective sanctions, authority relations, appropriable social organizations, and intentional organizations.

Obligations and Expectations. A social system that relies heavily on reciprocal actions creates obligations and expectations on the part of its participants. Each “favor” is expected to be repaid, and those who can provide “favors” are expected to do so when requested. This form of exchange engenders social capital for a group member who has done many favors without collecting reciprocal favors in return. These unreciprocated favors create obligations that allow the favor-granting member to request aid from those who are obligated to her or him. These unpaid obligations accrue in the form of social capital that the member can use.

This form of social capital has two critical elements: the mutual trust within the social system and the extent of outstanding obligations. Without trust that obligations will be reciprocated, there is no incentive to accrue social capital. For social capital to have value, there must be trust that the resources will be there to be drawn on when needed. Furthermore, it is the extent of outstanding obligations that denotes the amount of social capital an individual can draw on. Indeed, the overall number of outstanding obligations within a system can be a measure of its interconnectedness as members are obligated to one another. This connectedness also increases the resources available to each member.

Information Potential. By interacting with informed members, individuals can increase their knowledge without having to obtain the information directly, whether by reading the newspaper or by interpreting research findings. A member also may become privy to specialized information—

such as unadvertised business opportunities—through informal information exchange. Useful information can be the impetus for action that furthers the individual's on goals and can be a beneficial commodity.

Norms and Effective Sanctions. Within a social system, norms can support and provide rewards for specific behaviors. Norms that encourage the subjugation of self-interest to the needs of the community are an especially powerful form of social capital. By promoting certain activities, norms by nature constrain other activities. Criminal pursuits are an obvious example of activities that communities want to constrain. Less obvious examples would be that the promotion of athletic activities constrains the time available for other interests and that norms that promote conformity constrain innovation. Effective “norms can constitute a powerful form of social capital” (Coleman 1990, p. 311).

Authority Relations. Within groups organized to address a specific issue, a leader often is chosen and given the right to make decisions and speak for the group. Thus, the members of the group transfer the “rights of control” to one individual, who then has access to an extensive network of social capital that can be directed toward a specific goal. When the rights of control are located in one individual, the social capital of all the members is amplified. Examples of this form of social capital can be found in political action groups, business cartels, and grassroots organizations.

Appropriable Social Organizations. Social organizations usually are created to address a specific issue, and after that issue is resolved, the organization often continues to exist through a redefinition of its goals. Thus, an organization that was developed for one purpose can be appropriated for another purpose. This constitutes a form of social capital available for use.

Intentional Organizations. This form of social capital occurs when individuals join together to create an organization that will benefit them directly. An example of this can be a joint business venture or a voluntary association that produces a public good, such as a Parents and Teachers Association (PTA) chapter. This form of social capital advances the interests of those who invest in it. Additionally, it can create two by-products as social capital: a public good that benefits others who

did not invest directly and a social organization that can be appropriated for other purposes.

These six forms of social capital have certain properties that distinguish them from other assets. Social capital's value lies in its use and cannot be exchanged easily. Additionally, it is not the private property of those who benefit from it. Rather, it is most often a by-product of other intentioned actions. Individuals who invest in the creation of the necessary social structures (norms, reciprocal obligations, etc.) are not the primary beneficiaries of the social capital that is generated. Instead, the social capital profits all those who are part of the social structure. Thus, it is not necessarily in an individual's self-interest to bring social capital into being. If another form of assistance that does not incur an obligation, such as a government program, is available or if individuals can meet their needs through self-sufficiency, they may choose to utilize these resources rather than those which accrue social capital through reciprocity. Using such forms of assistance or sufficiency does not increase the general pool of social capital in the community.

Coleman (1990) identifies factors that can increase or diminish social capital. A high degree of *closure* in a social network strengthens its ability to engender norms and effective sanctions. Closure is also important in achieving mutual trust among members. Conversely, lower closure reduces the effective norms and trust that would lessen the social capital engendered. The *stability* of a social structure affects the development or destruction of social capital. Individual mobility can threaten the stability of an organization, which in turn threatens its social capital. Organizations and social relations that are dependent on specific individuals are less stable than are those which rely on positions that can be filled by various individuals. Those organized around positions have more stability and thus a more steady supply of social capital on which the members may draw. *Ideology* can create social capital by influencing individuals to act in the interest of the whole rather than in their own interests. Religious ideologies are an example of this factor. Alternatively, ideologies of self-sufficiency or individualism can hinder the generation of social capital. Other factors Coleman mentions include affluence, availability of official aid such as governmental support, and other factors that may make individuals less de-

pendent on each other. Additionally, social capital must be maintained, as it depreciates over time and must be renewed.

REFINING SOCIAL CAPITAL THEORY

Portes and Sensenbrenner (1993) have extended Coleman's basic theory of social capital, claiming that it contains two specific shortcomings. First, they call for a more defined discussion of the forms of social capital and how they are developed. Second, they question Coleman's optimistic instrumentalist orientation which focuses on the positive side of social capital. Furthermore, Portes and Sensenbrenner reidentify the sociological origins of notions of social capital by grounding their contribution in the works of classical social theorists. They begin by redefining social capital as "those expectations for action within a collectivity that affect the economic goals and goal-seeking behavior of its members" (1993, p.1323). This definition differs from Coleman's emphasis on social structures that can facilitate individual actions.

Portes and Sensenbrenner (1993) outline four different types of social capital, with each one corresponding to a classical tradition. From Parsons and Durkheim, they define *value introjection* as the first source of social capital because it promotes behaviors based on morals and values rather than on self-interest. From Durkheim's work, they conceive of economic transactions as reflections of an underlying moral order and contracts as reframing existing norms or values rather than creating new rules. Their second source of social capital—*reciprocity transactions*—comes from the work of Simmel and focuses on the dynamics of group membership. Reciprocity transactions are the obligations and expectations, backed by norms of reciprocity, that emerge through social networks of exchange. The third form of social capital is *bounded solidarity*, developed from Marx and Engels's writings on situational circumstances that lead to principled group action. This type of social capital is created when individuals join together in response for an adverse situation. The fourth form of social capital is drawn from Weber's distinction between formal and substantive rationality in market transactions; *enforceable trust*. Enforceable trust refers to the different mechanisms that formal institutions and particularistic group settings use to engender members' disciplined compliance with group norms

and expectations. Formal institutions use legal, rational mechanisms, whereas particularistic groups utilize substantive, social means.

Acknowledging the Negative Effects. Portes and Sensenbrenner also point out the negative effects of social capital in direct contrast to Coleman's more positive position. The same social structures "that give rise to appropriable resources for individual use can also constrain action or even derail it from its original goals" (1993, p. 1338). The costs of solidarity can be obligations and interconnections within the community. The costs of community conformity can constrain individual freedom. Obligations to the community can inhibit attempts to succeed in a broader network with a richer array of rewards. Individuals may come to see these costs of developing and maintaining social capital as being too high and not in their best interest.

In spite of its inchoate state and the ongoing debates, Coleman's optimistic discussion of social capital has become popular with policymakers who see it as the key to solving a variety of social problems. These policy proponents identify social capital as the features of social organizations (networks, norms, and social trust) that enable cooperative efforts for mutual benefit. Social capital is favored for its ability to promote and maintain voluntary associations that allow individuals to work together to resolve collective difficulties. In direct response, Portes and Landolt (1996) warn of the "downside" of social capital by making three specific criticisms of this use of social capital. First, social capital is discussed as the property of groups (communities), not individuals. Second, no distinction is made between the ability to access resources and the quality of those resources: Having networks is not enough; the networks need to have sufficient resources of value to make a difference. Third, policy proponents focus exclusively on the positive benefits of high levels of social capital and ignore the possibility of negative consequences.

Portes and Landolt (1996) specifically identify the less desirable possibilities of developing social capital. Social networks can promote "public bads" just as easily as public goods. Social capital can contribute to discrimination, restriction of individual freedom and creativity, lack of economic opportunity, and overwhelming obligations. Strong

voluntary associations, communities, and social networks that maintain high levels of solidarity often do so by excluding outsiders. Thus, noninsiders are disadvantaged within those groups. Additionally, high social capital is contingent on a high degree of conformity within the group, and non-conformists can be ostracized. This greatly impinges on personal freedom and expression. It also can result in a great deal of power for those in leadership positions in the group. Mafia-type power structures are an example of this.

Tight social networks also can undermine entrepreneurial activity. Successful business owners often are expected to help others, and this can affect their ability to maintain their businesses. Portes and Landolt (1996) identify further “downward leveling pressures” that can be consequences of social capital. The pressure to conform to group norms in order to access group resources (which may be perceived as the only resources available) can keep an individual from attempting to enter the mainstream and find a way up from poverty. Portes and Landolt use the examples of prostitution rings and youth gangs. The network norms function to keep individuals within the familiar group culture. Any attempt by a member to achieve something outside the network may be seen as a threat to group solidarity and is discouraged.

SOCIAL CAPITAL AND SOCIOLOGY

Within the discipline, sociologists recognize the need to conduct empirical investigations as an important component of theory building. The concept of social capital has been advanced in many diverse subfields of sociology. Sociologists have applied it to the macro issues of modernization, economic development or lack of it, networks, and organizations. Others have studied the empirical implications of social capital for families and youth behavior problems, schooling and education, community life, work and organizations, democracy and governance, and collective action (see Woolcock 1998 for an overview).

As a theoretical concept, social capital holds great promise for furthering the sociological understanding of social action. There is still much to learn; the perspective needs to be grounded in established bodies of empirical research before it can be translated into optimistic public policies. Its greatest promise, Woolcock (1998, p.188) points

out, “is that it provides a credible point of entry for sociopolitical issues into a comprehensive multi- and interdisciplinary approach to some of the most pressing issues of our time.” Social capital may be seen as a common theoretical language that can allow historians, political scientists, anthropologists, economists, sociologists, and policymakers to work together in an open and constructive manner.

SOCIAL CHANGE

Social change is ubiquitous. Although earlier social scientists often treated stability as normal and significant social change as an exceptional process that required a special explanation, scholars now expect to see change at all times and in all social organizations. Much of this type of change is continuous; it occurs in small increments and reveals long-term patterns such as growth. Discontinuous changes, however, are more common than has been assumed. From the perspective of individual organizations, these changes are relatively common and often result in sharp departures from

previous states such as when corporations are created, merged, or terminated. From the perspective of larger populations of such organizations, relatively few discontinuous changes result in comparably sharp departures from long-term patterns and trends. Even revolutions that result in dramatic changes of political and legal institutions generally do not transform all of society equally. Some previous patterns continue; others are restored.

Cumulative social change must be distinguished from recurrent fluctuations and the processual aspect of all social life. Both sociologists and historians study the latter by focusing on those dynamic processes through which the social lives of particular individuals and groups may change even though overall patterns remain relatively constant. Marriages and divorces are major changes in social relationships, but a society may have a roughly constant marriage or divorce rate for long periods. Similarly, markets involve a continuous flow of changes in regard to who possess money or goods, who stands in the position of creditor or debtor, who is unemployed or employed, and so forth. These specific changes, however, generally do not alter the nature of the markets. Researchers both study the form of particular transactions and develop models to describe the dynamics of large-scale statistical aggregations of such processes (see "Social Dynamics.")

As Bourdieu (1977, 1990) and Giddens (1986) suggest, it is necessary to see human social life as always being structured, but incompletely so. "Structuration," to use their term, is as much a process of change as a reflection of stability. Indeed, the existence of stable social patterns over long periods requires at least as much explanation as does social change. This situation has led to renewed attention to social reproduction, or the ways in which social patterns are re-created in social action. This contrasts with earlier views of continuity as a matter of inertia or simple endurance. Some continuity in the social order is achieved intentionally by actors with enough power to resist changes desired by others; rulers thus maintain their rule by force. Much social reproduction, however, works at a less consciously intentional level and is based on the ways in which people learn to think and act rather than on overt, material force. Bourdieu and Passeron (1977), for example, follow Weber in studying the ways in which

ingrained, habitual ways of deciding what new action fits an individual's situation work without conscious intention to reproduce overall social patterns. A pattern of inequality in educational attainment that is understood officially as meritocratic and is genuinely intended by teachers to be so thus may be reproduced in part because students from nonelite backgrounds unconsciously lower their expectations for themselves, expecting elites to do better. Teachers may unconsciously do the same thing. When decisions are to be made, such as whether to go to university, or which university to choose, elite students and their families are more likely to have the confidence and knowledge to invest in options with a higher long-term payoff.

To understand social change, thus, it is necessary also to understand what produces social continuity. It would be a mistake to explain social change always in terms of a new factor that intervenes in an otherwise stable situation. Rather, social change commonly is produced by the same factors that produce continuity. These factors may change in quantity or quality or in relation to each other.

Sometimes, however, specific processes of social life undergo long-term transformations. These transformations in the nature, organization, or outcomes of the processes are what is usually studied under the label "social change." Social life always depends, for example, on the processes of birth and death that reproduce populations through generations. These rates (adjusted for the age of a population) may be in equilibrium for long periods, resulting in little change in the overall size of a population. Alternatively birthrates may exceed death rates most of the time, resulting in gradual population growth, but periodic disasters such as war, famine, and pestilence may cut the population back. In this case, the population may show little or no cumulative growth, but instead exhibit a dynamic equilibrium in which every period of gradual increase is offset by one of rapid decline. Approximations to these two patterns characterize most of world history. Population growth generally has been quite slow, although periodic declines have not offset all the increases. In the last three hundred years, however, a new phenomenon has been noted. As societies industrialize and generally grow richer and change the daily lives of their members, they undergo a "fertility transition." First, improvements in nutrition, sanitation,

and health can allow people to live longer. This results in population growth that can be very rapid if the improvements are introduced together rather than gradually developing over a long period. After a time lag, this encourages people to have fewer children because more of the children they do have survive. As fertility rates (birthrates standardized by the number of women of child-bearing age) also drop, a new equilibrium may be reached; population growth will slow or stop. This is a cumulative transition, because after it, the typical rates of birth and death are much lower even though the population may be much larger. A variety of other changes may follow from or be influenced by this process. For example, family life may change with declining numbers of children, parents' (especially mothers') lives are likely to change as fewer of their years are devoted to bearing and raising children, and childhood deaths may become rarities rather than common experiences.

Social history is given its shape by such cumulative social changes. Many of these changes are quite basic, such as the creation of the modern state; others are more minor, such as the invention and spread of the handshake as a form of greeting. Most, such as the development of team sports, fast-food restaurants, and the international, academic conference, lie in the broad area in between. Thus, cumulative social changes may take place on a variety of different scales, from the patterns of small group life through institutions such as the business corporation or church to overall societal arrangements. Significant changes tend to have widespread repercussions, however, and so it is rare for one part of social life to change dramatically without changing other parts.

While certain important changes, such as an increasing population, are basically linear, others are discontinuous. There are two senses of discontinuity. The first is abruptness, such as the dramatic contraction of the European population in the wake of plague and other calamities of the fourteenth century and the occurrence of the Russian Revolution after centuries of tsarist rule and failed revolts. Second, some social changes alter not just the values of variables but the relationship of variables to each other. Thus, for much of history the military power and wealth of a ruler was based directly on the number of his or her subjects; growing populations meant an increasing total

product from which to extract tribute, taxes, and military service. With the transformation first of agriculture and then of industrial production in the early capitalist era or just before it, this relationship was in many cases upset. Increasingly, from the sixteenth through eighteenth centuries, for example, the heads of Scottish clans found that a small population raising sheep could produce more wealth than could a large one farming; their attempt to maximize this advantage contributed to the migration of Scots to Ireland and America. This process was of course linked also to growing demand for wool and the development of the industrial production of textiles. Those factors in turn involved new divisions of social labor and increased long-distance trade. At the same time, the development of industrial production and related weapons technologies reduced the military advantages of large population size by contrast to epochs when wars generally were won by the largest armies; indeed, population may be inversely related to power if it impedes industrialization.

This case provides an example of how shifts in the relationships of certain variables can alter not only overall social patterns but broad cultural orientations to social change. Along with industrialization (and other dimensions of modern social life) has come a continuous process of technological and social innovation. As Weber (1922) emphasized, this process is at odds with a traditional orientation to social life. Traditionalism implies an expectation of continuity and respect for the ways in which things have always been done. Constant innovation is linked to the pursuit of more efficient ways to do things and an expectation of continuous change. Leaders of China, long thought the absolute size of armies would be decisive in conflict. They were shocked when both Japan and Western powers were able to win victories in the nineteenth century mainly on the basis of superior technology rather than superior size. This helped produce not only the collapse of a specific imperial dynasty but a crisis in a whole pattern of traditionalism. Instead of assuming that the best lessons for military strategy lay in the teachings of the past, some leaders recognized that they needed to look for new ways in which to make the country strong. This produced a tension between trying to preserve cultural identity by continuing to do things the same way and trying to achieve technological and other gains by innovating. This tension is

common in societies that have undergone broad patterns of social change in the modern era. In China, after the death of Mao Zedong leaders decided that strengthening the country and improving people's lives depended on technological advancement and economic development. Recognizing both that large armies would not win wars against enemies with technologically advanced weapons and that rapid population growth would make it difficult to educate the whole population and produce rapid economic growth, Deng Xiaoping and other leaders introduced policies to reduce population growth rates. They also decided that they needed to liberalize the economy and encourage private business because state-owned enterprises could not innovate rapidly enough. On the one hand, they encourage innovation in economy and technology, and on the other hand, they resist change in politics and culture. Although perhaps contradictory, these two responses have been typical of leaders in societies undergoing the process of modernization. Although it is impossible to prevent major changes in technology and the economy from having an impact on politics and culture, it is possible to shape what those impacts will be.

Sociologists generally have taken three approaches to studying cumulative social changes. The first is to look for generalizable patterns in how all sorts of changes occur, the second is to seek an explanation for the whole overall pattern of history, and the third is to analyze historically specific processes of change.

Following the first of these approaches, sociologists have looked for characteristic phases through which any social innovation must pass, such as skepticism, experimentation, early diffusion among leaders, and later general acceptance. Ogburn ([1922] 1950) was a pioneer in this sort of research, examining topics such as the characteristic "lag" between cultural innovations and widespread adjustments to them or exploitation of their potential. In regard to the fertility transition, when improved health care and nutrition make it possible for nearly all children to survive to adulthood, it takes a generation or two before parents stop having large families as "insurance policies" to provide for support in their old age. Earlier researchers often hoped to find general laws that would explain the duration of such lags and account for other features of all processes of social change. Contemporary sociologists tend to place

much more emphasis on differences among various kinds of social change and their settings; accordingly, their generalizations are more specific. Researchers may limit their studies to the patterns of innovation among business organizations, for example, recognizing that those organizations may act quite differently from others. They also may ask questions such as, Why do innovations gain acceptance more rapidly in formal organizations (e.g., businesses) than in informal, primary groups (e.g., families), or what sorts of organizations are more likely to innovate? The changes may be very specific, such as the introduction of new technologies of production, or very general, such as the Industrial Revolution as a whole (Smelser 1958). The key distinguishing feature of these sorts of studies is that they regard changes as individual units of roughly similar sorts and aim to produce generalizations about them.

The second major sociological approach to cumulative change—seeking an explanation for the whole pattern of cumulation—was long the province of philosophies of history that culminated in the sweeping syntheses of the nineteenth century. Sociology was born partly out of the attempt to understand the rise of science, industry, and urban society. These and related transitions were conceptualized in frameworks that emphasized shifts from tradition to modernity, feudalism to capitalism, and monarchy to republicanism or democracy. As Sztompka (1993) points out, three basic visions were developed, each of which has left a mark on sociology and continues to be influential in research: cycles, evolutionary progress, and historical materialism. The roots of the cyclical vision stretch back to antiquity. The image of the human life cycle, from birth and infancy to old age and death, for example, was used to conceptualize the rise and fall of whole societies and of imperial dynasties that were thought to be vigorous in youth and feeble in old age. Few scientific sociologists have regarded such images as more than metaphors, but they have been influential among writers attempting to generalize about the course of history (e.g., Spengler [1918] 1939; Toynbee 1934–1961). A number of sociologists, however, have studied more specific cyclical patterns. Pareto ([1916] 1980) analyzed what he called the circulation of elites, a pattern in which specific groups rose into and then fell from social dominance. Sorokin (1937) analyzed cultural cy-

cles, especially the oscillating dominance of ideational (spiritual, intellectual) and sensate (sensual, materialist) orientations. More recently, sociologists have identified cycles in social movements and collective action (Tilly 1989; Tarrow 1998; Traugott, 1995).

Both historical materialism and evolutionism are indebted to another ancient idea, that of progress. Here the idea is that social change tends to produce a pattern of improvements in human life as measured in relationship to a standard of evaluation. In this regard, sociological evolutionism has commonly differed from evolutionary theory in biology, which has been less focused on the overall direction of change and normative evaluation. The great nineteenth-century evolutionary thinkers Comte ([1830–1842, 1851–1854] 1975) and Spencer (1893) conceptualized history as progress through a series of stages. Comte based his analysis on what he saw as improvements in social knowledge through theological, metaphysical, and positive stages. Spencer, who was also an originator of evolutionary theory in biology, had a much more complex and sophisticated theory, focusing on the way structures developed to meet functional imperatives and gaining direction from the idea that “incoherent homogeneity” progressively gives way to “coherent heterogeneity” through the process of structural differentiation. Spencer (1893) addressed particularly the transition from military to industrial societies, which he saw as basic to modernity. Durkheim (1893) developed a similar analysis in his description of the movement from mechanical to organic solidarity.

[¹ Schrecker (1991) has analyzed a pattern in which something similar to Spencer’s two stages alternated cyclically in Chinese society rather than forming the basis for a single evolutionary trend. Periods of increasing industrialization and commercialization (*fengjian*) were followed by eras in which agriculture and military prowess figured more prominently (*junxian*). Schrecker (1991) suggests that this intriguing combination of evolutionary and cyclical theories initially was developed by classical Chinese scholars, although it was recast after the importation of Spencerian evolutionary theory.]

Historical materialists, starting with Marx (1863), also analyzed stages in historical development (such as feudalism and capitalism), but with

three crucial differences from other evolutionary theories. First, Marx and his followers argued that material factors, especially the mode of production, shape the rest of society and that change is driven largely by improvements in the capacity for material production. Second, following a dialectical logic, Marxists emphasized the internal contradictions within each stage of development. Capitalism, for example, generated tremendous increases in productivity but distributed the resulting wealth so unequally that it was prone to economic crises and social revolutions. Rather than a simple, incremental progress, thus, Marxists saw evolution as taking place in discontinuous breaks marked by clashes and struggles. Third, most versions of Marxist theory gave greater emphasis to human agency or ability consciously to shape the direction of social change than was typical of evolutionary theory. The question of the extent to which evolution can be directed consciously has, however, recently come to the fore of non-Marxist evolutionary theory as well, as in in the work of the sociobiologist Wilson (Wilson and Wilson 1999).

The most important contemporary theories of social evolution attempt to generate not only overall descriptions of stages but causal explanations for social change. Lenski, for example, has argued that increases in technological capacity (including information processing as well as material production and distribution) account for most of the major changes in human social organization (Lenski et al. 1994). In his synthesis, Lenski arranges the major forms of human societies in a hierarchy based on their technological capacity and shows how other features, such as their typical patterns of religion, law, government, class inequality, and relations between the sexes, are rooted in those technological differences. In support of the idea that there is an overall evolutionary pattern, Lenski et al. (1994) point to the tendency of social change to move only in one direction. Thus, there are many cases of agricultural states being transformed into industrial societies but very few (if any) examples of the reverse. Of course, Lenski acknowledges that human evolution is not completely irreversible; he notes, however, not only that cases of reversal are relatively few but that they commonly result from an external cataclysm. Similarly, Lenski indicates that the direction of human social evolution is not strictly dictated from the start but only channeled in certain direc-

tions. There is room for human ingenuity to determine the shape of the future through a wide range of potential differences in invention and innovation. There are a number of other important versions of the evolutionary approach to cumulative social change. Some stress different material factors, such as human adaptation to ecological constraints (Harris 1979; White 1949); others stress culture and other patterns of thought more than material conditions (Parsons 1968; Habermas 1978).

Adherents to the third major approach to cumulative social change argue that there can be no single evolutionary explanation for all the important transitions in human history. They also stress differences as well as analogies among particular instances of specific sorts of change (Stinchcombe 1978). These historians and historical sociologists emphasize the importance of dealing adequately with particular changes by locating them in their historical and cultural contexts and distinguishing them through comparison (Abrams 1982; Skocpol 1984; Calhoun 1995, 1998). Weber was an important pioneer of this approach. A prominent variety of Marxism has stressed the view that Marx's mature analysis of capitalism emphasizes historical specificity rather than the use of the same categories to explain all of history (Postone 1993). Historical sociologists have argued that a particular sort of transformation, such as the development of the capacity for industrial production, may result from different causes and have different implications on different occasions. The original Industrial Revolution in eighteenth- and nineteenth-century Britain thus developed with no advance model and without competition from established industrial powers. Countries that are industrializing today are influenced by both models and competition from existing industrial countries, along with influences from multinational corporations. The development of the modern world system thus fundamentally altered the conditions of future social changes, making it misleading to lump together cases of early and late industrialization for the purpose of generalization. Similarly, prerequisites for industrial production may be supplied by different institutional formations; one should compare not just institutions but different responses to similar problems.

Accident and disorder also have played crucial roles in the development of the modern world system. Wallerstein (1974–1988) shows the cen-

trality of historical conjunctures and contingencies: the partially random relationships between different sorts of events (on historical accidents, see also Simmel 1977; Boudon 1986). For example, the outcome of military battles between Spain (an old-fashioned empire) and Britain (the key industrial-capitalist pioneer) were not foregone conclusions. There was room for bravery, weather, strategy, and a variety of other factors to play a role. However, certain key British victories, notably in the sixteenth century, helped make not only British history but world history different by creating the conditions for the modern world system to take the shape it did. Against evolutionary explanation, historical sociologists also argue that different factors explain different transformations. Thus, no amount of study of the factors that brought about the rise of capitalism and industrial production can provide the necessary insight into the decline of the Roman Empire and the eventual development of feudalism in Europe or the consolidation of China's very different regions into the world's most enduring empire and most populous state. These different kinds of events have their own different sorts of causes.

Predictably, some sociologists seek ways to combine some of the benefits of each type of approach to explaining cumulative social change. Historical sociologists who emphasize the singularity of specific transformations can learn from comparisons among such changes and achieve at least partial generalizations about them. Thus, different factors are involved in every social revolution, yet certain key elements seem to be present, such as crises (financial as well as political) in a government's capacity to rule (Skocpol 1979; Goldstone 1991). This recognition encourages one to focus on structural factors that may help create potentially revolutionary situations as well as the ideologies and actions of specific revolutionaries. Similarly, even though a variety of specific factors may determine the transition to capitalism or industrialization in every instance, some version of a fertility transition seems to play a role in nearly all cases. Although evolutionary theory is widely rejected by historical sociologists, some look to evolutionary arguments for suggestions about what factors might be important. Thus, Lenski's emphasis on technology and Marx's focus on the relationship of production and class struggle can provide foci for research, and that research can help deter-

mine whether those factors are equally important in all societal transformations and whether they work the same way in each one. More radically, evolutionary socioglogy might follow biology in focusing less on the selection of whole populations (societies) for success or failure and look instead at the selection of specific social practices (e.g., the bearing of large numbers of children) for reproduction or disappearance. Such an evolutionary theory might provide insight into how practices become more or less common, following biology in looking for mechanisms of reproduction and inheritance, the initiation of new practices (mutation), and the clustering of practices in interacting groups (speciation) as well as selection. It would, however, necessarily give up the capacity to offer a single explanation for all the major transitions in human social history, which is one of the attractions of evolutionary theory to its adherents.

Certain basic challenges are particularly important in the study of cumulative social change today. In addition to working out a satisfactory relationship among the three main approaches, perhaps the most important challenge is to distinguish social changes that are basic from those which are ephemeral or less momentous. Sociologists, like historians and other scholars, need to be able to characterize broad patterns of social arrangements. This is what sociologists do when they speak of “modernity” or “industrial society.” Such characterizations involve at least implicit theoretical claims about the crucial factors that distinguish these eras or forms. In the case of complex, large-scale societal processes, these factors are hard to pin down. How much industrial capacity does a society need to have before one can call it industrial? How low must employment in its increasingly automated industries become before one can call it postindustrial? Is current social and economic globalization the continuation of a long-standing trend or part of a fundamental transformation? Although settling such questions is difficult, debating them is crucial, for sociologists cannot grasp the historical contexts of the phenomena they study if they limit themselves to studying particulars or seeking generalizations from them without attempting to understand the differences among historical epochs (however hard to define sharply) and cultures (however much they may shade into each other with contact). Particularly because of the many current contentions that

humanity stands on the edge of a new age—postmodern, postindustrial, or something else—researchers and theorists need to give strong answers to the question of what it means to claim that one epoch ends and another begins (Calhoun 1999).

Many prominent social theorists have treated all of modernity as a continuous era and stressed its distinction from previous (or anticipated future) forms of social organization. Durkheim (1893) argued that a new, more complex division of labor is central to a dichotomous distinction of modern (organically solidary) from premodern (mechanically solidary) society. Weber (1922) saw Western rationalization of action and relationships as basic and as continuing without rupture through the whole modern era. Marx (1863) saw the transition from feudalism to capitalism as basic but held that no change in modernity could be considered fundamental unless it overthrew the processes of private capital accumulation and the commodification of labor. Recent Marxists thus argue that the social and economic changes of the last several decades mark a new phase within capitalism but not a break with it (Mandel 1974; Wallerstein 1974–1988; Harvey 1989). Many sociologists would add a claim about the centrality of increasing state power as a basic, continuous process of modernity (e.g., Tilly 1990; Mann 1986–1993). More generally, Habermas (1984–1988) has stressed the split between a life world in which everyday interactions are organized on the basis of mutual agreement and an increasingly prominent systemic integration through the impersonal relationships of money and power outside the reach of linguistically mediated cooperative understanding. Common to all these positions is the notion that there is a general *process* (not just a static set of attributes) common to all forms of modernity. Some claim to discern a causal explanation; others only point to the trends, suggesting that those trends may have several causes but that there is no single “prime mover” that can explain an overall pattern of evolution. All would agree that no really basic social change can be said to have occurred until the fundamental processes they identify have ended, been reversed, or changed their relationship to other variables. Obviously, a great deal depends on what processes are considered fundamental.

Rather than stressing the common processes that organize all forms of modernity, some scholars have followed Marx (and recent structuralist

theory) in pointing to the disjunctures between relatively stable periods. Foucault (1973), for example, emphasized basic transformations in the way knowledge is constituted and an order is ascribed to the world of things, people, and ideas. Renaissance culture was characterized by an emphasis on resemblances among the manifold different elements of God's single, unified creation. Knowledge of fields as diverse to modern eyes as biology, aesthetics, theology, and astronomy was thought to be unified by the matching of similar characteristics, with those in each field serving as visible signs of counterparts in the others. The "classical" modernity of the seventeenth and early eighteenth centuries marked a radical break by treating the sign as fundamentally distinct from the thing it signified, noting, for example, that words have only arbitrary relationships to the objects they name. The study of representation thus replaced that of resemblances. In the late eighteenth and early nineteenth centuries, another rupture came with the development of the modern ideas of classification according to hidden, underlying causes rather than superficial resemblances and an examination of human beings as the basic source of systems of representation. Only this last period could give rise to the "human sciences"—psychology, sociology, and so forth—as they are known today. Similarly, Foucault (1977) argued that the modern individual is a distinctive form of person or self, produced by an intensification of disciplining power and surveillance. Where most theories of social change emphasize processes, Foucault's "archaeology of knowledge" emphasizes the internal coherence of relatively stable cultural configurations and the ruptures between them.

Foucault's work has been taken as support for the claim (which was not his own) that the modern era has ended. Theories of "postmodernity" commonly argue that at some point the modern era gave way to a successor, though some scholars (e.g., Lyotard 1977) have indicated, against the implications of the label "postmodern," that they mean not a simple historical succession but a recurrent internal challenge to the dominant "modernist" patterns (see Lash 1990; Seidman 1995; Harvey 1989; Calhoun 1995). Generally, they hold that where modernity was rigid, linear, and focused on universality, postmodernity is flexible, fluidly multidirectional, and focused on differ-

ence. Some postmodernist theories emphasize the impact of new production technologies (especially computer-assisted flexible automation), while others are more exclusively cultural. The label "postmodernity" often is applied rather casually to point to interesting features of the present period without clearly indicating why they should be taken as revealing a basic discontinuous shift between eras.

At stake in debates over the periodization of social change is not just the labeling of eras but the analysis of what factors are most fundamentally constitutive of social organization. Should ecology and politics be seen as determinative over, equal to, or derivative of the economy? Is demography or technological capacity prior to the other? What gives capitalism, feudalism, a kinship system, or any other social order its temporary and relative stability? Such questions must be approached not just in terms of manifest influence at any single point in time or during specific events but also in terms of the way particular factors figure in long-term processes of cumulative social change.

SOCIAL COMPARISON PROCESSES

How do people come to understand themselves? A response to this age-old question involves what has been labeled everyone's "second favorite theory" (Goethals 1986): social comparison. The original formulation of social comparison theory (Festinger 1954) demonstrated how, in the absence of objective standards, individuals use other people to fulfill their informational needs to evaluate their own opinions and abilities. The process of social comparison underlies social evaluation (Pettigrew 1967) and relates to reference group processes (e.g., Hyman and Singer 1968), which in turn are critical to understanding diverse sociological issues pertaining, for example, to identity development, justice, interpersonal and intergroup rela-

tionships, and group decision making. Thus, the “second favorite” status of social comparison theory reflects the preference of researchers for particular theories about each of these topics, which nonetheless promote the centrality and breadth of social comparison processes in sociological pursuits. To explain the multifaceted role of social comparisons, this article first describes the theory and its elaborations and then shifts to a sampling of the extensive applications of that theory.

SOCIAL COMPARISON THEORY

For nearly fifty years, social comparison theory has shifted between the categories of “lost and found” (Goethals 1986): The theory flourishes for a while and then lies dormant. Suls (1977) outlines the first twenty years of social comparison research, beginning with its inception in 1954 by the psychologist Festinger and then describing its theoretical decline while applications to affiliation (Schachter 1959), emotions (Schachter and Singer 1962), and justice (Adams 1965) emerged; its momentary revival in a 1966 issue of the *Journal of Experimental Social Psychology*; and its second, more enduring revival in 1977 in the form of a landmark volume of collected essays (Suls and Miller, 1977). During its fourth decade, the resurgence of social comparisons research (Wood 1989) anchored it firmly in the “found” category. Almost fifty years after its inception, its contribution to numerous substantive areas appears to be unrivaled (Suls and Wills 1991).

Festinger (1954) incorporates his observations regarding research on aspiration levels and social pressures into the premises of his formal theory of social comparison. First, individuals are driven to evaluate their abilities and opinions. That drive increases with the importance of the ability or opinion, its relevance to immediate behavior, the relevance of the group to the ability or opinion, and the individual’s attraction to the group. These factors also increase the pressure toward uniformity with relevant others. Second, people first attempt to make these evaluations through objective, nonsocial means, but if those means are unavailable, they are likely to compare themselves with others. Third, individuals are likely to choose for comparison someone close to the opinion or ability in question (the “similarity hypothesis”). Festinger notes that social comparisons may be

based on the similarity of attributes related to the dimension under evaluation (the “related attributes hypothesis”). As a rationale for the preference for similar comparison others, he argues that comparisons with divergent others produce imprecise and unstable evaluations. Comparisons with moderately different others (those within tolerable limits of discrepancy), however, produce changes in individuals’ evaluations of their own or the others’ abilities or opinions. These changes ensure uniformity in the group and reinforce stable and precise evaluations.

Although Festinger (1954) treats abilities and opinions similarly in most respects, he notes a major distinction that may influence the consequences of comparisons. In the case of abilities, the cultural value of doing “better and better” encourages individuals to make upward comparisons. Typically, because of the pressure toward uniformity, the upward drive is limited to comparisons with those who are slightly better. This unidirectional drive upward, however, inspires competition among group members that may inhibit the emergence of social uniformity. In contrast, no upward drive characterizes comparisons of opinions. In light of the pressure toward uniformity, the absence of an upward drive and the greater flexibility of opinions (compared with the nonsocial constraints on changes in abilities) suggest that a state of social quiescence is more likely to emerge in terms of the evaluation of opinions.

Despite the greater likelihood of opinion uniformity, Festinger (1954) notes that if potential comparison others have highly discrepant opinions, the cessation of the comparison process may result in hostility toward or derogation of those others. These negative reactions stem from the belief that opinion discrepancy means that an individual’s opinions are incorrect. In contrast, no negative implications characterize discrepancy in abilities, which are more independent of relative value orientations, indicating different forms of “correctness.”

As is suggested by his emphasis on group uniformity, one of Festinger’s (1954) major concerns was to describe the role of social comparison processes in group formation and maintenance as well as social structure. Presumably, people who have similar abilities and opinions group together; as a result of their distinguishing themselves from

others, segments form in society. These two implications of social comparison processes are represented in research on group decision making and intergroup relations (see below). Although Festinger's perspective suggests a wide range of implications, his theory is not definitive; in fact, Arrowood (1986) has labeled the 1954 version a "masterpiece of ambiguity." Points of ambiguity involve theoretical issues regarding the nature of social comparison per se, the motivations that underlie comparison choices, and the choice of a comparison other (especially the meaning of similarity).

In Festinger's (1957) formulation, the nature of the social comparison is oblique, referring only to nonobjective information regarding abilities and opinions. Others have extended the domain of social comparisons to include emotions (Schachter and Singer 1962), outcomes (Adams 1965), health (Buunk and Gibbons 1997), relationships (VanYperen and Buunk 1994), and traits (Thornton and Arrowood 1966, but see Suls 1986). Nonobjective information may include personal comparisons (see Masters and Keil 1987). These comparisons involve information about the self and draw attention to time as an important factor in determining the nature of comparisons. Temporal comparisons (Albert 1977) involve a "now versus then" dimension, meaning that a person compares pieces of information about an ability or opinion at different points in time.

Arrowood (1986) describes several forms of nonobjective (ability) information used in social comparison studies, for example, the presentation of two ratings (the evaluator's and that of an unidentified other), the display of a distribution of ratings that includes the evaluator's, and the presentation of the evaluator's rating along with the identifying characteristics of potential comparison others and their ratings. The latter two factors allow the development of an estimate about others in general, with the last one also allowing an assessment of similarity. Compared with objective information, relative standing generally exerts greater influence except when the desirability of objective information is great (Klein 1997). Not all methods, however, truly capture social comparison. To address this problem, Wood (1996) stresses the need for consistency between definitions and measures and the need to be wary of alternative interpretations. Insofar as information presenta-

tion stimulates the comparison process, its effects may depend on the motivations that drive the comparison.

The most explicit but general, motivation included in Festinger's (1954) perspective is that people need information. Later work, however, demonstrates that the motivations underlying social comparisons are far more extensive. Twenty years ago, Fazio (1979) specified two types of information motivations that underlie self-evaluations: (1) the "construction" motivation, referring to a person's desire to obtain information he or she lacks, and (2) the "validation" motivation, representing the use of information to determine the valid source (e.g., the person or the entity) of a person's judgment about an entity. Fazio argues that individuals appear to be motivated by construction when they lack information and by validations when they have sufficient information. Validation, however, is distinct from a third motivation: self (or ego) enhancement. Festinger (1954) hinted at the possibility of self-enhancement when he posited that in evaluating abilities, individuals are likely to make upward comparisons; by noting "how close" an individual is to a superior performer, that individual enhances the evaluation of his or her own ability. In addition to self-evaluation and self-enhancement goals, one study (Hegeson and Mickelson 1995) lists four other motives for social comparison: common bond, self-improvement, altruism, and self-destruction.

A recent trend in distinguishing among motivations is to focus on the role of self-esteem in social comparisons. Generally, individuals low in self-esteem rely more on social comparison information to meet goals of accuracy, self-enhancement, and self-improvement than do those high in self-esteem (Wayment and Taylor 1995). However, insofar as people with low self-esteem are more oriented to self-protection, they are likely to seek social comparison information that is "safe" (i.e., that carries little risk of humiliation) after receiving success feedback (Wood et al. 1994). In effect, low-esteem individuals are seizing a safe form of self-enhancement. Threats to self-esteem, especially among those who have high self-esteem, seem to stimulate more egocentric contrasts in judgments of others (Beauregard and Dunning 1998), suggesting that individuals tailor their evaluations of others to affirm their own self-worth.

That tailoring of evaluations coincides with other evidence that challenges Festinger's assumption that individuals are rational and accurate in information processing. Wood (1989) demonstrates that people are not unbiased evaluators of information about themselves and potential comparison others, and Hoorens's (1995) study captures some of those biases. Subjects comparing themselves to another person show more unrealistic optimism and illusory superiority regarding future positive events and traits than do subjects who compare another person to themselves. In other words, people perceive themselves more favorably than they perceive others. Motivations, coupled with perceptual processes, are critical in determining the choice of comparison others.

In an extensive review of the choice of comparison others, Gruder (1977) examines the conflict between evaluation and enhancement motivations. He concludes that the evaluation motivation is important in new situations and that under such conditions, individuals are likely to choose others who are similar to themselves in terms of the ability or opinion at issue. Enhancement motivations arise when enhancement is feasible. For example, in the absence of threats to self-esteem, individuals are likely to make upward, self-enhancing comparisons that provide useful information for self-improvement (Collins 1996; Blanton et al. 1999). If an upward comparison is unavoidable, individuals may deflect a threat to their self-esteem by perceptually distorting through exaggeration the performance of the other person (Alicke et al. 1997). When self-esteem is unavoidably threatened, people are more likely to make downward (defensive) comparisons (e.g., Hakmiller 1966; Taylor and Lobel 1989). In effect, to protect their self-esteem, individuals choose dissimilar others (i.e., inferior performers) for their comparisons. Researchers are examining a number of additional factors that may affect responses to upward and downward comparisons (e.g., Aspinwall and Taylor 1993). Whether individuals choose similar or dissimilar others for comparison depends in part on the nature of the dimension under scrutiny, the context (including the characteristics of potential comparison others), and the importance of the enhancement goal (Wood 1989).

Questions about the choice of comparison others typically raise the issue of the meaning of similarity. Festinger (1984) offers different yet

potentially complementary definitions of similarity: closeness of ratings on abilities or opinions and attributes related to the evaluation dimension. Goethals and Darley (1977) note that similarity in the first sense is paradoxical: "[P]resumably the comparison is made in order to find out what the other's opinion or score is, yet prior knowledge of the similarity of his score or opinion is assumed as the basis for comparison" (p. 265). Those authors advocate the interpretation of similarity on the basis of "related attributes." One is likely to choose others for comparison who *should be* close to one's own ability or opinion by virtue of their standing on characteristics related to the evaluative dimension. Wheeler et al. (1982) review the extensive support for the related attributes hypothesis. Two trends, however, qualify that support. Kulik and Gump (1997) show that related attribute information has an effect only in the absence of information on relative performances. And Wood (1989) indicates that people choose comparisons with those with similar characteristics regardless of whether the attribute relates to the dimension under scrutiny; for example, people of the same sex are more likely to compare themselves to each other even if sex is unrelated to the ability that is being compared.

Concern with related attributes similarity and its evaluative consequences provides the basis for one of the main elaborations of social comparison theory: Goethals and Darley's (1977) attributional approach. Their approach applies Kelley's (1973) attributional concepts of discounting and augmentation (see Howard in this volume) to assess the certainty of one's standing on an ability or opinion. With regard to abilities, attribution logic focuses on the configuration of possible comparison others and one's own ability level. For example, a person who compares himself or herself to an advantaged other expects his or her performance to be worse. The implications for an ability evaluation are ambiguous, however, because other plausible causes (the superior related attributes) allow the discounting of low ability. In contrast, if an individual performed as well as or better than the advantaged other, he or she overcame inhibitory causes (the inferior related attributes), and this augments a claim to higher ability. In general, conclusive ability evaluations are likely when a person compares herself or himself to others with similar attributes. The role of attributions in evalu-

ating opinions is more complicated because the unexpected cases (disagreement with similar others and agreement with dissimilar others) result in more useful information for validating an opinion than do the expected cases (agreement with similar others and disagreement with dissimilar others). More recent research has concentrated less on attributions than on other cognitive processes (e.g., the use of heuristics and memory) (see Masters and Keil 1987) and perceived control (see Major et al. 1991) to better understand social comparisons.

Complementing the intra- and interpersonal level focus of psychologists are sociological extensions to the level of intergroup relations. Tajfel and Turner (1979) build on Festinger's (1934) assumption that a major consequence of social comparisons to similar others is the development of groups or, in their terminology, social categories. They argue that social comparisons between categories, complemented by individuals' needs for a positive group identity (i.e., the self-enhancement motive), are likely to stimulate in-group bias. People tend to emphasize the positive characteristics of their group while derogating those of other groups. Evidence of such bias is particularly strong in competitive situations. Intergroup discrimination and conflict are the potential consequences of these intergroup comparisons.

Intergroup comparison processes form the main thrust of current research and raise issues of motivations, identity, and choice of comparison. For example, results from Rothgerber and Worchel (1997) confirm Tajfel and Turner's (1979) expectations about perceptions of groups resulting from intergroup comparisons. Disadvantaged in-group members harmed and saw as more homogeneous a disadvantaged out-group whose performance was similar to or better than that of the in-group. The effects of group status and performance, however, may be conditioned by the extent to which actors identify with their groups. High identifiers are likely to demonstrate group solidarity when there are threats to group identity in the form of a superior-status out-group comparison (Spears, Doosje, and Ellemers 1997). And Major et al. (1993) show how upward and downward group comparisons influence self-evaluations: People who compared unfavorably with in-group members reported lower self-esteem and more depressed af-

fect than did those who compared unfavorably with out-group members.

Gartrell (1987) also emphasizes the connection between the individual and the group. Rather than relying on motives for a positive social identity, his analysis concentrates on networks—relations among concrete entities—to highlight an often overlooked aspect of comparison choice: the social context in which individuals make comparisons. The examination of a person's social network relations is a way to understand more clearly not only the selection of relevant comparisons but also whether people seek comparisons actively or passively accept those which are readily present in the network. In addition, network analyses may inform how comparison choices affect the network and influence the ties among a person's multiple networks.

SOCIAL COMPARISON AND SOCIAL BEHAVIOR: APPLICATIONS OF THE THEORY

This review of developments in social comparison theory raises issues at the individual, group, and intergroup levels. Similarly, the extensive applications of the theory cross levels of analysis.

Festinger's (1954) assumption that individuals are driven to evaluate themselves implies a concern with self-knowledge that underlies self-concept and identity formation as well as self-esteem. A number of studies examine the role of social comparisons in shaping individual identity through the life course. For example, Chafel (1988) concludes that during childhood, achievement identities reflect first autonomous self-generated norms, then social comparison norms, and finally an integration of the two. Another study (Young and Ferguson 1979) demonstrates that across all grade levels (grades 5, 7, 9, and 12), parents are the comparison choice for the evaluation of moral issues whereas peers typically serve as a reference point for social issues, especially among older students. Moreover, it appears that social comparisons remain a major source of self-evaluation throughout a person's life (Robinson-Whelen and Kiecolt-Glaser 1997).

Just as the choice of a comparison other provides the basis for self-knowledge, comparisons of opinions within a group affect group dynamics. A

large body of research examines choice shift or group polarization, in which the group voices a more extreme opinion than would be expected on the basis of initial individual opinions (see Myers and Lamm 1976). The social comparison explanation of polarization states that insofar as people want their own opinions to remain distinct from those of others, exposure to others' opinions stimulates shifts in stances to retain that uniqueness. Consequently, the subsequent group opinion is more extreme.

Concerns with justice potentially stimulate social comparisons at all levels. To assess justice, people evaluate how their rewards or outcomes stack up against what they have earned in the past (internal comparison), what another individual like them earns (local or egoistic comparison), what members of their group typically earn (referential comparison), and what their group earns compared to another group (intergroup or fraternalistic comparison). The type of comparison and the specific person or group chosen define whether an individual is likely to perceive himself or herself or the group as being unfairly treated. Justice obtains when outcomes (or the ratio of outcomes to inputs) are equal across the comparison. Equity theory (Adams 1965; "Equity" in this volume) focuses on local comparisons as the basis for individual reactions to an imbalance in outcome-input ratios, while relative deprivation theory (focusing on outcomes only) attempts to explain when an individual or group will feel deprived and opt for collective action to redress that deprivation (see Masters and Smith 1987; Olson et al. 1986).

Social comparisons underlying justice processes have been extended in two ways beyond the traditional concerns that were noted above. First, researchers have begun to explore the role of social comparisons in understanding procedural justice and its relationship to distributive justice. There is, however, contradictory evidence about whether internal self-referents (Van den Bos et al. 1998) or social referents exert greater influence on that relationship (Ambrose et al. 1991). A second emphasis is more applied: To what extent do comparisons contribute to an understanding of perceptions of fair levels of pay? For example, although women earn lower wages than men do, they do not necessarily perceive this inequality as unfair. It appears that women's perceptions stem

from their comparisons with other women rather than with men in general or even with men in their same occupations, resulting in lower pay entitlements (e.g., Moore 1991; Demarais and Curtis 1997).

Although justice concerns have been applied to close relationships, the role of social comparisons in those relationships is a relatively new area of inquiry. VanYperen and Buunk (1994) review research on individuals' decisions to compare themselves to their partners or to their reference groups and the implications of those decisions. For example, people with egalitarian sex-role beliefs are likely to use their partners as a source of comparisons and in doing so enhance their relationship satisfaction; in contrast, individuals with a more traditional sex-role orientation use reference group comparisons to ensure satisfaction. Highlighting the role of motivations in the research reviewed above, Beach et al. (1998) find that reactions to comparisons between individuals in a close relationship support a self-evaluation maintenance model. Comparisons made by intimate couples also appear to parallel those which are evident in intergroup relationships: Subjects have more positive beliefs and fewer negative ones about their own relationships than they do about other relationships (Lange and Rusbult 1995)

A growing body of research examines applications of social comparison theory to health concerns (see Buunk and Gibbons 1997); as in research on close relationships, the application confirms and extends existing theoretical ideas. For example, Buunk and Ybema (1997) introduce an identification-contrast model to explain the choice of comparisons among individuals coping with stress. They suggest that individuals attempt to maintain their self-esteem by identifying upward and by finding ways, such as downward comparisons, to feel that they are doing better than others are. Affleck and Tennen (1991) also stress that downward comparisons are a means for victims of illness to find meaning in their plight and mitigate threats to their self-esteem. These authors also raise important issues involving the role of temporal comparisons in coping with illness and the need to recognize the distinctions between the comparison process and the comparison conclusion. Further extending the domain of social comparison theory, Croyle (1992) attempts to incorporate comparison concerns into stan-

standard models of stress and coping and the self-regulation of illness behavior.

CONCLUSIONS AND FUTURE DIRECTIONS

The applications attest to the pivotal role of social comparisons in explaining diverse phenomena. They also reiterate a number of theoretical and empirical issues. Future research should examine conditions affecting the motivations that underlie social comparison processes. Such work also would entail the conditions, such as uncertainty, that stimulate comparisons. The establishment of social contexts activating various motivations will allow a clearer assessment of the cognitive processes that influence social comparisons. In turn, this knowledge may enhance understanding of the choice among comparison others and allow an assessment of the extent to which choices vary with nonmotivational factors. Finally, as much of the applied work suggests, additional studies may reveal the range of consequences of social comparisons for individuals, relationships, and groups. Specific theories about identity formation, group decision making, justice, intimate relationships, and health may be "favorites," but their explanatory success depends on everyone's second favorite theory: social comparison.

SOCIAL CONTROL

NOTE: *Although the following article has not been revised for this edition of the Encyclopedia, the substantive coverage is currently appropriate. The editors have provided a list of recent works at the end of the article to facilitate research and exploration of the topic.*

The study of social control has been an integral part of sociology since its inception. Originally, the concept was defined as any structure, process, relationship, or act that contributes to the social order. Indeed, to some extent, the study of social order and social control were indistinguishable. This conceptual problem was particularly evident in the early Chicago perspective in which the concepts *social disorganization*, *social control*, and *deviance* were not distinguished. Deviance was thought to be the consequence of lack of social control and was often used to measure the presence of social control. Within the structural functionalism of the late 1940s and 1960s, the study of social control was allocated to the sidelines. It dealt with residual problems of deviance in a social system assumed to be generally integrated and well functioning. By the early 1960s society was, again, assumed to be considerably less orderly and integrated and, again, the concept of social control rose to the forefront. Studies examined both the causes and the consequences of social control. Thus, by the mid-1960s the intellectual ground had been laid for renewed scholarly interest in the study of social control. This chapter reviews the study of social control from that time through the 1970s and 1980s.

A consensus is now emerging that distinguishes social control from the social order it is meant to explain and that distinguishes among social-control processes. One basic distinction is among processes of internal control and external control. The former refers to a process whereby people adhere to social norms because they believe in them, feeling good, self-righteous, and proud when they do and feeling bad, self-critical, and guilty when they do not. This process has recently been termed *socialization*. External control refers to a social process whereby people conform to norms or rules because they are rewarded with status, prestige, money, and freedom when they do and are punished with the loss of them when they do not. This process has sometimes been termed *coercive*, *external*, or just *social control*.

Reflecting contemporary usage, this chapter emphasizes social control as external or coercive control. Research is organized, first, and foremost by whether social control is studied as an independent or dependent variable and, second, by whether it is studied at the micro level (the study of individuals) or the macro level (the study of cities, states, regions, and countries).

SOCIAL CONTROL AS AN INDEPENDENT VARIABLE

Social-control theories assume that norm violations can frequently be so pleasurable and profitable that many, if not most, people are motivated to violate them. Thus, it is not necessary to study deviant motives; rather it is necessary to study what constrains or controls most people from acting on their deviance motives most of the time. Studies of social control as an independent variable focus on the relative effectiveness of social relationships and arrangements in constraining behavior to social norms and laws. Three general areas have developed. One examines the effectiveness of social ties (bonds, relationships, attachments) to conventional institutions in constraining people from acting on deviant motives. The second examines the effectiveness of macro structures and processes in providing the foundation for these ties. The third examines the effectiveness of the criminal justice system in constraining people from violating the law.

Drawing on a long tradition of work, Hirschi (1969) published an influential formulation of micro social-control theory. He states that the relationship between people and conventional society consists of four bonds: belief, attachment, commitment, and involvement. *Belief* refers to the extent to which conventional norms are internalized (another term for internal control). *Commitment* refers to the extent to which people's social rewards are tied to conformity; the more people have to lose upon being socially identified as norm violators, the lower their likelihood of violating the social norms. *Attachment* refers to people's sensitivity to the opinions of others; the more people are concerned with the respect and status afforded them by others, the more they are subject to social control. *Involvement* refers to the amount of time people spend on conventional activities; the more

people are involved in conventional activities, the less time they have left for deviant activities.

This theory has inspired considerable research on juvenile delinquency. Studies from the 1960s to the 1980s (e.g., Kornhauser 1978; and Matsueda 1982) show that, as attachment to parents and school increase, delinquency decreases. These studies, however, do not show the casual order underlying the relationship between social attachment and delinquency. The theory assumes that low attachment leads to high delinquency; yet high delinquency could very well lead to low attachment. Trying to unravel these causal processes, Liska and Reed (1985) show that low parent attachment leads to high delinquency and that high delinquency leads to low school attachment.

From the 1920s onward, sociologists at the University of Chicago have been interested in the ecological distribution of deviance. Their studies of delinquency, mental illness, and suicide, for example, show that deviance tends to center in cities, particularly in the area where residential and business activity intermesh. They argued that the ecological conditions that disrupt traditional social-control processes are accentuated in these areas, and, when social-control processes weaken, deviance occurs. Industrialization creates a need for the concentration of labor, thereby increasing population size and density through migration and immigration. Both industrialization and urbanization lead to value and norm conflicts, social mobility, cultural change, and weak primary ties. These social conditions, in turn, disrupt internal and external processes of social control. The internal process is weakened because people are unlikely to accept normative standards as right and proper when they experience value and norm conflicts and social change. The external process is weakened because people are unlikely to constrain their behavior to conventional norms when social support for unconventional behavior is readily visible and primary ties to family and conventional friends are weak. In small towns, for example, people may conform even though they may not accept the moral standard because their deviance is easily visible to family and conventional friends.

Perhaps the major problem with this line of research was the failure to measure the disruptive processes directly and the tendency to infer them

from either remote causes such as industrialization and urbanization or more immediate causes such as the social, racial, and class composition of areas. Unable to solve this problem, the theory withered from the 1950s through the 1970s.

During the 1980s a group of young sociologists reexamined the theory to understand the renewed disorder of cities. Directly addressing the problem of measuring the processes that disrupt social control, Sampson and Groves (1989) show how community structural characteristics (such as racial, class, and ethnic composition; residential mobility; and divorce rate) affect crime by weakening ties to conventional institutions. Contrary to the early Chicagoans, Bursik (1986) shows that the ecological distribution of crime is no longer stable over time, that crime rates actually influence community characteristics, and that changes in these structures influence social deviance.

A third body of research examines the effectiveness of the criminal justice system in controlling crime. The underlying theory (deterrence) ignores inner controls and emphasizes punishment as the means of social control, particularly state-administered punishment. It assumes that people are rational and that crime is the result of calculating the costs and benefits of law violations; therefore, it assumes that, the higher the costs of crime, the lower the level of crime. As state-administered punishment is a significant cost of crime, it follows that the higher the level of such punishment, the lower the level of crime.

Two types of deterrence processes have been studied: general and specific. *General* refers to a process by which the punishment of some law violators provides information about the costs of crime to those unpunished (the general public), thereby reducing their law violations. *Specific* refers to a process by which punishment reduces the future law violations of those punished. Research focuses on three dimensions of punishment: severity, certainty, and celerity. *Severity* refers to the harshness of punishment, such as the length of incarceration; *certainty* refers to the probability of punishment, such as the likelihood of being arrested; and *celerity* refers to the swiftness of punishment. In sum, deterrence theory predicts that crime is lowest when punishment is severe, certain, and swift.

The political climate of the 1980s stimulated considerable interest in this theory, leading to hundreds of studies (Cook 1980). Yet, after all this research, it is still difficult to find any firm evidence for either specific or general deterrence. Regarding general deterrence, which has generated the bulk of the research, there is little consistent evidence of a severity effect. There is somewhat more evidence for a certainty effect, although its strength and duration remain unclear. For example, some studies suggest that, as certainty of punishment increases, crime rates decrease but that the decrease does not occur until certainty reaches about 30 percent, which is infrequently reached (Tittle and Rowe 1974). Some studies suggest that the certainty effect only occurs for crimes about which people have the opportunity to think and calculate, like property crimes, but not for violent crimes. And some studies of drunken driving suggest that the certainty effect occurs only if high certainty is well publicized, and even this effect is short lived (Ross 1984).

In sum, assuming that people are generally motivated to deviate, researchers have tried to understand how people are constrained from acting on their motives. Contemporary studies of social control focus on three areas: the interpersonal relationships that constrain people from acting on their motives, the macro structures and processes that provide the social foundation for these relationships, and the criminal justice system as a source of legal constraints.

SOCIAL CONTROL AS A DEPENDENT VARIABLE

During the 1960s sociologists began to question the assumption of normative consensus and stability and, thus, by implication the viability of the theories built on them. Without clear and stable reference points from which to judge behavior, deviance is difficult to define. Many sociologists came to define it in terms of visible social efforts to control it. Deviance is thus defined as that behavior that society controls, and deviants are defined as those people whom society controls. Research shifts from studying social control as a cause of deviance to studying the causes of social control.

Micro-level studies examine the social processes by which acts and people are defined, labeled, and treated as deviants by family, friends,

the public, and formal agencies of social control such as the criminal justice and mental health systems. Drawing on labeling and conflict theories, many sociologists argue that social control is directed against those who are least able to resist (the disadvantaged and the unfortunate) and that social-control agencies are used by the powerful to control the behavior of others.

During the 1960s, research reported that resources and power (as indicated by class, ethnicity, and race) significantly affect defining, treating, and controlling people as criminals (Black and Reiss 1970), such as arresting, prosecuting, and sentencing them. Unfortunately, these studies do not adjust for the effects of legal considerations, such as seriousness and frequency of offense, which are related to social resources. Without examining the effects of both legal and social resource variables in the same analysis it is difficult to isolate the effects of one from those of the other.

During the 1970s studies addressed this issue. The results are inconsistent, some studies showing race and class effects and some showing no such effects (Cohen and Kleugel 1978).

During the 1980s research tried to resolve these inconsistencies. One group of researchers tried to show that the effect of resources depends on the stage of the criminal justice process (e.g., arrest, prosecution) and the characteristics of the local community. Some stages may be more sensitive to social status and social power than are others, and some communities may be more sensitive to status and power than are others. Dannefer and Schutt (1982) report more racial discrimination at the arrest stage than at other stages, arguing that police have more discretion than do other decision makers, and they report more racial discrimination when the percentage of nonwhites is high, arguing that a high percentage of nonwhites is threatening to authorities.

Macro studies of social control examine the level and the form of social control across such units as cities, states, regions, and countries. They study why one form of control (physical pain) occurs at one time and place and another form (incarceration) occurs at another time and place.

Since the 1970s, conflict theory has provided the major stimulus for this research. It assumes that social control is more likely when the ruling

class or the authorities perceive their interests to be threatened. Threat is thought to be associated with the presence of disruptive acts (crime, civil disorders, social movements) and problematic people (the unemployed, minorities, the urban lower class). The theory assumes that, as disruptive acts and problematic people increase, authorities expand the capacity for social-control bureaucracies and pressure existing bureaucracies to expand the level of control.

Research has focused on the expansion and contraction of three such bureaucracies: the criminal justice system, the mental health system, and the welfare system. It generally suggests that the expansion of the criminal justice system is not necessarily a response to crime, that the expansion of the mental health system is not necessarily a response to mental health, and that the expansion of the welfare system is not necessarily a response to economic need. Rather the expansion and contraction of all three are responses by authorities to the acts and people deemed threatening to their interests.

Studies of the criminal justice system have examined the expansion of the police force in the late 1960s and 1970s, as an indicator of the potential for social control, and the expansion of the prison population in the 1980s, as an indicator of the actual level of control. Liska, Lawrence, and Benson (1981) report that, while the size of the police force is sensitive to the crime rate, it may be even more sensitive to the level of civil disorders, the relative size and segregation of the minority population, and the level of economic inequality. Studies of the prison population and admission rates show that, while these rates, too, are sensitive to the crime rate, they are equally sensitive to the size of problematic or threatening populations such as the unemployed. Studies in England, Canada, and the United States show a substantial relationship between the prison admission rate and the unemployment rate, adjusting for the crime rate (Berk et al. 1981; Inverarity and McCarthy 1988).

Some historical studies (Foucault 1965) assert that mental asylums emerged in the seventeenth century as another social mechanism for controlling the poor urban masses. During the twentieth century the population of mental asylums in the United States continually increased, reaching about

550,000 by the mid-1950s, while the prison population, in comparison, was less than 200,000 at the time. The mental health system seemed to be taking over the role of the criminal justice system in controlling problematic populations. However, since that time the trends for both bureaucracies have reversed. The mental asylum population has decreased from 500,000 to 150,000 and the prison population has increased from 200,000 to 300,000. These trend reversals have stimulated research to examine the extent to which the two bureaucracies are functional alternatives for controlling threatening or problematic populations and acts. Some research (Steadman 1979) studies how various threatening populations that in the past might have been admitted directly into asylums are now first processed in the criminal justice system. Then some of them remain in local jails and others, through various mechanisms such as pleas of *Incompetent to Stand Trial* and *Not Guilty by Reason of Insanity* are channeled into asylums.

Welfare is frequently conceptualized as a form of social control. Piven and Cloward (1971) have stimulated considerable controversy by arguing that the welfare expansion in the United States during the mid- and late 1960s was a response to the urban riots of that period, an attempt to control an economically deprived and threatening population. Various studies provide some support for this thesis. Schram and Turbett (1983) report that the riots affected welfare in two stages. Riots during the mid-1960s prodded the federal government to liberalize welfare policies generally; these policies were then more likely to be implemented in the late 1960s by those states experiencing the most rioting.

In sum, the 1970s and 1980s evidenced a research effort to explain the expansion and contraction of bureaucracies of social control, not so much as responses to crime, mental illness, or economic need, but as responses by authorities to control acts and populations deemed threatening to their interests.

The study of social control has come a long way since its inception at the birth of sociology, at which time it was vaguely defined and not distinguishable from the concept *social order*. Contemporary usage distinguishes the sources of social order from the order itself. The concept *socialization* has come to refer to internal sources of con-

trol, and the concept *social control* has come to refer to external sources of control, the processes whereby people conform to social norms because they are rewarded when they do and punished when they do not. Studying social control as an independent variable, a body of research examines the relative effects of interpersonal relations, social institutions, and formal agencies in constraining social behavior. Studying social control as a dependent variable, another body of research examines how social resources influence social control and how the aggregate amount and form of control varies over time and place.
