with regard to the timing of population changes or the regional variations observed within nations undergoing change.

FAMILY

Inkeles (1980) explored the effects of putative convergent tendencies discussed above for family patterns. While he found evidence of convergence in some aspects of family life, other patterns continue “to be remarkably stable in the face of great variation in their surrounding socio-economic conditions” (p. 34). Aspects of family life that show clear convergent patterns include the trend toward falling fertility rates and a shift in relative power and resource control in the direction of increasing autonomy of women and declining authority of parents. Other aspects of the family, such as age at first marriage, appear to present a more complex picture, with short-term fluctuations obscuring long-term changes, and great variation from one culture to another. Still other characteristics of family life seem resistant to change; cited as examples in Inkeles (1980) are cultural patterns such as veneration of elders in many Asian societies, basic human needs for companionship and psychological support, and the role of husbands helping wives with housework. In all, Inkeles (1980) estimates that only about half the indicators of family life he examined showed any convergence, and even then not always of a linear nature.

EDUCATION

Following Inkeles’ (1981) reformulation of convergence theory, Inkeles and Sirowy (1983) studied the educational systems of seventy-three rich and poor nations. Among thirty different “patterns of change” in educational systems examined, they found evidence of marked convergence in fourteen, moderate convergence in four, considerable variability in nine, mixed results in two, and divergence in only one. Based on these findings, they conclude that the tendency toward convergence on common structures is “pervasive and deep. It is manifested at all levels of the educational system, and affects virtually every major aspect of that system” (p. 326). Also worthy of note is that while the authors take the conventional position

that convergence is a response to pressures arising from a complex, technologically advanced social and economic system, they also identify diffusion via integration of networks through which ideas, standards, and practices in education are shared. These networks operate largely through international organizations, such as UNESCO and the OECD; their role as mediating structures in a process leading toward cross-national similarities in education constitutes an important addition to convergence theory, with wide-ranging implications for convergence in other institutions.

THE WELFARE STATE

The development of the welfare state has inspired active theoretical debate and empirical research on convergence theory, with researchers divided over the nature and extent of convergence found across nations. On the one hand, there is indisputable evidence that extensive social security, health care, and related benefit programs is restricted to nations that have reached a level of economic development where a sufficient surplus exists to support such efforts. Moreover, the development of programs of the welfare state appears to be empirically correlated with distinct bureaucratic and demographic patterns that are in turn grounded in economic development. For example, Wilensky (1975) found that among sixty nations studied the proportion of the population sixty-five years of age and older and the age of social security programs were the major determinants of levels of total welfare-state spending as a percent of gross national product. Since levels of economic development and growth of the elderly population both represent areas of convergence among advanced societies, it is reasonable to expect that patterns of welfare-state development will also tend to converge. Indeed, in such respects as the development of large and expensive pension and health-care programs, of which the elderly are the major clientele, this is the case (Coughlin and Armour 1982; Hage et al. 1989). Other empirical studies have found evidence of convergence in public attitudes toward constituent programs of the welfare state (Coughlin 1980), in egalitarian political movements affecting welfare effort across nations (Williamson and Weiss 1979), and in levels of spending (Pryor 1968), normative patterns (Mishra 1976), and social control functions of welfare-state

programs across capitalist and communist nations (Armour and Coughlin 1985).

Other researchers have challenged the idea of convergence in the welfare state. In a historical study of unemployment programs in thirteen Western European nations, Alber (1981) found no evidence that programs had become more alike in eligibility criteria, methods of financing, or generosity of benefits, although he did find some evidence of convergence in duration of unemployment benefits in nations with compulsory systems. A study conducted by O'Connor (1988) testing the convergence hypothesis with respect to trends in welfare spending from 1960 to 1980 concluded that "despite the adoption of apparently similar welfare programmes in economically developed countries there is not only diversity but divergence in welfare effort. Further, the level of divergence is increasing" (p. 295). A much broader challenge to the convergence hypothesis comes from studies focusing on variations in welfare-state development among western capitalist democracies. Hewitt (1977), Castles (1978, 1982), and Korpi (1983), to cite a few leading examples, argue that variations across nations in the strength and reformist character of labor unions and social democratic parties account for large differences in the levels of spending for and redistributive impact of welfare-state programs. However, the disagreement among these studies and scholars arguing for convergence may be simply a function of case selection. For example, in a study of nineteen rich nations, Wilensky (1976, 1981) linked cross-national diversity in the welfare state to differences in "democratic corporatism," and secondarily to the presence of Catholic political parties, thus rejecting the simplistic idea that the convergence observed across many nations at widely different levels of economic development extends to the often divergent policy developments in the relatively small number of advanced capitalist societies.

The debate over convergence in the welfare state is certain to continue. A major obstacle in resolving the question involves disagreement on the nations chosen for study, selection and construction of measures (see Uusitalo 1984), and judgments about the time frame appropriate for a definitive test of the convergence hypothesis. Wilensky et al. (1985, pp. 11-12) sum up the mixed status of current research on convergence in welfare-state development as follows:

Convergence theorists are surely on solid ground when they assert that programs to protect against the seven or eight basic risks of industrial life are primarily responses to economic development However, showing that societies have adopted the same basic programs. . . is only a partial demonstration of convergence insofar as it does not demonstrate convergence in substantive features of the programs or in the amount of variation among affluent countries compared to poor countries.

GLOBALIZATION

Growing attention to a variety of large-scale changes in economic relations, technology, and cultural relations, broadly subsumed under the description "globalization," has inspired renewed interest in the ideas of convergence and modernity (see Robertson 1992 for a critical account). The literature on globalization has several threads. One approach focuses on the economic and cultural impact of transnational capitalist enterprises that are judged to be responsible for the spread of a pervasive ideology and culture of consumerism (Sklair 1995). Ritzer (1993) summarizes this phenomenon as the "McDonaldization of society"—a broad reference to the ubiquity and influence of the consumer brand names (and the large corporate interests behind them) that are instantly recognizable in virtually every country in the world today. The main implication of this perspective is that indigenous industries, habits, and culture are rapidly being driven aside or even into extinction by the "juggernaut" of the world capitalist economy dominated by a relatively few powerful interests.

Meyer et al. (1997) provide a different interpretation of globalization in their work on "world society." Although they argue that "many features of the contemporary nation-state derive from a worldwide model constructed and propagated through global cultural and associational processes" (pp. 144-145), the essence of their position is that nations are drawn toward a model that is "surprisingly consensual. . . in virtually all the domains of rationalized social life" (p. 145). Meyer et al. contend that various core principles, such as those legitimating human rights and favoring environmentalism, do not emerge spontaneously as an imperative of modernity, but rather diffuse

rapidly among nations worldwide through the agency of international organizations, networks of scientists and professionals, and other forms of association. Although not referring specifically to convergence theory, this world society and culture approach makes a strong case for the emergence of widely shared structural and cultural similarities, many of which hold out the promise of improvement, among otherwise diverse nation-states.

The rapid growth of telecommunications and computing technology, especially apparent in the emergence of the Internet as a major social and economic phenomenon of the 1990s, presents yet another aspect of globalization that holds profound implications for possible societal convergence. However important and wide-ranging, the precise patterns that will ultimately emerge from these technological innovations are not yet clear. While new computing and communication technologies compress the time and space dimensions of social interaction (Giddens 1990), and have the potential to undercut national identities and cultural differences along the lines envisioned by McLuhan's (1960) "global village," the same forces of advanced technology that can level traditional differences may ultimately reinforce the boundaries of nation, culture, and social class. For example, even as the computers and related communication technologies become more ever more widely disseminated, access to and benefits from the new technologies appear to be disproportionately concentrated among the "haves," leaving the "have nots" more and more excluded from participation (Wresch 1996). Over time, such disparities might well serve to widen differences both across and within nations, thus leading toward divergence rather than convergence.

Finally, interest in convergence has also been given a boost by various political developments in the 1990s. In particular, the twin developments of the collapse of communism in Eastern Europe and the Soviet Union and the progressive weakening of economic and political barriers in Europe are notable in this regard. The demise of state socialism has revived interest in the possibilities of global economic and political convergence among advanced industrial societies (see, for example, Lenski et al. 1991, p. 261; Fukuyama 1992). Although ongoing economic and political turmoil in the "transition to capitalism" in the former Soviet

Union during the 1990s may cast serious doubt on the long-term prospects for convergence, developments have clearly moved in that direction with astonishing speed.

The continuing movement toward unification in Europe associated with the European Union (EU, formerly the European Community) represents another significant case of political and economic convergence on a regional scale. The gradual abolition of restrictions on trade, the movement of labor, and travel among EU nations (and not least of all the establishment of a single currency in 1999), and the harmonization of social policies throughout the EU, all signal profound changes toward growing convergence in the region that promises to continue into the twenty-first century.

CONCLUSION

The idea of convergence is both powerful and intuitively attractive to sociologists across a range of backgrounds and interests (Form 1979). It is difficult to conceive of an acceptable macro theory of social change that does not refer to the idea of convergence in one way or another. Despite the controversy over, and subsequent disillusionment with, early versions of convergence theory in the study of modernization, and the often mixed results of empirical studies discussed above, it is clear that the concept of societal convergence (and convergence theories that allow for the possibility of divergence and invariance) provides a useful and potentially powerful analytical framework within which to conduct cross-national studies across a broad range of social phenomena. Even where the convergence hypothesis ultimately ends up being rejected, the perspective offered by convergence theories can provide a useful point of departure for research. Appropriately reformulated, focused on elements of the social system amenable to empirical study, and stripped of the ideological baggage associated with its earlier versions, convergence theories hold promise to advance the understanding of the fundamental processes and regularities of social change.

RICHARD M. COUGHLIN

CONVERSATION ANALYSIS

Conversation analysis has evolved over several decades as a distinct variant of ethnomethodology. Its beginnings can be traced to the mid-1960s, to the doctoral research and the unpublished but widely circulated lectures of Harvey Sacks. Sacks was a University of California sociologist who had studied with Harold Garfinkel, the founder of the ethnomethodological movement, as well as with Erving Goffman. While not an ethnomethodologist, Goffman’s proposal that face-to-face interaction could be an analytically independent domain of inquiry certainly helped inspire Sacks’s work. Two other key figures whose writings (separately and together with Sacks) contributed to the emergence of conversation analysis were Gail Jefferson, one of Sacks’s first students, and Emanuel A. Schegloff, another sociologist trained in the University of California system who was decisively influenced by Garfinkel and, in much the same manner as Sacks, by Goffman (Schegloff 1988).

Sacks, like Garfinkel, was preoccupied with discovering the methods or procedures by which humans coordinate and organize their activities, and thus with the procedures of practical, common-sense reasoning in and through which “social

order” is locally constituted (Garfinkel [1967] 1984). In addressing this problem, he devised a remarkably innovative approach. Working with tapes and transcripts of telephone calls to a suicide prevention center (and with recordings of other, somewhat more mundane sorts of conversations), Sacks began examining the talk as an object in its own right, as a fundamental type of social action, rather than primarily as a resource for documenting other social processes. In short, Sacks came to recognize that the talk itself was the action. It was in the details of the talk that we could discover just how what was getting done in the activity was accomplished, systematically and procedurally, then and there, by the coparticipants themselves. This appeared to be an especially fruitful way of investigating the local production of social order.

As Schegloff (1989, p. 199) later wrote in a memoir of these first years, Sacks’s strategy in his pioneering studies was to first take note of how members of society, in some actual occasion of interaction, achieved some interactional effect—for example, in the suicide center calls, how to exhibit (and have others appreciate) that one has reasonably, accountably, arrived at the finding “I have no one to turn to”—and then to ask: Was this outcome accomplished methodically? Can we describe it as the product of a method of conduct, such that we can find other enactments of that method that will yield the same outcome, the same recognizable effect? This approach provided, Sacks suggested, an opportunity to develop formal accounts of “members’ methods” for conducting social life.

In this way, Sacks sought to address the basic question of (as he put it in one of his early manuscripts) “what it is that sociology can aim to do, and . . . how it can proceed” (Sacks [1964–1968] 1984, p. 21). Sociology, he argued, could be a “natural observational science,” concerned with the methodic organization of naturally occurring events, rather than with behavior that was manipulated through experimental techniques or other interventions such as surveys, interviews, and the like. And it could be committed to direct observation of this organization *in situ*, rather than dependent upon analytic theorizing and a concomitant reliance on idealized models of action.

Naturalistic observation also met the ethnomethodological mandate that all evidence

for the use of members' methods, and for members' orientation to or tacit knowledge of them, was to be derived exclusively from the observed behavior of the coparticipants in an interactional event. As Schegloff and Sacks (1973, p. 290) subsequently summarized the logic of this stance, if the event, the recorded conversational encounter, exhibited a methodically achieved orderliness, it "did so not only to us [the observing analysts], indeed not in the first place for us, but for the co-participants who had produced" it. After all, the task was to discover members' methods for coordinating and ordering conversational events, and these could not in any way be determined by analysts' conceptual stipulations or deduced from inventive theories.

The contrast with other methods and approaches for studying interactional processes could not be sharper, particularly with those methods adopted by Bales (1950) and Homans (1961) and their many followers, with their commitment to theoretically derived and precise operational definitions of social phenomena as a prerequisite to any scientific investigation (see Sacks 1992, vol. 1, p. 28 and p. 105, for his thinking on Bales and Homans). But Sacks's methodological stance contrasts even with those traditions usually regarded as neighbors of conversation analysis, such as symbolic interactionism and Goffman's "micro-Durkheimian" approach. These approaches assume that without an analytically stipulated conceptual scheme, there is no orderliness (or the orderliness cannot be seen) in what Garfinkel (1991) terms "the plenum"—the plentitude of members' lived experience.

Sacks was also making a well-reasoned argument for the importance of studying mundane conversation, directly confronting the belief that sociology's overriding concern should be the study of "big issues"; that is, the belief that the search for social order should center on the analysis of large-scale, massive institutions. Social order, he insisted, can be found "at all points," and the close study of what from conventional sociology's point of view seemed like small (and trivial) phenomena—the details of conversation's organization—might actually give us an enormous understanding of the way humans do things and the kinds of methods they use to order their affairs (Sacks [1964–1968] 1984, p. 24).

This last proposition bears special emphasis, for Sacks felt that these details went unnoticed,

and perhaps could not even be imagined, by conventional analytic sociology. When had sociologists concerned themselves with the profoundly methodic character of things like how to avoid giving your name without refusing to give it, he argued, or with how to get help for suicidalness without requesting it? Or with members' methods for things like "doing describing" and "recognizing a description," methods that provide for hearing the first two sentences from a story told by a young child—"The baby cried. The mommy picked it up."—as saying: The mommy who picked up the baby is the baby's mommy, and she picked it up because it was crying. Though apparently mundane, this observation provided the basis for a series of investigations regarding members' categorization methods and eventually came to provide for an entirely different approach to studies of social institutions and phenomena like race and gender. Sacks noted that since every person can be categorized at any time in various ways (for example, in terms of age, gender, or stage of life), a person's use of, or reliance on, one category rather than another to guide his or her actions with others must be grounded in one of a multitude of discoverable systems of relevance, some of which are potentially applicable in any situation, such as age, race, and gender, and others that are more limited in their use, such as occupationally defined categories or those made relevant by the organization of conversation itself, such as speaker/hearer, caller/called, and the like.

As these last examples of categories suggest, "membership analysis"—making sense of who someone is for the purpose of appropriately designing some next action—is an unremitting problem for members of a society, one that has to be solved in real time, and for which there is no single solution. Furthermore, who a person relevantly "is" for the purposes of some next action can change from moment to moment. As a consequence, Sacks pointed out that sociologists can no longer innocently categorize populations whatever way they (and their theories) see fit. Instead, analysts must similarly demonstrate the relevance of a category *to the participants* in any scene, as well as its consequentiality for them in terms of how the action proceeds, in order to ground its use in any sociological investigation (see Silverman 1998 for a useful summary of this argument).

Such grounding would stand in contrast to the epidemiological uses of categorization that underpin standard social scientific research. Sacks's colleague, anthropologist Michael Moerman (1974, pp. 67–68), once noted that social scientists “have an apparent inability to distinguish between warm . . . human bodies and one kind of identification device which some of those bodies sometimes use.” Further, since Sacks was primarily concerned with categorization as a thoroughly practical, procedural activity for members he was not much interested in the content of categories, with drawing the cultural grids that preoccupied cognitive anthropologists and many social psychologists. Instead, Sacks believed that by starting with the close study of actual events—such as members' observable use of categories *in situ*—and showing that they happened in an endogenously, socially organized manner, a much sounder basis for studying and understanding social life could be established.

It should be evident, then, that the appellation *conversation analysis* does not really capture the enterprise's commitment to addressing the most basic problem for the social sciences: the underlying character and structure of social action. As the title of one of Sacks's first publications, “An Initial Investigation of the Usability of Conversational Data for Doing Sociology,” makes clear, the use of recorded conversational materials was more of an opportunistic research strategy than a commitment to studying talk *per se* (Sacks 1972). Tape recordings of conversations constituted a record of the details of actual, singular events that could be replayed and studied extensively, and would permit other researchers direct access to exactly these same details. Still, for these identical reasons, it is conversation's organization—its detectable, orderly properties—that has remained the concrete object of study for the enterprise.

During years since the “initial investigations,” conversation analysis has given rise to a substantial research literature. Pursuing the lines of analysis first identified in the early studies while simultaneously opening up many new avenues of inquiry, researchers working in this tradition have produced findings that are, in the words of one contemporary practitioner, “strikingly cumulative and interlocking” (Heritage 1987, p. 256). Important collections of papers include those of Sudnow (1972), Schenkein (1978), Atkinson and Heritage (1984), Button and Lee (1987), and ten Have and

Psathas (1995). Sacks's lectures have now been edited and published in complete form (Sacks 1992). Special issues of *Sociological Inquiry*, *Social Psychology Quarterly*, *Human Studies*, *Social Problems*, *Research on Language and Social Interaction*, *Text*, and the *Western Journal of Speech Communication* have also been devoted to ethnomethodological and conversation-analytic topics.

Three major domains in conversation's organization identified in this literature are the organization of sequences, of turn taking, and of repair. These organizations can be described as systems of naturally organized activity, systems known and used by members as courses of practical action and practical reasoning, and designed to resolve generic problems of coordination that confront any conversationalist (and perhaps members of all social species). A sketch of some research findings with respect to these organizations should serve to illustrate how they function in this fashion, as well as the interlocking nature of their domains.

Consider first the organization of sequences. Begin with the fact that even the most cursory inspection of conversational materials reveals that talk-in-interaction has a serial arrangement to it. For example, in a conversation between two parties, party A will talk first, then party B, then A, then B, and so forth. Accordingly, in two-party conversations, turns at talk constitute a series of alternately produced utterances: ABABAB. But overlaying this serial arrangement of utterances are distinctly characterizable conversational sequences, where turns at talk do not simply happen to occur one after the other but rather “belong together” as a socio-organizational unit, and where there is thus a methodic relationship between the various turns or parts.

This methodic, structurally linked relationship between sequence parts is central to how sequences work in resolving coordination problems in conversation. This point can be demonstrated by briefly focusing on one of the earliest studies of sequence organization by Schegloff (1968), an investigation into how the initiation of conversational interactions is coordinated. Schegloff directed attention to a frequently occurring initial exchange, which was called a “summons-answer sequence.” This sequence is composed, he discovered, of closely linked parts. The production of the

first turn in the sequence, the summons, projected a relevant next action, an answer, to be accomplished by the recipient of the summons in the very next turn. Moreover, the occurrence of the expected answer cannot properly be the final turn in the exchange. The summons–answer exchange is therefore nonterminal: Upon production of the answer, the summoner is then expected to speak again, to provide the reason for the summons. This provides for a coordinated entry into conversation, and for the possibility of an extended spate of talk.

Observe that a set of mutual obligations is established by the structural relationships between these sequence parts, with each current action projecting some “next.” In the strongest form of these obligations (sequence classes vary in this regard), the property of “conditional relevance” holds between the parts of a sequence unit. A “summons–answer” sequence is but one type of a large class of utterance units, known as “adjacency pairs,” that are characterized by this property. Examples here include “greeting–greeting,” “question–answer,” and “invitation–acceptance/declination.” In adjacency pairs, when one utterance or action is conditionally relevant on another, the production of the first provides for the occurrence of the second. It could be said, then, using the example above, that the issuance of a summons is an action that selects a particular next action, an answer, for its recipient. If this action does not occur, its nonoccurrence will be a noticeable event. That is to say, it is not only nonoccurring, it is notably, “officially” absent; accordingly, this would warrant various inferences and actions. For instance, the summoner might infer that a recipient “didn’t hear me,” which would provide for the relevance and grounds of a repetition of the summons.

The discovery that human activities like conversation were coordinated and organized in a very fundamental way by such methodic relationships between actions, with some current or “first” action projecting and providing for some appropriate “second,” led to investigations into the various methods by which the recipient of a first may accomplish a second, or recognizably hold its accomplishment in abeyance until issues relevant to its performance are clarified or resolved, or avoid its accomplishment altogether by undertaking some other activity. Researchers learned, for

example, that for some firsts, there was not a single appropriate second but rather a range of alternative seconds. Note that in the examples of adjacency pair structures listed just above, invitations project either an acceptance or a declination as a course of action available to the recipient. In this case, and in others like “request–granting/denial” and “compliment–acceptance/rejection,” it was found that the alternative second parts are not generally of equal status; rather, some second parts are preferred and others dispreferred, these properties being distinct from the desires or motivations of the coparticipants. “Preference” thus refers to a structural rather than dispositional relationship between alternative but nonequivalent courses of action. Evidence for this includes distributional data across a wide range of speakers and settings, and, more important, the fact that preferred and dispreferred alternatives are regularly performed in distinctively different ways. The preference status of an action is therefore exhibited in how it is done.

Related to this, conversation analytic researchers observed that the producers of a first action often dealt in systematic, methodic ways with these properties of preference organization. To take one example, the producer of a request can and often does analyze the recipient silence that follows as displaying or implicating a denial—a denial as-yet-unstated, but nevertheless projected—and seeks to preempt the occurrence of this dispreferred action by issuing a subsequent version of the request, before the recipient starts to speak. Subsequent versions attempt to make the request more acceptable and provide another opportunity for a favorable response (Davidson 1984).

Moreover, members were observed to orient to the properties of preference organization through their performance of actions plainly meant to be understood as specifically preliminary to some adjacency pair first action. Such “pre”-type actions are designed to explore the likelihood that producing that first part of some pair will not be responded to in a dispreferred way. For instance, an utterance like “Are you doing anything tonight?” provides, in a methodical way, an opportunity for its producer to determine, without yet having to actually issue the invitation, whether it would most likely be declined. Similarly, this provides an opportunity for the recipient of the “pre”

to indicate that a dispreferred action would be forthcoming without ever having to perform that action. Additionally, because “pre” actions themselves engender sequences by making some response to them a relevant next action, they constitute the first part of a “pre-sequence.” It follows that since these and other features of preference organization together maximize the likelihood of preferred actions and minimize the likelihood of dispreferred ones, they serve as important structural resources for maintaining social solidarity and “preserving face.”

These interrelated observations on the organization of sequences were generalized outward in conversation analytic research from the relatively simple adjacency pair organization by the recognition that virtually every utterance occurs at some sequentially relevant, structurally defined place in talk (see especially Atkinson and Heritage 1984, pp. 5–9). Moreover, it is this placement that provides the primary context for an utterance’s intelligibility and understanding. Put another way, utterances are in the first place contextually understood by reference to their placement and participation within sequences of action, and it is therefore sequences of action, rather than single utterances or actions, that have become the primary units of analysis for the conversation-analytic enterprise. Accordingly, researchers in this tradition have not restricted themselves to studying only especially “tight” sequence units, but have instead broadened their investigations to (mentioning just a few) the sequencing of laughter, disputes, story and joke telling, political oratory, and the initiation and closing of topics. In addition, the sequential organization of gaze and body movement in relation to turns at talk has been the focus of some truly pathbreaking research using video recordings (see, for example, Goodwin 1981, 1994; Heath 1986).

Now let us consider the organization of turn taking, surely a central feature of virtually all talk-in-interaction. Recall that the prior discussion on the organization of sequences frequently made reference to sequence parts as “turns,” implicitly trading on the understanding that talk in conversation is produced in and built for turns, with recurring speaker change and a consequent serial ordering of utterances. In conversation, this turn ordering, as well as the size and content of each

turn, is not predetermined or allocated in advance. Instead, it is locally determined, moment-by-moment, by the coparticipants in the talk. In fact, this completely local determination of who speaks when, how long they speak, and what they might say or do in their turn, is what provides for talk being hearable as a “conversation,” rather than as, say, a debate or a ceremony of some kind. But this does not tell us just how—*methodically*—speaker change is achieved such that, ordinarily, one party talks at a time and there is little or no silence (or “gap”) between turns. Clearly, this requires close coordination among coparticipants in any conversational encounter. The systematic practices by which this is accomplished are analyzed by Sacks, Schegloff, and Jefferson in a 1974 paper that remains one of the most important in the conversation-analysis literature.

Basic to the accomplishment of turn taking is the practice of changing speakers at possible utterance completion places, what Sacks, Schegloff, and Jefferson term *transition relevance places*. How are such places, where speaker change may relevantly occur but is in no way guaranteed or required, discernable by members? A key feature of the units by and through which turns are constructed offers one resource here: For an utterance to be usable as a turn constructional unit, it must have a recognizable completion, and that completion must be recognizable prior to its occurrence (Sacks, Schegloff, and Jefferson [1974] 1978, p. 12). That is to say, its completion is projectable, and a coparticipant in the conversation who wishes to speak next can therefore begin his or her turn just at the place where the current speaker projects completion.

Of course, this does not preclude this coparticipant, or any other, from starting to speak elsewhere in the course of a current speaker’s turn. (Indeed, what actually constitutes a “turn at talk” is as locally and mutually determined as any other aspect of conversation’s organization, even as the resources for doing so are general ones.) There are various interactional moves that could involve, as one way they might be accomplished, this sort of action. At the same time, however, research on turn-taking has revealed that turns beginning elsewhere may well be met with procedures systematically designed to enforce the practice of starting at possible completion places. Further, features of the turn taking system such as that

described just above account for a great deal of the overlapping speech that can occasionally be observed. For instance, a speaker might append a tag question like “you know?” to his or her turn, while a coparticipant, having no resources available to project such an action, starts to speak just prior to or at the beginning of that appended tag, at the place that was projectably the “first possible completion” of the turn. This would result in overlapping speech, with both parties talking simultaneously. This was just one example; studies of “more than one party at a time” speech have uncovered massive evidence that its occurrence and its resolution (the restoration of one party at a time), as well as the solution to the problem of which overlapping action should then be consequential for next action, is methodically organized.

Having described the function of turn constructional practices in turn taking, Sacks, Schegloff, and Jefferson still faced the issue of how coparticipants, at possible completion places, determine just who will be the “next speaker” (note in this regard that conversation can involve more than two parties) or even if there will be a next speaker, given that a current speaker might want to continue talking. They discovered that to deal with this problem, members have available a “turn allocational component” for the system. This component consists of a set of ordered rules that come into play at transition relevance places and which provide for the methodic allocation of the right to produce a next turn, or more accurately, a turn constructional unit. In related research, methods for securing the temporary suspension of turn-taking procedures (to tell an extended story, for example) and for coordinating exit from the system (to end the conversation) have been documented.

Finally there is the entire set of procedures by which any troubles in speaking, hearing, and understanding talk are systematically handled and “repaired.” As Schegloff (1979, p. 269) points out, insofar as “any of the systems and contingencies implicated in the production and reception of talk—articulatory, memory, sequential, syntactic, auditory, ambient noise, etc.—can fail,” any piece of talk is susceptible to, or can reveal, troubles in speaking, hearing, or understanding. As a consequence, members of society must have some systematically organized set of methods for managing such trouble when it arises. Further, in order for interaction to serve as a primary site for the

coordination of social activity, any such troubles must be located and dealt with as quickly as possible to avoid whole stretches of talk developing on a problematic basis. Finally, this set of methods must provide the opportunity to discover and display trouble in speaking, hearing, or understanding by any of the ratified coparticipants to the interaction, while simultaneously managing such trouble from the variety of quarters from which it might arise, whether the trouble is noticed or produced by the current speaker or her recipient, and whether its source is endogenous to the interaction or impinges on it from outside.

When Schegloff, Sacks, and Jefferson (1977) began examining the related set of practices through which speakers managed such troubles they discovered two important features. First, they noticed that participants in interaction treat the initiation of repair as a separate matter from the actual accomplishment of a solution. That is, they distinguish between the various practices for locating a trouble source and making it the focus of the interaction and the set of practices for implementing a solution. Second, they observed that these two activities were not distributed evenly among the parties: The organization of repair exhibited a preference for self-repair and a preference for self-initiation of repair. And they went on to show that this latter feature is primarily a product of the way that the organization of repair relies on, and is fitted to, the system for distributing turns.

The organization of repair initiation operates in a restricted “repair initiation opportunity space” that is organized around the trouble source or “repairable.” Within this repair initiation opportunity space each party to an interaction moves through a series of discrete opportunities to locate and indicate potential and actual troubles. In turn, these discrete opportunities to initiate repair shape where (relative to the trouble source) a repair is effected, and by whom. The current speaker has the first opportunity to initiate repair on any trouble source within his or her own turn while still in the midst of it, or just after it is complete but before a next speaker starts. If they do initiate repair during (or immediately following the possible completion of) their own turn, such speakers also have the first opportunity to effect repair as well.

Of course, as we noted above, conversation is characterized by the alternation between current

and next, thus once a current speaker completes her turn a next speaker begins, typically by addressing herself to that just-prior talk. Accordingly, if a next speaker has some trouble with the prior speaker's turn, the next turn is the place where she can initiate repair (using a variety of forms, including "what?" and "huh?" and other designs that vary in the degree to which they specify the exact source of trouble). By initiating repair using one of these methods, that speaker selects the speaker of the trouble source to speak next, and to offer a solution to the trouble indicated. If the next speaker has no trouble with the prior turn, and she uses it to move the action forward (instead of stopping it to initiate repair), her turn will display a variety of understandings regarding the talk it follows. In doing so, her turn may also reveal some type of misunderstanding (from the point of view of the speaker of the prior turn). If that occurs the speaker of the prior turn can then initiate repair in "turn after next" (or "third position") and offer a solution immediately. Perhaps the recurrent and recognizable format for this is "I don't mean *x*, I mean *y*."

Thus, the movement of talk through these three positions—current, next turn, and turn after next—systematically provides the various parties to the interaction the opportunity to detect any trouble in speaking, hearing, and understanding, whatever its source, and initiate repair on it. As a consequence almost all instances of repair are initiated in one of these adjacent locations. The localization of repair initiation opportunities, and the distribution of them over three turns, has several consequences for the organization of social life. First, the localization of repair within a finite, and relatively restricted, space ensures that trouble is dealt with swiftly. Second, and related to this, given the systematic relevance of repair, if speakers move through these three positions without any party initiating repair, a shared understanding of the talk is thereby confirmed *en passant*.

Finally, as with sequence organization, the issue of preference is best grasped as a structural property of the organization of talk-in-interaction (rather than being a product of concerns regarding the private desires of the parties). The two preferences observed by Schegloff, Sacks, and Jefferson are a product of the distribution of opportunities to initiate and effect repair that systematically favors the speaker of the trouble source over

others. As Sacks, Schegloff, and Jefferson ([1974] 1978, p. 40) put it, the organization of turn taking and the organization of repair "are thus 'made for each other' in a double sense." It is worth noting in this regard that insofar as interaction provides the primary site for the achievement of intersubjectivity, for what makes sociality possible, the organization of repair constitutes its last line of defense (Schegloff 1994).

Taken together, the operation of the turn-taking system and the practices involved in the organization of sequences and repair account for many of the detectable, orderly features of conversation. This orderliness was shown to be locally organized and managed, the product of members' methods. It will be useful to make note once again of the research strategy that enabled such findings. Because the data consisted of recordings of naturally occurring activity, a scientific account of the phenomenon under investigation could be empirically grounded in the details of actual occurrences. The investigation began with a set of observable outcomes of these occurrences—in the case of turn taking, for example, speaker change overwhelmingly recurred; overwhelmingly, one party talked at a time; turn order, size, and content were not fixed, but varied; and so on. It was then asked: Could these outcomes be described as products of certain social organized practices, of methods of conduct? At the same time, if members of society did in fact use such formal methods, how were they systematically employed to produce just those outcomes, in just those occurrences, in all their specificity? In addressing the problem in this way, then, conversation analysis was able to discover how cardinal forms of social order were locally constituted.

The research on turn taking in conversation has provided one starting point for more recent studies of interaction in "institutional" settings, such as news interviews, doctor-patient and other clinical consultations, courtrooms, plea bargaining sessions, job interviews, and citizen calls to emergency services. In many of these studies, researchers pursued Sacks, Schegloff, and Jefferson's ([1974] 1978, pp. 45–47) suggestion that the practices underlying the management of ordinary conversation are the "base" or primary ones (for an example, see Heritage and Maynard in press).

Other forms of interaction—in this case, so-called “institutional” forms—are in part constituted and recognizable through systematic variations from conversational turn taking, or through the narrowing and respecification of particular conversational practices involved in the organization of sequences, repair, and other activities.

Take the case of courtroom interaction. The turn-taking system operative in these encounters places restrictions on turn construction and allocation: Coparticipants ordinarily restrict themselves to producing turns that are at least minimally recognizable as “questions” and “answers,” and these turn types are pre-allocated to different parties rather than locally determined. The relatively restricted patterns of conduct observable in these settings is, in large part, the product of this form of turn taking. Accordingly, variation in turn taking in such settings has been shown to have a “pervasive influence both on the range and design of the interactional activities which the different parties routinely undertake and on the detailed management of such encounters” (Heritage 1987, p. 261; Atkinson and Drew 1979).

Note that throughout the above discussion, the term “institutional” has been presented with quotation marks around it. This was done to emphasize ethnomethodology’s preoccupation with the local production of social order. From this view, that some activity or encounter is recognizably either an “ordinary conversation” or more “institutional” in nature—for example, is recognizably a “cross-examination,” a “call to the police,” a “clinical consultation,” or whatever—is something that the coparticipants can and do realize, procedurally, at each and every moment of the encounter. The task for the analyst is to demonstrate how they actually do this; how, for example, they construct their conduct, turn by turn, so as to progressively constitute and thus jointly and collaboratively realize the occasion of their encounter, together with their own social roles in it, as having some distinctively institutional sense (Heritage and Greatbatch 1991). Conversation analytic research on “institutional” interaction has therefore undertaken, through its investigations into the methodic practices by which this gets done, a systematic study of a wide range of human activities.

This mode of research, with its commitment to understanding precisely how any activity becomes what it recognizably and accountably is—that is to say, how it acquires its social facticity—has tended to focus in the 1990s on work activities and settings, under the rubric of “workplace studies.” The scope of investigation has expanded to encompass all forms of “embodied action” (that is, not only the talk), with extensive use of video recordings and, influenced by Suchman’s (1987) pioneering study of human-machine interaction, with careful attention to how the machines, technologies, and other artifacts that saturate the modern work site are taken up and enter into the endogenous organization of work tasks (see, for example, Whalen (1995), and the papers collected in Luff, Hindmarsh, and Heath in press).

Research into conversation’s organization also continues to evolve. While there has been relatively little work that attempts to fundamentally deepen the original account of the turn-taking system developed by Sacks, Schegloff, and Jefferson (for a notable exception see Lerner 1996), there has been important research at the intersection of grammar and interaction—recognizing that talk-in-interaction is in fact the natural home of human language. This work demonstrates that the approach to language taken Chomsky’s Transformational Grammar could be supplanted by one based on naturalistic study of the “grammar for conversation.” Given that Chomsky’s approach has decisively shaped, both directly and indirectly, the understanding of language in cognitive science, psychology, computational linguistics, and the other disciplines that rely on a model of grammatical organization for their own research, these findings are plainly significant.

Conversation analytic work on grammar and interaction was launched by Schegloff’s (1979) paper on the “relevance of repair for a syntax for conversation.” This line of work has underscored the need for studies of language to draw on naturally occurring spates of talk. As Schegloff observed, while nearly every episode of ordinary talk contains instances of repair within the “sentences” (or sentential turn constructional units) out of which it is built, the entire view of language developed by linguists is based on imagined (or what might as well be imagined) instances of language

that are free of such repair. Schegloff went on to show that most instances of talk-in-interaction, at least in English, are organized by reference to the systematic relevance of repair, whether an instance of it actually occurs in the sentence or not.

Of course repair is not the only organization relevant for grammar, and so more recently scholars have begun to examine what more might be learned about language by studying it as produced in naturally occurring interaction. With respect to this problem, conversation analysts have argued that insofar as language most likely evolved in face-to-face encounters by members of our species, its structure and organization must have evolved, at least in part, to manage the basic exigencies confronted by speakers and hearers. Thus, in addition to the systematic relevance of repair, the structure and organization of grammar most likely evolved as resources that shape, and are shaped by, how opportunities to speak are distributed, what constraints are introduced by a current turn on subsequent ones, and how speakers' formulations of the events, persons, and objects are organized. Perhaps most developed are a series of findings that link the organization of grammar and the system for distributing turns at talk briefly described above.

As we stated earlier regarding turn-constructive units, one of their key features is that each sentence, or utterance, projects from its beginning roughly what it will take for it to be possibly complete. And over its course, each utterance projects in finer and finer detail the exact moment that a speaker may end her utterance. Thus, instead of expressing logical predicates or cognitive states, grammar may be best understood, in the first instance, as a sequentially sensitive resource that progressively projects the course and duration of turns at talk (Ford and Thompson 1996).

One of the most striking consequences of such a view of grammar is that the locus of its organization is transformed. While most approaches to grammar rely on the sentence as the basic unit of organization (with occasional nods to the organization of "discourse"), the grammatical units produced in interaction are fundamentally organized relative to their sequential environment, most proximally the just prior, current, and next turns. Thus, rather than the sentence, or even discourse, being the fundamental unit or environment of

analysis, interaction and sequences of turns appear to be that within which grammar is most proximally organized. This appears to be true even at levels beneath the turn whether a sentence, clause, or phrase. As Schegloff (1996) shows, turn beginnings and turn endings, as well as what happens in between, are sites of strategic manipulation. Through this manipulation, both grammatical and prosodic, speakers fit their utterances to prior talk, launch new actions, and shape when they will be heard as possibly complete. Any scientific analysis of language, then, must take into account this central function.

Thus, as the collection of papers assembled in Ochs, Schegloff, and Thompson (1996) suggest, rather than viewing grammar as an independent, clearly delineated, and internally coherent structure, it is best approached as one more of the interrelated set of resources through which interaction, and social life more broadly, is organized.

CORPORATE ORGANIZATIONS

NOTE: *Although the following article has not been revised for this edition of the Encyclopedia, the substantive coverage is currently appropriate. The editors have provided a list of recent works at the end of the article to facilitate research and exploration of the topic.*

Societies carry out many of their activities through formal organizations. Organizations are units in which offices, or positions, have distinct but interdependent duties. Organizations—hospitals, schools, governments, business firms—share certain features. Usually, at least one of the offices serves as the linchpin: It coordinates the separate duties within the organization. The key office has ultimate authority in that the orders it issues constrain the actions of lower-level offices.

But organizations also differ from one another. In some, the assets belong to particular individuals. In others, ownership resides in a collectivity. The latter represents a corporate organization or *corporation*. Three features describe the modern corporation. First, it has certain legal rights and privileges. By law, a corporation can sue and be sued in the courts, make contracts, and purchase and receive property. Second, it usually exists in perpetuity: It outlasts the individuals who set it up. Ownership rests with stockholders, whose numbers and makeup can change from one time to another. Third, the owners have only a limited responsibility for the obligations the corporation makes.

These features distinguish the corporate organization from two other forms of ownership: the

proprietorship and the *partnership*. In a proprietorship a particular person owns the property of the organization; in a partnership, two or more persons share it. The right to handle the property and affairs of the organization rests with a designated proprietor or set of partners. Significantly, proprietors and partners bear personal responsibility for the debts of the organization.

The corporation constitutes a social invention. The form evolved to handle problems that arose within religious, political, and other kinds of communities. It holds a place of importance in contemporary Western societies. Because it is the product of social conditions and an influence on them, the corporation represents a topic of substantial interest in sociology.

At present, the corporation appears commonly within the world of business. But when the corporation began to take shape during the Middle Ages, the questions to be resolved lay outside that realm. One of these questions had to do with church ownership. In medieval Germany, landowners often set up churches on their estates and placed a priest in charge of them. As priests gained authority over their charges, they argued that the church and the land surrounding it no longer belonged to the donor. Deciding the true owner proved to be difficult. A given priest could die or be replaced; hence, any particular priest seemed to have no claim to ownership. One practice regarded the owner to be the saint whose name the church bore. Eventually, the idea developed that ownership inhered in the church, and that the church constituted a body independent of its current leaders or members (Coleman 1974; Stone 1975).

Thorny problems also arose as medieval settlements formed into towns. A town required someone to manage its affairs such as collecting tolls and transacting other business. But the laws that prevailed at the time applied only to individuals. Any actions individuals took obligated them personally. By this principle, managers would have to meet any commitments they made on behalf of the town. To eliminate the dilemmas that the principle situation posed, new laws made the town a corporate person. The corporate person would have all the rights and privileges of any human being. This action reduced the risks that public service might otherwise entail. For many of the same reasons

that the church and town became corporate persons, the university of the Middle Ages moved towards the corporate form.

The early corporations played rather passive roles. Essentially, they held property for a collective, whose members might change from time to time. Contrastingly, the corporations of the twentieth century constitute spirited forces. They hire multitudes of employees. They produce goods and services and mold ideals and tastes. The decisions their leaders make about where to locate often determine which locales will prosper and which will languish.

The influence that corporations have produces concerns about the control of them. Much of the work on corporations that sociologists have undertaken highlights these concerns. The work on control and corporations covers three topics: the means through which corporations control their employees; the allocation of control between owners and managers; and the extent to which societies control corporations. For all three topics, control implies command over the affairs of and operations within the corporate organization.

CONTROL OVER EMPLOYEES

The corporate form has a long history, yet it did not typify the early factories that manufacturers established in the United States. Before the early 1900s, most factories operated as small operations under the control of a single entrepreneur. The entrepreneur hired an overseer who might in turn choose a foreman to hire, discipline, and fire workers. Through consolidation and merger, the economic landscape of the 1920s revealed far more large organizations than had the tableau of a half-century earlier.

More changed over the years of the late nineteenth and early twentieth centuries than just the size of organizations. The corporate form spread; the faceless corporation replaced the corporeal entrepreneur. Corporations moved towards professional management. Factories that businessmen once controlled personally now operated through abstract rules and procedures. The people whom the workers now contacted on a regular basis consisted of staff for the corporation and not the corporate owners themselves. Bureaucratic tenets took root.

A bureaucracy constitutes a particular mode that organizations can take. Consistent with all organizations, bureaucratic ones divide up duties. Two features separate a bureaucracy from other modes, however. First, a system of ranks or levels operates. Second, fixed rules and procedures govern actions. The rules define the tasks, responsibilities, and authority for each office and each level.

Few of the factories in nineteenth-century America operated as bureaucracies. Instead, the individuals who made the products decided how the work would be done. A minimum number of levels existed. Supervisors or foremen hired and fired workers, but workers made the rules on the work itself. The workers were craftsmen or artisans, and they contended that only those who possessed the skills that the work demands should decide how or if it should be divided. Gradually, machinery took over the skilled work. Machines and not workers controlled the pace. By the end of the 1920s, neither the laborers nor the machinery shaped the work. Professional managers did. These managers enforced rules and oversaw an organization where specialized tasks and graded authority prevailed (Nelson 1975; Clawson 1980; and Jacoby 1985).

The corporation of the late twentieth century continues to operate as a bureaucracy. Some sources argue that efficiency explains the adoption of the bureaucratic model (see especially Chandler 1980, 1984). Others challenge the emphasis on efficiency, charging it with being overly rational or too apolitical. The first challenge appears most notably in the work on organizations as institutions. This literature regards survival as the premier goal for any organization. The closer an organization approximates an institution—an element taken for granted in the society—the greater its chances for survival.

According to the institutional perspective, organizations adopt practices that appear to be reasonable. Myths develop about which patterns prove most useful and efficient, and any organization that does not adopt a pattern that the myth favors courts failure (Meyer and Rowan 1977; DiMaggio 1988; DiMaggio and Powell 1983; Tolbert and Zucker 1983; also see Scott 1987 for a review of the different branches of institutional theory).

A different argument maintains that the emphasis on efficiency fails to capture the politics of

corporations. This perspective treats corporations as systems in which the interests of owners clash with those of workers. Owners, it asserts, seek to reduce uncertainties and to eliminate the vagaries that can plague organizations. From this angle, bureaucracy serves the interests of owners primarily because it reduces the influence that workers exercise and thereby removes a source of uncertainty (Braverman 1974; Edwards 1979).

Workers need not have formal authority in order to affect outcomes within organizations. Studies document the creative ways in which employees enliven monotonous jobs and pursue their own ends (Roy 1952; Mechanic 1962; Burawoy 1979, 1985). Yet, officially, the higher levels have greater power than have the lower levels. This is the consequence of the bureaucratic nature of corporations, not of their pattern of ownership. The bureaucratic mode is not unique to corporations. Proprietorships and partnerships can display the traits of bureaucracy. The diffuseness of ownership that one finds in the corporation possibly makes formal control less obvious than obtains when ownership resides in identifiable persons.

OWNER VERSUS MANAGERIAL CONTROL

Managers occupy important places in the contemporary organization. One argument regards managers as more powerful than stockholders. Adolph Berle and Gardiner Means offered this argument in the 1930s. As Berle and Means saw the situation, stockholding had become too widely dispersed for any individual holder or even group of holders to command corporations. Managers, they contended, filled the void (Berle and Means 1932). Later discussions echoed the thesis that the expansion of the corporate form had raised the power of corporate managers (Berg and Zald 1978; also see Chandler 1962, 1977).

Critics contend that the thesis overstates the role and power of managers. They base their criticism on studies of the influence that corporate leaders wield. Maurice Zeitlin (1974) helped launch this line of research when he argued that few scholars had tested the Berle and Means thesis and that the handful of extant studies showed owners to be less fractious and fractionated than the thesis supposed. Michael Useem (1984), among others,

heeded the call from Zeitlin for research on the networks that link shareholders. Useem concluded from his study on contacts and networks among large shareholders that a corporate community operated, held together by an inner circle whose interests transcended company, region, and industry lines. Beth Mintz and Michael Schwartz (1985) examined the connections between financial institutions and other corporations and decided that control over corporate directions rested disproportionately in the world of finance. The work from the critics cautions us against the assumption that a multiplicity of owners implies control by managers.

SOCIAL CONTROL OVER CORPORATIONS

The corporate form constitutes a remarkable innovation. But as the corporation has become ever more active and entrenched, it has generated problems for society. Corporations have at times engaged in criminal behavior (Sutherland 1949; Clinard and Yeager 1980). At other times, their actions have violated no law but have put the well-being of the public at risk. Both situations often show the inadequacy of the mechanisms through which society attempts to control corporations.

Corporations are creatures of the state. Ostensibly, then, they operate only at the indulgence of the state. But myriad corporations now have greater resources than do the states that chartered them. Moreover, the laws that states have at their disposal often fit individuals better than they do corporations. Corporations can be sued for wrongdoing; but a fine that would bankrupt an individual might be a mere pittance for a large corporation. Both James Coleman (1974) and Christopher Stone (1975) have argued that the law can never be the sole means for controlling corporations; a sense of responsibility to the public must prevail within corporations.

Even if the law were shown to be effective in constraining corporations within a state, it might prove rather impotent in the case of multinational organizations. A multinational or transnational corporation holds a charter from one nation-state but transacts business in at least one other. The governmental entity that issues the charter cannot alter the policies the corporation pursues in its

other locales. In addition, the very size of many multinationals restricts the pressure that either the home or the host country can impose.

Through various actions corporations demonstrate that they are attentive to the societies they inhabit. Corporate leaders serve on the boards of social service agencies; corporate foundations provide funds for community programs; employees donate their time to local causes. The agenda of corporations long have included these and similar activities. Increasingly, the agenda organize such actions around the idea of corporate social responsibility. Acting responsibly means taking steps to promote the commonweal (Steckmest 1982).

Some corporations strive more consistently to advance social ends than do others. Differences in norms and values apparently explain the contrast. Norms, or maxims for behavior, indicate the culture of the organization (Deal and Kennedy 1982). The culture of some settings gives the highest priority to actions that protect the health, safety, and welfare of citizens and their heirs. Elsewhere, those are not what the culture emphasizes (Clinard 1983; Victor and Cullen 1988).

The large corporation had become such a dominant force by the 1980s that no one envisioned a return to an era of small, diffuse organizations. Yet, during that decade some sectors had started to move from growth to contraction. At times, the shift resulted from legislative action. When the Bell Telephone System divided in 1984, by order of the courts, the change marked a sharp reversal. For more than a century the system had glided toward integration and standardization (Barnett and Carroll 1987; Barnett 1990).

Whether through fiat or choice, corporations contract (Whetten 1987; Hambrick and D'Aveni 1988). Two perspectives associate the rise and fall in the fortunes of corporations to changes in the social context. The first perspective, resource dependence, centers on the idea that organizations must secure their resources from their environs (McCarthy and Zald 1977; Jenkins 1983). When those environs contain a wealth of resources—personnel in the numbers and with the qualifications the organization requires, funds to finance operations—the corporation can thrive. When hard times plague the environs, the corporation escapes that fate only with great difficulty.

The perspective known as population ecology likewise connects the destiny of organizations to conditions in their surroundings. Population ecologists think of organizations as members of a population. Changing social conditions can enrich or impoverish a population. Individual units within it can do little to offset the tide of events that threatens to envelop the entire population. (Hannan and Freeman 1988; Wholey and Brittain 1989; for a critique of the approach see Young 1988).

Neither resource dependency theory nor population ecology theory focuses explicitly on the corporate form. But just as analyses of corporations inform the discussions sociologists have undertaken on formal organizations, models drawn from studies of organizations have proved useful as scholars have tracked the progress of corporations.

The corporation clearly constitutes a power to be reckoned with. As with its precursors, the modern corporation serves needs that collectivities develop. In fact, the corporation rests on an assumption that is fundamental in sociology: A collectivity has an identity of its own. But the corporation of the twentieth century touches more than those persons who own its assets or produce its goods. This social instrument of the Middle Ages is now a social fixture.

CORRELATION AND REGRESSION ANALYSIS

In 1885, Francis Galton, a British biologist, published a paper in which he demonstrated with graphs and tables that the children of very tall

parents were, on average, shorter than their parents, while the children of very short parents tended to exceed their parents in height (cited in Walker 1929). Galton referred to this as “reversion” or the “law of regression” (i.e., regression to the average height of the species). Galton also saw in his graphs and tables a feature that he named the “co-relation” between variables. The stature of kinsmen are “co-related” variables, Galton stated, meaning, for example, that when the father was taller than average, his son was likely also to be taller than average. Although Galton devised a way of summarizing in a single figure the degree of “co-relation” between two variables, it was Galton’s associate Karl Pearson who developed the “coefficient of correlation,” as it is now applied. Galton’s original interest, the phenomenon of regression toward the mean, is no longer germane to contemporary correlation and regression analysis, but the term “regression” has been retained with a modified meaning.

Although Galton and Pearson originally focused their attention on bivariate (two variables) correlation and regression, in current applications more than two variables are typically incorporated into the analysis to yield partial correlation coefficients, multiple regression analysis, and several related techniques that facilitate the informed interpretation of the linkages between pairs of variables. This summary begins with two variables and then moves to the consideration of more than two variables.

Consider a very large sample of cases, with a measure of some variable, X , and another variable, Y , for each case. To make the illustration more concrete, consider a large number of adults and, for each, a measure of their education (years of school completed = X) and their income (dollars earned over the past twelve months = Y). Subdivide these adults by years of school completed, and for each such subset compute a mean income for a given level of education. Each such mean is called a *conditional mean* and is represented by $\bar{Y}|X$, that is, the mean of Y for a given value of X .

Imagine now an ordered arrangement of the subsets from left to right according to the years of school completed, with zero years of school on the left, followed by one year of school, and so on through the maximum number of years of school completed in this set of cases, as shown in Figure 1.

Assume that each of the $\bar{Y}|X$ values (i.e., the mean income for each level of education) falls on a straight line, as in Figure 1. This straight line is the *regression line of Y on X* . Thus the regression line of Y on X is the line that passes through the mean Y for each value of X —for example, the mean income for each educational level.

If this regression line is a straight line, as shown in Figure 1, then the income associated with each additional year of school completed is the same whether that additional year of school represents an increase, for example, from six to seven years of school completed or from twelve to thirteen years. While one can analyze curvilinear regression, a straight regression line greatly simplifies the analysis. Some (but not all) curvilinear regressions can be made into straight-line regressions by a relatively simple transformation of one of the variables (e.g., taking a logarithm). The common assumption that the regression line is a straight line is known as the *assumption of rectilinearity*, or more commonly (even if less precisely) as the *assumption of linearity*.

The slope of the regression line reflects one feature of the relationship between two variables. If the regression line slopes “uphill,” as in Figure 1, then Y increases as X increases, and the steeper the slope, the more Y increases for each unit increase in X . In contrast, if the regression line slopes “downhill” as one moves from left to right, Y *decreases* as X increases, and the steeper the slope, the more Y decreases for each unit increase in X . If the regression line doesn’t slope at all but is perfectly horizontal, then there is no relationship between the variables. But the slope does not tell how closely the two variables are “co-related” (i.e., how closely the values of Y cluster around the regression line).

A regression line may be represented by a simple mathematical formula for a straight line. Thus:

$$\bar{Y}|X = a_{yx} + b_{yx}X \quad (1)$$

where $\bar{Y}|X$ = the mean Y for a given value of X , or the regression line values of Y given X ; a_{yx} = the Y intercept (i.e., the predicted value of $\bar{Y}|X$ when $X = 0$); and b_{yx} = the slope of the regression of Y on X (i.e., the amount by which $\bar{Y}|X$ increases or decreases—depending on whether b is positive or negative—for each one-unit increase in X).

Figure 1. Hypothetical Regression of Income on Education

Equation 1 is commonly written in a slightly different form:

$$\hat{Y} = a_{yx} + b_{yx}X \quad (2)$$

where \hat{Y} = the regression prediction for Y for a given value of X, and a_{yx} and b_{yx} are as defined above, with \hat{Y} substituted for $\bar{Y}|X$.

Equations 1 and 2 are theoretically equivalent. Equation 1 highlights the fact that the points on the regression line are assumed to represent conditional means (i.e., the mean Y for a given X). Equation 2 highlights the fact that points on the regression line are not ordinarily found by computing a series of conditional means, but are found by alternative computational procedures.

Typically the number of cases is insufficient to yield a stable estimate of each of a series of conditional means, one for each level of X. Means based on a relatively small number of cases are inaccurate because of sampling variation, and a line connecting such unstable conditional means may not be straight even though the true regression line is. Hence, one assumes that the regression line is a straight line unless there are compelling reasons for assuming otherwise; one can then use the X and Y values for all cases together to estimate the Y intercept, a_{yx} , and the slope, b_{yx} , of the regression line that is best fit by the *criterion of least squares*. This criterion requires predicted values for Y that will minimize the sum of squared deviations between the predicted values and the observed values. Hence, a “least squares” regression line is the straight line that yields a lower sum of squared deviations between the predicted (regression line) values and the observed values than does any other straight line. One can find the parameters of the “least squares” regression line for a given set of X and Y values by computing

$$b_{yx} = \frac{\sum (X - \bar{X})(Y - \bar{Y})}{\sum (X - \bar{X})^2} \quad (3)$$

$$a_{yx} = \bar{Y} - b_{yx}\bar{X} \quad (4)$$

These parameters (substituted in equation 2) describe the straight regression line that best fits by the criterion of least squares. By substituting the X value for a given case into equation 2, one can then find \hat{Y} for that case. Otherwise stated, once a_{yx} and b_{yx} have been computed, equation 2 will yield a precise predicted income level (\hat{Y}) for each education level.

These predicted values may be relatively good or relatively poor predictions, depending on whether the actual values of Y cluster closely around the predicted values on the regression line or spread themselves widely around that line. The *variance* of the Y values (income levels in this illustration) around the regression line will be relatively small if the Y values cluster closely around the predicted values (i.e., when the regression line provides relatively good predictions). On the other hand, the variance of Y values around the regression line will be relatively large if the Y values are spread widely around the predicted values (i.e., when the regression line provides relatively poor predictions). The

variance of the Y values around the regression predictions is defined as the mean of the squared deviations between them. The variances around each of the values along the regression line are assumed to be equal. This is known as the assumption of *homoscedasticity* (homogeneous scatter or variance). When the variances of the Y values around the regression predictions are larger for some values of X than for others (i.e., when homoscedasticity is not present), then X serves as a better predictor of Y in one part of its range than in another. The homoscedasticity assumption is usually at least approximately true.

The variance around the regression line is a measure of the accuracy of the regression predictions. But it is not an easily interpreted measure of the degree of correlation because it has not been “normed” to vary within a limited range. Two other measures, closely related to each other, provide such a normed measure. These measures, which are always between zero and one in absolute value (i.e., sign disregarded) are: (a) the correlation coefficient, r , which is the measure devised by Karl Pearson; and (b) the square of that coefficient, r^2 , which, unlike r , can be interpreted as a percentage.

Pearson’s correlation coefficient, r , can be computed using the following formula:

$$r_{yx} = r_{xy} = \frac{\frac{\sum (X - \bar{X})(Y - \bar{Y})}{N}}{\sqrt{\left(\frac{\sum (X - \bar{X})^2}{N}\right)\left(\frac{\sum (Y - \bar{Y})^2}{N}\right)}} \quad (5)$$

The numerator in equation 5 is known as the *covariance* of X and Y. The denominator is the square root of the product of the variances of X and Y. Hence, equation 5 may be rewritten:

$$r_{yx} = r_{xy} = \frac{\text{Covariance (X, Y)}}{\sqrt{[\text{Variance (X)}][\text{Variance (Y)}]}} \quad (6)$$

While equation 5 may serve as a computing guide, neither equation 5 nor equation 6 tells why it describes the degree to which two variables covary. Such understanding may be enhanced by stating that r is the slope of the least squares regression line when both X and Y have been

transformed into “standard deviates” or “z measures.” Each value in a distribution may be transformed into a “z measure” by finding its deviation from the mean of the distribution and dividing by the standard deviation (the square root of the variance) of that distribution. Thus

$$Z_x = \frac{X - \bar{X}}{\sqrt{\frac{\sum (X - \bar{X})^2}{N}}} \quad (7)$$

When both the X and Y measures have been thus standardized, $r_{yx} = r_{xy}$ is the slope of the regression of Y on X, and of X on Y. For standard deviates, the Y intercept is necessarily 0, and the following equation holds:

$$\hat{Z}_y = r_{yx} Z_x \quad (8)$$

where \hat{Z}_y = the regression prediction for the “Z measure” of Y, given X; Z_x = the standard deviates of X; and $r_{yx} = r_{xy}$ = the Pearsonian correlation between X and Y.

Like the slope b_{yx} , for unstandardized measures, the slope for standardized measures, r , may be positive or negative. But unlike b_{yx} , r is always between 0 and 1.0 in absolute value. The correlation coefficient, r , will be 0 when the standardized regression line is horizontal so that the two variables do not covary at all—and, incidentally, when the regression toward the mean, which was Galton’s original interest, is complete. On the other hand, r will be 1.0 or -1.0 when all values of Z_y fall precisely on the regression line rZ_x . This means that when $r = +1.0$, for every case $Z_x = Z_y$ —that is, each case deviates from the mean on X by exactly as much and in the same direction as it deviates from the mean on Y, when those deviations are measured in their respective standard deviation units. And when $r = -1.0$, the deviations from the mean measured in standard deviation units are exactly equal, but they are in opposite directions. (It is also true that when $r = 1.0$, there is no regression toward the mean, although this is very rarely of any interest in contemporary applications.) More commonly, r will be neither 0 nor 1.0 in absolute value but will fall between these extremes, closer to 1.0 in absolute value when the Z_y values cluster closely around the regression line, which, in this standardized form, implies that the

slope will be near 1.0, and closer to 0 when they scatter widely around the regression line.

But while r has a precise meaning—it is the slope of the regression line for standardized measures—that meaning is not intuitively understandable as a measure of the degree to which one variable can be accurately predicted from the other. The square of the correlation coefficient, r^2 , does have such an intuitive meaning. Briefly stated, r^2 indicates the percent of the possible reduction in prediction error (measured by the variance of actual values around predicted values) that is achieved by shifting from (a) \bar{Y} as the prediction, to (b) the regression line values as the prediction. Otherwise stated,

$$r^2 = \frac{\text{Variance of Y values around } \bar{Y} - \text{Variance of Y values around } \hat{Y}}{\text{Variance of Y values around } \bar{Y}} \quad (9)$$

The denominator of Equation 9 is called the *total variance* of Y. It is the sum of two components: (1) the variance of the Y values around \hat{Y} , and (2) the variance of the \hat{Y} around \bar{Y} . Hence the numerator of equation 9 is equal to the variance of the \hat{Y} values (regression values) around \bar{Y} . Therefore

$$r^2 = \frac{\text{Variance of } \hat{Y} \text{ values around } \bar{Y}}{\text{Variance of Y values around } \bar{Y}} \quad (10)$$

= proportion of variance explained

Even though it has become common to refer to r^2 as the proportion of variance “explained,” such terminology should be used with caution. There are several possible reasons for two variables to be correlated, and some of these reasons are inconsistent with the connotations ordinarily attached to terms such as “explanation” or “explained.” One possible reason for the correlation between two variables is that X influences Y. This is presumably the reason for the positive correlation between education and income; higher education facilitates earning a higher income, and it is appropriate to refer to a part of the variation in income as being “explained” by variation in education. But there is also the possibility that two variables are correlated because both are measures of the same

dimension. For example, among twentieth-century nation-states, there is a high correlation between the energy consumption per capita and the gross national product per capita. These two variables are presumably correlated because both are indicators of the degree of industrial development. Hence, one variable does not “explain” variation in the other, if “explain” has any of its usual meanings. And two variables may be correlated because both are influenced by a common cause, in which case the two variables are “spuriously correlated.” For example, among elementary-school children, reading ability is positively correlated with shoe size. This correlation appears not because large feet facilitate learning, and not because both are measures of the same underlying dimension, but because both are influenced by age. As they grow older, schoolchildren learn to read better *and* their feet grow larger. Hence, shoe size and reading ability are “spuriously correlated” because of the dependence of both on age. It would therefore be misleading to conclude from the correlation between shoe size and reading ability that part of the variation in reading ability is “explained” by variation in shoe size, or vice versa.

In the attempt to discover the reasons for the correlation between two variables, it is often useful to include additional variables in the analysis. Several techniques are available for doing so.

PARTIAL CORRELATION

One may wish to explore the correlation between two variables with a third variable “held constant.” The *partial correlation coefficient* may be used for this purpose. If the only reason for the correlation between shoe size and reading ability is because both are influenced by variation in age, then the correlation should disappear when the influence of variation in age is made nil—that is, when age is held constant. Given a sufficiently large number of cases, age could be held constant by considering each age grouping separately—that is, one could examine the correlation between shoe size and reading ability among children who are six years old, among children who are seven years old, eight years old, etc. (And one presumes that there would be no correlation between reading ability and shoe size among children who are homogeneous in age.) But such a procedure requires a relatively large number of children in each age grouping.

Lacking such a large sample, one may hold age constant by “statistical adjustment.”

To understand the underlying logic of partial correlation, one considers the *regression residuals* (i.e., for each case, the discrepancy between the regression line value and the observed value of the predicted variable). For example, the regression residual of reading ability on age for a given case is the discrepancy between the actual reading ability and the predicted reading ability based on age. Each residual will be either positive or negative (depending on whether the observed reading ability is higher or lower than the regression prediction). Each residual will also have a specific value, indicating how much higher or lower than the age-specific mean (i.e., regression line values) the reading ability is for each person. The complete set of these regression residuals, each being a deviation from the age-specific mean, describes the pattern of variation in reading abilities that would obtain if all of these schoolchildren were identical in age. Similarly, the regression residuals for shoe size on age describe the pattern of variation that would obtain if all of these schoolchildren were identical in age. Hence, the correlation between the two sets of residuals—(1) the regression residuals of shoe size on age and (2) the regression residuals of reading ability on age—is the correlation between shoe size and reading ability, with age “held constant.” In practice, it is not necessary to find each regression residual to compute the partial correlation, because shorter computational procedures have been developed. Hence,

$$r_{xy \cdot x} = \frac{r_{xy} - r_{xz}r_{yz}}{\sqrt{(1 - r_{xz}^2)(1 - r_{yz}^2)}} \quad (11)$$

where $r_{xy \cdot z}$ = the partial coefficient between X and Y, holding Z constant; r_{xy} = the bivariate correlation coefficient between X and Y; r_{xz} = the bivariate correlation coefficient between X and Z; and r_{yz} = the bivariate correlation coefficient between Y and Z.

It should be evident from equation 11 that if Z is unrelated to both X and Y, controlling for Z will yield a partial correlation that does not differ from the bivariate correlation. If all correlations are positive, each increase in the correlation between the control variable, Z, and each of the focal

variables, X and Y, will move the partial, $r_{xy.z}$, closer to 0, and in some circumstances a positive bivariate correlation may become negative after controlling for a third variable. When r_{xy} is positive and the algebraic sign of r_{yz} differs from the sign of r_{xz} (so that their product is negative), the partial will be *larger* than the bivariate correlation, indicating that Z is a *suppressor variable*—that is, a variable that diminishes the correlation between X and Y unless it is controlled. Further discussion of partial correlation and its interpretation will be found in Simon 1954; Mueller, Schuessler, and Costner 1977; and Blalock 1979.

Any correlation between two sets of regression residuals is called a *partial correlation coefficient*. The illustration immediately above is called a *first-order partial*, meaning that one and only one variable has been held constant. A *second-order partial* means that two variables have been held constant. More generally, an *nth-order partial* is one in which precisely n variables have been “controlled” or held constant by statistical adjustment.

When only one of the variables being correlated is a regression residual (e.g., X is correlated with the residuals of Y on Z), the correlation is called a *part correlation*. Although part correlations are rarely used, they are appropriate when it seems implausible to residualize one variable. Generally, part correlations are smaller in absolute value than the corresponding partial correlation.

MULTIPLE REGRESSION

Earned income level is influenced not simply by one's education but also by work experience, skills developed outside of school and work, the prevailing compensation for the occupation or profession in which one works, the nature of the regional economy where one is employed, and numerous other factors. Hence it should not be surprising that education alone does not predict income with high accuracy. The deviations between actual income and income predicted on the basis of education are presumably due to the influence of all the other factors that have an effect, great or small, on one's income level. By including some of these other variables as additional predictors, the accuracy of prediction should be increased. Otherwise stated, one expects to predict Y better using both

X_1 and X_2 (assuming both influence Y) than with either of these alone.

A regression equation including more than a single predictor of Y is called a *multiple regression equation*. For two predictors, the multiple regression equation is:

$$\hat{Y} = a_{y.12} + b_{y1.2}X_1 + b_{y2.1}X_2 \quad (12)$$

where \hat{Y} = the least squares prediction of Y based on X_1 and X_2 ; $a_{y.12}$ = the Y intercept (i.e., the predicted value of Y when both X_1 and X_2 are 0); $b_{y1.2}$ = the (unstandardized) regression slope of Y on X_1 , holding X_2 constant; and $b_{y2.1}$ = the (unstandardized) regression slope of Y on X_2 , holding X_1 constant. In multiple regression analysis, the predicted variable (Y in equation 12) is commonly known as the *criterion variable*, and the X's are called predictors. As in a bivariate regression equation (equation 2), one assumes both rectilinearity and homoscedasticity, and one finds the Y intercept ($a_{y.12}$ in equation 12) and the regression slopes (one for each predictor; they are $b_{y1.2}$ and $b_{y2.1}$ in equation 12) that best fit by the criterion of least squares. The b's or regression slopes are *partial regression coefficients*. The correlation between the resulting regression predictions (\hat{Y}) and the observed values of Y is called the *multiple correlation coefficient*, symbolized by R.

In contemporary applications of multiple regression, the partial regression coefficients are typically the primary focus of attention. These coefficients describe the regression of the criterion variable on each predictor, holding constant all other predictors in the equation. The b's in equation 12 are *unstandardized* coefficients. The analogous multiple regression equation for all variables expressed in standardized form is

$$\hat{Z}_y = b^*_{y1.2}Z_1 + b^*_{y2.1}Z_2 \quad (13)$$

where \hat{Z}_y = the regression prediction for the “z measure” of Y, given X_1 and X_2 ; Z_1 = the standard deviate of X_1 ; Z_2 = the standard deviate of X_2 ; $b^*_{y1.2}$ = the standardized slope of Y on X_1 , holding X_2 constant; and $b^*_{y2.1}$ = the standardized slope of Y on X_2 , holding X_1 constant.

The standardized regression coefficients in an equation with two predictors may be calculated from the bivariate correlations as follows:

$$b_{y1.2}^* = \frac{r_{y1} - r_{y2}r_{y12}}{1 - r_{12}^2} \quad (14)$$

$$b_{y2.1}^* = \frac{r_{y2} - r_{y1}r_{12}}{1 - r_{12}^2} \quad (15)$$

where $b_{y1.2}^*$ = the standardized partial regression coefficient of Y on X_1 , controlling for X_2 ; and $b_{y2.1}^*$ = the standardized partial regression coefficient of Y on X_2 , controlling for X_1 .

Standardized partial regression coefficients, here symbolized by b^* (read “b star”), are frequently symbolized by the Greek letter beta, and they are commonly referred to as “betas,” “beta coefficients,” or “beta weights.” While this is common usage, it violates the established practice of using Greek letters to refer to population parameters instead of sample statistics.

A comparison of equation 14, describing the standardized partial regression coefficient, $b_{y1.2}^*$, with equation 11, describing the partial correlation coefficient, $r_{y1.2}$, will make it evident that these two coefficients are closely related. They have identical numerators but different denominators. The similarity can be succinctly expressed by

$$r_{y1.2}^2 = b_{y1.2}^* b_{1y.2}^* \quad (16)$$

If any one of the quantities in equation 16 is 0, all are 0, and if the partial correlation is 1.0 in absolute value, both of the standardized partial regression coefficients in equation 16 must also be 1.0 in absolute value. For absolute values between 0 and 1.0, the partial correlation coefficient and the standardized partial regression coefficient will have somewhat different values, although the general interpretation of two corresponding coefficients is the same in the sense that both coefficients represent the relationship between two variables, with one or more other variables held constant. The difference between them is rather subtle and rarely of major substantive import. Briefly stated, the partial correlation coefficient—e.g., $r_{y1.2}$ —is the regression of one standardized residual on another standardized residual. The corresponding standardized partial regression coefficient, $b_{y1.2}^*$, is the regression of one residual on another, but the residuals are standard measure discrepancies from standard measure predictions, rather than the

residuals themselves having been expressed in the form of standard deviates.

A standardized partial regression coefficient can be transformed into an unstandardized partial regression coefficient by

$$b_{y1.2} = b_{y1.2}^* \frac{s_y}{s_1} \quad (17)$$

$$b_{y2.1} = b_{y2.1}^* \frac{s_y}{s_2} \quad (18)$$

where $b_{y1.2}$ = the unstandardized partial regression coefficient of Y on X_1 , controlling for X_2 ; $b_{y2.1}$ = the unstandardized partial regression coefficient of Y on X_2 , controlling for X_1 ; $b_{y1.2}^*$ and $b_{y2.1}^*$ are standardized partial regression coefficients, as defined above; s_y = the standard deviation of Y; s_1 = the standard deviation of X_1 ; and s_2 = the standard deviation of X_2 .

Under all but exceptional circumstances, standardized partial regression coefficients fall between -1.0 and $+1.0$. The relative magnitude of the *standardized* coefficients in a given regression equation indicates the relative magnitude of the relationship between the criterion variable and the predictor in question, after holding constant all the other predictors in that regression equation. Hence, the *standardized* partial regression coefficients in a given equation can be compared to infer which predictor has the strongest relationship to the criterion, after holding all other variables in that equation constant. The comparison of *unstandardized* partial regression coefficients for different predictors in the same equation does not ordinarily yield useful information because these coefficients are affected by the units of measure. On the other hand, it is frequently useful to compare *unstandardized* partial regression coefficients across equations. For example, in separate regression equations predicting income from education and work experience for the United States and Great Britain, if the unstandardized regression coefficient for education in the equation for Great Britain is greater than the unstandardized regression coefficient for education in the equation for the United States, the implication is that education has a greater influence on income in Great Britain than in the United States. It would be hazardous to draw any such conclusion from the comparison of *standardized* coefficients for Great Britain and the United

States because such coefficients are affected by the variances in the two populations.

The multiple correlation coefficient, R , is defined as the correlation between the observed values of Y and the values of Y predicted by the multiple regression equation. It would be unnecessarily tedious to calculate the multiple correlation coefficient in that way. The more convenient computational procedure is to compute R^2 (for two predictors, and analogously for more than two predictors) by the following:

$$R^2 = b_{y1.2}^2 r_{y1} + b_{y2.1}^2 r_{y2} \quad (19)$$

Like r^2 , R^2 varies from 0 to 1.0 and indicates the proportion of variance in the criterion that is “explained” by the predictors. Alternatively stated, R^2 is the percent of the possible reduction in prediction error (measured by the variance of actual values around predicted values) that is achieved by shifting from (a) \bar{Y} as the prediction to (b) the multiple regression values, \hat{Y} , as the prediction.

VARIETIES OF MULTIPLE REGRESSION

The basic concept of multiple regression has been adapted to a variety of purposes other than those for which the technique was originally developed. The following paragraphs provide a brief summary of some of these adaptations.

Dummy Variable Analysis. As originally conceived, the correlation coefficient was designed to describe the relationship between continuous, normally distributed variables. Dichotomized predictors such as gender (male and female) were introduced early in bivariate regression and correlation, which led to the “point biserial correlation coefficient” (Walker and Lev 1953). For example, if one wishes to examine the correlation between gender and income, one may assign a “0” to each instance of male and a “1” to each instance of female to have numbers representing the two categories of the dichotomy. The unstandardized regression coefficient, computed as specified above in equation 3, is then the difference between the mean income for the two categories of the dichotomous predictor, and the computational formula for r (equation 5), will yield the point biserial correlation coefficient, which can be interpreted much like any other r . It was then only a small step to the

inclusion of dichotomies as predictors in multiple regression analysis, and then to the creation of a set of dichotomies from a categorical variable with more than two subdivisions—that is, to *dummy variable analysis* (Cohen 1968; Bohrnstedt and Knoke 1988; Hardy 1993).

Religious denomination—e.g., Protestant, Catholic, and Jewish—serves as an illustration. From these three categories, one forms two dichotomies, called “dummy variables.” In the first of these, for example, cases are classified as “1” if they are Catholic, and “0” otherwise (i.e., if Protestant or Jewish). In the second of the dichotomies, cases are classified as “1” if they are Jewish, and “0” otherwise (i.e., if Protestant or Catholic). In this illustration, Protestant is the “omitted” or “reference” category (but Protestants can be identified as those who are classified “0” on both of the other dichotomies). The resulting two dichotomized “dummy variables” can serve as the only predictors in a multiple regression equation, or they may be combined with other predictors. When the dummy variables mentioned are the only predictors, the unstandardized regression coefficient for the predictor in which Catholics are classified “1” is the difference between the mean Y for Catholics and Protestants (the “omitted” or “reference” category). Similarly, the unstandardized regression coefficient for the predictor in which Jews are classified “1” is the difference between the mean Y for Jews and Protestants. When the dummy variables are included with other predictors, the unstandardized regression coefficients are the same except that the difference of each mean from the mean of the “reference” category has been statistically adjusted to control for each of the other predictors in the regression equation.

The development of “dummy variable analysis” allowed multiple regression analysis to be linked to the experimental statistics developed by R. A. Fisher, including the analysis of variance and covariance. (See Cohen 1968.)

Logistic Regression. Early students of correlation anticipated the need for a measure of correlation when the predicted or dependent variable was dichotomous. Out of this came (a) the phi coefficient, which can be computed by applying the computational formula for r (equation 5) to two dichotomies, each coded “0” or “1,” and (b) the tetrachoric correlation coefficient, which uses

information in the form of two dichotomies to estimate the Pearsonian correlation for the corresponding continuous variables, assuming the dichotomies result from dividing two continuous and normally distributed variables by arbitrary cutting points (Kelley 1947; Walker and Lev 1953; Carroll 1961).

These early developments readily suggested use of a dichotomous predicted variable, coded "0" or "1," as the predicted variable in a multiple regression analysis. The predicted value is then the conditional proportion, which is the conditional mean for a dichotomized predicted variable. But this was not completely satisfactory in some circumstances because the regression predictions are, under some conditions, proportions greater than 1 or less than 0. *Logistic regression* (Retherford 1993; Kleinman 1994; Menard 1995) is responsive to this problem. After coding the predicted variable "0" or "1," the predicted variable is transformed to a logistic—that is, the logarithm of the "odds," which is to say the logarithm of the ratio of the number of 1's to the number of 0's. With the logistic as the predicted variable, impossible regression predictions do not result, but the unstandardized logistic regression coefficients, describing changes in the logarithm of the "odds," lack the intuitive meaning of ordinary regression coefficients. An additional computation is required to be able to describe the change in the predicted proportion for a given one-unit change in a predictor, with all other predictors in the equation held constant.

Path Analysis. The interpretation of multiple regression coefficients can be difficult or impossible when the predictors include an undifferentiated set of causes, consequences, or spurious correlates of the predicted variable. Path analysis was developed by Sewell Wright (1934) to facilitate the interpretation of multiple regression coefficients by making explicit assumptions about causal structure and including as predictors of a given variable only those variables that precede that given variable in the assumed causal structure. For example, if one assumes that Y is influenced by X_1 and X_2 , and X_1 and X_2 are, in turn, both influenced by Z_1 , Z_2 , and Z_3 , this specifies the assumed causal structure. One may then proceed to write multiple regression equations to predict X_1 , X_2 , and Y , including in each equation only those variables that come prior in the assumed causal order. For

example, the Z variables are appropriate predictors in the equation predicting X_1 because they are assumed causes of X_1 . But X_2 is not an appropriate predictor of X_1 because it is assumed to be a spurious correlate of X_1 (i.e., X_1 and X_2 are presumed to be correlated only because they are both influenced by the Z variables, not because one influences the other). And Y is not an appropriate predictor of X_1 because Y is assumed to be an effect of X_1 , not one of its causes. When the assumptions about the causal structure linking a set of variables have been made explicit, the appropriate predictors for each variable have been identified from this assumed causal structure, and the resulting equations have been estimated by the techniques of regression analysis, the result is a path analysis, and each of the resulting coefficients is said to be a "path coefficient" (if expressed in standardized form) or a "path regression coefficient" (if expressed in unstandardized form).

If the assumed causal structure is correct, a path analysis allows one to "decompose" a correlation between two variables into "direct effects"; "indirect effects"; and, potentially, a "spurious component" as well (Land 1969; Bohrnstedt and Knoke 1988; McClendon 1994).

For example, we may consider the correlation between the occupational achievement of a set of fathers and the occupational achievement of their sons. Some of this correlation may occur because the father's occupational achievement influences the educational attainment of the son, and the son's educational attainment, in turn, influences his occupational achievement. This is an "indirect effect" of the father's occupational achievement on the son's occupational achievement "through" (or "mediated by") the son's education. A "direct effect," on the other hand, is an effect that is not mediated by any variable included in the analysis. Such mediating variables could probably be found, but if they have not been identified and included in this particular analysis, then the effects mediated through them are grouped together as the "direct effect"—that is, an effect not mediated by variables included in the analysis. If the father's occupational achievement and the son's occupational achievement are also correlated, in part, because both are influenced by a common cause (e.g., a common hereditary variable), then that

part of the correlation that is attributable to that common cause constitutes the “spurious component” of the correlation. If the variables responsible for the “spurious component” of a correlation have been included in the path analysis, the “spurious component” can be estimated; otherwise such a “spurious component” is merged into the “direct effect,” which, despite the connotations of the name, absorbs all omitted indirect effects and all omitted spurious components.

“Stepwise” Regression Analysis. The interpretation of regression results can sometimes be facilitated without specifying completely the presumed causal structure among a set of predictors. If the purpose of the analysis is to enhance understanding of the variation in a single dependent variable, and if the various predictors presumed to contribute to that variation can be grouped, for example, into proximate causes and distant causes, a *stepwise regression analysis* may be useful. Depending on one’s primary interest, one may proceed in two different ways. For example, one may begin by regressing the criterion variable on the distant causes, and then, in a second step, introduce the proximate causes into the regression equation. Comparison of the coefficients at each step will reveal the degree to which the effects of the distant causes are mediated by the proximate causes included in the analysis. Alternatively, one may begin by regressing the criterion variable on the proximate causes, and then introduce the distant causes into the regression equation in a second step. Comparing the coefficients at each step, one can infer the degree to which the first-step regression of the criterion variable on the proximate causes is spurious because of the dependence of both on the distant causes. A stepwise regression analysis may proceed with more than two stages if one wishes to distinguish more than two sets of predictors. One may think of a stepwise regression analysis of this kind as analogous to a path analysis but without a complete specification of the causal structure.

Nonadditive Effects in Multiple Regression. In the illustrative regression equations preceding this section, each predictor has appeared only once, and never in a “multiplicative” term. We now consider the following regression equation, which includes such a multiplicative term:

$$\hat{Y} = a_{y.12} + b_{y1.2}X_1 + b_{y2.1}X_2 + b_{y.12}X_1X_2 \quad (20)$$

In this equation, Y is said to be predicted, not simply by an additive combination of X_1 and X_2 but also by their product, X_1X_2 . Although it may not be intuitively evident from the equation itself, the presence of a multiplicative effect (i.e., the regression coefficient for the multiplicative term, $b_{y.12}$, is not 0) implies that the effect of X_1 on Y depends on the level of X_2 , and vice versa. This is commonly called an *interaction effect* (Allison 1977; Blalock 1979; Jaccard, Turrisi and Wan 1990; Aiken and West 1991; McClendon 1994). The inclusion of multiplicative terms in a regression equation is especially appropriate when there are sound reasons for assuming that the effect of one variable differs for different levels of another variable. For example, if one assumes that the “return to education” (i.e., the annual income added by each additional year of schooling) will be greater for men than for women, this assumption can be explored by including all three predictors: education, gender, and the product of gender and education.

When product terms have been included in a regression equation, the interpretation of the resulting partial regression coefficients may become complex. For example, unless all predictors are “ratio variables” (i.e., variables measured in uniform units from an absolute 0), the inclusion of a product term in a regression equation renders the coefficients for the additive terms uninterpretable (see Allison 1977).

SAMPLING VARIATION AND TESTS AGAINST THE NULL HYPOTHESIS

Descriptions based on incomplete information will be inaccurate because of “sampling variation.” Otherwise stated, different samplings of information will yield different results. This is true of sample regression and correlation coefficients, as it is for other descriptors. Assuming a random selection of observed information, the “shape” of the distribution of such sampling variation is often known by mathematical reasoning, and the magnitude of such variation can be estimated. For example, if the true correlation between X and Y is 0, a series of randomly selected observations will rarely yield a correlation that is precisely 0. Instead, the observed correlation will fluctuate around 0 in the

“shape” of a normal distribution, and the standard deviation of that normal sampling distribution—called the *standard error* of r —will be

$$\sigma_r = \frac{1}{\sqrt{N-1}} \quad (21)$$

where σ_r = the standard error of r (i.e. the standard deviation of the sampling distribution of r , given that the true correlation is 0); and N = the sample size (i.e., the number of randomly selected cases used in the calculation of r). For example, if the true correlation were 0, a correlation coefficient based on a random selection of 400 cases will have a standard error of approximately $1/20$ or $.05$. An observed correlation of $.15$ or greater in absolute value would thus be at least three standard errors away from 0 and hence very unlikely to have appeared simply because of random fluctuations around a true value of 0. This kind of conclusion is commonly expressed by saying that the observed correlation is “significantly different from 0” at a given level of significance (in this instance, the level of significance cited could appropriately be $.01$). Or the same conclusion may be more simply (but less precisely) stated by saying that the observed correlation is “significant.”

The standard error for an unstandardized bivariate regression coefficient, and for an unstandardized partial regression coefficient, may also be estimated (Cohen and Cohen 1983; Kleinman, Kupper and Muller 1988; Hamilton 1992; McClendon 1994; Fox 1997). Other things being equal, the standard error for the regression of the criterion on a given predictor will decrease as (1) the number of observations (N) increases; (2) the variance of observed values around predicted values decreases; (3) the variance of the predictor increases; and (4) the correlation between the predictor and other predictors in the regression equation decreases.

PROBLEMS IN REGRESSION ANALYSIS

Multiple regression is a special case of a very general and adaptable model of data analysis known as the *general linear model* (Cohen 1968; Fennessey 1968; Blalock 1979). Although the assumptions underlying multiple regression seem relatively demanding (see Berry 1993), the technique is remarkably “robust,” which is to say that the technique yields valid conclusions even when the

assumptions are met only approximately (Bohrnstedt and Carter 1971). Even so, restricted or biased samples may lead to conclusions that are misleading if they are inappropriately generalized. Furthermore, regression results may be misinterpreted if interpretation rests on an implicit causal model that is misspecified. For this reason it is advisable to make the causal model explicit, as in path analysis or structural equation modeling and to use regression equations that are appropriate for the model as specified. “Outliers” and “deviant cases” (i.e., cases extremely divergent from most) may have an excessive impact on regression coefficients, and hence may lead to erroneous conclusions. (See Berry and Feldman 1985; Fox 1991; Hamilton 1992.) A ubiquitous but still not widely recognized source of misleading results in regression analysis is measurement error (both random and non-random) in the variables (Stouffer 1936; Kahneman 1965; Gordon 1968; Bohrnstedt and Carter 1971; Fuller and Hidiroglou 1978; Berry and Feldman 1985). In *bivariate* correlation and regression, the effect of measurement error can be readily anticipated: on the average, random measurement error in the *predicted* variable attenuates (moves toward zero) the correlation coefficient (i.e., the standardized regression coefficient) but not the unstandardized regression coefficient, while random measurement error in the *predictor* variable will, on the average, attenuate both the standardized and the unstandardized coefficients. In multiple regression analysis, the effect of random measurement error is more complex. The unstandardized partial regression coefficient for a given predictor will be biased, not simply by random measurement error in that predictor, but also by other features. When random measurement error is entailed in a given predictor, X , that predictor is not completely controlled in a regression analysis. Consequently, the unstandardized partial regression coefficient for every other predictor that is correlated with X will be biased by random measurement error in X . Measurement error may be non-random as well as random, and anticipating the effect of non-random measurement error on regression results is even more challenging than anticipating the effect of random error. Non-random measurement errors may be correlated errors (i.e., errors that are correlated with other variables in the system being analyzed), and therefore they have the potential to distort greatly the estimates of both standardized and

unstandardized partial regression coefficients. Thus, if the measures used in regression analysis are relatively crude, lack high reliability, or include distortions (errors) likely to be correlated with other variables in the regression equation (or with measurement errors in those variables), regression analysis may yield misleading results. In these circumstances, the prudent investigator should interpret the results with considerable caution, or, preferably, shift from regression analysis to the analysis of structural equation models with multiple indicators. (See Herting 1985; Schumacker and Lomax 1996.) This alternative mode of analysis is well suited to correct for random measurement error and to help locate and correct for non-random measurement error.

HERBERT L. COSTNER

COUNTERCULTURES

The enclaves in which people of the modern era live no longer resemble the small, integrated, and homogeneous communities of earlier times; rather, these have been replaced by large societies that are complex and diverse in their composition. The United States, a prime exemplar, is composed of multiple smaller groups holding characteristics, beliefs, customs, and interests that vary from the rest of society. While there are many cultural universals binding such groups to the mainstream, they also exhibit significant cultural diversity. Some of these groups display no clear boundaries demarcating them from the rest of society and fail to achieve any degree of permanence. Yet those that do, and that also share a distinctive set of norms, values, and behavior setting them off from the dominant culture, are considered *subcultures*. Subcultures can be organized around age, ethnicity, occupation, social class, religion, or lifestyle and usually contain specific knowledge, expressions, ways of dressing, and systems of stratification that serve and guide its members (Thornton 1997). Distinctive subcultures within the United States include jazz musicians, gangs, Chicanos, gay, college athletes, and drug dealers. While it was once hypothesized that these subcultures would merge together in a "melting pot," incorporating a mix

of the remnants of former subcultures (Irwin 1970), trends suggest that they resist total assimilation and retain their cultural diversity and distinct identity.

Some subcultures diverge from the dominant culture without morally rejecting the norms and values with which they differ. Others are more adamant in their condemnation, clearly conflicting with or opposing features of the larger society. Milton Yinger first proposed, in 1960, to call these *contracultures*, envisioning them as a subset of subcultures, specifically, those having an element of conflict with dominant norms, values, or both (Yinger 1960). Indeed, the feature he identified as most compelling about a contraculture is its specific organization in opposition to some cultural belief(s) or expression(s). Contracultures often arise, he noted, where there are conflicts of standards or values between subcultural groups and the larger society. Factors strengthening the conflict then strengthen the contracultural response. Contraculture members, especially from such groups as delinquent gangs, may be driven by their experiences of frustration, deprivation, or discrimination within society.

Yinger's conceptualization, although abstract and academic at first, came to enjoy widespread popularity with the advent of the 1960s and the student movement. Here was the kind of contraculture he had forecast, and his ideas were widely applied to the trends of the time, albeit under another label. Most analysts of contracultures preferred the term *counterculture*, and this soon overtook its predecessor as the predominant expression. In 1969 historian Theodore Roszak published his *The Making of a Counter Culture*, claiming that a large group of young people (ages fifteen to thirty) had arisen who adamantly rejected the technological and scientific outlook characteristic of Western industrialized culture, replacing this, instead, with a humanistic/mysticist alternative. In a more recent update, Roszak (1995) reflected back on that time, further locating the counterculture phenomenon as an historical aberration that arose out of the affluence of post-World War II America. Kenneth Keniston (1971) described this counterculture as composed of distinct subgroups (radicals, dropouts, hippies, drug users, communards, or those living in communes) rising from the most privileged children of the world's wealthiest nation. Jack Douglas (1970) also discussed the social,

political, and economic background to this movement and its roots in members' entrenchment in the welfare state and the existing youth and student cultures. While this movement was clearly political as well, Douglas outlined some of its social dimensions, including rejection of the workaday world and its idealization of leisure, feeling, openness, and antimaterialism. Richard Flacks (1971) and Fred Davis (1971) followed with descriptions of the counterculture's overarching lifestyles, values, political beliefs, and ideologies. Ralph Turner (1976), Nathan Adler (1972), and Erik Erikson (1968) explored the social psychological implications of this counterculture, positing, respectively, a transformation in the self from "institution" to "impulse," the rise of an antinomian personality, where individuals oppose the obligatoriness of the moral law, and the formation of the *negative identity*. John Rothchild and Susan Berns Wolf (1976) documented the vast extension of countercultural outposts around the country and their innovations in child rearing. Charles Reich (1970) emphatically stated that this counterculture, consisting mostly of students, was being reinforced by merging with nonstudent youth, educated labor, and the women's movement, already effecting a major transformation in Western laws, institutions, and social structure. There was strong belief that this movement would significantly and permanently alter both society and its consciousness (Wuthnow 1976). After researching one commune in depth, Berger (1981) later mused about the survival of the counterculture, acknowledging its failure to meet earlier expectations, yet examining how its ideals and values become incorporated into the mainstream culture (cf. Spates 1976).

Other subcultural analysts noted more broadly that these groups are typically popular among youth, who have the least investment in the existing culture, and that, lacking power within society, they are likely to feel the forces of social control swiftly moving against them, from the mass media to police action. Countercultures were further differentiated from subcultures by the fact that their particular norms and values, were not well integrated into the dominant culture, generally known among group members, and other mainstream subcultures.

Yinger reclaimed theoretical command of the counterculture concept with his reflective expansions on the term in a presidential address for the

American Sociological Association (Yinger 1977) and a book that serves as the definitive statement on the topic (1982). He asserted the fundamental import of studying these sharp contradictions to the dominant norms and values of a society as a means of gaining insight into social order. Countercultures, through their oppositional culture (polarity, reversal, inversion, and diametric opposition), attempt to reorganize drastically the normative bases of social order. These alternatives may range from rejecting a norm or value entirely to exaggerating its emphasis in their construction of countervalues. As a result, some countercultures fade rapidly while others become incorporated into the broader cultural value system. Examples of countercultural groups would include the 1960s student counterculture (in both its political and social dimensions); youth gangs (especially delinquent groups); motorcycle gangs (such as the Hell's Angels); revolutionary groups (the Weathermen of the Students for a Democratic Society, the Black Panthers, millennialists [Williams 1996]); terrorist organizations (such as the Symbionese Liberation Army); extremist racist groups (the Ku Klux Klan, skinheads [Baron 1997; Hamm 1995; Young and Craig 1997], the Aryan Nation); survivalists (Branch Davidians); punkers; bohemian Beats; "straight edgers;" Rainbow family; Earth First! (Lange 1990; Short 1991) and some extreme religious sects (such as the Amish and the Hare Krishnas [see Saliba 1996]).

VARIETIES OF COUNTERCULTURES

Yinger believed that countercultural groups could take several forms. The *radical activist* counterculture "preaches, creates, or demands new obligations" (Yinger 1977, p. 838). They are intimately involved with the larger culture in their attempts to transform it. Members of the *communitarian utopian* counterculture live as ascetics, withdrawing into an isolated community forged under the guidelines of their new values. *Mystical* countercultures search for the truth and for themselves, turning inward toward consciousness to realize their values. Theirs is more a disregard of society than an effort to change it. These three forms are not necessarily intended to describe particular groups. Rather, they are ideal types, offered to shed insights into characteristics or tendencies groups may combine or approximate in their formation. Hippie communities or bohemian Beat groups

combined the mystical and utopian features of countercultures in their withdrawal from conventional society and their search for a higher transcendence. Revolutionary youth gangs, such as the 1960s radicals, the Hell's Angels, and the punkers, fuse the mystical search for new experiences and insights (often through drug use) with an activist attack on the dominant culture and its institutional expressions. Survivalists, Amish, and Hare Krishnas fuse the radical critique of conventional values and lifestyles with a withdrawal into an isolated and protected community.

Countercultures can be differentiated by their primary breaks with the dominant culture. Some take odds with its *epistemology*, or the way society contends that it knows the truth. Hippies and other mystics, for example, have tended to seek insight in homespun wisdom, meditation, sensory deprivation, or drugs, rejecting the rationality of science and technology. Others assert an alternative system of *ethics*, or the values pursued in defining good or striving for the good life. Some, like skinheads or KKK members, may be quite conservative in their definition of the good life; others are libertarian, advocating for people to "do their own thing." Still other countercultures offer alternative *aesthetic standards* by which fashion, taste, and beauty are judged. Punk or acid rock musical movements, performance or postmodernist art movements, and bohemian or hippie fashion movements were all aesthetic statements that incorporated a radical rejection of the standards of conventional taste and its connection to conventional values. Thus, entire countercultural movements may be based on their advocacy of these competing beliefs.

COUNTERCULTURES AND SOCIAL CHANGE

Due to their intense opposition to the dominant culture, countercultures are variously regarded as "engines of social change, symbols and effects of change, or mere faddist epiphenomena" (Yinger 1982, p. 285). Examining these in reverse order, countercultures are often considered *mutations* of the normative social order, encompassing such drastic lifestyle changes that they invoke deep ambivalence and persecution. Most major countercultural mutations appear in the form of

religious movements. Other countercultures arise out of underlying or developing societal stress: rapid political or economic change; demographic transformations in the population (age, gender, location); a swift influx of new ideas; drastic escalation or diminishment of hopes or aspirations; weakening of ties to primary support circles (families, neighborhoods, work groups); and the erosion of meaning in the deepest symbols and rituals of society. These factors are then augmented by communication among people sharing such experiences or beliefs, leading them to coalesce into normatively and ideologically integrated groups. Countercultures can also precipitate social change if the norms and values they champion are incorporated into the mainstream. In commenting on the 1960s student movement, Chief Justice Warren Burger of the United States Supreme Court stated that "the turbulent American youth, whose disorderly acts [I] once 'resented,' actually had pointed the way to higher spiritual values" (cited in Yinger 1977, p. 848). Lasting influence may not always result from major countercultural movements, as witnessed by the rapid erosion in influence of Mao's cultural revolution after his death, yet it is possible. This occurs through a cultural dialectic, wherein each existing system, containing antithetical, contradictory ideas, gives rise to the oppositional values of a counterculture. These are ultimately incorporated into a future new order.

COUNTERCULTURE CASE STUDIES

While the student movement of the 1960s was undoubtedly the largest and most influential counterculture to arise in the United States, a review of three more contemporary American countercultures may yield further insight into the parameters and character of these movements. Let us focus on the Hare Krishnas, punks, and survivalists.

The Hare Krishna movement, also known as the International Society for Krishna Consciousness (ISKCON), is one of the religious movements that became popular in the United States during the great "cult" period of the 1970s (Judah 1974; Rochford 1985). Its rise after the decline of the 1960s student movement is not coincidental, for many people who were former hippies or who were influenced by or seeking the ideals and values of the 1960s turned toward new religions (Tipton

1982) in search of the same features of community, idealism, antimaterialism, mysticism, transcendence to a higher plane, and “a spiritual way of life, which stands outside the traditional institutions found in America” (Rochford 1985, p. 44). Its primary values conflicting with mainstream culture include the rejection of (1) material success through competitive labor; (2) education to promote that end; (3) possessions for sense gratification; (4) authority favoring the status quo; (5) imperialistic aggression; and (6) the hypocrisy of racial discrimination (Judah 1974, p. 16). After the death of its American spiritual master, Srila Prabhupada, in 1977, however, the movement peaked and became more commercialized, transferring its emphasis from self-expression and uniqueness perpetuation of the sect, thereby becoming more of a mass phenomenon.

In contrast to the religious and value components of the Hare Krishnas’ rejection of mainstream culture, the punk or punk rock counterculture of the late 1970s and early 1980s was more of a style movement (Hebdige 1981). As Fox (1987, p. 349) has noted, “The punks created a new aesthetic that revealed their lack of hope, cynicism, and rejection of societal norms.” This was expressed in both their appearance and their lifestyle. The punk belief system was antiestablishment and anarchistic, celebrating chaos, cynicism, and distrust of authority. Punks disdained the conventional system, with its bureaucracies, power structures, and competition for scarce goods (Fox 1987). Members lived outside the system, unemployed, in old abandoned houses or with friends, and engaged in heavy use of drugs such as heroin and glue. Hardcore commitment was usually associated with semipermanent alteration of members’ appearance through tattoos, shaven heads, or Mohawk hairstyles (Brake 1985). The musical scene associated with punks was contrary to established tastes as well and often involved self-abandonment characterized by “crash dancing” (Street 1986).

In contrast to the hippies, Krishnas, and punks, the survivalist counterculture was grounded in exaggeration of right-wing beliefs and values. While some of the former groups preached love, survivalists were characterized by hate. Formed out of extremist coalition splinter groups such as neo-Nazis, the *KKK*, the John Birch Society, fundamentalist Mormon Freemen, the White Aryan Resistance, and tax protesters from *Posse Comitatus*,

survivalists drew on long-standing convictions that an international conspiracy of Jews was taking over everything from banking, real estate, and the press to the Soviet Politburo, and that the white race was being “mongrelized” by civil-rights legislation. A cleansing nuclear war or act of God, with “secular” assistance, would soon bring the Armageddon, eradicating the “Beast” in their midst (Coates 1987). Members thus set about producing and distributing survivalist literature, stockpiling machine guns, fuel, food, and medical supplies on remote farms and in underground bunkers, joining survivalist retreat groups, and attending survivalist training courses (Peterson 1984). Within their retreat communities they rejected the rationalization, technologization, secularization, and commodification of society, creating an environment of creative self-expression where an individual could accomplish meaningful work with a few simple tools. In their withdrawn communities and “utopian” future scenario, men would reclaim their roles as heads of the family; women would regain mastery over crafts and nurturance. Theirs is thus a celebration of fantasy and irrationality (Mitchell, n.d.). Yet while they isolate themselves in countercultures composed of like-minded individuals, they try to influence mainstream society through activism in radical right-wing politics as well. Their actions and beliefs, although rejecting the directions and trends in contemporary society, arise out of and represent frustrations felt by embattled segments of the Moral Majority (mainly fundamentalist Christian, white groups).

Scholarly treatment of counterculture movements is not limited to the United States. In the field of new social movements research, many European scholars have looked at organizations that are designed to mobilize forces against nationalistic cultures. These studies, ranging in topics from nuclear weapons, ecology, squatters’ rights, gays, women, and other countercultural groups (i.e., Autonomes or terrorist organizations), have explored the common denominators inherent in all new social movements. Using quantitative data from protest events collected from newspaper sources in France, the Netherlands, Germany, and Switzerland, Hanspeter Kriesi and others (1995) outlined the “new cleavage” that exists in these Western European societies.

Countercultures thus stand on the periphery of culture, spawned by and spawning social trends

and changes [by their opposition to dominant culture]. As Yinger (1977, p. 850) noted, "Every society gets the countercultures it deserves, for they do not simply contradict, they also express the situation from which they emerge. . . . Countercultures borrow from the dominant culture even as they oppose it."

PATRICIA A. ADLER
PETER ADLER

COURT SYSTEMS AND LAW

Most sociological discussions of law begin with Weber’s definition in which a specific staff is charged with avenging norm violation or ensuring compliance (*Economy and Society* 1968, p. 34). Weber’s goal was to distinguish law from morality and convention, by which a whole community may act to impose sanctions. He also developed his now classic typology of formal legal systems (those limited only to legal as opposed to those legal systems he called “substantive,” based on religious, economic, or moral criteria) and rational (those legal systems based on rules as opposed to those involving use of oracles, oaths, and ordeals, for example). Although he was careful to call these distinctions “ideal-types,” that caution has not stopped persons from offering specific examples that are actually mixed types, as in speaking of “khadi justice” (a term, unfortunately, used by Weber himself) as a prime example of substantively irrational decision making in which a Moslem khadi sits under a palm tree and dispenses justice according to his personal feelings or inspiration. As Rosen (1989, ch. 1) shows, in actual cases he observed, the khadi does not exclude any evidence but relies on witnesses, notaries, documents, and any relevant evidence as well as testimony from interested parties. His goal, as in Islamic law generally, is to “put people back in the position of being able to negotiate their own permissible relationships . . .” (p. 17; see Nader 1969; Starr 1992). He follows a careful procedure, although the conduct of persons in his court may appear to Westerners to be more informal and more disorderly than that allowed in a typical Western court.

While anthropological studies of tribal societies have been shown to exhibit the whole panoply

of Weberian categories (cf. Gluckman 1954; Bohannan 1957, 1967; Howell 1954; Kuper and Kuper 1965), even the classic moot (eg. Gibbs 1963; Gulliver 1969), while classifiable as substantively irrational since it subjects disputes to discussion by a whole village of involved or even merely curious onlookers, still follows definite procedures and is guided by a mediator or authorized persons. See also Stone (1979) on miners’ meetings in the gold rush Yukon; MacLachland (1974) on the tribunal of the Acordada in eighteenth-century Mexico; and the People’s Courts in postrevolutionary Russia (Feifer 1964). The goal of the moot, as Gibbs notes, is not solely legal but is at least what he calls therapeutic since the end sought is restoration of relationships and harmony. It turns out that goal is quite consonant with what we find in formally rational systems in the Western world. In any case, bases of all legal systems include: first, a reasonable certainty and predictability on which persons can depend, which, in practice, means no retroactive laws (as Fuller 1969 notes); second, fairness, which comes down to treating like cases alike; and third, justice should not only be done but be seen to be done, which means that there are no secret decisions, and decisions are in accord with generally agreed values, assuming they exist. These similarities are more important than the many variations in detail that can be found in different legal systems (cf. Pospisil 1958).

In what follows, we shall focus on the two main systems of law, *common law* and *Civil law*, which are found widely in much of the world. In so doing, we can give only passing reference to such systems as Islamic, Jewish, or Tibetan law, or to the many subtle differences found in tribal law. To further complicate matters, many national legal systems are blends of other systems, especially as the result of conquest (as is the case in Japan, which took over a German code but then had common-law features of public law grafted onto it after its occupation by the United States in the 1940s). In modern society, legal systems have become identified with the nation-state so that Canadian law differs from American law, as does Scotch from French law. Nevertheless, many can be said to share one of the two traditions we are considering. Although the two systems have been converging in many respects, each is distinctive in outlook as well as in court organization and the kinds of legal careers likely to be found.

The *Civil law* is by far the older, going back at least to the *Corpus Juris Civilis* of the Emperor Justinian in the sixth century C. E., though some scholars would trace it back to the 12 Tables of Rome, said to have been put together in 450 B. C. E. This system is found throughout Western and now Eastern Europe, most of Central as well as South America, and in many other areas in Africa as well as Asia, plus the state of Louisiana (for an example see *Williams vs. Employers Liability Assurance Corporation, Limited*, 296 F.2d 569 (1961) U.S), the Canadian province of Quebec (Magnet 1980), and Scotland. The *common law* system is often dated from the Norman conquest of England in the eleventh century, when the Normans sought to impose a single system on the country, hence the name "common law." Common law is now found not only in Great Britain but in those countries that made up the British Empire, such as Canada, Australia, New Zealand, Ireland, India, as well as the United States, and is influential in many countries of Africa and Asia. During colonialism, the common law countries preserved legal ties with England through Privy Council appeal, a process largely abolished or greatly attenuated today. Comparable appeals or ties to a single place were largely unknown to the civil law system. Whether the European Community will establish some form of tie remains to be seen.

THE BASIC COURT PARADIGM: THE TRIADIC DILEMMA

When persons with a grievance decide to take action, they may: (1) act separately from each other as in direct attacks, seizure of property, etc. (see Black 1993, chs. 2, 5); (2) confront the other party; or (3) enlist the participation of a third party to help settle the dispute. Courts are preeminently concerned with this third option, what we call "the triadic dilemma." Although courts deal with matters other than dispute settlement, such as law making (when judges make a new policy in decision making) as well, of course, as social control, they all employ a variant of a triad. Two persons or collectivities who have been unable to settle their differences or who have accused others of public harm have in all societies sought the help or guidance of a third party. The hope of each party is that the third party will side with them. Although each may think it fairest if the third party is neutral, in practice each hopes for a decision in his or

her favor. As Simmel (1902; Wolff 1950; Caplow 1968) shows, parties of three are inherently unstable, being liable to break down when two of the three form a coalition to defeat the third, a phenomenon well-known to parents of small children.

The third party may be simply a go-between who offers his services unasked in the interest of preserving or restoring good relations. Or he or she may, as Shapiro (1986, ch. 1) notes, take a more active role as a mediator, though only with the consent of the two disputing parties. While mediators may seek to preserve their neutrality, in fact he may, as in the case of real estate agents, make proposals of their own and may shade the decision by how they handle the facts each shares with them. Less consent from the disputants is involved when an arbitrator appears who may be persons agreed to by the parties or persons imposed by the state or the terms of a labor contract, for example. Arbitrators are under no obligation of coming up with a solution agreeable to both, but they will usually try for such a solution. The most coercive situation of all is the appearance of a judge, either as required by law or by decision of a governmental body. Here the parties may have no say at all either in his appointment or on the body of rules he applies, which may be the terms of a contract or the rules of law.

The dilemma in all these triadic situations is, as noted, preventing the breakdown into two against one. Whatever the outcome, those who lose are likely to feel the other two have somehow combined against them or that they were defeated from the start. In common law systems, the myth of the neutral judge is much celebrated, although since judges are political figures who owe their position to their political activities and may even have been rewarded with the judgeship for their services, it is not surprising the loser feels he never had a chance. In Civil law systems, there is no pretence of neutrality. The judge is a member of the civil service and hence a part of government itself. With the prosecutor in criminal cases being also a member of the administration, the dice are loaded as two against one. On the other hand, this does not mean the civil law system is less fair or just.

Indeed, because of the many protections offered to the accused in common law systems, one author commented that if he were guilty, he would rather be tried in the United States but if innocent,

then he would prefer the Civil law system because, for reasons we shall explain, judges have far less power than they do in the United States, and the system is far less adversarial. The Civil law judge assumes a more neutral role in searching for “truth,” rather than winners or losers. Attempts are made in both systems to produce an outcome that each will feel is “just.” Disputants may be asked to submit voluntarily, and if they do, they will be felt to have offered at least a modicum of consent to the outcome. Alternatively, attempts are made to avoid an all-or-none outcome. For example, in auto accident cases, one party may be felt to be 70 percent at fault and the other 30 percent, with a division of property in that proportion. In criminal situations, as in the United States, a plea bargain may enable the accused to walk away with a much lesser penalty than he or she might otherwise have suffered.

Actually, although plea bargaining is thought of as peculiar to criminal proceeding, negotiation is equally common in what are called “civil situations” (involving actions between two or more persons) where, as in criminal proceedings, an estimated 90 percent of cases are settled without trial. Such resort to negotiation places a special strain on the triadic model, particularly where the judge may himself participate, at least to the point of interviewing the accused in case of crime, or the parties in civil law, to provide assurance, at least in his own mind, that the accused or the plaintiff is aware of what is happening and has voluntarily entered into the “deal.” (Klein 1976). What one needs to understand is that the ubiquity of negotiation in American law is an organizational model. Lawyers, both defending and prosecuting, as well as lawyers in other courtroom situations become “repeat players” (Galanter 1974), who deal routinely with one another as well as with judges, clerks, and others in the court. Gradually, their work becomes routinized, with all focusing on getting things moving and coming out with cases settled. The goal of the system, then, becomes one of efficiently moving cases through, with participants seeing themselves, however unwittingly, as agents of the system. As that takes place, the triad can be seen as disappearing altogether and being replaced by a work group consisting of three or more players who have an interest in the outcome of the game (see Eisenstein and Jacob 1977; Jacob 1983).

We proceed to a detailed examination of the two systems, beginning with the common law system as most familiar to American readers. But that very familiarity is likely to blind us to the assumptions of the system that contrast so sharply with the equally hidden assumptions of the civil law system.

THE COMMON LAW SYSTEM

Although most persons are taken with the image of justice as a “blind lady” who acts on the basis of the facts and the inherent justice of the situation, as Jacob (1996) points out, courts in common law systems are ridden with policy assumptions, no more so in the United States than in other places. While courts go about their business of settling disputes and ensuring orderly procedures, their procedures send symbolic messages (see Nelken 1997; Sarat and Kearns 1988). This is especially the case for appellate courts where, in contrast to European courts, judges are fond of wrapping up their decisions in opinions that are often more widely cited and influential than the decision itself. While conservatives are usually at pains to insist that judges confine themselves to being “strict constructionists,” their opinions resonate with what the legal scholar Dworkin (1977) calls “principles.” In the classic case of *Riggs vs Palmer* (115 N.Y. 506, 22 N.E. 188, 190, 1889), a presumptive heir on becoming alarmed at the possibility that his grandfather might change his will proceeded to eliminate that possibility by murdering him. The grandson was properly tried, but defended his right to his inheritance. The court refused to award the inheritance to him, leading a dissenting judge in the case to ask for the court’s reasoning for this decision. After all, wrote the dissenter, the will was in order, was it not? There were the required witnesses, and there was no question that it was the intent of the testator that the young man should receive the bulk of the estate. With barely a reference to those issues, the majority awarded the bulk of the estate to the deceased’s daughters, who, under the will, were to receive only token amounts. In sum, the majority proceeded to rewrite the will in direct contravention of the deceased’s clearly expressed wishes. Although the majority hunted mightily for a source for their decision, turning variously to Aristotle, the Bible, an ancient case from Bologna, the Napoleonic Code, Roman law and, finally, to a rather desperate assumption that no specific law was really

needed, anyhow. In the end they asserted that there is a “fundamental maxim” found in all “civilized countries,” namely:

No one shall be permitted to profit by his own fraud, or to take advantage of his own wrong, or to found any claim upon his own iniquity, or to acquire property by his own crime. (Riggs vs. Palmer 1889)

But the dissenter asked: What is the legal source of this “maxim?” It could not be found in any case previously decided, nor in any statute (such is no longer the case in most jurisdictions). Although he agreed that the principle had intuitive appeal and might be found in most religious and moral systems, the law, at least Western secular law, is not simply a set of religious or moral principles. In the United States, the Constitution specifically erects a wall between church and state. Since that case, the principle, once announced by the court, has been cited and is indeed now a part of U. S. (and most other common law countries) law. But we must not go too far and declare that common law is simply a set of principles. Rather, the law is informed by policy assumptions, often hidden, but influential nonetheless. Although civil law is equally political, attempts are much stronger to hide the policy assumptions with an insistence that only a legislature can make law. All judges are supposed to do is apply it with as little innovation or interpretation as possible, let alone enunciating “principles.” The overall issue of how much politics and governmental policy is reflected in judicial decision making clearly affects the triadic system’s functioning to produce or not produce a sense of justice done and seen to be done. It is this feature that has been seized upon by Marxists and proponents of socialist law who see both common law and civil law as simply disguised systems whereby bourgeois ideologies are foisted on a powerless proletariat by capitalist exploiters, whether governmental or private. Their answer to the triadic dilemma is that there never can be neutral third parties, with the result that the only reality is endless strife between parties with temporary truces as victors seek to pick up the spoils.

In addition to taking policy positions, courts in common law systems can have massive effects on society by judicial review of legislative acts, a phenomenon severely limited in civil law systems as we shall note. Courts also provide a major

alternate route to persons who lack funds or who have been stymied by attempts to influence legislation. Persons can convert a private grievance into a public cause (Savat and Scheingold 1998) by, for example, deciding that severe burns from hot coffee served at McDonald’s requires court action to impose punitive damages as a warning to all companies serving the public that consumer safety must be a part of the design even in private firms. So too, persons suffering from lung cancer who have been unable to get protective legislation against cigarette companies have turned to the courts, not simply for financial awards, but for vindication of what they feel are violations of their rights, as citizens, to life. When added up, the damage awards in such suits as well as those even in routine automobile accidents, violations of privacy, and tort and contractual disputes have never been totaled but constitute a huge shift in resources comparable to that involved in taxation. Nor have we touched on the part that lawyers’ fees play in such cases.

Finally, unlike judges in civil law jurisdictions who are part of the civil service from the start (judges in France, for example, even go to special schools), judges especially in the United States, often come to their judgeships in mid-life, after serving in political positions, business or other areas of life. Jacob points out that:

... between 1963 and 1992, between 58 and 73 percent of federal appeals judges had a record of party activism before their appointments; among federal district judges, between 49 and 61 percent had such a background. (1996, p.19)

Yet such a background should not lead to cynicism that judges are necessarily biased or pro-business or pro-party. Their background in ordinary society helps ensure a commitment to the importance of the rule of law, of procedural fairness, and of individual rights as a legitimate expectation of ordinary citizens.

A special characteristic of common law court is often the source of surprise and some envy on the part of those schooled in civil law systems. American courts are often perceived as a jumble, with multiple urban, country, and state systems, so that what is actionable in Montana may not be actionable in Idaho and that if one is not happy with treatments in a state court, one can, with

some issues, move to a federal court. Such “forum shopping” seems a travesty to those accustomed to single systems. Yet the United States has more a single system than have many European countries. In those countries, there are often two sets of courts—ordinary courts that try the vast majority of civil cases, and a second set of administrative courts for those who have quarrels with the government or administration. In the United States most regular courts can handle any case that comes before them (though there are many specializations), and ultimately, the U. S. Supreme Court sits at the top as the final arbiter of law (considering constitutional questions especially important and above all). Nor, it should be added, are courts entirely separate systems. They are dependent for salary and other resources on what Congress and legislatures will provide, and they do not appoint their own numbers. The U. S. Supreme Court is indeed supreme on law, but it is in no sense the apex of a bureaucracy that can appoint and discipline members of lower courts. Further, it is basically passive, waiting for cases to be brought to it when there is a “case or controversy,” thus severely limiting its ability to act autonomously as a conscience of the nation. Often citizens gnash their teeth as the U. S. Supreme Court refuses to hear a case or decides it on the narrow issue that happens to have been presented to it. In that sense, the entire legal system is the property of the lawyers and what they choose to present to the courts, a situation vastly different from what we find in civil law systems.

The impact of lawyers in common law systems is greater than in civil law and indeed in any other system known to the world. Two major factors help account for lawyer dominance. One is the dependence on case law. Although legislation and statutes are basic sources of law, the necessity for interpretation and application to particular cases places enormous power in the hands of courts. If all legal systems require a strong sense of certainty, then that certainty is provided in common law systems by the majestic procession of cases, whether simply confirming one another, adding details, or overruling contradictory cases. To argue a case in an American court is to recite cases, and if there are enough of them, lawyers and judges feel the outcome can be considered settled. On the other hand, civil law systems depend on codes as enacted by revolutionary regimes, which codes are felt to

be the ultimate source of law, supplemented by legislation that is still felt to be a kind of supplement to the code. In a sense, the code is thought to settle the matter of certainty with little need for lawyers to interpret it. (This is less true in Germany where lawyers play a larger role.)

But in addition, especially in America, the model of the triad is felt to be basic. A court case consists of two adversaries who argue before a (one hopes, neutral and just) judge. The emphasis is on the adversarial process itself, a situation that produces not necessarily “truth” but rather a victory for one side. Lawyers play the key role, a matter that often leaves the outcome to the skill of the lawyers as much as to other features of the case. The judge is felt, if not to be neutral, at least to be passive, waiting for lawyers to present objections or evidence as they wish. If a lawyer chooses not to present a piece of evidence or simply sloppily forgets to do so, the judge cannot intervene to instruct the lawyer on what he has left out. In civil law systems, the judge, while a mere civil servant, has more power to direct the course of the trial, assuming what is often spoken of as an “inquisitorial style.” Given the major role that lawyers play in common law systems, it is important to give attention to how that role is played out. Since data are more complete, we shall use U.S. sources. However, comparable rates of increase for most categories are found in Canada and Great Britain (see Galanter 1992). This is not meant to deny the differences, especially cultural variations, in those countries (see Atiyah and Summers 1987).

DOMINANCE OF LAWYERS IN COMMON LAW SYSTEMS

In spite of their widespread influence and frequently very high income, lawyers in America are not a happy lot. They are not esteemed (a Gallup Poll found that 46 percent of respondents rated lawyers “low” or “very low” in honesty and ethical standards, just barely above used-car salesmen). A survey by the California Bar Association in 1992 reported that 70 percent of those polled said they would choose another career if they could. Even more—75 percent—confessed that they would not want their children to become lawyers. Other studies report that lawyer job satisfaction is dropping, along with much higher levels

of alcoholism, drug abuse, and symptoms of depression than those found in the general population.

In spite of such indices of self-destruction, the number of lawyers in the United States has been rising, especially in the 1990s. From 374,000 in 1975, the number of lawyers will soon top one million as 31,000+ new lawyers are admitted to the bar every year. The field is proving attractive to minorities and women. From a low of only about 3 percent in 1971, female lawyers now make up over one-quarter of the total of practicing lawyers, and nearly one-half of students in entering law school classes. Female lawyers, as a group, are younger, with only 7 percent being over 50 compared to 30 percent of their male colleagues.

The location of practice has, however, not changed significantly. Private practice is dominant, even increasing, so that by 1991, 73 percent of lawyers were in private practice, with only 8.8 percent found in private industry, and 8.2 percent in government. But private practice has been undergoing profound changes. Solo practitioners have become scarcer as lawyers move increasingly to firms. The increase is mainly in larger firms (those with at least eleven lawyers). In 1980, the very large firms (one hundred or more lawyers) accounted for only 7 percent of firm employment. By 1991, that percent jumped to twenty-three. The large firms are the more common locus for men, with women being more likely to be found in government, legal aid, and in public defender's offices. Some of these differences are declining as more women enter the profession and attain experience. On the other hand, more women, proportionally, are leaving the profession.

It is the large firms that attract more and more of the new lawyers who seek distinguished and lucrative careers. The largest—often called “mega firms”—range from the Washington, D. C., firm of Williams & Connolly with 127 lawyers (sixty-one partners) producing revenues of \$78 million, to true giants, such as the New York firm of Skadden, Arps, Slate, Meagher & Flom, with over 1,000 lawyers (236 partners) earning well over half-a-billion dollars in gross revenue. Some firms are even larger. They are not, of course, all under one roof but scattered in different cities as well as in foreign countries. Not only are these the places where the largest salaries are found, but they are also the platforms from which government and

other influential careers are launched, including leading positions on major committees and boards, as well as ambassadorships and presidencies. Twenty-five of the forty-one U. S. presidents have been lawyers, as well as half of U. S. senators and nearly half of all members of Congress. Lawyers are widely found in governorships and state legislatures as well. If these are not the most esteemed members of society, they certainly are among the most powerful and perhaps the most feared.

Although most persons in common law systems are aware of the presence of lawyers in those settings, it is not the image most have when they think of lawyers, and it is not the setting in which they see them in television drama. Instead, it is the lawyer, often solo or in a small firm, arguing for his or her client in a courtroom before a jury. The television image runs counter to the image of real lawyers in the news, leading to charges that the United States is a “litigious” society, in which large awards are given for burns suffered from spills of hot coffee, and there are suits against arrest for breast-feeding in public or for recovery of expenses on being stood up for a date. Though most such cases are thrown out immediately by disgusted judges or settled out of court for modest sums, critics person who may never hear of those outcomes continue to demand that we follow the lead of the nonlitigious Japanese, for example, who make do with very few lawyers. Actually, the number of lawyers in Japan is deliberately kept low by the governing elite to preserve a hierarchical social order. Nor are the Japanese devoid of a taste for litigation by any means (Haley 1978, 1991, ch. 5).

Nor has the United States had a “litigation explosion” nearly as great as some have claimed. There was only a moderate increase at the state level in the 1990s. It is true that there has been a large increase in the number of federal cases, not of the trivial sort noted above but rather of big businesses suing each other. The news of most of those ends up on the back pages of the *Wall Street Journal*. Other federal cases deal with asbestos and similar injuries as well as other suits by government (Galanter 1983; Galanter and Palay 1991). The reason it seems that the U.S. is experiencing a litigation explosion is that there is an increasing prominence of what have been called “mega” cases, in which large masses of lawyers and experts pursue a single case, sometimes for years on end. Although most involve business, a few involve

highly prominent individuals who have the resources and will to fight, intimidate, and otherwise bring up issues, subsidiary issues, and more of what Damaska (1978, p. 240) has called “companion litigation” where, along with the main case, separate suits are filed on discovery, on legal fees, on standing, and on other issues, which lengthen proceedings and often do little more than harass the other side or both sides into exhaustion. Such cases take the form of a “prolonged clinch and . . . settlement” (Galanter 1983, p. 163) while rarely ever ending up in court. Meanwhile, such cases contribute to the image of the United States as a “litigious” society.

Yet, even granting all such cases, very few lawyers are involved in doing such things. Only a small minority of all dealings of U. S. lawyers ever result in a contested court action. Most legal practice takes place in offices for the benefit of business firms, and only a small minority deal with individual clients at all. Even in those cases, lawyers spend much of their time persuading suit-eager clients not to go to court but to work out a settlement. Lawyers generally limit themselves to cases they think they can win. Often filing a case is symbolic of seriousness of intent, forcing a response from the other party; but the cases are settled, sometimes on the very eve of the court date or even as the trial, if there is one, is in process.

What all this amounts to is that the legal profession in the United States is “split.” Most lawyers quietly carry on the journeymen work of settling disputes and assisting persons to compromise so that they can carry on with their lives. A very, very few carry out the courtroom battles of the O. J. Simpson type that dominate the front pages of the nation’s newspapers. In such cases, lawyers are not seen as settling disputes but they are seen by many people as “getting people off,” leading to cynicism or to despising lawyers, even when or even because they win. Many cases take place outside the large law firm, but the reputation of lawyers created by the sensational cases affects the public image of all lawyers, wherever located.

One special feature of the split deserves attention; namely, income. Solo and small-firm lawyers carry out much of the work of helping persons set up partnerships, get a divorce or settlement from

an insurance company, draw up wills, and deal with persons who are in minor trouble with the law. On the other hand, work in a large law office is carried out by specialists who do the complex work of big business. Large businesses often make use of their own “in-house counsel” for the routine work of contracts, labor-management negotiation, and other repetitive legal activities. The company turns to outside law firms for the unusual, once-only activity, such as mergers and acquisitions, floating new securities, takeovers, and bankruptcies. Such activities call for the highest degree of expertise and knowledge, far beyond what a solo lawyer might be called upon to have. A major study of Chicago lawyers (Heinz and Laumann 1982) asked them to rank legal specialties in prestige. At the top were securities, tax, antitrust, patents, banking, and public utilities—the activities in which large law firms are involved. At the bottom were criminal defense and prosecution, personal injury, consumer debt, landlord-tenant, divorce, and family—the concerns of the solo and small-firm lawyer. The income differentials between the two clusters are equally impressive. A major study reported salaries from large firms in Indianapolis and New York to average around \$300,000 per partner for the year, but many make much more. A New York law firm reported that each of its 121 lawyers (sixty-one equity partners) earned over \$1 million. Many others were not far behind. Lawyers in solo and small firms are not poor but make a good deal less. A 1995 survey reported that those lawyers earn somewhere between \$75,000 and \$100,000 a year, assuming they work a full two-thousand billable hours, which some do not. Associates (that is, nonpartners) start out, according to a 1996 study, from lows of \$40,000 to as high as \$70,000, but then rise with each year in the larger firms to \$150,000 and up, plus bonuses. Stories of such incomes add little to offset the low esteem in which lawyers are held, especially since most persons who deal with lawyers find the lawyer wants money “up front” or on a retainer basis, unless a contingency arrangement is made, and often even then. (Note: The preceding section draws from the author’s paper, Gross 1998.)

TOO MANY LAWYERS?

A final issue that troubles many observers both in common law and civil law countries is

Judges, Lawyers, and Civil Litigation in Selected Countries

Country	Judges		Lawyers		Civil Cases	
	Date	Number per Million	Date	Number per Million	Date	Number per Million
Australia	1977	41.6	1975	911.6	1975	62.06
Belgium	1975	105.7	1972	389.7	1969	28.31
Canada	1970	59.3	1972	890.1	1981-2	46.58
Denmark					1970	41.04
England/Wales	1973	50.9	1973	606.4	1973	41.1
France	1973	84.0	1973	206.4	1975	30.67
Italy	1973	100.8	1973	792.6	1973	9.66
Japan	1974	22.7	1973	91.2	1978	11.68
Netherlands	1975	39.8	1972	170.8	1970	8.25
New Zealand	1976	26.8	1975	1081.3	1978	53.32
Norway	1977	60.8	1977	450.0	1976	20.32
Spain	1970	31.0	1972	893.4	1970	3.45
Sweden	1973	99.6	1973	192.4	1973	35.0
United States	1980	94.9	1980	2348.7	1975	44.0
W. Germany	1973	213.4	1973	417.2	1977	23.35

Table 1

whether the United States, in particular, is “over-lawyered.” Some even see this question as helping account for the so-called litigiousness of American law. Whatever the numbers, an increasing number of civil cases are settled either during or after trial. Lawyers play their role in filing cases, but most of their work is done outside the court, which, of course, means lots of work for lawyers. Further, although cases may never reach court, as Mnookin and Kornhauser (1979) put it, much negotiation takes place in the “shadow of law.” That is, lawyers, well or poorly acquainted with actual court cases, call attention to what is “likely” to happen if they go to court, not to speak of the delay and expense. So law, or at least imagined law, plays a dominant role even when never specifically called into play (Ewick and Silbey 1998).

A useful table (table 1), if read with caution, is provided after careful research by Galanter (1983, p. 53).

Although we do not provide the sources, the results differ in dependability and the care with which they have been calculated. Still, the contrasts, however crude, are revealing. As to civil cases, the United States is seen to stand toward the middle, exceeded by Australia, New Zealand, and Canada, with many others being much lower. The United States is at the lower end in judges, being exceeded by W. Germany, Belgium, Italy, and

Sweden. But when we come to lawyers, the United States far exceeds other countries, though Australia, New Zealand, Canada, and Spain are also richly supplied. As we note later in the discussion of civil law countries, many others not called “lawyers” do what the United States would call “law.” Such persons include notaries, government officials of many kinds, law clerks in private firms, and, in Japan, the very high proportion of those who take the exam but are not allowed to practice (they do just about everything lawyers in the United States do except represent clients in court).

In making such international or intercultural comparisons, one should bear in mind differences in conceptions of what is worth disputing over and indeed what a dispute is in the first place. The studies by Felstiner, Abel, and Sarat (1980–81) suggest that a great many, perhaps most, injurious experiences are never perceived as such, but rather thought of as simply part of the risks of living. Some proportion of these are seen as violations of some right, but even many of those are simply “lumped,” that is, borne with equanimity or tolerated as not worth pursuing because of time or costs. A small proportion are, however, charged to a specific causal agent, and if a person or collectivity, then become what are called “grievances.” Some small proportion of those in turn, if voiced, turn into claims that, if rejected, become “disputes.” In turn, most (90 percent approximately)

disputes brought to lawyers are settled with varying degrees of satisfaction, lawyers often functioning to persuade the aggrieved that they should accept a settlement and move along with their lives. Whether persons are willing to pursue a grievance depends on technology and the ability to find a causal agent, as well as the existence of such legal devices as no-fault automobile insurance or divorce, which have the effect of diverting cases out of the legal system (see Kritzer, Bogart, and Vidmar 1991). Some countries, such as many on the European continent, have special labor tribunals and other systems that also divert cases out of what would, in the United States, be a legal case. The United States has fewer such alternative forums than is the case in the civil law world.

Jacob (1996, p. 52) speculates that the United States is, perhaps, more a nation of strangers, leading to a greater willingness to pursue disputes than is the case in countries with a stronger sense of community. In general, it may be said that the closer persons are, whether as family, neighbors or co-religionists, the less likely are they to sue one another. On the other hand, that does not mean there are fewer conflicts in such groups. Rather, there are internal mechanisms for settling them *within* such groups.

A final point about common law systems that contrasts with civil law systems is the widespread availability of appeal, particularly within the judicial systems. Although much of this is perfunctory and may involve little more than an attempt to satisfy clients with the appeals court routinely affirming the lower court, still appeal is possible, much more so than in civil law countries. Appellate judges often lack experience and are not required to have experience as trial judges. In some cases, judges have discretion on whether to hear an appeal, leading to selection of cases that may be controversial or present novel points of law. The extreme is presented by the U. S. Supreme Court which, in the 1990s, has elected to consider around 100 out of some 5,000 cases presented to it, usually reserving to hear constitutional cases and conflicts between the states or foreign governments. It is difficult to assess the impact of appeals on the civil or criminal process. Unlike trial judges, appeals judges do not merely decide cases but also give reasons. Such reasons are often examined by elite lawyers and are now

routinely discussed in the “legal” columns of popular magazines. It is not clear that the reasons affect policy in any obvious way. But the language of the court enters common discourse and affects thinking. School boards, church councils, Boy Scout boards, and even teachers’ decisions on classroom discipline become legalistic, with persons being given notice of charges, given chances to answer, and allowed to bring witnesses in their defense. In the United States, as in common law countries, the law seems to be everywhere (Galanter 1983), even if not formally invoked.

THE CIVIL LAW TRADITION

In drawing comparisons between the common law and civil law traditions, it is important not to dismiss variations as due simply to “historical experience” or to even vaguer influence of “culture.” History and culture are, of course, operative at all times, but we seek not simply a description but a sociological explanation. We must begin with the recognition of what Zweigert and Kotz (1987) call “functionalism.” By that they mean that all legal systems deal with generally similar problems as, say, medical systems do. Whether the society employs witchcraft, herbs, appeals to the gods, leeches, hot baths, or Western-style x-rays and surgery, they all deal with illnesses of the body. So, too, legal systems concern themselves with trouble presented by the fact that humans live in society and must deal with each other. In Chiangmai, Thailand, for example, it is not surprising to find that three main classes of law suits appear: crimes as offenses against public order or the state, which are dealt with seriously by the courts; private wrongs, such as those arising from marital disputes, which are settled by negotiation; and those conflicts involving contracts and property rights, which are settled by careful examination of written and especially certified documents (Engel 1978). The details are indeed “cultural,” involving what Watson (1977) speaks of as “legal transplants,” by which a society adopts some procedure borrowed from another society because it is accessible, written in a language the elite can read (such as Latin for Roman law), or more commonly simply the law of a conquering power as with England or India. One wastes one’s time if one looks for rational reasons or tries to account for such transplants on grounds of “efficiency,” although often people come to

believe in the superior efficiency of the system of law they happen to use.

On the other hand, a close examination of legal procedures can have much to teach about the assumptions taken for granted in the culture (Ross 1993; Nelken 1997). In a report on a personal experience in Indonesia, Lev (1972) tells of an accident in a hotel in which a toilet tank, affixed high up on a wall, fell, nearly hitting a friend. To Lev's amazement, the hotel presented him and his friend with a bill for repairs. Lev refused, turning for help to a local judge, who was also a friend, for support for what Lev felt were his legal rights. The judge, while agreeing that those were indeed his legal rights, proposed that Lev make a token payment as evidence of "good will." With reluctance, Lev did so since compromise or peace was, the judge reminded him, after all, more important than vindication of rights. An even more obvious example is presented in a Mexican case in which the supreme court absolved a court for liability for the theft of money and jewels left in the care of the court pending settlement of the case. After all, said the court, Mexico is a poor country that cannot afford safe deposit boxes or secure storage places, but they do the best they can. The court then quotes what it clearly sees as a universal "principle of law," "*impossibile nulla obligatio est*," which the court translates simply as "No one is obligated to do the impossible" (quoted in Merryman, Clark, and Haley 1994, p. 684). These considerations are spoken of by Glendon (1987) as the "hortatory" function of law in civil law systems. She contrasts that with a view that American and British law usually involve a command backed up by punishment. Yet, whatever the system, laws, whether self-consciously doing so (as in civil law systems) or inadvertently (as in common law systems), always teach lessons as persons observe their operations.

Understanding of the civil law systems requires recognition that they come to us in two widely separated parts. The first is what is owed (and that is a great deal) to Roman law as codified in the sixth century under the Emperor Justinian as the *Corpus Juris Civilis*. This magnificent collection includes the law of persons, family, inheritance, property, contracts, and remedies, all of which the juriconsults (the legal experts) of the day saw as forming a unified body of law and which has been largely seen that way ever since. The influence was not simply on the Civil law system as such

but has had a strong effect on civil law (narrowly conceived) in common law countries as well. Basic principles the Roman jurists developed echo through the ages up to the present.

With the invasions of Rome that followed, much of this law fell into disuse or was united with the local laws of German tribes. However, *canon law*, as developed by the Catholic Church for its own uses, came to be widely adopted and grafted onto classic Roman law, influencing family law and civil procedure as well as much else, though not public law for the most part. Then, with the Renaissance, classic Justinian law was revived, especially in Bologna, where scholars gathered from all over Europe to study it, in Latin of course, and then spread it, where it came to be known as the *jus commune*. However, as it spread, it was inevitably influenced by local laws and customs that were often simply added to it in the interests of utility for solutions of local problems. A third development was *commercial law*, also from Italy, at about the time of Crusades, when there was much transport of goods and persons. The guilds and towns that developed this law were, for the most part, only tangentially influenced by Roman law since the focus was on rules merchants developed for their own use. Such rules spread even more widely than the *jus commune* up to the present day, where much of it can be found in admiralty law and related fields. It is quite clear, for example, that when two ships approach one another on the high seas there had better be a clear understanding as whether they both keep to the right or to the left, and that understanding must be clear whatever the differences in language, culture, or tradition. It is the nearest thing law offers to a truly international and intercultural system.

But there is more to modern civil law than a revival and Renaissance enrichment. The system was almost totally transformed by the ideas that gave birth to the political revolutions that began in the seventeenth century and are far from over at the present day. The revolutions were, of course, the American and French Revolutions, the military and ideological events associated with the unification of Italy and Germany, the coming new nations as the Turkish Empire disintegrated, the movements for freedom from Spanish and Portuguese domination in the Americas, as well as the chaos that followed the great wars of the nineteenth and twentieth centuries. While the word

“chaos” may be useful in a strictly descriptive sense, it is better to speak of these changes in the term employed by Schumpeter (1976) as winds of “creative destruction,” for they did not simply destroy but created what we speak of as the modern world. What they destroyed was basically feudalism and the concept of status fixed at birth as well as the conception of a divinely ordained, and hence unchangeable, social universe. In Weber’s classic phrase, we witnessed a “disenchantment of the world” which left humans, in the words of the existentialists, fated to create their own world and take responsibility for it. This meant that law was secular, torn loose from any religious basis, but focused instead on what came to be called “positive law,” that is law enacted by legislatures and parliaments. The transformation was not merely procedural but involved substantive changes in the assumptions of legal rights. These were the now-familiar rights stated in the American and French revolutionary documents—rights to liberty and property, the opportunity to change one’s status through one’s own efforts, the right to own land in one’s own person rather than merely, as in feudalism, as a serf or dependant of a feudal lord. Along with these changes came fundamental changes in loyalty and allegiance. Instead of fealty and subordination to lord or guild master, allegiance came to be narrowed to a single, overarching focus on the nation-state. The power of the church was similarly destroyed or greatly attenuated, as in England, and with that decline went the jurisdiction of ecclesiastical courts as well, though some of the traditions of canon law as, for example, in civil procedure (where courts make use of written records of proceedings and much less, than in common law systems, of oral testimony in trials), were retained.

Although the state and the law created by legislators came to make up the substance of law, it should be noted that in time it became evident that some controls were necessary on the state itself. In the United States, this control is institutionalized in the doctrine of the separation of powers, especially the ability of the courts to rule on the constitutionality of legislative enactments as well as the authority and legality of administrative acts and regulations. The civil law countries also elaborated a separation of powers but a very different one. The concern there was the enormous power judges had during the feudal period to act, usually in

support of the landed classes and the aristocracy. As Stone (1986) points out, the French *parlements* (panels of judges) had almost limitless power—they could arrest seditious persons, ban public gatherings, evaluate regulations of all kinds, supervise guilds and universities, and act as censors of public morals. Somewhat similar powers were enjoyed by the *audiencia* as representatives of royal power by the Spanish conquerors of Latin America. Such power led to their becoming wealthy and powerful, which led, in the case of France, ironically, to their own undoing. Although their vast powers might (and did occasionally) act as a break on royal powers, instead in a final act of defiance of the royal power, they threatened to resign on the very eve of the French Revolution. The Constituent Assembly voted to place them on indefinite vacation and then abolished them altogether. In a sense, their very arrogance and posturing led to a recognition that they would be a permanent obstacle to the new freedoms the revolutionaries wished to establish. A result was that there was a serious attempt to reduce the judge forever to a mechanical figure who would simply carry out the expressed will of the parliament in the name of the people. As such, the judge would have no inherent powers at all but would become a clerk or servant. He was not to presume even to interpret the will of the parliament. But how was that to be achieved?

The answer was to create a code that could answer all legal questions for the judge. In terms of the triadic model, two adversaries would argue before a neutral third who would simply delve into the code, find the answer, and impose the solution on them. In practice, as we can see from our vantage point, matters could never be so simple. As time went on, the concept of a legislative or code monopoly of law gave way to systems whereby the judge could declare legislative or administrative acts unconstitutional, but the process involved much hedging by being careful, at first, at least to locate the places in which such review could take place outside the ordinary court systems in special constitutional courts (often not even called courts) as in France, Germany, Italy, and Spain, and in most Latin American countries, though in the latter, more influenced by U. S. practice, they were less reluctant to call them courts. There was little of this problem in England, which changed more slowly, retained more feudal practices, and, most important, did not go through a

bloody revolution to achieve the doctrine of parliamentary superiority (though the British did cut off at least one head and became, for a time, a republic).

Although one often speaks of common law systems as made up of cumulative, judge-dominated case systems, and Civil law countries as code systems, Merryman (1985, ch. v) reminds us that the contrast is overdrawn and misleading. All American law students are forced to master the Uniform Commercial Code, and many states routinely refer to their laws as “codes.” So too, there are code nations, such as Hungary, that actually did not enact a code until it became a socialist state, although it was a Civil law country before then. Instead, what is distinctive of codes in civil law systems is that they are unified documents that seek to express the spirit, ideology, and goals of the new state the revolution has created. Thus, the French code, the *Code Napoléon* of 1804, sought to express the ideology of the French Revolution—liberty, equality, and fraternity—in every clause. It was intended to be a blueprint for a utopia. Thus, every attempt was made to abolish or at least hide any earlier statutes or laws that were inconsistent with it and try to make a fresh start. Law would now begin with the *Code Napoléon*.

Further, in lines with the French *Declaration Rights of Man and of the Citizen*, the *Code Napoléon* must be one that the average Frenchman could read and interpret for himself without “humiliating” himself by going through clerks, officials, and other overlords to get to the courts. As such, lawyers would be unnecessary. For this to be possible, the code must be complete—without gaps. Everything would be covered. Although manifestly impossible, the Germans did make a valiant attempt to do so in the Prussian *Landrecht* of 1794, which laid out some 17,000 detailed “fact situations” that were felt to cover everything that could come up, thus eliminating any need for lawyers or interpreters. It failed, but it is a striking illustration of how persuasive was the ideology of the French Revolution, which created the belief that it could be done. In the *Code Napoléon* and others following it, the goal of completeness is achieved but only by broad statements that practically invite judicial interpretation. (For example, the Italian Civil Code of 1942 tells judges to follow the intention of the legislature, and if it is not entirely clear, then to reason by “analogy.”)

Germany, under Bismarck, did enact a code in the full sense but in what can only be seen as a very Germanic manner. The *Code Napoléon* began with certain assumptions about human nature (equality, liberty, etc.) and tried to produce a humanistic code that would, presumably, have universal application. Under the influence of Savigny, a major German historian, that approach was felt to be inappropriate. Instead, he insisted (in the face of heated controversy) that the German code (and he did agree that a code was necessary), since it was intended to represent the spirit of German society, must be based on the German *volkgeist* (folk spirit). But it was first necessary to decide what that was. To that end, and with help of German romantic writers, he felt it necessary to plumb German history for the basic elements of the *volkgeist* and build the code up from those elements. That code would then be not only historically oriented but also scientific (in being built up by logical and empirical deduction from basic principles) and professional. This code would not be revolutionary—quite the contrary—but would be a true code in being built up, paragraph by paragraph, from principles that could stand on their own as a legal document and manifesto of the new Germany. One difference from the French code was that with its complexity and its dependence on the many historical details that went into the *volkgeist*, it would require lawyers to explain and interpret it. Nevertheless, it was careful, like the French, to make sure judges would have little power, perhaps even less than was the case in France. For answers, the German litigant, with the help of his lawyers, was to go to the code and, above all, not to seek answers as American and common law lawyers do. That would just return power to the judges again.

Codes were also enacted in the many countries in Europe and elsewhere that followed the French or German systems (Japan tried doing both, with a dollop of the U. S. model thrown in as well (Haley 1991), though the German model eventually triumphed). When a code was shown to have gaps, scholars (in keeping with the tradition of drawing on the juriconsults in Roman law) would develop a new principle, as in an example provided by Watson (1981), wherein a doctrine similar to the British concept of *estoppel* was developed to cover cases where a person had acted contrary to his usual practice but others had come to rely on this new behavior. But when a new

interpretation (rather than a gap) was the problem, the court would draw on similar cases, not as precedents but to use as a basis for a new principle that would be held to govern the case at hand. In this manner, the spirit of a code based on permanent principles would be maintained.

The German approach to codification had a lasting effect in emphasizing the dominant role of the scholar in civil law systems generally. Although the scholars were everywhere evident, in the case of Germany, Savigny and his followers felt that in creating what they considered to be a code based on “scientific” principles they were creating a body of law that was indeed scientific in a sense not unlike that of the physical sciences. It was built up from empirical elements, could be found to be true or false, subject, as any science is, to modification as new facts came in. It came to be called “legal science,” which remains the dominant school of thought even up to the present, however much criticized. It had its own concepts, such as a “juridical act,” and was systematic in structure and therefore an infinite distance from such American schools of thought as “legal realism.” Above all, the Pandectists (as they came to be known, from the Latin word for Justinian’s *Digest–pandectae*) felt their great strength was their purity in being divorced from politics and everyday life.

Actually, as Merryman (1985, pp. 65) points out, the Pandectists were far from being value free. The doctrine was shot through and through with the basic assumptions of nineteenth-century European liberalism—private property, liberty of contract and, above all, individualism. They were most limited in their concept of law as a matter of transactions between private individuals, an assumption that was to collapse in the growth of giant collectivities, such as corporations and labor federations and, most important, the increased role of the state in managing economic and social life. Although civil law systems recognize the distinction between private and public law, even dividing up law in just that way, they hardly anticipated, nor could they, the merging of the two systems as states began to manage private life, and as private relations became imbued with public consequences as with pollution, the spilling over of populations across borders and, still later, the emergence of new national groups or even nations and new communities such as the European Community (cf. Gessner, Hoeland, and Varga 1996).

It is clear from the above that the Uniform Commercial Code in the United States, though called a code, has nothing in common with the civil law codes. It is not animated by any underlying utopian principles, it makes no claim to answer all questions, and it makes no attempt to supersede any laws. Instead, it is a collection that seeks to bring some order into the many elements of commercial law. States are free to ignore it (though few do so), and new laws can be tacked onto it at any time. It remains judge-made law, with judges being free to draw on it or not for precedent as they please.

Legal science did leave one imprint on American law, though a minor one. *Case law*, as taught in American law schools, was thought of as a kind of science, with cases as the raw materials. Conclusions from case accumulations might generate principles with wide applications. An attempt to state these principles took the form of what were called *restatements*, which are, from time to time, quoted by judges as they go about making law.

JUDGES

As we have noted, the position of judges in civil law countries is vastly different from that in common law countries, especially the United States. Merryman (1985) points out that judges are not only respected in the United States but that some, such as Marshall, Holmes, Brandeis, and Cardozo, are culture heroes. The opinions of U. S. Supreme Court judges are studied carefully, as noted earlier, for hints of policy changes and guidance on how to proceed in deciding on difficult issues such as euthanasia, product safety, and whether schools may require bilingualism of its teachers. There seems no limit to areas into which judges may wander. Nor do judges hesitate in passing judgment on any law (if appropriate, of course) or even on the private life of the President of the United States. As has often been noted, American law is judge-made law built up from cases that lawyers have presented for decision (and, note, the judge must limit himself to such presentations, since he is very limited in his power to bring up issues on his own initiative). The supreme doctrine is that of *stare decisis*, whereby judges are required to follow decided cases; new cases must be compared to those already decided. If similar facts, then a similar decision. If the facts are significantly different, then there is a different decision. As noted by

Clark (Merryman 1991, p. 898), this need to do such case research, which falls on the shoulders of lawyers, helps explain (though only partly) the fact that the United States has more lawyers per capita than any other country for which we have reliable statistics.

Nothing could be further from that image among civil law judges. To begin with, the status of “judge” is usually much lower than is the case for common law judges. A civil law judge is a government employee, a civil servant, appointed to his position, whose career will follow that of other civil servants in rising by seniority and merit. His prestige is not necessarily low but reflects the prestige of civil servants at his level. He likely identifies with other civil servants, though more closely with judges, resulting in a certain insularity from the general public and its concerns. He is particularly isolated from any creative role in decision making. In line with the continuing suspicion of the dangers of judicial power going back to the *parlements* of pre-Revolutionary France (as well as similar excesses in other countries), he must not interpret the law or review legislation. As noted, he is a kind of expert in the application of the law to particular cases. More recently, constitutional review has begun to make its appearance in Austria, Spain, Italy, and Germany, but this goal is achieved not through giving judges in the ordinary courts new powers but rather through the creation of special constitutional review bodies that often are not called “courts” but that in time perform court functions.

This is not to say that appeal from judicial decisions was or is impossible. Quite the contrary, appeal is common but still dominated by attempts, at least in form, to restrict the power of judges. Thus, in France, appeal for what is claimed to be a misinterpretation of a law may be made to the Court (originally called a tribunal) of Cassation which could quash an incorrect interpretation by a lower court. It would indicate the correct interpretation but then remand it to the lower court to modify its ruling. The courts could ignore this decision but in practice would rarely do so. The process was time-consuming, and, in the case of Germany, the higher court would not only quash the lower decision but go ahead and revise the decision itself. It was also possible to appeal administrative rulings, though not, as in the American case, by declaring a law unconstitutional or

lacking in validity because of vagueness or for being over-broad. Instead, another body outside the court system was created. These might be what would amount to administrative courts, with a council of state at the top, a process seen not only in France but also in Italy and Belgium, as well as in Germany and Austria, where they were actually called administrative courts. Such attempts to counter state power were not necessary in a country such as England, where courts have the power of *quo warranto* (questioning the legality of an act by a public official) and *mandamus* (the ability to order a public official to perform as required by law). As noted, similar powers are possessed by ordinary American courts, though it is difficult for courts to use them.

The attempts to control the power and initiative of judges was tied up with another concern of civil law traditions; namely, the search for certainty. As long as judges had interpretive powers, the law was a tool in their hands that could be twisted to suit particular interests. Instead, the hope was that if the code plus legislation was clear and complete the judge would not need to exercise any initiative. Such a concern with certainty is not foreign to common law, either—persons need to know what the law says for law to be a guide to behavior. However, in civil law there is little that resembles the concept of equity at law. *Equity*—the power of a judge to limit the harshness of a law or to adapt the law to fit particular situations—gives him great powers. In England, equity reached its greatest development in the creation of chancery courts as a way of appealing to the king against what was felt to be an unjust rule of law. Civil law countries, though occasionally, and grudgingly, conceding a place for equity, preferred to confine it to the legislature, which might grant equitable powers to a court for a particular case or might make what amounts to an equitable grant of power to a court by telling it that, when the law is unclear, the court is to see to it that the parties acted “in good faith.” But the suspicion of judicial discretion remains and is not always a simple prejudice. Thus, the Nazi regime in Germany was able to make use of such discretion by using the courts to provide a patina of legality to its racist decrees, a process more difficult in Mussolini’s Italy, where discretion was more restricted.

One other important difference is that the English and American courts include in equitable

powers that of *contempt*. A litigant or witness who refuses to follow court processes or who refuses to carry out the will of the court may be subject to the contempt power, which can include fines and imprisonment. This degree of power is quite unknown in civil law countries where it is felt to give the judge what amounts to discretion to impose criminal penalties in civil cases. The civil law judge must, in comparable cases, limit himself to drawing on the person's property which may, of course, be felt by the person, as no less painful than a period in prison might be for others.

THE LEGAL PROFESSIONS

In the United States, lawyers, as well as the general public, think of the legal profession in the singular, though specialties are recognized. This is especially the case, as noted earlier, since such a high proportion are in private practice (well over 70 percent) as compared, for example, to only 33 percent in Germany, 42 percent in Colombia and only 23 percent in Chile. The United States also has a very low proportion of the profession acting as judges (only 3 percent) compared to 17 percent in Germany, 23 percent in Chile, and 42 percent in Colombia. (Clark 1982, figures are for the 1960s and 1970s). In Germany, 70 percent of positions in general administration are filled by persons trained in law.

Apart from differences in distribution, the path to a legal career is very dissimilar in different cultures. In the United States, aspiring lawyers go to a graduate law school, then sit for the bar exam (often after an intensive cram course that prepares them for that exam), then after passing the bar (in most states, the success-rate percentage is over 60 percent, and higher for first-time exam takers) he or she enters directly into practice in a firm, in a small-firm partnership, or as a solo. There they learn as they go along. Persons may, and many do, shift around from service in a government department to a public prosecutor office to the corporate law office of a private firm, or elsewhere. They may run for political office and may end up being rewarded for service by appointment or election as judge of a lower-level court and, for a few, high judicial office in a circuit or even a supreme court.

In England, the distinction between solicitor and barrister, though less rigid than in the past, continues. The would-be barrister takes his pupillage

under a barrister in one of the Inns of Court where he may, under good conditions, receive an apprenticeship and possible appointment after passing an examination. Only barristers may argue cases in the higher courts. Solicitors maintain direct contact with clients, collect fees, and assist barristers in their work. Solicitors are now being allowed to argue cases in some lower courts. Some barristers may develop honored reputations, a few being chosen as judges as the culmination of a distinguished career. There is almost no shifting to other careers on the part of barristers and very little among solicitors. In that respect, they resemble the lawyers in civil law countries.

In civil law countries, a young lawyer must make an early choice as to whether he wishes to be a judge, a government lawyer, a regular lawyer in private practice, a public prosecutor, or a notary. If he finds later he made a mistake, exit to another legal career is difficult, and does his experience in one does not translate into credits in another. He spends his whole career in the one field, a process that often leads to rivalry and conflict between the fields. An attempt to deal with this problem is made in Germany (and some other countries) in the *referendarzeit*, where a lawyer spends two or so years of practical training as a government lawyer, a judge, and in private practice. If lawyers choose to be judge, they will begin their career in a low-level court but may move up as openings occur. Although this career process isolates the judges who take on guild-like characteristics as civil servants, it also means that judges are often better trained than is frequently the case in the United States (where it is not uncommon for judges to have had no judicial experience whatsoever). Further, the quality of judging may be higher since candidates are chosen from among the best law school graduates. At the top in constitutional courts, for example, the quality of decision making is the equal of that found anywhere.

Public prosecutor in Civil law countries are much like U. S. district attorneys, but they also are required to represent the public interest in proceedings between private persons in court situations. In Italy and France, the prosecutor is also a member of the judiciary, allowing some shifting back and forth from prosecutor to judge. Some degree of shifting back and forth also takes place in Germany. Those lawyers working for the government in administrative positions are career

bureaucrats. Closest to the U. S. lawyer in private practice is the French *avocat* (distinctions such as those between the *avoués*, who acted as solicitors in appeals courts, and the *conseil juridiques*, who give general advice and represent clients before commercial courts, are gradually being eliminated or reduced in significance), the German *anwalt* or Italian *avvocato* (Merryman et al., p. 918). Much different from that known in the United States is the notary who receives legal training and is an important person. He drafts important legal instruments, such as corporate charters, wills, and instruments transferring land, as well as contracts. Most important, he authenticates documents. Once he does so, the instrument is accepted in court without further question. They also have monopolistic control over assigned territories. In Germany the services of a notary are required to validate legal documents for purchase, sale, and mortgage of land, for official records of decisions of company meetings, and for sale of shares in a private company (Merryman et al., p 911). Academic lawyers are found in a law school where they carry on the tradition of the old Roman juriconsult. However, most academic lawyers work for a professor with little or no pay, and wait for a vacancy that may never come. In Latin American countries, such persons may hardly earn a living, having to take on regular work as a lawyer in private practice or in public office.

CIVIL AND CRIMINAL PROCEDURE

Something should be said, in brief, about variations in procedure between the two systems. Here, the word “civil” is used in contrast to criminal. There is no trial or jury in civil cases, as may often be the case in the United States, though not in England. The entire process is different. The presence of a jury in the United States forces an acceleration of the entire process because of the difficulty and expense of getting the jury assembled and empanelled. Once that is the case, the court proceeds immediately with the trial in an attempt to conclude as quickly as possible.

In Civil law jurisdictions, civil cases go much more slowly. There is a brief preliminary stage when pleadings are submitted to a hearing judge. Next follows an evidence-taking, where the hearing judge takes notes and prepares a written record. That is later submitted to the deciding judge

who receives briefs from the counsel and listens to arguments. All of this takes the form of a series of meetings as each issue is brought to the attention of the hearing judge. There is little surprise as each lawyer is notified of each issue as it comes up, and, without a jury, there is no cross-examination. Generally, questions are passed to the judge who may conduct the investigation. There are fewer of the rules of evidence familiar to American lawyers (such as the exclusionary rule whereby illegally gathered information is excluded from trial), though a number of rules are employed, such as excluding biased persons from testifying, as well as taking what is called a “decisory oath” in some countries. There is in many countries a “loser pays” rule, referring mostly to legal fees, though the amounts are usually limited by a court schedule. Contingent fees are usually considered illegal (France) or unethical (Germany) but are found in Japan, Indonesia, and Thailand (Merryman et al., p. 1026). Many foreign legal authorities are appalled by its prevalence in the United States, feeling that a lawyer should not be personally given a stake in the outcome of a case.

Although substantive criminal law is similar in both systems, civil law jurisdictions, in line with the revolutionary principle of limiting the power of judges, reject the American practice, which gives the judge power to award penal and general damages in criminal cases, not to speak of the contempt power (which is very rare), instead insisting the judge be limited to what is provided for in legislation. The contrast is often drawn (or overdrawn) between what is called the “accusatory” model in the United States and the “inquisitorial” model in civil law countries. Historically, the accusatory procedure is felt to have been a development from that of private vengeance in which the interested parties would be the main participants. Instead of settling their dispute by direct conflict or feud, a legal procedure would involve a neutral third party who would seek to secure a settlement. In such a triadic situation, as noted at the outset, the object was to secure an outcome that would settle the matter by leaving each party feeling justice had been done. In earlier times, when trial was by battle, ordeal, or other ways, although seeming to be a throwback to a time of “barbarous” cruelty, these methods, apart from their presumed psychological effects (the guilty party

feeling he would be caught and so offering confession at once), had the virtue that they brought the conflict to an end, and prevented further acts of vengeance that would disturb the peace of the community. With the accusatory practice, presumably conflict would also be terminated but might go on if each party felt justice had not been done.

The inquisitorial model introduced the state as an active participant in the trial. Now the judge, who is after all a representative of government, is in a coalition with the prosecution against the third party, the defendant. Although this biases the process, in practice, the introduction of the jury, the fact that proceedings are oral, as well as limitations on the power of the judge all combine to make the system fair, though excesses did and continue to exist.

The criminal trial is in three parts: the investigative phase, with the public prosecutor assuming an active role; the examining phase, presided over by a judge who assumes an active role in examining the evidence; and preparing a record and the trial. Judges may, if warranted, end the proceedings if they feel the evidence is not conclusive, or they may decide the case should go to trial. The accused is entitled to legal representation as well as the right to inspect the material the judge has collected. He can be questioned, but not sworn, and he or she may refuse to answer. Unlike the American system in which a defendant, if sworn, may then be cross-examined, no comparable procedure exists, though a refusal to answer by the accused may be taken into account by the jury. British judges assume a more active role in the trial process than is the case in the United States. However, this is not “inquisitorial” in a narrow sense but rather a reflection of the fact that in the English procedure the judge determines the relevancy of evidence, rather than the strict exclusionary and other rules emphasized in American courts. To do their jobs, English judges are much more willing to question witnesses or even raise issues (Glendon et al., 1982, ch.. 10).

Until the 1980s, plea bargaining was considered to be undesirable practice, only possible in America. But judicial scholars increasingly asked how could civil law jurisdictions possibly handle all the criminal cases they had to decide without some form of plea bargaining? After a spirited debate and careful research, it was finally concluded that

plea bargaining, though not exactly like that used in America, was in fact being used in European countries. In the case of Germany, Hermann (1991) reports that some kind of plea bargaining takes place in from 20 to 30 percent of all cases. While far from the American percentage of 90 percent, that is still considerable, particularly since it is accompanied by other forms of sentence reduction and mitigation of offenses. It is widely employed in complex cases, such as white-collar crimes, tax evasion, and drug offenses, which present nearly impossible evidentiary problems, as well as less serious crimes, which are settled with a fine. It is rare in cases involving violent crimes, however. Bargaining occurs at all stages of a criminal proceeding, often with the active participation of the judge, who may even take the initiative. A settlement may take the form of the accused agreeing to pay a sum of money to a charitable organization. Other alternatives include penal orders that are similar to *nolo contendere* pleas in which the accused agrees to a fine—usually for minor misdemeanor cases, such as traffic cases. Pleas also occur if the accused makes a confession. Normally, a confession does not lead to avoidance of a trial, as is the case in America. Instead, it usually leads to a reduction in the sentence. Other countries are also beginning to allow plea bargaining as many had been doing, but are now doing more openly. The most striking example is that of Italy, which even uses the term *patteggiamento*, the Italian word for bargain (Piazzi and Marafioti 1992; Merryman et al., pp. 1100 ff). However, there is no reduction of the charge, as in the American system, but there is a maximum reduction of one-third of the normal sentence, which may not exceed two years, which has the effect of limiting the practice to cases with shorter normal sentences. In Italy, as is the case in other civil law countries, the trial decision is made by a panel of judges, a practice which, however costly, is defended as superior to the American practice, which places what is felt to be excessive power in the hands of a single judge.

WILL COMMON LAW AND CIVIL LAW SYSTEMS PERSIST?

Although we have focused on differences between the two systems, and the differences are indeed substantial, there is considerable movement toward the convergence of common and Civil law systems. The attempts to severely limit the power

of judges have, over the years, been recognized as excessive and more a holdover from fears of arbitrary and class-based favoritism of judges. From the refusal to place limits on the power of legislatures, Civil law countries have developed constitutional limitations, even in the form of courts, though often hidden under other names. Historically, Civil law countries divided the field between private and public law, with most of the concern historically being with civil law (law of persons, marriage, contracts, torts, etc.). Public law was felt to be the concern of legislatures or the sovereign. However, the coming of the modern state has led to an enormous growth of administrative law, along with appropriate court systems, leading to situations not much different in essence from those found in developed common law countries.

Civil codes have receded in significance as state legislatures and parliaments enact more far-reaching laws never contemplated in earlier times, particularly those associated with large-scale industry, the welfare role of governments, complex bodies of labor law, and especially with the emergence of the government as an economic participant in national affairs. Perhaps of greatest significance is the emergence of new international entities, especially the European Community, before which national codes have been slowly giving way. Of course, that tendency may be reversed, but it seems strongly in process. On the other hand, common law countries have recognized the advantages of classic civil law procedures, such as the importance of certainty in legal decision making, though such certainty is sought not through a code but by a succession of cases. The power of judges to make decisions has been the object of attempts by the U. S. Congress to place caps on awards for injury, as well as the attempt of persons to bypass courts and seek justice through changes in legislation, as in cases of pollution, abortion, and other public issues.

Is one system better than the other? The question is unanswerable in that form. Even though civil law authorities continue to be suspicious of lawyers, they discover they must have them and grant them powers they would prefer not to. That is, of course, a well-known problem in the United States as well. Each system must be understood in the context of the culture and social structure of the country that employs it. Ultimately, any question of superiority must be answered in terms of

how well the system serves the legal needs of the country. Most countries, in fact, employ a mix of systems in which one finds bits and pieces of both common law and civil law systems.

COURTSHIP

Given the social centrality of the family institution and the role of courtship in the family formation process, it is not surprising that the study of courtship has received attention from several disciplines. Anthropologists have described practices

in primitive and other societies, historians have traced courtship patterns in America from colonial to contemporary times, psychologists and social psychologists have examined intra- and interpersonal components of relationships, and sociologists have developed research-based theories explaining the process of mate selection, and have investigated various courtships dynamics. Here, some attention will be given to each of these approaches, along the way selectively noting scholars who have made major contributions.

Historically, according to Rothman, the term *courtship* applied to situations where the intention to marry was explicit (if not formally—and mutually—stated). *Courting* was the broader term used to describe socializing between unmarried men and women” (Rothman 1984, p. 23, italics in original).

Scholars have disagreed as to whether dating—a twentieth-century term for a primarily recreational aspect of courting—should be considered a part of courtship since, according to Waller (1938) and others, dating may be merely thrill-seeking and exploitative, and not marriage oriented (but see Gordon 1981 for an opposing view). However, wooing (that is, seeking favor, affection, love, or any of these) may be integral to courtship and yet not result in marriage. For present purposes, then, courtship will be understood in its broadest sense—as a continuum from casual to serious. Thus, “the unattached flirt, the engaged college seniors, the eighth-grade ‘steadies,’ and the mismatched couple on a blind date are all engaging in courtship” (Bailey 1988, p. 6).

Queen, Habenstein, and Quadagno’s (1985) classic text provides much of the basis for the following brief and highly generalized overview of some mate-selection patterns unlike those found in contemporary America. Some of these systems involved little or no courtship. For example, among the ancient Chinese, Hebrews, and Romans, marriage was arranged by male heads of kin groups. Among the ancient Greeks and until recently among the Chinese, many brides and grooms did not meet until their wedding day. Around the turn of the century (1900), infant marriages were the rule among the Toda of south India, and the bride was deflowered at about age ten by a man who was not of her clan and not her husband. In medieval England, contrary to the literature of chivalry, love

had little to do with mate selection in any social class because marriages were arranged by lords or by parents with primary regard to the acquisition of property.

In societies where romantic love is not a basis for mate choice, such sentiments are seen as dangerous to the formation and stability of desirable marital unions—those that maintain stratification systems (see Goode 1969). Queen, Habenstein, and Quadagno (1985) describe still other mate-selection patterns that do involve some form of love, including the systems found on Israeli kibbutzim at midcentury, among ethnic immigrant groups in the United States, and among African-Americans during slavery (see also Ramu 1989). In the twentieth century, however, and especially since the 1920s, courtship in Western societies has been participant-run and based on ideas of romantic love. In the United States today, it is not uncommon for a couple to meet, woo, and wed almost without the knowledge of their respective kin. “Compared with other cultures, ours offers a wide range of choices and a minimum of control” (Queen, Habenstein, and Quadagno 1986, pp. 8–9).

In colonial America, practices differed somewhat between the North and South. In the North, mate choice was participant run, but a suitor’s father had control over the timing of marriage since he could delay the release of an adequate section of family land to his son while the son’s labor was still needed. Conjugal (but not romantic) love was thought to be the *sine qua non* of marriage, and couples came to know and trust one another during often lengthy courtships. In the South, a custom of chivalry developed, closely guarding the purity of (at least upper-class) women, but condoning promiscuity among men. Parental consent was required for the beginning of courtship and for marriage and open bargaining about property arrangements was commonplace. Unlike the colonial North, where marriage was considered a civil ceremony, in most parts of the South, Anglican church ministers were required to officiate at weddings. In both regions, banns were published prior to weddings.

During the 1800s, mate choice became more autonomous with the growth of cities and the spread of industrial employment. Choices were affected less by considerations of wealth than by

personal qualities—especially morality, spirituality, and “character.” Wooing was rather formal, with each participant carefully evaluating the qualities of the other. Courtship tended to be exclusive and directed toward marriage.

Then, from about 1900 to World War II, a system evolved in which there was much “playing the field” (casual dating), gradually more exclusive dating (“going steady”), engagement, and finally, wedding—a relatively fixed sequence. Following the war, stages of courtship were typically marked by symbols (e.g., wearing a fraternity pin, then an engagement ring), each stage implying increased commitment between the partners. By the 1950s, a separate youth culture had developed. Ages at first marriage declined dramatically, and dating started earlier than ever before. The sexual exploration that had previously been a part of the last stage of courtship now occurred earlier, even in very young couples.

During the 1960s, a time of “sexual revolution,” nonmarital cohabitation increased—not substituting for marriage but delaying it. In the post World War II. period and since, among the young especially, demands for both freedom and dependence (i.e., the right to sexual freedom without assuming responsibility for its multifaceted consequences) have been relatively widespread. Concurrently, rates of nonmarital pregnancy rose dramatically.

In general, every society attempts to control sexual activity among unmarried (and married) persons, but the forms of control (e.g., chaperonage) and the degree of enforcement have varied. Virginity, especially in women, is highly prized and guarded in some cultures but has no special value in others. Similarly, all societies attempt to limit the pool of those eligible to marry, but the precise constraints have differences across societies and from time to time. Typically, blood kin and relatives by marriage (and in some cases, baptismal relatives such as godparents) are delimited to greater or lesser degrees from the eligibility pool.

Where male elders have arranged marriages for their offspring (generally in ascription-based societies), the accumulation of family power and prestige has been of primary concern, with dowrys, bride prices, or both figuring prominently in prenuptial arrangements. In participant-run mate

selection (generally in achievement-based societies), the power and prestige of a dating partner (although defined in terms other than land, cattle, and the like) is still valuable. Good looks (however defined) in women, for instance, are a status symbol for men, and conspicuous consumption in men (cars, clothing, spending habits) provides status for women. Thus, within the field of eligibles is a smaller field of desirables. Unfortunately, the qualities that are valued in dates (from among whom a mate may be chosen) are not necessarily those one would want in a spouse.

Even in participant-run “free choice” systems, there is a tendency toward homogamy in the selection of partners, whether conscious or not. As a society becomes more varied in its mix of persons within residential, educational, religious, or work-related settings, the tendency toward heterogamy increases. That is, the field of eligibles and desirables broadens. Heterogeneity leads to a prediction of “universal availability” (Farber 1964) as the salience of social categories (such as race, age, religion and class) declines. For example, interracial relationships, once unthinkable (e.g., in the colonial American South), increased with urbanization, industrialization, and a general movement toward educational and income equality. Social class endogamy, however, is the general preference, although women are encouraged with varying degrees of subtlety to “marry up,” and a dating differential exists such that men tend to court women who are slightly younger, physically smaller, and somewhat less well educated or affluent than themselves.

Contemporary courtship, marked as it is by freedom of choice, has been likened to a market in which the buyer must be wary and in which there is no necessary truth in advertising. Persons compete, given their own assets, for the best marital “catch” or the most status-conferring date. Waller and Hill (1951) warned about the potential for exploitation in both casual and serious courtship and indeed, critics of conventional dating have decried it as a sexist bargaining arrangement in which men are exploited for money and women for sexual favors. The superficiality of dating, its commercialization, the deceit involved (given contradictory motives), and the high levels of anxiety provoked by fears of rejection (especially in men), are additional drawbacks. Since status differentials still characterize the sexes, dating may also be seen

as a contest in which a struggle for power and control between partners is part of the game. Thus, courtship’s emphasis on individualism, freedom, commercialism, competitive spirit, and success reflects the larger social system within which it functions. One may well ask whether such a system can prepare participants for marriage which, unlike courtship, requires cooperation and compromise for its successful survival.

Efforts to predict who marries whom and why, to delineate the courtship process itself, or both, have interested a number of scholars. Based on a large body of theoretical and empirical work, Adams (1979) developed a propositional theory to explain how courtship moves from initial acquaintance toward (or away from) marriage in an achievement-oriented society. The propositions, in slightly modified language, are as follows:

1. Proximity, which facilitates contact, is a precondition for courtship and marriage.
2. As time passes, marriage is increasingly more likely to be with a currently propinquitous than with a formerly propinquitous partner.
3. Propinquity increases the likelihood that one will meet, be attracted to, and marry someone of the same social categories as oneself.
4. Early attraction is a result of immediate stimuli such as physical attractiveness, valued surface behaviors, and similar interests.
5. The more favorable the reactions of significant others to an early relationship, the more likely the relationship will progress beyond the early attraction stage.
6. The more positive the reaction of the partners to self-disclosures, the better the rapport between them.
7. The better the rapport between the partners, the more likely the relationship will be perpetuated beyond the early attraction stage.
8. The greater the value compatibility—consensus between partners, the more likely that the relationship will progress to a deeper level of attraction.

9. The greater the similarity in physical attractiveness between the partners, the more likely that the relationship will progress to a deeper level of attraction.
10. The more the partners' personalities are similar, the more likely that the relationship will progress to a deeper level of attraction.
11. The more salient the categorical homogeneity of the partners, the more likely that the relationship will progress to a deeper level of attraction.
12. The more salient the categorial heterogeneity of the partners, the more likely that the relationship will terminate either before or after reaching a deeper level of attraction.
13. The greater the unfavorable parental intrusion, the more likely that the relationship will terminate either before or after reaching a deeper level of attraction.
14. An alternative attraction to the current partner may arise at any stage of a couple's relationship. The stronger that alternative attraction to either partner, the more likely that the original couple's relationship will terminate.
15. The greater the role compatibility of the partners, the more likely that the relationship will be perpetuated.
16. The greater the empathy between the partners, the more likely that the relationship will be perpetuated.
17. The more each partner defines the other as "right" or as "the best I can get," the less likely that the relationship will terminate short of marriage.
18. The more a relationship moves to the level of pair communality, the less likely it is that the relationship will terminate short of marriage.
19. The more a relationship moves through a series of formal and informal escalators, the less likely it is to terminate short of marriage (Adams 1979, pp. 260-267).

Adams (1979) also provides some warnings about these propositions. First, some factors (such as partner's good looks) have greater salience for

men than for women, while some (such as partner's empathic capacity) have greater salience for women than for men. Second, some factors such as parental interference may have different outcomes in the long run compared to the short run. Third, the timing of courtship may bring different considerations into play, e.g., courtship in later life such as following divorce or widowhood, or when children from previous marriages must be considered (see Bulcroft and O'Connor 1986). Finally, social class factors may affect the predictive value of the propositions. There is also a difference between traditional (male-dominated) and egalitarian relationships—the former more often found in the working class and among certain ethnic groups, the latter more likely to characterize the middle class. Thus, the kind of marriage one anticipates (traditional/egalitarian) may influence the mate-selection process. (See also Aronson 1972 for specifications of the conditions under which various interpersonal attraction predictors such as propinquity and similar interests operate).

Further, as courtship has moved away from the fixed-stage sequence of development, it may be viewed best from a circular-causal perspective (Stephen 1985) in which progress is strongly influenced by communication within the couple, leading to increased or decreased movement toward marriage.

The timing of marriage may be influenced by such factors as meaningful employment opportunities for women (which may diminish their motivation to marry), the increasing acceptability of nonmarital cohabitation and adult singlehood (see Stein 1981), and the effects of nonmarital pregnancy or of various intolerable conditions (such as violence) in the family of origin. Currently, a number of scholars are studying each of these topics. They affect not only the timing of marriage but also how we define courtship.

Regarding premarital factors that contribute to later marital adjustment, no scholar has presented evidence to refute Kirkpatrick's ([1955] 1963) conclusions: The happiness of parents' marriage; adequate length of courtship; adequate sex information in childhood; a happy childhood including a harmonious relationship with parents; approval of the courtship relationship by significant others; good premarital adjustment of the couple and strong motivation to marry; homogamy along age,

racial-ethnic, and religious lines; and, later age at marriage.

Murstein (1980) reviewed mate-selection scholarship from the 1970s and predicted that researchers would focus less on the “old standby” variables such as race, class, and religion and more on the dynamic aspects of courtship. He was correct. Some of the major themes that have interested scholars in recent years are identified below.

Studies of cohabitation included early efforts to identify its several types (both structural and motivational). Later studies focused on the effects of cohabitation on subsequent marital happiness, satisfaction, and stability. The general finding across such research is that living with someone prior to marriage has little or no positive effect. Instead, most studies show negative effects in terms of happiness, satisfaction, and stability. This research has been carried out in the United States, Canada, and other countries, and although the rates vary, they are quite uniform in showing that there is a greater tendency to divorce among those who have lived with someone (i.e., the future spouse or any other partner) prior to marriage than among those who did not previously cohabit. Most scholars point out that either or both of two factors are probably at work here; first, the less-than-full acceptance of cohabitation as a lifestyle (implying less or no social support for those who cohabit), and second, the kind of persons who choose a “deviant” lifestyle—persons who are risk-takers, and who are less commitment-oriented. (However, see Popenoe 1987 for a different view of cohabitation in a setting where it is more normative.)

As rates of sexual activity outside of marriage rose, and as sex was to some extent disengaged from procreation (since the arrival of the birth control pill in the 1960s), research and theoretical interest focused on changes in sexual behavior and values in courtship. (See Schur 1988 for a highly negative view of the “Americanization of sex.”) It should be noted that cohabitation appears to be a “sexier” arrangement than marriage (Call, Sprecher, and Schwartz 1955), which may account for why prior cohabitants’ marriages do not meet their expectations and thus, may be more divorce-prone.

Also on the negative side of the ledger, there is concern about the spread of sexually transmitted diseases, including AIDS, and on factors related to

the use or nonuse of “safe” sexual practices. Research continues to examine variations in premarital sexual activity rates and their effects. Frazier (1994) points out that the AIDS epidemic has not sidetracked the sexual revolution that began in the 1960s. This is because the forces that fueled the revolution are still in place, and some are intensifying—“mobility, democratization, urbanization, women in the workplace, birth control and other reproductive interventions, and media proliferation of sexual images, ideas, and variation” (p. 32). Moreover, cohabitation is increasing as are the single-person household and single parenthood. The pursuit of individuality and freedom continues. Many studies show that women are more sexual today than at any previous time in this century, says Frazier. On the positive side, a greater openness about sexuality-related information has occurred. The trend, as Frazier sees it, is away from the illusions of traditional ideas about romance and toward a more reality-based understanding between men and women. Also positive, and part of the same revolution, are expanded definitions of masculinity and femininity as the trend toward egalitarianism continues.

Unmarried households (i.e., single parenthood) have lost much of their past stigma, and increased numbers of women are choosing to remain single over the (potentially illusory) financial security of marriage, notes Frazier. This is largely a function of women’s increased earning capacities in an expanded set of labor market opportunities.

Along with the strong trend toward later marriages has come declining family size. The U. S. Department of Commerce (1992) tells us that the median age at marriage has been rising and in the 1990s was higher than it had been a century earlier. One outcome of this is, as noted earlier, a rise in nonmarital births. Related to this is a rise in the now considerable rate of child poverty, since women’s (i.e., single mothers) earnings are not as high as single fathers or of men in general.

Frazier, Arikian, Benson, Losoff, and Maurer (1996) report that, among unmarried singles over age thirty, reasons for remaining single have to do with barriers as well as choices and that men would like to marry more than would women. (This situation is reversed among younger adults, where women are more interested in marriage than are men.) Never-married adults want to marry more

than do divorced adults, and divorced women have the least desire for marriage. Again, this may have to do with the greater options (if not economic parity with men) open to women in recent years. Both men and women state their primary reasons for wanting to marry as love, the desire for a family, what they see as the “romantic” nature of marriage, a desire for economic security (which, as noted, may be illusory), and the opportunity for regular sexual activity. However, the desire to remain single—for both men and women—is linked to having unrestricted career opportunities, to the desire for an “exciting” lifestyle, and to having the freedom to change and experiment. Men also identify the restrictive nature of marriage and the limits on mobility and experiences as reasons to remain single, but women mention the desire to be self-sufficient and the possibility of poor communication in marriage as among their top reasons for choosing singlehood over marriage.

Around the world, childbearing by unwed women has increased, accounting for about one-third of all births in America and northern Europe in the mid-1990s. Despite the fact that there has been a recent decline in teen births in the United States, teen pregnancies are much higher in America than in other industrialized nations, for which our poor (or absent) sexuality education is often blamed (Ventura, Matthews, and Curtin 1998).

The rising age at marriage and its effects have interested scholars not only in developed countries (e.g., East Germany) but also in developing countries such as Sri Lanka, Java, and sub-Saharan Africa. One effect is the relatively large numbers of young adults still living in the parental home. Living arrangements and other family influences such as parental divorce or having had alcoholic parents have been studied for their effects on dating behavior, premarital pregnancy, violence in courtship, and on drinking behaviors of young adults.

Research shows that expectations of marriage among those of courting age are inflated, when compared to the expectations of persons with marital experience. Inflated expectations may be another of the causes of subsequent divorce. Moreover, scholars who study conduct on dates have uncovered the seeming paradox of egalitarian daters who behave traditionally during the earliest stages of courtship. Behavior that does not reflect

beliefs gives false impressions, and has obvious implications for the spontaneity and honesty (or lack of them) of the conditions under which courting partners get to know one another. In this era when dating/courtship has lost much of its coherence, we find advice books for young adults with names such as *Dating for Dummies* (1996) and *The Complete Idiot's Guide to Dating* (1996). The titles alone tell a story. Still other writers attempt to capitalize on the old notion of a war between the sexes, implying that in addition to knowing little about how to date/court, we know very little about one another since “men are from Mars and women are from Venus”—unless we study such guides as *Mars and Venus on a Date* (Gray 1988). Under the guise of assisting daters to communicate with one another, they present half-traditional, half-egalitarian versions of how to get along with persons who are seen as each others’ “opposites.” These popular books rest on the idea that by following their prescriptions, as in *The Rules* (Fein and Schneider 1996), our courtships will be successful and their outcomes happy. (*The Rules*, interestingly, is highly traditionalistic, and reads like a guide for 1950s “dating success.”)

In contrast to these for-profit offerings, scholars continue to study “close” or “intimate” premarital relationships as these have changed from stylized conventional dating to the more informal “hanging out” and “hooking up,” the latter an almost only just-for-sexual-purposes arrangement. These shifts follow in part from a weakened normative imperative to marry (Thornton 1989) and in part from the trend toward more egalitarian relationships between the sexes. However, in almost all research, male/female similarities and differences continue to form part of the data analysis. Recent studies have examined attraction in an effort to identify its bases, and, less broadly, have investigated “opening lines” used for meeting potential partners. Which lines work, which do not, and why are unsuccessful lines still in use? These are among the kinds of questions that are asked and answered by such investigations. Scholars working in criminal justice-related areas have provided information about the use of Rohypnol, a central nervous system depressant that is “abused throughout the United States by high school and college students, rave and nightclub attendees, and drug addicts and alcohol abusers.” Its use facilitates sexual assaults (Office of National Drug

Control Policy 1998). Other investigations examine dating among herpes- and HIV-infected persons. On the more positive and more conventional side, some of the standard variables such as age and education have been reexamined for their impact on mate choice patterns (Qian 1998).

Earlier, the trend toward expanded gender roles was noted. Considerable research interest has been devoted to identifying the components of conventional (traditional) masculinity and femininity and their effects, and on resistance to change in these stereotypes—for example, because of ongoing conventional socialization practices and, as communications experts have documented, because of the effects of various media portrayals supporting the *status quo ante*. Scholars have also noted the greater likelihood of relational success among androgynous than among conventionally masculine men and feminine women.

Research on courtship has extended to the study of “taboo” conversational topics, degrees and forms of honesty and deception, communication style differences between the sexes (one result of differential socialization), and methods of conflict resolution that enhance relationship survival or that presage relationship dissolution. Interest in failed relationships has attempted to identify factors at both individual and dyadic levels that might have predicted which pairings would last and which would not. In ongoing relationships, scholars have investigated the positive and negative effects of outside influences such as parental or peer pressure, and the parts played by same- and cross-sex friends. Other topics of interest have included barriers to the development of trust and the effect of its loss, the meanings of commitment, and the effects of self-disclosure, self-esteem, self-awareness, and jealousy on close relationships.

We have witnessed a virtual explosion in the study of love—attempts to identify its forms, its properties, and its distribution of types across women and men as well as the effects of all of these, especially in terms of romantic love. On the negative side, a number of studies of violence in courtship have shown relatively high rates of this kind of activity, especially between cohabitators—and also reveal that a sizable minority of those who have experienced violence in close relationships identify it with a loving motive. This seemingly odd

justification is explained by the practices of parents who, when using violence against their children, often indicate that they hit or spank “out of love.” Thus, the lesson (i.e., the rationalization) is learned early. Other negative aspects of courtship include the study of “mind games” and other facets of competition between partners, sexual aggression including date/acquaintance rape, and the effects of contrasts between idealized images and courtship realities.

As courtship itself has expanded, researchers have taken a interest in an expanded range of relationship types. For example, the romantic involvements between lesbian women and between gay men have been studied in their own right, and also for comparative purposes with heterosexual partnerships. A predictable area for future study is the legalization of marital relationships between same-sex partners.

Other innovations such as video- and computer-matching and personal advertisements in print media have also captured researchers’ attention, as has using the internet to make romantic contacts (sometimes called “cyberdating”). Scholars can be expected to pursue the study of the impact of prenuptial agreements on relationships. To a lesser extent, older lines of research have continued to probe the purported decline of, or changes in, the double standard, the “principle of least interest” (Waller 1938) as related to changes in gender roles, the dimensions of intimacy, and on desired traits in dating partners as these may differ between premarital partners and permanent mates.

As society grows more complex and the rate of change is increasingly rapid, confusion over the mate-selection process in all of its dimensions appears to be rife. A study of college student dating shows that these young adults have questions about virtually every aspect of the process and about the choices they make (Laner 1995). High divorce rates have produced a backlash of insecurity as the marriage decision approaches. This is reflected in the frequently asked question, “How can I be *sure* of making the right choice in a partner?” Sociologists and scholars in related disciplines continue to study a growing set of factors that shed light on the answer.

CRIME DETERRENCE

See Criminal Sanctions; Criminology; Social Control.

CRIME RATES

The interpretation of crime rates seems unproblematic, but those sociologists who study crime know that is not the case. Even simple counts of

crime raise difficult issues. To imagine the difficulties consider two men at a bar. One of them makes a rude comment to the other and the other person shoves him. The person shoved strikes the other person on the jaw before the fight is broken up. The person hit on the jaw calls the police to the scene and wants to press charges, but the person shoved claims self-defense and that the person who shoved him is guilty of an assault. The two men may decide that the matter is not worth pressing and the police may agree. On the other hand, the police may file a report that results in an arrest. If a grand jury thinks the evidence warrants it, the case may go to trial. Even if the case reaches trial, the jury may acquit the accused. Other possible steps in the process exist, but determining whether a crime occurred is often difficult. The process contains many decision points. Will the individuals involved report the incident to the police? Will the police determine that a crime occurred? Now imagine that an interviewer asks one of these men about their history of criminal offending or victimization. Would the individual report this incident to the interviewer? Would one of the individuals admit to an interviewer that he committed an assault? Crime counts constitute an important element in the calculation of crime rates, but they are only one factor.

Rather than report simple crime counts, social scientists often calculate crime rates. Depending on the context, they may do this because crime rates: (1) allow for the comparison of crime patterns across groupings of different sizes, (2) make possible the comparison of the relative frequency of crime over time, or (3) help in the assessment of the risk of victimization. In terms of comparability of patterns across groupings of different sizes, simply reporting the number of crimes in cities with 100,000 or more residents produces unsatisfactory results. Forty homicides may not represent a large number for New York City, but twenty homicides represent a large number in Eugene, Oregon. The calculation of homicide rates per 100,000 residents for New York City and Eugene makes comparisons between the two cities easier. Similar calculations of rates for different years facilitate comparisons over time. The number of homicides may have doubled in Los Angeles from 1920 to 1990 while the rate per 100,000 residents has decreased. In terms of the risk of motor vehicle theft, a rate based on the number of motor

vehicle thefts per 10,000 registered motor vehicles may be more helpful than the number of motor vehicles stolen.

Equation (1) represents the general formula for calculating a crime rate:

$$\text{Crime Rate Per Base} = \left(\frac{\text{Number of Incidents}}{\text{Relevant Population Size}} \right) \times \text{Base} \quad (1)$$

Each of the components in this formula: Base, Relevant Population Size, and Number of Incidents, represents an important decision point when calculating a crime rate. Determining the most appropriate measure for each component is not as straightforward as it might first appear.

Selecting a Base: If the base is 100,000, then the interpretation of the rate is the number of incidents per 100,000. With a base of 100 the interpretation is in terms of the number of incidents per 100 (a percent). Reports of crime rates often appear as rates per 100,000 or per 10,000. One reason for this is the relative infrequency of some crimes. For example, in 1997 the number of murders in the United States was 18,210 and the population of the United States was 268 million. If we choose 100 for the base, we find that the homicide rate per 100 is .0068 or .0068 percent. This figure challenges the intuition of most people. We should choose the base to make the rate easier to interpret. If we choose 100,000 for the base, we find that the homicide rate is 6.8 per 100,000; a much easier figure for most people to understand.

Relevant Population Size: The choice of the relevant population size depends upon the selection of an appropriate "relevant population." The Uniform Crime Reports (UCR) typically chooses the number of residents as the relevant population. This number is used to calculate crime rates for cities or for the United States as a whole in the UCR. The National Crime and Victimization Survey (NCVS) often uses the number of residents who are twelve years of age or older as the relevant population, since the survey only asks about crime incidents involving those in that age range. At other times households represent the relevant population as when victimization surveys calculate rates for households touched by crime.

General Definitions of Part I Offenses in the Uniform Crime Reports

Criminal Homicide	Murder and nonnegligent manslaughter: the willful (nonnegligent) killing of one human being by another. Deaths caused by negligence and justifiable homicide are excluded.
Forcible Rape	The carnal knowledge of a female forcibly and against her will. Included are rapes by force and attempts or assaults to rape. Statutory offenses (no force used and victim under age of consent) are excluded.
Robbery	The taking or attempting to take anything of value from the care, custody, or control of a person or persons by force or threat of force or violence or by putting the victim in fear.
Aggravated Assault	An unlawful attack by one person on another for the purpose of inflicting severe or aggravated bodily injury. This type of assault is usually accompanied by the use of a weapon or by means likely to produce death or great bodily harm. Simple assaults are excluded.
Burglary	Breaking or Entering: The unlawful entry of a structure to commit a felony or a theft. Attempted forcible entry is included.
Larceny	Theft (Except Motor Vehicle Theft): The unlawful taking, carrying, leading, or riding away of property from the possession or constructive possession of another. Attempted larcenies are included. Embezzlement, con games, forgery, worthless checks, etc., are excluded.
Motor Vehicle Theft	The theft or attempted theft of a motor vehicle. A motor vehicle is self-propelled and runs on the surface and not on rails. Specifically excluded from this category are motorboats, construction equipment, airplanes, and farming equipment.
Arson	Any willful or malicious burning or attempt to burn, with or without intent to defraud, a dwelling house, public building, motor vehicle or aircraft, personal property of another, etc.

Table 1

SOURCE: Federal Bureau of Investigation, 1998. *Crime in the United States—1997* (Appendix II).

Thus, the total number of people may not be the most appropriate “relevant population.” In the case of rape incidents, it might be more appropriate to compute rape rates using women as the relevant population. For motor vehicle theft, the relevant population might be the number of registered motor vehicles. For commercial burglaries, the relevant population might be the number of commercial establishments. Social scientists should choose these populations carefully.

Number of Incidents: Determining the value for the numerator of the crime rate formula raises particularly difficult issues. The UCR, for example, employs a complicated set of rules for counting the number of incidents. For example, the UCR “hierarchy rule” ensures that for Part I crimes (the most serious street crimes) only the *most* serious crime is recorded. Thus, if a person breaks into a store, is confronted by the owner and threatens the owner with a gun, and then kills the owner, the offense is recorded as a homicide, but not as a burglary or robbery or assault. The “hotel rule” is

invoked when a burglar breaks into several units in an apartment or hotel and only one burglary is counted. Researchers draw a distinction between an incident rate and a prevalence rate. This involves a distinction between the number of criminal incidents per some relevant population and the number of offenders per some relevant population. Using the number of offenders per some relevant population produces a prevalence rate.

Thus, many decisions help determine the most appropriate crime rate for a particular purpose. These decisions need to be considered when interpreting a particular rate or when attempting to compare one crime rate with another.

SOURCES OF CRIME DATA IN THE UNITED STATES

There are three major sources of crime data in the United States, and knowing the strengths and weaknesses of these data sources helps explain why crime rates derived from them often vary.

Crimes and Crime Indexes For the United States, 1997

Offenses	Number	Rate per 100,000 Inhabitants	Percent Change in the Rate From 1988 to 1997
Crime index total	13,175,100	4,922.7	-13.1
Violent crime index	1,634,770	610.8	-4.1
Homicide	18,210	6.8	-19.0
Forcible rape	96,120	35.9	-4.5
Robbery	497,950	186.1	-15.8
Aggravated assault	1,022,490	382.0	-3.2
Property crime index	11,540,300	4,311.9	-14.2
Burglary	2,461,100	919.6	-29.8
Larceny-theft	7,725,500	2,886.5	-7.9
Motor vehicle theft	1,353,700	505.8	-13.2

Table 2

SOURCE: Data are from *Crime in the United States-1997* (Federal Bureau of Investigation 1998, Table 1)

These three methods are similar to those used to collect crime data internationally: (1) official data collected by law enforcement agencies, (2) surveys of the victims of crimes, and (3) self-report studies based on offenders. Other sources also are available, but less commonly used (e.g., vital statistics, hospital records, and insurance records).

The Uniform Crime Reports. During the latter half of the 1920s the International Association of Chiefs of Police (IACP) developed uniform crime definitions and counting rules that would allow it to collect more comparable data from different law enforcement agencies. The IACP initiated the UCR in January of 1930. During the latter part of 1930 the Bureau of Investigation took over the UCR program, and it has remained a function of that bureau (renamed the Federal Bureau of Investigation, or FBI).

The general definitions of the UCR Part I offenses appear in Table 1, but more detailed definitions appear in the *Uniform Crime Reporting Handbook* (FBI 1985). As an example, the Uniform Crime Reporting System defines burglary as the unlawful entry of any fixed structure, vehicle, or vessel used for a regular residence, industry, or business, with or without force, with the intent to commit a felony, or larceny. Without uniform definitions, jurisdictions in which state law defines theft from a storage-shed as a burglary would report such an incident as a burglary to the FBI. In another jurisdiction, breaking and entering might be required for an incident to be classified as a

burglary. In such a jurisdiction an incident in which an offender entered a house through an open window in order to steal a stereo would be coded as unlawful entry with intent to commit a crime for the purposes of the state's law, but as a burglary for UCR purposes.

Participation in the UCR is voluntary. Local law-enforcement agencies send their data to the FBI or to state-level UCR programs that forward the data to the FBI. In the early years only the largest law enforcement agencies in the United States participated. But by the 1980s and 1990s, agencies representing about 97 percent of the population of the entire United States participated. The FBI reports two types of crime: Part I crimes and Part II crimes. For Part I crimes, data on crimes known to the police and on arrests are reported; for Part II crimes, only data on arrests are reported. Part I crimes include violent crimes (murder and non-negligent homicide, forcible rape, robbery, and aggravated assault), property crimes (burglary, larceny-theft, and motor vehicle theft), and arson. Each year the news media report crime rates derived from the FBI data and a summary of these data appear annually in *Crime in the United States*. This FBI publication provides crime rates for states, metropolitan statistical areas, counties, cities, other geographical subdivisions, and the nation as a whole.

Table 2 presents Part I crime data from the publication *Crime in the United States-1997* (FBI 1998). The second column presents the number of

incidents of a specific type, the third column reports the rate per 100,000 residents, and the final column indicates the change in the rate over a ten year period. In 1997, for example, 1,634,770 violent crimes were known to the police. The rate of violent crimes was 610.8 per 100,000 persons, which represents a decrease in the rate of violent crimes from 1988 to 1997 of 4.1 percent. Officially reported crime rates fell in all Part I categories from 1988 to 1997.

Crimes reported or discovered by the police and found through investigation to have occurred are labeled "crimes known to the police." A crime found not to have occurred is "unfounded," and does not appear as a crime known to the police. Although occasionally police discover a crime being committed (e.g., they happen upon a burglary in progress, or they arrest someone for resisting a police officer) they are highly dependent on citizen reports of criminal incidents.

The UCR also provides data on arrests for Part I and Part II crimes, and reports these crimes on the basis of the geographical divisions described above. Since these data are for arrests, the rates calculated from them should be labeled "arrest rates." Part II crimes include: other assaults (not including aggravated assaults), forgery and counterfeiting, fraud, embezzlement, stolen property (buying, receiving, and possessing), vandalism, weapons (carrying, possessing, etc.), prostitution and commercialized vice, sex offenses (except forcible rape and prostitution), drug abuse violations, gambling, offenses against family and children, driving under the influence, liquor law violations, drunkenness, disorderly conduct, vagrancy, curfew and loitering law violations, and runaways.

National Crime and Victimization Survey (NCVS). The NCVS data come from large surveys using probability samples of respondents. Since 1973 a national-level program has surveyed a probability sample of U.S. households. The U.S. Census Bureau conducts the survey, and during the 1990s the sample contained some 60,000 households and approximately 100,000 respondents. The results of this survey have been published annually since 1973 by The U.S. Department of Justice in *Criminal Victimization in the United States*.

The NCVS collects data on a much smaller number of crimes than the UCR. Since it is a

survey of the victims of crime, it does not record homicides, but it does record forcible rapes and sexual assaults, robberies, aggravated assaults, simple assaults, burglaries, larceny-thefts, and motor-vehicle thefts. It also provides details about the victims of crime not available in the UCR. These include the household income of the victim, any injuries sustained by the victim, insurance coverage, length of any hospitalization due to injuries, what protective measures the victim employed, and so on.

Careful field-testing preceded the initiation of data collection for NCVS in 1973 and before any changes made to its design since that time. An early decision involved the length of the reference period (the period the interviewers referred to when they asked whether victimizations occurred during the past period). Researchers chose a six-month reference period on the basis of the costs of doing more frequent surveys and studies that showed the effect of memory decay on remembering whether an event occurred. Respondents tend to telescope events into the reference period, and this can cause substantial increases in the number of victimizations reported during the past six months. To overcome this problem, each respondent remains in the sample for three years with interviews repeated every six months. Victimizations reported to the interviewer the first time a respondent is interviewed do not contribute to estimates of the crime rates. That first interview and subsequent interviews provide bounds for the six-month reference period. The interviewer asks about victimizations occurring since the last interview and has a list of incidents reported in the last interview to make sure that those incidents are not telescoped into the reference period.

To estimate rates for the entire nation from the NCVS data, researchers use the samples to estimate the number of victimizations occurring in the entire nation. They then use these estimates to calculate victimization rates. The derived estimates often contain large sampling errors, since they are based on only a "small" sample of the total population of the United States. These large sampling errors are greatest for the crimes least frequently reported by the respondents, for example, victimization rates for rapes involve more sampling error than rates for aggravated assault (O'Brien 1986).

Self-Reports. Unlike the UCR and NCVS, self-report studies refer to a collection of studies conducted by different researchers using a variety of methodologies. The basic methodology, however, involves sampling respondents and questioning them about criminal or delinquent acts. Although some isolated self-report studies occurred in the 1940s, the technique gained popularity with the work of Short and Nye (1957, 1958).

Perhaps the most ambitious self-report study is the National Youth Survey, or NYS (Elliott et al. 1983). This survey involves a national panel sample. When first instituted in 1976, the panel members were aged eleven to seventeen. Estimates of national-level crime rates for the age groups covered in this survey can be computed because the sample of respondents is a national one. These rates, unlike UCR- and NCVS-based rates, result from respondents answering questions about their offenses.

The NYS, and other self-report surveys, calculate two types of crime rates: "prevalence rates" and "incidence rates." To calculate these crime rates, the NYS uses the general formula represented in Equation (1). The prevalence rate uses the number of respondents who claimed they committed an offense for the numerator, the number of respondents for the relevant population size, and (we choose) 100 for the base. This yields the percentage of respondents who have committed a particular act. In the NYS in 1980, when the respondents were fifteen to twenty-one years old, the prevalence rate for robbery was 2. The incidence rate uses the number of times individuals claimed they committed a particular act as the numerator, the number of respondents as the relevant population size, and typically uses 100, 1000, or 10,000 for the base. We again use 100 for the base and find that in the 1980 NYS the incident rate for robbery was 10. Thus, there was an average of ten robberies per 100 respondents in this age group in 1980, with only two out of 100 respondents claiming involvement in a robbery.

As with the NCVS, self-report studies depend upon the accuracy of respondent reports. Therefore, issues such as telescoping, recall, and embarrassment are consequential for self-reports of criminal activities. In comparison to the UCR and NCVS, many of the crimes reported in self-report surveys are trivial crimes or not crimes at all (e.g., lying to

parents or cheating on a test). The sample sizes, even in the largest of such surveys, are not nearly as large as sample sizes in the NCVS. Therefore, given the relative infrequency of serious crimes, the rates for serious crimes are not very precisely measured by self-report surveys; that is, the estimates have large standard errors. Nonetheless, crime rates derived from self-report studies provide much of the data used to investigate the determinants of individual criminal offending.

SOME PROBLEMS WITH UCR, NCVS, AND SELF-REPORT DATA

Using information from official data (UCR), victimization surveys (NCVS), and self-report surveys helps us to gauge the accuracy of crime rates. Crime rates vary depending upon whether they derive from UCR, NCVS, or self-report data. To understand why crime-rate estimates vary depending upon their source, we briefly outline some problematic aspects of these three data sources.

UCR Data. The most obvious problem with UCR data involves underreporting of crimes to the police. The NCVS interviewers ask respondents whether they reported a particular incident to the police. In 1994, 78 percent of the respondents who reported a motor vehicle theft to the interviewer said they reported that crime to the police, 50 percent of the burglaries were reported, 50 percent of the robberies, and only 32 percent of rapes and sexual assaults (U.S. Department of Justice 1997).

Once an incident comes to the attention of the police a number of factors influence whether the incident is recorded as a crime or whether an arrest is made. There may be organizational pressures to raise or lower the crime rate (e.g., Bell 1960; Chambliss 1984; DeFleur 1975; McCleary et al. 1982; Selke and Pepinsky 1982; Sheley and Hanlon 1978; Wheeler 1967). The professional styles of particular police departments may affect the recorded crime rates (Beattie 1960; Skogan 1976; Wilson 1967, 1978). The interactions between officers and offenders also help determine the classification of an incident as a crime and whether an arrest is made (Black 1970; Smith and Visher 1981; Visher 1983). Given these and other problems, it is not surprising that crime rates recorded by the UCR are known to contain substantial errors.

NCVS Data. The NCVS may well provide a more accurate picture of crime rate trends and comparative crime rates than the UCR. As Sellin's (1931, p. 346) dictum suggests, "the value of a crime for index purposes decreases as the distance from the crime itself in terms of procedure increases." Further, the NCVS standardizes the procedures it uses in compiling crime incidents. When the NCVS changes its procedures, careful methodological studies evaluate the changes.

Although the incidents reported to NCVS interviewers need not depend upon a respondent contacting the police, the police responding to the contact, and eventually police recording of the incident as founded, respondents do need to respond appropriately in an interview situation in order for an incident to be recorded as a victimization in the NCVS. In this context, note that the interview situation is a social interaction. The interviewers have little to offer respondents for their time. Respondents may be reluctant to share embarrassing information with the interviewer, such as a fight at a bar, an assault by a relative, or a sexual assault. As noted earlier, sometimes respondents may forget about incidents or telescope the incidents into or out of the reference period.

Turner (1972) used "reverse record" checks to investigate 206 cases of robbery, assault, and rape found in police records. Interviewers interviewed these "known victims" using an NCVS-like technique. Only 63.1 percent of these "known incidents" were reported to interviewers. The percentage reporting these incidents to the interviewer was strongly related to the relationship of the offender to the victim. Respondents reported 76.3 percent of the incidents involving a stranger; 56.9 percent of the incidents involving known offenders; and only 22.2 percent of the incidents involving a relative.

Not all of this underreporting of incidents to the interviewers is attributable to embarrassment. Turner (1972) found a strong relationship between the number of months between the interview and the incident and the respondents' reporting of the incident to the interviewer. Respondents recalled 69 percent of the incidents occurring one to three months before the interview, 50 percent of those occurring four to six months before, 46 percent of those occurring six to nine months

before, and only 30 percent of those occurring ten to twelve months before.

Self-Report Data. Like UCR and NCVS data, self-report data contain their own weaknesses. As with the NCVS data, the survey research situation raises questions of honesty, forgetting, bounding the reference period, and so on. Some problems are more severe than those encountered by the NCVS. One of these problems is sample size; even the best-financed surveys—like the National Youth Survey (Elliot et al. 1983)—have samples of less than 2,000. Such small samples almost guarantee large sampling errors associated with the resulting crime rates (especially for serious crimes). Small sample size further limits the usefulness of these data for conducting regional analyses (e.g., estimating the crime rates for states or cities). Similarly, it limits the accuracy of these estimates for comparing the crime rates for groups such as Hispanics or Asian females. Unlike the NCVS, many self-report surveys do not involve panels in which respondents are reinterviewed over an extended period of time (the NYS is an exception) so that the interviews cannot be bounded. Often the response rates are quite low. In the NYS (Elliot et al. 1983), a sample of 2,360 eligible youth originally were selected and of these 73 percent agreed to participate in the first wave of data collection in 1976. By 1980 the sample size dropped to 1,494 or 63 percent of the original sample. This contrasts with initial response rates well in excess of 90 percent for the NCVS.

Two other issues need mention. First, self-report studies concentrate on relatively trivial behaviors, such as lying to parents, defying authority, or cheating on tests. One reason for concentrating on such behaviors is that they are more commonly reported. Given the small sample sizes typical of self-report studies, these behaviors may be more reliably measured. Second, some studies do not accurately gauge the frequency of "delinquent behaviors." They use response sets such as "no," "once or twice," or "several times." Experienced researchers now ask about a wide range of behaviors and more specifically ask about the frequency of these behaviors. In the NYS, Elliot et al. (1983) ask about "arson," "prostitution," and "physical threat for sex" as well as "skipped class" and "didn't return change." They use response categories such as "2-3 times a day," "once a day," "2-3 time a week," "once a week," "once every 2-3

weeks,” and “once a month,” as well as asking the exact number of times respondents offended during the past year.

COMPARISONS OF CRIME RATES GENERATED FROM UCR, NCVS, AND SELF- REPORTS

Fortunately, the problems outlined above do not mean that crime rates based on UCR, NCVS, and self-reports are not useful. Homicide rates, for example, are probably reasonably accurate in terms of absolute rates and in terms of homicide trends over the past sixty-five years. They also are appropriate for comparisons of homicide rates across large cities. When we judge the usefulness and accuracy of crime rates, the type of crime considered is important (e.g., homicide or rape). Further, even if a crime rate is inaccurate in terms of the absolute amount of crime it represents, it may be an accurate measure of the relative amount of that crime in different areas or across time. This would be the case if exactly half or some other proportion of the aggravated assaults were reported in different jurisdictions (or across time). Then we could perfectly compare the relative amount of crime across jurisdictions (or crime trends over time). If only approximately the same proportion of cases were reported across jurisdictions, then comparisons of the relative amount of crime would only be approximate.

Measuring Absolute Crime Rates. The most accurately measured UCR Part I crime almost certainly is homicide. The reasons for this include the seriousness of the crime and the physical evidence it produces (e.g., a body, weapon, or missing person), which make it unlikely that once detected this crime will be ignored. Cantor and Cohen (1980) compared homicide rates based on the U.S. Department of Health, Education, and Welfare's *Annual Vital Health Statistics Report* with those from the UCR for the years 1935–1975 and found a very close correspondence. Using a different approach, O'Brien (1996) found evidence that fluctuations in the homicide rate closely paralleled fluctuations in the rate of other violent crimes from 1973 to 1992.

Motor vehicle theft is the other Part I crime that appears to be well estimated in terms of

absolute rates. In 1994, for example, the NCVS estimated 1,764,000 motor vehicle thefts based on respondents' answers, while the UCR reported 1,539,100 motor vehicle thefts known to the police. Thus the NCVS estimate exceeded the UCR estimate by only 28 percent. When NCVS respondents report a motor vehicle theft they are asked if they reported the theft to the police. Based on their responses one would calculate that the police receive reports of only 1,379,448 motor vehicle thefts, which is fewer motor vehicle thefts than appear in the UCR records. This probably occurs because motor vehicle thefts from private citizens constitute only 80 to 85 percent of the total number of such thefts known to the police (Biderman and Lynch 1991). For the remaining Part I crimes covered by both the UCR and NCVS (personal robbery, aggravated assault, residential burglary, and rape), the NCVS and UCR data show greater differences in absolute rates. The smallest ratio of NCVS incidents to UCR incidents is 1.62 for rape and the largest 3.01 for residential burglary.

Difficulties arise when comparing the self-report rates to UCR and NCVS rates, because self-report studies typically only involve a sample of young people. The estimated crime rates for these young people, however, are so high that we may conclude that the rates generated by self-reports are far greater than those generated by either the NCVS or the UCR. The 1976 NYS produced an estimated incident rate for eleven to seventeen year-olds for aggravated assault of 170 per 1000 and for robbery a rate of 290 per 1000. This compares with rates for those twelve year-olds and over of 7.90 and 6.48 based on the NCVS and rates for all ages of 2.29 and 1.96 based on the UCR. Some part of this discrepancy results from differences in the age groups compared, but not all of it. In 1976 eleven to seventeen year-olds comprised 13.38 percent of the population. Thus, even if it were assumed that no assaults or robberies were committed by other age groups, the aggravated assault rate based on the NYS would be $[\.1338 \times 170 =] 22.75$ and the rate for robbery would be $[\.1338 \times 290 =] 38.80$.

Measuring Relative Crime Rates. If absolute rates are well measured, then relative rates of crimes across cities or other units probably are well measured. This means that both homicide rates and motor vehicle theft rates should be good

measures of the relative rate of crime. In the mid-1970s the NCVS conducted victimization studies with reasonably large size samples; 10,000 or more households containing some 22,000 respondents, in each of twenty-six large U.S. cities. The same cities, of course, reported UCR crime rates for Part I crimes. This provided the opportunity to compare the consistency of these estimates in terms of the relative crime rates measured by the NCVS and the UCR by correlating the two crime-rate measures across the twenty-six cities. The closer these correlations are to 1.00, the greater the degree to which cities with relatively high rates (low rates) on one of the measures have relatively high rates (low rates) on the other. Across these cities, the correlation of UCR and NCVS motor vehicle theft rates was .90 or higher (Nelson 1978, 1979; O'Brien, Shichor, and Decker 1980). The correlations were close to zero for rape, negative for aggravated assault, and positive and moderately strong for burglary and robbery. This indicates that for burglary and robbery the relative rates of crime in these cities are similar whether the UCR or NCVS measures are used, but they are not similar for rape and aggravated assault.

Overall, the use of homicide rates and motor vehicle theft rates to measure the relative amount of these crimes across cities is supported by the above findings. The use of burglary and robbery rates receives weaker support, and the use of rape and aggravated assault rates to compare the relative amount of these crimes across cities does not receive support.

Gender and Race Composition of Offenders.

Hindelang (1978, 1979) addressed the issue of whether the UCR and victim reports (NCVS) produce similar percentages of offenders identified as African American or white or as male or female. O'Brien (1995, 2000) replicated these findings using more recent data. These comparisons indicate that for those crimes in which the victim and offender come into contact (which enables the victim to identify the race and sex of the offender), the percentages based on the UCR and NCVS are fairly similar. For example, O'Brien (2000) aggregates data for the years 1992 to 1994 and finds that the percentages of males involved in these crimes, according to the UCR and NCVS, never differ by more than 3 percent. For race of the offender, rape produces the largest difference with victims

stating that 33.2 percent of the offenders are African American and the UCR arrest data indicating that 42.7 percent of those arrested are African American. For robbery, aggravated assault, and simple assault the differences do not exceed 5 percent.

Self-report data at one time were considered to be inconsistent with UCR data, which indicated that males committed crimes at a much higher rate than females and that African Americans also committed crimes at a much higher rate than whites. These large differences between males and females and African Americans and whites, however, are not found when self-report studies ask about more serious crimes and ask more carefully about the frequency of offending (Elliot and Ageton 1980; Hindelang, Hirschi, and Weis 1979).

These comparisons only touch on the issue of the appropriate uses of UCR, NCVS, and self-report data. The appropriate uses depend upon the type of crime and the type of comparison. (For helpful information on which to judge the appropriate uses of these data see Biderman and Lynch 1991; Gove Hughes and Geerken 1985; O'Brien 1985, 2000).

INTERNATIONAL DATA

Many nations collect data from law enforcement agencies, survey victims, and conduct self-report surveys. Difficulties arise, however, when comparing these data, since the definitions of crimes and the counting rules differ from nation to nation. In this section we note some of these problems and cautiously present crime-rate data for two nations. In addition, for a larger number of nations, we present homicide rates.

Perhaps the most comparable large national victimization surveys are the NCVS (conducted in the United States) and the British Crime Survey (conducted in England and Wales). But even in this case, there are important differences—the British Crime Survey (BCS) uses a twelve-month reference period and unbounded interviews, while the NCVS uses a six-month reference period and bounded interviews. The former difference should decrease the estimated victimization rates in the BCS due to “memory decay,” but the latter should increase these rates due to “telescoping.” The BCS does not ask about crimes involving victims

under the age of sixteen, while the NCVS does not ask about crimes involving victims under age twelve.

Further problems arise with the definitions of offenses. In the United States, for example, aggravated assaults include attempted murders and almost any assault in which a weapon is used or assaults for the purpose of inflicting severe or aggravated injury. In England attempted murders receive separate treatment while the assaults most similar to Part I aggravated assaults are "woundings." Woundings require some kind of cut or wound where the skin or a bone is broken, or medical attention is needed, whereas common assault occurs if the victim is punched, kicked or jostled, with negligible or no injury.

Since 1981 definitions of rape have changed substantially in England. Until 1981, to be classified as a rape an incident required a male offender and female victim and the penetration of the vagina by the penis. Husbands could not be convicted of raping their wives, and males under age fourteen could be convicted of a rape. By 1996 rapes could involve offenders as young as ten, spousal victims, male victims, and anal intercourse. In the United States, the UCR definition of rape includes male victims, male or female offenders, spousal victims, anal intercourse, and other sexual acts. With these nontrivial problems in mind, we compare crime rates (based both on surveys and police records) in England and the United States.

Table 3 presents victimization rates for robbery, assault, burglary, and motor vehicle theft in the United States and England (based on the NCVS and the BCS) for the years 1981 and 1995 (Langan and Farrington 1998). Perhaps the most surprising result is that the estimated victimization rates in England are higher than in the United States for these crimes in 1995. The surveys also indicate substantial increases in robbery, assault, burglary, and motor vehicle theft from 1981 to 1995 in England and decreases for all but motor vehicle theft in the United States. The cross-country comparisons of these absolute rates may be more problematic than over-time comparisons within the countries—given that the victimization survey methods and the definitions of these four crimes changed little in these countries over this period.

Table 4 presents crime rates based on police records (Langan and Farrington 1998). In this

**Victim Survey Crime Rates per 1,000
in the United States and England:
1981 and 1995**

	1981		1995	
	U.S.	England	U.S.	England
Robbery	7.4	4.2	5.3	7.6
Assault	12.0	13.1	8.8	20.0
Burglary	105.9	40.9	47.5	82.9
Motor Vehicle Theft	10.6	15.6	10.8	23.6

Table 3

SOURCE: Langan and Farrington 1998.

table, we report rates per 100,000 residents because of the relatively low rates for homicide and rape. The rates in Table 4 reinforce the patterns reported in Table 3, which showed a substantial increase in crime rates from 1981 to the mid-1990s in England for robbery, assault, burglary, and motor vehicle theft. Table 4 also shows higher rates for these crimes (except for robbery) in England than in the United States in 1996. Two new crimes appear in this table: Homicide, for which the rate in the United States is several times higher than in England, for both 1981 and 1996 (most criminologists agree that homicide rates in the United States are very high by international standards) and rape, which shows a dramatic increase from 4.19 to 21.77 per 100,00 in England (this results, at least in part, from changes in the legal definition of rape that occurred in England between 1981 and 1996).

Although we could attempt other comparisons, most such comparisons involve even greater difficulties than those between the United States and England. Some countries do not differentiate between simple and aggravated assaults; others do not record any but the most severe assaults when the assault occurs within the family. As noted, legal definitions of rape may differ widely (even over time within the same country), reports of burglaries may require breaking and entering into a business or residence, only entering, or even breaking into an outbuilding.

Homicide represents the crime with the most consistent definition across countries: the intentional taking of another person's life without legal justification. Even here some countries may not separate justifiable from unjustifiable homicides.

Police Recorded Crime Rates per 100,000 in the United States and England: 1981 and 1996

	1981		1996	
	U.S.	England	U.S.	England
Homicide	9.83	1.13	7.41	1.31
Rape	70.59	4.19	70.79	21.77
Robbery	258.75	40.86	202.44	142.35
Assault	289.73	197.49	388.19	439.60
Burglary	1649.47	1447.36	942.95	2239.15
Motor Vehicle Theft	474.72	670.09	525.93	948.83

Table 4

SOURCE: Langan and Farrington 1998.

The legal justifications for killing a spouse or even a person committing a crime may vary from country to country, as may the reporting and recording of homicides. Still, the data for this crime rate almost certainly are more accurate for international comparisons than those for rape, robbery, burglary, assault, theft, or arson.

Table 5 presents data for 1990 from the United Nations (United Nations Crime and Justice Network 1998) on intentional homicide rates per 100,000 for a selected set of countries. The rate for the United States was taken from the UCR (FBI 1991). Note the wide range of homicide rates, with Barbados and the United States with relatively high rates and Austria, Botswana, Denmark, Japan, Norway, and Spain with relatively low rates. There probably are real differences between these two sets of countries in terms of homicide rates. It is less clear that smaller differences across countries with rather different legal systems, levels of development, and cultural histories, represent differences in the unjustifiable intentional taking of another person's life. To reiterate the difficulty in making cross-national comparisons, we note that INTERPOL's international crime statistics come with the warning: "the information given is in no way intended for use as a basis for comparisons between different countries."

CONCLUSIONS

At the beginning of this article we noted that the computation of a crime rate might seem straightforward, but designating the most appropriate term for each component in equation (1) often is

Intentional Homicide Rates per 100,000 in Selected Nations in 1990

Austria	.52	Italy	3.11
Barbados	11.76	Japan	.50
Botswana	.46	Madagascar	1.31
Bulgaria	2.52	Norway	.99
Canada	2.22	Spain	.71
Denmark	.80	Sri Lanka	2.17
Egypt	1.07	Sweden	1.41
Fed. Rep. of Germany	2.13	Switzerland	1.64
India	4.24	Turkey	1.64
Israel	2.30	United States	9.4

Table 5

difficult. Designating the base represents the easiest decision. This choice does not greatly change the interpretation of the rate, although it may make the interpretation more or less intuitive for the reader. Choice of the appropriate relevant population size is more difficult; for example, basing rape rates on the number of females rather than the number of people or the motor vehicle theft rate on the number of registered motor vehicles rather than the number of people. Determining the number of incidents constitutes the most problematic component of calculating crime rates. Here, the differing definitions of crimes, varying counting rules, response rates, rates of reporting incidents to the police or interviewers, response categories, bounding of interviews, memory decay, police discretion in recording crimes, and so on, can greatly affect the estimated crime rate. These factors differentially affect estimates of the number of incidents based on self-reports, UCR, and NCVS data. Even so, within the United States for certain crimes and comparisons, data from these different sources lead to similar conclusions. Comparisons of crime rates across nations, with the possible exception of homicide, is extremely risky.

ROBERT M. O'BRIEN

CRIME, THEORIES OF

Most accounts of the rise of criminological inquiry indicate that it had its beginnings in mid-nineteenth-century developments in Europe, including the work of Cesare Lombroso, an Italian prison physician, who argued that many criminals are atavists, that is, biological throwbacks to a human type, *homo delinquens*, that allegedly existed prior to the appearance of *homo sapiens*. Since the time of Lombroso and other early figures in criminology, the field has grown markedly, both in terms of the variety of scholars who have tried to uncover the causes of crime and also in terms of the diverse theories that have been produced by these persons (Gibbons 1994). Currently legal theorists, psychologists, economists, geographers, and representatives of other scholarly fields engage in criminological theorizing and research. There has also been renewed interest in sociobiological theorizing and investigation regarding criminality. Even so, the largest share of work has been and continues to be carried on by sociologists. Thus, criminology is frequently identified as a subfield of sociology (Gibbons 1979, 1994).

Although a few scholars have argued that crime should be defined as consisting of violations of basic human rights or for some other "social" conception, most criminologists opt for the legalistic view that crime and criminal behavior are

identified by the criminal laws of nations, states, and local jurisdictions. Acts that are not prohibited or required by the criminal law are not crimes, however much they may offend some members of the community. Also, the reach of the criminal law in modern societies is very broad, involving a wide range of behavioral acts that vary not only in form but in severity as well. The criminal laws of various states and nations prohibit morally repugnant acts such as murder or incest, but they also prohibit less serious offenses such as vandalism, petty theft, and myriad other acts. Parenthetically, there is considerable controversy in modern America, both among criminologists and among members of the general public, as to whether certain kinds of behavior, such as marijuana use, various consensual sex acts between adults, or abortion, ought to be expunged from or brought into the criminal codes.

Persons of all ages violate criminal laws, although a number of forms of criminality are most frequent among persons in their teens or early twenties. Except for "status offense" violations such as running away, truancy, and the like, which apply only to juveniles (usually defined as persons under eighteen years of age), juvenile delinquency and adult criminality are defined by the same body of criminal statutes. However, criminologists have often constructed theories about delinquency separate from explanations of adult criminality. Although many theories of delinquency closely resemble those dealing with adult crime, some of the former are not paralleled by theories of adult criminality. In the discussion to follow, most attention is upon explanatory arguments about adult lawbreaking, but some mention is also made of causal arguments about juvenile crime.

CRIMINOLOGICAL QUESTIONS AND CAUSAL THEORIES

Given the broad compass of the criminal law, and given the variety of different perspectives from which the phenomenon of crime has been addressed, it is little wonder that there are many theories of crime. Most of these theories center on the explanation of crime patterns and crime rates, or what might be termed "crime in the aggregate," or are pitched at the individual level and endeavor to identify factors that account for the involvement of specific individuals in lawbreaking conduct (Cressey 1951; Gibbons 1992, pp. 35-39)

These are related but analytically separate questions about the causes of crime. As Donald Cressey (1951) argued many years ago, an adequate account of criminality should contain two distinct but consistent aspects: First, a statement that explains the statistical distribution of criminal behavior in time and space (epidemiology), and second, a statement that identifies the process or processes by which persons come to engage in criminal behavior.

Statistical distributions of criminal behavior in time and space are usually presented in the form of crime rates of one kind or another. One of the most familiar of these is the *index crime rate* reported annually for cities, states, and other jurisdictions by the Federal Bureau of Investigation. The index crime rate is comprised of the number of reported cases of murder, non-negligent manslaughter, forcible rape, aggravated assault, robbery, burglary, larceny, auto theft, and arson per jurisdiction, expressed as a rate per 100,000 persons in that jurisdiction's population.

Many crime rate patterns are well known, including relatively high rates of violence in the United States as compared to other nations, state-by-state variations in forcible rape rates, regional variations in homicide and other crimes within the United States, and so forth. However, criminological scholars continue to be hampered in their efforts to account for variations in crime across various nations in the world by the lack of detailed data about lawbreaking in nations and regions other than the United States (although see van Dijk, Mayhew, and Killias 1990).

Criminologists have developed a number of theories or explanations for many crime rate variations. One case in point is Larry Baron and Murray Straus's (1987) investigation of rape rates for the fifty American states, in which they hypothesized that state-to-state variations in gender inequality, social disorganization (high divorce rates, low church attendance, and the like), pornography readership, and "cultural spillover" (authorized paddling of school children, etc.) are major influences on forcible rape. Steven Messner and Richard Rosenfeld's (1994) *institutional anomie theory* is another example of theorizing that focuses on crime rate variations. They argued that in present-day America, cultural pressures to accumulate money and other forms of wealth are joined to

weak social controls arising from noneconomic elements of the social structure, principally the political system, along with religion, education, and family patterns. According to Messner and Rosenfeld, this pronounced emphasis on the accumulation of wealth and weak social restraints promotes high rates of instrumental criminal activity such as robbery, burglary, larceny, and auto theft.

Crime rates are important social indicators that reflect the quality of life in different regions, states, or areas. Additionally, theories that link various social factors to those rates provide considerable insight into the causes of lawbreaking. But, it is well to keep in mind that crime rates are the summary expression of illegal acts of individuals. Much of the time, the precise number of offenders who have carried out the reported offenses is unknown because individual law violators engage in varying numbers of crimes per year. Even so, crime rates summarize the illegal actions of individuals. Accordingly, theories of crime must ultimately deal with the processes by which these specific persons come to exhibit criminal behavior.

In practice, criminological theories that focus on crime rates and patterns often have had relatively little to say about the causes of individual behavior. For example, variations in income inequality from one place to another have been identified by criminologists as being related to rates of predatory property crime such as burglary, automobile theft, and larceny. Many of the studies that have reported this finding have had little to say about how income inequality, defined as the unequal distribution of income among an entire population of an area or locale, affects individuals. In short, explanations of crime rate variations often have failed to indicate how the explanatory variables they identify "get inside the heads of offenders," so to speak.

Although criminological theories about crime rates and crime patterns have often been developed independently of theories related to the processes by which specific persons come to exhibit criminal conduct, valid theories of these processes ought to have implications for the task of understanding the realities of individual criminal conduct. For example, if variations in gender inequality and levels of pornography are related to rates of forcible rape, it may be that males who carry out sexual assaults are also the individuals who most strongly

approve of discrimination against women and who are avid consumers of pornography. In the same way, if income inequality bears a consistent relationship to rates of predatory crime, it may be that individual predators express strong feelings of “relative deprivation,” that is, perceptions that they are economically disadvantaged and distressed about their situation. However, some additional factors may also have to be identified that determine which of the persons who oppose women’s rights or who feel relatively deprived become involved in illegal conduct and which do not.

PERSPECTIVES, THEORIES, AND HYPOTHESES

A number of arguments about crime patterns and the processes through which individuals get involved in lawbreaking are examined below. Before moving to these specific theories, however, two other general observations are in order. First, in criminology, as in sociology more generally, there is considerable disagreement regarding the nature of perspectives, theories, and hypotheses (as well as paradigms, frameworks, and other theoretical constructions). Even so, *perspectives* are often identified as broad and relatively unsystematic arguments; while *theories* are often described as sets of concepts, along with interconnected propositions that link the concepts together into an “explanatory package”; and *hypotheses* are specific research propositions derived from theories. In practice, however, many causal explanations that have been described as theories have been incomplete and also conceptually imprecise. Jack Gibbs (1985) has labeled such “theories” as being in “the discursive mode” rather than as formal theories. Discursive arguments are stated in everyday language and their underlying logic is often difficult to identify. According to Gibbs, because many criminological theories are discursive, precise predictions cannot be deduced from them, nor is it possible to subject predictions to empirical test, that is, to validation through research.

Many criminological theories involve relatively vague concepts, faulty underlying logic, and other problems. At the same time, it is possible to identify a number of general theoretical perspectives in criminology and to differentiate these from relatively formalized and precise theories. For example, many criminologists contend that

American society is *criminogenic* because it involves social and economic features that appear to contribute heavily to criminality. However, this is a general perspective rather than a theory of crime in that it does not identify the full range of factors that contribute to lawbreaking, and it also lacks a set of explicit and interrelated propositions. By contrast, the income inequality argument more clearly qualifies as a causal theory, as does the formulation that links gender inequality, pornography readership, and certain other influences to forcible rape.

A few other comments are in order on theoretical perspectives in criminology. During most of the developmental history of criminology in the United States, from the early 1900s to the present, sociological criminologists voiced support for the criminogenic culture thesis that directs attention to social-structural factors thought to be responsible for criminality. Thus, this view might also be referred to as “mainstream criminology.” Most criminologists have linked lawbreaking to major “rents and tears” in societal structure at the same time that most of them have assumed that these crime-producing features can be remedied or lessened through social and economic reforms of one kind or another (Gibbons 1992, 1994; Currie 1985).

In the 1970s, a markedly different perspective competed for attention. Often referred to as “radical-Marxist” or “critical” criminology, it asserted that the causes of crime arise out of societal characteristics that are inherent in corporate capitalism (Gibbons 1992, pp.122–130; Chambliss 1975; Quinney 1974, 1977). According to radical-Marxist criminologists, criminal laws serve the interests of the capitalist ruling class. In turn, the system of corporate capitalism over which the ruling class presides depends for its survival on the exploitation of the resources and people of other countries and the economic oppression of citizens within capitalist nations. These conditions create economic strains for many persons, contribute to the deterioration of family life, and drive many individuals into desperate acts of lawbreaking.

The radical-Marxist perspective received considerable attention in the 1970s. Those who criticized it claimed that it presented a one-dimensional, oversimplified account of the social sources of criminality. For example, while some criminal laws favor the interests of the owners of capital, many

others serve broader social interests. Similarly, while some forms of crime may be related to economic problems, others are not.

A number of other alternative perspectives began to appear in criminology in the 1980s and 1990s, so that theorizing about crime and criminality has become even more diversified. These “new criminologies” (Gibbons 1994, pp. 151–175) include postmodernist viewpoints, feminist arguments, and a number of other strains of thought, all of which differ in a number of ways from “mainstream” criminology.

Although broad theorizing has continued to proliferate in criminology, another major trend in recent years has taken criminology in a different direction, toward relatively detailed theories specific to one or another form of crime and toward research investigations of those theories. Baron and Straus’s (1987) formulation that links gender inequality, pornography, and specific flaws in the social control system is a case in point, as is Kenneth Polk’s (1994) theorizing and research regarding the various “scenarios” of social interaction that culminate in lethal violence. Indeed, contemporary criminology has a rich accumulation of empirical evidence that can be drawn upon by those who seek to understand the nature and causes of criminality in modern societies.

FORMS OF CRIME AND TYPES OF OFFENDERS

The legal codes of the various states and of the federal government include hundreds of specific offenses, but the explanatory task is to develop a relatively small set of theories that make sense of this diverse collection of illegal activities.

In their response to this task, Michael Gottfredson and Travis Hirschi (1990) have argued that virtually all forms of criminal activity, and many kinds of deviant behavior as well, share certain features in common: they are spontaneous, unplanned actions requiring little or no skill for their commission. Further, Gottfredson and Hirschi have claimed that lawbreakers rarely specialize in specific acts of criminality. They concluded that virtually all of these varying criminal and deviant acts can be accounted for by a single, general theory that asserts they are the work of persons who are

characterized by low self-control. Accordingly, in their view, there is no need for schemes that classify types of crime or kinds of offenders or for separate theories to account for them.

However, many criminologists contend that there are relatively distinct forms of crime that differ from each other and also that the behavior of many criminals is relatively patterned. For example, some offenders concentrate their efforts upon larcenous acts while others of them are mainly involved in acts of violence.

A number of criminologists have tried to sort the diverse collection of illegal activities into a smaller number of sociologically meaningful groupings or crime forms (Farr and Gibbons 1990; Gibbons 1994). Some have singled out crude property crime, consisting of larceny, burglary, robbery, and kindred offenses, as one type of crime; others have placed homicide and assaultive acts into another crime type; while still others have treated forcible rape and other sexual offenses as yet another broad form of lawbreaking. Then, too, “white-collar” or organizational crime has often been singled out as a crime pattern (Sutherland 1949; Schrager and Short 1978; Coleman 1987), consisting in large part of criminal acts such as antitrust violations, financial fraud, and the like, carried on by corporations and other large organizations. “Organized crime” is still another type that has received a good deal of criminological attention. Some persons have also pointed to a collection of offenses that receive little visibility in the mass media and elsewhere and have termed these “folk crimes” (Ross 1960–1961, 1973) or “mundane crimes” (Gibbons 1983). Finally, “political crime” has been identified as a major pattern of lawbreaking (Turk 1982).

Although these groupings identify forms of lawbreaking that may differ from each other in important ways, it is also true that they are relatively crude in form in that the underlying dimensions or variables on which they are based have not been spelled out. Further, there is disagreement among criminologists as to the specific crimes that should be identified as instances of white-collar crime, mundane crime, or some other category.

Criminologists have also developed systems for sorting individual offenders into behavioral types (Gibbons 1965). Although related to crime

classification efforts, categorization of lawbreakers into types is a separate activity. While it may be possible to identify groupings such as predatory property crime, it may not be true that individual offenders specialize in that form of crime, hence it may be incorrect to speak of "predatory offenders" as a type of criminal. Most offender classification systems have been deficient in one respect or another (Gibbons 1985), but the most serious flaw is that they are oversimplified. Researchers have discovered that many offenders engage in a fairly diverse collection of offenses over their criminal "careers" rather than being crime specialists such as "burglars," "robbers," or "drug dealers" (Chaiken and Chaiken 1982).

THEORIES OF CRIME

The number of theories regarding particular forms of crime is extensive, thus they cannot all be reviewed here (for a review of many of them, see Gibbons 1994). Additional to those theories mentioned previously, a sampling of the more important ones would include the *routine activities* explanation of predatory property crime. Lawrence Cohen and Marcus Felson (1979) contend that predatory property crime involves three major elements: the supply of motivated offenders, the supply of suitable targets, and the absence of capable guardians. In other words, these crimes are carried out by persons with criminal motives, but the incidence of such offenses also depends upon the number of opportunities to burglarize homes or to rob persons. Also, the number of burglaries from one community to another is influenced by the degree to which residents in local areas act as guardians by maintaining surveillance over homes in their neighborhoods or by taking other crime-control steps. This theory takes note of the fact that criminal opportunities have increased in the United States in recent decades at the same time that capable guardianship has declined, due principally to changes in employment patterns. In particular, the number of families in which both adult members work during the day has grown markedly, as has the number of employed, single-parent families. Research evidence lends considerable support to this theory (Cohen and Felson 1979).

Research evidence also indicates that income inequality is related to predatory property crime

(Braithwaite 1979; Carroll and Jackson 1983). Further, Leo Carroll and Pamela Jackson (1983) argue that the routine activities and income inequality arguments are interrelated. They suggest that the labor market trends identified in the former have led to increased crime opportunities, declines in guardianship, and heightened levels of income inequality.

THEORIES OF CRIMINAL BEHAVIOR

While theories about crime patterns and rates have been developed principally by sociological criminologists, representatives of a number of disciplines have endeavored to identify factors and processes that explain the involvement or noninvolvement of specific individuals in lawbreaking. Three basic approaches can be noted: the biogenic-sociobiogenic, psychogenic, and sociogenic orientations. *Biogenic-sociobiogenic views* attribute the genesis or causes of lawbreaking, entirely or in part, to constitutional and hereditary factors, while *psychogenic perspectives* often contend that lawbreakers exhibit personality problems to which their illegal conduct is a response. By contrast, sociologists have most often advanced *sociological theories*, arguing that criminal behavior is learned in a socialization process by individuals who are neither biologically nor psychologically flawed. Also, some persons have constructed theories that combine or integrate elements of these three approaches, one case being James Wilson and Richard Herrnstein's (1985) argument that the behavior of criminals has genetic and constitutional roots and that offenders tend to be more mesomorphic in body build, less intelligent, and more burdened with personality defects than their noncriminal peers. Wilson and Herrnstein also contend that various social factors such as unemployment, community influences, and the like play some part in criminality.

Three generalizations can be made about biological theories: First, conclusive evidence supporting these arguments has not yet been produced; second, biological factors cannot be ruled out on the basis of the empirical evidence currently on hand; and third, if biological factors are involved in criminality, they are probably intertwined with social and psychological influences (Trasler 1987; Fishbein 1990).

In the first half of the twentieth century, psychological arguments about criminals centered on claims that these persons were feeble-minded, or somewhat later, that many of them were suffering from serious mental pathology of one sort or another. However, a number of reviews of the evidence, particularly that having to do with the alleged role of low intelligence or personality defects in criminality, turned up little or no support for such claims (Schuessler and Cressey 1950; Waldo and Dinitz 1967; Tennenbaum 1977).

Even so, there is a lingering suspicion among a number of criminologists that the criminal acts of at least some lawbreakers, including certain kinds of sexual offenders, can be attributed to faulty socialization and aberrant personality patterns (Gibbons 1994). Additionally, some psychologists have argued that even though the broad theory that criminality is due to marked personality defects on the part of lawbreakers lacks support, it is nonetheless true that individual differences in the form of personality patterns must be incorporated into criminological theories (Andrews and Wormith 1989; Blackburn 1993; Andrews and Bonta 1998). Moreover, in the opinion of a number of sociological criminologists, the argument that individual differences make a difference, both in accounting for criminality and for conformity, is persuasive (Gibbons 1989, 1994). Personality dynamics play a part in the behavior patterns that individuals exhibit, thus such concepts as role and status are often not entirely adequate to account for the behavior of individuals. Lawbreaking is quite probably related to the psychic needs of individuals as well as social and economic influences that play upon them. On this point, Jack Katz (1988) has explored the personal meanings of homicidal acts, shoplifting, and a number of other kinds of criminality to the persons who have engaged in these acts.

Sutherland's theory of *differential association* (Sutherland, Cressey, and Luckenbill 1992, pp.88–90) has been one of the most influential sociological theories about the processes through which persons come to engage in criminality. Sutherland maintained that criminal behavior, including techniques of committing crime and conduct definitions favorable to lawbreaking activity, is learned in association with other persons. Many of the associations of persons involve face-to-face contact, but conduct definitions favoring criminality

can be acquired indirectly from reference groups, that is, from persons who are important to individuals but with whom they do not directly associate. Sutherland also contended that associations vary in frequency, duration, priority, and intensity (the personal meaning or significance to individuals of particular social ties).

A very different theory, directed mainly at the explanation of juvenile delinquency, is that if, through faulty socialization, individuals fail to become bonded or connected to others (that is, if they do not develop positive attachments to adult persons such as parents or teachers), they will then be unlikely to refrain from misbehavior (Hirschi 1969). The emphasis in this argument is on the failure to acquire prosocial, nondelinquent sentiments rather than on the learning of antisocial ones. In this view, delinquency is the result of defective socialization rather than of socialization patterns through which criminal attitudes are learned. A more recent but related version of this argument, noted earlier in this essay, is that of Gottfredson and Hirschi (1990), who have claimed that criminality and other forms of deviance are most often engaged in by persons who are low on self-control.

THEORETICAL INTEGRATION

Clearly, there is a wealth of differing arguments about the causes of crime and individual lawbreaking now in existence. Not surprisingly, then, a number of scholars have begun to ask whether it might be possible to amalgamate some or all of these varied lines of explanation into an integrated theory and thereby to develop a more powerful causal argument. Some criminologists have suggested that biological, psychological, and sociological contentions about crime all have some part to play in explaining crime and that, therefore, they should be integrated (Barak 1998). Others have proposed more limited forms of integration in which, for example, several sociological arguments might be merged into a single formulation (e.g., Tittle 1995; Braithwaite 1989) or in which psychological claims about lawbreaking might be linked or integrated with sociological ones. But to date, criminological investigators have not moved very far in the direction of sophisticated theoretical integrations. Further research on the interconnections between biological, psychological, and social factors in crime

and criminal conduct will probably be required if integrative efforts are to bear fruit.

CRIMINAL AND DELINQUENT SUBCULTURES

A subculture is derivative of, but different from, some larger referential culture. The term is used loosely to denote shared systems of norms, values, or interests that set apart some individuals, groups, or other aggregation of people from larger societies and from broader cultural systems. Common examples include youth subcultures, ethnic subcultures, regional subcultures, subcultures associated with particular occupations, and subcultures that develop among people who share special interests such as bird-watching, stamp collecting, or a criminal or delinquent behavior pattern.

Neither membership in a particular category (age, ethnicity, place of residence, occupation) nor behavior (bird-watching, stamp collecting, crime, or delinquency) is sufficient to define a subculture, however. The critical elements are, rather, (1) the degree to which values, norms, and identities associated with membership in a category or types of behaviors are shared, and (2) the nature of relationships, within some larger cultural system, between those who share these elements and those who do not.

In these terms, criminal or delinquent subcultures denote systems of norms, values, or interests that support criminal or delinquent behavior. The many behaviors specified in law as criminal or delinquent are associated with many criminal and delinquent subcultures. The norms, values, or interests of these subcultures may support particular criminal acts, a limited set of such acts (e.g., a subculture of pickpockets vs. a subculture of hustlers). "Professional criminals," for example, take pride in their craft, organize themselves for

the safe and efficient performance of the crimes in which they specialize, and generally avoid other types of criminal involvement that might bring them to the attention of the authorities (see Sutherland 1937; Cressey 1983). Not all criminal subcultures are this specific, however. Some are simply opportunistic, embracing several types of criminal behavior as opportunities arise. So it is with delinquent subcultures, where specialization is rare.

While delinquent subcultures typically are associated with a broad range of illegal behaviors, among delinquent groups and subcultures there is great variation in the nature and strength of group norms, values, and interests. Moreover, the extent to which delinquent behavior is attributable to these factors is problematic. Much delinquent behavior of highly delinquent gangs, for example, results from the operation of group processes rather than group norms per se (see Short 1997). The normative properties of groups vary greatly, but even the most delinquent gang devotes relatively little of its group life to the pursuit of delinquent behaviors. Further, when gangs do participate in delinquent episodes, some members of the gang typically do not become involved. This is so, in part, because subcultures typically consist of *collections of normative orders*—rules and practices related to a common value (Herbert 1998)—rather than norms oriented around a single value (such as being "macho," "cool," or exceptionally gifted in some way). In addition, individuals who are associated with a particular subculture tend also to be associated with other subcultures. Simply being associated with a subculture thus is unlikely to be a good predictor of the behavior of a particular individual.

For analytical purposes it is important to distinguish between subcultures and the particular individuals and groups who share the norms, values, and interests of the subculture. While members of a delinquent gang may be the sole carriers of a particular subculture in a particular location, some subcultures are shared by many gangs. Conflict subcultures, for example, are shared by rival fighting gangs among whom individual and group status involves values related to the defense of "turf" (territory) and "rep" (reputation) and norms supportive of these values. Subcultures oriented to theft and other forms of property crime vary in the extent to which they are associated with particular

groups. Some types of property crimes require organization and coordination of activities in order to be successful. Some also necessarily involve the efforts of others, such as “fences,” in addition to members of a criminally organized gang (see Klockars 1974). Others, such as mugging and other types of robbery, may be carried out by individual offenders, who nevertheless share a subculture supportive of such behavior. Most drug-using subcultures tend to be less oriented toward particular groups than are conflict subcultures because the subcultural orientation is toward drug consumption, and this orientation can be shared with other drug users in many types of group situations. To the extent that a subculture is oriented to experiences associated with a particular group, however, a drug-using subculture may also be unique to that group.

As this analysis suggests, cultures, subcultures, and the groups associated with them typically overlap, often in multiple and complex ways. To speak of youth culture, for example, is to denote a subculture of the larger adult-dominated and institutionally defined culture. Similarly, delinquent subcultures contain elements of both youth and adult cultures. Terry Williams’s (1989) lower class, minority, “cocaine kids,” for example, were entrepreneurial, worked long hours, and maintained self-discipline—all important elements in the achievement ideology of the American Dream (see Messner and Rosenfeld 1994; also Fagan 1996; Hagan, et al. 1998). Most saw their involvement in the drug trade as a way to get started in legitimate business or to pursue other conventional goals, and a few succeeded at least temporarily in doing so. The criminal subculture with which they identified shared a symbiotic relationship with their customers (including many middle- and upper-class persons), who shared subcultural values approving drug use but who participated in the subculture of drug distribution only as consumers. For the young drug dealers, selling drugs was a way to “be somebody,” to get ahead in life, and to acquire such things as jewelry, clothing, and cars—the symbols of wealth, power, and respect.

The nature of relationships between delinquent subcultures and larger cultural systems is further illustrated by Mercer Sullivan’s study of cliques of young men in Brooklyn, among whom the “cultural meaning of crime” was “constructed

in . . . interaction out of materials supplied from two sources: the local area in which they spend their time almost totally unsupervised and undirected by adults, and the consumerist youth culture promoted in the mass media” (1989, p. 249). In other words, crime becomes meaningful to young men when they interact with one another and when they participate in youth culture, with its highly commercialized messages. The research literature on criminal and delinquent subcultures is devoted largely to describing and accounting for these types of varied and complex relationships.

THEORY AND RESEARCH

Despite efforts to define the theoretical construct, “subculture”—and related constructs—more precisely and to describe and account for the empirical reality they represent, no general theory of subcultures has emerged (Yinger 1960, 1977). Instead, research has continued to reveal enormous variation in subcultures, and theory has proceeded by illustration and analogy, with little progress in measurement or formal theoretical development. Despite this scientifically primitive situation, principles of subcultural formation have been identified, and knowledge of it has advanced.

It is a “fundamental law of sociology and anthropology,” noted Daniel Glaser, that “social separation produces cultural differentiation” (1971, p. 90). More formally, and more cautiously, social separation is a necessary but not sufficient condition for the formation of subcultures. To the extent that groups or categories of persons are socially separated from one another, subcultural formation is likely to occur.

Albert Cohen argued that a “crucial” (perhaps necessary) “condition for the emergence of new cultural forms is the existence, in effective interaction with one another, of a number of actors with similar problems of adjustment” (1955, p. 59). While the notion of “similar problems of adjustment” can be interpreted to include problems faced by quite conventional people with special interests who find themselves “in the same boat” with others who have these same interests (let us say, bird-watchers), this condition seems especially appropriate to subcultures that embrace vandalism, “hell raising,” and other types of nonutilitarian

delinquent behavior. Observing that this type of behavior occurs most frequently among working-class boys, Cohen hypothesized that this type of delinquent subculture was formed in reaction to status problems experienced by working-class boys in middle-class institutions such as schools. Many working-class boys are inadequately prepared for either the educational demands or the discipline of formal education, and they are evaluated poorly in terms of this "middle-class measuring rod." Working-class girls are less pressured in these terms, Cohen argued, because they are judged according to criteria associated with traditional female roles, and they are subject to closer controls in the family.

The solution to their status problems, as some working-class boys see it, according to Cohen's theory, is to reject the performance and status criteria of middle-class institutions, in effect turning middle-class values upside down. The theory thus seeks to account for the highly expressive and hedonistic quality of much delinquency and for the malicious and negativistic quality of vandalism.

Cohen did not attempt to account for the delinquent behavior of particular individuals or for the behavior of all working-class boys. Most of the latter do not become delinquent—at least not seriously so. They choose instead—or are channeled into—alternative adaptations such as the essentially nondelinquent "corner boys" or the high-achieving "college boys" described by William Foote Whyte (1943).

The forces propelling youngsters into alternative adaptations such as these are not completely understood. Clearly, however, working-class and lower-class boys and girls tend to be devalued in middle-class institutional contexts. Their marginality sets the stage for subcultural adaptations. Delinquents and criminals occupy even more marginal positions. This is particularly true of persistent delinquents and criminals who commit serious crimes, in contrast to those who only rarely transgress the law and with little consequence. When marginality is reinforced by labeling, stigmatization, or prejudicial treatment in schools and job markets, "problems of adjustment" magnify. The common ecological location of many delinquents, in the inner-city slums of large cities, and their coming together in schools, provides the setting for

"effective interaction." The result often is the formation of delinquent youth gangs, an increasingly common organizational form taken by delinquent subcultures (see Thrasher 1927; Klein, 1995; Short 1997).

There is no universally agreed-upon definition of youth gangs. For theoretical purposes, however, it is useful to define gangs as groups whose members meet together with some regularity over time and whose membership is group-selected, based on group-defined criteria. Similarly, organizational characteristics are group determined. Most importantly, gangs are not adult-sponsored groups. The nature of relationships between young people and conventional adults is the most critical difference between gangs and other youth groups (see Schwartz 1987). Gang members are less closely tied to conventional institutions and therefore less constrained by institutional controls than are nongang youth. Group processes of status achievement, allocation, and defense are more likely to result in delinquent behavior among gangs than is the case among adult-sponsored groups.

HOW DO CRIMINAL AND DELINQUENT SUBCULTURES GET STARTED?

Delinquent and criminal subcultures have a long history in industrialized societies (Cressey 1983). Herman and Julia Schwendinger (1985) trace the origins of adolescent subcultures, including delinquent varieties, to social changes that began in the sixteenth century. Traditional economic and social relationships were greatly altered with the advent of capitalism and the Industrial Revolution in Western Europe, leaving in their wake large numbers of unemployed persons and disrupting communities, families, and other primordial groups. Cut adrift from traditional crafts and communities, thousands roamed the countryside, subsisting as best they could off the land or by victimizing travelers. The "dangerous classes" eventually settled in cities, again to survive by whatever means were available, including crime. Criminal subcultures and organizational networks often developed under these circumstances.

The Schwendingers emphasize that criminal subcultures developed as a result of structural

changes associated with capitalist values and their accompanying norms and interests—individualism and competitiveness, acquisitiveness and exploitativeness—and the relationships that developed during this period between capitalists and emerging nation-states. While many of the facts upon which this Marxist interpretation is based are generally accepted, careful historical analysis of economic and political systems and their consequences cautions against any simple or straightforward interpretation (see Chirot 1985). The connection between global phenomena and crime and delinquency always is mediated by historical, cultural, and local circumstances—by the historically concrete (see Tilly 1981).

James Coleman and his associates (1974) identified more recent social changes that were associated with the rise and spread of youth culture throughout the United States: the Baby Boom following World War II and the increased affluence of young people associated with post-World War II economic prosperity combined to create a huge youth market with great economic power. At the same time, young people were spending more time in school and therefore delaying their entrance into the labor force; growing numbers of women entered the work force, further separating mothers from youth in homes and neighborhoods; adults increasingly were employed in large organizations where young people were not present; and mass media, catering more and more to the youth market, were greatly expanded. At the close of the twentieth century, each of these broad social changes was more pronounced—and their influence was more widespread throughout the world—than was the case when these observations were made.

In contrast to accounts of the origins of Western European youth cultures, and of youth culture in the United States, Ko-lin Chin (1996) traces the development of Chinese youth gangs in the United States to ancient secret society traditions, and to the more recent Triad societies that formed in the late seventeenth century in China, and their counterpart tongs in the United States. Formed as political groups representing disfavored Chinese officials and the alienated poor, these groups initially stressed patriotism, righteousness, and brotherhood as primary values. However, their secret nature was conducive to clandestine activities such as gambling, prostitution, and running opium dens.

Competition among Triad societies in these activities often led to violence. Failure to achieve political power led to their further transformation into criminal organizations involved in extortion, robbery, drug trafficking, and other serious crimes.

Street gangs comprised of Chinese adolescents did not form in the United States until the late 1950s, but their numbers increased dramatically during the following decade, when changed immigration laws permitted more Chinese to enter the country. Conflict between foreign- and American-born youths led to the emergence of gangs, some seriously delinquent. Chin attributes this development to alienating problems experienced by immigrant Chinese youth in their families, schools, and communities, in dramatic contrast to their American-born counterparts. From the beginning, many Chinese youth gangs have been associated in a variety of ways with established adult secret societies in the United States, Hong Kong, or Taiwan, or in all three places. The existence of “Triad-influenced” organizations has been critical to the types of gangs that have emerged in Chinese communities and to the nature of their criminal activities.

While the origins of delinquent subcultures may reside in antiquity, the formation and evolution of modern variations of them can be explained in terms of more immediate macro-level developments. Some of these developments relate primarily to the ongoing activities and interests of gang members rather than to racial or ethnic changes, or to sweeping social changes. The nature of these influences is illustrated by a drug-using group studied by James Short, Fred Strodbeck, and their associates (Short and Strodbeck 1965; see also Short 1997, 1998). This gang was observed as it developed its own unique subculture. The subculture of the “Pill Poppers,” as they became known to the research team, evolved from their relationship with a larger, conflict-oriented gang of which they had previously been a part. The Pill Poppers’ preoccupation with drugs and their refusal to participate in the more bellicose activities of the larger gang led to their withdrawal and increasing isolation, by mutual agreement. The researchers were able to observe the evolution of this subculture, which was characterized by normative approval of drug consumption, an elevated value on “getting high,” and mutual interest in the

“crazy” things that happened to them when they were under the influence of drugs. The latter, in particular, became legendary within the group, being told and retold with nostalgia and humor when members of the gang were together. The subculture of this gang contrasted sharply with that of other gangs that were participating in a well-developed conflict subculture.

LEVELS OF EXPLANATION OF CRIMINAL AND DELINQUENT SUBCULTURES

The theories of criminal and delinquent subcultures are macro-level theories (Short 1998). Their purpose is to identify what it is about political, economic, and other social systems that explain the emergence and the social distribution of these phenomena. Other theories at this level focus on the impact of local and broader community opportunities on delinquent subcultures and on youth subcultures generally. Walter Miller (1958) related lower-class culture to gang delinquency, while Richard Cloward and Lloyd Ohlin (1960) found that different delinquent subcultures were associated with the availability of legitimate and illegitimate economic opportunities in local communities. Gary Schwartz (1987) stressed the importance of local community youth-adult authority relationships in determining the nature of youth subcultures, including the extent and the nature of delinquent activities associated with them. Mercer Sullivan (1989) related gang adaptations to more global economic developments such as the transfer of manufacturing jobs from the United States to other countries and an increasingly segmented labor market, which has resulted in the concentration of low-wage and surplus labor in inner-city minority communities (see also Hagedorn 1987, 1998).

William Julius Wilson (1987) provided the most compelling theoretical argument relating economic changes to crime and delinquency among the “truly disadvantaged.” Wilson argued that a permanent underclass emerged in the United States during the 1960s and 1970s. Research on delinquent subcultures supports this argument and documents related changes in gang membership. Because fewer good jobs were available to poor, minority young men, more gang members continued their association with gangs as they entered

adulthood. In the past, gang members typically “grew out of” the gang to take jobs, get married, and often become associated with adult social clubs in stable, ethnically-based communities. These options have become less viable among the poor of all races, but minorities have increasingly become the truly disadvantaged. Gang organization has been affected by this change, as older members assume or continue leadership roles. The result often has been that gang involvement in criminal activities has become more sophisticated and instrumental, and younger members have been exploited in criminal enterprise. Relationships between young people and conventional adults also suffer, as older, stable role models and monitors of youthful behavior are replaced by young adult, often criminal, role models for the young (see Anderson 1990, 1999).

Sullivan’s study of groups and young males in three Brooklyn communities—black, predominantly Latino, and white—is particularly significant in this regard. The young men in Hamilton Park, the white group, were able to find better jobs than were the others at all ages. More important, because “they had become more familiar with the discipline of the workplace,” as they grew older they were able to secure better-quality jobs and to hold on to them, compared to the minority youth studied by Sullivan. Familiarity with the discipline of the workplace is a type of *human capital* that was made possible by an important type of *social capital*—the superior personal networks that the Hamilton Park youth shared with the adult community (Sullivan 1989, pp. 105, 226). The minority youth were disadvantaged, with respect to both human and social capital, in the family and in other ways (see Coleman 1988). Thus, while individual human and social capital are acquired through personal experience, communities and neighborhoods also vary in their stock of human and social capital, qualitatively and quantitatively—yet another way in which delinquent and criminal subcultures reflect aspects of their “parent” (larger) cultures.

All macro-level theories make certain assumptions about the individual level of explanation. The most prominent of these assumptions is that individuals learn subcultural norms, values, and the behaviors they encourage, by interacting with others in their environment. The general processes of learning have been well established by research and theory (see Bandura 1986; Eron 1987).

The child's most important early learning experiences take place in the family, but other influences quickly assert themselves, especially as children associate with age and gender peers. With the beginning of adolescence, the latter become especially powerful as young people experience important biological and social changes. It is at this point that youth subcultures become especially significant.

Subcultures are dynamic and ever changing, influenced by both external and internal forces and processes. Substantial knowledge gaps exist at each level of explanation; precisely how they relate to each other is not well understood, however. By documenting the ongoing interaction among gang members and between gang members and others, group processes help to inform the nature of the relationship in ways that are consistent with what is known at the individual and macro levels of explanation. Both intragang and intergang fighting often serve group purposes, for example, by demonstrating personal qualities that are highly valued by the gang or by reinforcing group solidarity (see Miller, Geertz, and Cutter 1961; Jansyn 1966). Gang conflict often occurs when a gang believes its "rep," its "turf," or its resources (for example, its share of a drug market) are threatened by another gang. Threats to individual or group status often result in violent or other types of criminal behavior (Short 1997).

CONCLUSION

The rich research materials that have accumulated regarding criminal and delinquent subcultures suggest two conclusions: (1) there is a great variety of such adaptive phenomena, and (2) they are of an ever-changing nature. Because they both effect social change and adapt to it, subcultures—including criminal and delinquent subcultures—continue to be important theoretically, empirically, and practically (that is, as a matter of social policy). Robert Sampson and his colleagues (1997) find that willingness to intervene on behalf of the common good, together with collective efficacy (social cohesion among neighbors), is associated with lower rates of violent crime in Chicago neighborhoods. This suggests that developing ways to encourage identification of neighbors with each other and encouraging them to help one another in their common interests will enhance local social

control and help weaken the influence of subcultures that encourage criminal and delinquent behavior.

JAMES F. SHORT, JR.

CRIMINAL SANCTIONS

The quality and quantity of normative sanctions have been viewed as a reflection of the nature of social solidarity (Durkheim 1964; Black 1976). In simple societies where the level of willing conformity is high, normative sanctions tend to be informal in nature, substantive in application, and limited in use. In complex societies where levels of willing conformity are lower, normative sanctions are more likely to be formal in nature, procedural in application, and frequent in use (Michalowski 1985). The increasing stratification, morphology, and bureaucracy of modern society have given rise to the predominance of formal justice in the form of criminal law and criminal sanctions (Black 1976). Consequently, the nature of crime has been transformed from an offense committed by one individual against another in the context of community to an offense committed against the society as a whole (Christie 1977). Behaviors considered harmful to the moral, political, economic, or social well-being of society are defined as criminal and thereby worthy of formal state sanctions (Walker 1980). Criminal behaviors include transgressions of both the prohibitions and obligations that define a particular society. Behaviors come to be defined as crimes through the process of criminalization, which includes the calculation of proportional sanctions for each crime.

Criminal sanctions include capital punishment, imprisonment, corporal punishment, banishment,

house arrest, community supervision, fines, restitution, and community service. The type and severity of criminal sanctions are prescribed by criminal law (Walker 1980). The quality and quantity of criminal penalties are determined by both the perceived seriousness of the offense and the underlying philosophy of punishment. Punishment by the state on behalf of society has traditionally been justified on either consequential or nonconsequential grounds (Garland 1994). Consequentialism justifies punishment as a means to the prevention of future crime. The utilitarian approach, for example, allows society to inflict harm (by punishment) in order to prevent greater harms that would be caused by future crimes. The utilitarian approach to criminal sanctions is governed by a set of limiting principles (Beccaria 1980). According to utilitarianism criminal sanctions should not be used to penalize behavior that does not harm, the severity of the penalty should only slightly outweigh the benefit derived from the criminal behavior, and alternatives to punishment should be utilized when they prove to be as effective (Bentham 1995).

Nonconsequentialism, on the other hand, justifies punishment as an intrinsically appropriate response to crime (Duff and Garland 1994). The retributive approach, for example, mandates punishment as a way of removing the advantage originally gained by the criminal behavior or as a means of restoring the moral balance that was lost as a result of a crime. According to the retributivist perspective crime separates the offender from the community and it is only through punishment that the separation can be repaired (Morris 1981). While the utilitarian and retributivist justifications have dominated the philosophical discussion of punishment, more recent justifications such as rehabilitation (Rotman 1990) and incapacitation (Morris 1982) have also been viewed in terms of their consequential and nonconsequential nature. From a sociological perspective these philosophies of punishment represent ideal types against which the actual practice of punishment must be examined.

THE SOCIOLOGY OF CRIMINAL SANCTIONS

Several lines of inquiry comprise the sociology of criminal sanctions including the examination of

the criminalizing process, the empirical assessment of the effectiveness of particular sanctions, and the analysis of the relationship between social structural changes and the evolution of criminal law.

Critique of the Criminalization Process. The question of which behaviors become defined as criminal and deemed worthy of punitive sanctions has been central to the study of crime and law. The *functional perspective* of criminal law suggests that the criminalization of a particular behavior is the result of a consensus among members of a society (Durkheim 1964). In the *consensus view* criminal law encompasses the behaviors that have been determined to be most threatening to the social structure of society and the well-being of its members (Wilson 1979).

According to the functionalist perspective, criminal law adapts to changes in the normative consensus of society. As society evolves, behaviors once considered criminal may be decriminalized while behaviors that had previously been acceptable may become criminalized. In this context criminal law and its accompanying sanctions are viewed as the collective moral will of society. Punishment is viewed as serving the essential function of creating a sense of moral superiority among the law-abiding members of society, thereby strengthening their social solidarity (Durkheim 1964). Therefore, crime is considered to be inevitable in the functionalist view because the pressure exerted against those who do not conform to normative expectations is necessary to reinforce the willing conformity among members of society. Solidarity results from the social forces directed against transgressors, with the most powerful of these forces being criminal sanctions (Vold 1958). Criminal sanctions enable societies to distinguish between behaviors that are simply considered unacceptable and those behaviors that are considered truly harmful.

Conversely, the conflict perspective suggests that the designation of behaviors as criminal is determined within a context of unequal power. Although various forms of the conflict perspective identify different sources for this power imbalance, they are in general agreement as to the results of the criminalizing process. According to the conflict view, society is made up of groups with conflicting needs, values, and interests that are

mediated by an organized state that represents the needs, values, and interests of groups that possess the power to control the state. Such control includes the capacity to determine which behaviors are considered to be criminal and which behaviors are not. As a result behaviors more likely to be committed by the less powerful are defined as criminal while behaviors more likely committed by the powerful are not defined as criminal (Bernard 1983; Reiman 1998). Furthermore, the conflict view suggests that the application of both criminal law and criminal sanctions are skewed in favor of those with power. Within the conflict perspective various theories are differentiated according to their identified source of group conflict. Among the major conflict theories are those that identify a conflict of cultural groups (Sellin 1938), those that identify a conflict of norms (Vold 1958), those that identify a conflict of socioeconomic interests (Marx 1964), and those that identify a conflict of bureaucratic interests (Turk 1969). Despite their different origins, conflict theories are united in their assessment that criminal law and criminal sanctions are utilized to support the average best interest of those with power. As a result the state is assumed to apply criminal sanctions in such a manner that they are not perceived as overly coercive while at the same time preserving the existing power arrangements thereby maintaining the legitimacy of criminal law (Turk 1969).

An Empirical Context for Criminal Sanctions.

Empirical assessments of criminal sanctions have been primarily carried out within the contexts of *penology* and the *sociology of punishment*. Penology is a practically oriented form of social science that traces and evaluates various practices of penal institutions and other punitively oriented institutions of the modern criminal justice system (Duff and Garland 1994). Penology began as an extension of the prison itself that its sole purpose was to evaluate the objectives of the institution and develop more efficient ways of achieving these institutional objectives. More recently penology has expanded its inquiry to include the assessment of the entire criminal sanctioning process (studying the prosecution, the court process, as well as alternative sanctions such as probation, fines, electric monitoring, community service, and restitution). Increasingly, penology has been guided by the major theories of crime causation thus becoming a recognized area of study within the discipline of

criminology. Contemporary, penological research serves as the empirical foundation for policy development (Bottomley 1989). Despite its more recent criminological grounding, penological research is still viewed as primarily evaluative rather than critical. Penology assumes an exclusively punitive perspective toward transgressions of criminal law, therefore, it is primarily concerned with the relative effectiveness of the various punitive responses to criminal transgressions. The critical dimension of penology is limited to identifying problems within existing institutions and suggesting ways to more efficiently achieve the goal of punishment. Because penology is limited to the study of punishment systems any questions concerning alternative models of crime control such as compensation or conciliation are addressed by the sociological study of punishment (Garland 1990).

Unlike penology, the sociology of punishment raises more fundamental questions concerning the relative effectiveness of both punitive and nonpunitive responses to normative transgressions. Within the context of the sociology of punishment special attention is directed to the way in which society organizes and deploys its power to respond to transgressions (Duff and Garland 1994). It is primarily concerned with the relationship between punishment and society. Punishment is examined as a social institution that reflects the nature of social life. The sociology of punishment is fundamentally interested in why particular types of societies employ particular types of criminal sanctions (Garland 1990). In addition, the sociological analysis of punishment examines the social conditions that necessitate certain styles of normative sanctioning such as the use of penal sanctions in social situations that are characterized by high levels of inequality, heterogeneity, and bureaucratic interaction (Black 1976). The sociology of punishment also includes the study of correlations between the application of various sanctions (e.g. imprisonment, probation, fines, etc.) and demographic variables such as class, race, gender, occupation, and education (Reiman 1998; Zimring and Hawkins 1990). Because of the dominance of imprisonment as the preferred sanction for serious criminal transgressions in Western societies much attention has been directed to the effect of penal confinement on prisoners. Sociological inquiries into the inner world of the prison have examined the social adaptation of prisoners to the unique

requirements and relationships that characterized "The total institution" (Goffman 1961; Sykes 1958). The sociological study of punishment suggests that the adoption and application of criminal sanctions are better understood as a reflection of social, political, and economic reality than as the product of moral consensus (Garland 1990).

The Evolution of Criminal Sanctions. Sociologists have paid considerable attention to the qualitative evolution of criminal sanctions. Special attention has been directed to the relationship between changes in the socioeconomic structure and the evolution of criminal law in modern Western societies (Melossi and Pavarini 1981). Within the more general discussion of law and society, the study of punishment and social structure emerged (Rusche and Kirchheimer 1939). The sociology of penal systems argues that the transformation of penal systems cannot primarily be explained by the changing needs of crime control. Instead, the sociological analysis of shifts in the systems of punishment and criminal law are best understood in terms of their relationship to the prevailing system of production (Sellen 1976). Each society generates criminal law practices and types of punishments that correspond to the nature of its productive relationships. Research on punishment and social structure has focused attention on the origin and evolution of penal systems, the use or avoidance of specific punishments, and the intensity of penal practices in terms of larger social forces—particularly economic and fiscal forces (Rusche and Kirchheimer 1939). For example, in slave economies where the supply of slaves was inadequate, penal slavery emerged; the emergence of the factory system decreased the demand for convict labor, which in turn led to the rise of reformatories and industrial prisons (Melossi and Pavarini 1981). Although the economic analysis of criminal sanctions dominated the early literature on the sociology of punishment, later analysis has focused more broadly on all five aspects of social life (i.e., stratification, morphology, bureaucracy, culture, and social control).

CRIMINAL SANCTIONS AND THE ASPECTS OF SOCIAL LIFE

The comparative study of law has identified criminal law and criminal sanctions as quantifiable variables (Black 1976). By quantifying criminal law

and criminal sanctions it is possible to compare both the type and the amount of law utilized by one society versus another. The quantification of law can then be correlated to the nature of social life. The type and amount of criminal law can either be correlated to individual aspects of social life or the collective integration of all the variables of social life. Social life consists of five variable aspects: *stratification* is the vertical aspect of social life (the hierarchy of people relative to their power), *morphology* is the horizontal aspect of social life (the distribution of people in relation to each other), *bureaucracy* is the corporate aspect of social life (the capacity for collective action), *culture* is the symbolic aspect of social life (the representation of ideas, beliefs, and values), and *social control* is the normative aspect of social life (the definition of deviance and the response to it). The first four aspects of social life collectively determine the style of social control.

Comparative legal studies have identified five styles of social control; *penal control*, *compensatory control*, *therapeutic control*, *educative control* and *conciliatory control* (Fogel 1975). The response to normative transgressions under each style is consistent with the general standard of behavior recognized by society at large. Transgressions of the prohibition standard of the penal style of control require a punitive solution in order to absolve the guilt of the transgressor. Violation of the obligation standard of the compensatory style requires payment in order to eliminate the debt incurred by the violation. Behaviors that fall outside the standard of normality that characterizes the therapeutic style require treatment to restore predictability to social interaction. Failure to meet the knowledge standard of the educative style requires reeducation in order to attain a full understanding of society's norms and underlying values. Disruption of the harmony standard of the conciliatory style requires resolution in order to reestablish the relationships among members of the community (Fogel 1975).

Criminal law and punitive sanctions are inversely correlated to other forms of social control. In addition to law, social control is found in many intermediate social institutions, including family, churches, schools, occupations, neighborhoods, and friendships. In societies where such intermediate institutions are dominant, the need for law

and formal criminal sanctions is limited. Conversely, in societies where intermediate institutions are less dominant informal social control is less effective, thereby necessitating the expansion of formal social control that typically takes the form of criminal law and punitive sanctions. The quantity of criminal law increases as the quantity of informal social control decreases (Black 1976). The primary measurement of the quantity of criminal law is the frequency and severity of criminal sanctions.

The relative quantity of criminal law and other forms of social control have been linked to the relative presence or absence of the other aspects of social life. At the extremes, societies characterized by significant stratification, morphological diversity, bureaucratic interaction, and cultural multiplicity will employ a more penal style of social control while societies characterized by general equality, homogeneity, face-to-face interaction, and cultural consensus will employ a more conciliatory style of social control. The therapeutic, educative, and compensatory styles of social control are to be found in societies somewhere between the extremes. In Western societies the increase in stratification, morphology, bureaucracy, and cultural multiplicity have combined to lower the level of willing conformity and diminish the effectiveness of informal mechanisms of social control (Garland 1990). The decline of informal social control has been traced to the less efficient use of shaming. Literature on the effectiveness of various normative sanctions has suggested that shame can be either reintegrative or disintegrative in nature depending on the strength of intermediate institutions and the level of willing conformity (Braithwaite 1994). Although the phenomenon of shame is found in both formal and informal systems of social control it is a more central feature of informal social control.

FORMAL VERSUS INFORMAL SANCTIONS

Shaming is the central deterrent element of most informal mechanisms of social control. Its use in formal mechanisms of social control has until the 1990s been limited due to the concerns related to labeling (Becker 1963; Braithwaite 1994). Deterrence research has shown a much stronger shaming effect for informal sanctions than for formal legal

sanctions (Paternoster and Iovanni 1986). It has been suggested that sanctions imposed by groups with emotional and social ties to the transgressor are more effective in deterring criminal behavior than sanctions that are imposed by a bureaucratic legal authority (Christie 1977). Although the empirical evidence comparing the deterrent effect of informal versus formal sanctions is limited, it has consistently shown that there is a greater concern among transgressors for the social impact of their arrest than for the punishment they may receive (Sherman and Berk 1984). Perceptions of the certainty and severity of formal criminal sanctions appear to have little effect on the considerations that lead to criminal behavior. Whatever effect formal criminal sanctions do have on deterring future criminal behavior is primarily dependent on the transgressor's perception of informal sanctions (Tittle 1980).

Deterrence theory is predicated on the assumption of fear (Zimring and Hawkes 1973). It has been assumed that deviants and especially criminal offenders fear the loss directly related to formal sanctions (e.g. loss of liberty, loss of material possessions, etc.). Research on formal sanctions that are coupled with informal sanctions suggests to the contrary that to the extent transgressors would be deterred by fear, the fear that is most relevant is that their transgression will result in a loss of respect or status among their family, friends, or associates (Tittle 1980). In the cost-benefit analysis that is central to the "rational actor" model of crime causation, loss of respect and status weighs much more heavily for most individuals than the direct loss of liberty or material.

Deterrence is considered to be irrelevant to the majority of the populace, therefore, most people are believed to comply with the law because of their internalization of the norms and values of society (Toby 1964). For the majority of the populace failure to abide by the norms and values would call into question their commitment to that society. For the well-socialized individual, moral conscience serves as the primary deterrent. The conscience delivers an anxiety response each time an individual transgresses the moral boundaries of society. The anxiety response fulfills the three requirements of deterrence: it is immediate, it is certain, and it is severe. Formal criminal sanctions on the other hand may be severe but they are not always certain nor swift (Braithwaite 1994).

Criminal sanctions represent a denial of confidence in the morality of the transgressor. In a criminal law system norm compliance is reduced to the calculus of cost versus benefit. Conversely, informal sanctions can be a reaffirmation of the morality of the transgressor by showing disappointment in the transgressor for acting out of character. The shaming associated with the disappointment is reintegrative because its ultimate goal is the restoration of the transgressor to full membership in the group, community, or society. Shaming in the informal context is reintegrative because of its view of the transgressor as a whole and valued member of society and its goal of social restoration. Criminal sanctions, on the other hand, define the transgressor strictly in terms of his or her transgression thus causing a disconnection between the transgressor and society (Garfinkel 1965). Criminal sanctions lack both the incentive and mechanism for reintegration. Without reintegrative potential, criminal sanctions stigmatize rather than shame. Stigmatization is exclusively concerned with labeling while reintegrative shaming is equally concerned with delabeling. In the context of most informal sanctions community disapproval is coupled with gestures of reacceptance. The reintegrative character of informal sanctions ensures that the deviant label be directed to the behavior rather than the person thus avoiding the assignment of a master status to the person (Braithwaite 1994).

In the study of criminal sanctions much attention has been directed to the effects of labeling on the sanctioned transgressor. *Labeling theory* argues that the deviant characteristic (e.g., drug addict, criminal, etc.) assigned to a person may become a status such that the 'label' will dominate all positive characteristics (e.g. parent, teacher, church member, etc.) that might otherwise characterize the person. Such a deviant master status is believed to limit and in some cases preclude the reintegration of the transgressor. For those prevented from reintegrating, the label becomes a self-fulfilling prophecy eventually leading to secondary deviance, namely deviance caused by the label itself (Becker 1963). The possibility of secondary deviance as a result of the stigmatization of the transgressor has been included by some labeling theorists in their assessment of the relative effectiveness of criminal sanctions (Gove 1980). However, it has been alternatively suggested that

stigmatization might enhance crime control because the thought of being a social outcast serves as a stronger sanction and more effective deterrent than being shamed and eventually reintegrated (Silberman 1976). The potential effectiveness of sanctions is dependent upon whether deterrence is more effectively achieved through the fear of social marginalization associated with formal sanctions or the fear of community disapproval associated with informal sanctions (Braithwaite 1994).

CRIMINAL SANCTIONS AND DUE PROCESS

Despite the lack of conclusive evidence in support of the deterrent effect of criminal sanctions, the frequency and severity of such sanctions have significantly increased over the past quarter-century (Stafford and Warr 1993). The dramatic rise in both the prison population and persons under probationary supervision is a reflection of the increase in the age of the population most at risk to engage in criminal acts as well as a renewed commitment to the nonconsequential philosophy of punishment. A number of observers have pointed to the growing use of criminal sanctions as a sign of an increased emphasis on crime control; however, the increasing use of criminal sanctions has coincided with the expansion of legal protections for the accused. The limitations of criminal sanctions in the form of due process guarantees have produced a hybrid criminal process that legitimates the widespread use of punitive responses to normative transgressions by constraining the power of state-sponsored agents of control. The criminal process in the West includes both a strong crime-control component and a strong due process component (Packer 1968). The process is perceived as a contest between relatively equal actors, which helps to legitimate the pain associated with the imposition of criminal sanctions. The criminal process satisfies both society's demand for crime control and its desire to protect the liberty of the individual. Criminal sanctions are shaped by these competing demands of society. On the one hand the crime-control component is based on the assumption that the suppression of criminal conduct is by far the most important function of the criminal process, while the due process component is based on the assumption that ensuring that

only the guilty are punished is the most important function of the criminal process.

The crime-control model suggests that the failure to provide an adequate level of security for the general public will undermine the legitimacy of criminal law. In contrast, the due process model suggests that the wrongful punishment of an individual is a greater threat to the legitimacy of law (Turk 1969). Therefore, criminal sanctions must be severe enough to contribute to crime control and their application must be fair and consistent in order to satisfy due process requirements (Packer 1968). The additional constraint on criminal sanctions that they be applied only in cases where genuine intent can be conclusively determined has contributed to the rise of alternative systems of social controls.

SOCIAL CONTROL BEYOND CRIMINAL SANCTIONS

As the definition of what constitutes criminal behavior is narrowed, the social control of noncriminal normative transgression is transferred from the jurisdiction of criminal law to the jurisdictions of medicine and public health. Both public health and psychiatry have long been concerned with social control (Foucault 1965), but what is more significant is the dramatic expansion of their influence and control over the past half-century. Much of what was considered "badness" (and in some cases criminal) and thereby worthy of punishment has been redefined as sickness that requires a therapeutic response. Though the response is quite different, the objective of social control is fundamentally the same (Conrad and Schneider 1992). Some forms of normative transgressions have long been within the medical and public health domain (e.g., mental illness). Research has shown, however, that an increasing number of behaviors that had been punished in the past are now being treated within the medical jurisdiction (e.g., suicide, alcoholism, drug addiction, child abuse, violence, etc.). The most important implication in the shift of the locus of social control from law to medicine is the determination of individual responsibility. In the context of criminal law the full responsibility for normative transgressions is vested in the individual. In the medical context transgressors are not considered responsible for their

actions (or their responsibility is significantly mitigated), therefore, they cannot be punished for actions that are beyond their control. The societal response to behaviors so defined is therapeutic rather than punitive (Conrad and Schneider 1992).

The trend toward the decriminalization of normative transgressions can be traced to the emergence of *deterministic criminology*, which shifted the study of crime causation from rational action to biological, psychological, and sociological sources (Kittrie 1971). The deterministic perspective was initially applied to juvenile delinquency. The influence of deterministic criminology grew in proportion to the expansion of the juvenile justice system. As more questions were raised about the ability of criminal law and criminal sanctions to effectively deal with transgressors such as juvenile delinquents, alternative methods of control became more widely accepted. It has been suggested that the shift from simple to complex societies has necessitated an accompanying shift from punitive to therapeutic methods of social control (Kittrie 1971). For example, the strength of criminal sanctions is believed to be declining because of the increase in residential mobility coupled with the decrease in the influence of primary institutions such as family, church, and school (Braithwaite 1994). As the influence of primary institutions has waned, their ability to command conformity has declined. With the decline of informal social control and the perceived ineffectiveness of criminal sanctions society has increasingly turned to the promise of therapeutic social control as a means of responding to normative transgressions (Conrad and Schneider 1992).

PETER CORDELLA

CRIMINALIZATION OF DEVIANCE

A 1996 household survey dealing with drug abuse revealed that 13 percent of persons eighteen to twenty-five, 6 percent of persons twenty-six to thirty-four, and 2 percent of persons thirty-five years or older had smoked marijuana within the last thirty days (Maguire and Pastore 1998, p. 246). The same survey showed that nearly a quarter of persons eighteen to twenty-five had smoked marijuana within the past year and about half of persons eighteen to thirty-four had smoked marijuana at least once during their lifetimes. (The prevalence of marijuana use is considerably greater among males than among females, so these statistics understate marijuana use among young adult males.) A different population survey, also conducted in 1996, revealed that the legalization of marijuana use enjoys considerable support among young adults: 38 percent among respondents eighteen to twenty, 30 percent among respondents twenty-one to twenty-nine, and 28 percent among respondents thirty to forty-nine (Maguire and Pastore 1998, p. 151). Males are much more supportive of legalization than females, and those who claim no religion are most supportive of all.

A reasonable interpretation of these data is that no clear consensus exists that smoking marijuana is wrong. Rather, American society contains a large group, probably a majority, that considers smoking marijuana wrong and a smaller group (but a substantial proportion of young adult males) that uses marijuana, considers it harmless, and is probably indignant at societal interference. Since a nonconformist is immensely strengthened by having even one ally, as the social psychologist Solomon Asch demonstrated in laboratory experiments (Asch 1955), such sizable support for marijuana use means that controlling its use is no easy task. Many other kinds of behavior in contemporary societies resemble marijuana use in that some people disapprove of the behaviors strongly and others are tolerant or supportive. In short, modern societies, being large and heterogeneous, are likely to provide allies even for behavior that the majority condemns.

Yet moral ambiguity does not characterize American society on every issue. Consensus exists

that persons who force others to participate unwillingly in sexual relations and persons with body odor are reprehensible. Body odor and rape seem an incongruous combination. What they have in common is that both are strongly disapproved of by the overwhelming majority of Americans. Where they differ is that only one (rape) is a statutory crime that can result in police arrest, a court trial, and a prison sentence. The other, smelling bad, although deviant, is not criminalized. When deviance is criminalized, the organized collectivity channels the indignant response of individuals into public condemnation and, possibly, punishment.

Some sociologists maintain that when sufficient consensus exists about the wrongfulness of an act, the act gets criminalized. This is usually the case but not always. Despite consensus that failing to bathe for three months is reprehensible, body odor has not been criminalized. And acts *have* become criminalized, for example, patent infringement and other white-collar crimes that do not arouse much public indignation. In short, the correlation between what is deviant and what is criminal, though positive, is not perfect.

For a clue to an explanation of how and why deviance gets criminalized, note how difficult it is for members of a society to know with certainty what is deviant. Conceptually, deviance refers to the purposive evasion or defiance of a normative consensus. Defiant deviance is fairly obvious. If Joe, a high school student, is asked a question in class by his English teacher pertaining to the lesson, and he replies, "I won't tell you, asshole," most Americans would probably agree that he is violating the role expectations for high school students in this society. Evasive deviance is less confrontational, albeit more common than defiant deviance, and therefore more ambiguous. If Joe never does the assigned homework or frequently comes late without a good explanation, many Americans would agree that he is not doing what he is supposed to do, although the point at which he steps over the line into outright deviance is fuzzy. Both evasive and defiant deviance require other members of the society to make a judgment that indignation is the appropriate response to the behavior in question. Such a judgment is difficult to make in a heterogeneous society because members of the society cannot be sure how closely other people share their values.

To be sure, from living in a society the individual has a pretty good idea what sorts of behavior will trigger indignant reactions, but not with great confidence. The issue is blurred by subgroup variation and because norms change with the passage of time. Bathing suits that were entirely proper in 1999 in the United States would have been scandalous in 1929. A survey might find that a large percentage of the population disapproves now of nudity on a public beach. The survey cannot reveal for how long the population will continue to disapprove of public nudity. Nor can the survey help much with the crucial problem of deciding how large a proportion of the population that disapproves strongly of a behavior is enough to justify categorizing public nudity as “deviant.”

In short, the scientific observer can decide that a normative consensus has been violated only after first establishing that a consensus exists on that issue at this moment of time, and that is not easy. To determine this, individual normative judgments must somehow be aggregated, say, by conducting a survey that would enable a representative sample of the population to express reactions to various kinds of behavior. Ideally, these responses differ only by degree, but in a large society there are often qualitatively different conceptions of right and wrong in different subgroups.

In practice, then, in modern societies neither the potential perpetrator nor the onlooker can be certain what is deviant. Consequently the social response to an act that is on the borderline between deviance and acceptability is unpredictable. This unpredictability may tempt the individual to engage in behavior he would not engage in if he knew that the response would be widespread disapproval (Toby 1998a). It may also restrain onlookers from taking action against the behavior—or at least expressing disapproval—against persons violating the informal rules.

WHAT CRIME INVOLVES: A COLLECTIVE RESPONSE

Crime is clearer. The ordinary citizen may not know precisely which acts are illegal in a particular jurisdiction. But a definite answer is possible. A lawyer familiar with the criminal code of the State of New Jersey can explain exactly what has to be

proved in order to convict a person of drunken driving in New Jersey. The codification of an act as criminal does not depend on its intrinsic danger to the society but on what societal leaders *perceive* as dangerous. For example, Cuba has the following provision in its criminal code:

Article 108. (1) There will be a sanction of deprivation of freedom of from one to eight years imposed on anyone who: (a) incites against the social order, international solidarity or the socialist State by means of oral or written propaganda, or in any other form; (b) makes, distributes or possesses propaganda of the character mentioned in the preceding clause. (2) Anyone who spreads false news or malicious predictions liable to cause alarm or discontent in the population, or public disorder, is subject to a sanction of from three to four years imprisonment. (3) If the mass media are used for the execution of the actions described in the previous paragraphs, the sanction will be a deprivation of freedom from seven to fifteen years (Ripoll 1985, p. 20).

In other words, mere possession of a mimeograph machine in Cuba is a very serious crime because Fidel Castro considers the dissemination of critical ideas a threat to his “socialist State,” and in Cuba Castro’s opinions are literally law. Hence, possession of a mimeograph machine is a punishable offense. Members of Jehovah’s Witnesses who used mimeograph machines to reproduce religious tracts have been given long prison sentences. On the other hand, reproducing religious tracts may not arouse indignation in the Cuban population. It is criminal but not necessarily deviant.

In California or New Jersey, as in Cuba, a crime is behavior punishable by the state. But the difference is that in the fifty states, as in all democratic societies, the legislators and judges who enact and interpret criminal laws do not simply codify their own moral sentiments; they criminalize behavior in response to influences brought to bear on them by members of their constituencies. True, women, children, members of ethnic and racial minorities, and the poorly educated may not have as much political input as affluent, middle-aged, white male professionals. But less influence does not mean they don’t count at all. In a dictatorship, on the other hand, the political process is closed;

few people count when it comes to deciding what is a crime.

WHEN DEVIANCE IS CRIMINALIZED: POLITICIZATION

As was mentioned earlier, what is deviant is intrinsically ambiguous in a complex society whose norms are changing and whose ethnic mix has varied values. Criminalization solves the problem of predictability of response by transferring the obligation to respond to deviance from the individual members of society to agents of the state (the police). But criminalization means that some members of society are better able than others to persuade the state to enforce *their* moral sentiments. Criminalization implies the politicization of the social control of deviance. In every society, a political process occurs in the course of which deviant acts get criminalized. Generally, the political leadership of a society criminalizes an act when it becomes persuaded that without criminalization the deviant "contagion" will spread, thereby undermining social order (Toby 1996). The leaders may be wrong. Fidel Castro might be able to retain control of Cuban society even if Cubans were allowed access to mimeograph machines and word-processors. Nevertheless, leaders decide on crimes based on their perception of what is a threat to the collectivity. According to legal scholars (Packer 1968), the tendency in politically organized societies is to overcriminalize, that is, to involve the state excessively in the response to deviance. Political authorities, even in democracies, find it difficult to resist the temptation to perceive threats in what may only be harmless diversity and to attempt to stamp it out by state punishment.

Sociology's labeling perspective on deviance (Becker 1963; Lemert 1983) goes further; it suggests that overcriminalization may *increase* deviance by changing the self-concept of the stigmatized individual. Pinning the official label of "criminal" on someone stigmatizes him and thereby amplifies his criminal tendencies. Furthermore, an advantage of ignoring the deviance is that it may be ephemeral and will disappear on its own; thus in 1974 American society virtually ignored "streaking" instead of imprisoning streakers in large numbers for indecent exposure (Toby 1980),

and by 1975 streaking had become a historical curiosity. But whether deviance is self-limiting is an empirical question. The labeling perspective ignores the logical possibility that stigmatizing the deviant may be necessary to deter future deviance by bringing home to the offender (as well as potential offenders) the danger of antagonizing the community. In point of fact, the empirical evidence supports the deterrence possibility more than it does the amplification assumption (Gove 1980; Gibbs 1975). At its most extreme, the labeling perspective denies the desirability of any kind of criminalization:

"The task [of radical reform] is to create a society in which the facts of human diversity, whether personal, organic, or social, are not subject to the power to criminalize" (Taylor, Walton, and Young 1973, p. 282).

Thus, the labeling perspective flirts with philosophical anarchism. More reasonably, the issue is: which forms of deviance can be regarded as harmless diversity and which threaten societal cohesiveness sufficiently that they require criminalization in order to be contained within tolerable limits? Experience has taught us that the body odor of other people, though objectionable to most Americans, is tolerable. But what about consuming alcohol or cocaine to the point of chronic intoxication? What about sexual practices that shock most people such as sado-masochism or intercourse with a sheep? One way to finesse these thorny questions is to define such acts as the product of mental illness and therefore beyond the control of the individual. Instead of regarding drug abuse or alcoholism or bestiality as deviant choices in the face of temptations, society may choose to regard them as "addictions," that is to say, involuntary (Toby 1998b). Since the ill person is by definition unenviable, he is not a role model, and therefore the deviant contagion does not spread (Toby 1964). But suppose consensus does not exist that these acts are compulsive; suppose that many people feel that the perpetrators are perversely *choosing* to engage in these behaviors. Average citizens may become demoralized when they see their norms flouted or they may be tempted to engage in the deviant behavior themselves. This is why criminalization (and state-sponsored punishment) may be necessary. Punishment serves to deprive

the deviant of the benefits of his nonconformity, and therefore he becomes unenviable in the eyes of conformists.

Yes, society may stigmatize and perhaps imprison perpetrators, amid hope that imitators will be rare. But criminalization arouses opposition. Libertarians lean toward permitting almost any nonviolent behavior except the exploitation of children. Mental-health advocates perceive stealing to feed a passion for gambling as a symptom of illness; they may perceive even predatory violence as symptomatic of a sick personality for which the individual cannot be considered responsible. Pragmatists point out that when large numbers of people want to do something, such as gamble or use drugs, it is not practical to attempt to stop them by criminalizing the behavior. They argue that deviants cannot all be punished, certainly not by imprisonment; they corrupt police forces through bribes and deflect police efforts into tasks that cannot be accomplished instead of more feasible deviance-control activities; and the criminal organizations that emerge to cater to these forbidden pleasures promote crimes that would not have occurred in the absence of criminalization.

On the other side of the ledger is the tendency for the absence of criminalization to encourage individuals to engage in a behavior they would not have engaged in when faced with possible criminal sanctions. The Prohibition experiment of the 1920s, despite its perception as a failure, did succeed in reducing the incidence of alcoholism, as reflected in reduced incidence of alcoholic psychosis and of cirrhosis of the liver. But the social cost of criminalizing alcohol consumption was not only the proliferation of criminal enterprises to supply the demand of social drinkers; criminalization also prevented many people who wished to be social drinkers from having the freedom to do so. True, some of these would go on to become alcoholics, but most would not. Thus, the criminalization issue always involves a tradeoff between partially legitimating possibly harmful behavior, such as smoking cigarettes, or curtailing freedom by criminalizing the behavior. This judgment has to be made on a case by case basis. Most people who drink socially do not become alcoholics and most people who smoke do not get lung cancer; hence it is difficult to justify criminalizing drinking and

smoking despite the likelihood that more people become alcoholics and get lung cancer than would if smoking and drinking were criminalized. On the other hand, the tradeoff goes the other way with "hard" drugs; the main argument against decriminalizing the sale of heroin is that the health costs to the general population would be too great; decriminalization would inevitably increase experimentation with the drug and ultimately the number of addicts (Kaplan 1983).

OTHER CONSEQUENCES OF CRIMINALIZATION

The absence of criminal law—and consequently of state-imposed sanctions for violations—is no threat to small primitive communities: Informal social controls can be counted on to prevent most deviance and to punish what deviance cannot be prevented. In heterogeneous modern societies, however, the lack of some criminalization would make moral unity difficult to achieve. When Emile Durkheim spoke of the collective conscience of a society, he was writing metaphorically; he knew that he was abstracting from the differing consciences of thousands of individuals. Nevertheless, the criminal law serves to resolve these differences and achieve a contrived—and indeed precarious—moral unity. In democratic societies, the unity is achieved by political compromise. In authoritarian or totalitarian societies the power wielders unify the society by imposing their own values on the population at large. In both cases law is a unifying force; large societies could not function without a legal system because universalistic rules, including the rules of the criminal law, meld in this way ethnic, regional, and class versions of what is deviant (Parsons 1977, pp. 138–139).

The unifying effect of the criminal law has unintended consequences. One major consequence is the development of a large bureaucracy devoted to enforcing criminal laws: police, judges, prosecutors, jailers, probation officers, parole officers, prison guards, and assorted professionals like psychologists and social workers who attempt to rehabilitate convicted offenders. Ideally, these employees of the state should perform their roles dispassionately, not favoring some accused persons or discriminating against others. In practice, however, members of the criminal justice bureaucracy bring to their jobs the parochial sentiments

of their social groups as well as a personal interest in financial gain or professional advancement. This helps to explain why police are often more enthusiastic about enforcing some criminal laws than they are about enforcing others.

Another consequence of criminalization is that the criminal law, being universal in its reach, cannot make allowances for subgroup variation in sentiments about what is right and what is wrong. Thus, some people are imprisoned for behavior that neither they nor members of their social group regard as reprehensible, as in Northern Ireland where members of the Irish Republican Army convicted of assassinating British soldiers considered themselves political prisoners. They went on hunger strikes—in some cases to the point of death—rather than wear the prison uniform of ordinary criminals.

CONCLUSION

The more heterogeneous the culture and the more swiftly its norms are changing, the less consensus about right and wrong exists within the society. In the United States, moral values differ to some extent in various regions, occupations, religions, social classes, and ethnic groups. This sociocultural value pluralism means that it is difficult to identify behavior that everyone considers deviant. It is much easier to identify crime, which is codified in politically organized societies. The criminalization of deviance makes it clear when collective reprisals will be taken against those who violate rules.

Deviance exists in smaller social systems, too: in families, universities, and corporations. In addition to being subjected to the informal disapproval of other members of these collectivities, the deviant in the family, the university, or the work organization can be subjected to formally organized sanctioning procedures like a disciplinary hearing at a university. However, the worst sanction that these nonsocietal social systems can visit upon deviants is expulsion. A university cannot imprison a student who cheats on a final exam. Even in the larger society, however, not all deviance is criminalized, sometimes for cultural reasons as in the American refusal to criminalize the expression of political dissent, but also for pragmatic reasons as in the American failure to criminalize body odor, lying to one's friends, or smoking in church.

JACKSON TOBY

CRIMINOLOGY

The roots of modern criminology can be found in the writings of social philosophers, who addressed Hobbes's question: "How is society possible?" Locke and Rousseau believed that humans are endowed with free will and are self-interested. If

this is so, the very existence of society is problematic. If we are all free to maximize our own self-interest we cannot live together. Those who want more and are powerful can simply take from the less powerful. The question then, as now, focuses on how is it possible for us to live together. Criminologists are concerned with discovering answers to this basic question.

Locke and Rousseau, philosophers who are not considered criminologists, argued that society is possible because we all enter into a “social contract” in which we choose to give up some of our freedom to act in our own self-interest for the privilege of living in society. What happens though to those who do not make, or choose to break, this covenant? Societies enforce the contract by punishing those who violate it. Early societies punished violations of the social contract by removing the privilege of living in society through banishment or death. In the event of minor violations, sanctions such as ostracism or limited participation in the community for a time were administered. The history of sanctions clearly demonstrates the extreme and frequently arbitrary and capricious nature of sanctions (Foucault 1979).

The Classical School of criminology (Beccaria 1764; Bentham 1765) began as an attempt to bring order and reasonableness to the enforcement of the social contract. Beccaria in *On Crimes and Punishments* (1768) made an appeal for a system of “justice” that would define the appropriate amount of punishment for a violation as just that much that was needed to counter the pleasure and benefit from the wrong. In contemporary terms, this would shift the balance in a cost/benefit calculation, and would perhaps deter some crime. Bentham’s writings (1765) provided the philosophical foundation for the penitentiary movement that introduced a new and divisible form of sanction: incarceration. With the capacity to finally decide which punishment fits which crime, classical school criminologists believed that deterrence could be maximized and the cost to societal legitimacy of harsh, capricious, and excessive punishment could be avoided. In their tracts calling for reforms in how society sanctions rule-violators, we see the earliest attempts to explain two focal questions of criminology: Why do people commit crimes? How do societies try to control crime? The “classical school” of criminology’s answer to the first question is that individuals act rationally, and when the

benefits to violating the laws outweigh the cost then they are likely to choose to violate those laws. Their answer to the second question is deterrence. The use of sanctions was meant to discourage criminals from committing future crimes and at the same time send the message to noncriminals that crime does not pay. Beccaria and Bentham believed that a “just desserts” model of criminal justice would fix specific punishments for specific crimes.

In the mid-nineteenth century the early “scientific study” of human behavior turned to the question of why some people violate the law. The positivists, those who believed that the scientific means was the preeminent method of answering this and other questions, also believed that human behavior was not a product of choice nor individual free will. Instead they argued that human behavior was “determined behavior,” that is, the product of forces simply not in the control of the individual. The earliest positivistic criminologists believed that much crime could be traced to biological sources. Gall (Leek 1970), referred to by some as the “father of the bumps and grunts school of criminology,” studied convicts and concluded that observable physical features, such as cranial deformities and protuberances, could be used to identify “born criminals.” Lombroso (1876) and his students, Ferri and Garofalo, also embraced the notion that some were born with criminal constitutions, but they also advanced the idea that social forces were an additional source of criminal causation. These early positivists were critics of the Classical School. They did not go so far as to argue that punishment should not be used to respond to crime, but they did advance the notion that punishment was insufficient to prevent crime. Simply raising the cost of crime will not prevent violations if individuals are not freely choosing their behavior. The early positivists believed that effective crime control would have to confront the root causes of violations, be they biological or social in nature.

Around 1900, Ferri gave a series of lectures critiquing social control policies derived from classical and neo-classical theory. What is most remarkable about those lectures is that, considered from the vantage point of scholars at the end of the twentieth century, the arguments then were little different from public debates today about what are the most effective means of controlling crime.

Then, as now, the main alternatives were “get tough” deterrence strategies that assumed that potential criminals could be frightened into compliance with the law, versus strategies that would reduce the number of offenses by addressing the root causes of crime. We know far more about crime and criminals today than criminologists of the late nineteenth and early twentieth century knew, yet we continue the same debate, little changed from the one in which Ferri participated in.

The debates today pit those espousing *rational choice theories* of crime (control and deterrence theories being the most popular versions) against what still might best be called *positivistic theories*. To be sure, contemporary positivistic criminology is considerably different from the theories of Gall and Lombroso. Modern criminologists do not explain law-violating behavior using the shapes of heads and body forms. Yet there are still those who argue that biological traits can explain criminal behavior (Wilson and Herrenstein 1985; Mednick 1977), and still others who focus on psychological characteristics. But most modern criminologists are sociologists who focus on how social structures and culture explain criminal behavior. What all of these modern positivists have in common with their predecessors Gall, Lombroso, and company, is that they share a belief that human behavior, including crime, is not simply a consequence of individual choices. Behavior, they argue, is “determined” at least in part by biological, psychological, or social forces. The goal of modern positivistic criminologists is to unravel the combination of forces that make some people more likely than others to commit crimes.

Today the research of sociological criminologists focuses on three questions: What is the nature of crime? How do we explain crime? What are the effects of societies’ attempts to control crime? Approaches to answering these questions vary greatly, as do the answers offered by criminologists. For example the first question, what is the nature of crime, can be answered by detailing the characteristics of people who commit crimes. Alternatively, one can challenge the very definition of what crime, and consequently criminals, are. In an attempt to answer this question, some criminologists focus on how much crime there is. But of course, even this is a difficult question to answer because there are many ways to count crime, with each type

offering different and sometimes seemingly conflicting answers.

WHAT IS THE NATURE OF CRIME?

Simply defining crime can be problematic. We can easily define crime legally: Crime is a violation of the criminal law. The simplicity of this definition is its virtue, but also its weakness. On the positive side, a legalistic definition clearly demarcates what will be counted as crime—those actions defined by the state as a violation. However, it is not as clear as to whom will be defined as criminals. Do we count as criminals those who violate the law and are not arrested? What about those who are arrested and not convicted? Some criminologists would argue that even an act that may appear to be criminal cannot be called “crime” until a response or evaluation has been made of that act. For example, how can we know if an offensive act is a crime if there has been no evaluation of the intent of the perpetrator? In Anglo-American law, without criminal intent, an offensive action is not considered a criminal action. Other critics of a legalistic definition of crime argue that it is an overly limited conception that too narrowly truncates criminological inquiry; a legalistic definition of crime accepts the state’s definition of “legal” and equates that with “legitimate.” Critical criminologists (Quinney 1974; Chambliss 1975; Taylor, Walton, and Young 1973) argue that we should ask questions about the creation of law such as whose interests are being served by classifying a particular behavior as “illegal.” Questions such as these tend to be ignored if we simply accept a legalistic definition. Indeed, the particular definition used influences the kind of questions criminologists ask. When a legalistic definition is used, criminologists tend to ask questions such as: “How much crime occurs?” “Who commits crime?” “Why are some people criminal?” If a broader conception of crime is the focus (i.e., one that addresses the rule-makers as well as the rule-breakers), then one might ask these same questions, but add others: “Where does the law come from?” “Why are some offensive acts considered crimes while others are not?” “Whose interests do the laws serve?” This is not a debate that will ever be resolved. Students of criminology should understand however, that the definition of crime they employ will have important implications for the kinds of questions they will ask, the

kinds of data they will use to study crime, and the kinds of explanations and theories they will apply to understand crime and criminal behavior.

HOW IS CRIME STUDIED?

Having made choices about definitions, criminologists are then faced with an array of data and methodologies that can be brought to bear on criminological questions. The data and methodological approach used should be dictated by the definition of crime and the research question being asked. Some very interesting research problems require analysis of quantitative data while others require that the researcher use qualitative approaches to study crime or a criminal justice process. For example, if one is trying to describe the socio-demographic characteristics of criminals then one of several means of counting crimes and people who engage in them might be used. On the other hand, in his book *On The Take* (1978), because Chambliss was interested in the source and nature of organized crime, it was clearly more appropriate for him to spend time in the field observing and interviewing, rather than simply counting.

Methods of Criminological Research. For the most part, criminologists use the same types of research methods as do other sociologists. But a unique quality of crime is its “hiddenness.” The character of crime means that those who do it hide it. As a result, the criminologist must be a bit of a detective even while engaged in social science research. To do this criminologists use observational studies such as those conducted by Chambliss (1978) in studying organized crime, or Fisse and Braithwaite (1987) in studies of white-collar crime, or Sanchez-Jankowski (1992) in his studies of gang crime.

Those who use quantitative methods frequently use data generated by the criminal justice system, victimization surveys, or self-reports. All of these data collection procedures have strengths and weaknesses, and they are best used by criminologists who have an appreciation of both. The most widely used criminal justice data are produced by police departments and published by the Federal Bureau of Investigation each year in their *Uniform Crime Reports* (UCR). The UCR contains counts of the crimes reported to police, arrest data (including some characteristics of those arrested), police

manpower statistics, and other data potentially of interest to researchers. Victimization surveys may be conducted by individuals or teams of researchers. The National Crime Victimization Survey (NCVS) is conducted annually by the federal government and, as a consequence, is widely used. The virtue of victimization surveys is that they include criminal acts that are never reported to the police. As their name indicates, self-report studies simply ask a sample of people about their involvement in criminal activity. If done correctly, it is quite surprising what people will report to researchers.

Characteristics of criminals. It is always risky to speak of the characteristics of criminals because of the problems with crime data mentioned above. Also, one must take care to specify the types of crimes included in any description of those characteristics correlated with criminal involvement. For example, those engaging in white-collar crime have very different characteristics than perpetrators of what might be called “common crimes” or “street crime.” In order to engage in white-collar crime, one has to be old enough to have a white-collar job, and possess those characteristics (such as education) requisite for those jobs. Without these same requirements, the perpetrators of street crime can reasonably be expected to look different from white-collar criminals.

Criminologists frequently speak of “the big four correlates of crime”: age, sex, race, and social class. The first two are rather uncomplicated. Crime is, for the most part, a young person’s activity (Hirschi and Gottfredson 1983). Probable involvement escalates in the teen years reaching a peak at between ages 15 and 17 and then drops. Most people stop participating in criminal activity by their mid to late twenties, even if they have not been arrested, punished, or rehabilitated. The correlation between sex and crime is also quite straightforward. Males are more likely to engage in crime than females. Criminologists have not found a society where this pattern does not hold.

The correlation between race, or ethnicity, and crime is complex. Most Americans when asked state that they believe that minorities commit more crimes than whites. This oversimplification is not only inaccurate, but it obscures important patterns. First, some nonwhites in the United States are from groups with lower crime rates than whites

(e.g. Chinese and Japanese Americans), but even this pattern is more complex. Chinese Americans whose families have been in the United States for generations seem to have lower crime rates than white Americans, but more recent Chinese immigrants have higher rates than white Americans. The category "Asian Americans" is too diverse to make generalizations about the larger group's perpetration of crime. The same is true of Latinos and Latinas. African Americans have disproportionately high crime rates, but Africans and people of Caribbean island descent have lower crime rates than black Americans. To simply describe the correlations between broad racial categories and crime misses an important sociological point: The criminality associated with each group appears to be more a product of their experience in America than simply their membership in that racial/ethnic category. This point is buttressed by patterns of race, ethnicity, and crime in other countries. Visible minorities and immigrants are more likely to have higher crime rates and to be more frequently arrested in countries where they are subordinated (see Tonry 1997 for a collection of studies of race, ethnicity, crime, and criminal justice in several countries).

For decades, in fact probably for centuries, researchers assumed that people from the lower classes committed more crime than those of higher status. In fact, most sociological theories used to explain common crime are based on this assumption. In the mid-1970s several criminologists argued that there really is not a substantial correlation between social class and crime (Tittle, Villemez, and Smith 1978). Many criminologists today believe that if we are simply considering the likelihood of breaking the law then there probably is not much difference by social class. But if the criminal domain being studied is serious violent offenses, then there probably is a negative association between social class and crime. Still, the correlation between social class and violent crime is not as strong as most people would assume (Hindelang, Hirschi, and Weis 1981).

Where crime occurs. A very sociological way of describing crime is to examine the crime patterns that exist for different types of areas. The social "ecological" literature that does this usually focuses on states, metropolitan areas, cities, and

neighborhoods. When this occurs, we find that those areas with relatively large numbers of residents who are poor, African American, immigrants, young, and living in crowded conditions have higher crime rates. One must be very careful when interpreting these patterns. Because an area with relatively large numbers of people with these characteristics has a high crime rate, we cannot conclude that they are necessarily the people committing the crimes. For example, high poverty areas have high crime rates. The high crime rates found in poor neighborhoods however, could be produced by their victimization by the nonpoor. The interesting thing about these correlations, as well as patterns of individual crime correlations, are not the observed patterns themselves but rather the questions that arise from these observations.

Victims of crime. One of the more interesting things that we have learned from victimization studies is how similar the victims of crimes are to the offenders. Victims of crime tend to be young, male, and minority group members. In fact, the prototypical victim of violent crime in America is a young, African-American male. The poor and those with limited education are disproportionately the victims of crime as well. These patterns are obviously inconsistent with popular images of crime and victimization, but they are quite predictable when we examine what we know about crime.

CRIMINOLOGY THEORIES

Three theoretical traditions in sociology dominated the study of crime from the early and mid-twentieth century. Contemporary versions of these theories continue to be used today. The "Chicago School" tradition, or *social disorganization theory*, was the earliest of the three. The other two are *differential association strain theories* or *anomie theory* (including subculture theories).

Sociologists working in the Chicago School tradition have focused on how rapid or dramatic social change causes increases in crime. Just as Durkheim, Marx, Toennies, and other European sociologists thought that the rapid changes produced by industrialization and urbanization produced crime and disorder, so too did the Chicago School theorists. The location of the University of Chicago provided an excellent opportunity for

Park, Burgess, and McKenzie to study the social ecology of the city. Shaw and McKay found (1931) that areas of the city characterized by high levels of social disorganization had higher rates of crime and delinquency.

In the 1920s and 1930s Chicago, like many American cities, experienced considerable immigration. Rapid population growth is a disorganizing influence, but growth resulting from in-migration of very different people is particularly disruptive. Chicago's in-migrants were both native-born whites and blacks from rural areas and small towns, and foreign immigrants. The heavy industry of cities like Chicago, Detroit, and Pittsburgh drew those seeking opportunities and new lives. Farmers and villagers from America's hinterland, like their European cousins of whom Durkheim wrote, moved in large numbers into cities. At the start of the twentieth century Americans were predominately a rural population, but by the century's mid-point most lived in urban areas. The social lives of these migrants, as well as those already living in the cities they moved to, were disrupted by the differences between urban and rural life. According to social disorganization theory, until the social ecology of the "new place" can adapt, this rapid change is a criminogenic influence. But most rural migrants, and even many of the foreign immigrants to the city, looked like and eventually spoke the same language as the natives of the cities into which they moved. These similarities allowed for more rapid social integration for these migrants than was the case for African Americans and most foreign immigrants.

In these same decades America experienced what has been called "the great migration": the massive movement of African Americans out of the rural South and into northern (and some southern) cities. The scale of this migration is one of the most dramatic in human history. These migrants, unlike their white counterparts, were not integrated into the cities they now called home. In fact, most American cities at the end of the twentieth century were characterized by high levels of racial residential segregation (Massey and Denton 1993). Failure to integrate these migrants, coupled with other forces of social disorganization such as crowding, poverty, and illness, caused crime rates to climb in the cities, particularly in the

segregated wards and neighborhoods where the migrants were forced to live.

Foreign immigrants during this period did not look as dramatically different from the rest of the population as blacks did, but the migrants from eastern and southern Europe who came to American cities did not speak English, and were frequently Catholic, while the native born were mostly Protestant. The combination of rapid population growth with the diversity of those moving into the cities created what the Chicago School sociologists called social disorganization. More specifically, the disorganized areas and neighborhoods where the unintegrated migrants lived were unable to exercise the social control that characterized organized, integrated communities. Here crime could flourish. Crime was not a consequence of who happened to live in a particular neighborhood, but rather of the character of the *social ecology* in which they lived. That is, the crime rate was a function of the area itself and not of the people who lived there. When members of an immigrant or ethnic group moved out of that area (usually in succeeding generations), that group's crime rate would go down. But, the old neighborhood, with its cheaper housing and disorganized conditions, would attract another, more recent group migrating to the city. Those groups settled there because that is where they could afford to live. When they became more integrated in American urban life, like those who came before them, they would move to better neighborhoods and as a result have lower crime rates. Chicago School sociologists called the process of one ethnic group moving out to be replaced by a newly arriving group (with the first group passing on to newcomers both the neighborhood and its high crime) "ethnic succession." This pattern seems to have worked for most ethnic groups except African Americans. For African Americans, residential segregation and racial discrimination prohibited the move to better, more organized neighborhoods.

Contemporary social disorganization theorists (Sampson and Groves 1989) are less concerned with the effects of ethnic migration. The disorganizing effects of urban poverty (Sampson and Wilson 1994), racial residential segregation (Massey and Denton 1993), and the social isolation of the urban poor (Wilson 1987), and the consequent effect on

crime is the focus of current research. This line of research has developed intriguing answers to the question of why some racial or ethnic groups have higher crime rates.

Both the anomie and differential association traditions grew out of critiques of the Chicago School version of social disorganization theory. The latter was developed by Sutherland (1924), himself a member of the University of Chicago faculty. Sutherland believed that a theory of crime should explain not only how bad behavior is produced in bad living conditions, but also how bad behavior arises from good living circumstances. This theory should also explain why most residents of disorganized neighborhoods do not become criminals or delinquents. Sutherland explained this by arguing that crime is more likely to occur when a person has a greater number of deviant associations, relative to non-deviant associations.

Differential association occurs when a person has internalized an excess of definitions favorable to violations of the law. Sutherland believed that we all experience a variety of forms of exposure to definitions favorable to violation of the law—"It is OK to steal this because the insurance company will pay for it"—and definitions unfavorable to violation of the law—"It is not OK to steal from stores, because all of us are hurt when prices go up to pay the stores' higher insurance premiums." Sutherland was very careful to point out what differential association was not. It is not a simple count of favorable and unfavorable definitions. Differential association theory is not a theory that focuses on who a person associates with. Indeed Sutherland argued that it is possible to receive definitions favorable to violation from the law-abiding. Of course those spending time with delinquent peers will be exposed to more criminal definitions, but the theory should not be reduced to simply a peer group theory of crime and delinquency (Sutherland and Cressey 1974). As Cressey has pointed out, if crime were simply a consequence of prolonged proximity with criminals, then prison guards would be the most criminal group in the population. Differential association theory continues to be of influence in contemporary sociology, but it does not occupy as central a role as it did in the 1940s and 1950s. Matsueda

(1988), the theory's major contemporary proponent, has emphasized the interactive quality (similar to labeling theory) of differential association theory. Matsueda has suggested new ways to operationalize the key concepts of differential association, and the theory is "evolving" in his writings to bring in aspects of both *interactionist* and *rational choice theory*.

Anomie theory's roots are in the work of Durkheim, who used the concept *anomie* to describe the disruption of regulating norms resulting from rapid social change. Strain theories, including anomie theory, focus on social structural strains, inequalities, and dislocations, which cause crime and delinquency. Durkheim stressed that societal norms that restrained the aspirations of individuals were important for preventing deviance. However, unrealistically high aspirations would be frustrated by a harsh social reality, leading to adaptations such as suicide, crime, and addiction. Merton adapted Durkheim's notion of anomie by combining this idea with the observation that not only do societal norms affect the likelihood of achieving aspirations, but they also determine to a large degree what we aspire to (1938). In other words, society helps determine the goals that we internalize by defining which of them are legitimate but it also defines the legitimate means of achieving these goals. American society, for example, defines material comfort as legitimate goals, and taking a well-paid job as a legitimate means of achieving them. Yet legitimate means such as these and economic success are not universally available. When a society is characterized by a disjunction between its legitimate goals and the legitimate means available to achieve them, crime is more likely.

This conceptualization led a number of criminologists to focus on these "opportunity structure" strains (Cloward and Ohlin 1960), as well as cultural strains (Cohen 1955), to explain why crime would be higher in lower social class neighborhoods. Contemporary strain theorists have moved in two directions. Some have proceeded in ways that are quite consistent with Merton's original conceptualization, while others have set forward a more social psychological conception of strain (Agnew 1992). What ties these contemporary versions of anomie theory to the earlier tradition is the notion that there are individual adaptations to

social strain, or structurally based unequal opportunity, and that some of these adaptations can result in crime.

Subcultural explanations of crime are similar to both differential association and anomie theories. Like differential association, *subculture theories* have an important learning component. Both types of theories emphasize that crime, the behavior, accompanying attitudes, justifications, etc., are learned by individuals within the context of the social environment in which they live. And, as anomie and other versions of strain theory emphasize, subcultural explanations of crime tend to focus on lower-class life as a generating milieu in which procriminal norms and values thrive. Cohen's book *Delinquent Boys* (1955) describes delinquency as a product of class-based social strains, which lead to a gang subculture conducive to delinquency. Miller (1958) argued that a prodelinquency value system springs from situations where young boys grow up in poor, female-headed households. He felt that adherence to these values, which he called "the focal concerns of the lower class," made it more likely that boys would join gangs and involve themselves in delinquency. This idea enjoys recurring popularity in explanations of behavior in poor, and especially urban, minority neighborhoods (Banfield 1968; Murray 1984) even though it is notoriously difficult to test empirically.

A different version of subculture theory has been championed by Wolfgang (Wolfgang and Ferracuti 1967). Wolfgang and his colleagues argued that people in some segments of communities internalized, carried, and intergenerationally transferred values that were proviolence. Accordingly, members of this subculture of violence would more frequently resort to violence in circumstances where others probably would not. Critics of this thesis have argued that it is difficult to assess who carries "subculture of violence values" except via the behavior that is being predicted.

Along with most other institutions and traditions, mainstream criminology was challenged in the 1960s. Critics raised questions about the theories, data, methods, and even the definitions of crime used in criminology. The early challenges came from *labeling* theorists. This group used a variant of symbolic interaction to argue that law-violating behavior was widespread in the general

population, and the official labeling of a selected subset of violators was more a consequence of who the person was than of what the person had done (Becker 1963). Consequently, crime should not be defined as behavior that violates the law, because many people violate the law and are never arrested, prosecuted, or convicted. Rather, crime is a behavior that is selectively sanctioned, depending on who is engaging in it. It follows then that when criminologists use data produced by the criminal justice system, we are not studying crime but the criminal justice system itself. These data only tell us about the people selected for sanctioning, not about all of those who break the law. And, labeling theorists argued, most of our theories have been trying to explain why lower-class people engage disproportionately in crime, but since they do not—they are simply disproportionately sanctioned—the theories are pointless. What should be explained, labeling theorists argued, is why some people are more likely to be labeled and sanctioned as criminals than are others who engage in the same or similar behavior. The answer they offered was that those with sufficient resources—enough money, the right racial or gender status, etc.—to fend off labeling by the criminal justice system are simply less likely to be arrested.

A further contribution by labeling theorists is the idea that the labeling process actually creates deviance. The act of labeling people as criminals sets in motion processes that marginalize them from the mainstream, create in them the self-identification as "criminal," which in turn affects their behavior. In other words, the act of sanctioning causes more of the behavior the criminal justice system wishes to extinguish.

Marxist criminology actually began in 1916 with the publication of Bonger's *Criminality and Economic Conditions*, but it became central to criminological discourse in the late 1960s and 1970s (Chambliss 1975; Platt 1969; Quinney 1974; Taylor, Walton, and Young 1973). The Marxist critique of mainstream criminology can be summarized by focusing on the argument that it tends to ask three types of questions: Who commits crimes? How much crime is there? Why do people break the law? The Marxist perspective argues that these may be important questions, but more important are those that do not reify the law itself. Marxists argue that in addition to the above questions, criminologists should ask: Where does the

law come from? Whose interest does the law serve? Why are the laws structured and enforced in particular ways? Their answers to these questions are based on a class-conflict analysis. Power in social systems is allocated according to social class, and the powerful use the law to protect their interests and the status quo that perpetuates their superordinate status. So the law and criminal justice system practices primarily serve the interest of elites; while they at times serve the interests of other classes, their *raison d'être* is the interests of the powerful. Law is structured to protect the current status arrangements.

Both the labeling and Marxist perspectives experienced broad popularity among students of criminology. Many scholars responded to their critiques not by joining them, but by taking some lessons from the debate and moving forward to develop theories consistent with traditional directions and research methods that were not as dependent on data generated by the criminal justice system. Victimization surveys and self-report studies of crime have become more widely used, in part as a consequence of these critiques.

All of the theories mentioned so far have had significant empirical challenges. Most of the initial statements have been falsified or their proponents have had to revise the perspective in the face of evidence that did not support it. Several of these explanations of crime, or how societies control their members, are used today in a modified form, while others have evolved into contemporary theories that are being tested by researchers. No doubt when someone writes about criminology in the future, some or all of the more recent theories will have joined those that have been falsified or modified as a result of empirical analyses. Contemporary criminological theories tend to be in the control theory, rational choice, or conflict traditions. However, these are not mutually exclusive (e.g. some control theories are very much rational choice theories).

Control theorists begin by saying that we ask the wrong question when we seek to understand why some people commit crimes. We should instead seek to explain why most people do *not* violate the rules. Control theorists reason that we do not need to explain why someone who is hungry or has less will steal from those who have what they want or

need. We do not need to explain why the frustrated and angry among us will express their feelings violently. The interesting question is: Why *don't* most people who have less or have grievances engage in property or violent crime? Other versions of control theory (Nye 1958; Reckless 1961) preceded his, but Hirschi's (1969) classic answer to this question is that those who are "socially bonded" to critical institutions such as families, schools, conventional norms, etc., are less likely to violate the law. The bonds give them a "stake in conformity," something they value and would risk losing should they violate important rules. Though not initially stated in rational choice terms of classical school ideas, one can see similarities between Hirschi's notions of "stakes in conformity" and the Classical School of criminology's concept of the "social contract."

Control theory has evolved in a number of directions. Gottfredson and Hirschi (1990) have argued that crime and deviance are a consequence of the failure of some to develop adequate self-control. Self-control is developed, if at all, early in life—by the age of eight or ten. Those who do not develop self-control will, they argue, exhibit various forms (depending on their age) of deviance throughout their lives. These people will commit crimes disproportionately during the crime-prone ages, between adolescence and the late twenties. Sampson and Laub's (1993) "life-course" perspective argues that social bonds change for people at different stages of their lives. Bonds to families are important early, to schools and law-abiding peers later, and eventually bonds to spouses, one's own children, and jobs and careers ultimately tie people to conventional norms and prevent crime and deviance. Tittle (1995) has offered a *control balance theory* of deviance. He believes that those who balance control exerted by self with control by others that they are subjected to are the least likely to commit acts of crime and deviance. Those whose "control ratio" is out of balance, with too much or too little regulation by the self or others, have a higher probability of breaking rules.

The contemporary rational choice perspective of crime has been most explicitly articulated by economists (Becker 1968; Ehrlich 1973). Becker described the choices people make in social behavior, including crime, as much like those made in economic behavior. Before a purchase we weigh

the cost of an item against the utility, or benefit to be gained by owning that item. Likewise, before engaging in crime, a person weighs the cost—prison, loss of prestige, relationships, or even life—against the benefits to crime—pleasure, expression of anger, or material gain. Becker argued that when the benefits outweigh the cost individuals would be more likely to commit criminal actions.

Control theory can also be thought of as a rational choice theory. The “bonded” among us have a stake in conformity, or something to weigh on the “to be lost” side of a cost-benefit analysis. To engage in crime is to risk the loss of valued bonds to family, teachers, or employers. The bond in control theory, thought of in this way, is an informal deterrent. *Deterrence theory* (Geerken and Gove 1975) is ordinarily written of in terms of a formal system of deterrence provided by the criminal justice system. As originally conceived by Classical School criminologists, police, prosecutors, and the courts endeavor to raise the cost of committing crime so that those costs outweigh the benefits from illegal behavior. In the case of those convicted, the courts attempt to do this by varying the sentence so that those convicted become convinced that they must avoid crime in the future. This deterrence aimed at those already in violation is referred to as “specific” or “special” deterrence. The noncriminal public is persuaded by general deterrence to avoid crime. They perceive that crime does not pay when they see others sanctioned. So, when considering criminal options, they weigh the utility of illegal action against the potential cost in the forms of sanctions. According to deterrence theory, when those positive utilities are outweighed by the perceived cost—effective deterrence—they choose not to engage in crime.

A number of contemporary *conflict theories* of criminology are legacies of 1960s and 1970s-era critical perspectives. Most prominent among these is *feminist criminological theory* (Simpson 1989). Contemporary conflict theories, like earlier Marxist theory, address important questions about interest groups. They begin with the position that to understand social life, including crime and responses to crime, the social, political, and economic interests of contesting parties and groups must be taken into account (Marxists, of course, focus on economic conflict). Feminist criminology focuses on gender conflict in society. These

criminologists argue that to understand crimes by women, against women, and the reaction to both, we must consider the subordinate status of women. If poverty is one of the root causes of crime, then we should recognize first that the largest impoverished group in American society, and in most western industrialized societies, is children. Increasingly, children are raised in female-headed households whose poverty can be traced to the lower earnings of women, a consequence of gender stratification.

Other conflict analyses of crime focus on income inequality (Blau and Blau 1982), racial inequality (Sampson and Wilson 1994), and labor-market stratification (Crutchfield and Pitchford 1997). What these approaches share is the idea that to understand why individuals engage in crime, or why some groups or geographic areas have higher crime rates, or why patterns of criminal justice are the way they are, consideration of important social conflicts and cleavages must be brought into the analysis. Blau and Blau (1982) illustrated how income inequality, especially inequality based on race, is correlated with higher rates of violent crime. Those metropolitan areas with relatively high levels of inequality tend also to have more violence. Others (Williams 1984; Messener 1989) have argued that it is not so much relative inequality that leads to higher violent crime rates, but rather high levels of poverty. Sampson and Wilson (1994) argue that racial stratification is linked to economic stratification and this complex association accounts for higher levels of crime participation among blacks. Crutchfield and Pitchford (1997), studying a particular form of institutional stratification that was produced by segmented labor markets, found that those marginalized in the work force under some circumstances are more likely to engage in crime.

Hagan, Gillis, and Simpson (1985) developed what they call a “power control theory of delinquency.” They combine elements of social control theory and conflict theory to explain class and gender patterns of delinquency. They argue that because of gender stratification, parents seek to control their daughters more and because of class stratification, those in the higher classes have more capacity (because they have the available resources) to monitor (control) their children. Yet, children of the upper classes are actually free to commit

more delinquency by virtue of their social-class standing. Consequently, upper-class girls will be more controlled than their lower-class counterparts, but their brothers will have minor delinquency rates resembling those of lower-class boys.

SOCIETY'S ATTEMPT TO CONTROL CRIME

While the theories discussed above focus on the causes of crime, they are also important for describing how social systems control crime. Societies attempt to control the behavior of people living within their borders with a combination of formal and informal systems of control. Social disorganization theory and anomie theory are examples of how crime is produced when normative control breaks down. Differential association and subcultural explanations describe how informal social control is subverted by socialization that supports criminal behavior rather than compliant behavior. Control theories focus specifically on how weak systems of informal social control fail. The obvious exception to this last statement is that portion of control theories that are also deterrence theory. Deterrence theory does consider informal systems of control, but an important part of this thesis is aimed at explaining how formal systems, or the criminal justice system in western societies, attempt to control criminal behavior. Most criminologists believe that informal systems of control are considerably more efficient than formal systems. This makes sense if one remembers that police cannot regulate us as much as we ourselves can when we have internalized conventional norms, and similarly, police cannot watch our behavior nearly as much as our families, friends, teachers, and neighbors can. The criminal justice system then is reduced to supporting informal systems of control (thus the interest in block-watch programs by police departments), engaging in community policing and patrol patterns that discourage crime, or reacting after violations have occurred.

CONCLUSION

Criminologists are interested in answering questions about how crime should be defined, why crime occurs, and how societies seek to control

crime. The history of modern criminology, which can be traced to the early nineteenth century, has not produced definitive answers to these questions. To some students that is a source of frustration. To many of us the resulting ambiguity is the source of continuing interesting debate. More importantly, the disagreement among criminologists captures the complexity of social life. Oversimplification to achieve artificial closure on these debates will not produce quality answers to these questions, nor will it, to the consternation of some politicians, lead to workable solutions to crime problems. Most criminologists recognize that the complex debates about the answers to these three seemingly simple questions will ultimately be a more productive route to understanding crime and to finding effective means to address crime problems.

CRITICAL THEORY

The term *critical theory* was used originally by members of the Institute for Social Research in Frankfurt, Germany, after they emigrated to the United States in the late 1930s, following the rise of Hitler. The term served as a code word for their version of Marxist social theory and research (Kellner 1990a). The term now refers primarily to Marxist studies done or inspired by this so-called Frankfurt School and its contemporary representatives such as Jurgen Habermas. Critical sociologists working in this tradition share several common tenets including a rejection of sociological positivism and its separation of facts from values; a commitment to the emancipation of humanity from all forms of exploitation, domination, or oppression; and a stress on the importance of human agency in social relations.

THE FRANKFURT SCHOOL OF CRITICAL THEORY

The Institute for Social Research was founded in 1923 as a center for Marxist studies and was loosely affiliated with the university at Frankfurt, Germany. It remained independent of political party ties. Max Horkheimer became its director in 1931. Theodor Adorno, Erich Fromm, Leo Lowenthal, Herbert Marcuse, and, more distantly, Karl Korsch and Walter Benjamin were among the prominent theorists and researchers associated with the institute (Jay 1973). Initially, institute scholars sought to update Marxist theory by studying new social developments such as the expanding role of the

state in social planning and control. The rise of fascism and the collapse of effective opposition by workers' parties, however, prompted them to investigate new sources and forms of authoritarianism in culture, ideology, and personality development and to search for new oppositional forces. By stressing the importance and semiautonomy of culture, consciousness, and activism, they developed an innovative, humanistic, and open-ended version of Marxist theory that avoided the determinism and class reductionism of much of the Marxist theory that characterized their era (Held 1980).

"Immanent critique," a method of description and evaluation derived from Karl Marx and Georg W. F. Hegel, formed the core of the Frankfurt School's interdisciplinary approach to social research (Antonio 1981). As Marxists, members of the Frankfurt School were committed to a revolutionary project of human emancipation. Rather than critique existing social arrangements in terms of a set of ethical values imposed from "outside," however, they sought to judge social institutions by those institutions' own internal (i.e., "immanent") values and self-espoused ideological claims. (An example of the practical application of such an approach is the southern civil rights movement of the 1960s, which judged the South's racial caste system in light of professed American values of democracy, equality, and justice.) Immanent critique thus provided members of the Frankfurt School with a nonarbitrary standpoint for the critical examination of social institutions while it sensitized them to contradictions between social appearances and the deeper levels of social reality.

Immanent critique, or what Adorno (1973) termed "non-identity thinking," is possible because, as Horkheimer (1972, p. 27) put it, there is always "an irreducible tension between concept and being." That is, in any social organization, contradictions inevitably exist between what social practices are called—for example, "democracy" or "freedom" or "workers' parties"—and what, in their full complexity, they really are. This gap between existence and essence or appearance and reality, according to Adorno (1973, p. 5), "indicates the untruth of identity, the fact that the concept does not exhaust the thing conceived." The point of immanent critique is thus to probe empirically whether a given social reality negates its own claims—as, for example, to represent a

“just” or “equal” situation—as well as to uncover internal tendencies with a potential for change including new sources of resistance and opposition to repressive institutions.

Frankfurt School theorists found a paradigmatic example of immanent critique in the works of Karl Marx, including both his early writings on alienation and his later analyses of industrial capitalism. Best articulated by Marcuse (1941), their reading of *Capital* interpreted Marx’s text as operating on two levels. On one level, *Capital* was read as a historical analysis of social institutions’ progressive evolution, which resulted from conflicts between “forces” (such as technology) and “relations” (such as class conflicts) in economic production. Scientistic readings of Marx, however—especially by the generation of Marxist theorists immediately after the death of Marx—essentialized this dimension into a dogma that tended to neglect the role of human agency and stressed economic determinism in social history. But the Frankfurt School also read *Capital* as a “negative” or “immanent” critique of an important form of ideology, the bourgeois pseudo-science of economics. Here, Marx showed that the essence of capitalism as the exploitation of wage slavery contradicts its ideological representation or appearance as being a free exchange among equal parties (e.g., laborers and employers).

Members of the Frankfurt School interpreted the efforts that Marx devoted to the critique of ideology as an indication of his belief that freeing the consciousness of social actors from ideological illusion is an important form of political practice that potentially contributes to the expansion of human agency. Thus, they interpreted Marx’s theory of the production and exploitation of economic values as an empirical effort to understand the historically specific “laws of motion” of market-driven, capitalist societies. At the same time, however, it was also interpreted as an effort—motivated by faith in the potential efficacy of active opposition—to see through capitalism’s objectified processes that made a humanly created social world appear to be the product of inevitable, autonomous, and “natural” forces and to call for forms of revolutionary activism to defeat such forces of “alienation.”

Members of the Frankfurt School attempted to honor both dimensions of the Marxian legacy.

On the one hand, they sought to understand diverse social phenomena holistically as parts of an innerconnected “totality” structured primarily by such capitalistic principles as the commodity form of exchange relations and bureaucratic rationality. On the other hand, they avoided reducing complex social factors to a predetermined existence as shadowlike reflections of these basic tendencies (Jay 1984). Thus, the methodology of immanent critique propelled a provisional, antifoundationalist, and inductive approach to “truth” that allowed for the open-endedness of social action and referred the ultimate verification of sociological insights to the efficacy of historical struggles rather than to the immediate observation of empirical facts (Horkheimer 1972). In effect, they were saying that social “facts” are never fixed once and for all, as in the world of nature, but rather are subject to constant revisions by both the conscious aims and unintended consequences of collective action.

In their concrete studies, members of the Frankfurt School concentrated on the sources of social conformism that, by the 1930s, had undermined the Left’s faith in the revolutionary potential of the working class. They were among the first Marxists to relate Freud’s insights into personality development to widespread changes in family and socialization patterns that they believed had weakened the ego boundary between self and society and reduced personal autonomy (Fromm 1941). After they emigrated to the United States, these studies culminated in a series of survey research efforts, directed by Adorno and carried out by social scientists at the University of California, that investigated the relation between prejudice, especially anti-Semitism, and “the authoritarian personality” (Adorno et al. 1950). Later, in a more radical interpretation of Freud, Marcuse (1955) questioned whether conflicts between social constraints and bodily needs and desires might provide an impetus for revolt against capitalist repression if such conflicts were mediated by progressively oriented politics.

Once in the United States, members of the Frankfurt School emphasized another important source of conformism, the mass media. Holding that the best of “authentic art” contains a critical dimension that negates the status quo by pointing in utopian directions, they argued that commercialized and popular culture, shaped predominantly by market and bureaucratic imperatives, is

merely “mimetic” or imitative of the surrounding world of appearances. Making no demands on its audience to think for itself, the highly standardized products of the “culture industry” reinforce conformism by presenting idealized and reified images of contemporary society as the best of all possible worlds (see Kellner 1984–1985).

The most important contribution of the Frankfurt School was its investigation of the “dialectic of enlightenment” (Horkheimer and Adorno [1947] 1972). During the European Enlightenment, scientific reason had played a partisan role in the advance of freedom by challenging religious dogmatism and political absolutism. But according to the Frankfurt School, a particular form of reason, the instrumental rationality of efficiency and technology, has become a source of unfreedom in both capitalist and socialist societies during the modern era. Science and technology no longer play a liberating role in the critique of social institutions but have become new forms of domination. Dogmatic ideologies of scientism and operationalism absolutize the status quo and treat the social world as a “second nature” composed of law-governed facts, subject to manipulation but not to revolutionary transformation. Thus, under the sway of positivism, social thought becomes increasingly “one-dimensional” (Marcuse 1964). Consequently, the dimension of critique, the rational reflection on societal values and directions, and the ability to see alternative possibilities and new sources of opposition are increasingly suppressed by the hegemony of an eviscerated form of thinking. One-dimensional thinking, as an instrument of the totally “administered society,” thus reinforces the conformist tendencies promoted by family socialization and the culture industry and threatens both to close off and absorb dissent.

The Frankfurt School’s interpretation of the domination of culture by instrumental reason was indebted to Georg Lukacs’s ([1923] 1971) theory of reification and to Max Weber’s theory of rationalization. In the case of Lukacs, “reification” was understood to be the principal manifestation of the “commodity form” of social life whereby human activities, such as labor, are bought and sold as objects. Under such circumstances, social actors come to view the world of their own making as an objectified entity beyond their control at the same time that they attribute human powers to things.

For Lukacs, however, this form of life was historically unique to the capitalist mode of production and would be abolished with socialism.

In the 1950s, as they grew more pessimistic about the prospects for change, Horkheimer and Adorno, especially, came to accept Weber’s belief that rationalization was more fundamental than capitalism as the primary source of human oppression. Thus, they located the roots of instrumental rationality in a drive to dominate nature that they traced back to the origins of Western thought in Greek and Hebrew myths. This historical drive toward destructive domination extended from nature to society and the self. At the same time, Horkheimer and Adorno moved closer to Weber’s pessimistic depiction of the modern world as one of no exit from the “iron cage” of rationalization. In the context of this totalizing view of the destructive tendencies of Western culture—the images for which were Auschwitz and Hiroshima—the only acts of defiance that seemed feasible were purely intellectual “negations,” or what Marcuse (1964) termed “the great refusal” of intellectuals to go along with the one-dimensional society. Consequently, their interest in empirical sociological investigations, along with their faith in the efficacy of mass political movements, withdrew to a distant horizon of their concerns. Marcuse, like Benjamin before him, remained somewhat optimistic. Marcuse continued to investigate and support sources of opposition in racial, sexual, and Third World liberation movements.

Benjamin’s *Passagen-Werk* (Arcades project), originally titled *Dialectical Fairy Scene*, was an unfinished project of the 1930s that culminated in a collection of notes on nineteenth-century industrial culture in Paris. The Paris Arcade was an early precursor to the modern department store, a structure of passages displaying commodities in window showcases; it reached its height in the world expositions (e.g., the Paris Exposition in 1900). Through an interpretation of Benjamin’s notes, Susan Buck-Morss (1995) has brought this unfinished project to life. Benjamin drew on allegory as a method for analyzing the content and form of cultural images. In contrast to Horkheimer and Adorno’s “iron cage” view of mass culture, his dialectical approach held out hope for the revolutionary potential of mass-produced culture. Anticipating aspects of Symbolic Interactionism and feminist theories of performativity, Benjamin

explored the relationship between mass production as form (e.g., montage as a form of film production) and political subversion. In contrast to Horkheimer and Adorno who lamented the loss of authority in art and the family, Benjamin welcomed the abolition of traditional sources of authority and hailed the rapidity of technological change in mass production as potentially positive. He interpreted mass production as a form of mimicry that reproduced existing relations of authority and domination while lending itself to potentially subversive reinterpretations and reenactments of existing social relations and social meanings (Buck-Morss 1995).

While retaining an analysis of instrumental reason as a source of domination, Benjamin's allegorical approach worked to unveil the forces of contradiction that were crystallized as promise, progress, and ruin in mythical modern images. These images bore the revolutionary potential of the new to fulfill collective wishes for an unrealized social utopia contained in a more distant past. At the same time, they represented progress as the unrealized potential of capitalism to satisfy material needs and desires. For Benjamin, images of ruin represented the transitoriness, fragility, and destructiveness of capitalism as well as the potential for reawakening and a critical retelling of history (Buck-Morss 1995).

Even though some of the most prominent founders of the Frankfurt School abandoned radical social research in favor of an immanent critique of philosophy (as in Adorno 1973), the legacy of their sociological thought has inspired a vigorous tradition of empirical research among contemporary American social scientists. In large measure, this trend can be seen as a result of the popularization of Frankfurt School themes in the 1960s, when the New Left stressed liberation and consciousness raising, themes that continue to influence sociological practice. Stanley Aronowitz (1973), for example, along with Richard Sennet and Jonathan Cobb (1973), have rekindled the Frankfurt School's original interests in working-class culture in the context of consumer society. Henry Braverman (1974) has directed attention to processes of reification in work settings by focusing on scientific management and the separation of conception from labor in modern industry. Penetrating analyses also have been made of the

impact of commodification and instrumental rationalization on the family and socialization (Lasch 1977), law (Balbus 1977), education (Giroux 1988), advertising culture (Haug 1986), and mass media (Kellner 1990b), as well as other institutional areas. Feminist theorists have contributed a "doubled vision" to critical theory by showing the "systematic connectedness" of gender, class, and race relations (Kelly 1979) and by criticizing critical theory itself for its neglect of gender as a fundamental category of social analysis (Benjamin 1978; Fraser 1989). Among the most far-reaching and innovative contemporary studies are those of the contemporary German sociologist and philosopher Jurgen Habermas.

THE CRITICAL THEORY OF JURGEN HABERMAS

Perhaps no social theorist since Max Weber has combined as comprehensive an understanding of modern social life with as deeply reflective an approach to the implications of theory and methods as Jurgen Habermas. Habermas has attempted to further the emancipatory project of the Frankfurt School by steering critical theory away from the pessimism that characterized the closing decades of Frankfurt School thought. At the same time, he has resumed the dialogue between empirical social science and critical theory to the mutual benefit of both. Further, he has given critical theory a new ethical and empirical grounding by moving its focus away from the relationship between consciousness and society and toward the philosophical and sociological implications of a critical theory of communicative action.

In sharp contrast to the Frankfurt School's increasing pessimism about the "dialectic of enlightenment," Habermas has attempted to defend the liberative potential of reason in the continuing struggle for freedom. While agreeing with the Frankfurt School's assessment of the destruction caused by instrumental rationality's unbridled domination of social life, he nonetheless recognizes the potential benefits of modern science and technology. The solution he offers to one-dimensional thought is thus not to abandon the "project of modernity" but rather to expand rational discourse about the *ends* of modern society. In order to further this goal, he has tried to unite science and ethics (fact and values) by recovering the

inherently rational component in symbolic interaction as well as developing an empirical political sociology that helps to critique the political effects of positivism as well as to identify the progressive potential of contemporary social movements.

From the beginning, Habermas (1970) has agreed with the classical Frankfurt School's contention that science and technology have become legitimating rhetorics for domination in modern society. At the same time, he has argued that alternative ways of knowing are mutually legitimate by showing that they have complementary roles to play in human affairs, even though their forms of validity and realms of appropriate application are distinct. That is, plural forms of knowledge represent different but complementary "knowledge interests" (Habermas 1971).

"Instrumental knowledge," based on the ability to predict, represents an interest in the technical control or mastery of nature. "Hermeneutical knowledge" represents an interest in the clarification of intersubjective understanding. Finally, "emancipatory knowledge" is best typified in the self-clarification that occurs freely in the nondirective communicative context provided by psychoanalysis. In the context of a democratic "public sphere," such self-clarification would have a macro-social parallel in the form of ideology critique had this space not been severely eroded by elite domination and technocratic decision making (Habermas 1989). Emancipatory knowledge thus has an interest in overcoming the illusions of reification, whether in the form of neurosis at the level of psychology or ideology at the level of society. In contrast to testable empirical hypotheses about objectified processes, the validity of emancipatory knowledge can be determined only by its beneficiaries. Its validity rests on the extent to which its subjects find themselves increasingly free from compulsion. Thus, a central problem of modern society is the hegemony of instrumental knowledge that, though appropriate in the realm of nature, is used to objectify and manipulate social relations. Instrumental knowledge thus eclipses the interpretive and emancipatory forms of knowledge that are also essential for guiding social life.

When sufficient attention is paid to interpersonal communication, Habermas (1979) contends that every act of speech can be seen as implying a

universal demand that interpersonal understanding be based on the free exchange and clarification of meanings. In other words, an immanent critique of language performance (which Habermas terms "universal pragmatics") reveals the presumption that communication not be distorted by differences in power between speakers. Thus, human communication is implicitly a demand for freedom and equality. By this form of immanent critique—consistent with the methodological standards of the Frankfurt School—Habermas attempts to demonstrate the potential validity of emancipatory knowledge so that it can be seen as a compelling challenge to the hegemony of instrumental knowledge. The purpose of Habermas's communication theory is thus highly partisan. By showing that no forms of knowledge are "value free" but always "interested," and that human communication inherently demands to occur freely without distortions caused by social power differentials, Habermas seeks politically to delegitimize conventions that confine social science to investigations of the means rather than the rational ends of social life.

In his subsequent works, Habermas has tried to reformulate this philosophical position in terms of a political sociology. To do so, he has profoundly redirected "historical materialism," the Marxist project to which he remains committed (see Habermas 1979). Habermas contends that Marx gave insufficient attention to communicative action by restricting it to the social class relations of work. This restriction, he argues, inclined the Marxist tradition toward an uncritical attitude toward technological domination as well as toward forms of scientism that contribute to the suppression of critique in regimes legitimated by Marxist ideology. Habermas relates his immanent critique of language performance to historical materialism by showing that sociocultural evolution occurs not only through the increasing rationality of technical control over nature (as Marx recognized) but also through advances in communicative rationality, that is, nondistorted communication. Thus, instrumental rationality and communicative rationality are complementary forms of societal "learning mechanisms." The problem of modernity is not science and technology in and of themselves, because they promise increased control over the environment, but rather the fact that instrumental rationality has eclipsed communicative rationality in social life. In other words, in

advanced industrial society, technical forms of control are no longer guided by consensually derived societal values. Democratic decision making is diminished under circumstances in which technical experts manipulate an objectified world, in which citizens are displaced from political decision making, and in which “reason”—identified exclusively with the “value free” prediction of isolated “facts”—is disqualified from reflection about the ends of social life.

More recently, Habermas (1987) has restated this theory sociologically to describe an uneven process of institutional development governed by opposing principles of “system” and “lifeworld.” In this formulation, the cultural lifeworld—the source of cultural meanings, social solidarity, and personal identity—is increasingly subject to “colonization” by the objectivistic “steering mechanisms” of the marketplace (money) and bureaucracy (power). On the levels of culture, society, and personality, such colonization tends to produce political crises resulting from the loss of meaning, increase of anomie, and loss of motivation. At the same time, however, objectivistic steering mechanisms remain indispensable because large-scale social systems cannot be guided by the face-to-face interactions that characterize the lifeworld. Thus, the state becomes a battleground for struggles involving the balance between the structuring principles of systems and lifeworlds. Habermas contends that it is in response to such crises that the forces of conservatism and the “new social movements” such as feminism and ecology are embattled and that it is here that the struggle for human liberation at present is being contested most directly. As formulated by Habermas, a critical theory of society aims at clarifying such struggles in order to contribute to the progressive democratization of modern society.

CURRENT DEBATES: CRITICAL THEORY AND POSTSTRUCTURALISM

In the late 1980s and early 1990s, the heightened influence of poststructuralism sparked intense debate between critical theorists and poststructuralists. Theorists staked out positions that tended to collapse distinct theories into oppositional categories (critical theory *or* poststructuralism) yet they agreed on several points. Both critical and poststructural theorists critiqued the transcendental claims of

Enlightenment thought (e.g., that truth transcends the particular and exists “out there” in its universality), understood knowledge and consciousness to be shaped by culture and history, and attacked disciplinary boundaries by calling for supra-disciplinary approaches to knowledge construction. Polarization, nonetheless, worked to emphasize differences, underplay points of agreement, and restrict awareness of how these approaches might complement one another (Best and Kellner 1991; Fraser 1997).

Because critical theory aspires to understand semiautonomous social systems (e.g., capital, science and technology, the state, and the family) as interconnected in an overarching matrix of domination (Best and Kellner 1991, p. 220), poststructuralists charge that it is a “grand theory” still mired in Enlightenment traditions that seek to understand society as a totality. In viewing the path to emancipation as the recovery of reason through a critical analysis of instrumentalism, scientism, and late capitalism, critical theory is seen as promoting a centralized view of power as emitting from a macro-system of domination. That is, by promoting a view of social subjects as overdetermined by class, critical theory is said to reduce subjectivity to social relations of domination that hover in an orbit of capitalist imperatives. By theorizing that subjectivity is formed through social interaction (e.g., intersubjectivity), Habermas departs from Horkheimer and Adorno’s view of the social subject as ego centered—as a self-reflexive critical subject (Best and Kellner 1991). Nonetheless, poststructuralists contend that Habermas, like his predecessors, essentializes knowledge. In other words, the capacity to recover reason either through critical reflexivity (Horkheimer, Adorno, and Marcuse) or through a form of communicative action that appeals to a normative order (Habermas) promotes a false understanding of subjectivity as “quasi-transcendental.”

In rebuttal, critical theorists argue that poststructuralist views of power as decentralized and diffuse uncouple power from systems of domination (Best and Kellner 1991). Poststructuralists view social subjectivity as a cultural construction that is formed in, and through, multiple and diffuse webs of language and power. Critics charge that such a diffuse understanding of power promotes a vision of society as a “view from everywhere” (Bordo 1993). Social identities are seen as

indeterminate and social differences as differences of equivalency (Flax 1990). This perspective results in analyses that focus on identity to the exclusion of systemic forms of domination. Thus, for example, while feminists who adhere to critical theory tend to analyze gender as a system of patriarchal domination, poststructuralist feminists, by contrast, tend to focus on the cultural production of gendered subjects, that is, on representation and identity. Habermas ([1980] 1997) and others argue that the avoidance of analyses of systems in favor of more fragmentary micro-analyses of discrete institutions, discourses, or practices is an antimodern movement that obscures the emancipatory potential of modernity (Best and Kellner 1991).

Although this debate is still stirring, some scholars are moving away from oppositional positions in favor of more complex readings of both traditions in order to synthesize or forge alliances between approaches (Best and Kellner 1991; Kellner 1995; Fraser 1997). Thus poststructuralism may serve as a corrective to the totalizing tendencies in critical theory while the latter prevents the neglect of social systems and calls attention to the relationship between multiple systems of domination and social subjectivities. In other words, critical theory points to the need to understand systemic forms of domination while poststructuralism warns against the reduction of social subjectivity to macro-overarching systems of domination. Thus drawing on both traditions, Nancy Fraser (1997, p. 219) suggests that a more accurate picture of social complexity “might conceive subjectivity as endowed with critical capacities and as culturally constructed” while viewing “critique as simultaneously situated and amenable to self-reflection.”

Theoretical and empirical applications of such a “both/and approach” abound. For instance, in recognizing that all knowledge is partial, black feminist theorists such as Patricia Hill Collins (1990) articulate both critical theoretical tenets and poststructuralist sensibilities by conceptualizing identity as socially constructed, historically specific, and culturally located while stressing systemic forms of domination without reducing identities to single systems of oppression (also see Agger 1998). Postcolonial theories likewise draw on both traditions in order to understand the fluid relationships among culture, systems of domination, social subjectivity, the process of “othering,” and

identity formation (see Williams and Chrisman 1993). Douglas Kellner’s (1997) empirical work on media culture likewise employs a multiperspectival approach that combines insights from cultural studies and poststructuralism with critical theory in order to understand mass media as a source of both domination and resistance, and as a way to account for the formation and communicative positionality of social subjects constituted through multiple systems of race, class, and gender. Habermas’s (1996) current theorizing on procedural democracy reflects a move toward the poststructuralism of Ernesto Laclau and Chantal Mouffe’s (1985) theory of radical democracy that stresses the potential collaboration of diverse agents in progressive social movements that aim at defending and expanding citizen participation in public life.

CROSS-CULTURAL ANALYSIS

Cross-cultural research has a long history in sociology (Armer and Grimshaw 1973; Kohn 1989; Miller-Loessi 1995). It most generally involves social research across societies or ethnic and subcultural groups within a society. Because a discussion of macro-level comparative historical research appears in another chapter of this encyclopedia, the focus here is primarily on cross-cultural analysis of social psychological processes. These include communicative and interactive processes within social institutions and more generally the relation between the individual and society and its institutions.

Although all sociological research is seen as comparative in nature, comparisons across

subcultural or cultural groups have distinct advantages for generating and testing sociological theory. Specifically, cross-cultural research can help “distinguish between those regularities in social behavior that are system specific and those that are universal” (Grimshaw 1973, p. 5). In this way, sociologists can distinguish between generalizations that are true of all cultural groups and those that apply for one group at one point in time. The lack of cross-cultural research has often led to the inappropriate universal application of sociological concepts that imply an intermediate (one cultural group at one point in time) level (Bendix 1963).

In addition to documenting universal and system-specific patterns in social behavior, cross-cultural analysis can provide researchers with experimental treatments (independent variables) unavailable in their own culture. Thus, specific propositions can be investigated experimentally that would be impossible to establish in a laboratory in the researcher’s own country (Strodtbeck 1964). Finally, cross-cultural analysis is beneficial for theory building in at least two respects. First, the documentation of differences in processes across cultures is often the first step in the refinement of existing theory and the generation of novel theoretical models. Second, cross-cultural analysis can lead to the discovery of unknown facts (behavioral patterns or interactive processes) that suggest new research problems that are the basis for theory refinement and construction.

INTERPRETIVE AND INFERENTIAL PROBLEMS

Cross-cultural researchers face a number of challenging interpretive and inferential problems that are related to the methodological strategies they employ (Bollen, Entwisle, and Alderson 1993). For example, Charles Ragin (1989) argues that most cross-cultural research at the macro level involves either intensive studies of one or a small group of representative or theoretically decisive cases or the extensive analysis of a large number of cases. Not surprisingly, extensive studies tend to emphasize statistical regularities while intensive studies search for generalizations that are interpreted within a cultural or historical context. This same pattern also appears in most micro-level cross-cultural research, and it is clearly related to both theoretical orientation and methodological preferences.

Some scholars take the position that cultural regularities must always be interpreted in cultural and historical context, while others argue that what appear to be cross-cultural differences may really be explained by lawful regularities at a more general level of analysis. Those in the first group most often employ primarily qualitative research strategies (intensive ethnographic and historical analysis of a few cases), while those in the second usually rely on quantitative techniques (multivariate or other forms of statistical analysis of large data sets).

METHODOLOGICAL TECHNIQUES AND AVAILABLE DATA SOURCES

The wide variety of techniques employed in cross-cultural analysis reflect the training and disciplinary interests of their practitioners. We discuss the methods of anthropologists, psychologists, and sociologists in turn. Anthropologists generally rely on different types of ethnographic tools for data collection, analysis, and reporting. Ethnographic research has the dual task of cultural description and cultural interpretation. The first involves uncovering the “native’s point of view” or the criteria the people under study use “to discriminate among things and how they respond to them and assign them meaning, including everything in their physical, behavioral, and social environments” (Goodenough 1980, pp. 31–32); while the second involves “stating, as explicitly as we can manage, what the knowledge thus attained demonstrates about the society in which it is found and, beyond that, about social life as such” (Geertz 1973, p. 27).

Three types of ethnographic approaches and methodological tools are generally employed in cross-cultural research. The first involves long-term participant observation and the thick description of the culture under study in line with Clifford Geertz’s (1973) interpretive perspective of culture. From this perspective, culture is seen as “layered multiple networks of meaning carried by words, acts, conceptions and other symbolic forms” (Marcus and Fisher 1986, p. 29). Thus the metaphor of culture in the interpretive approach is that of a text to be discovered, described, and interpreted. The second involves methods of ethno-science including elicitation tasks and interviews with key informants that yield data amenable to logical and statistical analysis to generate the “organizing principles underlying behavior” (Tyler 1969; also see

Werner and Schoepfle 1987). Ethnoscience views these organizing principles as the “grammar of the culture” that is part of the mental competence of members. The final type of ethnographic research is more positivistic and comparative in orientation. In this approach cross-cultural analysis is specifically defined as the use of “data collected by anthropologists concerning the customs and characteristics of various peoples throughout the world to test hypotheses concerning human behavior” (Whiting 1968, p. 693).

All three types of ethnographic research generate data preserved in research monographs or data archives such as the Human Relations Area Files, the *Ethnographic Atlas*, and the ever-expanding World Cultures data set that has been constructed around George Murdock and Douglas White’s (1968) *Standard Cross Cultural Sample*. A number of scholars (Barry 1980; Lagacé 1977; Murdock 1967; Whiting 1968; Levinson and Malone 1980) have provided detailed discussions of the contents, coding schemes, and methodological strengths and weaknesses of these archives as well as data analysis strategies and overviews of the variety of studies utilizing such data.

Most cross-cultural research in psychology involves the use of quasi-experimental methods. These include classical experimentation, clinical tests and projective techniques, systematic observation, and unobtrusive methods (see Berry, Poortinga, and Pandey, 1996; Triandis and Berry 1980). However, a number of psychologists have recently turned to observational and ethnographic methods in what has been termed “cultural psychology” (Shweder 1990). Much of the recent research in this area focuses on culture and human development and spans disciplinary boundaries and involves a wide variety of interpretive research methods (Greenfield and Suzuki 1998; Shweder et al. 1998).

Sociologists have made good use of intensive interviewing (Bertaux 1990) and ethnography (Corsaro 1988, 1994; Corsaro and Heise 1992) in cross-cultural analysis. However, they more frequently rely on the survey method in cross-cultural research and have contributed to the development of a number of archives of survey data (Kohn 1987; Lane 1990). The growth of such international surveys in recent years has been impressive. The World Fertility Survey (WFS) is an early example.

In one of the first efforts of its kind, women in forty-two developing countries were interviewed between 1974 and 1982 about their fertility behavior, marital and work history, and other aspects of their background. The WFS spawned hundreds of comparative studies that have contributed greatly to the understanding of human fertility (see, for example, Bohgaarts and Watkins 1996; Kirk and Pillet 1998). The Demographic and Health Survey (DHS) largely took up where the WFS left off. In this ongoing project, begun in 1984, nationally representative samples of women aged 15–49 in forty-seven countries have been surveyed regarding lifetime reproduction, fertility preferences, family planning practices, and the health of their children. For some countries, detailed data are available for husbands also and, for a few countries, in-depth interview data are also available.

Less specialized is the international counterpart to the U.S. General Social Survey (GSS); the International Social Survey Program (ISSP). The ISSP got its start in 1984 as researchers in the United States, Germany, Britain, and Australia agreed to field common topical modules in the course of conducting their regular national surveys. Beginning 1985 with a survey of attitudes toward government in the four founding countries, the ISSP has expanded to include surveys on topics as diverse as social networks and social support and attitudes regarding family, religion, work, the environment, gender relations, and national identity. Some specific modules have been replicated and, overall, a large proportion of the items from earlier surveys are carried over to new modules, giving the ISSP both a cross-cultural and longitudinal dimension. At present, thirty-one nations are participating in the ISSP. A number of non-member nations have also replicated specific modules. An interesting offshoot of the ISSP is the International Survey of Economic Attitudes (ISEA). Building on an ISSP module concerning beliefs regarding social inequality, the ISEA collects a wide array of information on attitudes regarding income inequality, social class, and economic policy. The first round was carried out between 1991–1993 in three countries. A second round was carried out in five countries over the 1994–1997 period, and a third round is currently under way. Some of the important reports based on data from these surveys include Jones and Broyfield (1997), Kelley and Evans (1995), and Western (1994).

Also of general interest are the surveys undertaken under the auspices of the World Values Survey Group and Eurobarometer. The World Values Survey (WVS) (originally termed the "European Values Survey") began in 1981 as social scientists in nine Western European countries administered a common survey of social, political, moral, and religious values in their respective countries. Between 1981 and 1984, this survey was replicated in fourteen additional countries, including a number of non-European countries. In 1990–1993, a second wave of the World Values Survey was conducted in a broader group of forty-three nations and a third wave was undertaken in 1995–1996. In terms of content, the WVS is broadly organized around values and norms regarding work, family, the meaning and purpose of life, and topical social issues. Specifically, respondents are queried on everything from their views on good and evil to their general state of health, from their associational memberships to their opinions of the value of scientific discoveries (see Inglehart 1997; MacIntosh 1998). The Eurobarometer surveys began in 1974 as an extension of an earlier series of European Community surveys. Designed primarily to gauge public attitudes toward the Common Market and other EU institutions, the Eurobarometer surveys, carried out every Fall and Spring, have expanded to include a variety of special topics of interest to sociologists, ranging from attitudes regarding AIDS to beliefs about the role of women (see Pettigrew 1998; Quillian 1995).

Finally, there are two more specialized projects that are deserving of note for their scale and scope. Of interest to students of crime and deviance is the International Crime (Victim) Survey (IC(V)S). Begun in 1989 and carried out again in 1992 and 1996, the IC(V)S gathers reports of crime, in addition to surveying attitudes regarding the police and the criminal justice system, fear of crime, and crime prevention (see Alvazzi del Frate and Patrignani 1995; Zvekic 1996). At present, over fifty countries have participated in the IC(V)S. Scholars interested in cross-cultural dimensions of poverty and development have benefitted from the Living Standards Measurement Study (LSMS). In this World Bank-directed program of research, surveys have been conducted in over two dozen developing countries since 1980 with the aim of gauging the welfare of households, understanding household behavior, and assessing the impact of

government policy on standards of living. The central instrument is a household questionnaire that details patterns of consumption. Other modules, collecting information regarding the local community, pricing, and schools and health facilities, have also been administered in a number of cases (see Grosh and Glewwe 1998; Stecklov 1997).

CHALLENGES AND PROBLEMS IN CROSS-CULTURAL RESEARCH

There are numerous methodological problems in cross-cultural research including: acquiring the needed linguistic and cultural skills and research funds; gaining access to field sites and data archives; defining and selecting comparable units; ensuring the representativeness of selected cases; and determining conceptual equivalence and measurement reliability and validity. These first two sets of problems are obvious, but not easily resolved. Cross-cultural analysis is costly in terms of time and money, and it usually demands at least a minimal level (and often much more) of education in the history, language, and culture of groups of people foreign to the researcher. The difficulties of gaining access to, and cooperation from, individuals and groups in cross-cultural research "are always experienced but rarely acknowledged by comparative researchers" (Armer 1973, pp. 58–59). Specific discussions of, and development of strategies for, gaining access are crucial because research can not begin without such access. Additionally, casual, insensitive, or ethnocentric presentation of self and research goals to foreign gatekeepers (officials, scholars, and those individuals directly studied) not only negatively affects the original study, but can also cause serious problems for others who plan future cross-cultural research (Form 1973; Portes 1973). Given the cultural isolation of many social scientists in the United States, it is not surprising that these practical problems have contributed to the lack of cross-cultural research in American sociology. However, the internationalization of the social sciences and the globalization of social and environmental issues are contributing to the gradual elimination of many of these practical problems (Sztompka 1988).

For the cross-cultural analysis of social psychological processes the unit of analysis is most often interactive events or individuals that are sampled

from whole cultures or subunits such as communities or institutions (e.g., family, school, or workplace). The appropriateness of individuals as the basic unit of analysis has been a hotly debated issue in sociology. The problem is even more acute in cross-cultural analysis, especially in cultures “that lack the individualistic, participatory characteristics of Western societies” (Armer 1983, p. 62). In addition to the special difficulties of representative, theoretical, or random sampling of cases (Elder 1973; Van Meter 1990), cross-cultural researchers must also deal with “Galton’s problem.” According to the British statistician, Sir Francis Galton, “valid comparison requires mutually independent and isolated cases, and therefore cultural diffusion, cultural contact, culture clash or outright conquest—with their consequent borrowing, imitation, migrations etc.—invalidates the results of comparative studies” (Sztompka 1988, p. 213). Although several researchers have presented strategies for dealing with Galton’s problem for correlational studies of data archives (see Naroll, Michik, and Naroll 1980), the problem of cultural diffusion is often overlooked in many quantitative and qualitative cross-cultural studies.

Undoubtedly, ensuring conceptual equivalence and achieving valid measures are the most challenging methodological problems of cross-cultural research. Central to these problems is the wide variation in language and meaning systems across cultural groups. Anthropologists have attempted to address the problem of conceptual equivalence with the distinction between “emic” and “etic.” Emics refer to local (single culture) meaning, function and structure, while etics are culture-free (or at least operate in more than one culture) aspects of the world (Pike 1966). A major problem in cross-cultural analysis is the use of emic concepts of one culture to explain characteristics of another culture. In fact, many cross-cultural studies involve the use of “imposed etics,” that is Euro-American emics that are “imposed blindly and even ethnocentrically on a set of phenomena which occur in other cultural systems” (Berry 1980, p. 12). A number of procedures have been developed to ensure emic-etic distinctions and to estimate the validity of such measures (Brislin 1980; Naroll, Michik, and Naroll 1980).

Addressing conceptual relevance in cross-cultural research does not, of course, ensure valid measures. All forms of data collection and analysis

are dependent on implicit theories of language and communication (Cicourel 1964). As social scientists have come to learn more about communicative systems within and across cultures, there has been a growing awareness that problems related to language in cross-cultural analysis are not easily resolved. There is also a recognition that these problems go beyond the accurate translation of measurement instruments (Brislin 1970; Grimshaw 1973), to the incorporation of findings from studies on communicative competence across cultural groups into cross-cultural research (Briggs 1986; Gumperz 1982).

THE FUTURE OF CROSS-CULTURAL ANALYSIS

There is a solid basis for optimism regarding the future of cross-cultural analysis. Over the last twenty years there has been remarkable growth in international organizations and cooperation among international scholars in the social sciences. These developments have not only resulted in an increase in cross-cultural research, but also have led to necessary debates about the theoretical and methodological state of cross-cultural analysis (Øyen 1990; Kohn 1989).

Cooperation among international scholars in cross-cultural analysis has also contributed to the breaking down of disciplinary boundaries. In the area of childhood socialization and the sociology of childhood, for example, there have been a number of cross-cultural contributions to what can be termed “development in sociocultural context” by anthropologists (Heath 1983), psychologists (Rogoff 1990), sociologists (Corsaro 1997), and linguists (Ochs 1988). Developing interest in children and childhood in sociology has resulted in the establishment of a new research committee (“Sociology of Childhood”) in the International Sociological Association (ISA) and a new journal titled *Childhood: A Global Journal of Child Research*, as well as the publication of several international reports and edited volumes (see Qvortrup, Bardy, Sgritta, and Wintersberger 1994). Less interdisciplinary, perhaps, but no less impressive, has been the degree of international cooperation that has developed around a number of other research committees of the ISA. The ISA Research Committee on Stratification, for instance, has had a

long history of such collaboration. This has involved the development of a common agenda (official and unofficial) and the pursuit of a common program of research by scholars around the globe (Ganzeboom, Treiman, and Ultee 1991). In addition to these developments, the growth of international data sets and their ready availability due to the new technologies such as the Internet are also grounds for optimism regarding cross-cultural research.

Despite growing international and multi-discipline cooperation and recognition of the importance of comparative research, it is still fair to say that cross-cultural analysis remains at the periphery of American sociology and social psychology. Although there has been some reversal of the growing trend toward narrow specialization over the last ten years, such specialization is still apparent in the nature of publications and the training of graduate students in these disciplines. There is a clear need to instill a healthy skepticism regarding the cultural relativity of a great deal of theory and method in social psychology in future scholars. Only then will future sociologists and social psychologists come to appreciate fully the potential of cross-cultural analysis.

WILLIAM A. CORSARO

CROWDS AND RIOTS

Crowds are a ubiquitous feature of everyday life. People have long assembled collectively to observe, to celebrate, and to protest various happenings in their everyday lives, be they natural events, such as a solar eclipse, or the result of human contrivance, such as the introduction of machinery into the production process. The historical

record is replete with examples of crowds functioning as important textual markers, helping to shape and define a particular event, as well as strategic precipitants and carriers of the events themselves. The storming of the Bastille and the sit-ins and marches associated with the civil rights movement are examples of crowds functioning as both important markers and carriers of some larger historical happening. Not all crowds function so significantly, of course. Most are mere sideshows to the flow of history. Nonetheless, the collective assemblages or gatherings called crowds are ongoing features of the social world and, as a consequence, have long been the object of theorizing and inquiry, ranging from the psychologistic renderings of Gustav LeBon (1895) and Sigmund Freud (1921) to the more sociological accounts of Neil Smelser (1963) and Ralph Turner and Lewis Killian (1987) to the highly systematic and empirically grounded observations of Clark McPhail and his associates (1983, 1991).

Crowds have traditionally been analyzed as a variant of the broader category of social phenomena called collective behavior. Broadly conceived, collective behavior refers to group problem solving behavior that encompasses crowds, mass phenomena, issue-specific publics, and social movements. More narrowly, collective behavior refers to "two or more persons engaged in one or more behaviors (e.g., orientation, locomotion, gesticulation, tactile manipulation, and/or vocalization) that can be judged common or convergent on one or more dimensions (e.g., direction, velocity tempo, and/or substantive content)" (McPhail and Wohlstein 1983, pp. 580-581). Implicit in both conceptions is a continuum on which collective behavior can vary in terms of the extent to which its participants are in close proximity or diffused in time and space. Instances of collective behavior in which individuals are in close physical proximity, such that they can monitor one another by being visible to, or within earshot of, one another, are constitutive of crowds. Examples include protest demonstrations, victory celebrations, riots, and the dispersal processes associated with flight from burning buildings. In contrast are forms of collective behavior that occur among individuals who are not physically proximate but who still share a common focus of attention and engage in some parallel or common behaviors without developing the debate characteristic of the public or the

organization of social movements, and who are linked together by social networks, the media, or both. Examples of this form of collective behavior, referred to as diffuse collective behavior (Turner and Killian 1987) or the mass (Lofland 1981), include fads and crazes, deviant epidemics, mass hysteria, and collective blaming. Although crowds and diffuse collective behavior are not mutually exclusive phenomena, they are analytically distinct and tend to generate somewhat different literatures—thus, the focus on crowds in this selection.

Understanding crowds and the kindred collective phenomenon called “riots” requires consideration of five questions: (1) How do these forms of collective behavior differ from the crowd forms typically associated with everyday behavior, such as audiences and queues? (2) What are the distinctive features of crowds as collective behavior? (3) What are the conditions underlying the emergence of crowds? (4) What accounts for the coordination of crowd behavior? and (5) What are the correlates and/or predictors of individual participation?

DISTINGUISHING BETWEEN THE CROWDS OF COLLECTIVE BEHAVIOR AND EVERYDAY BEHAVIOR

There has been increasing recognition of the continuity between collective behavior and everyday behavior, yet the existence of collective behavior as an area of sociological analysis rests in part on the assumption of significant differences between collective behavior and everyday institutionalized behavior. In the case of crowds, those commonly associated with everyday life, such as at sports events and holiday parades, tend to be highly conventionalized in at least two or three ways. Such gatherings are recurrent affairs that are scheduled for a definite place at a definite time; they are calendarized both temporally and spatially. Second, associated behaviors and emotional states are typically routinized in the sense that they are normatively regularized and anticipated. And third, they tend to be sponsored and orchestrated by the state, a community, or a societal institution, as in the case of most holiday parades and electoral political rallies. Accordingly, they are typically socially approved affairs that function to reaffirm rather than challenge some institutional arrangement or the larger social order itself.

In contrast, crowds commonly associated with collective behavior, such as protest demonstrations, victory celebrations, and riots, usually challenge or disrupt the existing order. This is due in part to the fact that these crowds are neither temporally nor spatially routinized. Instead, as David Snow, Louis Zurcher, and Robert Peters (1981) have noted, they are more likely to be unscheduled and staged in spatial areas (streets, parks, malls) or physical structures (office buildings, theaters, lunch counters) that were designed for institutionalized, everyday behavior rather than contentious or celebratory crowds. Such crowd activities are also extrainstitutional, and thus unconventional, in the sense that they are frequently based on normative guidelines that are emergent and ephemeral rather than enduring (Turner and Killian 1987), on the appropriation and redefinition of existing networks or social relationships (Weller and Quarantelli 1973), or on both.

Crowd behavior has long been described as “extraordinary” in the sense that its occurrence indicates that something unusual is happening. Precisely what it is that gives rise to the sense that something “outside the ordinary” is occurring is rarely specified unambiguously, however. John Lofland (1981) suggests that it is increased levels of emotional arousal, but such arousal is not peculiar to crowd episodes. The conceptualization offered here suggests several possibilities: It is the appropriation and use of spatial areas, physical structures, or social networks and relations for purposes other than those for which they were intended or designed that indicates something extraordinary is happening.

THE CHARACTERISTIC FEATURES OF CROWDS

Crowds have been portrayed historically and journalistically as if they are monolithic entities characterized by participant and behavioral homogeneity. Turner and Killian (1987, p. 26) called this image into question, referring to it as “the illusion of unanimity,” but not until the turn toward more systematic empirical examination of crowds was it firmly established that crowd behaviors are typically quite varied and highly differentiated, and that crowd participants are generally quite heterogeneous in terms of orientation and behavior.

Variation in Crowd Behaviors and "Riots."

Based on extensive field observation of crowds, Sam Wright (1978) differentiated between two broad categories of crowd behaviors: crowd activities and task activities. "Crowd activities" refer to the redundant behavior seemingly common to all incidents of crowd behavior, such as assemblage, milling, and divergence. In their overview of empirical research on behaviors within crowds, McPhail and Ronald Wohlstein (1983) include collective locomotion, collective orientation, collective gesticulation, and collective vocalization among the types of crowd behaviors "repeatedly observed across a variety of gatherings, demonstrations, and some riots" (p. 595).

Taking these observations together, one can identify the following "crowd activities" (Wright 1978) or "elementary forms" of crowd behavior (McPhail and Wohlstein 1983): assemblage/convergence; milling; collective orientation (e.g., common or convergent gaze, focus, or attention); collective locomotion (e.g., common or convergent movement or surges); collective gesticulation (e.g., common or convergent nonverbal signaling); collective vocalization (e.g., chanting, singing, booing, cheering); and divergence/dispersal. Given the recurrent and seemingly universal character of these basic crowd behaviors, it is clear that they do not distinguish between types of crowds, that is, between demonstrations, celebrations, and riots.

To get at the variation in types of crowds, attention must be turned to what Wright conceptualized as "task activities" (1978). These refer to joint activities that are particular to and necessary for the attainment of a specific goal or the resolution of a specific problem. It is these goal-directed and problem-oriented activities that constitute the primary object of attention and thus help give meaning to the larger collective episode. Examples of task activities include parading or mass marching, mass assembly with speechmaking, picketing, proselytizing, temporary occupation of premises, lynching, taunting and harassment, property destruction, looting, and sniping.

Several caveats should be kept in mind with respect to crowd task activities. First, any listing of task activities is unlikely to be exhaustive, because they vary historically and culturally. Charles Tilly's (1978) concept of "repertoires of collective action" underscores this variation. Tilly has stressed

that while there are innumerable ways in which people could pursue collective ends, alternatives are in fact limited by sociohistorical forces. His research suggests, for example, that the massed march, mass assembly, and temporary occupation of premises are all collective task activities specific to the twentieth century.

Second, crowd task activities are not mutually exclusive but are typically combined in an interactive fashion during the history of a crowd episode. The mass assembly, for example, is often preceded by the massed march, and property destruction and looting often occur together. Indeed, whether a crowd episode is constitutive of a protest demonstration, a celebration, or a riot depends, in part, on the particular configuration of task activities and, in part, on who or what is the object of protest, celebration, or violence. Both of these points can be illustrated with riots.

It is generally agreed that riots involve some level of collective violence against persons or property, but that not all incidents of collective violence are equally likely to be labeled riots. Collective violence against the state or its social control agents is more likely to be labeled riotous, for example, than violence perpetrated by the police against protesting demonstrators. Traditionally, what gets defined as a riot involves interpretive discretion, particularly by the state. But even when there is agreement that riots are constituted by some segment of a crowd or gathering engaging in violence against person(s) or property, distinctions are often made between types of riots, as evidenced by Morris Janowitz's (1979) distinction between "communal riots" and "commodity riots," Gary Marx's (1972) distinction between "protest riots" and "issueless riots," and the Walker Report's (1968) reference to "police riots." Communal riots involve religious, ethnic, and/or racial intergroup violence in which the members or property of one group are violently assaulted by members of another group, as occurred in the United States in Miami in 1980 (Porter and Dunn 1984) and in South Central Los Angeles in 1992 (Bergesen and Herman 1998). Commodity or property riots, in contrast, typically involve looting, arson, and vandalism against property, which has generally been posited as one of the defining features of the many urban riots that occurred across major U.S. cities

in the 1960s. But it has been argued that many of these riots, such as those that occurred following the assassination of Martin Luther King, Jr. in 1968, were also protest riots, or at least had elements of protest associated with them (Fogelson 1971). Even though there has been some effort to identify the conditions that lead to the designation of elements of crowd behavior as protest (Turner 1969), it is clear that communal, commodity, and protest riots are overlapping rather than mutually exclusive crowd phenomena and that distinguishing among them therefore involves some interpretive discretion (Turner 1994). The same is true, as well, with the category of issueless riots, such as the sporting victory celebrations that sometimes take on the flavor of property riots among some of the celebrants. Even in the case of police riots, which involve a loss of discipline and control among the ranks, as occurred during the 1968 Democratic National Convention in Chicago, there is often debate as to whether the assaultive behavior of the police is justified. That there is some level of ambiguity and debate associated with categorizing and distinguishing any crowd episode as not only a riot, but as particular kind of riot, is not surprising considering that all crowd episodes share various task activities or elementary forms even when they differ in terms of their defining task activities.

Following from these observations is a final caveat: The task activities associated with any given crowd episode vary in the degree to which they are the focus of attention. Not all are equally attended to by spectators, social control agents, or the media. Consequently, task activities can be classified according to the amount of attention they receive. One that is the major focus of attention and thus provides the phenomenal basis for defining the episode constitutes "the main task activity," whereas those subordinate to the main task activity are "subordinate or side activities." The main task activity is on center stage and typically is the focus of media attention, as illustrated by the extensive media coverage of property vandalism and looting associated with commodity riots. In contrast, the remaining task activities are sideshows, occasioned by and often parasitic to the focal task activity. Examples of subordinate task activity in the case of property or communal riots, or both, include spectating or observing, informal, unofficial attempts at social control, and even the work of the media.

Variation in Participation Units. Just as empirical research on crowds has discerned considerable heterogeneity in behavior, so there is corresponding variation in terms of participants. Some are engaged in various task activities, some are observing, and still others are involved in the containment and control of the other participants and their interactions. Indeed, most of the individuals who make up a crowd fall into one of three categories of actors: task performers, spectators or bystanders, and social control agents. Task performers include the individuals performing both main and subordinate tasks. In the case of an antiwar march, for example, the main task performers would include the protesting marchers, with counterdemonstrators, peace marshals, and the press or media constituting the subordinate task performers.

Spectators or bystanders, who constitute the second set of actors relevant to most instances of crowd behavior, have been differentiated into proximal and distal groupings according to proximity to the collective encounter and the nature of their response. Proximal spectators, who are physically co-present and can thus monitor firsthand the activities of task performers, have generally been treated as relatively passive and nonessential elements of crowd behavior. However, research on a series of victory celebrations shows that some spectators do not merely respond passively to the main task performance and accept the activity as given, but can actively influence the character of the activity as well (Snow, Zurcher, and Peters 1981). Accordingly, proximal spectators can vary in terms of whether they are passive or animated and aggressive. "Distal spectators" refer to individuals who take note of episodes of crowd behavior even though they are not physically present during the episodes themselves. Also referred to as "bystander publics" (Turner and Killian 1987), they indirectly monitor an instance of crowd behavior and respond to it, either favorably or unfavorably, by registering their respective views with the media and community officials. Although distal spectators may not affect the course of a single episode of crowd behavior, they can clearly have an impact on the career and character of a series of interconnected crowd episodes.

Social control agents, consisting primarily of police officers and military personnel, constitute

the final set of participants relevant to most instances of crowd behavior. Since they are the guardians of public order, their primary aim with respect to crowds is to maintain that order by controlling crowd behavior both spatially and temporally or by suppressing its occurrence. Given this aim, social control agents can clearly have a significant impact on the course and character of crowd behavior. This is evident in most protest demonstrations and victory celebrations, but it is particularly clear in the case of riots, which are often triggered by overzealous police activity and often involve considerable interpersonal violence perpetrated by the police. The urban riots of the 1960s in the United States illustrate both tendencies: police-citizen scuffles occasioned by traffic citation encounters or arrests sometimes functioned as a triggering event (Kerner 1968); and the vast majority of riot-associated deaths were attributed to social control agents (Bergesen 1980; Kerner 1968). This was not the case, however, with the riots in Miami in 1980 and in South Central Los Angeles in 1992, in which the clear majority of deaths were at the hands of civilians (McPhail 1994; Porter and Dunn 1984). Although these different sets of findings caution against premature generalization regarding the attribution of responsibility for riot-related deaths, they do not belie the important role of social control agents in affecting the course and character of crowd episodes (Della Porta and Reiter 1998).

Although there is no consensual taxonomy of crowd behaviors and interacting participation units, the foregoing observations indicate that behavioral and participant heterogeneity are characteristic features of most crowd episodes. In turn, the research on which these observations are based lays to rest the traditional image of crowds as monolithic entities composed of like-minded people engaged in undifferentiated behavior.

CONDITIONS OF EMERGENCE

Under what conditions do individuals come together collectively to engage in crowd task activities constitutive of protest or celebration, and why do these occurrences sometimes turn violent or riotous? Three sets of interacting conditions are discernible in the literature: (1) conditions of conduciveness; (2) precipitating ambiguities or grievances; and (3) conditions for mobilization.

Conditions of Conduciveness. The concept of conduciveness directs attention to structural and cultural factors that make crowd behavior physically and socially possible (Smelser 1963). Conditions of conduciveness constitute the raw material for crowd behavior and include three sets of factors: ecological, technological, and social control. Ecological factors affect the arrangement and distribution of people in space so as to facilitate interaction and communication. One such factor found to be particularly conducive is the existence of large, spatially concentrated populations. The vast majority of campus protest demonstrations in the 1960s occurred on large universities, for example. Similarly, the urban riots of the 1960s typically occurred in densely populated residential areas, where there were large, easily mobilizable black populations. Seymour Spilerman's (1976) aggregate-level research on the occurrence of these riots found an almost linear relationship between the size of a city's black population and the likelihood and number of disorders experienced, thus suggesting that there was a threshold population size below which riots were unlikely. More recent analyses of the 1960 riots have found that "the propensity to riot was a function of far more than simply the number of Blacks available for rioting in a particular city" (Myers 1997, p. 108; Olzak, Shanahan, and McEneaney 1996), but such findings do not suggest that concentrated population density and the prospect of rioting are unrelated. Thus, these findings, in conjunction with the earlier observations, provide support for the hypothesis that, all other things being equal, the greater the population density, the greater the probability of crowd behavior.

The heightened prospect of interpersonal interaction and communication associated with population concentration can also be facilitated by the diffusion of communication technology, namely telephone, radio, television, and Internet access. But neither the diffusion of such technology nor population density guarantee the emergence of crowd behavior in the absence of a system of social control that allows for freedom of assembly and speech. It has been found repeatedly that incidence of public protest against the state diminishes considerably in political systems that prohibit and deal harshly with such crowd behavior, whereas the development of a more permissive attitude

toward public protest and a corresponding relaxation of measures of social control is frequently conducive to the development of protest behavior. Two concrete examples of this political-opportunity principle include the proliferation of public protest throughout Eastern Europe in 1989 and 1990 following the break-up of the Soviet Union, and prison riots, which research reveals are sparked in part by the erosion of prison security systems and the increased physical vulnerability of those systems (Useem and Kimball 1989).

Precipitating Events and Conditions. However conducive conditions might be for crowd behavior, it will not occur in the absence of some precipitating event or condition. Although the specific precipitants underlying the emergence of crowd behavior may be quite varied, most are variants of two generic conditions: (1) ambiguity; and (2) grievances against corporate entities, typically the state or some governmental, administrative unit, or against communal or status groups such as ethnic, racial, and religious groups.

Ambiguity is generated by the disruption or breakdown of everyday routines or expectancies, and has long been linked theoretically to the emergence of crowd behavior (Johnson and Feinberg 1990; Turner and Killian 1987). Evidence of its empirical linkage to the emergence of crowd behavior is abundant, as with the materialization of crowds of onlookers at the scene of accidents and fires; the celebrations that sometimes follow high-stakes, unanticipated athletic victories; the collective revelry sometimes associated with the disruption of interdependent networks of institutionalized roles, as in the case of power blackouts and police strikes; and prison riots that frequently follow on the heels of unanticipated change in administrative personnel, procedures, and control.

The existence of grievances against the state or some governmental, administrative unit, or against communal or status groups, can be equally facilitative of crowd behavior, particularly of the protest variety. Grievances against the state or other corporate actors are typically associated with the existence of economic and political inequities that are perceived as unjust or political decisions and policies that are seen as morally bankrupt or advantaging some interests to the exclusion of others. Examples of protest crowds triggered in

part by such grievances include the hostile gatherings of hungry citizens and displaced workers in industrializing Europe; the striking crowds of workers associated with the labor movement; and the mass demonstrations (marching, rallying, picketing, vigiling) associated with the civil rights, student, antiwar, and women's movements of the 1960s and 1970s.

Grievances against communal or status groups appear to occur most often in a context of competition and conflict between two or more ethnic or racial groups. A second generation of quantitative research on urban racial rioting in the United States has shown it to be associated with increasing intergroup competition sparked by patterns of hypersegregation of blacks (Olzak, Shanahan, and McEneaney 1996), heightened nonwhite unemployment (Myers 1997), and rapid ethnic succession (Bergesen and Herman 1998). Indeed, if there is a single structural-based source of grievance associated with intergroup rioting throughout much of modern history, it is probably intergroup competition triggered by ethnic/racial displacement and succession.

Crowd violence—"riotous" task activities such as property destruction, looting, fighting, and sniping—has been an occasional corollary of protest crowds, but it is not peculiar to such crowds. Moreover, the occurrence of crowd violence, whether in association with protest demonstrations or celebrations, is relatively infrequent in comparison to other crowd behaviors (Eisinger 1973; Gamson 1990; Lewis 1982). When it does occur, however, there are two discernible tendencies: interpersonal violence most often results from the dynamic interaction of protestors and police (Kritzer 1977; MacCannell 1973); and property violence, as in the case of riot looting, often tends to be more selective and semi-organized than random and chaotic (Berk and Aldrich 1972; Quarantelli and Dynes 1968; Tierney 1994).

Conditions for Mobilization. A precipitating condition coupled with a high degree of conduciveness is rarely sufficient to produce an instance of crowd behavior. In addition, people have to be assembled or brought into contact with one another, and attention must be focused on the accomplishment of some task. On some occasions in everyday life the condition of assemblage is already met, as in the case of the pedestrian crowd

and conventional audience. More often than not, however, protest crowds, large-scale victory celebrations, and riots do not grow out of conventional gatherings but require the rapid convergence of people in time and space. McPhail and David Miller (1973) found this assembling process to be contingent on the receipt of assembling instructions; ready access, either by foot or by other transportation, to the scene of the action; schedule congruence; and relatively free or discretionary time. It can also be facilitated by lifestyle circumstances and social networks. Again, the ghetto riots of the 1960s are a case in point. They typically occurred on weekday evenings or weekends in the summer, times when people were at home, were more readily available to receive instructions, and had ample discretionary time (Kerner 1968).

The focusing of attention typically occurs through some “keynoting” or “framing” process whereby the interpretive gesture or utterance of one or more individuals provides a resonant account or stimulus for action. It can occur spontaneously, as when someone yells “Cops!” or “Fire!”; it can be an unintended consequence of media broadcasts; or it can be the product of prior planning, thus implying the operation of a social movement.

COORDINATION OF CROWD BEHAVIOR

Examination of protest demonstrations, celebratory crowds, and riots reveals in each case that the behaviors in question are patterned and collective rather than random and individualistic. Identification of the sources of coordination has thus been one of the central tasks confronting students of crowd behavior.

Earlier theorists attributed the coordination either to the rapid spread of emotional states and behavior in a contagion-like manner due to the presumably heightened suggestibility of crowd members (LeBon [1895] 1960; Blumer 1951) or to the convergence of individuals who are predisposed to behave in a similar fashion because of common dispositions or background characteristics (Allport 1924; Dollard et al. 1939). Both views are empirically off the mark. They assume a uniformity of action that glosses the existence of various categories of actors, variation in their behaviors, ongoing interaction among them, and the

role this interaction plays in determining the direction and character of crowd behavior. These oversights are primarily due to the perceptual trap of taking the behaviors of the most conspicuous element of the episode—the main task performers—as typifying all categories of actors, thus giving rise to the previously mentioned “illusion of unanimity” (Turner and Killian 1987).

A more modern variant of the convergence argument attributes coordination to a rational calculus in which individuals reach parallel assessments regarding the benefits of engaging in a particular task activity (Berk 1974; Granovetter 1978). Blending elements of this logic with strands of theorizing seemingly borrowed from LeBon and Freud, James Coleman (1990) argues that crowd behavior occurs when individuals make a unilateral transfer of control over their actions. Such accounts are no less troublesome than the earlier ones in that they remain highly individualistic and psychological, ignoring the extent to which crowd behavior is the product of collective decision making involving the “framing” and “reframing” of probable costs and benefits and the extent to which this collective decision making frequently has a history involving prior negotiation between various sets of crowd participants.

A sociologically more palatable view holds that crowd behavior is coordinated by definition of the situation that functions in normative fashion by encouraging behavior in accordance with the definition. The collective definition may be situationally emergent (Turner and Killian 1987) or preestablished by prior policing strategies or negotiation among the relevant sets of actors (Della Porta and Reiter 1998; Snow and Anderson 1985). When one or more sets of actors cease to adjust their behaviors to this normative understanding, violence is more likely, especially if the police seek to reestablish normative control, and the episode is likely to be labeled as riotous or mob-like.

Today it is generally conceded that most instances of crowd behavior are normatively regulated, but the dynamics underlying the emergence of such regulations are still not well understood empirically. Consequently, there is growing research interest in detailing the interactional dynamics underlying the process by which coordinating understandings emerge and change. Distinctive to

this research is the view that social interaction among relevant sets of actors, rather than the background characteristics and cognitive states of individuals, holds the key to understanding the course and character of crowd behavior (Snow and Anderson 1985; Turner 1994; Waddington, Jones, and Critcher 1989).

THE CORRELATES AND PREDICTORS OF PARTICIPATION

Crowd phenomena associated with collective behavior have been distinguished from everyday, conventionalized crowds, the characteristic features of crowds have been elaborated, the major sets of conditions that facilitate the emergence or occurrence of crowds and riots have been identified, and the issue of behavioral coordination in crowd contexts has been explored. In addressing these orienting issues, only passing reference has been made to factors that make some individuals more likely than other individuals to participate in crowd episodes. For example, it is clear that the odds of participating in some crowd episodes are greater with increasing spatial proximity and access to those episodes, schedule congruence, and discretionary time (McPhail and Miller 1973). As well, individuals whose daily routines and expectancies have been rendered ambiguous or who share grievances that are linked to the occurrence of a crowd episode would appear to be more likely candidates for participation. But both of these sets of conditions typically hold for a far greater number of individuals than those who end up participating in a crowd episode in some capacity other than a social control agent or media representative. So what can be said about the personal and interpersonal correlates or predictors of participation?

There is no simple answer to this question or standard formula for predicting crowd participation. However, research on this question suggests at least four general, sensitizing observations, particularly with respect to participation in protest crowds and riots. The first general observation is that commonsensical psychological indicators of protest and riot participation, such as intense frustration or strong feelings of deprivation, have not been found to be valid or reliable predictors. For example, studies of individual riot participation,

which have been numerous, have failed to find consistently significant empirical correlations between measures of frustration or deprivation and participation (McPhail 1994). This is not to suggest that riot or protest participants may not sometimes feel deeply frustrated or deprived as compared to others, but that these psychological states do not reliably explain their participation or typically differentiate them from nonparticipants. Such findings are consistent with the second general observation: There are a diversity of motivations for participation in crowd episodes, ranging from curiosity to exploitation of the situation for personal gain (e.g., fun, material goods) to sympathy with the issue for which the episode is a marker or carrier to embracement of and identification with the cause from either a self-interested or altruistic standpoint (Turner and Killian 1987). That neither a distinctive psychological state or deficit nor a dominant motive have been found to be associated with crowd and riot participation does not mean that psychological or personality factors are without relevance to this issue. To the contrary, one such factor that appears to be consistently associated with participation as a main task performer in protest crowds and riots is the existence of a sense of "personal efficacy"—the belief that one's participation will make a difference, the confidence that one's efforts will contribute to the larger cause (Snow and Oliver 1995). This finding, which constitutes the third general observation regarding participation correlates, makes good sense when considered in conjunction with the fourth general observation: Participants in crowd episodes—whether they are victory celebrations, protest events, or riots—seldom participate alone. Instead, rather than being isolates or loners, they are typically in the company of friends or acquaintances; they are, in other words, part of a social network. Additionally, recruitment into many crowd episodes occurs through the very same social networks (Snow and Oliver 1995). Thus, participation in crowd episodes, particularly planned ones such as protest events, tends to be embedded in social networks, which also function to nurture a greater sense of both personal and collective efficacy. When these factors are coupled with the previously mentioned conditions for assemblage, and either ambiguity or target-specific grievances, participation becomes more likely and perhaps even more predictable.

CULTURE

To produce a definition of culture, one can examine the concept in the abstract, that is, explore the concept theoretically from a variety of standpoints and then justify the definition that emerges through deductive logic. Or one can explore how the concept is used in practice, that is, describe how sociologists, both individually and collectively, define culture in the research process and analyze how they inductively construct a shared definition. This essay takes the latter collective-inductive approach to defining culture. Such an approach is inherently sociological and does not presume to produce an independent definition for the field, rather it seeks to document how successful participants in the field have been in producing a shared definition for themselves. To produce such a "working" definition of culture, one starts by examining the social science roots that have helped determine the current status of the sociology of culture.

The focus on culture in sociology has flourished over the past twenty years, as evidenced by the fact that the Culture Section in the American Sociological Association has become one of the largest and is still one of the fastest-growing sections in the discipline. The growth of interest in culture is also nicely documented by the number of survey review articles and books written during this period (e.g., Denzin 1996; Crane 1994, 1992; Hall and Neitz 1993; Munch and Smelser 1992; Peterson 1990, 1989, 1979; Alexander and Seidman 1990; Wuthnow and Witten 1988; Blau 1988; Mukerji and Schudson 1986). As is clear from the reviews, interest in cultural analysis has grown significantly. The focus on culture in all spheres of research has increased tremendously; and culture is now readily accepted as a level of explanation in its own right. Even in traditionally materialist-oriented research arenas, such as stratification and Marxist studies, cultural activities and interests are not treated as subordinate to economic explanations in current research (e.g., Halle 1994; Nelson and Grossberg 1988; Bourdieu 1984; Williams 1981, 1977). Cultural studies and analysis have become one of the most fertile areas in sociology.

The rapid growth in the focus on culture and cultural explanation has produced some definitional boundary problems. The term *culture* has been

used in contemporary sociological research to describe everything from elite artistic activities (Becker 1982) to the values, styles, and ideology of day-to-day conduct (Swidler 1986). Along with art and everyday conduct, included among the “mixed bag” of research that takes place under the auspices of the sociology of culture is work in science (Latour 1987; Star 1989), religion (Neitz 1987), law (Katz 1988), media (Schudson 1978; Gitlin 1985; Tuchman 1978), popular culture (Peterson 1997; Weinstein 1991; Chambers 1986), and work organization (Fine 1996; Lincoln and Kalleberg 1990).

With such an extensive variety in the empirical focus of research in culture, the question for many participants in the field is how to translate this eclecticism into a coherent research field. This goal has not yet been reached, but while a coherent concept of culture is still evolving and the boundaries of the current field of sociology of culture are still fluid and expanding, it is possible to explore how different types of researchers in the social sciences, both currently and historically, have approached the concept of culture. In this inventory process, a better understanding of the concept of culture will emerge, that is, what different researchers believe the concept of culture includes, what the concept excludes, and how the distinction between categories has been made. This essay will provide a historical overview of the two major debates on the appropriate focus and limitations of the definition of culture, and then turn to the contemporary social context in an effort to clarify the issues underlying the current concept of culture.

THE CULTURE–SOCIAL STRUCTURE DEBATE

From the turn of the century until the 1950s, the definition of culture was embroiled in a dialogue that sought to distinguish the concepts of culture and social structure. This distinction was a major bone of contention among social scientists, most noticeably among anthropologists divided between the cultural and social traditions of anthropology. Researchers in the cultural or ethnological tradition, such as Franz Boas (1896/1940), Bronislaw Malinowski (1927, 1931), Margaret Mead (1928, 1935), Alfred Kroeber (1923/1948, 1952), and Ruth Benedict (1934) believed culture was the central concept in social science. “Culturalists”

maintained that culture is primary in guiding all patterns of behavior, including who interacts with whom, and should therefore be given priority in theories about the organization of society. This position was countered by researchers in the structural tradition, such as A.R. Radcliffe-Brown ([1952] 1961) and E. E. Evans-Pritchard (1937, 1940) from the British school of social anthropology, and Claude Levi-Strauss ([1953] 1963) in French structuralism. “Structuralists” contended that social structure was the primary focus of social science and should be given priority in theories about society because social structure (e.g., kinship) determines patterns of social interaction and thought. Both schools had influential and large numbers of adherents.

The culturalists took a holistic approach to the concept of culture. Stemming from Edward Tylor’s classic definition, culture was “. . . that complex whole which includes knowledge, belief, art, morals, law, custom, and any other capabilities and habits acquired by man as a member of society” ([1871] 1924, p.1). This definition leaves little out, but the orientation of the late nineteenth century intended the concept of culture to be as inclusive as possible. Culture is what distinguishes man as a species from other species. Therefore culture consists of all that is produced by human collectivities, that is, all of social life. The focus here stems from the “nature” vs. “nurture” disputes common during this period. Anything that differentiates man’s accomplishments from biological and evolutionary origins was relevant to the concept of culture. That includes religion as well as kinship structures, language as well as nation-states.

Following Boas, the study of culture was used to examine different types of society. All societies have cultures, and variations in cultural patterns helped further the argument that culture, not nature, played the most significant role in governing human behavior. In addition, the cultural variances observed in different societies helped break down the nineteenth-century anthropological notion of “the psychic unity of mankind, the unity of human history, and the unity of culture” (Singer 1968, p. 527). The pluralistic and relativistic approaches to culture that followed emphasized a more limited, localized conception. Culture was what produced a distinctive identity for a society,

socializing members for greater internal homogeneity and identifying outsiders. Culture is thus treated as differentiating concept, providing recognition factors for internal cohesion and external discrimination.

Although this tradition of ethnographic research on culture tended to be internal and localized, what is termed an “emic” approach in cognitive anthropology (Goodenough 1956), by the 1940s there emerged a strong desire among many anthropologists to develop a comparative “etic” approach to culture, that is, construct a generalized theory of cultural patterns. In the comparison of hundreds of ethnographies written in this period, A.L. Kroeber and Clyde Kluckhohn sought to build such a general definition of culture. They wrote,

Culture consists of patterns, explicit and implicit, of and for behavior acquired and transmitted by symbols, constituting the distinctive achievement of human groups, including their embodiments in artifacts; the essential core of culture consists of traditional (i.e., historically derived and selected) ideas and especially their attached values; culture systems may, on the one hand, be considered as products of action, on the other as conditioning elements of further action ([1952] 1963, p. 181).

Milton Singer (1968) characterized this “pattern theory” definition as a condensation of what most American anthropologists in the 1940s and 1950s called culture. It includes behavior, cultural objects, and cognitive predispositions as part of the concept, thus emphasizing that culture is both a product of social action and a process that guides future action. The pattern theory stated simply that behavior follows a relatively stable routine, from the simplest levels of custom in dress and diet to more complex levels of organization in political, economic, and religious life. The persistence of specific patterns is variable in different arenas and different societies, but larger configurations tend to be more stable, changing incrementally unless redirected by external forces. In addition, the theory emphasized that the culture from any given society can be formally described, that is, it can be placed in formal categories representing different spheres of social life to facilitate comparison between societies. As such, universal patterns of culture can be constructed.

In comparison, anthropological structuralists in this period conceive of culture less comprehensively. The structuralists’ concept of culture is made distinct through emphasis on a new concept of social structure. Largely through the efforts of Radcliffe-Brown, a theory emerged that argues social structure is more appropriately represented by a network or system of social relations than a set of norms. The structuralist argument is intended to clarify how actors in a society actively produce and are socially produced by their cultural context. By distinguishing the actors and interaction in a social system from the behavioral norms, structuralists seek to establish a referent for social structure that is analytically independent of the culture and artifacts produced in that system. The production of culture is thus grounded clearly in an international framework. Norms of interaction are also produced by interacting participants, but the question of causal primacy between culture and social structure can be considered separately. The initial effort here is simply not to reify the origins of culture.

The exact relationship of culture and social structure, however, becomes the central issue of the structuralist/culturalist debate. For example, how to identify the boundaries of a society one is researching is problematic when the society is not an isolate. Structuralists tend to give social relations, that is, the extent of a network, priority in identifying boundaries, while culturalists focus on the extent of particular types of cultural knowledge or practices. Since both elements are obviously operating interdependently, the efforts to disentangle these concepts make little headway. The arguments to establish causal priority for one concept vis-à-vis the other settle into a fairly predictable exchange. Structuralists base their priority claims on the fact that the interaction of actors in a society is empirically preliminary to the development and application of cultural elements. Culturalists respond that interaction itself is at least partially cultural phenomenon, and that in most complex societies cultural patterns have been well established prior to ongoing social relationships.

By the late 1950s, the concept of culture was becoming increasingly important to sociologists. To help resolve the now tired debate over cultural and structural foci and precedence, A.L. Kroeber and Talcott Parsons published a report in the

American Sociological Review titled "The Concepts of Culture and Social System" (1958), which seeks to establish some ground rules for differentiating the two concepts. At least for sociologists, many of whom identify explicitly with the structural-functional theories of the anthropological structuralists, acknowledgement of a separate social system component that delimits the scope of culture is not difficult. More difficult is ascertaining where the appropriate limits for the concept of culture lie within this domain. Kroeber and Parsons suggest restricting the usage of culture to, "transmitted and created content and patterns of values, ideas, and other symbolic-meaningful systems as factors in the shaping of human behavior and the artifacts produced behavior" (1958, p. 583). This definition emphasized the predispositional aspect of a cultural referent, limiting the scope of culture to a cognitive perspective, and concentrates on a carefully worded description of "symbolic-meaningful systems" as the appropriate referent for culture. While no longer the omnibus conception of a traditional, Tylor-derived approach, this type of cultural analysis is still potentially applicable to any realm of social activity.

THE HIGH-MASS CULTURE DEBATE

In the 1950s and early 1960s, the concept of culture became enmeshed in a new debate that like the previously documented dialogue has both influential and significant numbers of participants on each side of the dispute. Sociologists, however, are more central to the discussion, pitting those who support a broadly conceived, anthropological interpretation of culture that places both commonplace and elite activities in the same category, against a humanities oriented conception of culture that equates the identification of cultural activity with a value statement. This debate attempts to do two things: to classify different types of cultural activity, and to distinguish a purely descriptive approach to the concept of culture from an axiological approach that defines culture through an evaluative process.

That an axiological approach to culture can be considered legitimate by a "scientific" enterprise is perhaps surprising to contemporary sociologists entrenched in the positivistic interpretation of science, yet a central issue for many sociologists in

this period was how and whether to approach questions of moral values. For example, the critical theorist Leo Lowenthal (1950) characterized this period of social science as "applied asceticism" and stated that the moral or aesthetic evaluation of cultural products and activities is not only sociologically possible, but also should be a useful tool in the sociological analysis of cultural differentiation.

These evaluative questions certainly play a part in the analysis of "mass culture," a term that the critic Dwight McDonald explains is used to identify articles of culture that are produced for mass consumption, "like chewing gum" (McDonald 1953, p. 59). A number of commentators, including both sociologists and humanists, observe the growth of mass culture production in the post-World War II United States with a mixture of distaste and alarm. The concern of McDonald and critics like him is the decline of intrinsic value in cultural artifacts, a decline in quality that stems from, or is at least attributed to, a combination of economic and social factors associated with the growth of capitalism. For example, mass culture critics argue that the unchecked growth of capitalism in the production and distribution phases of culture industries leads to a "massification" of consumption patterns. Formerly localized, highly differentiated, and competitive markets become dominated by a single corporate actor who merges different sectors of the consumer landscape and monopolizes production resources and distribution outlets. Within these giant culture industry organizations the demand for greater efficiency and the vertical integration of production lead to a bureaucratically focused standardization of output. Both processes function to stamp out cultural differences and create greater homogeneity in moral and aesthetic values, all at the lowest common denominator.

Regardless of the causes of the mass culture phenomena, the critics of mass culture believe it to be a potentially revolutionary force that will transform the values of society. One critic states that "mass culture is a dynamic, revolutionary force, breaking down the old barriers of class, tradition, taste, and dissolving all cultural distinctions. It mixes and scrambles everything together, producing what might be called homogenized culture. . . It thus destroys all values, since value judgements imply discrimination" (McDonald 1953, p. 62).

In launching this attack, mass culture opponents see themselves as the saviors of a “true” or “high” culture (e.g., McDonald, Greenberg, Berelson, and Howe; see Rosenberg and White 1957). They argue that the consumption of mass culture undermines the very existence of legitimate high culture, that is, the elite arts and folk cultures. Without the ability to differentiate between increasingly blurred lines of cultural production, the average consumer turns toward mass culture due to its immediate accessibility. Further, simply through its creation, mass culture devalues elite art and folk cultures by borrowing the themes and devices of different cultural traditions and converting them into mechanical, formulaic systems (Greenberg 1946). Thus critics of mass culture argue that it is critical for the health of society to discriminate between types of culture.

Defenders of mass culture, or at least those who feel the attack on mass culture is too extreme, respond that mass culture critics seek to limit the production and appreciation of culture to an elitist minority. They contend that the elitist criticism of culture is ethnocentric and that not only is mass, popular, or public culture more diverse than given credit for (e.g., Lang 1957; Kracuer 1949), but also the benefits of mass cultural participation far outweigh the limitations of a mass media distribution system (White 1956; Seldes 1957). Post-World War II America experienced an economic boom that sent its citizens searching for a variety of new cultural outlets. The increase in cultural participation certainly included what some critics might call “vulgar” activities, but it also included a tremendous increase in audiences for the arts across the board. Essentially mass culture defenders assert that the argument over the legitimacy of mass culture comes down to a matter of ideology, one that positions the elitist minority against the growing democratization of culture.

To extricate themselves from this axiological conundrum, many sociologists of culture retreated from a morally evaluative stance to a normative one. As presented by Gertrude Jaeger and Philip Selznick (1964), the normative sociological approach to culture, while still evaluative, seeks to combine anthropological and humanist conceptions of culture through a diagnostic analysis of cultural experience. The emphasis here is on elaborating the nature of “symbolically meaningful” experience, the same focus for culture that Kroeber

and Parsons (1958) take in their differentiation of culture and social system. To do this, Jaeger and Selznick adopt a pragmatist perspective (Dewey 1958) that accords symbolic status to cultural objects or events through a social signification process. Interacting individuals create symbols through the communication of meaningful experience, using both denotative and connotative processes. By creating symbols, interacting individuals create culture. Thus the definition of culture becomes: “Culture consists of everything that is produced by, and is capable of sustaining, shared symbolic experience” (Jaeger and Selznick 1964, p. 663). In establishing this sociological definition of culture emphasizing the shared symbolic experience, Jaeger and Selznick also seek to maintain a humanist-oriented capability to distinguish between high and mass culture without marginalizing the focus on high culture. Following Dewey, they argue that the experience of art takes place on a continuum of cultural experience that differs in intensity from ordinary symbolic activities, but has essentially the same basis for the appreciation of meaning. Art or high culture is simply a more “effective” symbol, combining “economy of statement with richness of expression” (Jaeger and Selznick 1964, p. 664). As such, art, like all culture, is identified through the normative evaluation of experience.

In sum, the high culture-mass culture debate shifted the focus on the concept of culture from a question of appropriate scope to a question of appropriate values. From a functionalist point of view, the health of a society’s culture is not simply an issue of what type of values are advocated, but of how culture serves a moral and integrative function. Yet the mass culture critique was often unable to distinguish the cultural values of elite intellectuals from the effect of these values on society. To escape from this ethnocentric quagmire, contemporary sociologists have generally turned away from an evaluative position toward culture.

THE CONTEMPORARY APPROACH TO CULTURE: MAPPING THE TERRAIN

As mentioned at the beginning of this essay, the contemporary approach to culture is quite eclectic. Despite the elaborate historical lineage of the concept, there is no current, widely accepted, composite resolution for the definition of culture.

Instead, culture is still currently defined through an extensive variety of perspectives, sanctioning a broad, historically validated range of options. While the omnibus definition from the cultural anthropology tradition has been generally relegated to introductory texts, and the elitist attack on mass culture has been largely replaced by an antiethnocentric, relativist position open to a wide spectrum of symbolic arenas and perspectives, many of the elements of these old debates still appear in new cultural analyses.

For example, as categorized by Richard Peterson introducing a review of new studies in cultural analysis at the beginning of the 1990s, culture tends to be used two ways in sociological research; as a “code of conduct embedded in or constitutive of social life,” and as symbolic products of group activity” (Peterson 1990, p. 498). The first perspective is clearly indebted to the traditional cultural anthropology approach and indeed is used to analyze and characterize social units ranging from whole societies (e.g., Cerulo 1995; Bellah et al. 1985) to specific subcultures (e.g., Hebdige 1990, 1979; Willis 1977). Empirical applications using this perspective are also made to geographically dispersed social worlds that organize collective activities (e.g., Lofland 1993 on the peace movement; Fine 1987 on Little League baseball; Latour and Woolgar 1979 on scientific research in biology; Traweek 1988 on scientific research in physics). The second perspective takes the more concrete course of treating culture as specific socially constructed symbols and emphasizes the production and meaning of these specific forms of cultural expression. Most examples of this latter form of cultural research are conducted in substantive arenas collectively known as the “production of culture” (Peterson 1979; Crane 1992), however, the range of empirical focus for this perspective is considerable and includes research in such areas as the moral discourse on the abortion issue (Luker 1984), the politics and aesthetics of artistic evaluation and reception (DeNora 1995; Lang and Lang 1990; Griswold 1986), and the motivational and ideological context of organizational, professional, and work cultures (e.g., Fine 1996; Martin 1992; Katz 1999; Fantasia 1988; Harper 1987; Burawoy 1979).

From the array of activities mentioned above, it is clear that the contemporary concept of culture

in sociology does not exclude any particular empirical forms of activity, except perhaps through an emphasis on shared or collective practices, thus discounting purely individual foci. Since all collective social practices are potentially symbolic and therefore culturally expressive, any collective activity can be reasonably studied under the rubric of the sociology of culture. This “open borders” philosophy has at times made it difficult for participants in the sociology of culture to establish any kind of nomothetic perspective for cultural theory. The vast differentiation and sheer complexity of the expression of culture in various forms of social life resists ready categorization. Instead, participants in the sociology of culture have usually opted for the preliminary step of surveying and mapping the terrain of research in the sociology of culture with the goal of helping to define emerging theoretical perspectives in the field. Two particularly informative efforts are the contributions of John Hall and Mary Jo Neitz (1993) and Diana Crane (1992, 1994).

In *Culture: Sociological Perspectives* (1993), Hall and Neitz provide an excellent overview of the substantive and theoretical directions in which research in the sociology of culture has proliferated. They identify five “analytic frames” (p. 17) through which researchers can focus on particular aspects of culture and that emphasize associated processes of inquiry. The first frame is a focus on “institutional structures”: that is, research on culture specifically linked with social institutions and such issues as the construction of social and personal identity and conventional or moral conduct (e.g., Bellah et al. 1985; Gilligan 1982; Warner 1988). In the second analytic frame, Hall and Neitz describe “cultural history” and the influence of past cultural practices on the present. Research in this area includes a focus on the significance of rituals (e.g., Douglas 1973; Goffman 1968, 1971; Neitz 1987), the effects of rationalization on social processes and cultural consumption (e.g., Foucault 1965; Mukerji 1983; Born 1995), and the creation of mass culture (e.g., Ewen 1976; Schudson 1984). In the third analytic frame, Hall and Neitz focus on “the production and distribution of culture” with a special emphasis on stratification and power issues. Research in this area includes work on the socioeconomic differentiation of cultural strata (e.g., Gans 1974; Bourdieu 1984; Lamont 1992), gender and ethnic cultural differentiation and

their effect on inequality (e.g., Radway 1984; Lamont and Fournier 1992), and the production of culture (e.g., Becker 1982; Gilmore 1987; Hirsch 1972; Coser, Kadushin, and Powell 1982; Faulkner 1983; Crane 1987). The fourth analytic frame, "audience effects," looks at how cultural objects affect the people who consume them and the precise patterns of shared meaning and interpretive ideology that provide a compatible environment for the popular and critical success of particular cultural forms (e.g., Wuthnow 1987; Baxandall 1985; Long 1985). Finally the fifth analytic frame, "meaning and social action," refers to how actors in varied mainstream and subcultural settings use culture to guide behavior and establish social identity. In a range of ethnic, political, and ideological contexts, participants use visible expressive symbols and styles to assert cultural difference and communicate the social and personal significance of cultural objects (e.g., Rushing 1988; Ginsberg 1990; Schwartz 1991; Fine 1987).

These frames serve different purposes. For the nonsociologist or for sociologists from outside the field of culture, they provide a guide to current cultural research and a reasonably accurate descriptive picture of research segmentation within the field. For the sociologist of culture, however, these frames represent not only a "division of labor in sociohistorical inquiry, in the sense that any particular frame seems to generate boundaries. . . (within in the field), as Hall and Neitz claim (1993, p. 19), but a strategy to bring analytic coherence to a field that has experienced remarkable growth and empirical diffusion over a relatively short period. As such, in the future these frames may emerge through collective activity as problem areas within the field of culture that will guide empirical and methodological tendencies within particular research communities and influence theoretical interaction, that is, co-citation among researchers. The precise impact in the field, however, still remains to be seen.

A somewhat different mapping, primarily in terms of theoretical emphasis, is offered by Diana Crane in her book *The Production of Culture* (1992) and through her efforts as editor of *The Sociology of Culture: Emerging Theoretical Perspectives* (1994). Like Hall and Neitz, Crane seeks to help codify research segmentation in the field of culture, but she does not try to accomplish this daunting task simply by producing a comprehensive survey of

current research in the field. Instead, she attempts to give the reader a guide to theoretical issues in the sociology of culture, particularly the place of the concept of culture in the discipline of sociology as a whole, and how the centrality of culture as a variable in mainstream sociological models will determine the significance of future research in the field.

To start, Crane argues that culture has traditionally been regarded as "peripheral" to mainstream concerns in American sociology because of its relationship to classical theory (i.e., Marx, Weber, Durkheim). In comparison to the emphasis by these theorists on social structure, organization, and market forces, cultural elements have been consistently treated as secondary in their impact on peoples' behavior and attitudes, particularly surrounding significant life issues (e.g., economic considerations). One reason for this secondary status may be the difficulty classical and mainstream theorists have in conceptualizing and documenting everyday cultural practices. Crane states, "To American and some British structuralists, culture as a concept lacks a suitably rigorous definition" (Crane 1994, p. 2). And from Archer (1988, p. 1), "the notion of culture remains inordinately vague. . . In every way, 'culture' is the poor relation of 'structure.'" Thus culture, approached as the values, norms, beliefs, and attitudes of a population or subgroup, is treated as "an implicit feature of social life. . ." (Wuthnow and Witten 1988, p. 50-51), difficult to put one's finger on, and therefore difficult to document through specific empirical referents.

But Crane argues that culture in contemporary society is much more than implicit features. She states, "Culture today is expressed and negotiated almost entirely through culture as explicit social constructions or products, in other words, through *recorded culture*, culture that is recorded either in print, film, artifacts or, most recently, electronic media" (Crane 1994, p. 2). Further, contemporary sociologists of culture have tended to focus on this "recorded culture" as the principal empirical referent through which various types of contemporary culture are expressed and thus can easily be explored. Not surprisingly then, the primary direction through which the new sociology of culture has proliferated is in areas like art, science, popular culture, religion, media, technology, and other social worlds where recorded

forms of culture are readily accessible. These culture subfields have become the central substantive foci through which the field as a whole has undertaken to build theoretical coherence.

At the same time outside the boundaries of the field of culture per se, it is also clear from recent research in the 1990s that the concept of culture has gained significant relevance in many mainstream areas of the discipline that have traditionally been dominated by macrostructuralist approaches. For example, in both Ewa Morawska and Willfried Spohn's (1994), and Mabel Berezin's (1994) contributions to Crane's *The Sociology of Culture: Emerging Theoretical Perspectives*, the impact of cultural forces are discussed in a variety of macroinstitutional contexts. Morawska and Spohn's focus on examples from the historical perspective includes research on the effect of ideology in the macrostructural analysis of revolution and social change (e.g., Sewell 1985; Skocpol 1985; Goldstone 1991), issues of working-class consciousness and capitalist development (e.g., Aminzade 1981; Calhoun 1982), and the articulation of new forms of religious and ideological doctrines in a social-institutional context (e.g., Wuthnow 1989; Zaret 1985). Berezin's chapter examines the relationship of culture and politics in macromodels of political development and state formation (e.g., Greenfeld 1992; Mitchell 1991). Additional examples in organizational or economic contexts (e.g., Dobbin 1994; Granovetter 1985) only further emphasize the point, that the expanding application of cultural analysis to mainstream models means that for many sociologists, culture is more an explanatory perspective than a substantive area of study. As such, future limitations on the explanatory potential of cultural analysis in sociology will likely be conceptual, not empirical, and the above research suggests a broadly fertile spectrum of empirical possibilities.

Finally, a significant elaboration of the explanatory potential of cultural analysis has taken place in a field organized largely outside the discipline of sociology. "Cultural studies," identifying a loosely connected, interdisciplinary network of scholars from a wide spectrum of perspectives, including the humanities, the social sciences, the arts, and various status-specific programs (e.g., ethnic studies, feminist studies, gay and lesbian studies), has produced a tremendous number of

new kinds of cultural analyses that have implications for the sociology of culture. The approach to cultural analysis, however, is often radically different, both empirically and theoretically, than that conventionally used by sociologists. Cultural studies approaches range from a cultural text-based analysis that interprets meaning and sources of social influence directly from cultural objects (e.g., Hooks 1994; Giroux 1992; see Fiske 1994), to complex interpretative decodings of narratives around issues such as identity politics (e.g., Trinh 1989; Hall 1992) and postcolonial repression and resistance (e.g., Appadurai 1990; Grossberg et al. 1992). As a consequence, the history and emerging relationship of cultural studies to sociology is rather piecemeal. Indeed, Norman Denzin (1996) characterizes the potential association to be one of "colonization"; that is, "the attempt to locate and place cultural studies on the boundaries and margins of academic, cultural sociology" (Denzin 1996, p. XV). Others see the possibility of more reciprocal exchange with the possibility of a "revitalization" for sociological cultural perspectives (Seidman 1996). Whichever way the relationship develops, it is clear that efforts to rethink the concept of culture, the impact of cultural values, and approaches to cultural analysis that take place outside of sociology and even outside of academia will have an invigorating effect on the sociological conceptualization of culture. These battles (i.e., "culture wars") already have had important consequences for policy and resource allocation in education (e.g., Nolan 1996; Hunter 1991). There is no reason to think that sociology will or should be immune to these external influences.

In sum, there is a new appreciation of the salience of culture as an explanatory perspective in contemporary sociological research. Whether it involves the convention-setting influence of art worlds, the moral authority of organizational cultures, or the facilitation of class privileges through habitus, the concept of culture is used to explain behavior and social structure from a distinct and powerful perspective. The future elaboration of this perspective in sociology looks very promising.

D

DATA BANKS AND DEPOSITORIES

CONCEPT AND HISTORY OF DATA-BANKS

The tradition of thought that gave rise to the social sciences was based on the quest to understand the laws or regularities governing the emerging industrial societies with democratic political regimes. The political and economic revolutions that were shaking the world substituted the relative predictability of the traditional ways of handling power and production with the disconcerting uncertainties of political consensus and the new market of commodities.

Finding such laws was not easy. The model for scientific inquiry established by the successful endeavors in the various fields of physical and natural sciences was not applicable to social science research. For a period social scientists believed that the complexity of the social object and the immaturity of the field were responsible for the failure of the natural science model. Social scientists gradually became aware, however, that the epistemological foundations of the social sciences were different: in practical terms, because creating an experimental situation in social matters is extremely difficult; and in theoretical terms, because society is a moving target, readily reacting to changes in circumstances. In the end, mainstream social scientists learned to live with these difficulties.

The Newtonian challenge of formulating hypotheses, collecting the relevant data, and accepting only those hypotheses that fit observational

data, has been in one way or another the stimulus and the standard of advances in knowledge in the many fields that later composed the social sciences. The systematic collection of empirical observations has been the ballast that has kept modern social sciences from drowning in second-rate philosophy or outright ideology. Numerous social researchers and thinkers have stood up to the challenge of providing reliable observations on the social world. (Since every observer is also a member of society, it is not easy to stand aside and look at it from a fixed point of view.)

In retrospect it is understandable that different paths to the common goal of collecting systematic reliable data were tested with various methodological and technical tools, not always being understood as part of the same endeavor. In the latest bout of cultural dominance of Marxist theories, Karl Marx and his school were viewed as “grand theorists” squarely opposed to the “abstract empiricism” of contemporary sociology. But this was a misconception that completely overlooked the many years spent by Marx painstakingly collecting data on industrial society, and by desire to be a scientist like Charles Darwin—to whom he dedicated the book produced by his gigantic research effort, *Das Kapital*.

Despite the apparent confusion and turmoil, there was an underlying paradigm. Social sciences had to be empirical. No matter how radically critical and antipositivistic have been the epistemological conclusions of the various *Methodenstreiten*, the mainstream has resisted the idea of a data-free

social science. Altogether such theoretical orientation has provided this disciplinary area with a fairly resilient ballast against ideological nebulosities. And this can be said safely without underestimating the humongous and repetitive production of irrelevant trivia in tabular or graphic form produced over the years by the low-brows of “abstract empiricism”. Data, however, are a peculiar commodity insofar that they have to be produced. Which means most of the time it is costly, painstaking, and time consuming to produce data. By and large, data belong to one of two families. *Primary data* are collected by the researcher himself. *Secondary data* are collected by other agencies, mainly public and private large-scale organizations, in which case the researcher can only perform what is known as *secondary analysis*, and he obviously has no control over the collection of this data. In the latter case it is also useful to further distinguish between data collected for analytical purposes by agencies like the various census bureaus, and those collected for administrative purposes, such as data on health collected by hospitals, or data on education collected by educational institutions, or mortality data collected by governments and other agencies. These are *process-produced data*; data created as by-products of administrative activities.

There are disciplinary areas that have a high degree of institutional stability and control over their data such as physics, but also engineering, medicine or law. The latter two fields, of course, provided the original kernel for the development of universities and *studia generalia*, in Bologna, Padova, or Salerno. Other fields are less stable, usually in the area of the humanities and the social sciences. But in all cases the organized character of the type of knowledge provided by academic disciplines is predominant.

Organized knowledge is the practical rather than speculative knowledge accumulated by governments and their administrative apparatuses, by corporations, political parties, trade unions, churches, and other institutions. Thomas Kuhn has been the leading figure in analyzing innovation processes in the institutions of *organized knowledge* (Kuhn 1962). These types of secondary data are essential for social scientists, and in fact, as noticed long ago by Paul F. Lazarsfeld and Stein Rokkan, among others (Rokkan 1976), the work of sociologists,

especially in Europe, is largely based on interactions with the institutions in charge of this type of knowledge.

Le Suicide by Emile Durkheim is an excellent example of the advantages and drawbacks of secondary analysis of process-produced data. This masterpiece of sociological research gave empirical evidence of the theoretical tenet that a cogent collective agent can influence individual behavior even to the extreme gesture of annihilating the genetic commandment. It could not have been written without access and a hard sweated one at that, to secondary data. No individual scientific actor could collect data on events that are so numerous, and so highly dispersed in time and space. On the other hand, relying on data collected by other agencies means that the researcher relies on somebody else’s definition of events. One of the most damaging critiques to Durkheim’s work is that his sophisticated theoretical definition of suicides, is nullified by the fact that the cases of suicides in the data used were defined by officers or judges according to completely different, and uncontrollably variable, criteria.

The work of historians, too, would probably not be possible without access to the *organized knowledge* embodied in the archives of agencies of all kind. The early development of economics as a quantitative discipline was greatly favored by the availability of organized knowledge collected by public administrations. The same applies to demography, which could base itself also on data accumulated by the church, and in general to the whole field of statistics, which could today be defined as policy sciences (Cavalli 1972).

The Durkheim syndrome, the need to use data not collected by scholars, but by public employees, is a constant problem for social scientists using information coming from the realm of organizational knowledge. At the beginning of the nineteenth century Melchiorre Gioja expresses the irritation of a scholar dependent on low-quality public data. He took issue with “the many questions that various inept busybodies called secretaries send from the capital to the province. Questions that never produced other than the following three effects:

1. fear that the Government seeks the basis for some aggravation, and therefore opportunistically false answers;

2. ridicule resulting by the silliness, inconsistency, and imprecision of the questions, and thus answers biased by contempt;
3. heaps of paper uselessly encumbering archives, if the government mistrust them, or very serious mistakes if it uses them, not to speak of the time stolen from the municipal or provincial administrators who must prepare the answers." (Gioja 1852, p. 5)

A powerful answer to these problems came from the development of *survey research*, particularly from the 1940s on by American sociologists who developed the "art of asking why"; namely the inquiry into the rational motivations of individual behavior. It is not surprising that these new methods originally developed in two crucial areas of behavior: the choice of candidates in an electoral process, and the choice of a product in consumption behavior. There has been much criticism of mercantile attitudes in voting, and of course it is quite clear that some of the value motivations that are mobilized in choosing a candidate are evidently not the same as those that are mobilized in picking up one granola package rather than another from a shelf. But the critics miss the point. The two areas of behavior are similar, and the inquiry into behavioral motivations should not be diverted by undue considerations of political or ethical correctness. Little wonder that scholars had to develop new data collection tools on this type of behavior. And equally not surprising is that political and economic elites are willing to invest resources in the arduous enterprise of predicting the aggregate outcome of individual behavior. A prudent politician today constantly monitors the opinion of the electorate. And economists make use not only of large-scale models of the behavior of macroeconomic systems, but also of assessments of consumer behavior. Politicians, bureaucrats, entrepreneurs, and managers would have a hard time doing without the tools provided by the social sciences.

Survey data collection methods, however, presented the social scientist and his institutions with novel problems. Pollsters and survey people in general produce huge quantities of individually uninteresting questionnaires. Punched cards were developed to hold data; at first the cards were processed manually as the "McBee cards," but

soon after machine-readable cards were developed, such as those punched with the Hollerith code (universally known as IBM card). Cards were easier to store than questionnaires, but it was easy, in a routine research process, to lose the "codebook" of the research so that in many cases the cards were useless, even if they contained relevant information (Rokkan 1976). Thus the storing, handling, processing, and redistributing of punched cards required specific skills. Furthermore, the traditional institutional structure of universities and research centers is not well adapted to take on these tasks. Originally social scientists turned to libraries to store their data (Lucci and Rokkan 1957), but in the late 1950s and early 1960s libraries were not equipped to handle large masses of data requiring mainframe computers. The big machines were housed in separate structures and tended by IBM technicians. Social scientists had limited access to the mainframe computers and therefore, the data, until the scientists developed their own separate institutions on the model of the Inter University Consortium for Political Research at Ann Arbor, Michigan (ICPR, later turned into ICPSR when social research was added). In Europe the vision and farsightedness of scholars such as Philip Abrams in the United Kingdom, Stein Rokkan in Norway, and Erwin Scheuch in Germany, helped establish the first archives in Essex, the Social Science Research Center, in Bergen, the Norwegian Data Service, and in Koeln, the Zentralarchiv für Empirische Sozialforschung. Later on these archives developed their own organizations, first IFDO, International Federation of Data Organizations, and later on CESSDA, Council of European Social Science Data Archives. Archives developed in Italy at the Istituto Superiore di Sociologia of Milano (ADPSS), in Denmark (DDA), in the Netherlands (the Steinmetz archive), in Belgium (BASS), and in France (BDSP in Grenoble and in several other places).

SOCIAL SCIENCE DATA ARCHIVES

Cultural and technological changes led to the creation of Social Science Data Archives (SSDA). SSDA are scientific institutions that retrieve, store, and distribute large amounts of data on social science. The oldest and the most important SSDA were established in the United States—where an emphasis on quantitative social research is deeply rooted—when there was growing attention by both

public administration and the scientific community to the use of social indicators as standards for the population welfare level. These social actors turned to social indicators for help in planning, applying, and the evaluating public-assistance programs when it became apparent that using economic indicators alone was insufficient and inappropriate.

The first major contribution of social indicators is the *Recent Social Trends* study, supervised by the sociologist William Ogburn and prescribed by the U.S. Government toward the end of the 1920s (Bauer 1966). In 1946 the *Employment Act* was published, which was a systematic collection of information on economy intended to affect policies and programs that would sustain employment rates. Most of the studies and undertakings of the 1960s described a "great society," which could overcome the widening economic and social gap.

The consciousness of social problems, together with the necessity of endowing a collection of social data, prompted the publication of *Towards a Social Report* at the end of the 1960s (Olson 1974). This publication was intended to be "a first step toward the evolution of a regular system in social reporting;" but still, like other similar and contemporary writings, data were used just as illustrations supplementing the text.

Technological developments that contributed to the establishment of SSDA include previously unseen data collection techniques and new quantitative methods to organize and analyze those same data. Throughout the 1960s improvements in computing technologies, specifically in data gathering and storing, allowed researchers to do previously unthinkable levels of analysis (Deutsch 1970).

The first SSDA were born autonomously, unrestricted by publicly administered archives or by the institutions traditionally related to the collection and promotion of data (libraries, museums, and data archives). The earliest SSDA were created in the United States, where in 1947 the Roper Public Opinion Research Center opened, followed by the Inter-University Consortium for Political and Social Research (ICPSR) in 1962 at the University of Michigan in Ann Arbor. In 1960, the University of Koln in Germany developed the Zentralarchiv für Empirische Sozialforschung (ZA). A few years later, in 1964, the Steinmetzarchief settled in at the

Amsterdam Arts and Sciences Real Academy. The Economic and Social Research Council Data Archive (ESRC-DA) was created at the University of Essex in 1967. These archives specialized in public opinion surveys and social research, but they also focused attention on the great amount of data compiled by statistical bureaus and public agencies (Herichsen 1989).

SSDA developed a culture of data sharing; data exchange and the repeated use of available data for new research projects intensified with the introduction of statistical packages for the social sciences and more compact media for data transfer. As data production and SSDA grew, more systematic acquisition policies were implemented, and transborder cooperation resulted in the exchange of data processing tools and of emerging archiving and service standards (Mochmann 1998).

In the early 1970s SSDA were created: in Norway in 1971, in Denmark in 1973, and in the United States (at the University of Wisconsin in Madison, U.C.L.A., and the University of North Carolina in Chapel Hill). In the 1980s SSDA were created in Sweden (1980), France (1981), Austria (1985), and then Canada, Hungary, Israel, Australia, New Zealand, and Switzerland (1993).

Currently, the most important SSDA is the ICPSR at the University of Michigan, which has over 40,000 data files and gathers information from more than 300 institutions. Besides data retrieval, processing, researching, and transferring, it publishes an annual catalog and a four-monthly bulletin, cooperates in great projects concerning data collection (e.g. the *General Social Surveys* and the *Panel Study on Income Dynamics*), conducts formative training (it organizes a summer school on methodology and statistics for social science), and offers educational activities. The ICPSR has been open to foreign institutions since the early 1970s.

SSDA differ on budget and staff size, functions, amount of data files in archives, and technical characteristics (e.g. type of hardware and software used, online data accessibility) (IFDO 1991). The SSDA network is tied, however, by international associations such as the Council of European Social Science Data Archives (CESSDA was instituted in 1976 to facilitate cooperation between the most important European SSDA), and

the International Federation of Data Organizations (IFDO was founded in 1977 to enhance the cooperation already started by CESSDA).

CESSDA promoted the acquisition, archiving, and distribution of data for social research throughout Europe, facilitated the exchange of data and technology among data organizations, and supported the development of standards for study description schemes to inform users about the archival holdings, classification schemes for access to variables by subject and continuity guides for coherent data collections. In the 1970s and 1980s, European membership grew continuously and CESSDA started to associate and cooperate with other international organizations sharing similar objectives. Today Europe has a good coverage of CESSDA member archives, while planning processes are under way in several more countries that still lack a social science infrastructure.

Recent trends reveal a type of limitation to the growth and proliferation of national SSDA. This occurs partly through the opening of decentralized bureaus and partly through more specialized data file collections—ones with more well-defined inquiry areas. Exemplary regarding this last issue is the *Rural Data Base* of the ESRC, or even the CESSDA internal agreement aiming at a study field subdivision between the different European SSDA (Tannenbaum 1986).

SSDA have been useful not only in their specific field (especially retrieving, storing, gathering, and making available data) but also have improved general quantitative research techniques, secondary analysis, statistical and administrative software packages, and have made available the best hardware in social research. Most of the SSDA publish their own bulletins, organize methodology schools for social science, hold updating seminars, and cooperate in research projects. In the second half of the 1980s SSDA were particularly active in defining the standards for the information system to be used among these institutions. More recently, SSDA have been working on international access practices on two levels: developing standard study description procedures (to define each data file) and promoting access to online archives.

SOCIAL SURVEY INSTRUMENTS

Major social survey instruments are those institutionalized initiatives that have produced some of the most interesting results from the autonomous research applied to problems of general interest. The *General Social Surveys*, the *Continuous National Surveys*, and the *U.S. National Surveys* are the most interesting examples of longitudinal studies. Eurobarometers and the International Social Survey Program (ISSP) are discussed here because, although not strictly comparable to general social surveys, they are two of the most comprehensive and continuous academic survey programs. Although it is not discussed here, a student of the social sciences should examine the *European Household Panels*. This project integrated national household panels from Germany (since 1984), Sweden (since 1984), Luxembourg (since 1985), France (since 1985), Poland (since 1987), Great Britain (since 1991), and Belgium and Hungary (since 1992). These panels include variables on household composition, employment, earnings, occupational biographies, health, and satisfaction indicators. (In order to create an international comparative database for microdata from these projects, the Panel Comparability Project (PACO) was formed).

General Social Surveys. General Social Surveys (GSS) were developed to set out data on demographic, social, and economic characteristics of the population, as well as opinion data on social life (e.g. family, politics, institutions, relationships). This important survey instrument improved over time. In the mid 1940s the Survey Research Center of the University of Michigan conducted panel studies on a national level on specific issues, such as political behavior, socioeconomic status, and consumers' attitudes. In the early 1970s, the National Opinion Research Center (NORC) of the University of Chicago organized the first GSS, which was immediately followed by the Continuous National Surveys program.

Following the consolidation of the research method based on enlarged quantitative surveys on a national level, some institutions committed to the transfer of the results, both within the U.S. academic community and toward universities and research centers worldwide. One should note that data provided by the GSS are given a particular treatment inside the ICPSR, which, besides transferring the data, gathers the sociologists interested

in the study and the arrangement of social indicators. The importance of the GSS in U.S. social research is exemplified by the more than 1,000 publications related to GSS data analysis listed in the catalog prepared by NORC.

The GSS is done through interviews of a representative sample of U.S. residents who are over 18 years old and are not institutionalized. Representativeness is guaranteed by a complex sampling mechanism, which relies on a multilevel selection over metropolitan areas, municipalities, regions, and individuals. Sampling criteria have been modified throughout the course of different GSS, but to keep the results comparable between one edition and the following ones correctors have been added to allow for these adjustments.

The GSS questionnaire consists of standard questions that are asked each time, and sometimes groups of questions on specific themes are included. The topics treated are the ones most interesting in the study of society and its trends, with a particular focus on family, economic and social status, gender and ethnic group relationships, and moral questions. Political behavior and working activity are not included because the former is already studied in detail through surveys organized by the Institute for Social Research of the University of Michigan, and the latter is well described in the research on labor forces arranged by the U.S. Bureau of the Census.

Given that one of the fundamental aims of the GSS is to provide a general view of time trends, not only in population characteristics, but also and overall in opinions, evaluations, and behaviors over the most important topics describing the social scenery, these questions are included only from time to time, so the questionnaire is not weighted excessively. Some questions are included only two years in three, others every 10 years, and some only after particular and significant events. Over 100 sociologists worked on the first draft of the questionnaire (in 1972). These sociologists devised a final, definite version by voting for each single question. Every year the selection of questions is done by an ad hoc committee, selected by American Sociological Association members.

Some questions utilized in the GSS come from the national surveys run before 1972 that were promoted by commercial research institutes (e.g.

Gallup, Harris), university research institutes (especially ICPSR), and also federal commissions organized to study particular phenomena. Data comparability is assured by the question scheme, which is the same of the original study.

Continuous National Surveys. The *Continuous National Surveys* (CNS) are national studies (the first one dates back to 1973) conducted monthly, with the aim of supplying the various governmental agencies with the necessary data (e.g. welfare indicators) to schedule social programs. The sample plan consists of persons selected on the basis of their living groups. On this regard, the NORC has carefully prepared a master probability sample of households, that is, a multi-stage sample to collect on a first stage municipalities or else groups of municipalities. From them, all districts or block groups are selected, and then the proper cohabitational groups in which to choose the individuals to interview are selected.

U.S. National Surveys. U.S. national surveys on representative samples of U.S. population have been held since 1974 by the Survey Research Center of the University of Michigan. Some of these studies are held regularly (e.g. the *Surveys of Consumer Finances*, the *Survey of Consumer Attitudes and Behavior*, and the *Panel Studies of Income Dynamics*). In particular, the yearly *Panel Study of Income Dynamics* is one of the most interesting surveys on income trends, and, specifically, on the possible causes for changes in the economic status both of households and single individuals.

The representative sample initially extracted consisted of 2,930 households, to which has been added 1,872 households that were already survey subjects by the U.S. Bureau of the Census on the income topic in the two previous years. Each year these households are re-interviewed, and the sample has grown as members of the original sample established new households. For the first time ever, phone interviews were tested in these researches, and since then the telephone has become broadly used in social research and panel studies.

Eurobarometers. Eurobarometers are opinion studies that have been held twice a year since 1973 in what are now the European Union countries. These studies sample about 1,000 individuals for each country, which represents the population

over 15 years-old. The aim of these comparative surveys is to learn about the attitudes of European citizens on some broad interest topics. Questions regard public attitudes toward European integration, but sometimes also address specific problems of a single country or more generally economic, political, and social conditions. Two important functions of Eurobarometers are: being cross-national and easily comparable surveys, they helped integrate social research throughout Western Europe; and, they allowed (and still allow) analysis on social changes in Western Europe. As a matter of fact, there is no survey similar to eurobarometers in what concerns a regular check over time (more than 20 years to date) and space (every single European country). Eurobarometers are now at the disposal of the academic community thanks to the ICPSR and the ZA of Koln.

The International Social Survey Program. The International Social Survey Program (ISSP) combines a cross-national survey with a longitudinal time dimension by replicating particular question modules, ideally in five year intervals. The first survey on the “role of government” started in 1985 in four countries (the United States, Great Britain, West Germany, and Australia). Since then the ISSP has grown rapidly and now covers more than 30 countries around the world, including Bulgaria, the Czech Republic, Hungary, Latvia, Poland, Russia, and Slovenia. Topics of the ISSP have included social networks (1986), social inequality (1987, 1992), family and changing gender roles (1988, 1994), work orientations (1989, 1997), religion (1991), and environment (1993). Role of government was replicated in 1990 and 1996. The official data archive of the ISSP is the ZA, which makes the integrated data sets available via the archival network.

DEPOSITED, ACCESS PROCEDURES AND USE

The existence of SSDA in Europe and in the United States has had a positive effect on the scientific community because SSDA allow access to some data that is particularly useful in secondary analysis. In other words, researchers can collect and use data from different surveys (with particular hypothesis and conceptual frames) to support their own works.

SSDA vary on the type and volume of data that is held and delivered and on the exact services offered. The data differ within and between SSDA in terms of subject matter, time period, and geographical area covered. The data may be individual or aggregate, and the variables may be cross-sectional or time series and suitable for comparative or longitudinal analysis, or both. Charging policies differ from one SSDA to the next and depend upon the type of service being provided, the specific data set demanded, and the institutional affiliation of the requester.

Many data formats are used by SSDA to preserve and deliver the data that is increasingly required to be machine readable, and there is also an increasing demand for the archiving and disseminating of machine-readable metadata.

Despite the heterogeneity of SSDA, there are common goals and tasks. Although we know more about the SSDA in Western Europe, we hope to represent all SSDA in the following list of goals and tasks:

- To promote the acquisition, archiving, and distribution of electronic data for social science teaching and research and to exchange data and technology;
- To exploit the potential of the Internet by the expansion of web-based services and the improvement of dissemination to allow users more direct and immediate access to the data;
- To develop and use metadata standards for the management of data;
- To provide users access to comparative data and to multiple data sources across national boundaries;
- To allow users to receive all or subsets of data via download or on portable media in one of a number of formats;
- To extend the users' base beyond traditional boundaries;
- To better serve the needs of an increasing number of novice users, particularly in terms of data analysis software and improved searching aids through the development and use of social science thesauri and user-friendly interfaces.

The technological changes that contributed to the creation of SSDA have had far-reaching significance for social scientists. The changes throughout the 1990s were considerable: from simple writing (word processing) to data production (especially computer assisted interviewing technique); from archiving (from punch cards to floppy disks and CD-ROMs) to data analysis (the creation of various new software); from bibliographic reference (online access to bibliographic databases) to communication (e-mail) (Cooley and Ryan 1985). The boundaries of technological innovations are not yet clear. The compound archive of integrated data, text, images, and sounds (Garvel 1989), and the Geographical Information System, by which we can analyze data concerning space are examples of previously unimagined products that are possible because of computers (Unwin 1991). These instruments require high-level storing proceedings so that data can be a real resource in the development of empirical knowledge.

While social research in earlier decades lamented the lack of reliable data (in the 1960s the social sciences were considered data poor, and infrastructural support for social research was lacking) the situation has changed. Thousands and thousands of data sets, some of them dating back to the 1940s, are stored for secondary analysis in SSDA. These data sets represent a vast potential for comparative research on historical developments and social change.

PROSPECTS FOR THE FUTURE

In 1994, the European Commission recognized Social Science Data Archives as legitimate institutions to be considered as applicants to the large-scale facility program for scientific research. This is tantamount to recognizing that the social sciences have infrastructure needs equal to those of the "hard" sciences. This goal was originally pursued through the work of a study panel created by the General Directorate for Science and Technology of the European Commission and particularly its Training and Mobility of Researchers program. The study panel met twice, and was entrusted with the tasks of: a) identifying the future priorities of European scientists concerning access to large installations in the social sciences, both in the

short and in the medium term (i.e. in the period 1994–2004); b) suggesting ways to meet these priorities—with an indication of their respective costs and benefits—in light of the present and expected availability of large installations, taking into account existing and planned future international cooperations, both within the community and outside as well as the particular needs of researchers working in regions where such installations do not exist; and c) consulting representatives from member states and reporting on what facilities, if any, might be available for possible support in the frame of successor programs. A large-scale facility has, to date, been defined as a large research installation that is rare or unparalleled in Europe and that is necessary for high-level good-quality research. Such facilities tend to have high initial costs of investment and comparatively high operating costs. The large-scale facilities program is intended to provide scientists with access to large installations within and especially outside their own countries, thereby promoting the mobility of researchers and encouraging the creation of a Europe-wide research community. And likewise, these installations are better utilized when their services, facilities, and knowledge are available to a wider community of users. Thus the beneficiaries of the large-scale facilities program are researchers who are provided with access to the facilities and the organizations that receive support for the use and improvement of their equipment. The level of support for such facilities has, to date, been based on the quality and unique features of the facility and the value—particularly in advanced training—to potential users.

As a sequel to the work and recommendations of the study panel, between 1994 and 1999 three Social Science Data Archives, the SSRC Essex archive, the German ZA, and the NSD in Bergen have been included in the large-scale facilities program together with other social science institutions. In addition the General Directorate for Science and Technology created a round table on large-scale facilities in the social sciences. This round table was constituted by the European Union commission to suggest actions needed to support a given field of scientific activity. The prospects of Social Science Data Archives are thus quite positive, and for the first time they have been given a tool capable of furthering their original aims.

GUIDO MARTINOTTI
SONIA STEFANIZZI

DEATH AND DYING

This essay asks three questions about death and dying: 1) Why should an entry on such phenomena, which are clearly of interdisciplinary interest, appear in an encyclopedia of sociology? 2) What

related topics have been studied by sociology? 3) What issues are currently pending that call for sociological attention?

DEATH AND DYING AS A FIELD OF SOCIOLOGICAL INQUIRY

The answer to the first question is not readily found in the history of sociological thought, although Victor Marshall once bemoaned the fact that Georg Simmel in 1908 had identified but had not pursued the topic as suitable for sociological inquiry, and a half century later the topic was thought to be a neglected area for sociology (Faunce and Fulton 1958). On other hand, Fulton reminds us that "sociological interest in death is coexistent with the history of sociology" (Fulton and Bendiksen 1994; Fulton and Owen 1988). Both Marshall and Fulton are correct in that the "interest" has typically been peripheral. Herbert Spencer had noted that social progress depended on the separation of the world of the living from the world of the dead, but that was hardly his central theory. Emile Durkheim's *Suicide* depends on an elaborate theory of "anomie," not on any theory of death. Max Weber deals with the fact of death in that it interrupts the pursuit of one's calling—a basic observation later developed by Talcott Parsons. William Graham Sumner wrote widely about such death-related topics as fear of ghosts, mortuary rituals, widowhood, infanticide, war, and even the right to die, but all such references were illustrative of some more general point. In 1956 Herman Feifel chaired a conference on death for the American Psychological Association.

There may well be other precursors, but a bit of history suggests how and when sociology may have staked out its disciplinary claim in a field that had long been cultivated by medicine, theology, ethics, philosophy, law, and psychology.

In May 1967, as part of a new program on "Death Education" at the University of Minnesota, Robert Fulton, a sociologist, arranged perhaps the first interdisciplinary conference on death and dying in the United States. Fulton had just published his ground-breaking book *Death and Identity* (1965), the purpose of which was to help in "preserving rather than losing . . . personal identity . . ." when facing death. It was a time of broad and diverse interest in the subject. Examples had been popping up in many domains: Jay Lifton's notes

on the Hiroshima bombing; Eric Lindemann's report on the psychiatric effects of the disastrous Coconut Grove fire in Boston; Avery Weisman's clinical studies of dying patients; Lloyd Warner's interpretation of the meaning of ceremonial events that honor the dead; Herman Feifel's work on social taboos; Richard Kalish's early essays on teaching; Parsons' emerging theory of the relationship of social action to death, and so on. Fulton, clearly aware of these varying expressions of interest, was prompted to try to interpret the diversity and "get it all together." What Fulton did in *Death and Identity* (1965) was to piece together some three dozen edited excerpts from the works of a wide range of experts who had written on an equally wide range of death-related topics. He found American society to be essentially death denying.

The Minnesota Conference, 1967. At the Minnesota Conference of 1967, Alber Sullivan of the Minnesota Medical School and Jacques Choron of the New School of Social Research spoke to various medical and philosophical issues; Jeanne Quint from the University of California reported on the role of the nurse in dealing with terminal patients; Eric Lindemann of Harvard Medical School discussed the symptomatology of acute grief; Herman Feifel of the Veterans Administration, famous for his work on taboos, emphasized that death always carries many meanings; and Talcott Parsons from Harvard probed the topic in broad theoretical terms.

It was a heady agenda but there were some strange omissions. Elizabeth Kubler-Ross, then known to be working on the "stages" of dying (*On Death and Dying*, 1969) was scarcely mentioned, nor was much made of the equally influential work of Barney Glaser and Anselm Strauss (1965), whose book *Awareness of Dying* had been published two years earlier. The participants in the Minnesota Conference were intrigued by various sociological questions. They wrestled with Karl Mannheim's thought experiment of what society would be like if there were no death (Mannheim 1928, 1959). They wondered what mortality and fertility rates had been historically and how they are related (cf. Riley and Riley 1986). They debated Robert Blauner's thesis (Blauner 1966) that death in all known societies imposes imperatives (a corpse must be looked after, property must be reallocated, vacated roles must be reassigned, the solidarity of the

deceased's group must be reaffirmed). They attacked hospital regimens that depersonalized terminal patients, and they challenged the medical profession for treating death as "the enemy" and prolonging life at any cost.

The conference produced extravagant results in anticipating two critical issues: the norms and arrangements for dealing with dying persons were both confused and hazy; and the greater attention paid to caregivers than to dying persons. But the fact that the conference was consistent in insisting that dying always involves at least two persons turned out to be its most important message for the future agenda. Sociological interest in death and dying, of course, did not start with the Minnesota Conference, but what the conference did was to underscore the often overlooked sociological proposition that the dying process is essentially social in nature.

A REVIEW OF SOCIOLOGICAL INQUIRIES

The answer to the second question about related research is more straightforward. A bit of American history shows the range of topics that has received sociological attention. In the 1930s sociological interest in death and dying had focused mainly on the economic plight of the bereaved family (Eliot 1932). In the 1950s attention turned to the high cost of dying and the commercialization of funerals (Bowman 1959). Twenty years later, it shifted to a medley of popular topics of peripheral sociological interest, with many books written on various aspects of death and dying, such as *On the Side of Life*; *On Dying and Denying*; *After the Flowers Have Gone*; *Widow*; *Caretaker of the Dead*; *Death in the American Experience*; *Last Rights*; *Someone You Love is Dying*; *The Practice of Death*; *Grief and Mourning*; *No More Dying*; *Life After Life*; *The Way We Die*; *Death as a Fact of Life*; *The Immortality Factor*; *Facing Death*; *Death and Obscenity*; and *Living Your Dying*. One sociologist termed that burst of literature a "collective bustle," and characterized the "discovery" of death during the 1970s as "the happy death movement" (Lofland 1978). There can be no argument that the topic had become more open. Furthermore, the increasing use of life-sustaining technologies dictated that the circumstances of dying became more controllable and negotiable, even as increasing proportions of all deaths were occurring in the later years.

Little Theoretical Work. Interest in death and dying was varied and diverse during the 1970s and 1980s, and no widely accepted conceptual framework for its study emerged, except that Kathy Charmaz published a seminal book titled *The Social Reality of Death* in 1980. Sociologists had been critical both of the title and content of Kubler-Ross's widely read book *On Death and Dying* (1969) but they recognized the appeal of the subject matter (Riley 1968, 1983). In earlier decades death had been typically viewed as a social transition, as a "rite de passage," but new threads running through the literature were emerging. Formal "arrangements" were being negotiated prior to death, dying persons were generally more concerned about their survivors than they were about themselves, dying individuals were able to exercise a significant degree of control over the timing of their deaths, tensions typically existed between the requirements of formal care and the wishes of dying patients, and similar tensions almost always existed between formal and informal caregivers—between hospital bureaucracies and those significant others who were soon to be bereaved (Kalish 1985a, 1985b; Riley 1970, 1983).

Little systematic attention from sociologists, however, had emerged. *The Encyclopedia of the Social Sciences* (1968) contained but two entries, both on the social meanings of death. Similarly, there are only two indexed references in the 1988 *Handbook of Sociology* (Smelser 1988): one to poverty resulting from the death of breadwinners, the other to the role of death in popular religion. Sociologists had failed to generate any overarching theory. There have been, however, many attempts. Several kernels illustrate the broad range of these theoretical efforts. Parsons (1963) related the changing meanings of death to basic social values; Mannheim (1928, 1952) used mortality to explain social change; Renee Fox (1980, 1981) found that "life and death were coming to be viewed less as absolute . . . entities. . . and more as different points on a meta-spectrum..a new theodicy"; Dorothy and David Counts (1985) specified the role of death in the various social transformations from preliterate to modern societies; Paul Baker (1990), following Lloyd Warner (1959) and others (e.g. Karl and Rinaldi 1983) elaborated the long-recognized theory that images of the dead exert profound influences on the living, and Michael Kears wrote a more general statement in 1989. And

more recently, Fulton has published an essay on "Society and the Imperative of Death" (1994) in which he discusses the role of such customs and rituals as the Mardi Gras, the bullfight, the "Dani" of primitive societies, and other symbolic events in which either societal survival or individual salvation is at stake.

One exception to these various theoretical efforts is found in the sustained work of Marshall and collaborators. Starting in 1975 with a seminal article in *The American Journal of Sociology*, followed by his book *Last Chapters* (1980), he collaborated with Judith Levy in a review titled "Aging and Dying" (Marshall and Levy 1990). Marshall began his work with an empirical field study of socialization for impending death in a retirement village, followed by a compelling theoretical essay on age and awareness of finitude in developmental gerontology, and has been consistently engaged in such theoretical efforts. His basic postulate is that "awareness of finitude" operates as a trigger that permits socialization to death.

Empirical Research Largely Topical. In contrast to theoretical work, the empirical literature shows that sociological research on death and dying has been, and largely continues to be, essentially topical. Studies range widely, from the taboo on death to funerals and the social "causes" of death (Riley 1983; Marshall and Levy 1990). They include the following examples:

Planning for Death. A national survey conducted in the late 1960s showed that the great majority of Americans (85 percent) are quite realistic and consider it important to "try to make some plans about death," and to talk about it with those closest to them (Riley 1970). In addition, bereavement practices, once highly structured, are becoming increasingly varied and individually therapeutic; dying is feared primarily because it eliminates opportunities for self-fulfillment; and active adaptations to death tend to increase as one approaches the end of the life course (i.e. the making of wills, leaving instructions, negotiating conflicts).

Death and Dying in a Hospital. Among such studies, a detailed account of the "social organization" of death in a public hospital describes rules for dealing with the corpse (the body must be washed, catalogued, and ticketed). Dignity and

bureaucratic efficiency are typically found to be at odds (Sudnow 1967). A contrasting account of hospital rules governing disposition of the body in contemporary Ireland is even more sociological in its emphasis (Prior 1989). In another hospital study the “caring issue” has been seen as the main social problem. The selfhood of the dying person is found to be at risk since the hospital is essentially dedicated to efficiency (Kalish 1985b). However, studies suggest that an increasing proportion of deaths may now be occurring at home or under hospice care, which “mediates between the families and formal institutions that constitute the social organization of death and dying” (Marshall and Levy 1990; see also Bass 1985).

The Funeral. The funeral as a social institution has long been of sociological concern (cf. Habenstein 1968). For example, a massive cross-cultural study attests to its worldwide function in marking a major social transition (Habenstein and Lamers 1963; Howarth 1996). Durkheim had emphasized its ceremonial role in facilitating social regrouping. Later sociologists have shown that elaborate and extravagant funeral rites may be more reflective of commercial interests than of human grief or mourning (Parsons and Lidz 1967).

The Bereaved Family. The now classic study (Eliot 1932) of the economic consequences of death on the family stimulated a large literature that documents the general proposition that survivors—particularly significant others—require various types of social supports to “get through” the period of intense personal grief and the more publicly expressed mourning. In today’s societies, the time devoted to bereavement activities is generally shorter (Pratt 1981). This is consistent with Parsons’s (1963) position that in societies characterized by an “active” orientation, the bereaved are expected to carry out their grief work quickly and privately.

Social Stressors as “Causes” of Death. Sociologists and psychologists have investigated a range of individually experienced “social stressors” as causes of death, such as bereavement and retirement. The hypothesis that a bereaved spouse is at higher risk of death (the “broken heart” syndrome, or “death causes death”) has been widely investigated but with no conclusive results. Similarly, retirees in some longitudinal studies have been

shown to experience excess mortality, whereas other investigations have reported opposite results. Retirement is a complex process, not a simple or single event, and the mortality impact of retirement is moot.

In an era in which nursing homes play an important role in the lives of many older people, the mortality consequences of relocation have come under critical scrutiny. Several studies have reported that the “warehousing” of the frail elderly results in increased mortality while in other studies feelings of security in the new “home” are shown to enhance a sense of well-being resulting in lower mortality. Similar caveats apply to macro-level studies that attempt to relate such collectively experienced stressors as economic depressions, wars, and technological revolutions to trends in mortality. Advances in mathematical modelling and the increasing availability of large and relevant data sets make this problem an attractive area for continuing sociological research (see Riley 1983 for details and sources).

Self-Motivated Death. Durkheim’s studies of suicide spawned a wide, diverse, and sometimes confusing research literature. In most such studies social integration is the operative concept. If the theoretical relationship is believed to be unambiguous, the empirical relationship is far from tidy. The literature is vast and well beyond the reach of this review. Apart from suicide, it is a sociological truism that individuals are often socially motivated to influence the time of their own deaths. It has long been noted, for example, that both Thomas Jefferson and John Adams delayed their dying in order to participate in Independence Day celebrations. Several empirical studies have explored this so-called “anniversary effect” in which social events of significance are preceded by lower-than-expected mortality (Phillips and Feldman 1973). Such studies rest on Durkheim’s insight that if some people are so detached from society that they commit suicide, others may be so attached that they postpone their deaths in order to participate in social events of great significance (Phillips and Smith 1990). An example of the mortality impact of personal and local events is seen in studies of the “birthday dip.” One year-long study, in a test area, coded all obituaries for birthdates. The results were striking. Fewer than 10 percent of the deaths occurred during the three months prior to the birth date, whereas nearly half

were reported during the following three months. Along similar lines, several sociological investigations have explored the proposition that some people die socially before they die biologically. These studies center on the notion of "levels of awareness" of death (Glaser and Strauss 1965). When both the dying person and his or her significant others are cognizant of death as a soon-to-be-experienced event, the ensuing "open" awareness may enable them to negotiate various aspects of the final phase of life. Other research on "dying trajectories" involves certainties and uncertainties as to the time of death (Glaser and Strauss 1968).

"The Right to Die." As a final and critical example in this review of disparate empirical work, a basic and far-reaching question is being asked: Does the individual, in a society deeply committed to the preservation of life, have a "right" to die? This has become one of the most profound, complex, and pressing issues of our time (Glick 1992). It involves the "rights" and wishes of the dying person, the "rights" and responsibilities of his or her survivors, the "rights" and obligations of attending physicians, and the "rights" and constraints of the law. The human side of such issues is producing a tidal wave of expressions of public interest in television documentaries, opinion surveys, editorials, pamphleteering, and radio talk shows. The issue of euthanasia is openly debated in leading medical journals, an unthinkable topic only a few years ago. Hospital rules, in which do not resuscitate (DNR) orders were written on blackboards then quickly erased, are being changed. Certain aspects of the issue have reached the Supreme Court. A major book has proposed the rationing of medical resources (Callahan 1987). Radical movements have sprung up that advocate active euthanasia and offer recipes for self-deliverance. *Final Exit*, the Hemlock Society's handbook, was an instant best-seller (Humphry 1991). The costs of the last days of life have been dramatized, sometimes spoofed as a myth (Alliance for Aging Research 1996), and sometimes reported with great care (Congressional Research Service). Jack Kevorkian, often referred to as "Dr. Death," has become both hero and despised public enemy. In short, the problems and dilemmas inherent in the "management" of death have captured both popular and scientific attention (see various issues of the Hastings Center Reports). In both instances doctors and lawyers play ambiguous but critical

roles. It is, however, the "negotiation" that is of sociological interest. Norms designed to reduce the perplexities in wrenching decisions or to reassure the decision makers (including dying persons) are generally lacking (Wetle 1994). The need for relevant norms governing "the dying process" has been noted earlier (Riley and Riley 1986), and the main considerations have been specified (Logue 1989). The U. S. Office of Technology Assessment (1987) and the Hastings Center (1987) have issued medical and ethical guidelines, respectively, on the use of life-sustaining procedures. Many years ago sociologists developed research models for studying the social aspects of heroic operations and the treatment of nonsalvageable terminal patients (Fox and Swazey 1974; Crane 1975). Yet models necessary to the formation of norms capable of handling the "rights" and wishes of the various parties to the process of dying are still clearly needed. Furthermore, the conceptual problem of distinguishing between the two actors in the dying process, which the Minnesota Conference had emphasized, has not been resolved.

CURRENT ISSUES

With roots in these diverse studies, a set of three issue-laden topics cry out for more research and understanding: 1) dying individuals want a clearer voice in how their last days are to be treated; 2) policy questions are being raised that call attention to potential conflicts between the rights of individuals and the imperatives of society; and 3) programs and campaigns designed to reduce the difficulties of dying are demanding wide social action. These issues can be grouped under three shorthand labels: the living will; assisted suicide; and the quality of dying. While these issues are of great sociological interest, they are only now beginning to be framed in terms for sociological inquiry. The following discussions, consequently, rely largely on commission reports, conferences, public forums, social commentary in the media, brief reports in such journals as *Omega*, *Issues in Law and Medicine*, *Journal of the American Geriatrics Society*, *Hospice Journal*, and various unpublished materials.

The Living Will. As noted above, one of the most easily understood and practical developments in response to the dilemmas of dying in America is the "living will," the so-called durable power of

attorney, or some other form of advance directive. These are quasi-legal instruments, signed by the patient, that instruct attending physicians (or surrogates) as to the patient's preferred treatment at the end of life. Such directives are widely varied as to their specificity and the conditions of application, and it is currently impossible to know how many and what types of directives have been executed. There is, however, ample evidence that they are in widespread use. Simple do-it-yourself forms are available in stationery stores, and countless specialized directives have been developed to cover a wide variety of conditions and contingencies. But both the effectiveness and the ethics of such directives have become subject to wide debate: When and under what conditions is the withdrawal of food or fluids legally and medically permissible? When may guardians or surrogates act for incompetent patients? When does the constitutional right to privacy prevail? Under what conditions may the patient refuse treatment or take the initiative and disconnect respirators or tubes? When do oral directives, if ever, take precedence over written ones? The answers to such questions tend to be moot, although a broad legal doctrine has been promulgated that bears on the availability and use of advance directives. There must be "clear and convincing evidence" that the directive accurately reflects the patient's precise intentions—or would in cases of incompetency. This legal dictum, however, has proved to be both burdensome and murky. The well-known Karen Anne Quinlan case is illustrative. This young woman "existed" in a persistent vegetative state for ten years while the legal process could determine whether Karen's parents had met the "clear and convincing evidence" test (Karen's parents had testified that they knew their daughter well enough to be certain that she would not wish to live in such circumstances). In another widely cited case, Nancy Cruzan "lived" in a similar state for seven years while the intricacies of the law were being debated. These and other such cases point to the need for more useful and practical evidentiary tests. The Hastings Center published a special supplement titled "Advance Care Planning" in 1993.

In 1990, the Patient Self-Determination Act (PSDA) raised a set of new questions. The PSDA requires hospitals, nursing homes, and health providers to inform patients of their right to prepare a living will or some document of end-of-life

preferences. The significance of the PSDA was underscored by an occasionally distributed joint statement by the American Medical Association and the Harvard Medical School:

Modern medicine can keep one alive long after any reasonable prospect of mental, spiritual, or emotional life is gone. The only way for a person to retain autonomy in such a situation is to record his or her preferences for medical care before they are needed. (Published in The Harvard Health Letter and elsewhere.)

The force of the PSDA, however, has not been great and today it is generally believed that its lasting importance will be found in its power to enhance understanding of the still-developing and changing doctor-patient relationship. Indeed, the drama of that relationship has now been moved to a larger stage that involves both assisted suicide and the quality of dying.

Assisted Suicide. The role of law in cases where patients or their surrogates seek to control end-of-life decisions has always been debated. The early cases in the 1950s and 1960s had revolved around "informed consent." This rule surfaced when medical treatments resulted in unanticipated negative consequences, and when it could be shown that the patient had not been informed of the risks. Not surprisingly, this rule led to more complicated ones and, during the 1970s, the increasing demand for patient control resulted in an implied "right" to die by refusing treatment. Of sociological interest, it was popular experience—not statutory law or court decisions—that was bringing about social change (see M. W. Riley 1978 for a theoretical statement). Nor was it long before demands for the "right" to receive treatments specifically designed to hasten death were seriously being discussed and in some states actually outlawed. As these events unfolded they have been reported by major news services, and analyzed by Hastings Center reports beginning in 1995.

In 1996 the U.S. Court of Appeals for the Ninth Circuit struck down a Washington state statute that had been passed specifically to deny such a right. The presiding judge included this noteworthy statement:

A competent, terminally ill adult, having lived nearly the full measure of his life, has a strong liberty interest in choosing a dignified and

humane death rather than being reduced at the end of his existence to a childlike state of helplessness—diapered, sedated, incompetent.

The case was striking not only for its human interest but also because it invoked the guarantee of personal liberty in the Fourteenth Amendment to the U.S. Constitution. Shortly thereafter a New York statute was struck down by the U.S. Court of Appeals for the Second Circuit (Quill 1996), which had argued that if physicians were allowed to help people die it would put society on a slippery slope leading inevitably to abuse. The court pointed out, however, that physicians are not killers if they prescribe drugs to hasten death any more than they are killers when they discontinue life supports.

As expected, both cases were sent to the U.S. Supreme Court which has, at this writing, let stand state laws that prohibit any form of physician-assisted suicide. But the issue is far from settled. The Court's decision concluded with this surprising statement by Chief Justice Rehnquist:

Throughout the nation, Americans are engaged in an earnest and profound debate about the morality, legality and practicality of physician-assisted suicide. Our holding permits this debate to continue.

This statement was all the more remarkable since the chief justice, in his long opinion, rejected both the "liberty" and "due process" constitutional arguments, but came far short of putting the matter to rest. Indeed, continuing developments indicate that the question of physician-assisted suicide is not likely to go away soon. For example, the State of Oregon has passed two voter referenda, the most recent in 1998 with a 60 percent majority support which makes Oregon the only state (as of 1998) to permit, under strict conditions, physician-assisted suicide. The State of Michigan has rejected an Oregon-type statute and has finally convicted Dr. Kevorkian of second degree murder. Several other states are reported to be experimenting with alternatives that enhance the "right" of the individual to choose to die (for details of these developments see The Hastings Center reports). It may be that the law is overreaching its capacity to deal with such a basic and philosophical issue. The question is profound. Is there any logical (or sociological) difference between the right to refuse treatment designed to prolong

life and a parallel right to receive treatment designed to hasten death? Sociologists would ask: What is the distinction between the acceptance of death and its acceleration? Is the question so abstract that it defies empirical inquiry? Both the medical and legal answers to the issue are ambiguous and have been discussed in a book by a physician who publicly admitted helping a patient to die. Dr. Timothy Quill not only was the main plaintiff in the New York case, but he has become the leading medical voice on issues of assisted suicide. He writes with authority and sensitivity: "Death seems antithetical to modern medicine—no longer a natural and inevitable part of the life cycle, but a medical failure to be fought off, ignored, and minimized. The dark side of this desperate battle has patients spending their last days in the intensive care units of acute hospitals, tubes inserted into every body part, vainly trying to forestall death's inevitability. No one wants to die, but if we have to, there must be a better way" (for an account of the issues see Quill 1996).

The Quality of Dying. Sociological concern with assisted suicide has been paralleled with concern for how people die. It had been hoped that the PSDA not only would make advance directives more effective, but would also bring about better communications between doctors and terminal patients. The act, however, was deemed a failure even before it was formally put in place. An impressive experiment, of great sociological interest, was designed to solve these basic issues. Funded and launched by the Robert Wood Johnson Foundation, it was the advance directive problem cast in research terms. The "Study to Understand Prognoses and Preferences in Risks of Treatment" carried such an unwieldy title that it was quickly shortened to the acronym SUPPORT (for a detailed account see The Hastings Center special supplement that carries the subtitle "The Lessons of SUPPORT" 1995). Five teaching hospitals were invited to participate in this multimillion dollar project. Phase One called for baseline data on the end-of-life experiences of some 9,000 dying patients. When the data were analyzed, the researchers were not surprised to find much to criticize in various regimens of hospital care. Their main finding, however, was that doctors and attending nurses must attend not only to the physical comfort and pain management needs of patients but, more importantly, to their psychosocial needs.

Phase Two, consequently, called for experimentation. The 9,000 cases were randomized and an experimental intervention consisting of a protocol designed to sensitize doctors to attend more closely to psychosocial needs was administered to one-half of the cases and withheld from the other half, which had served as a control group. The experiment was continued for two years and expectations were high. Much to the chagrin of the study directors, when the two groups were compared, no differences were found! The experimental intervention showed no effects. This negative finding was so shocking that a number of evaluation panels were enlisted to reanalyze the data and scrutinize the research design. Their efforts, however, only served to corroborate the original analysis and Daniel Callahan (1995), then president of The Hastings Center, concluded with this statement, "This painstaking scrutiny into how people die only goes to show how difficult it is to make the process any better. . . . We thought that the care of dying patients could be set right by . . . some good talk between doctor and patient . . . we thought that we just needed reform . . . it is now obvious that we need a revolution" (Callahan 1995).

Callahan's dramatic statement had the effect of nourishing a spate of organizations and proposals that had sprung up to improve the care of dying patients. For example "Project Death in America" (PDIA), centered at Sloan Kettering Hospital in New York was funded by the billionaire George Soros; the "Center to Improve Care of the Dying" (CICD), based in the George Washington Medical School and originally funded by the Retirement Research Foundation in 1995, enjoys wide institutional support and in 1997 launched a program for individual advocacy, "Americans for Better Care of the Dying" (ABCD); the American Board of Internal Medicine (ABIM) began publishing educational materials on techniques to improve care of the dying in 1996; and the American Medical Association (AMA) began alerting its members to the most recent developments in end-of-life care. And finally, the Robert Wood Johnson Foundation, which has long served as the collective voice for issues on dying, launched "Last Acts" in 1997, which is designed to involve the public through such participating organizations as the Institute of Medicine, the American Hospital Association, the Health Care Financing Administration, the National Hospice Organization, the Veterans Health

Administration, the American College of Physicians, and a host of specialized associations such as the American Pain Society, the American Cancer Society, Choice in Dying, Partnership for Organ Donation, Memorial Societies of America, Wellness Councils of America, and on and on. Former First Lady Roslyn Carter, in a nationally broadcast speech, proclaimed that, "We need this coalition so that fewer people will die alone, in pain, and attached to machines, with the result that more people. . . can experience dying for what it ought to be. . . the last act in the journey of life." The President of the Robert Wood Johnson Foundation was both optimistic and enthusiastic:

With all that is going on. . . we are seizing the moment, "Last Acts" will be much more than platitudes about a good death. . . it will undertake to improve care at the end of life. . . If the campaign succeeds . . . we will find a significant decrease in the number of people dying in pain, an increase in referrals to hospice, more people dying at home outside the hospital, and fewer requests for physician-assisted suicide (1997).

If, however, the campaign does not live up to expectations, the foundation will work with the American Medical Association "on helping physicians to work with patients on advance care planning, and providing opportunities for physicians to increase their skills in palliative medicine and comfort care." It is too early to estimate the long-term effects of this blizzard of efforts to improve the way people die, but it is not too early to predict that any improvements in the quality of dying based only on comfort care are likely to be short term. But change is in the air. Dying persons are pressing for more participation in when and how they die, and caregivers are coming under increasing criticism of the limitations of their caring regimens.

AN EVOLVING PERSPECTIVE

As indicated by this review of past research and current issues, the limitations of both legal and medical approaches to the problems of dying in contemporary society mean that the perspectives of sociology will be brought to bear. Perhaps future sociological attention will focus on the uniquely sociological principle that the dying process is not understandable in individual terms. This,

in turn, provokes a series of predictions: Sociologists will focus on how dying persons are defined by their survivors and caregivers as well as on the sociological hypothesis that dying persons are more concerned for others than they are for themselves. Sociologists will be required to disentangle the concatenation of forces that has produced today's caregiving regimens in which terminal patients tend to be treated more as objects than as persons. Sociologists will be asked to explain how the process of socialization has seemingly been reversed, with the individual being figuratively stripped of years of social experience and defined as a nonperson. In effect, sociologists will be asked to explain the historical alchemy whereby dying persons themselves have been conned into believing that all they needed was palliation and comfort care.

JOHN W. RILEY, JR.

DECISION-MAKING THEORY AND RESEARCH

Decision making must be considered in any explanation of individual behavior, because behaviors are based on decisions or judgments people have made. Thus, decision-making theory and research is of interest in many fields that examine behavior, including cognitive psychology (e.g., Busemeyer, Medin, and Hastie 1995), social psychology (e.g., Ajzen 1996), industrial and organizational psychology (e.g., Stevenson, Busemeyer, and Naylor 1990), economics (e.g., Lopes 1994), management (e.g., Shapira 1995), and philosophy (e.g., Manktelow and Over 1993), as well as sociology. This section will be an overview of decision-making theory and research. Several excellent sources of further information include: Baron (1994), Dawes (1997), Gilovich (1993), and Hammond (1998).

DECISION-MAKING THEORIES

Most decision-making theory has been developed in the twentieth century. The recency of this development is surprising considering that gambling has existed for millennia, so humans have a long history of making judgments of probabilistic events. Indeed, insurance, which is in effect a form of gambling (as it involves betting on the likelihood of an event happening, or, more often, not happening), was sold as early as the fifteenth and sixteenth centuries. Selling insurance prior to the development of probability theory, and in many early cases without any statistics for, or even frequencies of, the events being insured led to bankruptcy for many of the first insurance sellers (for more information about the history of probability and decision making see Hacking 1975, 1990; Gigerenzer et al. 1989).

Bayes's Theorem. One of the earliest theories about probability was *Bayes's Theorem* (1764/1958). This theorem was developed to relate the probability of one event to another; specifically, the

probability of one event occurring given the probability of another event occurring. These events are sometimes called the cause and effect, or the hypothesis and the data. Using H and D (hypothesis and data) as the two events, Bayes's Theorem is: $P(H|D) = P(H)P(D|H)/P(D)$ [1] or $P(H|D) = P(D|H)P(H)/[P(D|H)P(H)+P(D|-H)P(-H)]$ [2] That is, the probability of H given D has occurred is equal to [1] the probability of H occurring multiplied by the probability of D occurring given H has occurred divided by the probability of D occurring, or [2] the probability of D given H has occurred multiplied by the probability of H then divided by the probability of D given H has occurred multiplied by the probability of H plus the probability that D occurs given H has not occurred multiplied by the probability that H does not occur.

The cab problem (introduced in Kahneman and Tversky 1972) has been used in several studies as a measure of whether people's judgments are consistent with Bayes's Theorem. The problem is as follows: A cab was involved in a hit-and-run accident at night. Two cab companies, the Green and the Blue, operate in the city. You are given the following data: (a) 85 percent of the cabs in the city are Green and 15 percent are Blue. (b) a witness identified the cab as Blue. The court tested the reliability of the witness under the same circumstances that existed on the night of the accident and concluded that the witness correctly identified each one of the two colors 80 percent of the time and failed 20 percent of the time. What is the probability that the cab involved in the accident was Blue rather than Green? Using the provided information and formula [2] above, $P(\text{Blue Cab}|\text{Witness says "Blue"}) = P(\text{Witness says "Blue"}|\text{Blue Cab})P(\text{Blue Cab})/[P(\text{Witness says "Blue"}|\text{Blue Cab})P(\text{Blue Cab}) + P(\text{Witness says "Blue"}|\text{Green Cab})P(\text{Green Cab})]$ or $P(\text{Blue Cab}|\text{Witness says "Blue"}) = (.80)(.15)/[(.80)(.15)+(.20)(.85)] = (.12)/[(.12)+(.17)] = .41$

Thus, according to Bayes's Theorem, the probability that the cab involved in the accident was Blue, given the witness testifying it was Blue, is 0.41. So, despite the witness's testimony that the cab was Blue, it is more likely that the cab was Green (0.59 probability), because the probabilities for the base rates (85 percent of cabs are Green and 15 percent Blue) are more extreme than those for the witness's accuracy (80 percent accuracy).

Generally, people will rate the likelihood that the cab was Blue to be much higher than .41, and often the response will be .80—the witness's accuracy rate (Tversky and Kahneman 1982).

That finding has been used to argue that people often ignore base rate information (the proportions of each type of cab, in this case; Tversky and Kahneman 1982), which is irrational. However, other analyses of this situation are possible (cf. Birnbaum 1983; Gigerenzer and Hoffrage 1995), which suggest that people are not irrationally ignoring base rate information. The issue of rationality will be discussed further below.

Expected Utility (EU) Theory. Bayes's Theorem is useful, but often we are faced with decisions to choose one of several alternatives that have uncertain outcomes. The best choice would be the one that maximizes the outcome, as measured by utility (i.e., how useful something is to a person). Utility is not equal to money (high-priced goods may be less useful than lower-priced goods), although money may be used as a substitute measure of utility. EU Theory (von Neumann and Morganstern 1947) states that people should maximize their EU when choosing among a set of alternatives, as in: $EU = \sum (U_i * P_i)$; where U_i is the utility for each alternative, i , and P_i is the probability associated with that alternative.

The earlier version of this theory (Expected Value Theory, or EV) used money to measure the worth of the alternatives, but utility recognizes people may use more than money to evaluate the alternatives. Regardless, in both EU and EV, the probabilities are regarded similarly, so people only need consider total EU/EV, not the probability involved in arriving at the total.

However, research suggests that people consider certain probabilities to be special, as their judgments involving these probabilities are often inconsistent with EU predictions. That is, people seem to consider events that have probabilities of 1.0 or 0.0 differently than events that are uncertain (probabilities other than 1.0 or 0.0). The special consideration given to certain probabilities is called the *certainty effect* (Kahneman and Tversky 1979). To illustrate this effect, which of these two options do you prefer? A. Winning \$50 with probability .5 B. Winning \$30 with probability .7 Now which of these next two options do you prefer? C. Winning

\$50 with probability .8 D. Winning \$30 with probability 1.0

Perhaps you preferred A and D, which many people do. However, according to EU, those choices are inconsistent, because D does not have a higher EU than C (for D, $EU = \$30 = (1.0 * \$30)$; for C, $EU = \$40 = (.8 * \$50)$). Recognize that A and B differ from C and D by a .3 increase in probability, and EU prescribes selecting the option with the highest EU. The certainty effect may also be seen in the following pair of options. E. Winning \$1,000,000 with probability 1.0 F. Winning \$2,000,000 with probability .5

According to EU, people should be indifferent between E and F, because they both have the same EU ($\$1,000,000 * 1.0 = \$2,000,000 * .5$). However, people tend to prefer E to F. As the cliché goes, a bird in the hand is worth two in the bush. These results (choosing D and E) suggest that people are risk averse, because those are the certain options, and choosing them avoids risk or uncertainty. But risk aversion does not completely capture the issue. Consider this pair of options: G. Losing \$50 with probability .8 H. Losing \$30 with probability 1.0

If people were risk averse, then most would choose H, which has no risk; \$30 will be lost for sure. However, most people choose G, because they want to avoid a certain loss, even though it means risking a greater loss. In this case, people are risk seeking.

The tendency to treat certain probabilities differently from uncertain probabilities led to the development of decision-making theories that focused on explaining how people make choices, rather than how they should make choices.

Prospect Theory and Rank-Dependent Theories. Changing from EV to EU acknowledged that people do not simply assess the worth of alternatives on the basis of money. The certainty effect illustrates that people do not simply assess the likelihood of alternatives, so decision theories must take that into account. The first theory to do so was prospect theory (Kahneman and Tversky 1979).

Prospect theory proposes that people choose among prospects (alternatives) by assigning each prospect a subjective value and a decision weight (a value between 0.0 and 1.0), which may be functionally equal to monetary value and probability,

respectively, but need not be actually equal to them. The prospect with the highest value as calculated by multiplying the subjective value and the decision weight is chosen. Prospect theory assumes that losses have greater weight than gains, which explains why people tend to be risk seeking for losses but not for gains. Also, prospect theory assumes that people make judgments from a subjective reference point rather than an objective position of gaining or losing.

Prospect theory is similar to EU in that the decision weight is independent of the context. However, recent decision theories suggest weights are created within the context of the available alternatives based on a ranking of the alternatives (see Birnbaum, Coffey, Mellers, and Weiss 1992; Luce and Fishburn 1991; Tversky and Kahneman 1992). The need for a rank-dependent mechanism within decision theories is generally accepted (Mellers, Schwartz, and Cooke 1998), but the specifics of the mechanism are still debated (see Birnbaum and McIntosh 1996).

Improper Linear Models. Distinguishing between alternatives based on some factor (e.g., value, importance, etc.) and weighting the alternatives based on those distinctions has been suggested as a method for decision making (Dawes 1979). The idea is to create a linear model for the decision situation. Linear models are statistically derived weighted averages of the relevant predictors. For example: $L(\text{lung cancer}) = w_1 * \text{age} + w_2 * \text{smoking} + w_3 * \text{family history}$, where $L(\text{lung cancer})$ is the likelihood of getting lung cancer, and w_x is the weight for each factor. Any number of factors could be included in the model, although only factors that are relevant to the decision should be included. Optimally, the weights for each factor should be constructed from examining relevant data for the decision.

However, Dawes (1979) has demonstrated that linear models using equal weighting are almost as good as models with optimal weights, although they require less work, because no weight calculations need be made; factors that make the event more likely are weighted +1, and those that make it less likely are weighted -1.

Furthermore, linear models are often better than a person's intuition, even when the person is an expert. Several studies of clinical judgment

(including medical doctors and clinical psychologists) have found that linear models always do as well as, if not better than, the clinical experts (see Einhorn 1972). Similarly, bank loan officers asked to judge which businesses will go bankrupt within three years of opening was about 75 percent accurate, but a statistical model was 82 percent accurate (Libby 1976).

Arkes, Dawes, and Christensen (1986) demonstrated this point with people knowledgeable about baseball. Participants were asked to identify “which of . . . three players won the MVP [most valuable player] award for that year.” Each player’s season statistics were provided. One of the three players was from the World Series winning team, and subjects were told that 70 percent of the time the MVP came from the World Series winning team, so if they were uncertain, they could use that decision rule.

Participants moderately knowledgeable of baseball did better than the participants highly knowledgeable, although the highly knowledgeable participants were more confident. The moderately knowledgeable group did better because they used the decision rule more. Yet, neither group did as well as they could have, if they had used the decision rule for every judgment. How a little knowledge can influence judgment will be further explained in the next section on how people make decisions.

DECISION PROCESSING

Decision theories changed because studies revealed that people often do not make judgments that are consistent with how the theories said they should be making judgments. This section will describe evidence about how people make judgments. Specifically, several *heuristics* will be discussed, which are short cuts that people may use to process information when making a judgment (Kahneman, Slovic, and Tversky 1982, is a classic collection of papers on this topic).

Availability. Consider the following questions: What is the first digit that comes to mind?, What is the first one-digit number that comes to mind?, and What is the first digit, such as one, that comes to mind? Kubovy (1977) found that the second statement, which mentions “1” in passing, resulted in more “1” responses than either of the other

two statements. The explanation is that mentioning “1” made it more available in memory. People are using *availability*, when they make a judgment on the basis of what first comes to mind.

Interestingly, the third statement, which mentions “1” in an explicit manner, resulted in fewer “1” responses than the first statement, which does not mention “1” at all. Kubovy suggests there are fewer “1” responses, because people have an explanation of why they are thinking of “1” following that statement (it mentions “1”), so they do not choose it, because “1” has not been thought of at random. Thus, information must not only be available, but it must be perceived as relevant also.

Mood. Information that is available and may seem relevant to a judgment is a person’s present mood (for a review of mood and judgment research see Clore, Schwarz, and Conway 1994). Schwarz and Clore (1983) suggest that people will use their mood state in the judgment process, if it seems relevant to that judgment. They contacted people by phone on cloudy or sunny days, and predicted that people would be happier on the sunny days than on the cloudy days. That prediction was verified. However, if people were first asked what the weather was like, then there was no difference in people’s happiness on sunny and cloudy days. Schwarz and Clore suggested that asking people about the weather gave them a reason for their mood, so they did not use their mood in making the happiness judgment, because it did not seem relevant. Thus, according to Schwarz and Clore, people will use their mood as a heuristic for judgment, when the situation elicits actions from people as if they ask themselves, how do I feel about this?

Quantity and Numerosity. An effect that is also similar to availability was demonstrated in a series of experiments by Josephs, Giesler, and Silvera (1994). They found that subjects relied on observable quantity information when making personal performance judgments. They called this effect the *quantity principle*, because people seemed to use the size or quantity of material available to make their judgment. The experimenters had participants proofread text that was either attached to the source from which it came (e.g., a book or journal) or not, which was an unfamiliar task for the participants. They found that performance

estimations on an unfamiliar task were affected by the quantity of the task work completed. Participants whose work resulted in a large pile of material rated their performance higher than participants whose work resulted in small pile. However, the amount of actual work done was the same. Moreover, if the pile was not in sight at the time of judgment, then performance estimates did not differ.

Pelham, Sumarta, and Myaskovsky (1994) demonstrated an effect similar to the quantity principle, which they called the *numerosity heuristic*. This heuristic refers to the use of the number of units as a cue for judgment. For example, the researchers found that participants rated the area of a circle as larger when the circle was presented as pieces that were difficult to imagine as a whole circle than if the pieces were presented so that it was easy to imagine, and larger than the undivided circle. This result suggests that dividing a whole into pieces will lead to those pieces being thought of as larger than the whole, and this will be especially so when it is hard to imagine the pieces as the whole. That is, the numerosity of the stimulus to be rated can affect the rating of that stimulus.

Anchoring. *Anchoring* is similar to availability and quantity heuristics, because it involves making a judgment using some stimulus as a starting point, and adjusting from that point. For example, Sherif, Taub, and Hovland (1958) had people make estimates of weight on a six-point scale. Prior to each estimation, subjects held an “anchor” weight that was said to represent “6” on the scale. When the anchor’s weight was close to the other weights, then subjects’ judgments were also quite close to the anchor, with a modal response of 6 on the six-point scale. However, heavier anchors resulted in lower responses. The heaviest anchor produced a modal response of 2.

However, anchoring need not involve the direct experience of a stimulus. Simply mentioning a stimulus can lead to an anchoring effect. Kahneman and Tversky (1972) assigned people the number 10 or 65 by means of a seemingly random process (a wheel of fortune). These people then estimated the percentage of African countries in the United Nations. Those assigned the number 10 estimated 25 percent, and those assigned the number 65 estimated 45 percent (at the time the actual percentage was 35). This indicates the psychological

impact of one’s starting point (or anchor), when making a judgment.

An anecdotal example of someone trying to fight the anchoring phenomenon is a writer who tears up a draft of what she is working on, and throws it away, rather than trying to work with that draft. It may seem wasteful to have created something, only to throw it out. However, at times, writers may feel that what they have produced is holding them in a place that they do not want to be. Thus, it could be better to throw out that draft, rather than trying to rework it, which is akin to pulling up anchor.

Endowment Effect. Related to anchoring is the tendency people have to stay where they are. This tendency is known as the *endowment effect* (Thaler 1980) or the *status quo bias* (Samuelson and Zeckhauser 1988). This tendency results in people wanting more for something they already have than they would be willing to pay to acquire that same thing. In economic terms, this would be described as a discrepancy between what people are willing to pay (WTP) and what they are willing to accept (WTA). Kahneman, Knetsch, and Thaler (1990) found WTA amounts much higher for an item already possessed than WTP amounts to obtain that item. In their study, half of the people in a university class were given a university coffee mug, and half were not. A short time later, the people with the mugs were asked how much money they wanted for their mug (their WTA amount), and those without the mug were asked how much they would pay to get a mug (their WTP amount). The median WTA amount was about twice the median WTP amount: WTA = \$7.12, WTP = \$2.87. Thus, few trades were made, and this is consistent with the idea that people often seem to prefer what they have to what they could have.

Representativeness. People may make judgments using *representativeness*, which is the tendency to judge events as more likely if they represent the typical or expected features for that class of events. Thus, representativeness occurs when people judge an event using an impression of the event rather than a systematic analysis of it. Two examples of representativeness misleading people are the gambler’s fallacy and the conjunction fallacy.

The gambler’s fallacy is the confusion of independent and dependent events. Independent events are not causally related to each other (e.g., coin

flips, spins of a roulette wheel, etc.). Dependent events are causally related; what happened in the past has some bearing on what happens in the present (e.g., the amount of practice has some bearing on how well someone will perform in a competition). The confusion arises when people's expectations for independent events are violated. For example, if a roulette wheel comes up black eighteen times in a row, some people might think that red must be the result of the next spin. However, the likelihood of red on the next spin is the same as it is each and every spin, and the same as it would be if red, instead of black, had resulted on each of the previous eighteen spins. Each and every roulette wheel spin is an independent event.

The conjunction fallacy (Tversky and Kahneman 1983) occurs when people judge the conjunction of two events as more likely than (at least) one of the two events. The "Linda scenario" has been frequently studied: Linda is thirty-one years old, single, outspoken, and very bright. She majored in philosophy. As a student, she was deeply concerned with issues of discrimination and social justice, and also participated in anti-nuclear demonstrations. Following that description, subjects are asked to rank order in terms of probability several statements including the following: Linda is active in the feminist movement. [F] Linda is a bank teller. [B] Linda is a bank teller and is active in the feminist movement. [B&F]

The conjunction fallacy is committed if people rank the B&F statement higher (so more likely) than either the B or F statement alone, because that is logically impossible. The likelihood of B&F may be equal to B or F, but it cannot be greater than either of them, because B&F is a subset of the set of B events and the set of F events.

People find events with multiple parts (such as B&F) more plausible than separate events (such as B or F alone), but plausibility is not equal to likelihood. Making an event more plausible might make it a better story, which could be misleading and result in erroneous inferences (Markovits and Nantel 1989). Indeed, some have suggested that people act as if they are constructing stories in their minds and then make judgments based on the stories they construct (Pennington and Hastie 1993). But of course good stories are not always true, or even likely.

INDIVIDUAL DIFFERENCES

Another question about decision processing is whether there are individual differences between people in their susceptibility to erroneous decision making. For example, do some people tend to inappropriately use the heuristics outlined above, and if so, is there a factor that accounts for that inappropriate use?

Stanovich and West (1998) had participants do several judgment tasks and related the performance on those tasks to assessments of cognitive ability and thinking styles. They found that cognitive capacity does account for some performance on some judgment tasks, which suggests that computational limitations could be a partial explanation of non-normative responding (i.e., judgment errors). Also, independent of cognitive ability, thinking styles accounted for some of the participants' performance on some judgment tasks.

A similar suggestion is that some erroneous judgments are the result of participants' conversational ability. For example, Slugoski and Wilson (1998) show that six errors in social judgment are related to people's conversational skills. They suggest that judgment errors may not be errors, because participants may be interpreting the information presented to them differently than the researcher intends (see also Hilton and Slugoski 1999).

Finally, experience affects decision-making ability. Nisbett, Krantz, Jepson, and Kunda (1983) found that participants with experience in the domain in question preferred explanations that reflected statistical inferences. Similarly, Fong, Krantz, and Nisbett (1986) found that statistical explanations were used more often by people with more statistical training. These results suggest that decision-making ability can improve through relevant domain experience, as well as through statistical training that is not domain specific.

GROUP DECISION MAKING

Social Dilemmas. *Social dilemmas* occur when the goals of individuals conflict with the goals of their group; individuals face the dilemma of choosing between doing what is best for them personally and what is best for the group as a whole (Lopes 1994). Hardin (1965) was one of the first to write about these dilemmas in describing the "tragedy

of the commons.” The tragedy was that individuals tried to maximize what they could get from the common and, or the “commons,” which resulted in the commons being overused, thereby becoming depleted. If each individual had only used his allotted share of the commons, then it would have continued to be available to everyone.

Prisoner’s Dilemma. The best-known social dilemma is the prisoner’s dilemma (PD), which involves two individuals (most often, although formulations with more than two people are possible). The original PD involved two convicts’ decision whether or not to confess to a crime (Rapoport and Chammah 1965). But the following example is functionally equivalent.

Imagine you are selling an item to another person, but you cannot meet to make the exchange. You agree to make the exchange by post. You will send the other person the item, and receive the money in return. If you both do so, then you each get 3 units (arbitrary amount, but amounts received for each combination of choices is important). However, you imagine that you could simply not put the item in the post, yet still receive the money. Imagine doing so results in you getting 5 units and the other person -1 units. However, the other person similarly thinks that not posting the money would result in getting the item for free, which would result in 5 units for the other person and -1 for you. If you both do not put anything in the post, although you agreed to do so, you would be at the status quo (0 units each).

Do you post the item (i.e., cooperate) or not? Regardless of what the other person does, you will get more out of not cooperating (5 v. 3, when the other person cooperates, and 0 v. -1 , when other does not). However, if you both do not cooperate, that produces an inferior group outcome, compared to cooperating (0 [0+0] v. 6 [3+3], respectively). Thus, the dilemma is that each individual has an incentive to not cooperate, but the best outcome for the group is obtained when each person cooperates. Can cooperation develop from such a situation?

Axelrod (1984; cf. Hofstadter 1985) investigated that question by soliciting people to participate

in a series of PD games (social dilemmas are often referred to as games). Each person submitted a strategy for choosing to cooperate or not over a series of interactions with the other strategies. Each interaction would result in points being awarded to each strategy, and the strategy that generated the most points won. The winning strategy was Tit for Tat. It was also the simplest strategy. The Tit for Tat strategy is to cooperate on the first turn, and then do whatever the other person just did (i.e., on turn x , Tit for Tat will do whatever its opponent did on turn $x-1$).

Axelrod suggested that four qualities led to Tit for Tat’s success. First, it was a *nice* strategy, because it first cooperates, and Tit for Tat will cooperate as long as the other person cooperates. But when the other person does not cooperate, then it immediately retaliates. That is, it responds to noncooperation with noncooperation, which illustrates its second good quality. Tit for Tat is *provocable*, because it immediately reacts to noncooperation, rather than waiting to see what will happen next, or ignore the noncooperation. However, if the opponent goes back to cooperating, then Tit for Tat will also go back to cooperating. That is quality three: *forgiveness*. Tit for Tat will not continue punishing the other player for previous noncooperations. All that counts for Tit for Tat is what just happened, not the total amount of noncooperation that has happened. Finally, Tit for Tat has *clarity*, because it is simple to understand. A complex strategy can be confusing, so it may be misunderstood by opponents. If the opponent’s intentions are unclear, then noncooperation is best, because if or when a complex strategy is going to be cooperative cannot be predicted.

Thus, a cooperative strategy can be effective even when there are clear incentives for noncooperation. Furthermore, Axelrod did another computer simulation in which strategies were rewarded by reproducing themselves, rather than simply accumulating points. Thus, success meant that the strategy had more of its kind to interact with. Again, Tit for Tat was best, which further suggests that a cooperative strategy can be effective and can flourish in situations that seem to be designed for noncooperation.

Bargaining and Fairness. Bargaining and negotiation have received increasing attention in decision theory and research (e.g., Pruitt and Carnevale 1993), as has the issue of justice or fairness (e.g., Mellers and Baron 1993). These issues are involved in the “ultimatum game,” which involves two people and a resource (often a sum of money). The rules of the game are that one person proposes a division of the resource between them (a bargain), and the other person accepts or rejects the proposal. If the proposal is rejected, then both people get nothing, so the bargain is an ultimatum: this or nothing.

Expected utility (EU) theory suggests that the person dividing the resource should offer the other person just enough to get him to accept the bargain, but no more. Furthermore, EU suggests the person should accept any division, because any division will be more than zero, which is what the person will receive if the bargain is refused. However, typically the bargain is a fifty-fifty split (half of the resource to each person). Indeed, if people are offered anything less than a fifty-fifty split, they will often reject the offer, although that will mean they get nothing, rather than what they were offered, because that seems unfair.

In studies, people have evaluated these bargains in two ways. People can rate how attractive a bargain is (e.g., on a 1–7 scale). Possible divisions to be rated might be: \$40 for you, \$40 for the other person; \$50 for you, \$70 for the other person, and so on. Thus, bargains are presented in isolation, one after another, as if each was an individual case unrelated to anything else. This type of presentation is generally referred to as “absolute judgment” (Wever and Zener 1928).

Alternatively, people may evaluate bargains in pairs, and choose one. For example, do you prefer a bargain where you get \$40, and the other person gets \$40, or a bargain where you get \$50, and the other person gets \$70? Thus, the bargains are presented such that they can be compared, so people can see the relative outcomes. This type of presentation is generally referred to as “comparative judgment.”

Absolute and comparative judgment have different results in the “ultimate” bargaining game.

Blount and Bazerman (1996) gave pairs of participants \$10 to be divided between them. In absolute judgment (i.e., is this bargain acceptable?), the money holder accepted a minimum division of \$4 for him and \$6 for the other person. But asked in a comparative judgment format (i.e., do you prefer this bargain or nothing?), participants were willing to accept less (a minimum division of \$2.33 for the money holder and \$7.67 for the other person). This result suggests that considering situations involving the division or distribution of resources on a case-by-case basis (absolute judgment) may result in sub-optimal choices (relative to those resulting from comparative judgment) for each person involved, as well as the group as a whole.

Comparative and absolute judgment can be applied to social issues as adoption. There has been controversy about adoption, when the adopting parents have a different cultural heritage than the child being adopted. Some argue that a child should be adopted only by parents of the same cultural heritage as the child to preserve the child’s connection to his or her culture. That argument views this situation as an absolute judgment: should children be adopted by parents of a different cultural heritage or not?

However, there is an imbalance between the cultural heritages of the children to be adopted and those of the parents wanting to adopt. That imbalance creates the dilemma of what to do with children who would like to be adopted when there are no parents of the same cultural heritage wanting to adopt them. That dilemma suggests this comparative judgment: should children be adopted by parents of a different cultural heritage than their own, or should children be left unadopted (e.g., be brought up in a group home)?

The answers to these absolute and comparative judgments may differ, because the answer may be that a child should not be adopted by parents of a different cultural heritage as an absolute judgment, but as a comparative judgment the answer may be that a child should be adopted by such parents, despite the cultural differences, because having parents is better than not having parents. Thus, the best answer may differ depending on

how the situation is characterized. Such situations may involve more than one value (in this case, the values are providing parents for a child and preserving the cultural heritage that the child was born into). Typically, absolute judgements reflect an acceptance or rejection of one value, while comparative judgments reflect more than one value.

GENERAL JUDGMENT AND DECISION-MAKING ISSUES

That the best solution for a situation can seem different if the situation is characterized differently is one of the most important issues in judgment and decision making. The theories mentioned above (Bayes's, EU, prospect, and rank-dependent) assume problem invariance. That is, they assume that people's judgments will not vary with how the problem is characterized. However, because the characterization of the problem affects how people frame the problem, people's decisions often do vary. (Tversky and Kahneman 1981).

An implication of this variability is that eliciting people's values becomes difficult (Baron 1997; 1998). However, different methods can produce contradictory results. For example, choice and matching tasks often reveal different values preferences. Choice tasks are comparative judgments: Do you prefer A or B? Matching tasks require participants to estimate one dimension of an alternative so that its attractiveness matches that of another alternative (e.g., program A will cure 60 percent of patients at a cost of \$5 million, what should B cost if it will cure 85 percent of patients?).

The difference produced by these tasks has been extensively examined in studies of *preference reversals* (Slovic and Lichtenstein 1983). Tversky, Sattath, and Slovic (1988) have suggested that the dimension of elicitation (e.g., probability or value) will be weighted most, so reversals can result from changing the elicitation dimension. Fischer and Hawkins (1993) suggested that preference reversals were the result of the compatibility between people's strategy for analyzing the problem and the elicitation mode. Preference reversals clearly occur, but the cause of them continues to be debated (cf. Payne, Bettman, and Johnson 1992).

Ideas about rationality have also been influenced by the variability of people's judgments. Generally, the idea of rationality originated with a theory and then examined whether people behaved in that way, rather than examining how people behave and then suggesting what is rational. That is, rationality has typically been examined based on a prescriptive theory, such as Bayes's or EU, about how people should make decisions rather than a descriptive theory based on how people actually process information. When studies resulted in judgments that were inconsistent with those prescriptive theories of decision making, researchers concluded that people often acted irrationally.

However, there is growing recognition that study participants may be thinking of situations differently than researchers have assumed (Chase, Hertwig, and Gigerenzer 1998), which has led several researchers to create theories about decision processing (e.g., Dougherty, Gettys, and Ogden in press; Gigerenzer, Hoffrage, and Kleinbolting 1991) and use those theories to address rationality issues rather than the reverse. Approaches that focus on processing have been present in decision theory for some time (cf. Brunswick 1952; Hammond 1955), but they have not been dominant in the field. The acknowledgement of multiple views of rationality coupled with the poor explanations of prescriptive theories for people's actual decision behavior may shift the emphasis to processing models.

Further consideration of the decision-making process has led to other questions that are garnering increased attention. For example, how do people make decisions within dynamic environments? Generally, people make decisions in a dynamic world (Brehmer 1990; Busemeyer and Townsend 1993; Diehl and Serman 1995), but many decision-making theories (such as those reviewed above) do not account for the dynamics of the environment. Also, how do people's emotions affect the decision-making process? Decisions can involve topics that evoke emotion or have emotional consequences (such as regret, Gilovich and Medvec 1995). Some decision theories have tried to include emotional considerations in decision

making (e.g., Bell 1982), but this topic deserves more attention. These questions, as well as the issues discussed above, will make decision theory and research an area of continued interest and relevance.

DEMOCRACY

Democracy is one of the most important subjects in the social sciences. From the work of de Tocqueville in the early nineteenth century through the work of the best contemporary scholars, democracy has been studied closely and debated widely (Tocqueville 1969). Democracy has drawn this attention primarily because, in spite of the fact that it is quite rare historically, it has come to have enormous legitimacy in the eyes of many individuals worldwide. This has not always been the case. Democracy has been severely criticized by those on both the political right and left. But few scholars today question whether democracy is a social good.

Democracy is also important because many historically undemocratic countries have adopted it as a system of government. Many such changes have occurred only in the years since the Cold War (Huntington 1991). By 1994, over half the countries in the world had some form of democratic governance, a doubling of the number of nation-states so organized within 25 years (Lipset 1994).

At the core of most discussions of democracy is a common understanding that democracy is a method of governance or decision making for organizations or societies in which the members of that organization or society participate, directly or indirectly, in the decision making of that group. Further, members affect decision making to such an extent that they can be thought of as actually governing that organization or society. In short, democracy is a system of governance in which members control group decision making.

Not all considerations on democracy have shared this understanding. For example, those working in the Marxist tradition saw any state, democratic or not, as the expression of a class struggle. As such, any state was inherently undemocratic, absent the creation of a classless, communist, and hence truly democratic, society (Held

1995). Subsequent to the collapse of the Soviet Union and its affiliated states, and the full exposure of the failures of those regimes, such an extreme view has been almost entirely rejected.

The common understanding of democracy as participation by members or citizens in the decision making of an organization or society still leaves considerable room for dispute. Two issues are central: First, who are, or should be, considered members of the society? Second, what does, or should, constitute a minimum level of control over decision making by members for a system to be thought of as democratic? In short, how much participation is necessary for a system to be democratic? These questions are not simply matters of empirical observation of the world, but also matters for moral and political philosophy.

Three additional factors add to the difficulty of approaching democracy as a field of sociological research. First, analysts of democracy all too often use different definitions of democracy, or fail to define democracy clearly. Democratic systems of governance can be characterized by many attributes—frequency of member participation, the form of member participation, and so forth. Establishing whether a particular system of governance is democratic, involves making decisions about which attributes are essential to a democratic system. Where there is no specific definition of democracy or where definitions conflict, evaluating research on democracy can be tasking (Macpherson 1972).

A second factor increasing the difficulty of this subject matter is that democracy is a system of governance found in many different kinds of collectivities, including states, formal organizations, and informal groups. It is thus necessary to be cautious in applying models, findings, and relationships across different types of collectivities. When general propositions about democracy are advanced, it is important to evaluate those propositions at multiple levels of analysis.

A third difficulty is that social scientists are interested in democracy not just for its own sake, but also because it is thought to be associated with other critical issues. Many important questions

involve considerations of democracy: What is the effect of democracy on the success of organizations and nation-states? Does democracy promote individual liberty? What is the effect of democracy on income inequality and social stratification? What is the relationship between democracy and civil society? Can market economies prosper in the absence of democracy? All these and more force sociologists to consider the consequences, as well as the causes, of democracy.

While the difficulties of studying democracy are daunting, much significant work has been done in this field. Democracy has been studied as an outcome and as a cause, and has been studied at both the level of the nation-state, and at the level of the organization.

To begin with, there is work in the sociology of democracy on the question of who is or should be members or citizens of a democratic polity. Most systems commonly thought to be democratic have throughout history excluded some portion of those subject to the will of the democracy from participation in the decision-making process. Such exclusion has occurred on the basis of race, sex, income, relationship to property, criminal status, mental health, religion, age, and other characteristics. While use of many of these categories as a justification for excluding individuals from participation has declined in recent times, others remain, and there is continuing disagreement about the moral and political bases for excluding or including specific groups or categories of individuals. Migrant workers in Western Europe, for example, are subject to the action of the state on a long-term basis and yet remain excluded from full political participation in those states (Brubaker 1989). At the level of the organization, there are individuals affected by the decisions of the organization who may have little or no say in the decisions that affect them. These can include individuals both outside the organization (“stakeholders”) and inside the organization. Regarding affected individuals outside the organization, there are occasional movements to increase the power of stakeholders over the decisions of the organization (Nader, Green, and Seligman 1976). While unsuccessful at a general level, there has been a shift toward permitting

stakeholders increased access to legal redress, for example, in class action lawsuits and in environmental litigation. And regarding those within the organization, one way to understand the management trends toward “total quality management,” participatory management, and economic democracy is that they are attempts to increase democratic participation of workers in decisions that affect them (Jarley, Fiorito, and Delaney 1997).

Sociologists have often focused on the forms of influence and participation that individuals have in decision making. *Representative democracy* is that form of governance in which members of the organization or polity exercise their control over the organization through the regular election of members of a decision-making body. It is traditional to view representative democracies as democratic because they provide for the expression of interests through the election of representatives. For example, in the United States, citizens directly elect senators and representatives to the U.S. Congress, which in turn makes political decisions about the actions of the federal government. Theorists since the Enlightenment have argued that representative democracy is an appropriate means for conveying participation in decision making in large-size organizations, where individuals are thought not to be able to participate in all decisions (Hobbes 1968; Locke 1980; Mill 1962; Rousseau 1977).

But this view has been attacked by numerous critics, many of them sociologists. One of the most scathing criticisms, building on work by Mosca, is the analysis of democracy by Michels (Mosca 1939). Michels’s argument is that in any large organization (and, by extension, in any nation-state), a democratic system of governance inevitably leads to the rise of an oligarchy, and worse, to an oligarchy whose leaders have interests that differ from those of the ordinary members or citizens (Michels 1949). Why is this inevitable? In every instance of large democratic organization, Michels argues, oligarchy arises as a result of the organization’s requirement for experienced, skilled leaders. Experience in leadership, however, tends to give leaders access to key organizational resources, such as mailing lists, publicity, and greater experience, that are significant resources that the leadership

can use to return themselves to office year after year. And as leaders remain in office over an extended time, their interests and attitudes are likely to diverge from those of members. The divergence of interests is a result of the changed work and social experiences that accrue to leaders. Hence Michels, while arguing that formal organization is necessary for social life, and especially for politics, also believes that democracy in such organizations is essentially impossible.

Michels’s analysis has been taken very seriously in the social sciences, and there is some supporting evidence for his propositions. Weber described, and Hecló and Wilson separately concede, that there is a tendency for the civil service and bureaucracy to become unresponsive to the wishes of the people, as their experiences and needs differ from the people (Hecló 1977; Weber 1978; Wilson 1989). Lincoln and Zeitz have shown that as unions tend to get more professional, there is less member participation in decision making (Lincoln and Zeitz 1980). And for both unions and social movement organizations, Michels’s critique is taken so seriously as to generate sometimes drastic proposals for counteracting the oligarchical tendencies in these organizations (Kochan 1980). Piven and Cloward argue that reform movements of the poor should waste few resources on creating long-lasting organizations, but should instead create massive and disruptive protests (Piven and Cloward 1977).

However, Michels is not without his critics. Nyden argues that democratic unions are possible (Nyden 1985). Weber himself, who was Michels’s teacher, was critical of his conclusions. Michels overstated the case, Weber argued, because he insisted on relying upon too pure or strict a definition of democracy. Having started with such an idealistic vision of democracy, Michels was bound to find that reality comes up short (Scaff 1981).

That too pure a definition of democracy can lead to a misplaced understanding of how democracy works, and a failure to appreciate its achievements, is the key assumption behind the most significant defense of democracy in the 1950s and 1960s—the *pluralist* account of democracy. Dahl’s

account defends democracy by admitting its weakness: voting in elections is not a terribly effective system for ensuring that the will of the people will be carried out. Instead, Dahl focuses attention on whether non-electoral forms of influence can yield democratic decision making in keeping with the wishes and interests of the public. Interest groups thus become not the bane, but the hope of democracy. Through lobbying in all its forms, interest groups are able to exert power and influence over decision making beyond elections; if they do this, then the system, with all its flaws, can be considered democratic (Dahl 1961).

A problem with the pluralist view is that not all groups in society may be able effectively to form interest groups to pursue their goals. Olson, in an early effort in what is now known as *rational choice theory*, argued that individuals must be assumed to be rational, and that rational individuals will not contribute to the formation of interest groups when they will obtain the benefits achieved by the interest group anyway. This is the *free rider* or *collective action* problem: if an interest group lobbies for clean air, and a person cannot be denied clean air because he or she does not belong to the interest group, why should that person contribute to the group? Only those interest groups with a particularly small constituency or those interest groups who are able to use “special” incentives—those available only to members of the group—to attract contributors will be able to form to lobby to advance their interests. Groups representing weak and powerless individuals may be unable to supply such special incentives (Olson 1971).

Olson’s pessimism about the chances for the disadvantaged to gain a voice in decision making has been the focus of much attention. Oliver and Marwell suggest that social movements are more likely to be formed as interest groups grow in size (Oliver and Marwell 1988). Knoke argues that the use of selective incentives may attract apathetic members, whereas a focus on the goal of lobbying may attract highly active members, thereby creating more effective organizations (Knoke 1988). Clemens points out that as interest groups come into existence, they are themselves models or templates for others to imitate. Those templates will

then increase the likelihood of the formation of more interest groups (Clemens 1997). These criticisms of Olson’s analysis of the collective action problem may actually serve to strengthen the pluralist account of democracy.

Yet many sociologists remain deeply critical of the pluralist account. Domhoff argues that pluralism is flawed not because the collective action problem retards the capacity of the disadvantaged to organize. Rather, pluralism is flawed because in the United States, and in other industrialized democracies, there is a governing class (Domhoff 1998). This governing class is composed of elites from business, the social upper class, and those in charge of organizations, both within and outside government, that are powerfully involved in the formation of public policy. While Domhoff admits that there is some conflict within these groups, he views them as cohesive in their opposition to the interests of the poor and the working class. Through their control of important organizations, through the strength of their social ties, and through the use of agenda-setting, the governing class achieves enormous power. And, Domhoff argues, the governing class is able to use that power consistently to defeat the interests of the majority.

Other critics of the pluralist account have drawn attention to the relationship between social class and voting. For some years, it appeared that class-based voting in the United States appeared to be declining (Clark, Lipset, and Rempel 1993; Manza, Hout, and Brooks 1995). Yet some scholars believe that class remained a significant factor in voting behavior (Burnham 1981). Piven and Cloward argued that the pluralist account failed because there was a systematic pattern to who voted and who did not. Because the poor and the working classes disproportionately failed to vote in elections, they were inadequately represented in the competition between interests; hence the poor were excluded from the pluralist democracy (Piven and Cloward 1988). It has been shown that class remains a powerful determinant of how people vote, even if the working class no longer votes for the Democratic party in the United States with as great a frequency as it did in the years immediately after WWII (Hout, Brooks, and Manza 1995).

Researchers in the 1970s and 1980s criticized pluralism for adopting a definition of democracy that was too satisfied with the status quo of only limited participation in decision making. These participatory democratic theories emphasized that as members participate in decision making, they learn more about the criteria that need to be used in effective decision making and become better at making decisions. But members also, it was argued, become better at evaluating the choice of candidates where representatives must be elected. Accordingly, empirical researchers began to investigate the causes and consequences of increased participation in decision making (Finley 1973; Pateman 1970).

In keeping with this view, researchers increasingly moved to consider cases of participation throughout society (Alford and Friedland 1975). Participation in decision making in unions, community organizations, municipalities, and protest groups has been analyzed and touted (Gans 1989; Cole 1975). In organization theory, research on different forms of worker participation in organizational decision making has gained increasing prominence. Total quality management, participatory management, and worker control all have been studied closely, not just for improvement in productivity and quality, but also for democracy. Much of this research emphasizes how democracy is consistent with both effectiveness and the improvement of the condition of workers (Jarley, Fiorito, and Delaney 1997). Some have even come to see the spread of democratic management as inevitable, although this is almost certainly exaggerated (Collins 1997). Yet many have worked to show that democratic systems of management are more broadly possible than has been thought, although the conditions under which such systems of decision making can be created and maintained remain under debate (Burawoy 1982; Kanter 1983).

Renewed definitions of democracy beg a central question in democratic research: Where do democracies come from? The question has been most closely studied for nation-states. Lipset identifies a set of central conditions that are associated with the rise of democracy in nation-states. The presence of a market economy appears to be a

necessary, although not a sufficient, condition for democracy. A minimum level of economic development is associated with democracy, although a key debate is the extent to which development leads to democracy (Bollen and Jackman 1995; Muller 1995). Also associated with democracy is a political culture in which the tolerance for the rights of others is recognized. Finally, countries with Protestant religious traditions have been more likely to be democratic, though the significance of that effect may be fading in the recent transition to democracy (Lipset 1994).

One of the most significant contributions to the account of the origins of democracy is that by Moore (Moore 1966). His analysis, standing in contrast to a Marxist emphasis on the role of the working class as a force in history, identified the relationship between peasant and lord prior to capitalism as the critical factor in determining whether a society became democratic or autocratic. In countries such as China, France, Japan, or Germany, repressive control over peasants by a dominant class led either to revolution or to continued autocracy. In China, revolution led to Communist autocracy; in France, because of the existence of a commercial class, revolution led, through fits and starts, to democracy. In Japan and Germany, the failure or absence of revolution led to continued dominance of repressive classes, leading to the rise of fascist regimes. Moore argued that in a country such as England, however, the greater status of labor, coupled with the nobility's increasing dependence on market-based agriculture, led to an eventual democratic solution to social conflict.

Moore's work has provoked considerable criticism and extension (Ross et al. 1998). Downing has shown conclusively that the nature of military conflicts affects the success of democracy in a country. How a nation fights its wars, and how often it must fight, is critically determinative of the need for repression in the mobilization of men and weapons to fight. England's peculiar move toward democracy is thus critically dependent on its position as an island nation, free from the necessity to fight long-term, massive land wars on the continent of Europe, and the necessity to

maintain a state and military administrative structure capable of that task (Downing 1992). Friedman has shown that former British colonies tend to be democratic, whereas countries ruled by Leninist parties tend to remain autocratic (Friedman 1998).

Students of social movements have tended to argue that social movements are significant sources of democracy (Giugni, McAdam, and Tilly 1998). There is evidence that social movements can push the transition to democracy faster (Hipsher 1998; Sandoval 1998). Certainly this is consistent with Tilly's theoretical model of democratization, in which he argues that social conflict, as embodied in social movements, and where mediated by third parties, can lead to the creation of rights essential for democracy (Tilly 1998). But surely the effects of social movements on democracy are contingent on many factors, and sociologists must be careful not to assume that the outcome of social protest will be democratization (Melucci and Lyyra 1998). Clearly this has not always been the case.

The sources of democracy in organizations is an understudied area. Two findings are worth noting. Knoke has argued that in the present-day United States, a minimum level of democratic procedure is just a part of the institutional building blocks from which organizations are constructed; in short, organizations such as unions may have democratic procedures simply because everybody expects them to have those procedures (Knoke 1990). And, returning to the tension between democracy and effectiveness identified by Michels, Jarley has found that the causes of democratic procedures in unions are independent of those which drive bureaucratization (Jarley, Fiorito, and Delaney 1997). Yet much more systematic work needs to be done in this area.

The other side of the coin in the study of democracy is the question of the relationship between democracy and other core subjects of sociological interest. The relationship between democracy and equality is a central issue and has been a focus of research since de Tocqueville (Tocqueville 1969). In recent years, research has centered around this specific question: Does democracy promote or retard income inequality in nation-states? There is

some evidence that democracy does not increase inequality, at least directly, and it might lead to increased equality (Bollen and Jackman 1985; Muller 1988).

Another question is whether democracies can be effective. The central issue, echoing Michels, is whether or not organizations, such as unions or parties or, for that matter, businesses, can be successful in competitive environments against organizations that are autocratically run. The evidence is conflicting. Some argue that democracy and effectiveness are in conflict in the context of unions (Lipset, Trow, and Coleman 1959; Piven and Cloward 1977). Others argue that democracy leads to effectiveness in achieving goals (Stepan-Norris and Zeitlin 1994). As yet, there seems to be no definitive answer, and the issue certainly merits more research.

Finally, the subject of democracy has been intimately tied in the 1990s to two related subjects.

The first is the subject of globalization. As the world has become more closely connected, as communications technologies radically change again, and as the world economy has grown larger, some have raised questions about the implications of this trend for democracy. Held, for example, has argued that decisions that affect citizens are increasingly being made at a level beyond that of the nation-state; in supra-national organizations and in the international economy. As a consequence of this globalization, the extent of democratic control over decisions is seen to have weakened (Held 1995). Others have criticized this argument, and the subject is still very much subject to research and debate (Hirst and Thompson 1996).

The second related subject is civil society. A focus of scholarly attention in part because of the demands for it from those who have emerged from socialist rule, civil society is commonly conceived as space for associational activity between the state and the individual (Gellner 1994). Many now see organizations and associations, independent of the state, as crucial to democracy, constituting a critical element of democratic society (Streeck and Schmitter 1985). Certainly, they are not the same: as Hall puts it, "Democracy can be

decidedly uncivil" (Hall 1995). But democracy depends on civil society (Somers 1993). This view echoes Tocqueville's assertion that the knowledge of how to combine is fundamental to democracy (Tocqueville 1969). Already attracting significant attention, much room remains to answer questions about the relationship between civil society and democracy.

In conclusion, it is well to remember that there are many forms of democracy: those with weaker or stronger civil liberties; those with weaker or stronger civil societies; those with weaker or stronger tolerance for diversity. Nor can it be assumed that these different forms are internally consistent: the rights of the community to choose what it wishes to be, and the rights of the individual to live as he or she wishes, are not easily reconciled.

It is also well to remember that democracy is not inevitable (Berger 1992). Neither, we should also recall, is democracy a simple outcome that, once achieved, is a permanent condition (Friedman 1998). Democracy can be strengthened; democracy can be weakened. And it can, as it has in the past, disappear. While democracy is today in the ascendant, the lessons of the French Revolution and of Weimar Germany should not be forgotten; although in both instances democracy was regained, it was not regained quickly or without cost. And in Germany, as in Japan, democracy was not regained from within, but imposed from without. History should teach us that we still have much to learn about democracy.

ANDREW L. CREIGHTON

DEMOGRAPHIC METHODS

Demographic methods are used to provide researchers and policymakers with useful information about the size and structure of human populations and the processes that govern population changes. A population, of course, may range in size from a small number of individuals surveyed locally to a large national population enumerated in periodic censuses to even larger aggregated entities.

We use demographic methods not only in purely demographic applications, but also in a variety of other fields, among them sociology, economics, anthropology, public health, and business. Demographers, like all researchers, must pay careful attention to the quality of data that enter into their analyses. Some circumstances under which we use these methods are more trying than others. In cases in which the data are viewed to be accurate and complete, the methods we use to analyze them are more straightforward than those that are applied to data of imperfect quality.

DESCRIPTION OF DATA

First we must develop ways to describe our data in a fashion that allows the most important facts to leap out at us. As one example, let us examine a population's age structure or distribution. Simple descriptive statistics are doubtless helpful in summarizing aspects of population age structure, but demographers often use age "pyramids" to convey to an audience the youthfulness of a population, for example, or even to convey a rough sense of a nation's history.

We might note, for example, that 20 percent of Norway's population in 1997 was under the age of fifteen. In contrast, 39 percent of Mexico's population seven years earlier fell into this category. But it is perhaps more dramatic to create a visual display of these figures in the form of age pyramids.

An age pyramid is typically constructed as a bar graph, with horizontal bars—one representing each sex—emanating in both directions from a central vertical age axis. Age increases as one proceeds up the axis and the unit of the horizontal axis is either the proportion of the total population in each age group or the population size itself.

We see in panel A of figure 1 that Mexico's population is described by a very broad-based pyramid—actually, in two-dimensional space, a triangle, but by convention we refer to it as a pyramid—which reveals a remarkably large proportion of the population not yet having reached adulthood. The median age of this population is about twenty years. Such a distributional shape is common particularly among high fertility populations. In stark contrast we have the pyramid shown in panel B, representing the population of Norway. Rather than triangular, its age distribution is somewhat more rectangular in shape, which is typically seen among countries that have experienced an extended period of low fertility rates. It is easy to see that Norway's median age (about thirty-six years) is considerably higher than that of Mexico.

As mentioned above, not only can we examine the age structure of populations through the use of pyramids, but we can also gain much insight into a nation's history insofar as that history has either directly or indirectly influenced the size of successive birth cohorts. Note, for example, the age pyramid reflecting the population age structure of France on 1 January 1962 (figure 2).

In this figure, several notable events in France's history are apparent. We see (1) the military losses experienced in World War I by male birth cohorts of the mid to late 1890s, (2) the remarkable birth dearth brought about by that war (the cohort aged in their mid-forties or so in 1962), followed by (3) the return of prewar childbearing activity once the

war ended (the cohort who in 1962 were in their early forties), and a similar pattern revolving around World War II, during which (4) a substantial decline in births took place (the cohort around age twenty in 1962), succeeded by (5) a dramatic baby boom in the years immediately following (those around age fifteen in 1962).

COMPARISON OF CRUDE RATES

Much of the work in which social scientists are engaged is comparative in nature. For example, we might seek to contrast the mortality levels of the populations of two countries. Surely, if the two countries in question have accurate vital registration and census data, this task would appear to be trivial. For each country, we would simply divide the total number of deaths (D) in a given year by the total population (P) at the midpoint of that year. Thus we would define the crude death rate (CDR) for country A as:

$$CDR^A = \frac{D^A[t, t+1]}{P^A[t+.5]} = \frac{\sum_{x=0, n}^{\omega-n} [{}_nM_x^A \cdot {}_n P_x^A]}{\sum_{x=0, n}^{\omega-n} {}_n P_x^A} \quad (1)$$

where t denotes the beginning of the calendar year, ω is the oldest age attained in the population, ${}_nM_x^A$ is the death rate of individuals aged x to $x+n$, and ${}_n P_x^A$ is the number of individuals in that same age group. ${}_nM_x^A$ and ${}_n P_x^A$ are centered on the midpoint of the calendar year. The rightmost segment of this equation reminds us that the crude death rate is but the sum of the age-specific death rates weighted by the proportion of the population at each age.

Unfortunately, comparisons of crude death rates across populations can lead to misleading conclusions. This problem is in fact general to any sort of comparison based on crude rates that do not account for the confounding effects of factors that differentiate the two populations.

Let us examine the death rates of two very different countries, Mexico and Norway. The crude death rate (for both sexes combined) in Mexico in 1990, 5.2 per 1000, was approximately half that for

Figure 1

NOTE: Age pyramids for Mexico and Norway

Norway, 10.1, seven years later, in 1997. Knowing nothing else about these two countries, we might infer that the health of the Mexican population was considerably superior to that of the Norwegian population. However, once we standardize the crude death rates of the two countries on a common population age structure, we find just the reverse is true.

To accomplish this standardization, instead of applying the above equation to our data, we use the following:

$$ASCDR^A = \frac{\sum_{x=0,n}^{\omega-n} [{}_nM_x^A \cdot {}_nP_x^S]}{\sum_{x=0,n}^{\omega-n} {}_nP_x^S} \quad (2)$$

where $ASCDR^A$ is the age-standardized crude death rate of country A, and ${}_nP_x^S$ is the number of individuals in the standardized population of that same age group. Any age distribution may be chosen as the standard, however, it is common simply to use the average of the two proportionate

age distributions (i.e., each normalized to one in order to account for unequal population sizes).

Table 1 gives the death rates and number of persons for each country by five-year age groups (zero through four, five through nine, and so on through eighty and above). The first fact we glean from the table is that the mortality rates of the Norwegian population are substantially lower than those of their Mexican counterparts at virtually all ages. We see that nearly 40 percent of the Mexican population is concentrated in the three age groups having the lowest death rates (ages five through nineteen). Only half that proportion of the Norwegian population is found in the same age range. In contrast, only 6 percent of the Mexican population is above sixty years of age, an age range with which its highest level of mortality is associated. At the same time, about 20 percent of the Norwegian population is sixty or older. Compared with the Mexican crude death rate, then, the Norwegian rate is disproportionately weighted toward the relatively high age-specific death rates that exist in the older ages.

Figure 2

NOTE: Age pyramid France

Applying the standardization method described by the above equation to the average of Norway's and Mexico's proportionate age distributions, we find that the resulting crude death rates are consistent with what we would infer from the two series of age-specific mortality rates. Mexico's age-standardized crude death rate, 8.7 per 1000 population, is one-third greater than that of Norway, 6.6 per 1000.

LIFE TABLES

The *life table* is a methodological device used by demographers and others to examine the life—either literal or figurative—of a particular duration-dependent phenomenon. The original application of the life table was to the mortality patterns of human populations. Today, the life table technique is applied to such diverse areas as contraceptive efficacy, marital formation and dissolution, and organizational failure. Thus it is a remarkably

general tool for examining the time-dependent survivorship in a given state.

To illustrate the use of the life table method, suppose we use as an example the mortality experience of the United States population in 1996. We might wish to derive the average number of years that an individual would live, subject to the series of age-specific death rates attributed to that population. To find the answer, we could construct a *complete life table*, as in table 2. It is complete in the sense that it is highly age-detailed, focusing on single years of age. This is in contrast to the *abridged life table*, which is usually constructed using five-year age groups. The abridged life table shown in table 3 refers also to the total population of the United States in 1996.

Most life tables that we see are called *period* or *current life tables*. They refer to a particular snapshot in time. Although they describe the mortality experience of an actual population, they do not

NOTE: *This is technically an “interpolated life table” and not a complete life table based on single-year data.

SOURCE: This life table is available on the web at <http://www.cdc.gov/nchswww/datawh/statab/unpubd/mortabs/lewk2.htm>

describe the experience of an actual birth cohort—that is, a group of individuals who are born within a (narrowly) specified interval of time. If we wished to portray the mortality history of the birth cohort of 2000, for example, we would have to wait until the last individual of that cohort has died, or beyond the year 2110, before we would be able to calculate all of the values that comprise the life table. In such a life table, called a *generation* or *cohort life table*, we can explicitly obtain the probability of individuals surviving to a given age. As is intuitively clear, however, a generation life table is suitable primarily for historical analyses of cohorts now extinct. Any generation life table that we could calculate would be very much out of date and would in no way approximate the present mortality experience of a population. Thus, we realize the need for the period life table, which

treats a population at a given point in time as a *synthetic* or *hypothetical cohort*. The major drawback of the period life table is that it refers to no particular cohort of individuals. In an era of mortality rates declining at all ages, such a life table will underestimate true life expectancy for any cohort.

The most fundamental data that underlie the formation of a period life table are the number of deaths attributed to each age group in the population for a particular calendar year (${}_nD_x$), where x refers to the exact age at the beginning of the age interval and n is the width of that interval, and the number of individuals living at the midpoint of that year for each of those same age groups (${}_nP_x$).

To begin the life table’s construction, we take the ratio of these two sets of input data— ${}_nD_x$ and ${}_nP_x$ —to form a series of age-specific death rates, or ${}_nM_x$:

Abridged Life Table for the United States, 1996

Exact Age x	${}_nD_x$	${}_nP_x$ (in 1,000s)	${}_nq_x$	l_x	${}_nd_x$	${}_nL_x$	T_x	e_x
0	28,487	3,769	.00732	100,000	732	99,370	7,611,825	76.1
1	5,948	16,516	.00151	99,268	150	396,721	7,512,455	75.7

Table 3

SOURCE: ${}_nD_x$ and ${}_nP_x$ values are obtained from Peters, Kochanek, and Murphy 1998, and from the web site, <http://www.cdc.gov/nchswww/datawh/statab/unpubd/mortabs/pop6096.htm>, respectively.

$${}_nM_x = \frac{{}_nD_x}{{}_nP_x} \tag{3}$$

For each death rate, we compute the corresponding probability of dying within that age interval, given that one has survived to the beginning of the interval. This value, denoted by ${}_nq_x$, is computed using the following equation:

$${}_nq_x = \frac{n \cdot {}_nM_x}{1 + (n - {}_na_x) \cdot {}_nM_x} \tag{4}$$

where ${}_na_x$ is the average number of years lived by those who die within the age interval x to $x+n$. (Except for the first year of life, it is typically assumed that deaths are uniformly distributed within an age interval, implying that ${}_na_x = n/2$.) Given the values of q and a , we are able to generate the entire life table.

The life table may be thought of as a tracking device, by which a cohort of individuals is followed from the moment of their birth until the last surviving individual dies. Under this interpretation, the various remaining columns are defined in the following manner: l_x equals the number of individuals in the life table surviving to exact age x . We arbitrarily set the number “born into” the life

table, l_0 , which is otherwise known as the *radix*, to some value—most often, 100,000. We generate all subsequent l_x values by the following equation:

$$l_{x+n} = l_x \cdot [1 - {}_nq_x] \tag{5}$$

${}_nd_x$ equals the number of deaths experienced by the life table cohort within the age interval x to $x+n$. It is the product of the number of individuals alive at exact age x and the conditional probability of dying within the age interval:

$${}_nd_x = l_x \cdot {}_nq_x \tag{6}$$

The concept of “person-years” is critical to understanding life table construction. Each individual who survives from one birthday to the next contributes one additional person-year to those tallied by the cohort to which that person belongs. In the year in which the individual dies, the decedent contributes some fraction of a person-year to the overall number for that cohort.

${}_nL_x$ equals the total number of person-years experienced by a cohort in the age interval, x to $x+n$. It is the sum of person-years contributed by those who have survived to the end of the interval

and those contributed by individuals who die within that interval:

$${}_nL_x = [n'l_{x+n}] + [{}_na_x \cdot {}_nd_x] \quad (7)$$

T_x equals the number of person-years lived beyond exact age x :

$$T_x = \sum_{a=x,n}^{\infty} {}_nL_a = T_{x+n} + {}_nL_x \quad (8)$$

e_x equals the expected number of years of life remaining for an individual who has already survived to exact age x . It is the total number of person-years experienced by the cohort above that age divided by the number of individuals starting out at that age:

$$e_x = \frac{T_x}{l_x} \quad (9)$$

The ${}_nL_x$ and T_x columns are generated from the oldest age to the youngest. If the last age category is, for example, eighty-five and above (it is typically “open-ended” in this way), we must have an initial value for T_{85} in order to begin the process. This value is derived in the following fashion: Since for this oldest age group, $l_{85} = {}_{\infty}d_{85}$ (due to the fact that the number of individuals in a cohort who will die at age eighty-five or beyond is simply the number surviving to age eighty-five) and $T_{85} = L_{85}$, we have:

$$e_{85} = \frac{T_{85}}{l_{85}} = \frac{1}{l_{85} / T_{85}} = \frac{1}{{}_{\infty}d_{85} / L_{85}} \approx \frac{1}{{}_{\infty}M_{85}} \quad (10)$$

From the life table, we can obtain mortality information in a variety of ways. In table 2, we see, for example, that the expectation of life at birth, e_0 , is 76.1 years. If an individual in this population survives to age eighty, then he or she might expect to live 8.4 years longer. We might also note that the probability of surviving from birth to one’s tenth birthday is l_{10}/l_0 , or 0.99022. Given that one has already lived eighty years, the probability that one survives five additional years is l_{85}/l_{80} , or 33,629/49,276=0.68246.

POPULATION PROJECTION

The life table, in addition, is often used to project either total population size or the size of specific age groups. In so doing, we must invoke a different interpretation of the ${}_nL_x$ ’s and the T_x ’s in the life table. We treat them as representing the age distribution of a *stationary population*—that is, a population having long been subject to zero growth. Thus, ${}_5L_{20}$, for example, represents the number of twenty- to twenty-four-year-olds in the life table “population,” into which l_0 , or 100,000, individuals are born each year. (One will note by summing the ${}_nd_x$ column that 100,000 die every year, thus giving rise to stationarity of the life table population.)

If we were to assume that the United States is a *closed population*—that is, a population whose net migration is zero—and, furthermore, that the mortality levels obtaining in 1996 were to remain constant for the following ten years, then we would be able to project the size of any U.S. cohort up to ten years into the future. Thus, if we wished to know the number of fifty- to fifty-four-year-olds in 2006, we would take advantage of the following relation that is assumed to hold approximately:

$$\frac{{}_nP_{x+t}^{\tau+t}}{{}_nP_x^{\tau}} \approx \frac{{}_nL_{x+t}^{\tau+t}}{{}_nL_x^{\tau}} \quad (11)$$

where τ is the base year of the projection (e.g., 1996) and t is the number of years one is projecting the population forward. This equation implies that the fifty- to fifty-four-year-olds in 2006, ${}_5P_{50}^{2006}$, is simply the number of forty- to forty-four-year-olds ten years earlier, ${}_5P_{40}^{1996}$, multiplied by the proportion of forty- to forty-four-year-olds in the life table surviving ten years, ${}_5L_{50}/{}_5L_{40}$.

In practice, it is appropriate to use the above relation in population projection only if the width of the age interval under consideration, n , is sufficiently narrow. If the age interval is very broad—for example, in the extreme case in which we are attempting to project the number of people aged ten and above in 2006 from the number zero and above (i.e, the entire population) in 1996—we cannot be assured that the life table age distribution within that interval resembles closely enough the age distribution of the actual population. In other words, if the actual population’s age distribution within a broad age interval is significantly

different from that within the corresponding interval of the life table population, then implicitly by using this projection device we are improperly weighing the component parts of the broad interval with respect to survival probabilities.

Parenthetically, if we desired to determine the size of any component of the population under t years old—in this particular example, ten years old—we would have to draw upon fertility as well as mortality information, because at time τ these individuals had not yet been born.

HAZARDS MODELS

Suppose we were to examine the correlates of marital dissolution. In a life table analysis, the break-up of the marriage (as measured, e.g., by separation or divorce) would serve as the analogue to death, which is the means of exit in the standard life table analysis.

In the study of many duration-dependent phenomena, it is clear that several factors may affect whether an individual exits from a life table. Certainly, it is well-established that a large number of socioeconomic variables simultaneously impinge on the marital dissolution process. In many populations, whether one has given birth premaritally, cohabited premaritally, married at a young age, or had little in the way of formal education, among a whole host of other factors, have been found to be strongly associated with marital instability. In such studies, in which one attempts to disentangle the intricately related influences of several variables on survivorship in a given state, we invoke a hazards model approach. Such an approach may be thought of as a multivariate statistical extension of the simple life table analysis presented above (for theoretical underpinnings, see, e.g., Cox and Oakes 1984 and Allison 1984; for applications to marital stability, see, e.g., Menken, Trussell, Stempel, and Babakol 1981 and Bennett, Blanc, and Bloom 1988).

In the marital dissolution example, we would assume that there is a hazard, or risk, of dissolution at each marital duration, d , and we allow this duration-specific risk to depend on individual characteristics (such as age at marriage, education, etc.). In the *proportional hazards model*, a set of individual characteristics represented by a vector

of covariates shifts the hazard by the same proportional amount at all durations. Thus, for an individual i at duration d , with an observed set of characteristics represented by a vector of covariates, Z_i , the hazard function, $\mu_i(d)$, is given by:

$$\mu_i(d) = \exp[\lambda(d)] \exp[Z_i\beta] \quad (12)$$

where β is a vector of parameters and $\lambda(d)$ is the underlying duration pattern of risk. In this model, then, the underlying risk of dissolution for an individual i with characteristics Z_i is multiplied by a factor equal to $\exp[Z_i\beta]$.

We may also implement a more general set of models to test for departures from some of the restrictive assumptions built into the proportional hazards framework. More specifically, we allow for time-varying covariates (for instance, in this example, the occurrence of a first marital birth) as well as allow for the effects of individual characteristics to vary with duration of first marriage. This model may be written as:

$$\mu_i(d) = \exp[\lambda(d)] \exp[Z_i(d)\beta(d)] \quad (13)$$

where $\lambda(d)$ is defined as in the proportional hazards model, $Z_i(d)$ is the vector of covariates, some of which may be time-varying, and $\beta(d)$ represents a vector of parameters, some of which may give rise to nonproportional effects. The model parameters can be estimated using the method of maximum likelihood. The estimation procedure assumes that the hazard, $\mu_i(d)$, is constant within duration intervals. The interval width chosen by the analyst, of course, should be supported on both substantive and statistical grounds.

INDIRECT DEMOGRAPHIC ESTIMATION

Unfortunately, many countries around the world have poor or nonexistent data pertaining to a wide array of demographic variables. In the industrialized nations, we typically have access to data from rigorous registration systems that collect data on mortality, marriage, fertility, and other demographic processes. However, when analyzing the demographic situation of less developed nations, we are often confronted with a paucity of available data on these fundamental processes. When such data are in fact collected, they are often sufficiently

inadequate to be significantly misleading. For example, in some countries we have learned that as few as half of all actual deaths are recorded. If we mistakenly assume the value of the actual number to be the registered number, then we will substantially overestimate life expectancy in these populations. In essence, we will incorrectly infer that people are dying at a slower rate than is truly the case.

The Stable Population Model. Much demographic estimation has relied on the notion of stability. A *stable population* is defined as one that is established by a long history of unchanging fertility and mortality patterns. This criterion gives rise to a fixed proportionate age distribution, constant birth and death rates, and a constant rate of population growth (see, e.g., Coale 1972). The basic stable population equation is:

$$c(a) = be^{-ra}p(a) \quad (14)$$

where $c(a)$ is the proportion of the population exact age a , b is the crude birth rate, r is the rate of population growth, and $p(a)$ is the proportion of the population surviving to exact age a . Various mathematical relationships have been shown to obtain among the demographic variables in a stable population. This becomes clear when we multiply both sides of the equation by the total population size. Thus, we have:

$$N(a) = Be^{-ra}p(a) \quad (15)$$

where $N(a)$ is the number of individuals in the population exact age a and B is the current annual number of births. We can see that the number of people aged a this year is simply the product of the number of births entering the population a years ago—namely, the current number of births times a growth rate factor, which discounts the births according to the constant population growth rate, r (which also applies to the growth of the number of births over time)—and the proportion of a birth cohort that survives to be aged a today. Note that the constancy over time of the mortality schedule, $p(a)$, and the growth rate, r , are crucial to the validity of this interpretation.

When we assume a population is stable, we are imposing structure upon the demographic relationships existing therein. In a country where data

are inadequate, indirect methods allow us—by drawing upon the known structure implied by stability—to piece together sometimes inaccurate information and ultimately derive sensible estimates of the population parameters. The essential strategy in indirect demographic estimation is to infer a value or set of values for a variable whose elements are either unobserved or inaccurate from the relationship among the remaining variables in the above equation (or an equation deriving from the one above). We find that these techniques are robust with respect to moderate departures from stability, as in the case of quasi-stable populations, in which only fertility has been constant and mortality has been gradually changing.

The Nonstable Population Model. Throughout much of the time span during which indirect estimation has evolved, there have been many countries where populations approximated stability. In recent decades, however, many countries have experienced rapidly declining mortality or declining or fluctuating fertility and, thus, have undergone a radical departure from stability. Consequently, previously successful indirect methods, grounded in stable population theory, are, with greater frequency, ill-suited to the task for which they were devised. As is often the case, necessity is the mother of invention and so demographers have sought to adapt their methodology to the changing world.

In the early 1980s, a methodology was developed that can be applied to populations that are far from stable (see, e.g., Bennett and Horiuchi 1981; and Preston and Coale 1982). Indeed, it is no longer necessary to invoke the assumption of stability, if we rely upon the following equation:

$$c(a) = b \cdot \exp \left[-\int_0^a r(x) dx \right] \cdot p(a) \quad (16)$$

where $r(x)$ is the growth rate of the population at exact age x . This equation holds true for any closed population, and, indeed, can be modified to accommodate populations open to migration.

The implied relationships among the age distribution of living persons and deaths, and rates of growth of different age groups, provide the basis for a wide range of indirect demographic methods that allow us to infer accurate estimates of basic

demographic parameters that ultimately can be used to better inform policy on a variety of issues. Two examples are as follows.

First, suppose we have the age distribution for a country at each of two points in time, in addition to the age distribution of deaths occurring during the intervening years. We may then estimate the completeness of death registration in that population using the following equation (Bennett and Horiuchi 1981):

$$\tilde{N}(a) = \int_a^{\infty} D(x) \exp \left[\int_a^x r(u) du \right] dx \quad (17)$$

where $\hat{N}(a)$ is the estimated number of people at exact age a , $D(x)$ is the number of deaths at exact age x and $r(u)$ is the rate of the growth of the number of persons at exact age u between the two time points. By taking the ratio of the estimated number of persons with the enumerated population, we have an estimate of the completeness of death registration in the population relative to the completeness of the enumerated population. This relative completeness (in contrast to an “absolute” estimate of completeness) is all that is needed to determine the true, unobserved age-specific death rates, which in turn allows one to construct an unbiased life table.

A second example of the utility of the nonstable population framework is shown by the use of the following equation:

$$\frac{N(x)}{N(a)} = {}_{x-a}P_a \exp \left[\int_a^x r(u) du \right] \quad (18)$$

where $N(x)$ and $N(a)$ are the number of people exact ages x and a , respectively, and ${}_{x-a}P_a$ is the probability of surviving from age a to age x according to period mortality rates. By using variants of this equation, we can generate reliable population age distributions (e.g., in situations in which censuses are of poor quality) from a trustworthy life table (Bennett and Garson 1983).

MORTALITY MODELING

The field of demography has a long tradition of developing models that are based upon empirical regularities. Typically in demographic modeling, as in all kinds of modeling, we try to adhere to the

principle of parsimony—that is, we want to be as efficient as possible with regard to the detail, and therefore the number of parameters, in a model.

Mortality schedules from around the world reveal that death rates follow a common pattern of relatively high rates of infant mortality, rates that decline through early childhood until they bottom out in the age range of five to fifteen or so, then rates that increase slowly through the young and middle adult years, and finally rising more rapidly during the older adult ages beyond the forties or fifties. Various mortality models exploit this regular pattern in the data. Countries differ with respect to the overall level of mortality, as reflected in the expectation of life at birth, and the precise relationship that exists among the different age components of the mortality curve.

Coale and Demeny (1983) examined 192 mortality schedules from different times and regions of the world and found that they could be categorized into four “families” of life tables. Although overall mortality levels might differ, within each family the relationships among the various age components of mortality were shown to be similar. For each family, Coale and Demeny constructed a “model life table” for females that was associated with each of twenty-five expectations of life at birth from twenty through eighty. A comparable set of tables was developed for males. In essence, a researcher can match bits of information that are known to be accurate in a population with the corresponding values in the model life tables, and ultimately derive a detailed life table for the population under study. In less developed countries, model life tables are often used to estimate basic mortality parameters, such as e_0 or the crude death rate, from other mortality indicators that may be more easily observable.

Other mortality models have been developed, the most notable being that by Brass (1971). Brass noted that one mortality schedule could be related to another by means of a linear transformation of the logits of their respective survivorship probabilities (i.e., the vector of l_x values, given a radix of one). Thus, one may generate a life table by applying the logit system to a “standard” or “reference” life table, given an appropriate pair of parameters that reflect (1) the overall level of mortality in the population under study, and (2) the relationship between child and adult mortality.

**MARRIAGE, FERTILITY, AND
MIGRATION MODELS**

Coale (1971) observed that age distributions of first marriages are structurally similar in different populations. These distributions tend to be smooth, unimodal, and skewed to the right, and to have a density close to zero below age fifteen and above age fifty. He also noted that the differences in age-at-marriage distributions across female populations are largely accounted for by differences in their means, standard deviations, and cumulative values at the older ages, for example, at age fifty. As a basis for the application of these observations, Coale constructed a standard schedule of age at first marriage using data from Sweden, covering the period 1865 through 1869. The model that is applied to marriage data is represented by the following equation:

$$g(a) = \frac{E}{\sigma} 1.2813 \exp\left\{-1.145 \left(\frac{a-\mu}{\sigma} + 0.805\right) - \exp[-1.896 \left(\frac{a-\mu}{\sigma} + 0.805\right)]\right\} \quad (20)$$

where $g(a)$ is the proportion marrying at age a in the observed population and μ , σ , and E are, respectively, the mean and the standard deviation of age at first marriage (for those who ever marry), and the proportion ever marrying.

The model can be extended to allow for covariate effects by stipulating a functional relationship between the parameters of the model distribution and a set of covariates. This may be specified as follows:

$$\left. \begin{aligned} \mu_i &= \mathbf{X}_i' \alpha \quad , \\ \sigma_i &= \mathbf{Y}_i' \beta \quad , \\ E_i &= \mathbf{Z}_i' \gamma \quad , \end{aligned} \right\} \quad (20)$$

where \mathbf{X}_i , \mathbf{Y}_i , and \mathbf{Z}_i are the vector values of characteristics of an individual that determine, respectively, μ_i , σ_i , and E_i , and α , β , and γ are the associated parameter vectors to be estimated.

Because the model is parametric, it can be applied to data referring to cohorts who have yet to complete their marriage experience. In this fashion, the model can be used for purposes of projection (see, e.g., Bloom and Bennett 1990). The model has also been found to replicate well

the first birth experience of cohorts (see, e.g., Bloom 1982).

Coale and Trussell (1974), recognizing the empirical regularities that exist among age profiles of fertility across time and space and extending the work of Louis Henry, developed a set of model fertility schedules. Their model is based in part on a reference distribution of age-specific marital fertility rates that describes the pattern of fertility in a *natural fertility population*—that is, one that exhibits no sign of controlling the extent of child-bearing activity. When fitted to an observed age pattern of fertility, the model's two parameters describe the overall level of fertility in the population and the degree to which their fertility within marriage is controlled by some means of contraception. Perhaps the greatest use of this model has been devoted to comparative analyses, which is facilitated by the two-parameter summary of any age pattern of fertility in question.

Although the application of indirect demographic estimation methods to migration analysis is not as mature as that to other demographic processes, strategies similar to those invoked by fertility and mortality researchers have been applied to the development of model migration schedules. Rogers and Castro (1981) found that similar age patterns of migration obtained among many different populations. They have summarized these regularities in a basic eleven-parameter model, and, using Brass and Coale logic, explore ways in which their model can be applied satisfactorily to data of imperfect quality.

The methods described above comprise only a small component of the methodological tools available to demographers and to social scientists, in general. Some of these methods are more readily applicable than others to fields outside of demography. It is clear, for example, how we may take advantage of the concept of standardization in a variety of disciplines. So, too, may we apply life table analysis and nonstable population analysis to problems outside the demographic domain. Any analogue to birth and death processes can be investigated productively using these central methods. Even the fundamental concept underlying the above mortality, fertility, marriage, and migration models—that is, exploiting the power to be found in empirical regularities—can be applied fruitfully to other research endeavors.

DEMOGRAPHIC TRANSITION

The human population has maintained relatively gradual growth throughout most of history by high, and nearly equal, rates of deaths and births. Since about 1800, however, this situation has changed dramatically, as most societies have undergone major declines in mortality, setting off high growth rates due to the imbalance between deaths and births. Some societies have eventually had fertility declines and emerged with a very gradual rate of growth as low levels of births matched low levels of mortality.

There are many versions of demographic transition theory (Mason 1997), but there is some consensus that each society has the potential to proceed sequentially through four general stages of variation in death and birth rates and population growth. Most societies in the world have passed through the first two stages, at different dates and speeds, and the contemporary world is primarily characterized by societies in the last two stages, although a few are still in the second stage.

Stage 1, presumably characterizing most of human history, involves high and relatively equal birth and death rates and little resulting population growth.

Stage 2 is characterized by a declining death rate, especially concentrated in the years of infancy and childhood. The fertility rate remains high, leading to at least moderate population growth.

Stage 3 involves further declines in mortality, usually to low levels, and initial sustained declines in fertility. Population growth may become quite high, as levels of fertility and mortality increasingly diverge.

Stage 4 is characterized by the achievement of low mortality and the rapid emergence of low fertility levels, usually near those of mortality. Population growth again becomes quite low or negligible.

While demographers argue about the details of demographic change in the past 200 years, clearcut declines in birth and death rates appeared on the European continent and in areas of overseas European settlement in the nineteenth century, especially in the last three decades. By 1900, life expectancies in “developed” societies such as the United States were probably in the mid-forties, having increased by a few years in the century (Preston and Haines 1991). By the end of the twentieth century, even more dramatic gains in mortality were evident, with life expectancies reaching into the mid- and high-seventies.

The European fertility transition of the late 1800s to the twentieth century involved a relatively continuous movement from average fertility levels of five or six children per couple to bare levels of replacement by the end of the 1930s. Fertility levels rose again after World War II, but then began another decline about 1960. Some countries now have levels of fertility that are well below long-term replacement levels.

With a few exceptions such as Japan, most other parts of the developing world did not experience striking declines in mortality and fertility until the midpoint of the twentieth century. Gains in life expectancy became quite common and very rapid in the post-World War II period throughout the developing world (often taking less than twenty years), although the amount of change was quite variable. Suddenly in the 1960s, fertility transitions emerged in a small number of societies, especially in the Caribbean and Southeast Asia, to be followed in the last part of the twentieth century by many other countries.

Clear variations in mortality characterize many parts of the world at the end of the twentieth century. Nevertheless, life expectancies in countries throughout the world are generally greater than those found in the most developed societies in 1900. A much greater range in fertility than mortality characterizes much of the world, but fertility declines seem to be spreading, including in “laggard” regions such as sub-Saharan Africa.

The speed with which the mortality transition was achieved among contemporary lesser-developed countries has had a profound effect on the magnitude of the population growth that has occurred during the past few decades. Sweden, a

model example of the nineteenth century European demographic transition, peaked at an annual rate of natural increase of 1.2 percent. In contrast, many developing countries have attained growth rates of over 3.0 percent. The world population grew at a rate of about 2 percent in the early 1970s but has now declined to about 1.4 percent, as fertility rates have become equal to the generally low mortality rates.

CAUSES OF MORTALITY TRANSITIONS

The European mortality transition was gradual, associated with modernization and raised standards of living. While some dispute exists among demographers, historians, and others concerning the relative contribution of various causes (McKeown 1976; Razzell 1974), the key factors probably included increased agricultural productivity and improvements in transportation infrastructure which enabled more efficient food distribution and, therefore, greater nutrition to ward off disease. The European mortality transition was also probably influenced by improvements in medical knowledge, especially in the twentieth century, and by improvements in sanitation and personal hygiene. Infectious and environmental diseases especially have declined in importance relative to cancers and cardiovascular problems. Children and infants, most susceptible to infectious and environmental diseases, have showed the greatest gains in life expectancy.

The more recent and rapid mortality transitions in the rest of the world have mirrored the European change with a movement from infectious/environmental causes to cancers and cardiovascular problems. In addition, the greatest beneficiaries have been children and infants. These transitions result from many of the same factors as the European case, generally associated with economic development, but as Preston (1975) outlines, they have also been influenced by recent advances in medical technology and public health measures that have been imported from the highly-developed societies. For instance, relatively inexpensive vaccines are now available throughout the world for immunization against many infectious diseases. In addition, airborne sprays have been distributed at low cost to combat widespread

diseases such as malaria. Even relatively weak national governments have instituted major improvements in health conditions, although often only with the help of international agencies.

Nevertheless, mortality levels are still higher than those in many rich societies due to such factors as inadequate diets and living conditions, and inadequate development of health facilities such as hospitals and clinics. Preston (1976) observes that among non-Western lesser-developed countries, mortality from diarrheal diseases (e.g., cholera) has persisted despite control over other forms of infectious disease due to the close relationship between diarrheal diseases, poverty, and ignorance—and therefore a nation's level of socioeconomic development.

Scholars (Caldwell 1986; Palloni 1981) have warned that prospects for future success against high mortality may be tightly tied to aspects of social organization that are independent of simple measures of economic well-being: Governments may be more or less responsive to popular need for improved health; school system development may be important for educating citizens on how to care for themselves and their families; the equitable treatment of women may enhance life expectancy for the total population.

Recent worldwide mortality trends may be charted with the help of data on life expectancy at age zero that have been gathered, sometimes on the basis of estimates, by the Population Reference Bureau (PRB), a highly respected chronicler of world vital rates. For 165 countries with relatively stable borders over time, it is possible to relate estimated life expectancy in 1986 with the same figure for 1998. Of these countries, only 13.3 percent showed a decline in life expectancy during the time period. Some 80.0 percent had overall increasing life expectancy, but the gains were highly variable. Of all the countries, 29.7 percent actually had gains of at least five years or more, a sizable change given historical patterns of mortality.

An indication of the nature of change may be discerned by looking at Figure 1, which shows a graph of the life expectancy values for the 165 countries with stable borders. Each point represents a country and shows the level of life expectancy in 1986 and in 1998. Note the relatively high

levels of life expectancy by historical standards for most countries in both years. Not surprisingly, there is a strong tendency for life expectancy values to be correlated over time. A regression straight line, indicating average life expectancy in 1998 as a function of life expectancy in 1986 describes this relationship. As suggested above, the levels of life expectancy in 1998 tend to be slightly higher than the life expectancy in 1986. Since geography is highly associated with economic development, the points on the graph generally form a continuum from low to high life expectancy. African countries tend to have the lowest life expectancies, followed by Asia, Oceania, and the Americas. Europe has the highest life expectancies.

The African countries comprise virtually all the countries with declining life expectancies, probably a consequence of their struggles with acquired immune deficiency syndrome (AIDS), malnutrition, and civil disorder. Many of them have lost several years of life expectancy in a very short period of time. However, a number of the African countries also have sizeable increases in life expectancies.

Asian and American countries dominate the mid-levels of life expectancy, with the Asian countries showing a strong tendency to increase their life expectancies, consistent with high rates of economic development.

Unfortunately, Figure 1 does not include the republics of the former Soviet Union, since exactly comparable data are not available for both time points. Nevertheless, there is some consensus among experts that life expectancy has deteriorated in countries such as Russia that have made the transition from communism to economically-unstable capitalism.

WHAT DRIVES FERTILITY RATES?

The analysis of fertility decline is somewhat more complicated analytically than mortality decline. One may presume that societies will try, if given resources and a choice, to minimize mortality levels, but it seems less necessarily so that societies have an inherent orientation toward low fertility, or, for that matter, any specific fertility level. In addition, fertility rates may vary quite widely across

Figure 1

societies due to factors (Bongaarts 1975) that have little relationship to conscious desires such as prolonged breastfeeding which suppresses reproductive ovulation in women, the effectiveness of birth control methods, and the amount of involuntary foetal abortion. As a result of these analytic ambiguities, scholars seem to have less consensus on the social factors that might produce fertility than mortality decline (Hirschman 1994; Mason 1997).

Coale (1973), in an attempt to reconcile the diversity of circumstances under which fertility declines have been observed to occur, identified three major conditions for a major fall in fertility:

1. Fertility must be within the calculus of conscious choice. Parents must consider it an acceptable mode of thought and form of behavior to balance the advantages and disadvantages of having another child.

2. Reduced fertility must be viewed as socially or economically advantageous to couples.
3. Effective techniques of birth control must be available. Sexual partners must know these techniques and have a sustained will to use the them.

Beyond Coale's conditions, little consensus has emerged on the causes of fertility decline. There are, however, a number of major ideas about what causes fertility transitions that may be summarized in a few major hypotheses.

A major factor in causing fertility change may be the mortality transition itself. High-mortality societies depend on high fertility to ensure their survival. In such circumstances, individual couples will maximize their fertility to guarantee that at least a few of their children survive to adulthood, to perpetuate the family lineage and to care for

them in old age. The decline in mortality may also have other consequences for fertility rates. As mortality declines, couples may perceive that they can control the survival of family members by changing health and living practices such as cleanliness and diet. This sense of control may extend itself to the realm of fertility decisions, so that couples decide to calculate consciously the number of children they would prefer and then take steps to achieve that goal.

Another major factor may be the costs and benefits of children. High-mortality societies are often characterized by low technology in producing goods; in such a situation (as exemplified by many agricultural and mining societies), children may be economically useful to perform low-skilled work tasks. Parents have an incentive to bear children, or, at the minimum, they have little incentive not to bear children. However, high-technology societies place a greater premium on highly-skilled labor and often require extended periods of education. Children will have few economic benefits and may become quite costly as they are educated and fed for long periods of time.

Another major factor that may foster fertility decline is the transfer of functions from the family unit to the state. In low-technology societies, the family or kin group is often the fundamental unit, providing support for its members in times of economic distress and unemployment and for older members who can no longer contribute to the group through work activities. Children may be viewed as potential contributors to the unit, either in their youth or adulthood. In high-technology societies, some of the family functions are transferred to the state through unemployment insurance, welfare programs, and old age retirement systems. The family functions much more as a social or emotional unit where the economic benefits of membership are less tangible, thus decreasing the incentive to bear children.

Other major factors (Hirschman 1994; Mason 1997) in fertility declines may include urbanization and gender roles. Housing space is usually costly in cities, and the large family becomes untenable. In many high-technology societies, women develop alternatives to childbearing through

employment outside their homes, and increasingly assert their social and political rights to participate equally with men in the larger society. Because of socialization, men are generally unwilling to assume substantial child-raising responsibilities, leaving partners with little incentive to participate in sustained childbearing through their young adult lives.

No consensus exists on how to order these theories in relative importance. Indeed, each theory may have more explanatory power in some circumstances than others, and their relative importance may vary over time. For instance, declines in mortality may be crucial in starting fertility transitions, but significant alterations in the roles of children may be key for completing them. Even though it is difficult to pick the “best” theory, every country that has had a sustained mortality decline of at least thirty years has also had some evidence of a fertility decline. Many countries seem to have the fertility decline precondition of high life expectancy, but fewer have achieved the possible preconditions of high proportions of the population achieving a secondary education.

EUROPEAN FERTILITY TRANSITION

Much of what is known about the process of fertility transition is based upon research at Princeton University (known as the European Fertility Project) on the European fertility transition that took place primarily during the seventy-year period between 1870 and 1940. Researchers used aggregate government-collected data for the numerous “provinces” or districts of countries, typically comparing birth rates across time and provinces.

In that almost all births in nineteenth-century Europe occurred within marriage, the European model of fertility transition was defined to take place at the point marital fertility was observed to fall by more than 10 percent (Coale and Treadway 1986). Just as important, the Project scholars identified the existence of varying levels of natural fertility (birth rates when no deliberate fertility control is practiced) across Europe and throughout European history (Knodel 1977). Comparative use of natural fertility models and measures derived from these models have been of enormous use to demographers in identifying the initiation and progress of fertility transitions in more contemporary contexts.

Most scholars have concluded that European countries seemed to start fertility transitions from very different levels of natural fertility but moved at quite similar speeds to similar levels of controlled fertility on the eve of World War II (Coale and Treadway 1986). As the transition progressed, areal differences in fertility within and across countries declined, while the remaining differences were heavily between countries (Watkins 1991).

Although some consensus has emerged on descriptive aspects of the fertility transition, much less agreement exists on the social and economic factors that caused the long-term declines. Early theorists of fertility transitions (Notestein 1953) had posited a simple model driven by urban-industrial social structure, but this perspective clearly proved inadequate. For instance, the earliest declines did not occur in England, the most urban-industrial country of the time, but were in France, which maintained a strong rural culture. The similarity of the decline across provinces and countries of quite different social structures also seemed puzzling within the context of previous theorizing. Certainly, no one has demonstrated that variations in the fertility decline across countries, either in the timing or the speed, were related clearly to variations in crude levels of infant mortality, literacy rates, urbanization, and industrialization. Other findings from recent analysis of the European experience include the observation that in some instances, reductions in fertility preceded reductions in mortality (Cleland and Wilson 1987), a finding that is inconsistent with the four-stage theory of demographic transition.

The findings of the European Fertility Project have led some demographers (Knodel and van de Walle 1979) to reformulate ideas about why fertility declined. They suggest that European couples were interested in a small family well before the actual transition occurred. The transition itself was especially facilitated by the development of effective and cheap birth control devices such as the condom and diaphragm. Information about birth control rapidly and widely diffused through European society, producing transitions that seemed to occur independently of social structural factors such as mortality, urbanization, and educational attainment. In addition, these scholars argue that “cultural” factors were also important in the decline. This is based on the finding that provinces of some countries such as Belgium differed in their

fertility declines on the basis of areal religious composition (Lesthaeghe 1977) and that, in other countries such as Italy, areal variations in the nature of fertility decline were related to political factors such as the Socialist vote, probably reflecting anticlericalism (Livi-Bacci 1977). Others (Lesthaeghe 1983) have also argued for “cultural” causes of fertility transitions.

While the social causes of the European fertility transition may be more complex than originally thought, it may still be possible to rescue some of the traditional ideas. For instance, mortality data in Europe at the time of the fertility transition were often quite incomplete or unreliable, and most of the studies focused on infant (first year of life) mortality as possible causes of fertility decline. Matthiessen and McCann (1978) show that mortality data problems make some of the conclusions suspect and that infant mortality may sometimes be a weak indicator of child survivorship to adulthood. They argue that European countries with the earliest fertility declines may have been characterized by more impressive declines in post-infant (but childhood) mortality than infant mortality.

Conclusions about the effects of children’s roles on fertility decline have often been based on rates of simple literacy as an indicator of educational system development. However, basic literacy was achieved in many European societies well before the major fertility transitions, and the major costs of children would occur when secondary education was implemented on a large scale basis, which did not happen until near the end of the nineteenth century (Van de Walle 1980). In a time-series analysis of the United States fertility decline from 1870 to the early 1900s, Guest and Tolnay (1983) find a nearly perfect tendency for the fertility rate to fall as the educational system expanded in terms of student enrollments and length of the school year. Related research also shows that educational system development often occurred somewhat independently of urbanization and industrialization in parts of the United States (Guest 1981).

An important methodological issue in the study of the European transition (as in other transitions) is how one models the relationship between social structure and fertility. Many of the research reports from the European Fertility Project seem to assume that social structure and fertility had to be

closely related at all time points to support various theories about the causal importance of such factors as mortality and children's roles, but certain lags and superficial inconsistencies do not seem to prove fundamentally that fertility failed to respond as some of the above theories would suggest. The more basic question may be whether fertility eventually responded to changes in social structure such as mortality.

Even after admitting some problems with previous traditional interpretations of the European fertility transition, one cannot ignore the fact that the great decline in fertility occurred at almost the same time as the great decline in mortality and was associated (even if loosely) with a massive process of urbanization, industrialization, and the expansion of educational systems.

FERTILITY TRANSITIONS IN THE DEVELOPING WORLD

The great majority of countries in the developing world have undergone some fertility declines in the second half of the twentieth century. While the spectacularly rapid declines (Taiwan, South Korea) receive the most attention, a number are also very gradual (e.g. Guatemala, Haiti, Iraq, Cambodia), and a number are so incipient (especially in Africa) that their nature is difficult to discern.

The late twentieth century round of fertility transitions has occurred in a very different social context than the historical European pattern. In the past few decades, mortality has declined very rapidly. National governments have become very attuned to checking their unprecedented national growth rates through fertility control. Birth control technology has changed greatly through the development of inexpensive methods such as the intrauterine device (IUD). The world has become more economically and socially integrated through the expansion of transportation and developments in electronic communications, and "Western" products and cultural ideas have rapidly diffused throughout the world. Clearly, societies are not autonomous units that respond demographically as isolated social structures.

Leaders among developing countries in the process of demographic transition were found in East Asia and Latin America, and the Caribbean

(Coale 1983). The clear leaders among Asian nations, such as South Korea and Taiwan, generally had experienced substantial economic growth, rapid mortality decline, rising educational levels, and exposure to Western cultural influences (Freedman 1998). By 1998, South Korea and Taiwan had fertility rates that were below long-term replacement levels. China also experienced rapidly declining fertility, which cannot be said to have causes in either Westernization or more than moderate economic development, with a life expectancy estimated at seventy-one years and a rate of natural increase of 1.0 percent (PRB 1998).

Major Latin American nations that achieved substantial drops in fertility (exceeding 20 percent) in recent decades with life expectancies surpassing sixty years include Argentina, Brazil, Chile, Columbia, the Dominican Republic, Jamaica, Mexico, and Venezuela. All of these have also experienced substantial changes in mortality, education, or both, and economic development.

Unlike the European historical experience, fertility declines in the post-1960 period have not always sustained themselves until they reached near replacement levels. A number of countries have started declines but then leveled off with three or four children per reproductive age woman. For instance, Malaysia was considered a "miracle" case of fertility decline, along with South Korea and Taiwan, but in recent years its fertility level has stabilized somewhat above the replacement level.

Using the PRB data for 1986 and 1998, we can trace recent changes for 166 countries in estimated fertility as measured by the Total Fertility Rate (TFR), an indicator of the number of children typically born to a woman during her lifetime. Some 80.1 percent of the countries showed declines in fertility. Of all the countries, 37.3 percent had a decline of at least one child per woman, and 9.0 percent had a decline of at least two children per woman.

The region that encompasses countries having the highest rates of population growth is sub-Saharan Africa. Growth rates generally exceed 2 percent, with several countries having rates that clearly exceed 3 percent. This part of the world has been one of the latest to initiate fertility declines, but in the 1986-1998 period, Botswana, Kenya,

and Zimbabwe all sustained fertility declines of at least two children per woman, and some neighboring societies were also engaged in fertility transition. At the same time, many sub-Saharan countries are pre-transitional or only in the very early stages of a transition. Of the twenty-five countries that showed fertility increases in the PRB data, thirteen of them were sub-Saharan nations with TFRs of at least 5.0.

In general, countries of the Middle East and regions of Northern Africa populated by Moslems have also been slow to embark on the process of fertility transition. Some (Caldwell 1976) found this surprising since a number had experienced substantial economic advances and invited the benefits of Western medical technology in terms of mortality reduction. Their resistance to fertility transitions had been attributed partly to an alleged Moslem emphasis on the subordinate role of women to men, leading them to have limited alternatives to a homemaker role. However, the PRB data for 1986–1998 indicate that some of these countries (Algeria, Bangladesh, Jordan, Kuwait, Morocco, Syria, Turkey) are among the small number that achieved reduction of at least two children per woman.

The importance of the mortality transition in influencing the fertility transition is suggested by Figure 2. Each dot is a country, positioned in terms of graphical relationship in the PRB data between life expectancy in 1986 and the TFR in 1998. The relationship is quite striking. No country with a life expectancy less than fifty has a TFR below 3.0. Remember that before the twentieth century, virtually all countries had life expectancies below fifty years. In addition, the figure shows a very strong tendency for countries with life expectancies above seventy to have TFRs below 2.0.

For a number of years, experts on population policy were divided on the potential role of contraceptive programs in facilitating fertility declines (Davis 1967). Since contraceptive technology has become increasingly cheap and effective, some (Enke 1967) argue that modest international expenditures on these programs in high-fertility countries could have significant rapid impacts on reproduction rates. Others (Davis 1967) point out, however, that family planning programs would only permit couples to achieve their desires, which may not be compatible with societal replacement

level fertility. The primary implication was that family planning programs would not be effective without social structures that encouraged the small family. A recent consensus on the value of family planning programs relative to social structural change seems to have emerged. Namely, family planning programs may be quite useful for achieving low fertility where the social structure is consistent with a small family ideal (Mauldin and Berelson 1978).

While the outlook for further fertility declines in the world is good, it is difficult to say whether and when replacement-level fertility will be achieved. Many, many major social changes have occurred in societies throughout the world in the past half-century. These changes have generally been unprecedented in world history, and thus we have little historical experience from which to judge their impact on fertility, both levels and speed of change (Mason 1997).

Some caution should be exercised about future fertility declines in some of the societies that have been viewed as leaders in the developing world. For instance, in a number of Asian societies, a strong preference toward sons still exists, and couples are concerned as much about having an adequate number of sons survive to adulthood as they are about total sons and daughters. Since pre-birth gender control is still difficult, many couples have a number of girl babies before they are successful in bearing a son. If effective gender control is achieved, some of these societies will almost certainly attain replacement-level fertility.

In other parts of the world such as sub-Saharan Africa, the future of still-fragile fertility transitions may well depend on unknown changes in the organization of families. Caldwell (1976), in a widely respected theory of demographic transition that incorporates elements of both cultural innovation and recognition of the role of children in traditional societies in maintaining net flows of wealth to parents, has speculated that the traditional extended kinship family model now predominant in the region facilitates high fertility. Families often form economic units where children are important work resources. The extended structure of the household makes the cost of any additional member low relative to a nuclear family structure. Further declines in fertility will depend on the

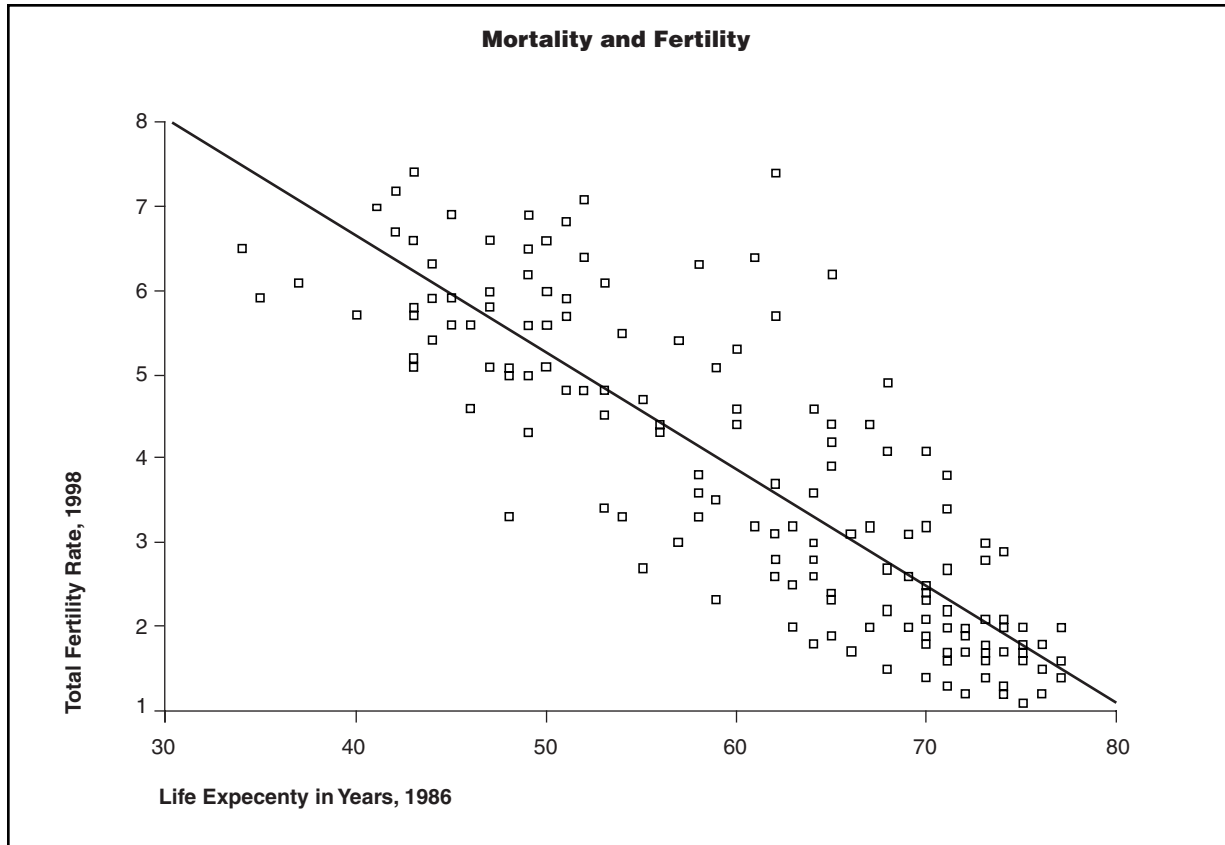

Figure 2

degree to which populations adopt the “Western” nuclear family, either through cultural diffusion or through autonomous changes in local social structure.

Taking the long view, the outlook for a completed state of demographic transition for the world population as a whole generally appears positive if not inevitable, although demographers are deeply divided on estimates of the size of world population at equilibrium, the timing of completed transition, the principal mechanisms at work, and the long-term ecological consequences. Certainly, the world population will continue to grow for some period of time, if only as a consequence of the previous momentum of high fertility relative to mortality. Most if not all demographers, however, subscribe to the view expressed by Coale (1974, p. 51) that the entire process of global demographic transition and the phase of phenomenal population growth that has accompanied

it will be a transitory (albeit spectacular) episode in human population history.

DEMOGRAPHY

Demography is the study of human populations. It is an important part of sociology and the other social sciences because all persisting social aggregates—societies, states, communities, racial or ethnic groups, professions, formal organizations, kinship groups, and so on—are also populations. The size of the population, its growth or decline, the location and spatial movement of its people, and their changing characteristics are important features of an aggregate whether one sees it as a culture, an economy, a polity, or a society. As a result some anthropologists, economists, historians, political scientists, and sociologists are also demographers, and most demographers are members of one of the traditional social science disciplines.

A central question for each of the social sciences is: How does the community, society, or whatever, seen as a culture, an economy, a polity, or whatever, produce and renew itself over the

years? Formal demography answers this question for aggregates seen as populations. This formal part of demography is fairly independent of the traditional social sciences and has a lengthy history in mathematics and statistics (Smith and Keyfitz 1977; Stone 1997; Desrosières 1998). It depends on a definition of age and on the relationship of age to fertility and mortality. Those relationships certainly are socially conditioned, but their major outlines are constrained by biology.

Beyond pursuing formal demography, the task of most social scientist-demographers is detailing the relationships between demographic change and other aspects of social change. Working with concepts, methods, and questions arising from the traditions of each of the social science disciplines as well as those of demography per se, scholars have investigated the relationship between demographic changes and such social changes as those in the nature of families (Davis 1985; Sweet and Bumpass 1987; Bumpass 1990; Waite 1995), levels of economic growth (Johnson and Lee 1987; Nerlove and Raut 1997), the development of colonialism (McNeill 1990), changes in kinship structures (Dyke and Morrill 1980), nationalism and interethnic strife (Tietelbaum and Winter 1998), and the development of the nation-state (Watkins 1991).

FORMAL DEMOGRAPHY

At the heart of demography is a body of strong and useful mathematical theory about how populations renew themselves (Keyfitz 1968, 1985; Coale 1972; Bourgeois-Pichat 1994). The theory envisions a succession of female birth cohorts living out their lives subject to a schedule of age-specific mortality chances and age-specific chances of having a female baby. In the simplest form of the model the age-specific rates are presumed constant from year to year.

Each new annual birth cohort is created because the age-specific fertility rates affect women in earlier birth cohorts who have come to a specific age in the year in question. Thus, the mothers of a new cohort of babies are spread among previous cohorts. The size of the new cohort is a weighted average of the age-specific fertility rates. The sizes of preceding cohorts, survived to the year in question, are the weights.

As a cohort of women age through their fertile period, they die and have children in successive years according to the age-specific rates appropriate to those years. Thus, the children of a single birth cohort of women are spread over a sequence of succeeding birth cohorts.

The number of girls ever born to a birth cohort, taken as a ratio to the initial size of the cohort, is implicit in the age-specific fertility and mortality rates. This ratio, called the net reproduction rate, describes the growth rate over a generation that is implicit in the age-specific rates. The length of this generation is also implicit in the age-specific rates as the average age of mothers at the birth of the second-generation daughters. With a rate of increase over a generation and a length of the generation, it is clear that an annual rate of increase is intrinsic to the age-specific rates.

The distribution of the children of a birth cohort over a series of succeeding cohorts has an important effect. If an unusually small or large birth cohort is created, the effects of its largeness or smallness will be distributed among a number of succeeding cohorts. In each of those succeeding cohorts, the effect of the unusual cohort is averaged with that of other birth cohorts to create the new cohort's size. Those new cohorts' "inherited" smallness or largeness, now diminished by averaging, will also be spread over succeeding cohorts. In a few generations the smallness or largeness will have averaged out and no reflection of the initial disturbance will be apparent.

Thus, without regard to peculiarities in the initial age distribution, the eventual age distribution of a population experiencing fixed age-specific fertility and mortality will become proportionately constant. As this happens, the population will take on a fixed aggregate birth and death rate and, consequently, a fixed rate of increase. The population so created is called a stable population and its rates, called intrinsic rates, are those implicit in the net reproduction rate and the length of a generation. Such rates, as well as the net reproduction rates, are frequently calculated for the age-specific fertility and mortality rates occurring for a single year as a kind of descriptive, "what if" summary.

This theory is elaborated in a number of ways. In one variant, age-specific rates are not constant but change in a fixed way (Lopez 1961). In another

elaboration the population is divided into a number of states with fixed age-specific migration or mobility among the states (Land and Rogers 1982; Schoen 1988). States may be geographic regions, marital circumstances, educational levels, or whatever.

In part, the value of this theory is in the light it sheds on how populations work. For example, it explains how a population can outlive all of its contemporary members and yet retain its median age, percent in each race, and its regional distribution.

The fruit of the theory lies in its utility for estimation and forecasting. Using aspects of the theory, demographers are able to elaborate rather modest bits and pieces of information about a population to a fairly full description of its trajectory (Coale and Demeny 1983). Combined with this mathematical theory is a body of practical forecasting techniques, statistical estimation procedures, and data-collection wisdom that makes up a core area in demography that is sometimes called formal demography (United Nations 1983; Shryock and Siegel 1976; Pollard, Yusuf, and Pollard 1990; Namboodiri 1991; Hinde 1998).

DEMOGRAPHIC DATA

Generating the various rates and probabilities used in formal demography requires two different kinds of data. On the one hand are data that count the number of events occurring in the population in a given period of time. How many births, deaths, marriages, divorces, and so on have occurred in the past year? These kinds of data are usually collected through a vital registration system (National Research Council 1981; United Nations 1985, 1991). On the other hand are data that count the number of persons in a given circumstance at a given time. How many never-married women age twenty to twenty-four were there on July 1? These kinds of data are usually collected through a population census or large-scale demographic survey (United Nations 1992; Anderson 1988; Anderson and Fienberg 1999). From a vital registration system one gets, for example, the number of births to black women age twenty. From a census one collects the number of black women at age twenty. The division of the number of events by the population exposed to the risk of having the event occur to them yields the demographic rate, that is, the fertility rate for black women age twenty. These

two data collection systems—vital statistics and census—are remarkably different in their character. To be effective, a vital statistics system must be ever alert to see that an event is recorded promptly and accurately. A census is more of an emergency. Most countries conduct a census every ten years, trying to enumerate all of the population in a brief time.

If a vital registration system had existed for a long time, were very accurate, and there were no uncounted migrations, one could use past births and deaths to tally up the current population by age. To the degree that such a tallying up does not match a census, one or more of the data collections systems is faulty.

SOCIAL DEMOGRAPHY

One of the standard definitions of demography is that given by Hauser and Duncan: “Demography is the study of the size, territorial distribution and composition of populations, changes therein, and the components of such change, which may be identified as natality, mortality, territorial movement (migration) and social mobility (change of status)” (1959, p. 2). Each of these parts—size, territorial distribution, and composition—is a major arena in which the relationships between demographic change and social change are investigated by social scientist-demographers. Each part has a somewhat separate literature, tradition, method, and body of substantive theory.

Population Size. The issue of population size and change in size is dominated by the shadow of Malthus (Malthus 1959), who held that while food production can grow only arithmetically because of diminishing returns to investment in land and other resources, population can grow geometrically and will do so, given the chance. Writing in a time of limited information about birth control and considerable disapproval of its use, and holding little hope that many people would abstain from sexual relations, Malthus believed that populations would naturally grow to the point at which starvation and other deprivations would curtail future expansion. At that point, the average level of living would be barely above the starvation level. Transitory improvements in the supply of food would only lead to increased births and subsequent deaths as the population returned to its

equilibrium size. Any permanent improvement in food supplies due to technological advances would, in Malthus's theory, simply lead to a larger population surviving at the previous level of misery.

Although there is good evidence that Malthus understood his contemporary world quite well (Lee 1980; Wrigley 1983), he missed the beginnings of the birth control movement, which were contemporaneous (McLaren 1978). The ability to limit births, albeit at some cost, without limiting sexual activity requires important modifications to the Malthusian model.

Questions of the relationship among population growth, economic growth, and resources persist into the contemporary period. The bulk of the literature is in economics. A good summary of that literature can be found in T. P. Schultz (1981), in Rosensweig and Stark (1997), and in a National Research Council report on population policy (1985). A more polemical treatment, but one that may be more accessible to the noneconomist, is offered by the World Bank (1985).

Sharing the study of population size and its change with Malthusian issues is a body of substantive and empirical work on the *demographic revolution* or *transition* (Notestein 1945). The model for this transition is the course of fertility and mortality in Europe during the Industrial Revolution. The transition is thought to occur concurrently with "modernization" in many countries (Coale and Watkins 1986) and to be still in process in many less developed parts of the world (United Nations 1990). This transition is a change from (1) a condition of high and stable birthrates combined with high and fluctuating death rates, through (2) a period of initially lowering death rates and subsequently lowering birthrates, to (3) a period of low and fairly constant death rates combined with low and fluctuating birthrates. In the course of part (2) of this transition, the population grows very considerably because the rate of increase, absent migration, is the difference between the birthrate and the death rate.

In large measure because of anxiety that fertility might not fall rapidly enough in developing countries, a good deal of research has focused on the fertility part of the transition. One branch of this research has been a detailed historical investigation of what actually happened in Europe, since that is the base for the analogy about what is

thought likely to happen elsewhere (Coale and Watkins 1986). A second branch was the World Fertility Survey, perhaps the largest international social science research project ever undertaken. This project conducted carefully designed, comparable surveys with 341,300 women in seventy-one countries to investigate the circumstances of contemporary fertility decline (Cleland and Hobcraft 1985). In 1983, a continuation of this project was undertaken under the name Demographic and Health Surveys. To date, this project has provided technical assistance for more than 100 surveys in Africa, Asia, the Near East, Latin America, and the Caribbean. For more complete information about current activities see their web site at <http://www.macrout.com/dhs/>.

Scholars analyzing these projects come to a fairly similar assessment of the roots of historical and contemporary fertility decline as centering in an increased secular rationality and growing norms of individual responsibility.

Detailed investigation of the mortality side of the European demographic transition has primarily been conducted by historians. A particularly useful collection of papers is available in Schofield, Reher, and Bideau (1991). For the United States, a particularly useful book on child and infant mortality at the turn of the twentieth century is by Haines and Preston (1991).

The utility of the idea of a demographic transition to understand population change in the developing world has, of course, been a matter of considerable debate. A good summary of this literature is found in Jones et al. (1997).

Territorial Distribution. Research on the territorial distribution of populations is conducted in sociology, geography, and economics. The history of population distribution appears to be one of population dispersion at the macroscopic level of continents, nations, or regions, and one of population concentration at the more microscopic level of larger towns and cities.

The diffusion of the human population over the globe, begun perhaps as the ice shields retreated in the late Pleistocene, continues to the present (Barracough 1978; Bairoch 1988). More newly inhabited continents fill up and less habitable land becomes occupied as technological and social change makes it possible to live in previously

remote areas. Transportation lines, whether caravan, rail, or superhighway, extend across remote areas to connect distant population centers. Stops along the way become villages and towns specializing in servicing the travelers and the goods in transit. These places are no longer "remote." Exploitation of resources proximate to these places may now become viable because of the access to transportation as well as services newly available in the stopover towns.

As the increasing efficiency of agriculture has released larger and larger fractions of the population from the need to till the soil, it has become possible to sustain increasing numbers of urban people. There is a kind of urban transition more or less concomitant with the demographic transition during which a population's distribution by city size shifts to larger and larger sizes (Kelley and Williamson 1984; Wrigley 1987). Of course, the continuing urban transition presents continuing problems for the developing world (United Nations 1998).

Population Composition. The characteristics included as compositional ones in demographic work are not predefined theoretically, with the exception, perhaps, of age and sex. In general, compositional characteristics are those characteristics inquired about on censuses, demographic surveys, and vital registration forms. Such items vary over time as social, economic, and political concerns change. Nonetheless, it is possible to classify most compositional items into one of three classes. First are those items that are close to the reproductive core of a society. They include age, sex, family relationships, and household living arrangements. The second group of items are those characteristics that identify the major, usually fairly endogenous, social groups in the population. They include race, ethnicity, religion, and language. Finally there is a set of socioeconomic characteristics such as education, occupation, industry, earnings, and labor force participation.

Within the first category of characteristics, contemporary research interest has focused on families and households because the period since 1970 has seen such dramatic changes in developed countries (Van de Kaa 1987; Davis 1985; Farley 1996, ch. 2). Divorce, previously uncommon, has become a common event. Many couples now live together without record of a civil or religious

ceremony having occurred. Generally these unions are not initially for the purposes of procreation, although children are sometimes born into them. Sometimes they appear to be trial marriages and are succeeded by legal marriages. A small but increasing fraction of women in the more developed countries seem to feel that a husband is not a necessary ornament to motherhood. Because of these changes, older models of how marriage comes about and how marriage relates to fertility (Coale and McNeil 1972; Coale and Trussell 1974) are in need of review as demographers work toward a new demography of the family (Bongaarts 1983; Keyfitz 1987).

Those characteristics that indicate membership in one or another of the major social groupings within a population vary from place to place. Since such social groupings are the basis of inequality, political division, or cultural separation, their demography becomes of interest to social scientists and to policy makers (Harrison and Bennett 1995). To the degree that endogamy holds, it is often useful to analyze a social group as a separate population, as is done for the black population in the United States (Farley 1970). Fertility and mortality rates, as well as marital and family arrangements, for blacks in the United States are different from those of the majority population. The relationship between these facts, their implications, and the socioeconomic discrimination and residential segregation experienced by this population is a matter of historic and continuing scholarly work (Farley and Allen 1987; Lieberman 1980; Farley 1996, ch. 6).

For other groups, such as religious or ethnic groups in the United States, the issue of endogamy becomes central in determining the continuing importance of the characteristic for the social life of the larger population (Johnson 1980; Kalmijn 1991). Unlike the black population, ethnic and religious groups seem to be of decreasing appropriateness to analyze as separate populations within the United States, since membership may be a matter of changeable opinion.

The socioeconomic characteristics of a population are analyzed widely by sociologists, economists, and policy-oriented researchers. Other than being involved in the data production for much of this research, the uniquely demographic contributions come in two ways. First is the consideration

of the relationship between demographic change and change in these characteristics. The relationship between female labor force participation and changing fertility patterns has been a main topic of the "new home economics" within economic demography (Becker 1960; T. W. Schultz 1974; T. P. Schultz 1981; Bergstrom 1997). The relationship between cohort size and earnings is a topic treated by both economists and sociologists (Winsborough 1975; Welch 1979). A system of relationships between cohort size, economic well-being, and fertility has been proposed by Easterlin (1980) in an effort to explain both fertility cycles and long swings in the business cycle.

A second uniquely demographic contribution to the study of socioeconomic characteristics appears to be the notion of a cohort moving through its socioeconomic life course (Duncan and Hodge 1963; Hauser and Featherman 1977; Mare 1980). The process of leaving school, getting a first job, then subsequent jobs, each of which yields income, was initially modeled as a sequence of recursive equations and subsequently in more detailed ways. Early in the history of this project it was pointed out that the process could be modeled as a multistate population (Matras 1967), but early data collected in the project did not lend itself to such modeling and the idea was not pursued.

POPULATION POLICY

The consideration and analysis of various population policies is often seen as a part of demography. Population policy has two important parts. First is policy related to the population of one's own nation. The United Nations routinely conducts inquiries about the population policies of member nations (United Nations 1995). Most responding governments claim to have official positions about a number of demographic issues, and many have policies to deal with them. It is interesting to note that the odds a developed country that states its fertility is too low has a policy to raise the rate is about seven to one, while the odds that a less developed country that states that its fertility is too high has a policy to lower the rate is about 4.6 to one. The prospect of declining population in the United States has already begun to generate policy proposals (Teitelbaum and Winter 1985).

The second part of population policy is the policy a nation has about the population of other

countries. For example, should a country insist on family-planning efforts in a developing country prior to providing economic aid? A selection of opinions and some recommendations for policy in the United States are provided in Menken (1986) and in the National Research Council (1985).

IMPORTANT CURRENT RESEARCH AREAS

Three areas of demographic research are of especially current interest. Each is, in a sense, a sequela of the demographic transition. They are:

1. Institutional arrangements for the production of children,
2. Immigration, emigration, ethnicity, and nationalism,
3. Population aging, morbidity, and mortality.

Institutional arrangements for the production of children. The posttransition developed world has seen dramatic changes in the institutional arrangements for the production of children. Tracking these changes has become a major preoccupation of contemporary demography. Modern contraception has broken the biological link between sexual intercourse and pregnancy. Decisions about sexual relations can be made with less concern about pregnancy. The decision to have a child is less colored by the need for sexual gratification. People no longer must choose between the celibate single life or the succession of pregnancies and children of a married one. Women are employed before, during, and after marriage. Their earning power makes marriage more an option and a context for child raising than an alternative employment. Women marry later, are older when they have children, and are having fewer children than in the past. Divorce has moved from an uncommon event to a common one. Cohabitation is a new, and somewhat inchoate, lifestyle that influences the circumstances for childbearing and child rearing. Although only a modest number of children are currently born to cohabiting couples, most children will spend some time living with a parent in such a relationship before they are adults (Bumpass and Lu 1999). Changes such as these have occurred in most of Europe and North America and appear to be increasing in those parts of Asia where the demographic transitions occurred first. The changes have, of course, been met with

considerable resistance in many places. Will they continue to occur in other countries as the demographic transitions proceed around the world? How serious will the resistance be in countries more patriarchal than those of Europe? These issues await future demographic research.

Immigration, emigration, ethnicity, and nationalism. The difference between immigration and emigration is, of course, net migration as a component of population growth. In general, the direct impact of net migration on growth has been modest. Certainly emigration provided some outlet for population growth in Europe during the transition (Curtin 1989) and played a role in the population of the Americas, Australia, and New Zealand. Most of the effect of immigration to the New World was indirect, however. It was the children of immigrants who peopled the continents rather than the immigrants themselves. Contemporary interest in international migration has three sources. First is an abiding concern for refugees and displaced persons. Second is interest in a highly mobile international labor force in the construction industry. Third, and perhaps most important, is the migration of workers from less developed countries to developed ones in order to satisfy the demand for labor in a population in real or incipient decline (Teitelbaum and Winter 1998). In France, Germany, and England immigrants who come and stay change the ethnic mix of the population. In the United States, legal and illegal immigration from Mexico has received considerable attention (Chiswick and Sullivan 1995). The immigration of skilled Asians raises issues of another kind. In all of these countries, the permanent settlement of new immigrants arouses powerful nationalistic concerns. The situation provides ample opportunity for the investigation of the development of ethnicity and the place of endogamy in its maintenance. As with changes for child rearing, these changes seem consequences of the demographic transition. Below-replacement fertility seems to generate the need for imported workers and their consequent inclusion in the society. If this speculation is true, how will countries more recently passing through the transition react to this opportunity and challenge? This is another arena for future demographic investigation.

Population aging, morbidity, and mortality. Accompanying the reduction of fertility and of

population growth is the aging of the population (Treas and Torrecilha 1995). Much of the developed world is experiencing this aging and its concomitants. Countries that made a rapid demographic transition have especially dramatic imbalances in their age distribution. Concerns about retirement, health, and other programs for the elderly generate interest in demographic research in these areas. Will increasing life expectancy add years to the working life so that retirement can begin later? Or will the added years all be spent in nursing homes? These questions are currently of great policy interest and pose interesting and difficult problems for demographic research (Manton and Singer 1994). Traditional demographic modeling has assumed that frailty, the likelihood of death, varies according to measurable traits such as age, sex, race, education, wealth, and so on, but are constant within joint values of these variables. But what happens if frailty is a random variable? In survival models, randomness in frailty is not helpful, or at least benign, as it is in so many other statistical circumstances. Rather, it can have quite dramatic effects (Vaupel and Yashin 1985). How one models frailty appears to make a considerable amount of difference in the answers one gets to important policy questions surrounding population aging.

DEMOGRAPHY AS A PROFESSION

Most demographers in the United States are trained in sociology. Many others have their highest degree in economics, history, or public health. A few are anthropologists, statisticians, or political scientists. Graduate training of demographers in the United States and in much of the rest of the world now occurs primarily in centers. Demography centers are often quasi-departmental organizations that serve the research and training needs of scholars in several departments. In the United States there are about twenty such centers, twelve of which have National Institutes of Health grants. The Ford Foundation has supported similar demography centers at universities in the less developed parts of the world.

Today, then, most new demographers, without regard for their disciplinary leanings, are trained at a relatively few universities. Most will work as faculty or researchers within universities or at

demography centers. Another main source of employment for demographers is government agencies. Census bureaus and vital statistics agencies both provide much of the raw material for demographic work and employ many demographers around the world. There is a small but rapidly growing demand for demographers in the private sector in marketing and strategic planning.

Support for research and training in demography began in the United States in the 1920s with the interest of the Rockefeller Foundation in issues related to population problems. Its support led to the first demography center, the Office of Population Research at Princeton University. The Population Council in New York was established as a separate foundation by the Rockefeller brothers in the 1930s. Substantial additional foundation support for the field has come from the Ford Foundation, the Scripps Foundation, and, more recently, the Hewlett Foundation. Demography was the first of the social sciences to be supported by the newly founded National Science Foundation in the immediate post-World War II era. In the mid-1960s the National Institute of Child Health and Human Development undertook support of demographic research.

HALLIMAN H. WINSBOROUGH

DEPENDENCY THEORY

Conceived in the 1960s by analysts native to developing countries, dependency theory is an alternative to Eurocentric accounts of modernization as universalistic, unilinear evolution (Addo 1996). Instead, contemporary underdevelopment is seen as an outgrowth of asymmetrical contacts with capitalism. The thesis is straightforward: Following the first wave of modernization, less-developed countries are transformed by their interconnectedness with other nations, and the nature of their contacts, economies, and ideologies (Keith 1997). Interaction between social orders is never merely a benign manifestation of economic or cultural diffusion. Rather, both the direction and pace of change leads to internal restructuring designed to bolster the interests of the more powerful exchange partner without altering the worldwide distribution of affluence.

Widely utilized as both a heuristic and empirical template, dependency theory emerged from neo-Marxist critiques of the failure of significant capital infusion, through the United Nations Economic Commission for Latin America, to improve overall quality of life or provide significant returns

to countries in the region. Dependency theory quickly became an instrument for political commentary as well as an explanatory framework as it couched its arguments in terms of the consequences of substituting cash crops for subsistence farming and replacing local consumer goods with export commodities destined for developed markets. Frank (1967, 1969), an early proponent, established the premise for dependency theory; contemporary underdevelopment is a result of an international division of labor exploited by capitalist interests.

Frank's innovation was to incorporate the vantagepoint of underdeveloped countries experiencing capital infusion into the discussion of the dynamics of economic, social, and political change. In so doing he discounted Western and European models of modernization as self-serving, ethnocentric, and apolitical. He asserted that explanations of modernization have been disassociated from the colonialism that fueled industrial and economic developments characteristic of the modern era. However, much of the first wave of modernization might have been driven by intrinsic, internal factors; more recent development has taken place in light of change external to individual countries. Central to Frank's contention was a differentiation of undeveloped from underdeveloped countries. In the latter, a state of dependency exists as an outgrowth of a locality's colonial relationship with "advanced" areas. Frank referred to the "development of underdevelopment" and the domination of development efforts by advanced countries, using a "metropolis-satellite" analogy to denote the powerful center out of which innovations emerge and a dependent hinterland is held in its sway. He spoke of a chain of exploitation—or the flow and appropriation of capital through successive metropolis-satellite relationships, each participating in a perpetuation of relative inequalities even while experiencing some enrichment. Galtung (1972) characterized this same relationship in terms of "core and periphery," each with something to offer the other, thereby fostering a symbiotic but lopsided relationship. The effect is a sharp intersocietal precedence wherein the dominant core grows and becomes more complex, while the satellite is subordinated through the transfer of economic surpluses to the core in spite of any absolute economic changes that may occur (Hechter 1975).

Dos Santos (1971) extended Frank's attention to metropolis-satellite relationships. He maintained that whatever economic or social change that does take place occurs primarily for the benefit of the dominant core. This is not to say that the outlying areas are merely plundered or picked clean; to ensure their long-run usefulness, peripheral regions are allowed, indeed encouraged, to develop. Urbanization, industrialization, commercialization of agriculture, and more expedient social, legal, and political structures are induced. In this way the core not only guarantees a stable supply of raw materials, but a market for finished goods. With the bulk of economic surplus exported to the core, the less-developed region is powerless to disseminate change or innovation across multiple realms. Dos Santos distinguished colonial, financial-industrial, and technological-industrial forms of dependencies. Under colonialism there is outright control and expropriation of valued resources by absentee decision makers. The financial-industrial dimension is marked by a locally productive economic sector characterized by widespread specialization and focus ministering primarily to the export sector that coexists alongside an essential subsistence sector. The latter furnishes labor and resources but accrues little from economic gains made in the export sector. In effect, two separate economies exist side by side.

In the third form of dependency, technological-industrial change takes place in developing regions but is customarily channeled and mandated by external interests. As the core extends its catchment area, it maximizes its ascendancy by promoting a dispersed, regionalized division of labor to maximize its returns. International market considerations affect the types of activities local export sectors are permitted to engage in by restricting the infusion of capital for specified purposes only. So, for example, the World Bank makes loans for certain forms of productive activity while eschewing others, and, as a result, highly segmented labor markets occur as internal inequities proliferate. The international division of labor is reflected in local implementation of capital-intensive technology, improvements in the infrastructure—transportation, public facilities, communications—and, ultimately, even social programming occurring principally in central enclaves or along supply corridors that service export trade (Hoogvelt 1977; Jaffee 1985; So 1990). Dos Santos

maintained that the balance of payments is manipulated, *ex parte*, not only to bring about desired forms of change, but to ensure the outflow of capital accumulation to such a degree that decapitalization of the periphery is inescapable. Or, at the very least, that capitalist-based economic development leaves local economies entirely dependent on the vagaries of markets well beyond their control. International interests establish the price of local export products and also set purchase prices of those technological-industrial products essential to maintaining the infrastructure of development. There may be a partial diffusion of technology, since growth in the periphery also enhances profits for the core, but it also creates unequal pockets of surplus labor in secondary labor markets, thereby impeding growth of internal markets as well as deteriorating the quality of life for the general populace (Portes 1976; Jaffee 1985).

Because international capital is able to stipulate the terms of the exchange, external forces shape local political processes if only through disincentives for capitalization of activities not contributing to export trade (Cardoso and Faletto 1979). As Amin (1976) pointed out, nearly all development efforts are geared to enhancing productivity and value in the export sector, even as relative disadvantages accrue in other sectors and result in domestic policies aimed at ensuring stability in the export sector above all else. Internal inequalities are thereby exacerbated as those facets of the economy in contact with international concerns become more capital intensive and increasingly affluent while other sectors languish as they shoulder the transaction costs for the entire process. One consequence of the social relations of the new production arrangements standing side by side with traditional forms is a highly visible appearance of obsolescence as status is conferred by and derived from a "narrow primary production structure" (Hoogvelt 1977, p.96). DeJanvry (1981) spoke of the social disarticulation that results as legitimization and primacy are granted to those deemed necessary to maintain externally valued economic activities. Although overall economic growth may occur as measured by the value of exports relative to Gross Domestic Product (GDP), debt loads remain high and internal disparities bleak as few opportunities for redistribution occur even if local decision makers were so inclined in the face of crushing debt-service. As Ake

(1988) put it, even per capita income figures may be insufficient as they represent averages while GDP may be suspect in light of differences between economic growth and distributive development. Finally, although local economies may manifest substantial growth, profits are exported along with products so that capital accumulation is not at the point of production in the periphery but at the core. In its various guises, and despite substantial criticisms, dependency theory provides global-orienting principles for analyses of international capitalism, interlocking monetary policies, and their role in domestic policy in developing countries.

Baran's (1957) analysis of the relationship between India and Great Britain is frequently cited as an early effort to examine the aftermath of colonialism. The imperialism of Great Britain was said to exploit India, fostering a one-sided extraction of raw materials and the imposition of impediments to industrialization, except insofar as they were beneficial to Great Britain. Precolonial India was thought to be a locus of other-worldly philosophies and self-sustaining subsistence production. Postcolonial India came to be little more than a production satellite in which local elites relished their relative advantages as facilitators of British capitalism. In Baran's view, Indian politics, education, finance, and other institutional arrangements were restructured to secure maximal gain to British enterprise. With independence, sweeping changes were undertaken, including many exclusionary practices, as countermeasures to the yoke of colonial rule.

Latin American concerns gave rise to the dependency model, and many of the *dependistas*, as they were originally known, have concentrated on regional case studies to outline the nature of contact with international capitalism. For the most part they focused less on colonialism *per se* and more on Dos Santos's (1971) second and third types of dependency. Despite substantial resources, countries in the region found themselves burdened with inordinate trade deficits and international debt loads which had the potential to inundate them (Sweezy and Magdoff 1984). As a consequence, one debt restructuring followed another to ensure the preservation of gains already made, to maintain some modicum of political stability, and to ensure that interest payments continued or, in worst-case scenarios, bad debts

could be written down and tax obligations reduced. In many instances the World Bank and the International Monetary Fund (IMF) exercised control and supervision, one consequence of this action being promotion of political regimes unlikely to challenge the principle of the loans (So 1990). Chile proved an exception, but one with disastrous and disruptive consequences. In all cases, to default would be to undermine those emoluments and privileges accorded local elites likely to seek further rather than fewer contacts with external capital.

Dos Santos's third form of dependency has also been widely explored. Landsberg (1979) looked to Asia to find empirical support. Through an analysis of manufacturing relationships in Hong Kong, Singapore, Taiwan, and South Korea with the industrial West, he concluded that despite improvement in local circumstances, relative conditions remained little affected due to the domination of manufacturing and industrial production by multinational corporations. These corporations moved production "off-shore," to Asia or other less-developed regions, in order to limit capitalization and labor costs while selling "on-shore," thereby maximizing profits. Landsberg asserted that because external capital shapes the industrialization of developing nations, the latter becomes so specialized as to have little recourse when international monopolistic practices become unbearable.

Few more eloquent defenders of the broad dependency perspective have emerged than Brazil's Cardoso (1973, 1977). He labeled his rendering a *historical-structural model* to connote the manner in which local traditions, preexisting social patterns, and the time frame of contact serve to color the way in which generalized patterns of dependency play out. He also coined the phrase *associated-dependent development* to describe the nurturing of circumscribed internal prosperity in order to enhance profit realization on investments (Cardoso 1973). He recognized that outright exploitation may generate immediate profit but can only lead to stagnation over the long run. Indeed, the fact that many former colonies remain economic losers seems to suggest that global development has not been ubiquitous (Bertocchi and Conova 1996). Instead, foreign capital functions as a means to development, underwriting dynamic progress in those sectors likely to further exports

but able, as well, to absorb incoming consumer goods. In the process, internal inequalities are heightened in the face of wide-ranging economic dualities as the physical quality of life for those segments of the population not immediately necessary to export and production suffer as a consequence.

In his analysis of Brazil, Cardoso also broadened the discussion to political consequences of dependency spurred by capital penetration. His intent was not to imply that only a finite range of consequences may occur, but to suggest that local patterns of interaction, entitlements, domination, conflict, and so on have a reciprocal impact on the conditions of dependency. By looking at changes occurring under military rule in Brazil, Cardoso succeeded in demonstrating that foreign capital predominated in essential manufacturing and commercial arenas (foreign ownership of industries in Brazil's state of Rio Grande do Sul were so extensive that Brazilian ownership was notable for being an exception). At the same time, internal disparities were amplified as interests supportive of foreign capital gained advantage at the expense of any opposition. In the process, wages and other labor-related expenses tended not to keep pace with an expanding economy, thereby resulting in ever-larger profit margins. As the military and the bourgeoisie served at the behest of multinational corporations, they defined the interests of Brazil to be consonant with their own.

By the early 1980s the Brazilian economy had stagnated, and as the country entered the new millennium it appeared headed for recursive hard times. Evans (1983) examined how what he termed the "triple alliance"—the state, private, and international capital interests—combined to alter the Brazilian economic picture pretty drastically while managing to preserve their own interests. In an effort to continue an uninterrupted export of profits, international capitalists permitted some accumulation among a carefully circumscribed local elite, so that each shared in the largess of favorable political decisions and state-sponsored ventures. Still, incongruities abounded; per capita wages fell as GDP increased and consumer goods flourished as necessities became unattainable. At the same time, infant and female mortality remained high and few overall gains in life expectancy were experienced. An exacerbation of local

inequalities may have contributed to the downswing but so too did international financial shifts which eventually dictated that the majority of new loans were earmarked for servicing old debts.

In the face of these shifts, foreign capital gained concessions, subsidies, and favored-nation accommodations. The contradictions proliferated. Unable to follow through on promises to local capital, the Brazilian government had little choice but to rescind previous agreements, at the same time incurring the unintended consequence of reducing regional market-absorption capabilities. Without new orders and in the face of loan payments, local capital grew disillusioned and moderated its support for state initiatives despite a coercive bureaucracy that sent Brazil to the verge of economic failure. The value of Evans's work is that it highlights the entanglements imposed on local politics, policies, and capitalists by a dependent-development agenda lacking significant national autonomy. What became apparent was that governments legitimate themselves more in terms of multinational interests than in terms of local capital—and certainly more than in terms of local less-privileged groups seeking to influence government expenditures. In an examination of forty-five less-developed countries, Semyonov and Lewin-Epstein (1996) discovered that though external influences shape the growth of productive services, internal processes frequently remain capable of moderating the effect these changes have on other sectors.

In an analysis of Peru, Becker (1983) contended that internal alignments created close allegiances based on mutual interests and that hegemonic control of alliances in local decision making leads to the devaluing and disenfranchising of those who challenge business as usual or represent old arrangements. Bornschieer (1981) asserted that internal inequalities increase and the rate of economic growth decreases in inverse proportion to the degree of dependency and in light of narrow sectoral targeting of foreign capital's development dollars. A recurrent theme running through their findings and those of other researchers is that internal economic disparities grow unchecked as tertiary-sector employment eventually becomes the predominant form (Bornschieer 1981; Semyonov and Lewin-Epstein 1986; Delacroix and Ragin 1978; Chase-Dunn 1981; Boyce 1992).

Nearly all advocates of dependency models contend that many facets of less-developed countries, from structure of the labor force to mortality, public health, forms and types of services provided, and the role of the state in public welfare programs, are products of the penetration of external capital and the particulars of activities in the export sector. As capital-intensive production expands, surplus labor is relegated back to agrarian pursuits or to other tertiary and informal labor. It also fosters a personal-services industry in which marginal employees provide service to local elites but whose own well-being is dependent on the economic well-being of the elites. Distributional distortions, as embodied in state-sponsored social policies, are also thought to reflect the presence of external capitalism (Kohli et al. 1984; Clark and Phillipson 1991). Evans is unmistakable: the relationship of dependency and internal inequality “. . . is one of the most robust, quantitative, aggregate findings available” (1979, p.532).

Not everyone is convinced. As investigations of dependency theory proliferated, many investigators failed to find significant effects that could be predicted by the model (Dolan and Tomlin 1980). In fact, Gereffi's (1979) review of quantitative studies of “third world” development led him to maintain that there was little to support the belief that investment of foreign capital had any discernable effect on long-term economic gain. In fact, it is commonly claimed that most investigations rely on gross measures of the value of exports relative to GDP, thus treating all exports as contributing equally to economic growth (Talbot 1998). But when a surplus of primary commodities, “raw” extraction or agricultural products, is exported, prices become unstable, with the consequences being felt most explicitly in producing regions. When manufactured goods are exported, prices remain more stable, and local economies are less affected. Relying on covariant analysis of vertical trade (export of raw materials, import of manufactured goods), commodity concentration, and export processing, Jaffee (1985) maintained that when exports grow so too does overall economic viability. Yet he did note that consideration of economic vulnerabilities and export enclaves does yield “conditional effects” whereby economic growth is significantly reduced or even takes a negative turn.

In their research on what is sometimes termed the “resource curse” in resource-rich countries,

Auty (1993) and Khalil and Mansour (1993) suggest that competition between export sectors such as minerals, oil, and agriculture often impedes prosperity of the other two or one another. In countries where that occurs, governments tend to adopt lax economic policies that, for example, increase agricultural dependencies in favor of oil exports. Internal conflicts then become self-perpetuating and play out in the physical and economic well-being of the populace. Some investigators also point out that the internal dynamics of different types of export commodities will have differential impacts on the economy as a whole and on state bureaucracies as differing degrees of infrastructure are implicated (Talbot 1998).

A number of critics have asserted that dependency theory is flawed, fuzzy, and unable to withstand empirical scrutiny (Peckham 1992; Ake 1988; Becker 1983). Even Marxist theorists find fault with dependency theory for overemphasizing external, exploitative factors at the expense of attention to the role of local elite (Shannon 1996). Other critics have focused on the evidence mustered and suggested that only about one-third of the variance in inequality among nations is accounted for by penetration of multinational corporations or other forms of foreign investment (Kohli et al. 1984; Bornschier, Chase-Dunn, and Rubinson 1978). Interestingly, still others have concluded that economic development of the type being discussed here is a significant facilitator for political democracy (Bollen 1983).

Defenders react by challenging measures of operationalization, the way variables are defined, and whether the complex of concepts embraced by the multidimensionality of the notion of dependency can be assessed in customary ways or in the absence of a comparative framework juxtaposing developing nations with their industrial counterparts (Ragin 1983; Robinson and Holtzman 1982; Boyce 1993). Efforts to isolate commodity concentration and multinational corporate investments have not proven to be reliable indicators and, as noted, even per capita GDP has its detractors. While important questions on heterogeneity, dispersion, or heteroskedasticity can be addressed by slope differences and recognized estimation techniques (Delacroix and Ragin 1978), proponents of the model are adamant that contextualized historical analysis is not only appropriate but mandated by the logic of dependency itself (Bach

1977; Bertocchi and Canova 1996). In their investigation of former colonies in Africa, Bertocchi and Canova (1996) concluded that colonial status is central to explaining relatively poor economic performance in ensuing years.

Proponents have also turned to sophisticated statistical procedures to elucidate their claims. For example, Bertocchi and Canova (1996) ran regression models on forty-six former colonies and dependencies in Africa to test their contention that colonialization makes a difference in subsequent societal and economic well-being. In a separate examination of state size and debt size among African nations, Bradshaw and Tshandu (1990) concluded that international capital penetration in the face of a mounting debt crisis may precipitate antagonism and austerity measures as the IMF and foreign capital debt claims are pitted against local claimants such as governmental subsidies and wages. In discussing capital penetration and the debt crises facing many developing nations, Bradshaw and Huang (1991) attributed incidences of political turmoil to austerity measures imposed on domestic welfare programs by IMF conditions and transnational financial institutions. They went on to assert that dependency theorists must take into consideration international recessions and global monetary crises if they are to understand structural accommodations and shifts in the quality of life in developing nations. In light of interlocking monetary policies, a single country teetering on the brink of economic adversity portends consequences for not only its trading partners but many other countries as well.

Several dependency analysts have utilized advanced analytic techniques to examine whether income inequality within countries is related to status in the world economy (Rubinson 1976; London and Robinson 1989; Boyce 1993). Both Rubinson (1976) and London and Robinson (1989) looked at interlocking world economies and their affect on governmental bureaucracies and internal structural differentiation. London and Robinson (1989) noted that the extent of multinational corporate penetration, and indirectly, its affect on income inequality, is associated with political malaise. Walton and Ragin (1990) concurred, maintaining that the involvement of international economic interests in domestic political-economic policy combine with "overurbanization" and associated dependency to help pave the way to political protest.

Boswell and Dixon (1990) carried the analysis a step further. Using regression and path analysis, they examined both economic and military dependency, concluding that both forms contribute to political instability through their effects on domestic class and state structures. They asserted that corporate penetration impedes real growth while exacerbating inequalities and the type of class polarization that leads to political violence. In his analysis of the economic shambles created in the Philippines under Ferdinand Marcos, Boyce (1993) concluded that the development strategies adopted during the Marcos era were economically disastrous for the bulk of the populace as “imperfections” in world markets precluded even modest capital accumulation for all but a privileged few. Though not speaking strictly in terms of dependency theory, Milner and Keohane (1996) point out that domestic policies are inevitably affected by global economic currents insofar as new policy preferences and coalitions are created as a result, by triggering domestic political and economic crises or by the undermining of governmental autonomy and thereby control over local economic policy. Dependency theorists customarily incorporate attention to all three in addressing the role international markets play in local economic policy.

Alternative interpretations of underdevelopment began to gain strength in the early 1970s. The next step was a world systems perspective, which saw global unity accompanied by an international division of labor with corresponding political alignments. Wallerstein (1974), Chirot and Hall (1982), and others shifted the focus from spatial definitions of nation-states as the unit of analysis to corporate actors as the most significant players able to shape activities—including the export of capital—according to their own interests. Wallerstein suggested that the most powerful countries of the world constitute a *de facto* collective core that disperses productive activities so that dependent industrialization is an extension of what had previously been geographically localized divisions of labor. World systems analysts see multinational corporations rather than nation-states as the means by which articulation of global economic arrangements is maintained. So powerful have multinationals become that even the costs of corporate organization are borne by those countries in which the corporations do business, with costs calculated according to terms dictated by the multinational

corporations themselves. Yet state participation is undoubtedly necessary as a kind of subsidization of multinational corporate interests and as a means for providing local management that, in addition to facilitating political compliance and other functions, promotes capital concentration for more efficient marketing and the maintenance of demand for existing goods and services. Thus production, consumption, and political ideologies are transplanted globally, legitimated, and yield a thoroughgoing stratification that, while it cuts across national boundaries, always creates precedence at the local level.

Dependency theory and collateral notions have become dispositional concepts utilized by numerous investigations of the effect of dependent development on diverse dimensions of inequality. Using a liberal interpretation of the model, many investigators have sought to understand how political economy affects values, types of rationality, definitions of efficiency and so on, as well as evaluations of those who do not share those values, views, or competencies. The social organization of the marketplace is thus thought to exert suzerainty over many types of social relationships and will continue to drive analysis of internal disparities in underdeveloped regions (Zeitlin 1972; Hechter 1975; Ward 1990; Shen and Williamson 1997). It remains to be seen how the absence of Soviet influence, often underemphasized during the formative period of dependency theory, will play out in analyses of international economic development in the twenty-first century (Pai 1991).

Substituting a figurative, symbolic relationship for spatial criteria, a generalized dependency model alloyed ideas of internal colonialism and has been widely employed as an explanatory framework wherein social and psychological distance from the center of power is seen as a factor in shaping well-being and other aspects of quality of life such as school enrollment, labor force participation, social insurance programs, longevity and so on. Likely as not, the political economics of development will continue to inform analysis of ancillary spheres for some time to come.

Gamson's (1968) concept of “stable unrepresentation” helped emphasize how the politics of inequality are perpetuated by real or emblematic core complexes. Internal colonialism and

political economic variants have been widely adopted in examinations of many types of social problems. Blauner's (1970) analysis of American racial problems is illustrative of one such application. So too is Marshall's (1985) investigation of patterns of industrialization, investment debt, and export dependency on the status of women in sixty less-developed countries. While she was unable to draw firm conclusions relative to dependency per se, Marshall did assert that with thoughtful specification, gender patterns in employment and education may be found to be associated with dependency-based economic change. In a manner similar to Blauner, Townsend (1981) spoke of "the structured dependency of the elderly" as a consequence of economic utility in advanced industrial societies. Many analysts have advocated the use of dependency-driven approaches to examine various consequences of dependency and development such as fertility, mortality, differential life expectancy, health patterns, and education (Hendricks 1982, 1995; Neysmith and Edwardth 1984; London 1988; Ward 1990; Lena and London 1993; Shen and Williamson 1997). Such a perspective casts the situation of the elderly as a consequence of shifts in economic relationships and state policies designed to provide for their needs. For example, Neysmith (1991) maintained that as debts are refinanced to retain foreign capital, domestic policies are rewritten in such a way as to disenfranchise vulnerable populations within those countries in favor of debt service. To support her point, Neysmith cites a United Nations finding that human development programs tend to benefit males, households in urban areas, and middle- or higher-income people, while relatively fewer are targeted at women, rural residents, or low-income persons (United Nations Department of International Economic and Social Affairs 1988). Interestingly, according to a United Nations report issued two decades ago, women account for approximately half the world's adult population, one-third of the formal labor force, and two-thirds of all the recorded work hours, yet receive one-tenth of the earned income (cited in Tiano 1988; Ward 1990). In an examination of capital penetration in eighty-six countries, Shen and Williamson (1997) suggest that as penetration increases and sectorial inequalities are exacerbated between tertiary and informal labor markets vis-à-vis other sectors, there is a degradation of women's status in all economic activities. At the same time, fertility rates remain

high partly because child labor provides an integral component of household income.

Variation in the life experiences of subpopulations is one of the enduring themes of sociology. Despite wide disparities, a central focus has been the interconnections of societal arrangements and political, economic, and individual circumstances. It is through them that norms of reciprocity and distributive justice are fostered and shared. As contexts change, so too will norms of what is appropriate. The linkage between political and moral economies is nowhere more apparent than in dependency theory as it facilitates our understanding of the dynamic relationship between individuals and structural arrangements.

JON HENDRICKS

DEPRESSION

INTRODUCTION

The term "depression" covers a wide range of thoughts, behaviors, and feelings. It is also one of the most commonly used terms to describe a wide range of negative moods. In fact there are many

types of depression, each of which vary in the number of symptoms, their severity, and persistence. The prevalence of depression is surprisingly high. Between 5 and 12 percent of men and 10 to 20 percent of women in the United States will suffer from a major depressive episode at some time in their lives. Approximately half of these individuals will become depressed more than once, and up to 10 percent will experience manic phases where they are elated and excited, in addition to depressive ones; an illness known as “manic-depressive” or bipolar disorder. Depression can involve the body, mood, thoughts, and many aspects of life. It affects the way people eat and sleep, the way they feel about themselves, and the way they think about things. Without treatment, symptoms can last for weeks, months, or years. Appropriate treatment, however, can help most people who suffer from depression.

TYPES OF DEPRESSION

Depression can be experienced for either a short period of time or can extend for years. It can range from causing only minor discomfort, to completely mentally and physically crippling the individual. The former case of short-term, mild depression is what is most commonly referred to as “the blues” or when people report “feeling low.” It is technically referred to as *dysphoric mood*. Feelings of depression tend to occur in almost all individuals at some point in their lives, and dysphoric mood has been associated with many key life events varying from minor to major life transitions (e.g., graduation, pregnancy, the death of a loved one). The feelings of separation and loss associated with leaving a town one has grown up in, moving to a new city for a job or school, or even leaving a work environment that one has grown accustomed to, can cause bouts of depression signaled by a loss of motivation and energy, and sadness. Other common features of dysphoric mood, include sighing, an empty feeling in the stomach, and muscular weakness, are also associated with changes such as the breakup of a dating relationship, divorce, or separation. In the case of bereavement, most survivors experience a dysphoric mood that is usually called grief (although some studies have shown that these feelings may be distinct from depression).

Many of these feelings are seen as representing the body’s short-term response to stress. Other

kinds of stressful events like losing a job; being rejected by a lover; being unable to pay the rent or having high debts; or losing everything in a fire, earthquake, or flood; may also bring on feelings of depression. Most of these feelings based on temporary situations are perfectly normal and tend to fade away.

A more severe type of depression than dysphoric mood, *dysthymia* (from the Greek word for defective or diseased mood), involves long-term, chronic symptoms that do not disable, but keep those individuals from functioning at their best or from feeling good. People with dysthymia tend to be depressed most of the day, more days than not, based on their own description or the description of others. Dysthymics have a least two of the following symptoms: eating problems, sleeping problems, tiredness and concentration problems, low opinions of themselves, and feelings of hopelessness. Unlike major depression, dysthymics can be of any age. Often people with dysthymia also experience major depressive episodes.

If “the blues” persist, it is more indicative of major depression, also referred to as *clinical depression* or a *depressive disorder*. Major depression is manifested by a combination of symptoms that interfere with the ability to work, sleep, eat, and enjoy once-pleasurable activities. These disabling episodes of depression can occur once, twice, or several times in a lifetime. Clinical practitioners (both clinical psychologists and psychiatrists) make use of a multiple-component classification system designed to summarize the diverse information relevant to an individual case rather than to just provide a single label. Using a specified set of criteria in the *Diagnostic and Statistical Manual of Mental Disorders* (referred to as *DSM-IV*, American Psychiatric Association 1994), a diagnosis of depressive disorder includes symptoms such as dissatisfaction and anxiety; changes in appetite, sleep, and psychological and motor functions; loss of interest and energy; feelings of guilt; thoughts of death; and diminished concentration. It is important to keep in mind that many of these symptoms are also reported by individuals who are not diagnosed with clinical depression. Only having many of these symptoms at any one time qualifies as depression. An individual is said to be experiencing a “major depressive episode” if he or she experiences a depressed mood or a loss of interest

or pleasure in almost all activities and exhibits at least four other symptoms from the following list: marked weight loss or gain when not dieting, constant sleeping problems, agitated or greatly slowed-down behavior, fatigue, inability to think clearly, feelings of worthlessness, and frequent thoughts about death or suicide. Anyone experiencing these symptoms for a prolonged period of time should see a doctor or psychiatrist immediately.

Another type of depression is *bipolar disorder*, formerly called manic-depressive illness. Not nearly as prevalent as other forms of depressive disorders, bipolar disorder involves interspersed periods of depression and elation or mania. Sometimes the mood switches are dramatic and rapid, but most often they are gradual. When in the depressed cycle, individuals have any or all of the symptoms of a depressive disorder. When in the manic cycle, individuals tend to show inappropriate elation, social behavior, and irritability; have disconnected and racing thoughts; experience severe insomnia and increased sexual appetite; talk uncontrollably; have grandiose notions; and demonstrate a marked increase in energy. Mania often affects thinking, judgment, and social behavior in ways that cause serious problems and embarrassment. For example, unwise business or financial decisions may be made when an individual is in a manic phase. Bipolar disorder is often a chronic condition. For more details on types of depression, including symptoms, see either a good textbook on abnormal psychology (e.g., Sarason and Sarason 1999), DSM-IV (American Psychiatric Association 1994) or use the search term "depression" on the web site for the National Institute of Health (<http://search.info.nih.gov/>).

THEORIES OF DEPRESSION

Most theorists agree that depression can be best studied using what health psychologists refer to as a *biopsychosocial approach*. This holds that depression has a biological component (including genetic links and biochemical imbalances), a psychological component (including how people think, feel, and behave), and a social component (including family and societal pressures and cultural factors). Individual theories have tended to emphasize one or the other of these components. The main theories of depression are biological and

cognitive in nature, although there are also psychodynamic and behavioral explanations which are discussed below.

Psychodynamic Theories of Depression. The psychological study of depression was essentially begun by Sigmund Freud and Karl Abraham, a German physician. Both described depression as a complex reaction to the loss of a loved person or thing. This loss could be real or imagined, through death, separation, or rejection. For Abraham (1911/1968), individuals who are vulnerable to depression experience a marked ambivalence toward people, with positive and negative feelings alternating and blocking the expression of the other. These feelings were seen to be the result of early and repeated disappointments. Depression, or melancholy, as Freud called it, was grief out of control (Freud 1917/1957). Unlike those in mourning, however, depressed persons appeared to be more self-denigrating and lacking self-esteem. Freud theorized that the anger and disappointment that had previously been directed toward the lost person or thing was internalized, leading to a loss of self-esteem and a tendency to engage in self-criticism. Theorists who used a similar approach and modified Freud's theories for depression were Sandor Rado and Melanie Klein, and most recently John Bowlby (1988).

Behavioral Theories of Depression. In contrast to a focus on early-childhood experiences and internal psychological processes, behavioral theories attempt to explain depression in terms of responses to stimuli and the overgeneralization of these responses. For example, loss of interest to a wide range of activities (food, sex, etc.) in response to a specific situation (e.g., loss of a job). The basic idea is that if a behavior is followed or accompanied by something good (a reward), the behavior will increase and persist. If the reward is taken away, lessened, or worse still, if the behavior is punished, the behavior will lessen or disappear. B. F. Skinner, a key figure in the behaviorist movement, postulated that depression was the result of a weakening of behavior due to the interruption of an established sequence of behavior that had been positively reinforced by the social environment. For example, the loss of a job would stop a lot of the activities that having a salary provides (e.g., dining out often, entertainment). Most behavioral theories extended this idea, focusing on specific

others as the sources of reinforcement (e.g., spouses, friends).

Cognitive Theories of Depression. Although it is probably indisputable that the final common pathways to clinical depression and even dysphoric mood involve biological changes in the brain, the most influential theories of depression today focus on the thoughts of the depressed individual. This cognitive perspective also recognizes that behavior and biochemistry are important components of depression, but it is more concerned with the quality, nature, and patterns of thought processes. Cognitive therapists believe that when depressive cognitions are changed, behavior and underlying biological responses change as well. Cognitive theories of depression differ from behavioral theories in two major ways (see Gotlieb and Hammen 1992 for a more detailed description). First, whereas behavioral theories focus on observable behaviors, cognitive theories emphasize the importance of intangible factors such as attitudes, self-statements, images, memories, and beliefs. Second, cognitive approaches to depression consider maladaptive, irrational, and in some cases, distorted thoughts to be the cause of the disorder and of its exacerbation and maintenance. Depressive behaviors, negative moods, lack of motivation, and physical symptoms that are seen to accompany depression are all seen as stemming from faulty thought patterns. There are three main cognitive theories of depression: *Beck's cognitive-distortion model*, *Seligman's learned helplessness model*, and the *hopelessness theory of depression*.

Beck's cognitive-distortion model. The most influential of these theories is Aaron Beck's cognitive-distortion model of depression (1967). Beck believes that depression is composed of three factors: negative thoughts about oneself, the situation, and the future. A depressed person misinterprets facts in a negative way, focuses on negative aspects of a situation, and has no hope for the future. Thus any problem or misfortune experienced, like the loss of a job, is completely assumed to be one's own fault. The depressed individual blames these events on his or her own personal defects. Awareness of these presumed defects becomes so intense that it overwhelms any positive aspects of the self and even ambiguous information is interpreted as evidence of the defect in lieu of positive explanations. A depressed person might focus on

a minor negative exchange within an entire conversation and interpret this as a sign of complete rejection. These types of thought patterns, also referred to as "automatic thoughts" when responses based on insufficient information are made, are persistent and act as negative filters for all of life's experiences. Excellent descriptions of the way these thoughts operate can be found in books by the psychologist Norman Endler (*Holiday of Darkness*, 1990) and the writer William Styron (*Darkness Visible: A Memoir of Madness*, 1982).

Together with the idea that depressed individuals mentally distort reality and engage in faulty processing of information, the most important part of Beck's cognitive model of depression is the notion of a "negative self-schema." A schema is a stored body of knowledge that affects how information is collected, processed, and used, and serves the function of efficiency and speed. In the context of depression, schemas are mental processes that represent a stable characteristic of the person, influencing him or her to evaluate and select information from the environment in a negative and pessimistic direction. Similar to psychoanalytical theories, negative self-schemas are theorized to develop from negative experiences in childhood. These schemas remain with the individual throughout life, functioning as a vulnerability factor for depression. Cognitive treatments of depression necessarily work to change these negative schemas and associated negative-automatic thought patterns.

Seligman's learned helplessness model. Based on work on animals (later replicated in humans), Martin Seligman's (1975) theory of learned helplessness and his model of depression holds that when individuals are exposed to uncontrollable stress they fail to respond to stimulation and show marked decrements in the ability to learn new behaviors. Because this theory did not sufficiently account for the self-esteem problems faced by depressed individuals, it was reformulated by Abramson who hypothesized that together with uncontrollable stress, people must also expect that future outcomes are uncontrollable. When they believe that these negative uncontrollable outcomes are their own doing (internal versus external), will be stable across time and will apply to everything they do (global), they feel helpless and depressed.

Hopelessness theory of depression. The most recent reformulation of the learned helplessness theory, referred to as the “hopelessness theory” of depression (Abramson, Seligman, and Alloy 1989) holds that depression is a result of expectations that highly undesired outcomes will occur and that one is powerless to change these outcomes. The hopelessness theory of depression is receiving a large amount of attention as it has been found to be particularly useful in predicting the likelihood of suicide among depressed people.

Biological Theories of Depression. The most compelling of the recent theories of depression rely heavily on the biological bases of behavior. Biological theories assume the cause of depression lies in some physiological problem, either in the genes themselves or in the way neurotransmitters (the chemicals that carry signals between nerve cells in our brains and around our bodies) are produced, released, transported, or recognized (see Honig and van Praag 1997 for a detailed review of biological theories of depression). Most of the work focuses on neurotransmitters, especially a category of chemicals in our bodies called the monoamines, the main examples of which are norepinephrine (also called noradrenalin), dopamine, and serotonin. These chemicals first attracted attention in the 1950s when physicians discovered that severe depression arose in a subset of people who were treated for hypertension with a drug (reserpine) that depleted monoamines. Simultaneously, researchers found that a drug that increased the monoamines, this time given to medicate tuberculosis, elevated mood in users who were depressed. Together these results suggested that low levels of monoamines in the brain cause depression. The most important monoamine seems to be norepinephrine although it is now acknowledged that changes in levels of this neurochemical do not influence moods in everyone. Nevertheless, this biochemical theory has received much experimental support.

Apart from the neurochemicals, there are also other physiological differences between depressed and nondepressed individuals. Hormones are chemical substances that circulate in the blood and enable communication between different systems of the body. Some hormones control the release of other hormones which then stimulate growth and help prepare the body to deal with,

and respond to, stress (e.g., adrenocorticotrophic hormone or ACTH). Depressed patients have repeatedly been demonstrated to show abnormal functioning of these hormones (see Nemeroff 1998 for a detailed review). Another difference is seen in one of the major systems of the body that affects how we respond to stress; the hypothalamic-pituitary-adrenal (HPA) axis. From the late 1960s and early 1970s, researchers have found increased activity in the HPA axis in unmedicated depressed patients as evidenced by increased levels of stress markers in bodily fluids. Now a large volume of studies confirm that substantial numbers of depressed patients display overactivity of the HPA axis. According to Charles Nemeroff (1998) and his colleagues, and based on studies on animals, all these biological factors including genetic inheritance of depression, neurotransmitter and hormonal levels, and HPA axis and related activity, could relate to early childhood abuse or neglect, although this theory has yet to be fully substantiated. The antecedents and consequences notwithstanding, it is well accepted that one of the major causes of depression is based in our biology.

RISK FACTORS

Depression can have many different causes as indicated by the different theories that have been formulated to explain it. Accordingly, there are different factors that indicate a risk for depression. Some of the main risk factors for long-term depression include heredity, age, gender, and lack of social support.

Studies of twins and of families clearly suggest a strong genetic component to clinical depression, which increases with genetic closeness. There is a much greater risk of developing a major depression if one's identical twin has had it than if one's parent, brother, or sister developed it. Chances are even less if no close relatives have ever had it. Furthermore, the younger people are when they experience depression, the higher the chances that one of their relatives will also get severely depressed. Relatives of people who were over forty when they first had a major depression have little more than the normal risk for depression.

One of the most clear risk factors is gender. Women are at least twice as likely to experience

all types of depressed states than are men and this seems to occur from an early age. There are no gender differences in depression rates in prepubescent children, but after the age of fifteen, girls and women are about twice as likely to be depressed as boys and men. Many models have been advanced for how gender differences in depression might develop in early adolescence. For example, one model suggests that the causes of depression can be assumed to be the same for girls and boys, but these causes become more prevalent in girls than in boys in early adolescence. According to another model, there are different causes of depression in girls and boys, and the causes of girls' depression become more prevalent than the causes of boys' depression in early adolescence. The model that has received the most support suggests that girls are more likely than boys to carry risk factors for depression even before early adolescence, but these risk factors lead to depression only in the face of challenges that increase in early adolescence (Nolen-Hoeksema and Girgus 1994). For a review of the epidemiology of gender differences in depression including prominent theories for why women are more vulnerable to depression, cross-cultural studies of gender differences in depression, biological explanations for the gender difference in depression (including postpartum depression, premenstrual depression, pubescent depression), personality theories (relationship with others, assertiveness), and social factors for the gender difference (increases in sexual abuse in adolescent females) see Susan Nolen-Hoeksema (1995).

Age by itself is a major risk factor for depression, although as described this varies for each gender. For women, the risk for a first episode of depression is highest between the ages of twenty and twenty-nine. For men, the risk for a first episode is highest for those aged forty to forty-nine. A related risk concerns when a person was born. People born in recent decades have been found to have an increased risk for depression as compared to those born in earlier cohorts.

Another significant risk factor for depression is the availability and perception of social support. People who lack close supportive relationships are at added risk for depression. Additionally, the presence of supportive others may prevent depression in the face of severe life stressors. Support is

especially important in the context of short-term depression that can result from events like conflictual work or personal interactions, unemployment, the loss of a job, a relationship break-up, or the loss of a loved one.

MEASUREMENT OF DEPRESSION

Most of the commonly used techniques to assess for depression come from clinical psychology and are heavily influenced by the cognitive theories of depression. For example, the work of Beck and other cognitive theorists has led to the development of many ways to measure the thoughts that depressed individuals may have. Most of these measures are completed by the individuals themselves, while some are administered in an interview format where the therapist asks a series of questions. Some interviews are delivered by trained clinical administrators (e.g., the Structured Clinical Interview for DSM-IV), while others are highly structured, can be computer scored to achieve diagnoses based on the DSM-IV, and can be administered by lay interviewers with minimal training (e.g., the Diagnostic Interview Schedule). Separate measures have also been designed for adults and children to compensate for differences in level of comprehension and sophistication, although measures of symptoms and diagnoses in children and adolescents are less-extensively studied. The methods used work well for children provided that information from both parent and child sources are included in the final decisions.

There are different types of self-report measures for depression. It can be assessed by having the patient fill out a questionnaire. Because our thought processes may operate at varying levels of consciousness, we may not always be able to access what they are to report on them. For this reason different cognitive measures of depression were designed to operate at various levels of consciousness. For example, the most direct measures ask about the frequency with which negative automatic thoughts have "popped" into a person's head in the past week (e.g., "no one understands me"). Another type of measure attempts to get at the cognitive and social cognitive mechanisms by which people formulate their beliefs and expectations. Because many negative thoughts take the form of comparing the self with others, these types of

scales try to understand the negative comparisons. An example of this type of measure is one where individuals are asked about the circumstances (interactions with people, idle thoughts, etc.), the dimensions (social skills, intelligence), the gender, and the type of relationship with the comparison target, and the individual's mood before and after the interaction. To get at the least-accessible level of thoughts, those that are believed to store, organize, and direct the processing of personally relevant information, researchers have used measures like the Stroop color-word task. Individuals are asked to name the color of the ink in which a word is printed but to ignore the meaning of the word itself. Slower response rates are thought to indicate greater effort to suppress words that are highly descriptive of the self. For example, depressed individuals take longer to name the color in which words like "sad" and "useless" are printed compared to the color for positive words.

In health, clinical, and counseling research and evaluation settings, the two most common measures of depression are the Beck Depression Inventory (BDI) and the Center for Epidemiological Studies Depression Scale (CESD). The BDI was designed to measure "symptom-attitude categories" associated with depression (Beck 1967). These include, among others, mood, pessimism, and sense of failure as well as somatic preoccupation. Many of the items reflect Beck's belief in the relevance of negative cognitions or self-evaluations in depression. Each item includes a group of statements that reflect increasing levels of one of these symptom-attitude categories. The test taker is asked to choose the statement within each item that reflects the way he or she has been feeling in the past week. The items are scored on a scale from 0–3, and reflect increasing levels of negativity. A sample item includes 0 = "I do not feel like a failure," to 3 = "I feel I am a complete failure as a person." The CESD is a twenty-item scale, is a widely used measure of depressive symptomatology, and has been shown to be valid and reliable in many samples. Participants are asked to best describe how often they felt or behaved during the previous week, in a variety of ways reflective of symptoms of depression, using a scale ranging from 0 (*Rarely or none of the time [less than 1 day]*) to 3 (*Most or all of the time [5–7 days]*). For example, participants are asked how often their sleep was restless or they felt that everything they did was an

effort. Other self-report measures include the Minnesota Multiphasic Personality Inventory Depression Scale (MMPI-D), the Zung Self-Rating Depression Scale (SDS), and the Depression Adjective Check List (DACL). Complete descriptions of these scales can be found in Constance Hammen (1997).

TREATMENT

As can be expected, the type of treatment depends on the type of depression and to some extent the favored theory of the health-care provider (physician, psychologist, or therapist) one goes to for treatment.

Biologically based treatments. The most common treatment for depression that is thought to have a physiological basis is antidepressant medication. Based on biological theories suggesting that depression results from low levels of the monoamines serotonin, norepinephrine, and dopamine, antidepressant medications act to increase the levels of these chemicals in the bloodstream. These drugs work by either preventing the monoamines from being broken down and destroyed (referred to as monoamine oxidase (MOA) inhibitors and tricyclics) or by preventing them from being removed from where they work (referred to as selective serotonin inhibitors [SSRIs]). Elavil, Norpramin, and Tofranil are the trade names of some MAO inhibitors. Prozac, Paxil, Zoloft, and Luvox are examples of SSRIs.

Although these medications have been proven to be effective in reducing depression, they also have a variety of side effects and need to be taken only under medical supervision. For example, tricyclics also cause dry mouth, constipation, dizziness, irregular heartbeat, blurred vision, ringing in the ears, retention of urine, and excessive sweating. Some of the SSRIs were developed with an eye toward reducing side effects and are correspondingly more often prescribed. Unfortunately, they are most commonly associated with prescription drug overdoses resulting in many thousands of deaths a year.

Several medicinal herbs have antidepressant effects. The most powerful is St. John's wort, a natural MAO inhibitor. In addition, ginkgo and caffeine may also help. Although much more research remains to be done, studies to date support

the effectiveness of such alternative medicine. For example, a group of researchers in Texas, in collaboration with German scientists, surveyed studies including a total of 1,757 outpatients with mainly mild or moderately severe depressive disorders, and found that extracts of St. John's wort were more effective than placebos (i.e., inactive pills) and as effective as standard antidepressant medication in the treatment of depression. They also had fewer side effects than standard antidepressant drugs (Linde et al. 1996).

In extreme cases of depression when drugs have been tried and found to not have an effect, and when the patient does not have the time to wait for drugs to take an effect (sometimes up to two or three weeks), electroconvulsive therapy (ECT) is recommended. ECT involves passing a current of between 70 and 130 volts through the patient's head after the administration of an anesthetic and muscle relaxant (to prevent injury from the convulsion caused by the charge). ECT is effective in treating severe depression although the exact mechanisms by which it works have not been determined.

Cognitive treatments. Cognitive therapists focus on the thoughts of the depressed person and attempt to break the cycle of negative automatic thoughts and negative self-views. Therapy sessions are well structured and begin with a discussion of an agenda for the session, where a list of items is drawn up and then discussed one by one. The therapist then tries to identify, understand, and clarify the misinterpretations and unrealistic expectations held by the client. Therapists use several techniques to identify these thoughts including asking direct questions, asking the client to use imagery to evoke the thoughts, or role-playing. Identifying these thoughts is a critical part of cognitive therapy and clients are also asked to keep daily diaries to list automatic thoughts when they occur as they are often unnoticed by depressed individuals. The client is then asked to provide a written summary of the major conclusions from the session to solidify what has been achieved and finally, the therapist prescribes a "homework assignment" designed to help the client practice skills and behaviors worked on during the session. Behavioral therapy is closely related to cognitive therapy and involves training the client to have better social skills and behaviors that enable them to develop better relationships with others.

Which are more effective treatments: cognitive or biological? A large National Institute of Mental Health study suggests that there is little difference in the effectiveness of the two therapies although the two treatments seem to produce different effects over time. Patients who received cognitive therapy were less likely to have a return of depression over time as compared to patients with biological therapy, although the small sample size used in this study precludes a definite answer to this question. Both therapies have been found to be effective, and it is likely that one is better with some forms of depression than the other, depending on how long the person has been depressed and the exact nature of his or her symptoms. In general both treatments, whether cognitive or biological, are recommended to be continued for a short time after the depressed episode has ended in order to prevent relapse.

CONCOMITANTS

A wide body of research has documented the links between depression and a wide variety of other factors. It is both a component of many other psychological disorders as well as something that follows many other disorders. In fact, some studies have shown that out of all the people at a given time with depression, only 44 percent of them display what can be called "pure" depression, whereas the others have depression and at least one other disorder or problem. The most common of these associated problems are anxiety, substance abuse, alcoholism, and eating disorders (see Hammen 1997 for more details). Given the symptoms of depression, individuals with the disorder also experience associated social problems including strained relationships with spouses, family, and friends, and in the workplace. Most alarming perhaps is that the children of depressed parents (especially mothers) are especially at risk for developing problems of their own.

Depression has also been linked to positive factors although not always with good results. For example, there is some evidence that depression is linked to creativity. Artists tend to suffer more than their share of depression according to psychiatrists at Harvard medical school, who charted the psychological histories of fifteen mid-twentieth-century artists. They found that at least half of

them, including artists like Jackson Pollock and Mark Rothko, suffered from varying degrees of depression (Schildkraut and Aurora 1996). Many of these artists eventually committed suicide, which is perhaps one of the most significant and dangerous results of depression. At least 15 percent of people with depression complete the act of suicide, but an even higher proportion will attempt it. Consequently, individuals with severe cases of depression may experience many suicide-related thoughts and sometimes need constant surveillance.

Depression is often seen in patients with chronic or terminal illnesses and in patients who are close to dying. For example, depression is a common experience of AIDS patients, and is related to a range of factors such as physical symptomatology, number of days spent in bed, and in the perceived sufficiency of social support. Depression has also been linked to factors that influence mortality and morbidity. Higher depressed mood has been significantly associated with immune parameters pertinent to HIV activity and progression: lower levels of CD4 T cells, immune activation, and a lower proliferative response to PHA (a natural biological reaction that is essential to good health). Depression is also a critical variable with respect to compliance with treatment, especially in HIV-positive women of low-socioeconomic status.

Depression is strongly related to the number and duration of stressors experienced, or chronic burden. Chronic burden, defined by Leonard Pearlin and Carmi Schooler (1978) as ongoing difficulties in major social roles, including difficulties in employment, marriage, finances, parenting, ethnic relations, and being single/separated/divorced contributes to depression and increases vulnerability to health problems by reducing the ability of the body to respond to a physiological challenge, such as mounting an immune response to a virus. Related to chronic burden, many aspects of depression are concomitants of low-socioeconomic status, traditionally measured by education, income, and occupation. Research showing clear social-class differences in depression also suggest the contribution of the stress of poverty, exposure to crime, and other chronic stressors that vary with social class. Jay Turner, Blair Wheaton, and David Lloyd (1995) found that individuals of low-socioeconomic status were exposed to more chronic strain in the form of life difficulties in

seven domains (e.g., parenting, relationships, and financial matters) than individuals of high-socioeconomic status, which could account for higher levels of depression.

The influence of culture is one factor that has not been sufficiently studied in the context of depression. To date, most clinical-disorder classification systems do not sufficiently acknowledge the role played by cultural factors in mental disorders. The experience of depression has very different meanings and forms of expression in different societies. Most cases of depression worldwide are experienced and expressed in bodily terms of aching backs, headaches, fatigue, and a wide assortment of symptoms that lead patients to regard this condition as a physical problem (Sarason and Sarason 1999). Only in contemporary Western societies is depression seen principally as an internal psychological experience. For example, many cultures tend to view their mental health problems in terms of physical bodily problems. That is, they tend to manifest their worries, guilt feelings, and strong negative emotions (such as depression) as physical complaints. This could be because bodily complaints do not carry the stigma or negative social consequences that psychological problems do, and are correspondingly easier to talk about.

Although not an essential part of aging, many people over age sixty-five develop clinical depression. Surveys suggest that only about 5 percent of healthy elderly people living independently suffer depression at any given moment, but more than 15 percent experience depression at some point during their elderly years, and the condition tends to be more chronic than in younger people. In addition, some 25 percent of elderly individuals experience periods of persistent sadness that last two weeks or longer, and more than 20 percent report persistent thoughts of death and dying. The likelihood of depression varies with the situation the person is in, and is more likely when the elderly person is away from his or her family in a novel setting. For example, some 20 percent of nursing home residents are depressed. Depression is also antagonized by serious medical conditions that elderly men and women may have. Correspondingly, depression is commonly associated with illnesses like cancer, heart attack, and stroke. Depression often goes undiagnosed and untreated in the elderly and is something that caregivers (spouse,

children, family, and friends) should be especially watchful for given the relationship between depression and suicide.

CONCLUSIONS

Many people still carry the misperception that depression is either a character flaw, a problem that happens because of personal weaknesses, or is completely “in the head.” As described above, there are psychological, physiological, and societal components to depression. Most importantly, it is something that can and should be treated. There are too few people who see a doctor when they recognize symptoms of depression or think of getting medical treatment for it. Depression is so prevalent that it is often seen as a natural component of life events like pregnancy and old age, and depressed mothers and elderly men and women often do not get the attention they need. Today, much more is known about the causes and treatment of this mental-health problem, with the best form of treatment being a combination of medication and psychotherapy. Depression need not be “the end.”

DESCRIPTIVE STATISTICS

Descriptive statistics include data distribution and the summary information of the data. Researchers use descriptive statistics to organize and describe the data of a sample or population. The characteristics of the sample are statistics while those of the

population are parameters. Descriptive statistics are usually used to describe the characteristics of a sample. The procedure and methods to infer the statistics to parameters are the statistical inference. Descriptive statistics do not include statistical inference.

Though descriptive statistics are usually used to examine the distribution of single variables, they may also be used to measure the relationship of two or more variables. That is, descriptive statistics may refer to either univariate or bivariate relationship. Also, the level of the measurement of a variable, that is, nominal, ordinal, interval, and ratio level, can influence the method chosen.

DATA DISTRIBUTION

To describe a set of data effectively, one should order the data and examine the distribution. An eyeball examination of the array of small data is often sufficient. For a set of large data, the aids of tables and graphs are necessary.

Tabulation. The table is expressed in counts or rates. The *frequency table* can display the distribution of one variable. It lists attributes, categories, or intervals with the number of observations reported. Data expressed in the frequency distribution are *grouped data*. To examine the central tendency and dispersion of large data, using grouped data is easier than using ungrouped data. Data usually are categorized into intervals that are mutually exclusive. One case or data point falls into one category only. Displaying frequency distribution of quantitative or continuous variables by intervals is especially efficient. For example, the frequency distribution of age in an imaginary sample can be seen in Table 1.

Here, age has been categorized into five intervals, i.e., 15 and below, 16–20, 21–25, 26–30, and 31–35, and they are mutually exclusive. Any age falls into one category only. This display is very efficient for understanding the age distribution in our imaginary sample. The distribution shows that twenty cases are aged fifteen or younger, twenty-five cases are sixteen to twenty years old, thirty-six cases are twenty-one to twenty-five years old, twenty cases are twenty-six to thirty years old, and nineteen cases are thirty-one to thirty-five years old. To compare categories or intervals and to

compare various samples or populations, the reporting percent or relative frequency of each category is important. The third column shows the percent of sample in each interval or category. For example, 30 percent of the sample falls into the range of twenty-one to twenty-five years old. The fourth column shows the proportion of observation for each interval or category. The proportion was called *relative frequency*. The cumulative frequency, the cumulative percent, and the cumulative relative frequency are other common elements in frequency tabulation. They are the sum of counts, percents, or proportions below or equal to the corresponding category or interval. For instance, the cumulative frequency of age thirty shows 101 persons or 84.2 percent of the sample age thirty or younger.

The frequency distribution displays one variable at a time. To study the *joint distribution* of two or more variables, we cross-tabulate them first. For example, the joint distribution of age and sex in the imaginary sample can be expressed in Table 2.

This table is a two-dimensional table: age is the column variable and sex is the row variable. We call this table a “two-by-five” table: two categories for sex and five categories for age. The marginal frequency can be seen as the frequency distribution of the corresponding variables. For example, there are fifty seven men in this sample. The marginal frequency for age is called *column frequency* and the marginal frequency for sex is called *row frequency*. The joint frequency of age and sex is *cell frequency*. For example, there are seventeen women twenty-one to twenty-five years old in this sample. The second number in each cell is *column percentage*; that is, the cell frequency divided by the column frequency and times 100 percent. For example, 47 percent in the group of twenty-one to twenty-five year olds are women. The third number in each cell is *row percentage*; that is, the cell frequency divided by the row frequency. For example, 27 percent of women are twenty-one to twenty-five years old. The *marginal frequency* can be seen as the frequency distribution of the corresponding variables. The row and column percentages are useful in examining the distribution of one variable conditioning on the other variable.

Charts and Graphs. Charts and graphs are efficient ways to show data distribution. Popular

Age Distribution of an Imaginary Sample					
Codes	Frequency	Percent	Relative Frequency	Cumulative Frequency	Cumulative Percent
15 and below	20	16.7	.17	20	16.7
16–20	25	20.8	.21	45	37.5
21–25	36	30.0	.30	81	67.5
26–30	20	16.7	.17	101	84.2
31–35	19	15.8	.16	120	100
Total	120	100	1.0		

Table 1

graphs for single variables are *bar graphs*, *histograms*, and *stem-and-leaf plots*. The bar graph shows the relative frequency distribution of discrete variables. A bar is drawn over each category with height of the bar representing the relative frequency of observations in that category. The histogram can be seen as a bar graph for the continuous variable. By connecting the midpoints of tops of all bars, a histogram becomes the *frequency polygon*. Histograms effectively show the shape of the distribution.

Stem-and-leaf plots represent each observation by its higher digit(s) and its lowest digit. The value of higher digits is the stem while the value of the final digit of each observation is the leaf. The stem-and-leaf plot conveys the same information as the bar graph or histogram. Additionally, it tells the exact value of each observation. Despite providing more information than bar graphs and histograms, stem-and-leaf plots are used mostly for small data.

Other frequently used graphs include *line graphs*, *ogives*, and *scatter plots*. Line graphs and ogives show the relationship between time and the variable. The line graph usually shows trends. The ogive is a form of a line graph for cumulative relative frequency or percentage. It is commonly used for survival data. The scatter plot shows the relationship between variables. In a two-dimensional scatter plot, x and y axes label values of the data. Conventionally, we use the horizontal axis (x -axis) for the explanatory variable and use the vertical axis (y -axis) for the outcome variable. The plain is naturally divided into four areas by two axes. For continuous variables, the value at the joint point of two axes is zero. When the x -axis

goes to the right or y -axis goes up, the value ascends; when the x -axis goes to the left or y -axis goes down, the value descends. The data points, determined by the joint attributes of the variables, are scattered in four areas or along the axes.

SUMMARY STATISTICS

We may use measures of central tendency and dispersion to summarize the data. To measure the central tendency of a distribution is to measure its center or typicality. To measure the dispersion of a distribution is to measure its variation, heterogeneity, or deviation.

Central Tendency. Three popular measures of the central tendency are *mean*, *median*, and *mode*. The arithmetic mean or average is computed by taking the sum of the values and dividing by the number of the values. It is the balanced point of the sample or population weighted by values. Mean is an appropriate measure for continuous (ratio or interval) variables. However, the information might be misleading because the arithmetic mean is sensitive to the extreme value or outliers in a distribution. For example, the ages of five students are 21, 19, 20, 18, and 20. The ages of another five students are 53, 9, 12, 13, and 11. Though their distributions are very different, the mean age for both groups is 19.6.

Median is the value or attribute of the central case in an ordered distribution. If the number of cases is even, the median is the arithmetic average of the central two cases. In an ordered age distribution of thirty-five persons, the median is the age of the eighteenth person, while, in a distribution of thirty-six persons, the median is the average age of

DESCRIPTIVE STATISTICS

Sex	Age					Total
	15 and below	16–20	21–25	26–30	31–25	
Male	9	12	19	9	8	57
	45.0%	48.0%	52.8%	45.0%	42.1%	47.5%
	15.8%	21.1%	33.3%	15.8%	14.0%	
Female	11	13	17	11	11	63
	55.0%	52.0%	47.2%	55.0%	57.9%	52.5%
	17.5%	20.6%	27.0%	17.5%	17.5%	
Total	20	25	36	20	19	120
	16.7%	20.8%	30.0%	16.7%	15.8%	100%

Table 2

the seventeenth and eighteenth persons. The median, like mean, can only tell the value of the physical center in an array of numbers, but cannot tell the dispersion. For example, the median of 21, 30, 45, and 100 is 27.5 and the median of 0, 27, 28, and 29 is also 27.5, but the two distributions are different. The mode is the most common value, category, or attribute in a distribution. Like the median, the mode has its limitations. For a set of values of 0, 2, 2, 4, 4, 4, 4, 5, and 10, the mode is four. For a set of values of 0, 0, 1, 4, 4, 4, 5, and 6, the mode is also four. One cannot tell one distribution from the other simply by examining the mode or median alone. The mode and median can be used to describe the central tendency of both continuous and discrete variables, and values of mode and median are less affected by the extreme value or the outlier than the mean.

One may also use upper and lower quartiles and percentiles to measure the central tendency. The n percentile is a number such that n percent of the distribution falls below it and $(100-n)$ percent falls above it. The lower quartile is the twenty-fifth percentile, the upper quartile is the seventy-fifth percentile, and the median is the fiftieth percentile. For example, the lower quartile or the twenty-fifth percentile is two and the upper quartile or the seventy-fifth percentile is seven for a set of values of 1, 2, 3, 4, 5, 6, 7, and 8. Apparently, the upper and lower quartiles and the percentiles can provide more information about a distribution than the other measures of the central tendency.

Dispersion. The central tendency per se does not provide much information on the distribution. Yet the combination of measures of central tendency and dispersion becomes useful to study a

distribution. The most popular measures of dispersion are *range*, *standard deviation*, and *variance*. Range is the crude measure of a distribution from the highest value to the lowest value or the difference between the highest and the lowest values. For example, the range for a set of values of 1, 2, 3, 4, and 5 is one to five. The range is sensitive to the extreme value and may not provide sufficient information about the distribution. Alternatively, the dispersion can be measured by the distance between the mean and each value. The standard deviation is defined as the square root of the arithmetic mean of the squared deviation from the mean. For example, the standard deviation for a set of values of 1, 2, 3, 4, and 5 is 1.44. We take the square root of the squared deviation from the mean because the sum of the deviation from the mean is always zero. The variance is the square of the standard deviation. The variance is two in the previous array of numbers. The standard deviation is used as a standardized unit in statistical inference. Comparing with standard deviation, the unit of the variance is not substantively meaningful. It is, however, valuable to explain the relationship between variables. Mathematically, the variance defines the area of the normal curve while the standard deviation defines the average distance between the mean and each data point. Since they are derived from the distance from the mean, standard deviation and variance are sensitive to the extreme values.

The *interquartile range (IQR)* and *mean absolute deviation (MAD)* are also commonly used to measure the dispersion. The IQR is defined as the difference between the first and third quartiles. It is more stable than the range. MAD is the average

absolute values of the deviation of the observations from the mean. As standard deviation, MAD can avoid the problem that the sum of the deviation from the mean is zero, but it is not as useful in statistical inference as variance and standard deviation.

Bivariate Relationship. One may use the *covariance* and *correlation coefficients* to measure the direction and size of a relationship between two variables. The covariance is defined as the average product of the deviation from the mean between two variables. It also reports the extent to which the variables may vary together. On average, while one variable deviates one unit from the mean, the covariance tells the extent to which the corresponding value of the other variable may deviate from its own mean. A positive covariance suggests that, while the value of one variable increases, that of the other variable tends to increase. A negative covariance suggests that, while the value of one variable increases, that of the other variable tends to decrease. The correlation coefficient is defined as the ratio of the covariance to the product of the standard deviations of two variables. It can also be seen as a covariance rescaled by the standard deviation of both variables. The value of the correlation coefficient ranges from -1 to 1 , where zero means no correlation, -1 means perfectly negatively related, and 1 means perfectly positively related. The covariance and correlation are measures of the bivariate relationship between continuous variables. Many measures of association between categorical variables are calculated using cell frequencies or percentages in the cross-tabulation, for example, Yule's Q , ϕ , Goodman's τ , Goodman's γ , and Somer's d . Though measures of association alone show the direction and size of a bivariate relationship, it is statistical inference to test the existence of such a relationship.

RELATIONSHIPS BETWEEN GRAPHS AND SUMMARY STATISTICS

The *box plot* is a useful tool to summarize the statistics and distribution. The box plot is consisted of a rectangular divided box and two extended lines attached to the ends of the box. The ends of the box define the upper and lower quartiles. The range of the distribution on each side is shown by an extended line attached to each quartile. A line

dividing the box shows the median. The plot can be placed vertically or horizontally. The box plot became popular because it can express the center and spread of the data simultaneously. Several boxes may be placed next to one another for comparison.

The order of mode, median, and mean is related to the shape of the distribution of a continuous variable. If mean, median, and mode are equal to each other, the shape of the histogram approximates a bell curve. However, a uniform distribution, in which all cases are equally distributed among all values and three measures of the central tendency are equal to each other, has a square shape with the width as the range and the height as the counts or relative frequency. In a bimodal distribution, two modes are placed in two ends of the distribution equally distanced from the center where the median and the mean are placed. We seldom see the true bell-curved, uniform, and bimodal distributions. Most of the distributions are more or less skewed to the left or to the right. If the mean is greater than median and the median is greater than mode, the shape is skewed to the right. If the mean is smaller than the median, and the median is smaller than the mode, the shape is skewed to the left. The outliers mainly lead the direction.

The shape and direction of the scatter plot can diagnose the relationship of two variables. When the distribution directs from the upper-right side to the lower-left side, the correlation coefficient is positive; when it directs from the upper-left side to the lower-right side, the correlation coefficient is negative. The correlation of a loosely scattered plot is weaker than that of a tightly scattered plot. A three-dimensional scatter plot can be used to show a bivariate relationship and its frequency distribution or a relationship of three variables. The former is commonly seen as a graph to examine a joint distribution.

Descriptive statistics is the first step in studying the data distribution. In omitting this step, one might misuse the advanced methods and thus be led to wrong estimates and conclusions. Some summary statistics such as standard deviation, variance, mean, correlation, and covariance, are also essential elements in statistical inference and advanced statistical methods.

DEVIANCE

See Alienation; Anomie; Criminalization of Deviance; Deviance Theories; Legislation of Morality.

DEVIANCE THEORIES

Since its inception as a discipline, sociology has studied the causes of deviant behavior, examining why some persons conform to social rules and expectations and why others do not. Typically, sociological theories of deviance reason that aspects of individuals' social relationships and the social areas in which they live and work assist in explaining the commission of deviant acts. This emphasis on social experiences, and how they contribute to deviant behavior, contrasts with the focus on the internal states of individuals taken by disciplines such as psychology and psychiatry.

Sociological theories are important in understanding the roots of social problems such as crime, violence, and mental illness and in explaining how these problems may be remedied. By specifying the causes of deviance, the theories reveal how aspects of the social environment influence the behavior of individuals and groups. Further, the theories suggest how changes in these influences may yield changes in levels of deviant behaviors. If a theory specifies that a particular set of factors cause deviant behavior, then it also implies that eliminating or altering those factors in the environment will change levels of deviance. By developing policies or measures that are informed

by sociological theories, government agencies or programs focused on problems like crime or violence are more likely to yield meaningful reductions in criminal or violent behavior.

Despite their importance, deviance theories disagree about the precise causes of deviant acts. Some look to the structure of society and groups or geographic areas within society, explaining deviance in terms of broad social conditions in which deviance is most likely to flourish. Others explain deviant behavior using the characteristics of individuals, focusing on those characteristics that are most highly associated with learning deviant acts. Other theories view deviance as a social status conferred by one group or person on others, a status that is imposed by persons or groups in power in order to protect their positions of power. These theories explain deviance in terms of differentials in power between individuals or groups.

This chapter reviews the major sociological theories of deviance. It offers an overview of each major theory, summarizing its explanation of deviant behavior. Before reviewing the theories, however, it may prove useful to describe two different dimensions of theory that will structure our discussion. The first of these, the *level of explanation*, refers to the scope of the theory and whether it focuses on the behavior and characteristics of individuals or on the characteristics of social aggregates such as neighborhoods, cities, or other social areas. *Micro-level* theories stress the individual, typically explaining deviant acts in terms of personal characteristics of individuals or the immediate social context in which deviant acts occur. In contrast, *macro-level* theories focus on social aggregates or groups, looking to the structural characteristics of areas in explaining the origins of deviance, particularly rates of deviance among those groups.

Theories of deviance also vary in relation to a second dimension, *causal focus*. This dimension divides theories into two groups, those that explain the social origins of norm violations and those explaining societal reactions to deviance. *Social origin* theories focus on the causes of norm violations. Typically, these theories identify aspects of the social environment that trigger norm violations; social conditions in which the violations are most likely to occur. In contrast, *social reaction* theories argue that deviance is often a matter of

social construction, a status imposed by one person or group on others and a status that ultimately may influence the subsequent behavior of the designated deviant. Social reaction theories argue that some individuals and groups may be designated or labeled as deviant and that the process of labeling may trap or engulf those individuals or groups in a deviant social role.

These two dimensions offer a four-fold scheme for classifying types of deviance theories. The first, *macro-level origin theories*, focus on the causes of norm violations associated with broad structural conditions in the society. These theories typically examine the influences of such structural characteristics of populations or communities like the concentration of poverty, levels of community integration, or the density and age distribution of the population on areal rates of deviance. The theories have clear implications for public policies to reduce levels of deviance. Most often, the theories highlight the need for altering structural characteristics of society, such as levels of poverty, that foster deviant behavior.

The second, *micro-level origin theories* focus on the characteristics of the deviant and his or her immediate social environment. These theories typically examine the relationship between a person's involvement in deviance and such characteristics as the influence of peers and significant others, persons' emotional stakes in conformity, their beliefs about the propriety of deviance and conformity, and their perceptions of the threat of punishments for deviant acts. In terms of their implications for public policy, micro-level origin theories emphasize the importance of assisting individuals in resisting negative peer influences while also increasing their attachment to conforming lifestyles and activities.

A third type of theories may be termed *micro-level reaction theories*. These accord importance to those aspects of interpersonal reactions that may seriously stigmatize or label the deviant and thereby reinforce her or his deviant social status. According to these theories, reactions to deviance may have the unintended effect of increasing the likelihood of subsequent deviant behavior. Because labeling may increase levels of deviance, micro-level reaction theories argue that agencies of social control (e.g. police, courts, correctional systems) should adopt policies of "nonintervention."

Finally, *macro-level reaction theories* emphasize broad structural conditions in society that are associated with the designation of entire groups or segments of the society as deviant. These theories tend to stress the importance of structural characteristics of populations, groups, or geographic areas, such as degrees of economic inequality or concentration of political power within communities or the larger society. According to macro-level reaction theories, powerful groups impose the status of deviant as a mechanism for controlling those groups that represent the greatest political, economic, or social threat to their position of power. The theories also imply that society can only achieve reduced levels of deviance by reducing the levels of economic and political inequality in society.

The rest of this article is divided into sections corresponding to each of these four "types" of deviance theory. The article concludes with a discussion of new directions for theory—the development of explanations that cut across and integrate different theory types and the elaboration of existing theories through greater specification of the conditions under which those theories apply.

MACRO-LEVEL ORIGINS OF DEVIANCE

Theories of the macro-level origins of deviance look to the broad, structural characteristics of society, and groups within society, to explain deviant behavior. Typically, these theories examine one of three aspects of social structure. The *first* is the pervasiveness and consequences of poverty in modern American society. Robert Merton's (1938) writing on American social structure and Richard Cloward and Lloyd Ohlin's (1960) subsequent work on urban gangs laid the theoretical foundation for this perspective. Reasoning that pervasive materialism in American culture creates unattainable aspirations for many segments of the population, Merton (1964) and others argue that there exists an environmental state of "strain" among the poor. The limited availability of legitimate opportunities for attaining material wealth forces the poor to adapt through deviance, either by achieving wealth through illegitimate means or by rejecting materialistic aspirations and withdrawing from society altogether.

According to this reasoning, deviance is a byproduct of poverty and a mechanism through

which the poor may attain wealth, albeit illegitimately. Thus, “strain” theories of deviance interpret behaviors such as illegal drug selling, prostitution, and armed robbery as innovative adaptations to blocked opportunities for legitimate economic or occupational success. Similarly, the theories interpret violent crimes in terms of the frustrations of poverty, as acts of aggression triggered by those frustrations (Blau and Blau 1982). Much of the current research in this tradition is examining the exact mechanisms by which poverty and economic inequality influence rates of deviant behavior.

Although once considered a leading theory of deviance, strain theory has come under criticism for its narrow focus on poverty as the primary cause of deviant behavior. Recent efforts have sought to revise and extend the basic principles of the theory by expanding and reformulating ideas about strain. Robert Agnew (1992) has made the most notable revisions to the theory. His reformulation emphasizes social psychological, rather than structural, sources of strain. Agnew also broadens the concept of strain, arguing that poverty may be a source of strain, but it is not the *only* source. Three sources of strain are important: failure to achieve positively valued goals, removal of positively valued stimuli, and confrontation with negative stimuli. The first type of strain, failure to achieve positively valued goals, may be the result of a failure to live up to one’s expectations or aspirations. Strain may also result if an individual feels that he or she is not being treated in a fair or just manner. The removal of a positively valued stimulus, such as the death of a family member or the loss of a boyfriend or girlfriend, can also result in strain. Finally, strain can also be produced by the presentation of negative stimuli, such as unpleasant school experiences. Thus, although this reformulation of strain theory retains the notion that deviance is often the result of strain, the concept of strain is broadened to include multiple sources of strain.

The second set of macro-level origin theories examine the role of culture in deviant behavior. Although not ignoring structural forces such as poverty in shaping deviance, this class of theories reasons that there may exist cultures within the larger culture that endorse or reinforce deviant values; deviant subcultures that produce higher rates of deviance among those segments of the population sharing subcultural values.

Subcultural explanations have their origin in two distinct sociological traditions. The first is writing on the properties of delinquent gangs that identifies a distinct lower-class culture of gang members that encourages aggression, thrill seeking, and antisocial behavior (e.g., Miller 1958). The second is writing on cultural conflict that recognizes that within complex societies there will occur contradictions between the conduct norms of different groups. Thorsten Sellin (1938) suggests that in heterogeneous societies several different subcultures may emerge, each with its own set of conduct norms. According to Sellin, the laws and norms applied to the entire society do not necessarily reflect cultural consensus but rather the values and beliefs of the dominant social groups.

Subcultural theories emerging from these two traditions argue that deviance is the product of a cohesive set of values and norms that favors deviant behavior and is endorsed by a segment of the general population. Perhaps most prominent among the theories is Marvin Wolfgang and Franco Ferracuti’s (1967) writing on subcultures of criminal violence. Wolfgang and Ferracuti reason that there may exist a distinct set of beliefs and expectations within the society; a subculture that promotes and encourages violent interactions. According to Wolfgang and Ferracuti, this violent subculture is pervasive among blacks in the United States and may explain extremely high rates of criminal homicide among young black males.

Although Wolfgang and Ferracuti offer little material specifying the subculture’s precise causes, or empirical evidence demonstrating the pervasiveness of subcultural beliefs, other writers have extended the theory by exploring the relationship between beliefs favoring violence and such factors as the structure of poverty in the United States (Curtis 1975; Messner 1983), the history of racial oppression of blacks (Silberman 1980), and ties to the rural South and a southern subculture of violence (Gastil 1971; Erlanger 1974). Even these writers, however, offer little empirical evidence of violent subcultures within U.S. society.

A third class of theories about the macro-level origins of deviance began with the work of sociologists at the University of Chicago in the 1920s. Unlike strain and subcultural theories, these stress the importance of the social integration of neighborhoods and communities—the degree to which

neighborhoods are stable and are characterized by a homogenous set of beliefs and values—as a force influencing rates of deviant behavior. As levels of integration increase, rates of deviance decrease. Based in the early work of sociologists such as Clifford Shaw and Henry McKay, the theories point to the structure of social controls in neighborhoods, arguing that neighborhoods lacking in social controls are “disorganized,” that is, areas in which there is a virtual vacuum of social norms. It is in this normative vacuum that deviance flourishes. Therefore, these theories view deviance as a property of areas or locations rather than specific groups of people.

Early writers in the “disorganization” tradition identified industrialization and urbanization as the causes of disorganized communities and neighborhoods. Witnessing immense growth in eastern cities such as Chicago, these writers argued that industrial and urban expansion create zones of disorganization within cities. Property owners move from the residential pockets on the edge of business and industrial areas and allow buildings to deteriorate in anticipation of the expansion of business and industry. This process of natural succession and change in cities disrupts traditional mechanisms of social control in neighborhoods. As property owners leave transitional areas, more mobile and diverse groups enter. But the added mobility and diversity of these groups translate into fewer primary relationships—families and extended kinship and friendship networks. And as the number of primary relationships decline, so will informal social controls in neighborhoods. Hence, rates of deviance will rise.

Recent writing from this perspective focuses on the mechanisms by which specific places in urban areas become the spawning grounds for deviant acts (Bursik and Webb 1982; Bursik 1984; and others). For example, Rodney Stark (1987) argues that high levels of population density are associated with particularly low levels of supervision of children. With little supervision, children perform poorly in school and are much less likely to develop “stakes in conformity”—that is, emotional and psychological investments in academic achievement and other conforming behaviors. Without such stakes, children and adolescents are much more likely to turn to deviant alternatives. Thus, according to Stark, rates of deviance will be high in densely populated areas because social

controls in the form of parental supervision are either weak or entirely absent.

Similarly, Robert Crutchfield (1989) argues that the structure of work opportunities in areas may have the same effect. Areas characterized primarily by secondary-sector work opportunities—low pay, few career opportunities, and high employee turnover—may tend to attract and retain persons with few stakes in conventional behavior—a “situation of company” in which deviance is likely to flourish.

Recent writing from the disorganization perspective has also taken the form of ethnographies; qualitative studies of urban areas and the deviance producing dynamics of communities. As Sullivan (1989, p. 9) states, ethnographies describe the community “as a locus of interaction, intermediate between the individual and the larger society, where the many constraints and opportunities of the total society are narrowed to a subset within which local individuals choose.” At the heart of Sullivan’s argument is the idea that social networks in neighborhoods are important in understanding whether individuals are capable of finding meaningful opportunities for work. For example, youth were less likely to turn to crime in those neighborhoods where they could take advantage of family and neighborhood connections to blue collar jobs. Because of the greater employment opportunities in these neighborhoods, even youth who become involved in crime were less likely to persist in high-risk criminal behaviors.

Similarly, Jay MacLeod (1995) attempts to explain how the aspirations of youth living in urban areas have been “leveled,” or reduced to the point where the youths have little hope for a better future. In an analysis of two urban gangs, MacLeod argues that the youths’ family and work experiences, along with their relationships with their peers, help explain why a predominantly white gang had lower aspirations and engaged in more delinquent and antisocial behavior than the other gang, predominantly comprised of African Americans. According to MacLeod, the parents of white youth were much less likely to discipline their children or to encourage them to achieve and do well in school. Also, white youth had more experience on the job market than the African American youth. This contributed to a more pessimistic outlook and a lowering of their future aspirations.

Finally, MacLeod argues that the white youths' immersion in a subculture, which emphasized rejecting the authority of the school, reinforced their negative attitudes to a much greater extent than the African American peer group.

In sum, theories of the macro-level origins of deviance argue that many of the causes of deviance may be found in the characteristics of groups within society, or in the characteristics of geographic areas and communities. They offer explanations of group and areal differences in deviance—for example, why some cities have relatively higher rates of crime than other cities or why blacks have higher rates of serious interpersonal violence than other ethnic groups. These theories make no attempt to explain the behavior of individuals or the occurrence of individual deviant acts. Indeed, they reason that deviance is best understood as a property of an area, community, or group, regardless of the individuals living in the area or community, or the individuals comprising the group.

The theories' implications for public policy focus on the characteristics of geographic areas and communities that lead to deviance. The impact of change on neighborhoods, for example, can be reduced if the boundaries of residential areas are preserved. By preserving such boundaries, communities are less likely to become transitional neighborhoods that foster deviance and crime. Also, by maintaining residential properties people become invested in their own community, which helps foster the mechanisms of informal social control that make deviance less likely. Strengthening schools and other stabilizing institutions in neighborhoods, such as churches and community centers, can also contribute to a reduction in deviance. Finally, establishing networks for jobs and job placement in disadvantaged areas may increase the opportunities of employment among youth. If they succeed in increasing employment, the networks should decrease the chances that youth will turn to careers in crime.

MICRO-LEVEL ORIGINS OF DEVIANCE

Many explanations of deviance argue that its causes are rooted in the background or personal circumstances of the individual. Micro-level origin theories have developed over the past fifty years, identifying mechanisms by which ordinarily conforming

individuals may become deviant. These theories assume the existence of a homogeneous, pervasive set of norms in society and proceed to explain why persons or entire groups of persons violate the norms. There exist two important traditions within this category of theories. The first tradition involves "social learning theories"—explanations that focus on the mechanisms through which people learn the techniques and attitudes favorable to committing deviant acts. The second tradition involves "social control theories"—explanations that emphasize factors in the social environment that regulate the behavior of individuals, thereby preventing the occurrence of deviant acts.

Edwin Sutherland's (1947) theory of differential association laid the foundation for learning theories. At the heart of this theory is the assumption that deviant behavior, like all other behaviors, is learned. Further, this learning occurs within intimate personal groups—networks of family members and close friends. Thus, according to these theories individuals learn deviance from persons closest to them. Sutherland specified a process of differential association, reasoning that persons become deviant in association with deviant others. Persons learn from others the techniques of committing deviant acts and attitudes favorable to the commission of those acts. Further, Sutherland reasoned that persons vary in their degree of association with deviant others; persons regularly exposed to close friends and family members who held beliefs favoring deviance and who committed deviant acts would be much more likely than others to develop those same beliefs and commit deviant acts.

Sutherland's ideas about learning processes have played a lasting role in micro-level deviance theories. Central to his perspective is the view that beliefs and values favoring deviance are a primary cause of deviant behavior. Robert Burgess and Ronald Akers (1966) and subsequently Akers (1985) extended Sutherland's ideas, integrating them with principles of operant conditioning. Reasoning that learning processes may best be understood in terms of the concrete rewards and punishments given for behavior, Burgess and Akers argue that deviance is learned through associations with others and through a system of rewards and punishments, imposed by close friends and relatives, for participation in deviant acts. Subsequent empirical studies offer compelling support for elements

of learning theory (Matsueda 1982; Akers et al. 1979; Matsueda and Heimer 1987).

Some examples may be useful at this point. According to the theory of differential association, juveniles develop beliefs favorable to the commission of delinquent acts and knowledge about the techniques of committing deviant acts from their closest friends, typically their peers. Thus, sufficient exposure to peers endorsing beliefs favoring deviance who also have knowledge about the commission of deviant acts will cause the otherwise conforming juvenile to commit deviant acts. Thus, if adolescent peer influences encourage smoking, drinking alcohol, and other forms of drug abuse—and exposure to these influences occurs frequently, over a long period of time, and involves relationships that are important to the conforming adolescent—then he or she is likely to develop beliefs and values favorable to committing these acts. Once those beliefs and values develop, he or she is likely to commit the acts.

The second class of micro-level origin theories, control theories, explores the causes of deviance from an altogether different perspective. Control theories take for granted the existence of a cohesive set of norms shared by most persons in the society and reason that most persons want to and will typically conform to these prevailing social norms. The emphasis in these theories, unlike learning theories, is on the factors that bond individuals to conforming lifestyles. The bonds act as social and psychological constraints on the individual, binding persons to normative conformity (Toby 1957; Hirschi 1969). People deviate from norms when these bonds to conventional lifestyles are weak, and hence, when they have little restraining influence over the individual. Among control theorists, Travis Hirschi (1969) has made the greatest contributions to our knowledge about bonding processes and deviant behavior. Writing on the causes of delinquency, he argued that four aspects of bonding are especially relevant to control theory: emotional attachments to conforming others, psychological commitments to conformity, involvements in conventional activities, and beliefs consistent with conformity to prevailing norms.

Among the most important of the bonding elements are emotional attachments individuals may have to conforming others and commitments

to conformity—psychological investments or stakes people hold in a conforming lifestyle. Those having weak attachments—that is, people who are insensitive to the opinions of conforming others—and who have few stakes in conformity, in the form of commitments to occupation or career and education, are more likely than others to deviate (see, e.g., Paternoster et al. 1983; Thornberry and Christenson 1984; Liska and Reed 1985). In effect, these individuals are “free” from the constraints that ordinarily bond people to normative conformity. Conversely, individuals concerned about the opinions of conforming others and who have heavy psychological investments in work or school will see the potential consequences of deviant acts—rejection by friends or loss of a job—as threatening or costly, and consequently will refrain from those acts.

A related concern is the role of sanctions in preventing deviant acts. Control theorists like Hirschi reason that most people are utilitarian in their judgments about deviant acts, and thus evaluate carefully the risks associated with each act. Control theories typically maintain that the threat of sanctions actually prevents deviant acts when the risks outweigh the gains. Much of the most recent writing on sanctions and their effects has stressed the importance of perceptual processes in decisions to commit deviant acts (Gibbs 1975, 1977; Tittle 1980; Paternoster et al. 1982, 1987; Piliavin et al. 1986; Matsueda, Piliavin, and Gartner 1988). At the heart of this perspective is the reasoning that individuals perceiving the threat of sanctions as high are much more likely to refrain from deviance than those perceiving the threat as low, regardless of the actual level of sanction threat.

Writing from the social control perspective attempts to build on and extend the basic assumptions and propositions of control theory. Michael Gottfredson, in conjunction with Hirschi, has developed a general theory of crime that identifies “low self-control,” as opposed to diminished social control, as the primary cause of deviant behavior (Hirschi and Gottfredson 1987; Gottfredson and Hirschi 1990). Arguing that all people are inherently self-interested, pursuing enhancement of personal pleasure and avoiding pain, Gottfredson and Hirschi suggest that most crimes, and for that matter most deviant acts, are the result of choices to maximize pleasure, minimize pain, or both.

Crimes occur when opportunities to maximize personal pleasure are high and when the certainty of painful consequences is low. Further, people who pursue short-term gratification with little consideration for the long-term consequences of their actions are most prone to criminal behavior. In terms of classical control theory, these are individuals who have weak bonds to conformity or who disregard or ignore the potentially painful consequences of their actions. They are “relatively unable or unwilling to delay gratification; they are indifferent to punishment and the interests of others” (Hirschi and Gottfredson 1987, pp. 959–960).

Building on traditional control theory, Charles Tittle (1995) reasons that it helps explain why individuals conform, but it also helps to explain why they engage in deviant behavior. Tittle (1995, p. 135) argues that “the amount of control to which an individual is subject, relative to the amount of control he or she can exercise, determines the probability of deviance occurring as well as the type of deviance likely to occur.” Conformity results when individuals are subjected to and exert roughly equal amounts of control—there is “control balance.” According to Tittle, however, individuals who are subjected to more control than they exert will be motivated to engage in deviance in order to escape being controlled by others.

Robert Sampson and John Laub (1993) have also expanded on the basic propositions of control theory. In their research, Sampson and Laub focus on stability and change in the antisocial behavior of individuals as they grow from juveniles to adults. Sampson and Laub argue that family, school, and peer relationships influence the likelihood of deviant behavior among juveniles. In particular, Sampson and Laub argue that the structure of the family (e.g., residential mobility, family size) affects family context or process (e.g., parental supervision, discipline), which, in turn, makes deviance among children more or less likely. Many adolescent delinquents grow up to become adult criminals because their juvenile delinquency makes the formation of adult social bonds to work and family less likely. Despite this continuity in antisocial behavior from adolescence to adulthood, however, Sampson and Laub argue that many juvenile delinquents do not commit deviant acts as adults because they develop adult social bonds, such as attachment to a spouse or commitment to a job.

In sum, micro-level origin theories look to those aspects of the individual’s social environment that influence her or his likelihood of deviance. Learning theories stress the importance of deviant peers and other significant individuals, and their impact on attitudes and behaviors favorable to the commission of deviant acts. These theories assume that the social environment acts as an agent of change, transforming otherwise conforming individuals into deviants through peer influences. People exposed to deviant others frequently and sufficiently, like persons exposed to a contagious disease who become ill, will become deviant themselves. Control theories avoid this “contagion” model, viewing the social environment as a composite of controls and restraints cementing the individual to a conforming lifestyle. Deviance occurs when elements of the bond— aspects of social control—are weak or broken, thereby freeing the individual to violate social norms. Sanctions and the threat of sanctions are particularly important to control theories, a central part of the calculus that rational actors use in choosing to commit or refrain from committing deviant acts.

The policy implications of micro-level origin theories are obvious. If, as learning theories argue, deviance is learned through association with deviant peers, then the way to eliminate deviance is to assist youths in resisting deviant peer influences and helping them to develop attitudes that disapprove of deviant behavior. Control theories, on the other hand, suggest that deviance can be reduced with programs that help families develop stronger bonds between parents and children. Control theory also implies that programs that help youths develop stronger commitments to conventional lines of activity and to evaluate the costs and benefits of deviant acts will also result in a reduction of problematic behavior.

MICRO-LEVEL REACTIONS TO DEVIANCE

Unlike micro-level origin theories, micro-level reaction theories make no assumptions about the existence of a homogeneous, pervasive set of norms in society. These theories take an altogether different approach to explaining deviant behavior, viewing deviance as a matter of definition; a social status imposed by individuals or groups on others. Most argue that there exists no single pervasive set

of norms in society and that deviant behavior may best be understood in terms of norms and their enforcement. These theories typically stress the importance of labeling processes—the mechanisms by which acts become defined or labeled as “deviant—and the consequences of labeling for the person so labeled. Many of these theories are concerned with the development of deviant lifestyles or careers; long-term commitments to deviant action.

One of the most important writers in this tradition is Howard Becker (1963). Becker argues that deviance is not a property inherent in any particular form of behavior but rather a property conferred on those behaviors by audiences witnessing them. Becker (1963, p. 9) notes that “. . . deviance is *not* a quality of the act the person commits, but rather a consequence of the application by others of rules and sanctions to an ‘offender.’ The deviant is one to whom that label has been successfully applied; deviant behavior is behavior that people so label.” Thus, Becker and others in this tradition orient the study of deviance on rules and sanctions, and the application of labels. Their primary concern is the social construction of deviance—that is, how some behaviors and classes of people come to be defined as “deviant” by others observing and judging the behavior.

Building on the idea that deviance is a property conferred on behavior that is witnessed by a social audience, Becker (1963) also developed a simple typology of deviant behavior. The dimensions upon which the typology is based are whether or not the individual is perceived as deviant and whether or not the behavior violates any rule. *Conforming* behavior is behavior that does not violate any rules and is not perceived as deviant. Individuals in the opposite scenario, in which the person both violates rules and is perceived by others as deviant, Becker labeled *pure deviants*. Some individuals, according to Becker, may be perceived as deviant, even though they have not violated any rules. Becker identified these individuals as the *falsely accused*. Finally, the *secret deviant* is one who has violated the rules, but, nonetheless, is not perceived by others as being deviant.

Equally important is the work of Edwin Lemert (1951). Stressing the importance of labeling to subsequent deviant behavior, he argues that repetitive deviance may arise from social reactions to

initial deviant acts. According to Lemert (1951, p. 287), deviance may often involve instances where “a person begins to employ his deviant behavior. . . as a means of defense, attack or adjustment to the. . . problems created by the consequent social reactions to him.” Therefore, a cause of deviant careers is negative social labeling; instances where reactions to initial deviant acts are harsh and reinforce a “deviant” self-definition. Such labeling forces the individual into a deviant social role, organizing his or her identity around a pattern of deviance that structures a way of life and perpetuates deviant behavior (Becker 1963; Schur 1971, 1985).

Perhaps the most significant developments in this tradition have contributed to knowledge about the causes of mental illness. Proponents of micro-level reaction theories argue that the label “mental illness” can be so stigmatizing to those labeled, especially when mental-health professionals impose the label, that they experience difficulty returning to nondeviant social roles. As a result, the labeling process may actually exacerbate mental disorders. Former mental patients may find themselves victims of discrimination at work, in personal relationships, or in other social spheres (Scheff 1966). This discrimination, and the widespread belief that others devalue and discriminate against mental patients, may lead to self-devaluation and fear of social rejection by others (Link 1982, 1987). In some instances, this devaluation and fear may be associated with demoralization of the patient, loss of employment and personal income, and the persistence of mental disorders following treatment (Link 1987).

Hence, micro-level reaction theories reason that deviant behavior is rooted in the process by which persons define and label the behavior of others as deviant. The theories offer explanations of individual differences in deviance, stressing the importance of audience reactions to initial deviant acts. However, these theories make no attempt to explain the origins of the initial acts (Scheff 1966). Rather, they are concerned primarily with the development and persistence of deviant careers.

Micro-level reaction theories have very different implications for public policy than macro- and micro-level origins theories. Micro-level reaction theories argue that unwarranted labeling can lead

to deviant careers. In effect, the reaction to deviance can cause deviant behavior to escalate. Thus, in order to reduce deviance, agencies of social control must adopt policies of nonintervention. Rather than being formally sanctioned and labeled as deviant, nonintervention policies must encourage diversion and deinstitutionalization. Formal sanctioning must be highly selective, focusing only on the most serious and threatening deviant acts.

MACRO-LEVEL REACTIONS TO DEVIANCE

The final class of theories looks to the structure of economic and political power in society as a cause of deviant behavior. Macro-level reaction theories—either Marxist or other conflict theories—view deviance as a status imposed by dominant social classes to control and regulate populations that threaten political and economic hegemony. Like micro-level reaction theories, these theories view deviance as a social construction and accord greatest importance to the mechanisms by which society defines and controls entire classes of behavior and people as deviant in order to mediate the threat. However, these theories reason that the institutional control of deviants has integral ties to economic and political order in society.

Marxist theories stress the importance of the economic structure of society and begin with the assumption that the dominant norms in capitalist societies reflect the interests of the powerful economic class; the owners of business. But contemporary Marxist writers (Quinney 1970, 1974, 1980; Spitzer 1975; Young 1983) also argue that modern capitalist societies are characterized by large “problem populations”—people who have become displaced from the workforce and alienated from the society. Generally, the problem populations include racial and ethnic minorities, the chronically unemployed, and the extremely impoverished. They are a burden to the society and particularly to the capitalist class because they create a form of social expense that must be carefully controlled if the economic order is to be preserved.

Marxist theories reason that economic elites use institutions such as the legal, mental-health, and welfare systems to control and manage society’s problem populations. In effect, these institutions define and process society’s problem populations as deviant in order to ensure effective

management and control. In societies or communities characterized by rigid economic stratification, elites are likely to impose formal social control in order to preserve the prevailing economic order.

Conflict theories stress the importance of the political structure of society and focus on the degree of threat to the hegemony of political elites, arguing that elites employ formal social controls to regulate threats to political and social order (Turk 1976; Chambliss 1978; Chambliss and Mankoff 1976). According to these theories, threat varies in relation to the size of the problem population, with large problem populations substantially more threatening to political elites than small populations. Thus, elites in societies and communities in which those problem populations are large and perceived as especially threatening are more likely to process members of the problem populations as deviants than in areas where such problems are small.

Much of the writing in this tradition has addressed the differential processing of people defined as deviant. Typically, this writing has taken two forms. The first involves revisionist histories linking the development of prisons, mental asylums, and other institutions of social control to structural changes in U.S. and European societies. These histories demonstrate that those institutions often target the poor and chronically unemployed independent of their involvement in crime and other deviant acts, and thereby protect and serve the interests of dominant economic and political groups (Scull 1978; Rafter 1985).

A second and more extensive literature includes empirical studies of racial and ethnic disparities in criminal punishments. Among the most important of these studies is Martha Myers and Suzette Talarico’s (1987) analysis of the social and structural contexts that foster racial and ethnic disparities in the sentencing of criminal offenders. Myers and Talarico’s research, and other studies examining the linkages between community social structure and differential processing (Myers 1987, 1990; Peterson and Hagan 1984; Bridges, Crutchfield, and Simpson 1987; Bridges and Crutchfield 1988), demonstrate the vulnerability of minorities to differential processing during historical periods and in areas in which they are perceived by whites as serious threats to political and social order. In effect, minorities accused of crimes during these

periods and in these geographic areas are perceived as threats to white hegemony, and therefore become legitimate targets for social control.

In addition to studying the connections between community social structure and the differential processing of racial and ethnic minorities, researchers have also begun to examine how court officials' perceptions of offenders can influence disparities in punishments. Bridges and Steen (1998), for example, show how court officials' perceptions of white and minority youths differ, and how these different perceptions contribute to different recommendations for sentencing. Probation officers often attribute the offenses of minority youths to internal characteristics of the youths (i.e., aspects of their personality), while attributing the offenses of white youths to external characteristics (i.e., aspects of their environments). As a result of these differential attributions, minority youths are perceived as more threatening, more at risk for re-offending than whites and more likely to receive severe recommendations for sentences.

Thus, macro-level reaction theories view deviance as a by-product of inequality in modern society, a social status imposed by powerful groups on those who are less powerful. Unlike micro-level reaction theories, these theories focus on the forms of inequality in society and how entire groups within the society are managed and controlled as deviants by apparatuses of the state. Like those theories, however, macro-level reaction theories make little or no attempt to explain the origins of deviant acts, claiming instead that the status of "deviant" is, in large part, a social construction designed primarily to protect the interests of the most powerful social groups. The primary concern of these theories is explicating the linkages between inequality in society and inequality in the labeling and processing of deviants.

Since macro-level reaction theories view deviance as a status imposed by powerful groups on those with less power, the most immediate policy implication of these theories is that imbalances in power and inequality must be reduced in order to reduce levels of deviance and levels of inequality in the sanctioning of deviance. More effective monitoring of government agencies that are used to control problem populations, such as the criminal

justice system, can also help to reduce the disproportionate processing of less powerful groups, such as racial minorities, as deviant.

NEW THEORETICAL DIRECTIONS

A recurring issue in the study of deviance is the contradictory nature of many deviance theories. The theories often begin with significantly different assumptions about the nature of human behavior and end with significantly different conclusions about the causes of deviant acts. Some scholars maintain that the oppositional nature of these theories—the theories are developed and based on systematic rejection of other theories (Hirschi 1989)—tends toward clarity and internal consistency in reasoning about the causes of deviance. However, other scholars argue that this oppositional nature is intellectually divisive—acceptance of one theory precludes acceptance of another—and "has made the field seem fragmented, if not in disarray" (Liska, Krohn, and Messner 1989, p. 1).

A related and equally troublesome problem is the contradictory nature of much of the scientific evidence supporting deviance theories. For each theory, there exists a literature of studies that supports and a literature that refutes major arguments of the theory. And although nearly every theory of deviance may receive empirical confirmation at some level, virtually no theory of deviance is sufficiently comprehensive to withstand empirical falsification at some other level. The difficult task for sociologists is discerning whether and under what circumstances negative findings should be treated as negating a particular theory (Walker and Cohen 1985).

In recent years, these two problems have renewed sociologists' interest in deviance theory and, at the same time, suggested new directions for the development of theory. The oppositional nature of theories has spawned interest in theoretical integration. Many scholars are dissatisfied with classical theories, arguing that their predictive power is exceedingly low (see Elliott 1985; Liska, Krohn, and Messner 1989). Limited to a few key explanatory variables, any one theory can explain only a limited range and amount of deviant behavior. And because most scholars reason that the causes of deviance are multiple and quite complex, most also contend that it may be "necessary to combine different theories to capture the

entire range of causal variables" (Liska, Krohn, and Messner 1989, p. 4).

Because it combines the elements of different theories, the new theory will have greater explanatory power than theories from which it was derived. However, meaningful integration of deviance theories will require much more than the simple combination of variables. Scholars must first reconcile the oppositional aspects of theories, including many of their underlying assumptions about society, the motivations of human behavior, and the causes of deviant acts. For example, learning theories focus heavily on the motivations for deviance, stressing the importance of beliefs and values that "turn" the individual to deviant acts. In contrast, control theories accord little importance to such motivations, examining instead those aspects of the social environment that constrain people from committing deviant acts. Reconciling such differences is never an easy task, and in some instances may be impossible (Hirschi 1979).

The problem of contradictory evidence suggests a related but different direction for deviance theory. Theories may vary significantly in the conditions—termed *scope conditions*—under which they apply (Walker and Cohen 1985; Tittle 1975; Tittle and Curran 1988). Under some scope conditions, theories may find extensive empirical support, and under others virtually none. For instance, macro-level origin theories concerned with the frustrating effects of poverty on deviance may have greater applicability to people living in densely populated urban areas than those living in rural areas. The frustration of urban poverty may be much more extreme than in rural areas, even though the actual levels of poverty may be the same. As a result, the frustrations of urban poverty may be more likely to cause deviant adaptations in the form of violent crime, drug abuse, and vice than those of rural poverty. In this instance, "urbanness" may constitute a condition that activates strain theories linking poverty to deviance. Obviously, the same theories simply may not apply in rural areas or under other conditions.

Effective development of deviance theory will require much greater attention to the specification of such scope conditions. Rather than combining causal variables from different theories as integrationists would recommend, this approach

to theory development encourages scholars to explore more fully the strengths and limitations of their own theories. This approach will require more complete elaboration of extant theory, explicitly specifying those circumstances under which each theory may be meaningfully tested and thus falsified. The result will be a greater specification of each theory's contribution to explanations of deviant behavior.

These two directions have clear and very different implications for the development of deviance theory. Theoretical integration offers overarching models of deviant behavior that cut across classical theories, combining different levels of explanation and causal focuses. If fundamental differences between theories can be reconciled, integration is promising. The specification of scope conditions offers greater clarification of existing theories, identifying those conditions under which each theory most effectively applies. Although this direction promises no general theories of deviance, it offers the hope of more meaningful and useful explanations of deviant behavior.

DIFFUSION THEORIES

The concept of *diffusion* inherently focuses upon *process*. Diffusion refers to the dissemination of any physical element, idea, value, social practice, or attitude through and between populations. Diffusion is among the rare concepts used across the physical, natural, and social sciences, as well as in the arts. Diffusion is most closely associated with the social sciences, particularly rural sociology, anthropology, and communication. Diffusion thinking offers a logic through which to describe and perhaps explain myriad types of change that involve equally diverse foci, ranging from the adoption of internet technology (Adams 1997), to the spread of belief systems (Dean 1997).

Work connected to the concept of diffusion is arguably structured as theory. Certainly there is no

single, unified, deductively structured collection of propositions, widely regarded by social scientists as identifying the principal mechanisms of diffusion that could be employed across all substantive areas. There are however, many distinct collections of propositions, a few well-tested over decades, that describe different diffusion phenomena in different content areas. Indeed, in the area of innovation diffusion, Everett Rogers (1983) produced a formal theory that is broadly recognized, often tested, and that has been adapted to other content areas including disaster research and technology transfer. Part of the problem in formalizing diffusion theories is that the concept does not inherently specify content (rather a framework or process to structure thinking). However, it cannot be examined empirically without tying it to some substance. That is, studies of diffusion focus on *something* (a technology, idea, practice, attitude, etc.) that is being diffused. Consequently, the research on diffusion that would drive theory building has remained scattered in the literatures of different sciences, and as such it is not readily pulled together. These conditions do not facilitate ready assembly of information that would encourage creation of a general theory of diffusion. Thus, one must look to the growth of formal theory in sub-areas, although Rogers (in press) has begun to cross content spheres.

There are at least three traditions or theory families that can be historically discerned in the study of diffusion. Rogers (1983, p. 39) has pointed out that for many years these traditions remained largely distinct, with little overlap and cross-fertilization. Since the late 1970s the level of research and theoretical isolation has decreased, leading to an enhanced awareness among the perspectives and some integration of empirical findings into more general theoretical statements. The three theory families are: (1) cultural diffusion; (2) diffusion of innovations; and (3) collective behavior.

CULTURAL DIFFUSION

The earliest social scientific use of the term *diffusion* is found in Edward Tylor's (1865) treatment of culture change. Anthropologists have long attempted to explain similarities and differences among cultures, especially those that were geographically adjacent. Tylor's work on culture change first

proposed the notion of diffusion as a means of explaining the appearance of similar culture elements in different groups and of understanding the progressive alteration of elements within the same group. As the twentieth century began, diffusion arose as an alternative to evolution as a basis for understanding cultural differences and change. Evolutionists argued that cultural similarities probably arose through independent invention. Those who embraced diffusion presented it as a more parsimonious explanation, emphasizing that traits and institutions could pass between groups by means of contact and interaction.

Historical Development. The English anthropologists W. J. Perry and Elliot Smith devised the most extreme position on cultural diffusion. These scholars held that human culture originated in Egypt and progressively diffused from that center over the remainder of the earth. In Germany, Fritz Graebner (1911) argued that critical aspects of cultures—toolmaking, for example—originated in a small number of geographically isolated societies. This hypothesis formed the basis for *culture circles* (“*kulturkreise*”), collections of societies sharing similar cultures. Unlike British diffusionists who emphasized tracking the movement of single culture elements, Graebner and others in his tradition focused on the dissemination of collections of elements or cultural complexes.

American anthropologists are credited with developing a social scientifically workable concept of diffusion. Franz Boas (1896) conceived of diffusion as a viable mechanism for culture exchanges among geographically adjacent areas. His view figured prominently in the intellectual move away from the deterministic view of diffusion proposed by early British anthropologists. Alfred Kroeber (1923, p. 126) and Robert Lowie (1937, p. 58)—students of Boas—subsequently developed a position called *moderate diffusionism*, which is currently widely accepted in anthropology. This position allowed for the coexistence of a variety of mechanisms of change and transfer—independent invention, acculturation, etc.—in addition to diffusion in accounting for culture change and differentiation. Clark Wissler (1929), a Kroeber contemporary, established an empirical basis for culture diffusion by identifying ten culture areas (regions with similar cultural inventories) in North and South America and the Caribbean.

Theory in Cultural Diffusion. In terms of theory development, *cultural diffusion* is the actual movement of a given social institution or physical implement, while *stimulus diffusion* is the exchange or movement of the *principle* upon which an institution or implement is based. In the cultural diffusion literature, scholars have enumerated assumptions, stated principles, and reviewed empirical work with the objective of identifying propositions tested repeatedly and not found to be false. Indeed, beginning with the work of early twentieth century anthropologists, one can identify at least five broadly accepted and empirically supported claims that form the core of what is called cultural diffusion theory. First, borrowed elements usually undergo some type of alteration or adaptation in the new host culture. Second, the act of borrowing depends on the extent to which the element can be integrated into the belief system of the new culture. Third, elements that are incompatible with the new culture's prevailing normative structure or religious belief system are likely to be rejected. Fourth, acceptance of an element depends upon its utility for the borrower. Finally, cultures with a history of past borrowing are more likely to borrow in the future. These claims constitute the "core propositions" of culture diffusion theory; over the years, each has been qualified and elaborated upon, and corollaries have been created (Stahl 1994).

Currently, diffusion is seen as a mechanism for culture change that typically accounts for a large proportion of any particular culture inventory. The deterministic, linear view of diffusion has been discredited by the empirical record. The concept of culture diffusion as a means of understanding cultural inventories is entrenched in the field of cultural anthropology. As the twenty-first century dawns, a principal controversy among cultural anthropologists centers on the definition of culture, rather than upon the acceptability of culture diffusion. Diffusion theory remains prominent in the archaeology literature, particularly as a means of tracing culture inventories for groups over time (Posnansky and DeCorse 1986).

Sociologists were initially involved in the use of cultural diffusion theory as a means of looking at cultural change (largely in terms of nonmaterial culture) in the United States. Initially theory drawn from anthropology was used (Chapin 1928), but

over time the sociological focus became identifying social psychological motivations and mechanisms supporting the diffusion process (Park and Burgess 1921, p. 20). Recently, sociological work directly on culture is bifurcated, with one group of scientists still emphasizing the social psychological issues in culture meaning (Wuthnow and Witten 1988), and another more concerned with structural (mathematical or statistical) models of culture processes themselves (Griswold 1987). Neither group has especially focused on diffusion theory as a mechanism to track or identify the content-outcomes of culture change.

DIFFUSION OF INNOVATIONS

The diffusion of innovations has historically focused on the spread of an idea, procedure, or implement within a single social group or between multiple groups. For the most part, scholars of this tradition define diffusion as the process through which some innovation is communicated within a social system. Also important is the notion of a time dimension reflecting the *rate* of diffusion, and the importance of the individual adopter (or non-adopter) reflecting the role of social influence.

The study of innovation diffusion began rather narrowly, grew to dominate the field of rural sociology for a time, contracted in popularity for many years, and then spawned wide interest across several disciplines. Innovation diffusion study contains several groups: those who focus on content or the specific innovation being diffused; those who emphasize theoretical elaborations of generic principles of innovation diffusion; and those concerned with creating structural models to track diffusion. Particularly in the past decade, the literature has seen much cross-fertilization, although mathematical modelers tend to appear less often in the work of other diffusion scholars. Although the roots of innovation diffusion theory are seen to be largely in rural sociology, more recently the field has become distinctly interdisciplinary with major advancements made especially in the discipline of communication.

Historical Development. The definitive history of the diffusion of innovations as a paradigm was published by Thomas Valente and Everett Rogers (1995). The roots of innovation diffusion

are usually traced to Gabriel Tarde (1890) who didn't use the term *diffusion*, but was the first to address the notions of *adopters* and the role of social influence in adoption, as well as to identify the S-shaped curve associated with the rate of an innovation's adoption. The formative empirical work on innovation diffusion can be traced to Bryce Ryan's Iowa State University-based study of hybrid corn seeds (published with Gross in 1943), and Raymond Bowers's (1937) study of the acceptance and use of ham radio sets. For more than two decades following this pioneering work, the study of innovation diffusion and particularly theory development took place within the context of rural sociology. This circumstance was a function of a variety of forces, principal among which were the location of rural sociologists in land grant institutions charged with the dissemination of agricultural innovations to farmers (Hightower 1972) and the communication and stimulation accorded by the North Central Rural Sociology Committee's (a regional professional society) formation of a special subcommittee to deal with the issue of diffusion of agricultural innovations (Valente and Rogers 1995, p. 254).

Most scholars agree that contemporary views of innovation diffusion grew from hybrid corn seeds; specifically the research on adoption done by Bryce Ryan and Neal Gross (1943). These studies ultimately defined most of the issues that occupied diffusion researchers and builders of innovation diffusion theory for decades to come: the role of social influence, the timing of adoptions, the adoption process itself, and interactions among adopter characteristics and perceived characteristics of the innovation. From the middle 1940s through the 1950s, rural sociologists vigorously developed a body of empirical information on the diffusion of innovations. Most of these studies remained tied to agriculture and farming, and focused on the diffusion of new crop management systems, hybridizations, weed sprays, insect management strategies, chemical fertilizers, and machinery. A common criticism of the studies of this era is that many of the studies seem to be almost replications of the Ryan and Gross work, the main difference among them being the specific innovation studied. While it is true that these studies tend to share a common methodology and linear conception of diffusion, it is also true that they provide a strong foundation of empirical case studies.

Indeed, the replications that these studies represent substantially facilitated the later sophisticated theoretical work initiated in the early 1960s (Rogers 1962), and continued in the 1980s (Rogers 1983, 1988).

The 1960s marked the beginning of the decline of the central role of rural sociologists in innovation diffusion research. In large part this was due to changes in the field of rural sociology, but it also reflected the increasing involvement of researchers from other disciplines, changing the sheer proportion of rural sociologists working on innovation diffusion. After more than two decades of extensive research on the diffusion of agricultural innovations, rural sociologists—like other social scientists of the time—began to devote more time to the study of social problems and the consequences of technology. Indeed, Crane (1972) argued that around 1960 rural sociologists began to believe that the critical questions about innovation diffusion had already been answered. Although the late 1960s saw rural sociologists launch a series of diffusion studies on agricultural change in the international arena (particularly Latin America, Asia and Africa), by 1965 research on diffusion of innovations was no longer dominated by members of that field. Of course, innovation diffusion research by rural sociologists has continued, including studies of the impacts of technological innovation diffusion, and diffusion of conservation practices and other ecologically-based innovations (Fliegel 1993).

The infusion of researchers from many disciplines studying a variety of specific innovations initiated the process of expanding the empirical testing of innovation diffusion tenets. This began with studies in education addressing the diffusion of kindergartens and driver education classes in the 1950s, as well as Richard Carlson's (1965) study of the diffusion of modern math. Another major contribution came from the area of public health. Elihu Katz, Herbert Menzel, and James Coleman launched extensive studies of the diffusion of a new drug (the antibiotic tetracycline); first in a pilot study (Menzel and Katz 1955) and then in studies of four Illinois cities (Coleman, Menzel, and Katz 1957; Coleman, Katz, and Menzel 1966). This research greatly expanded knowledge of interpersonal diffusion networks, and in particular its influence in adoption. Interestingly, as Elihu Katz, M. L. Levine, and Harry Hamilton

(1963) indicated, the drug studies truly represented an independent replication of the principles of innovation diffusion developed by rural sociologists because the public health researchers were unaware of the agricultural diffusion research. Other studies in the public health arena focused on dissemination of new vaccines, family planning, and new medical technology.

Beginning in the late 1960s, there was a substantial increase in the amount of diffusion research in three disciplines: business marketing, communication, and transportation-technology transfer. Marketing research principally addressed the characteristics of adopters of new products and the role of opinion leaders in the adoption process (Howes 1996). This literature is based almost exclusively on commercial products, ranging from coffee brands and soap to touch-tone telephones, the personal computer, and internet services. The studies tend to be largely atheoretical, methodologically similar, and aimed simply at using knowledge of diffusion either to improve marketing and sales of the product or to describe product dissemination.

In sharp contrast, work done on innovation diffusion by scholars trained in communication has been considerably more theoretically oriented. Throughout the 1960s, universities in America began to establish separate departments of communication (Rogers 1994). Since diffusion of innovations was widely seen as one type of communication process, scholars in these new departments adopted this type of research as one staple of their work. Beginning with studies of the diffusion of news events (Deutschmann and Danielson 1960), this research tradition has branched out to study the dissemination of a wide variety of specific innovations (McQuail 1983, p. 194). Scholars working in this tradition have been principally responsible for the progressive refinements of formalized theory of innovation diffusion. Everett Rogers has consistently remained the leader in theory development in communication, revising and extending his 1962 book *Diffusion of Innovations* with help from co-author Floyd Shoemaker to produce *Communication of Innovations* in 1971. Subsequently, Rogers (1983, in press) restored the original title *Diffusion of Innovations*, broadened the theoretical base and incorporated diffusion studies and thinking from other disciplines. Generally, Rogers and other communication scholars

have studied the diffusion of many target material elements, phenomena, and other intangibles, but they have continued to produce theoretical statements dealing with communication channels, diffusion networks, interpersonal influence and the innovation-decision process. Finally, the technology dissemination and transfer issues have involved work by geographers, engineers, and others beginning in the 1970s. The primary focus of such studies has been the spread or dissemination of technology (Sahal 1981) and the development of network models of innovation diffusion (Valente 1995).

Theory in Innovation Diffusion. The theoretical work of Everett Rogers initially resulted in the collection of knowledge gained from the rural sociology tradition, then facilitated the transition to communication perspectives, and now has served as the mainstay of what is developing as a more cross-disciplinary focus on innovation diffusion. His contribution is twofold. First, he created inventories of findings from many disciplines and from many types of innovation. These inventories provided impetus for the development of a definition of innovation diffusion that was not bound by discipline. Second, Rogers assembled and refined theoretical structures aimed at explaining the principal features of innovation diffusion. The theoretical work has cemented a core of knowledge and principles that are widely identified (and used empirically) as the bases of the diffusion of innovations. Rogers's (1983) theory includes eighty-one generalizations (propositions) that have undergone empirical testing.

The theory of innovation diffusion may be understood as capturing the innovation-decision process, innovation characteristics, adopter characteristics, and opinion leadership. The innovation-decision process represents the framework on which diffusion research is built. It delineates the process through which a decision maker (representing any unit of analysis) chooses to adopt, reinvent (modify), or reject an innovation. This process consists of five stages. *Knowledge* is the initial stage when the decision maker detects the existence of the innovation and learns of its function. In the *persuasion* stage, the decision maker forms a positive or negative attitude toward the innovation. The third stage, *decision*, deals with the decision-maker's choice to accept or reject the

innovation. *Implementation*, the fourth stage, follows a decision to accept and involves putting the innovation into some use (in either its accepted form or some modified form). During the final stage of *confirmation*, decision makers assess an adopted innovation, gather information from significant others, and choose to continue to use the innovation as is, modify it (reinvention), or reject it. While some have criticized the stage model as too linear, Rogers (1983) has convincingly argued that existing formulations afford a degree of interpretative and predictive flexibility that averts historical problems with stage models in social science.

Different innovations have different probabilities of adoption and hence, different adoption rates. That is, they travel through the innovation-decision process at varying speeds. The literature demonstrates that five characteristics of innovations influence the adoption decision. *Compatibility* refers to the congruence between an innovation and the prevailing norms, values, and perceived needs of the potential adopter. Higher levels of compatibility are associated with greater likelihood of adoption. Innovation *complexity*, on the other hand, is negatively associated with adoption. The extent to which use of an innovation is visible to the social group—called *observability*—is positively related to adoption. *Relative advantage* refers to the extent to which an innovation is perceived to be “better” than the idea, practice, or element that it replaces. Higher relative advantage increases the probability of adoption. Finally, *trialability*—the extent to which an innovation may be experimented with—also increases the probability of adoption.

The third component of diffusion of innovation theory addresses adopter characteristics. Adopter categories are classifications of individuals by how readily they adopt an innovation. Rogers (1983, p. 260) identifies nine socioeconomic variables, twelve personality variables, and ten personal communication characteristics that have been demonstrated to bear upon adoption choices. In general, the literature holds that early adopters are more likely to be characterized by high socioeconomic status, high tolerance of uncertainty and change, low levels of fatalism and dogmatism, high integration into the social system, high exposure to mass media and interpersonal communication channels, and frequent engagement in information seeking.

Identifying the characteristics of people who adopt innovations raises the question of interpersonal influence. Three issues are addressed in the development of propositions about the role of interpersonal influence in the innovation decision process: information flow, opinion leadership, and diffusion networks. Over time, information flow has been seen as a “hypodermic needle” model, a two-step flow (to opinion leaders, then other adopters), and a multi-step flow. Currently, information flows are seen as multi-step in nature and are described in terms of *homophily* and *heterophily*—the degree to which pairs of interacting potential adopters are similar or dissimilar. Opinion leadership denotes the degree to which one member of a social system can influence the attitude and behavior of others. This concept is presently discussed relative to spheres of influence, wherein a given person may be a leader or follower depending upon the part of the diffusion network being referenced. The diffusion or communication network is the structural stage upon which social influence takes place. Considerable attention has been devoted to developing analysis strategies and tactics for such networks (Wigand 1988).

COLLECTIVE BEHAVIOR

While diffusion is not a commonly used term in collective behavior, processes of diffusion are important in connection with understanding crowds, fashion, and some aspects of disaster behavior. In all cases, analytic concern centers on the dissemination of emotions, social practices, or physical elements through a collectivity. The study of human behavior in disasters is recent and multidisciplinary. In this field there has been a concern with diffusion in the classic sense of tracking ideas and practices through networks. The principle foci of research have been the adoption of protective measures and the dissemination of warning messages (Lindell and Perry 1992), with the aim of research being both the development of general theories of protective behaviors and more effective protection of endangered populations.

All three diffusion theory traditions converge in the study of crowd behavior. In proposing *imitation* as an explanatory mechanism for crowd actions, Gabriel Tarde (1890, p. 45) drew upon Edward Tylor’s concept of cultural diffusion. Subsequently, Gustave LeBon (1895) and Gabriel Tarde

(1901) approached crowd behavior in terms of *social contagion*: rapid dissemination of emotions among interacting people. Although Floyd Allport (1924) and Herbert Blumer (1939) extended and formalized the concept of contagion, it has been largely displaced as a theory of crowd behavior by convergence theory (Turner and Killian 1987, p.19).

Changes in dress have been conceptualized as diffusion processes. Alfred Kroeber (1919) studied *fashion cycles* which he believed diffused systematically through civilizations. Katz and Lazarsfeld (1955, p. 241) moved away from the initial concern with movement of fashion through networks to focus more on social influence. Herbert Blumer (1969) firmly established social psychological motivations as the basis for fashion behavior. Current theoretical work on fashion continues to emphasize social psychological approaches wherein fashion diffusion issues are peripheral (Davis 1985; Nagasawa, Hutton, and Kaiser 1991).

RONALD W. PERRY

DISASTER RESEARCH

SOCIOHISTORY OF THE FIELD

Descriptions of calamities exist as far back as the earliest human writings, but systematic empirical studies and theoretical treatises on social features of disasters appeared only in the twentieth century. The first major publications in both instances were produced by sociologists. Samuel Prince (1920) wrote a doctoral dissertation in sociology at Columbia University that examined the social

change consequences of a munitions ship explosion in the harbor of Halifax, Canada. Pitirim Sorokin (1942) two decades later wrote *Man and Society in Calamity* that mostly speculated on how war, revolution, famine, and pestilence might affect the mental processes and behaviors, as well as the social organizations and the cultural aspects of impacted populations. However, there was no building on these pioneering efforts.

It was not until the early 1950s that disaster studies started to show any continuity and the accumulation of a knowledge base. Military interest in possible American civilian reactions to post-World War II threats from nuclear and biological warfare led to support of academic research on peacetime disasters. The National Opinion Research Center (NORC) undertook the key project at the University of Chicago between 1950 and 1954. This work, intended to be multidisciplinary, became dominated by sociologists as were other concurrent studies at the University of Oklahoma, Michigan State, and the University of Texas (Quarantelli 1987, 1994). The NORC study not only promoted field research as the major way for gathering data, but also brought sociological ideas from the literature on collective behavior and notions of organizational structure and functions into the thinking of disaster researchers (Dynes 1988; Dynes and Tierney 1994).

While the military interest quickly waned, research in the area obtained a strategic point of salience and support when the U.S. National Academy of Sciences in the late 1950s created the Disaster Research Group (DRG). Operationally run by sociologists using the NORC work as a prototype, the DRG supported field research of others as well as conducted its own studies (Fritz 1961). When the DRG was phased out in 1963, the Disaster Research Center (DRC) was established at the Ohio State University. DRC helped the field of study to become institutionalized by its continuous existence to the present day (having moved to the University of Delaware in 1985). In its thirty-six years of existence DRC has trained dozens of graduate students, built the largest specialized library in the world on social aspects of disasters, produced over six hundred publications and about three dozen Ph. D. dissertations (see <http://www.udel.edu/DRC/homepage.htm>), continually and consciously applied a sociological perspective to new disaster research topics, initiated an

interactive computer net of researchers in the area, and intentionally helped to create international networks and critical masses of disaster researchers.

DRC was joined in time in the United States by two other major social science research centers (both currently headed by sociologists). The Natural Hazards Center at the University of Colorado has as part of its prime mission the linking of disaster researchers and research-users in policy and operational areas. The Hazards Reduction and Recovery Center at Texas A & M University has a strong multidisciplinary orientation. The organization of these groups and others studying disasters partly reflects the fact that the sociological work in the area was joined in the late 1960s by geographers with interest in natural hazards (Cutter 1994), in the 1980s by risk analysts (including sociologists such as Perrow 1984; Short 1984) especially concerned with technological threats, and later by political scientists who initially were interested in political crises (Rosenthal and Kouzmin 1993). More important, in the 1980s disaster research spread around the world, which led to the development of a critical mass of researchers. This culminated in 1986 in the establishment within the International Sociological Association of the Research Committee on Disasters (# 39) (<http://sociweb.tamu.edu/ircd/>), with membership in over thirty countries; its own professional journal, *The International Journal of Mass Emergencies and Disasters* (www.usc.edu/dept/sppd/ijmed); and a newsletter, *Unscheduled Events*. At the 1998 World Congress of Sociology, this committee organized fourteen separate sessions with more than seventy-five papers from several dozen countries. The range of papers reflected that the initial focus on emergency time behavior has broadened to include studies on mitigation and prevention, as well as recovery and reconstruction.

CONCEPTUALIZATION OF “DISASTER”

Conceptualizations of “disaster” have slowly evolved from employing everyday usages of the term, through a focus on social aspects, to attempts to set forth more sociological characterizations. The earliest definitions equated disasters with features of physical agents and made distinctions between “acts of God” and “technological” agents. This

view was followed by notions of disasters as phenomena that resulted in significant disruptions of social life, which, however, might not involve a physical agent of any kind (e.g., a false rumor might evoke the same kind of evacuation behavior that an actual threat would). Later, disasters came to be seen as crises resulting either from certain social constructions of reality, or from the application of politically driven definitions, rather than necessarily from one initial and actual social disruption of a social system. Other researchers equated disasters with occasions where the demand for emergency actions by community organizations exceeds their capabilities for response. By the late 1980s, disasters were being seen as overt manifestations of latent societal vulnerabilities, basically of weaknesses in social structures or systems (Schorr 1987; Kreps 1989).

Given these variants about the concept, it is not surprising that currently no one formulation is totally accepted within the disaster research community (see Quarantelli 1998 where it is noted that postmodernistic ideas are now also being applied). However, there would be considerable agreement that the following is what is involved in using the term “disaster” as a sensitizing concept: Disasters are relatively sudden occasions when, because of perceived threats, the routines of collective social units are seriously disrupted and when unplanned courses of action have to be undertaken to cope with the crisis.

The notion of “relatively sudden occasions” indicates that disasters have unexpected life histories that can be designated in social space and time. Disasters involve the perceptions of dangers and risks to valued social objects, especially people and property. The idea of disruption of routines indicates that everyday adjustive social mechanisms cannot cope with the perceived new threats. Disasters necessitate the emergence of new behaviors not available in the standard repertoire of the endangered collectivity, a community, which is usually the lowest social-level entity accepted by researchers as able to have a disaster. In the process of the refinement of the concept, sociologists have almost totally abandoned the distinction between “natural” and “technological” disasters, derived from earlier notions of “acts of God” and “man-made” happenings. Any disaster is seen as inherently social in nature in origin, manifestation, or consequences. However, there is lack of

consensus on whether social happenings involving intentional, deliberate human actions to produce social disruptions such as occur in riots, civil disturbances, terrorist attacks, product tampering or sabotage, or wars, should be conceptualized as disasters. The majority who oppose their inclusion argue that conflict situations are inherently different in their origins, careers, manifestations, and consequences. They note that in disaster occasions there are no conscious attempts to bring about negative effects as there are in conflict situations (Quarantelli 1993). Nevertheless, there is general agreement that both conflict- and consensus-type crises are part of a more general category of collective stress situations, as first suggested by Allan Barton (1969).

MAJOR RESEARCH FINDINGS

While the research efforts have been uneven, much has been learned about the behavior of individuals and households, organizations, communities, and societies in the pre-, trans-, and postimpact time periods (Quarantelli and Dynes 1977; Kreps 1984; Drabek 1986). A separation of the disaster-planning cycle into mitigation, preparedness, response, and recovery phases has won partial acceptance at some policy and operational levels in the United States. However, international usage of the terms is far from total and there also is disagreement regarding what should be considered under mitigation. Therefore we will continue to discuss findings under the older "time" breakdown.

Preimpact behavior. *Individuals and households.* Most residents show little concern about disasters before they happen, even in risk-prone areas and where threats are recognized. Citizens tend to see disaster planning as primarily a moral even more than a legal responsibility of the government. Very few households ever plan in any concrete way for possible disasters. Exceptions to these passive attitudes are where there are many recurrent experiences of disasters as occur in some localities, where disaster subcultures (institutionalized expectations) have developed, and where potential disaster settings (such as at chemical complexes or nuclear plants) are the focus of activist citizen groups.

Organizations. Except for some disaster-oriented groups such as police and fire departments,

there usually is little organizational planning for disasters. Even agencies that plan tend to think of disasters as extensions of everyday emergencies and fail, according to researchers, to recognize the qualitative as well as quantitative differences between routine crises and disaster occasions. In disasters the responding organizations have to quickly relate to more and different groups than normal, adjust to losing part of their autonomy to overall coordinating groups, apply different performance standards and criteria, operate within a closer-than-usual public and private interface, and cannot function well when their own facilities and operations may be directly impacted by the disaster agent.

Communities. Low priority usually is given to preparing localities for disasters, and when there is some effort it is usually independent of general community development and planning. This reflects the reactive rather than proactive orientation of most politicians and bureaucrats and the fact that the issue of planning very seldom becomes a matter of broad community interest as would be indicated by mass media focus, discussions in the political arena, or the existence of advocacy groups. Efforts to initiate overall disaster preparedness often are hindered by prior organizational and community conflicts, cleavages, and disputes. Starting in the 1990s, major systematic efforts from the top down have been made in a few countries to push for the implementation of local mitigation measures. For programs to be implemented, however, people must accept the realistic criticism that while a disaster may be a high-impact, it is a very low-probability event.

Societies. Generally, disaster planning does not rank very high on the agenda of most societies. However, increasingly there are exceptions in developing countries when major recurrent disasters have had major impact on the gross national product and developmental programs. Also, in developed societies certain even distant catastrophes such as a Bhopal or Chernobyl can become symbolic occasions that lend impetus to instituting preparedness measures for specific disaster agents. Increasingly too, attention to national-level disaster planning has increased as citizens have come to expect their governments to provide more security in general for the population. Also, mitigation or prevention of disasters is being given higher priority than in the past.

Transemergency Period Behavior. *Individuals and households.* When disasters occur, individuals generally react very well. They are not paralyzed by a threat but actively seek relevant information and attempt to do what they can in the emergency. Victims while usually very frightened, not only act positively but also show little deviant behavior; they extremely seldom break in panic flight; they do not act irrationally especially from their perspective; and they very rarely engage in antisocial activities, although stories of such contrary behavior as looting may circulate very widely. Prosocial behavior especially comes to the fore, with the initial search and rescue being undertaken quickly and mostly by survivors in the immediate area. Most sudden needs, such as emergency housing, are met by kin and friends rather than official relief agencies. Family and household relationships are very important in affecting immediate reactions to disasters such as whether evacuation will occur or if warnings will be taken seriously, because mass media reports are filtered through primary ties.

Organizations. As a whole, organizations do not react as well to disasters as do individuals and households. But while there are many organizational problems in coping with the emergency time demands of a disaster, these difficulties are often not the expected ones. Often it is assumed that if there has been organizational disaster planning, there will be successful crisis or emergency management. But apart from the possibility of planning being poor in the first place, planning is not management and the former does not always translate well into the latter in community disasters. There typically are problems in intra- and interorganizational information flow, and in communication between and to organizations and the general public. Groups initially often have to struggle with major gaps in knowledge about the impacts of a disaster. There can be organizational problems in the exercise of authority and decision making. These can stem from losses of higher-echelon personnel because of overwork, conflict regarding authority over new disaster tasks, and clashes over organizational jurisdictional differences. Generally, there is much decentralization of organizational response which in most cases is highly functional. Organizations operating with a command and control model of response do not do well at emergency times. There often too are

problems associated with strained organizational relationships created by new disaster tasks and by the magnitude of a disaster impact.

Communities. Since disasters almost always cut across formal governmental boundaries, problems of coordination among different impacted political entities are all but inevitable. The greater the impact of a disaster, the more there will be the emergence of new and adaptive community structures and functions, especially emergent groups (that is, those without any preimpact existence). The greater the disaster also, the more organized improvisations of all kinds appear accompanied by pluralistic decision making. In addition, the mass convergence of outside but nonimpacted personnel and resources on impacted communities, while functional in some ways, creates major coordination problems.

Societies. Few societies ignore major disasters, but this sometimes occurs especially in the case of slow and diffuse occasions such as droughts and famines, especially if they primarily affect subgroups not in the mainstream of a developing country. In responding to domestic disasters, typically massive help is provided to impacted areas. Increasingly, most societies, including governmental officials at all levels, obtain their view of what is happening in their disasters from mass media accounts (what has been called the “CNN syndrome”); this also affects what is often remembered about the occasions. There is also a spreading belief, so far unsupported by research, that new technologies—especially computer-related ones—will allow major improvements in disaster planning and management.

Postimpact Behavior. *Individuals and households.* Overall, there is little personal learning as a result of undergoing a single disaster. While the experience of a major disaster is a memorable one from a social-psychological point of view, there are seldom lasting and widespread negative behavioral consequences. Disasters very seldom produce new psychoses or severe mental illnesses. They often, but not always, generate subclinical, short-lived and self-remitting surface reactions, such as loss of appetite, sleeplessness, and anxiety. More common are many problems in living that stem more from inefficient and ineffective relief and recovery efforts of helping organizations rather

than from the direct physical impacts of disasters. However, not all postimpact effects are negative; sometimes, the experience of undergoing a disaster results in positive self-images and closer social ties among victims.

Organizations. Organizational changes, whether for planning for disasters or for other purposes in the postimpact period, is not common and selective at best. Most modifications are simply accelerations of noncrisis-related changes already planned or underway. Postimpact discussion of how to improve disaster planning seldom gets translated into concrete actions (unlike civil disturbances which in American society in the 1960s led to many changes in organizations). However, overall, both in the United States and elsewhere, there have been in recent decades the growth of small, locally based, formal social groups primarily concerned with emergency time disaster planning and management. Partly because of seemingly constantly escalating economic losses, certain businesses in such sectors as banking and insurance have increasingly become interested in disaster preparedness and recovery.

Communities. There are selective longer-run outcomes and changes in communities that have been impacted by disasters. There can be acceleration of some ongoing and functional community trends (e.g., in local governmental arrangements and power structures), and generation of some limited new patterns (e.g., in providing local mental-health services or some mitigation measures such as floodproofing regulations). On the other hand, particularly as the result of rehousing and rebuilding, there can be magnifications of preimpact community conflicts as well as the generation of new ones; some of the latter is manifested in blame assignation, which, however, tends to deflect attention away from social structural flaws to mass-media-influenced search for individual scapegoats. It is also being recognized after disasters that changes in technology that create diffuse networks and systems, such as among lifeline organizations, are increasingly creating the need for regional rather than just community-based disaster planning.

Societies. In developed societies, there are few long-run negative consequences of disaster losses whether of people or property, since such effects are absorbed by the larger system. In developing

societies and very small countries, this is not necessarily true; a catastrophic disaster may reduce the gross national product five to ten percent as well as producing tens of thousands of casualties. Nevertheless, changes or improvement in national disaster planning often does not occur except in certain cases such as after the Mexico City earthquake where an unusual set of circumstances existed, including a "political will" to do something. But increasingly, in the aftermath of major disasters, to the extent that planning is instituted or improved, it is being linked to developmental planning, a move strongly supported by international agencies such as the World Bank.

UNIVERSALITY OF GENERALIZATIONS FROM AN UNEVEN RESEARCH BASE

Cross-societal and comparative research increased markedly in the 1990s. Studies have ranged from cooperative work on local mass-media reporting of community disasters in Japan and the United States (Mikami, Hiroi, Quarantelli, and Wenger 1992) and flood responses and crisis management in four Western European countries (Rosenthal and Hart 1998), to comparisons of perceptions of recurrent floods in Bangladesh by European engineers and local residents (Schmuck-Widmann 1996), and cross-national analyses of post-disaster political unrest in a dozen countries (Olson and Drury 1997), as well as methodological issues involved in cross-societal research in Italy, Mexico, Turkey, Peru, the United States, and Yugoslavia (Bates and Peacock 1993). However, this kind of comparative empirical research so far has been limited. Furthermore, although the bulk of disasters occur in developing countries, the majority of studies from which the generalizations advanced have been derived, have been done in developed societies. Thus, the question of the universality of disaster behaviors in different social systems has increasingly been raised. Some universals appear to have been found: Prosocial rather than antisocial behavior clearly predominates in responses everywhere; household members and significant others are crucial in validating warning messages, and the larger kin system is vital in providing emergency assistance; emergent groups always appear at the height of the crisis period; organizations have relatively more difficulty in adjusting to and coping with disasters than do individuals and

small groups; the disaster recovery period is fraught with problems at the household, organization, and community levels; mitigation measures are given little priority even in disaster-prone localities; and social change is seldom an outcome of most disasters.

Generalizations of a more limited nature also seem to exist. There are social-system-structure-specific behaviors. For example, there often is a major delay in the response to catastrophic disasters from centralized, compared to decentralized, governmental systems. There also may be culturally specific differences. For example, reflecting cultural values, individual volunteers in disasters very rarely appear in some societies such as Japan whereas they are typical in almost all American disasters.

THE FUTURE

There is a dialectical process at work: There will be more and worse disasters at the same time that there will be more and better planning. Why more and worse disasters? Risks and threats to human beings and their societies are increasing. Traditional natural-disaster agents, such as earthquakes and floods, will simply have more to impact as the result of normal population growth and higher, denser concentration of inhabitants in risk-prone localities, such as floodplains or hurricane-vulnerable shorelines that otherwise are attractive for human occupancy. There is an escalating increase in certain kinds of technological accidents and mishaps in the chemical, nuclear, and hazardous-waste areas that were almost unknown before World War II. There are technological advances that create risks and complexities to old threats such as when fires are prevented in high-rise buildings by constructing them with highly toxic materials, or when the removal of hazardous substances from solid sewage waste generates products that contain dangerous viruses and gases. New versions of old threats are also appearing, such as the increasing probability of urban rather than rural droughts, or the potential large-scale collapse of the infrastructure of older metropolitan area life-line systems. Finally, there is the continual development of newer kinds of risks ranging from the biological threats that are inherent in genetic engineering, to the crises that will be generated as the

world increasingly becomes dependent on computers that are bound to fail somewhere at some key point, with drastic consequences for social systems. In addition, the newer threats are frequently dangerous at places and times distant from their initial source or origin as dramatized by the Chernobyl nuclear radiation fallout in European countries and smog pollution episodes such as forest fires in Indonesia which had negative effects in many Southeast Asian countries.

On the other hand, there is increasing concern and attention being paid to disaster planning of all kind. The future augers well for more and better planning. Citizens almost everywhere are coming to expect that their governments will take steps to protect them against disasters; this is often actualized in planning for emergency preparedness and response. Whereas two decades ago a number of societies had no preimpact disaster planning of any kind, this is no longer the case. A symbolic manifestation of this trend was the proclamation by the United Nations of the 1990s as The Decade for Natural-Disaster Reduction. This international attention accelerated efforts to prevent, prepare for, respond to, and recover from disasters. The effect was especially notable in the increased disaster planning in developed countries.

In developed societies, a focus on disaster planning and crisis management had started earlier, partly as a result of sociological and related research. By the 1980s, social scientists were increasingly influencing policies, political agenda settings, and operational matters regarding disasters. This can be seen in a variety of ways. Social scientists were represented on almost all national committees set up for the U. N. Decade, and contributed significantly to the reports prepared to mark the midpoint of the decade. The Board on Natural Disasters, established in 1992 in the U.S. National Academy of Sciences, always has had members from sociology and related disciplines. Sociologists have had major roles in national-disaster legislation in Greece and Italy. American social science disaster researchers typically testify before state and congressional committees considering disaster-related laws and policies. Many sociological disaster researchers provide both paid and unpaid consultant services to international, national, and local public and private groups involved in disaster-related activities. In places such

as the United States, Australia, New Zealand, and some European countries, the emergency-management and disaster-planning community has become more open to recognizing the practical implications of social science research.

However, a caveat is in order for the generally correct view that studies by sociologists and others have increasingly influenced policy decisions and operational activities in the disaster area. Research results and questions are sometimes more than counterbalanced by other factors: These include the vested interests of powerful professional and bureaucratic elites to maintain traditional stances, resistance to seriously questioning the viabilities and competencies of specific organizations, and an unwillingness to face up to false assumptions of some cultural beliefs and values. Research to the contrary, for example, has had little effect on the fad-like spread of the "Incident Command System" as a model for the emergency time operations of organizations, or an ever-spreading acceptance that victims are likely to suffer posttraumatic stress disorders, or the current common belief that mitigation measures are necessarily a better strategy for disaster planning than giving priority to improving resilience and response to crises.

RELATIONSHIP TO SOCIOLOGY

Although not true everywhere, sociologists have been increasingly accepted as having an important contribution to make to disaster planning and management. In part this stems from the fact that in many countries such as Germany, Italy, Russia, and the United States, they have played the lead role among social scientists in undertaking disaster studies. While many reasons account for this, probably the crucial factor has been that much in general sociology can be used in doing research in the area.

There has been a close relationship between disaster studies and sociology from the earliest days of work in the area. In part this is because sociologists, being among the leading pioneers and researchers in the area, have tended to use what they could from their discipline. Thus, sociology has contributed to the research techniques used (e.g., field studies and open-ended interviewing), the research methodology utilized (e.g., the

"grounded theory" approach and the employment of inductive analytical models), the theoretical ideas used (e.g., the notion of emergence from collective-behavior thinking and the idea of informal and formal structures of organizations), and the general perspectives employed (e.g., that there can be latent as well as dysfunctional aspects of any behavior and that societies and communities have a social history that is not easily set aside). In the volume entitled *Sociology of Disasters: Contributions of Sociology to Disaster Research* (Dynes, De Marchi, and Pelanda 1987), these and other contributions to disaster theory, disaster research methods, disaster models, and disaster concepts are set forth in considerable detail.

The relationship has not been one-sided, since disaster research has also contributed to sociology. The field of collective behavior has been most influenced and this has been explicitly noted (Wenger 1987). Other significant contributions include the study of formal organizations, social roles, social problems, organizational and social change, mass communications, medical sociology, and the urban community (see Drabek 1986; Dynes, De Marchi, and Pelanda 1987; Dynes and Tierney 1994). A symposium on social structure and disaster, coattended by disaster researchers and prominent sociological theorists, examined how disaster studies not only are informed by but could also inform sociological theory; the proceedings were published in *Social Structure and Disaster* (Kreps 1989). It is also perhaps of interest that for several decades now, many introductory sociology textbooks have a section on disaster behavior, usually in the collective behavior chapter.

E. L. QUARANTELLI

DISCRIMINATION

Discrimination, in its sociological meaning, involves highly complex social processes. The term derives from the Latin *discriminatio*, which means to perceive distinctions among phenomena or to be selective in one's judgment. Cognitive psychology retains the first of these meanings, popular usage the second. Individual behavior that limits the opportunities of a particular group is encompassed in many sociological considerations of discrimination. But exclusively individualistic approaches are too narrow for robust sociological treatment. Instead, sociologists understand discrimination not as isolated individual acts, but as a complex system of social relations that produces intergroup inequities in social outcomes.

This definitional expansion transforms "discrimination" into a truly sociological concept. But in its breadth, the sociological definition leaves room for ambiguity and controversy. Obstacles to consensus on what constitutes discrimination stem from two sources—one empirical, the other ideological and political. First, deficiencies in analysis and evidence limit our ability to trace thoroughly the dynamic web of effects produced by discrimination. Second, because social discrimination is contrary to professed national values and law, a judgment that unequal outcomes reflect discrimination is a call for costly remedies. Variable willingness to bear those social costs contributes to dissension about the extent of discrimination.

The broadest sociological definitions of discrimination assume that racial minorities, women, and other historical target groups have no inherent characteristics that warrant inferior social outcomes. Thus, all inequality is seen as a legacy of discrimination and a social injustice to be remedied. By contrast, political conservatives favor a far narrower definition that limits the concept's scope by including only actions *intended* to restrict a group's chances. For solid conceptual reasons, sociologists seldom follow suit (but see Burkey 1978, p. 79). First, an intentionality criterion returns the concept to the realm of psychology and deflects attention from restraining social structure. Second, the invisibility of intentions creates insuperable obstacles to documenting discrimination.

DIRECT AND INDIRECT DISCRIMINATION

Sociologists' understanding of intricate societal patterns sensitizes them to the fact that disadvantage accruing from intentional discrimination typically cumulates, extends far beyond the original injury, and long outlives the deliberate perpetration. Many sociologists distinguish between *direct* and *indirect* discrimination (Pettigrew 1985). Direct discrimination occurs at points where inequality is generated, often intentionally. When decisions are based explicitly on race, discrimination is direct. Indirect discrimination is the perpetuation or magnification of the original injury. It occurs when the inequitable results of direct discrimination are used as a basis for later decisions ("past-in-present discrimination"), or decisions in linked institutions ("side-effect discrimination") (Feagin and Feagin 1986). Hence, discrimination is indirect when an ostensibly nonracial criterion serves as a *proxy* for race in determining social outcomes.

To illustrate with wages, direct discrimination exists when equally qualified blacks and whites or men and women are paid at different rates for the same work. Indirect discrimination exists when the two groups are paid unequally because *prior* discrimination in employment, education, or housing created apparent differences in qualifications or channeled the groups into better- and worse-paying jobs. This direct/indirect distinction resembles the legal distinction between disparate treatment and disparate impact. While intentional direct discrimination may have triggered the

causal chain, the original injury is often perpetuated and magnified by unwitting accomplices. Intentionality criteria deny that the continuing disadvantage is a legacy of discrimination.

Years ago, Williams outlined the concept differently: "Discrimination may be said to exist to the degree that individuals of a given group who are otherwise *formally qualified* are not treated in conformity with these nominally *universal institutionalized codes*." (Williams 1947, p. 39, italics added). For Antonovsky (1960, p. 81), discrimination involves "... injurious treatment of persons on grounds *rationally irrelevant* to the situation" (italics added). Economists use starker terms. Becker (1968, p. 81) held that economic discrimination occurs "... against members of a group whenever their earnings fall short of the amount '*warranted*' by their *abilities*'" (italics added).

Two problems arise with these definitions. First, the assessment of "abilities" and of what treatment is "rationally" relevant or "warranted" is no easy task. Critical examination of common practice uncovers many instances where formal qualifications and "nominally universal institutionalized codes" prove *not* to provide a logical basis for distinctions. Employment testing litigation demonstrates that when hiring criteria once legitimized by tradition or "logic" are put to scientific test, they often fail to predict job performance in the assumed fashion. Analogous fallacies have been identified in the conventional wisdom guiding admission to advanced education. Hence, nominally universalistic standards may provide an altogether illogical basis for decision making. If such misguided selection procedures also work to the disadvantage of historical victims of discrimination, these practices are not exempted from the charge of discrimination by their universalistic facade.

The second problem with these definitions is that they ignore another, prevalent form of indirect discrimination. Even where nominally universalistic standards do serve some legitimate social function, such as selecting competent workers, adverse impact of these standards on those who bear the cumulated disadvantage of historical discrimination cannot be disregarded.

The complexity of discrimination and unresolved issues about its definition impede easy application of social science methods to inform institutional policy. Apparently rigorous quantitative

analyses often only camouflage the crucial issues, as critical examination of wage differential decompositions reveals.

THE DECOMPOSITION APPROACH

Assessments of discrimination produced by decomposing gross race or gender differences in wages or other social outcomes are common in sociology (e.g., Corcoran and Duncan 1978; Farley 1984, Rosenfeld and Kalleberg 1990) as well as in economics (e.g., Gill 1989). One segment of the gross intergroup differential is defined by its empirical linkage to “qualifications” and other factors deemed legitimate determinants of social rewards. The second, residual segment not demonstrably linked to “legitimate” determinants of the outcomes often is presented as the estimate of discrimination. However, in the absence of better information than usually available and greater agreement on what constitutes discrimination, no *unique* estimate is possible. Through their choice of control variables to index “legitimate” determinants of social outcomes and their interpretation of findings, researchers wittingly or unwittingly shape their answers. Any appearance of scientific certitude is an illusion. For example, estimated proportions of the gender earnings gap caused by discrimination in the United States range from Sanborn’s (1969) 10 percent or less to Blinder’s (1973) 100 percent. Predictably, each has been challenged (Bergman and Adelman 1973; Rosensweig and Morgan 1976).

An Illustrative Decomposition Study. An analysis of gender differentials in faculty salaries at a large university illustrates the difficulty of separating “legitimate” wage differentials from inequity (Taylor 1988). About 90 percent of a \$10,000 gender difference in faculty salaries was empirically linked to three factors widely considered legitimate determinants of faculty pay: academic rank, age, and discipline. Women tend to hold lower academic rank, to be younger, and more often to be affiliated with poorly-paid disciplines than men. Insofar as women’s lower salaries are linked to rank, age, and discipline, is the salary differential untainted by gender discrimination? Conventional wage differentials imply an unequivocal yes. If a simple answer is given, it should be no. But in truth, when policy makers ask for dollar estimates

of inequity that the institution is obliged to remedy, the answers are neither unequivocal nor simple.

If the university’s promotion system has operated fairly, a gender gap reflecting differences in rank may be warranted. If gender bias has existed in the university’s promotion system, depressing the average academic rank of women faculty, the resulting deficit in women’s salaries reflects indirect discrimination. Attention should then be directed to the offending promotion processes. However, direct salary adjustments may also be in order, because gender bias in promotions weakens the link between rank and merit. Inequitable depression of women’s ranks would not necessarily lessen their actual contributions to the faculty, just their status. Using rank as a universalistic determinate of salary would then undermine the goal this practice is claimed to promote—the matching of rewards to contributions.

Salary differences tied to the age differential of female and male faculty also raise troublesome questions. If the relative youth of women faculty reflects lower retention and higher turnover as a result of discriminatory review processes or generally inhospitable conditions, salary differentials tied to age differences are again examples of indirect discrimination. The evidence would signal a need for institutional efforts to improve the retention of women faculty. But here it is not clear that salary adjustments are warranted. Because faculty contributions may be a function of experience, application of the universalistic age criterion is arguably reasonable. Any gender gap in salary tied to age differentials could, then, be both a legacy of discrimination and a reasonable conditioning of rewards on contributions. Complicating the issue further is the fact that affirmative action efforts often meet with greatest success in recruiting junior candidates. Thus, without supplementary data, it is not even clear whether an age-linked gender gap in salary reflects continuing institutional discrimination or affirmative hiring.

Gender differences in salary associated with discipline present even more complicated interpretational problems. Women and men are distributed across academic disciplines in a fashion that mirrors the gender distribution across occupations. Disciplinary differences in average salary likewise mirror wage differentials across occupations. But are the differing occupational

distributions simply a matter of gender differences in preferences or abilities with no implication of discrimination? Or are women steered away from lucrative fields, so that gender differentials in salary linked to disciplinary affiliation represent indirect discrimination in training, recruitment, and hiring? Or does the pattern of occupational wage differentials mirrored in disciplinary differences represent direct discrimination, an influence of gender composition per se on occupational wage structures (England et al. 1988)? In the latter case, assignment of responsibility for remedy presents particular problems. The university, like any other single employer, is simultaneously vulnerable to competitive forces of the wider labor market and a constituent element of that market. Defiance of the market by a single organization is costly to that organization; adherence by all organizations to the broader occupational wage structure perpetuates gender inequity and carries broader costs.

This faculty salary study did not examine the role of scientific “productivity.” But the inclusion of productivity measures among the control variables raises further difficulties. On standard “productivity” measures, women faculty average lower scores than men (Fox 1990). Thus, an institutional study of salary differentials might find some segment of the male/female salary gap linked to productivity differences. Fox’s research demonstrates, however, that gender differences in scientific productivity reflect contrasting levels of resources that institutions provide to male and female faculty. Like age and rank, the gender difference in productivity may itself be a product of institutional discrimination. Thus, salary differentials based on male/female productivity differences also may represent indirect discrimination. The new ingredient here is that institutional shaping of productivity is subtle. Scientific productivity is ordinarily seen as an outgrowth of talent and effort, not potentially gender-biased institutional resource allocation. Solid documentation of this indirect discrimination process offers another challenge for researchers.

COMPLEXITIES OF DISCRIMINATION AND REMEDY

Critical reflection on this decomposition study highlights a set of interrelated points about the

complex nature of discrimination and unresolved issues of remedy.

1. In American society today, the injuries of indirect discrimination are often far more extensive than those of direct discrimination. This conclusion does not imply that direct discrimination no longer exists (Reskin 1998). The continued operation of direct forms of discrimination is indicated by employment complaint records. American women and minorities have filed almost 1.5 million job discrimination complaints since 1965 (Blumrosen 1996, p. 4). In 1994 alone, over 150,000 such complaints were filed; 91,000 to local and state agencies and 64,000 to the U.S. Equal Employment Opportunity Commission (Leonard 1994, p. 24). Of course, not all complaints reflect genuine discrimination; on the other hand, not all discrimination prompts formal complaints. Many major corporations were found guilty of direct race or gender discrimination in the 1990s. And employment audits using paired, equally qualified applicants reveal widespread direct discrimination (Reskin 1998, pp. 25–29).
2. Apparently reasonable universalistic principles may on closer examination be unnecessary or even dysfunctional. Scrutiny of employment criteria prompted by the Supreme Court’s 1971 *Griggs v. Duke Power Co.* decision has provided useful models for challenging nominally universalistic standards. Where it is possible to substitute standards that do as well or better at screening or evaluation without adversely affecting historical targets of discrimination, there are gains for all involved.
3. When gaps in actual qualifications are a legacy of discrimination, more extensive remedies are needed. Where training deficits impair employability, or inadequate preparation impedes admission to higher education, attention should be given to the earlier schooling processes that generated these deficiencies. This form of remedy aids future generations. In the meantime, compensatory training can

reduce the liabilities of those who have already fallen victim to inferior schools.

4. Microcosms cannot escape the discriminatory impact of the societal macrocosm. Just as salary differences across academic disciplines reflect general occupational wage structures, institutions are often both prey to and participant in broader social forces. Narrow, legalistic approaches to remedy are inadequate for addressing this dynamic of discrimination.
5. Empirical research on group discrimination must mirror the phenomenon in its variety and complexity. The regression decomposition approach has proven useful but has its limitations (see also Dempster 1988, and the ensuing commentary). Regression analyses could provide more pertinent information if based on more homogeneous job groups (Conway and Roberts 1994) and on structural equation models that test reciprocal causation. Most important, if the aim is to guide policy, a framework far more complex than the dichotomous discrimination-or-not approach is required. The sociological arsenal of methods offers other promising approaches. Research that traces the actual processes of institutional discrimination is essential (e.g., Braddock and McPartland 1987, 1989). Also needed is attention to victims' perceptions of discrimination (e.g., Feagin and Sikes 1994) and investigation of the changes generated by anti-discrimination efforts. Another approach involves cross-national comparative research, which we consider below.

EFFECTIVE REMEDIAL INTERVENTIONS

Direct racial and gender discrimination in the United States has declined in recent decades—more slowly in the 1980s and 1990s than in the 1960s and 1970s. But what caused this decline? Many factors were involved, but governmental intervention was an important impetus. For example, blacks in South Carolina made dramatic economic gains in manufacturing during the late 1960s. Heckman and Payner (1989) demonstrated that human capital, supply shifts, and tight labor

markets could not explain the sudden improvements. It was federal anti-discrimination programs, they concluded, that made a decisive contribution to the gains.

More general assessments also show that anti-discrimination legislation did reduce direct job discrimination nationally (Burstein 1985). It did not, however, eliminate the problem. Nor did such laws effectively attack indirect discrimination. For this more difficult problem, affirmative action programs were needed and have had some success (Reskin 1998). The resistance to such programs, however, underscores the difficulty of establishing effective remedies for the more subtle forms of discrimination.

DISCRIMINATION IN WESTERN EUROPE

Beyond racial and gender discrimination in the United States, the same basic concerns and principles arise for other nations and targets. Discrimination against Western Europe's new immigrant minorities is pervasive (Castles 1984; MacEwen 1995; Pettigrew 1998). Both direct and indirect discrimination are involved, though the indirect forms are largely unrecognized in Europe.

Investigators have repeatedly uncovered direct discrimination in England (Amin et al. 1988; Daniel 1968; Gordon and Klug 1984; Smith 1976). Controlled tests reveal the full litany of discriminatory forms involving employment, public accommodations, housing, the courts, insurance, banks, even car rentals. Employment discrimination poses the most serious problem. In every European Union nation, minorities have far higher unemployment rates than the majority group. In 1990 in the Netherlands, Moroccans and Turks had unemployment rates above 40 percent compared with the native Dutch rate of 13 percent (Pettigrew and Meertens 1996). During the 1974–1977 recession, West German manufacturing reduced its labor force by 765,000—42 percent of whom were foreign workers (Castles 1984, p. 148).

As in the United States, there are many reasons for minority unemployment disparities. The “last-in, first-out” principle selectively affects the younger minority workers. Typically less skilled, they are more affected by job upgrading. Minorities also are more likely to be in older, declining

industries. But these patterns are not accidental. Planners put minorities into these industries for cheaper labor precisely because of their decline. In addition, these multiple factors offer insufficient explanations for the greater unemployment of minorities. Veenman and Roelandt (1990) found that education, age, sex, region, and employment level explained only a small portion of the differential unemployment rates in the Netherlands.

Indirect discrimination arises when the inability to obtain citizenship restricts the opportunities of non-European Union minorities. It limits their ability to get suitable housing, employment, and schooling. A visa is necessary in order to travel to other European Union countries. In short, the lives of Europe's non-citizens are severely circumscribed (Wilpert 1993). Castles (1984) contends that the guest-worker system that brought many of the immigrants to Europe was itself a state-controlled system of institutional discrimination. It established the newcomers as a stigmatized "out-group" suitable for low-status jobs but not citizenship. Widespread indirect discrimination was inevitable for these victims of direct discrimination.

Anti-discrimination remediation has been largely ineffective in Europe. Basic rights in Germany are guaranteed only to citizens. So, the disadvantages of non-citizenship include limited means to combat discrimination. There is extensive German legislation to combat anti-Semitism and Nazi ideology, but these laws have proved difficult to apply to non-citizens. The German constitution explicitly forbids discrimination on the basis of origin, race, language, beliefs, or religion—but not citizenship. Indeed, the Federal Constitutional Court has ruled that differential treatment based on citizenship is constitutional if there is a reasonable basis for it and if it is not wholly arbitrary. Hence, a German court upheld higher taxes for foreign bar owners than German bar owners. And restaurants can refuse service to Turks and others on the grounds that their entry might lead to intergroup disturbances (Layton-Henry and Wilpert 1994).

Few means of combatting discrimination are available in France either. Commentators often view discrimination as "natural," as something universally triggered when a "threshold of tolerance" (*seuil de tolerance*) is surpassed (MacMaster

1991). Without supporting evidence, this rationalization supports quotas and dispersal policies that limit minority access to suitable housing.

The Netherlands, United Kingdom, and Sweden have enacted anti-discrimination legislation that specifically applies to the new immigrant minorities. And the Dutch have instituted modest affirmative action programs for women and minorities (De Vries and Pettigrew 1994). Not coincidentally, these countries make citizenship easier to obtain than Germany. Yet this legislation has been largely ineffective for two interrelated reasons. First, European legal systems do not allow class action suits—a forceful North American weapon to combat discrimination. Second, European efforts rely heavily on individual complaints rather than systemic remediation. Britain's 1976 Act gave the Commission for Racial Equality the power to cast a broad net, but individual complaints remain the chief tool (MacEwen 1995).

It is a sociological truism that individual efforts are unlikely to alter such systemic phenomena as discrimination. Mayhew (1968) showed how individual suits and complaints are largely non-strategic. Minorities bring few charges against the worst discriminators, because they avoid applying for jobs with them in the first place. Complaints about job promotion are common, but they are made against employers who hire minorities. Thus, effective anti-discrimination laws must provide broad powers to an enforcement agency to initiate strategic, institutionwide actions that uproot the structural foundations of discrimination. Mayhew's American analysis proves to be just as accurate in Western Europe.

CONCLUSIONS

A comprehensive understanding of societal discrimination in both North America and Western Europe must encompass two propositions.

1. The long-lasting character of discrimination means that the effects typically outlive the initiators of discriminatory practices. Apart from its importance to the law, this feature of modern discrimination has critical implications for sociological theory. Discrimination is fundamentally normative; its structural web operates in large part independent of the dominant group's

present “tastes,” attitudes, or awareness. Hence, models based primarily on individual prejudice or “rationality,” whether psychological or economic, will uniformly understate and oversimplify the phenomenon.

2. Discrimination is typically cumulative and self-perpetuating. For example, an array of research on black Americans has demonstrated that neighborhood racial segregation leads to educational disadvantages, then to occupational disadvantage, and thus to income deficits (Pettigrew 1979, 1985). To be effective, structural remedies must reverse this “vicious circle” of discrimination. Affirmative action programs are one such remedy.

Seen in sociological perspective, then, discrimination is considerably more intricate and entrenched than commonly thought. The complexity of discrimination presents major challenges to social-scientific attempts to trace its impact. This complexity also precludes any one-to-one correspondence between perpetration and responsibility for remedy. Broad social programs will be necessary if the full legacy of direct and indirect discrimination is finally to be erased.

DIVISION OF LABOR

The division of labor is a multifaceted concept that applies to several levels of analysis: small groups, families, households, formal organizations, societies, and even the entire "world system" (Wallerstein 1979). Each level of analysis requires a slightly different focus; the division of labor may refer to the emergence of certain roles in groups, to the relative preponderance of industrial sectors (primary, secondary, tertiary) in an economy, to the distribution of societal roles by sex and age, or to variability among occupational groupings. Sociologists at the micro-level are concerned with "who does what," while macrosociologists focus on the larger structural issues of societal functions.

All of the major sociological theorists considered the division of labor to be a fundamental concept in understanding the development of modern society. The division of labor in society has been a focus of theoretical debate for more than a century, with some writers most concerned about hierarchical divisions, or the vertical dimension, and others emphasizing the heterogeneity or the horizontal dimension, of a social system. The analysis here is primarily theoretical, and so does not deal with debates about the technical problems of measurement (but see Baker 1981; Clemente 1972; Gibbs and Poston 1975; Land 1970; Rushing and Davies 1970).

THE DIVISION OF LABOR IN SMALL GROUPS

Most small groups exhibit "role differentiation," as first described by Simmel (1890), Whyte (1943), and Bales and Slater (1955). The research on informal work groups stresses a hierarchical form of the division of labor, or the emergence of leadership; in particular, the emergence of both a "task leader" and a "social leader." It appears that defining group goals and enforcing norms is a type of activity incompatible with maintaining group cohesion, and therefore most groups have a shared leadership structure. Even in same-sex groups, this structure of coleadership is apparent; also, the degree of role differentiation appears to be greater in larger groups. The functional need for a social leader depends in part on the degree to which group members are task oriented, and on the degree to which the task leader is perceived as a legitimate authority (with the power to reward and punish other group members). Burke (1969) has also noted that a "scapegoat" role may emerge within task groups, reducing the need for a social leader to maintain harmony among the rest of the group members.

HOUSEHOLD AND FAMILY DIVISION OF LABOR

When the family or household is the unit of analysis, issues concerning the division of tasks between spouses are of primary interest to sociologists. One major finding has been the persistence of disproportionately high levels of traditional housework by the wife, even when she is employed

outside the home. This reflects the "provider" vs. "homemaker" role distinction that formerly characterized most nuclear families in industrialized societies. Another major family role, occupied almost exclusively by the wife, is that of "kinkeeper." The maintenance of family traditions, the recording of important family anniversaries, and the coordination of visits between households are all vital elements of this role. The classic works by Bott (1957) and Blood and Wolfe (1960) documented the spousal division of labor as it was influenced by wider social networks and the relative power of the husband and wife. Kamo (1988) has noted that cultural ideology is a strong factor in the determination of spousal roles, although it is not entirely independent of the resources available to husband and wife.

Within a household, both age and sex structure the division of labor. Young children have few responsibilities, while parents have many, and males and females tend to do very different tasks. For example, White and Brinkerhoff (1981) studied the reported allocation of a variety of household tasks among a sample of Nebraska households, and found that the youngest cohort of children (aged two to five) performed relatively few household tasks and showed little differentiation by sex. Older children, however, diverged considerably in their roles (males doing more outdoor work, females more responsible for cooking or childcare). At the other end of the lifespan, the roles of the grandparent generation were strongly influenced by geographical proximity, the ages of the grandparents, and the ages of the children. Divorce among the parental generation can also substantially impact the roles adopted by grandparents (see Bengston and Robertson 1985).

FORMAL ORGANIZATIONS AND OCCUPATIONAL SPECIALIZATION

Formal organizations are always structured by an explicit division of labor (an organization chart contains the names of functions, positions, or subunits). The horizontal differentiation in an organization, or task specialization, is normally based on functional units that are of roughly equivalent levels in the hierarchy of authority. The division of labor may also be constructed on a geographical basis, with the extreme examples being

transnational corporations that draw raw resources and labor from the developing nations, and management from the developed nations.

Labor is also organized hierarchically, into levels of authority. Max Weber was one of the first sociologists to analyze the emergence of modern bureaucracies, where the division of labor is fundamental. Weber's approach suggests a maximum possible level of specialization, so that each position can be filled by individuals who are experts in a narrow area of activity. An extreme form of the bureaucratic division of labor was advocated by Frederick Taylor's theory of "Scientific Management" (1911). By studying in minute detail the physical motions required to most efficiently operate any given piece of machinery, Taylor pioneered "time and motion studies." Along with Henry Ford, he also made the assembly line a standard industrial mode of production in modern society. However, this form of the division of labor can lead to isolation and alienation among workers, and so more recent organizational strategies, in some industrial sectors, emphasize the "craft" approach, in which a team of workers participate more or less equally in many aspects of the production process (see Blauner 1964; Hedley 1992).

SOCIETAL DIVISION OF LABOR

Macrosociologists measure the societal division of labor in a number of ways, most commonly by considering the number of different occupational categories that appear in census statistics or other official documents (see Moore 1968). These lists are often implicitly or explicitly ranked, and so both horizontal and vertical division of labor can be analyzed. This occupational heterogeneity is dependent in part on the official definitions, but researchers on occupational prestige (the vertical dimension) have shown comparable levels in industrialized societies such as the United States, Canada, England, Japan, Sweden, Germany, and France (see Treiman 1977). The "world system" as described by Wallerstein (1979) is the upper limit of the analysis of the division of labor. Entire societies are characterized as "core" or "periphery" in Wallerstein's analysis of the global implications of postindustrialism.

THEORETICAL APPROACHES

Adam Smith, in *The Wealth of Nations* (1776), produced the classic statement of the economic efficiencies of a complex division of labor. He observed that the manufacture of steel pins could be more than two hundred times more productive if each separate operation (and there were more than a dozen) were performed by a separate worker. The emergence of the systematic and intentional division of labor probably goes back to prehistoric societies, and is certainly in evidence in the ancient civilizations of China, Egypt, Greece, and Rome. The accumulation of an agricultural surplus and the establishment of markets both created and stimulated the differentiation of producers and consumers. Another phase in the transformation in Europe was the decline of the "craft guilds" that dominated from the twelfth to the sixteenth centuries. When labor became free from the constraints of the journeyman/apprentice system and when factories began to attract large numbers of laborers, the mechanization of modern work flourished. (For economic and political perspectives on the division of labor see Krause 1982; Putterman 1990).

Early sociologists such as Herbert Spencer considered the growth of societies as the primary determinant of the increased specialization and routinization of work; they also emphasized the positive impacts of this process. Spencer, like other functionalists, viewed human society as an organic system that became increasingly differentiated as it grew in size, much as a fertilized egg develops complex structures as it develops into a full-fledged embryo. In his *Principles of Sociology* (1884), Spencer considered the evolution of human society as a process of increasing differentiation of structure and function.

Karl Marx (1867) argued that the increasing division of labor in capitalist societies is a primary cause of alienation and class conflict, and therefore is a force in the eventual transformation to a socialist/communist society. In fact, a specific question asking for details of the division of labor appeared on one of the earliest questionnaire surveys in sociology done by Marx in 1880. Marx and his followers called for a new form of the division of labor, supported by an equalitarian ethos, in which individuals would be free to choose

their productive roles; labor would not be alienating because of the common ideology and sense of community.

Weber (1947) painted a darker picture when he documented the increasing “rationalization” of society, especially the ascendance of the bureaucratic division of labor with its coordinated system of roles, each highly specialized, with duties specified in writing and incumbents hired on the basis of their documented competence at specific tasks. The ideal-type bureaucracy was in actuality subject to the negative consequences of excessive specialization, however. Weber pointed out that the “iron cage” placed stifling limits on human freedom within the organization, and that decisions by bureaucrats often became so rule bound and inflexible that the clients were ill served.

Georg Simmel’s “differentiation and the principle of saving energy” (1976 [1890]) is a little-known essay that similarly describes the inevitable problems that offset the efficiencies gained by the division of labor; he called these “friction, indirectness, and superfluous coordination.” He also echoed Marx and Engels when he described the effects of high levels of differentiation upon the individual:

... differentiation of the social group is evidently directly opposed to that of the individual. The former requires that the individual must be as specialized as possible, that some single task must absorb all his energies and that all his impulses, abilities and interests must be made compatible with this one task, because this specialization of the individual makes it both possible and necessary to the highest degree for him to be different from all other specialized individuals. Thus the economic setup of society forces the individual for life into the most monotonous work, the most extreme specialization, because in this way he will acquire the skill which makes possible the desired quality and cheapness of the product. (Simmel 1976, p. 130)

While the foregoing theorists contributed substantially to the understanding of the division of labor, Emile Durkheim’s *The Division of Labor in Society* (1893) stands as the classic sociological statement of the causes and consequences of the historical shift from “mechanical solidarity” to

“organic solidarity.” The former is found in smaller, less-advanced societies where families and villages are mostly self-sufficient, independent, and united by similarities. The latter is found in larger, urbanized societies where specialization creates interdependence among social units.

Following Spencer’s lead, Durkheim noted that the specialization of functions always accompanies the growth of a society; he also observed that increasing population density—the urbanization of society that accompanies modernization—greatly increases the opportunities for further increases in the division of labor.

It should be noted that the shift to a modern division of labor could not have occurred without a preexisting solidarity; in his chapter on “organic and contractual solidarity” he departed from Spencer’s utilitarian explanation of social cohesion, and noted that the advanced division of labor can occur only among members of an existing society, where individuals and groups are united by preexisting similarities (of language, religion, etc.).

A sense of trust, obligation, and interdependence is essential for any large group in which there are many diverse roles; indirect exchanges occur; and individuals form smaller subgroupings based on occupational specialization. All of these changes create high levels of interdependence, but with increasing specialization, and different world views develop, along with different interests, values, and belief systems. This is the problem Durkheim saw in the shift from mechanical to organic solidarity; he feared the “anomie” or lack of cohesion that might result from a multiplicity of views, languages, and religions within a society (as in the France of his times, and even more so today). The problems of inequality in modern industrial society were not lost on Durkheim, either; he noted how the “pathological form of the division of labor” posed a threat to the full development of social solidarity (see Giddens 1971). Although many simplistic analyses of Durkheim’s approach suggest otherwise, he dealt at length with the problems of “the class war” and the need for justice and fraternity.

The division of labor is treated as a key element in Peter Blau’s book, *Inequality and Heterogeneity* (1977). This important work emphasizes the primacy of differentiation (division of labor) as an

influence on mobility, prejudice, conflict, affiliation, intermarriage, and inequality. In Blau's scheme, a society may be undifferentiated (all persons or positions are independent, self-sufficient, etc.) or strongly differentiated (a high degree of specialization and interdependence). This differentiation may be a matter of degree, on dimensions such as authority, power, prestige, etc.; this constitutes inequality. Or the differentiation may be a matter of kind, such as occupational differentiation—the division of labor.

Blau, like Durkheim, distinguished two major types of division of labor: *routinization* and *expert specialization*.

The two major forms of division of labor are the subdivision of work into repetitive routines and its subdivision into expert specialties. . . when jobs are divided into repetitive routines, the training and skills needed to perform them are reduced, whereas when they are divided into fields of specialists, the narrower range of tasks permits greater expertness to be acquired and applied to the work, increasing the training and skills required to perform it.
(Blau 1977, p. 188)

Blau has shown that the division of labor always increases inequality in the organization. The managerial and technical experts coordinate the increasing number and diversity of routinized positions. As organizations and societies increase in size and population density, the division of labor increases. At the same time, the forces of industrialization and urbanization require and encourage further specialization, and in most cases, increase inequality, and indirectly, social integration. Some of the confounding boundaries include the degree of linguistic, ethnic, or cultural heterogeneity (all of which can inhibit integration), and social or geographic mobility (which can increase integration).

In a rare display of explicitly stated definitions and propositions, Blau created a landmark theory of social organization. Here are the most important of Blau's assumptions and theorems relating to the division of labor:

- The division of labor depends on opportunities for communication.
- Population density and urbanization increase the division of labor.

- Rising levels of education and qualifications promote an advanced division of labor.
- Large work organizations promote the division of labor in society.
- Linguistic heterogeneity impedes the division of labor.
- The more the division of labor is in the form of specialization rather than routinization, the higher are rates of associations among different occupations, which produces higher integration.
- The more the division of labor intersects with other nominal parameters (including kinship, language, religion, ethnicity, etc.) the greater is the probability that intergroup relations strengthen society's integration.
- The smaller an organization, the more its internal division of labor increases the probabilities of intergroup and interstratum associations, and therefore the higher the degree of integration.
(Summarized from Blau 1977, pp. 214–215)

Blau concludes by noting that “Advances in the division of labor tend to be accompanied by decreases in various forms of inequality but by increases in inequality in power. Although the advancing division of labor does not generate the growing concentration of power, the two are likely to occur together, because the expansion of work organizations promotes both.” (p. 214).

CONCLUSION

Ford's moving assembly lines began to produce the frames for Model T automobiles in 1913, at a rate of about one every two working days, but within months, refinements on the assembly process reduced this to four units per day. This eightfold increase in efficiency was accompanied by a decrease in the price of the cars and indirectly stimulated a very large industry. Now, automated factories, using robotics and highly specialized computer systems, have dramatically increased the efficiency of the automobile industry. The effects on morale and the environment, however, appear to be less salutary.

PAUL MORGAN BAKER

DIVORCE

Divorce is of sociological significance for several reasons. To begin, divorce rates are often seen as indicators of the health of the institution of marriage. When divorce rates rise or fall, many sociologists view these changes as indicating something about the overall quality of marriages or, alternatively, the stability of social arrangements more generally. Viewed from another perspective, divorce interests sociologists as one of several important transitions in the life course of individuals. The adults and children who experience divorce have been studied to understand both the causes and consequences. From this perspective, a divorce is as much an event in the biography of

family members, as other life-course transitions (remarriage, childbirth, and retirement). The sociological interest in divorce also focuses on the social trends it is part of, figuring prominently in any sociological analysis of industrialization, poverty rates, educational attainment, strategies of conflict resolution, or law.

For sociologists, divorce may characterize an individual, a family, a region, a subgroup, a historical period, or an entire society. It may be studied as either the cause or consequence of other phenomena. Still, the overriding concern of almost all research on this topic has been the increase in divorce over time. Divorce is now almost as common as its absence in the lives of recently married couples. The National Center for Health Statistics estimates that 43 percent of marriages begun in the early 1990s will end in divorce (NCHS 1998), a significant decline from the estimates of 50 percent to 65 percent in the late 1980s (Martin and Bumpass 1989). The decline in divorce rates in the recent past is probably a result of the aging of the post-World War II Baby Boom generation who are no longer at high risk of divorce because of their age. It is also possible that American marriages are becoming somewhat more stable than they were a decade ago. Still, the fluctuations in divorce rates one decade to the next do not mask the more general trend for the past two centuries. Understanding the increase in divorce has been the larger sociological endeavor regardless of the particular perspective employed. A historical account of trends is necessary before considering contemporary issues associated with divorce.

A BRIEF HISTORICAL RECORD OF DIVORCE IN AMERICA

The Colonial Period. Divorce was not legal in any but the New England settlements. The Church of England allowed for legal separations (*a mensa et thoro*), but not for divorce. The New England Puritans who first landed at Plymouth in 1621, however, were disenchanted with this, as well as many other Anglican doctrines. Divorce was permitted on the grounds of adultery or seven-year desertion as early as 1639 in Plymouth. Other New England colonies followed similar guidelines. Divorce governed by rudimentary codified law was granted by legislative decree. Individual petitions for divorce were debated in colonial legislatures

and were effected by bills to dissolve a particular marriage. Still, though legal, divorce was very rare. During the seventeenth century, there were fifty-four petitions for divorce in Massachusetts, of which forty-four were successful (Phillips 1988, p. 138). The middle colonies provided annulments or divorces for serious matrimonial offenses such as prolonged absence or bigamy. The southern colonies afforded no provisions for divorce whatsoever.

Post-Revolutionary War. Immediately after the Revolutionary War, without British legal impediments to divorce, the states began discussion of laws to govern divorce. In New England and the middle states, divorce became the province of state courts while in the more restrictive southern states it was more often a legislative matter. By the turn of the nineteenth century, almost all states had enacted some form of divorce law. And by the middle of the century, even southern states were operating within a judicial divorce system.

The shift to judicial divorce is significant. By removing divorce deliberations from legislatures, states were forced to establish grounds that justified a divorce. Such clauses reflected the prevailing sentiments governing normative marriage—they indicated what was expected of marriage at the time. And by investing judges with the authority to interpret and adjudicate, such changes significantly liberalized the availability of divorce. Northern and southern states permitted divorces for specific offenses such as adultery, desertion, bigamy, and increasingly with time, cruelty. In the newer frontier western states, grounds resembled those of the East plus “any other cause for which the court shall deem it proper that the divorce shall be granted” (Phillips 1988, p. 453).

Throughout the nineteenth century, there was a gradual liberalization of divorce laws in the United States and a corresponding increase in divorce as well. Where divorces totaled a few hundred at the beginning of the nineteenth century, the numbers grew exponentially as the century wore on; 7,380 divorces in 1860, 10,962 in 1870, 19,663 in 1880, 33,461 in 1890, and 55,751 in 1900 (U.S. Bureau of the Census 1975). These figures assume greater significance when growth in population is removed from them. Whereas the divorce rate (number of divorces per 1,000 marriages) was but 1.2 in 1869, it had climbed to 4.0 by 1900. In short, the increase

in divorce outstripped the increase in population several times.

A number of factors have been identified as causes of such dramatic increases. In part, these can be described as social changes, which made marriage less essential. The growth of wage labor in the nineteenth century afforded women an alternative to economic dependence on a husband. In an economy dominated by individuals rather than families, marriage was simply less essential. Life as a single individual gradually lost its legal or social stigma (New England settlements had forbidden solitary dwelling while southern communities had taxed it heavily).

More important, however, were fundamental shifts in the meaning of marriage. Divorce codes reflected the growing belief that marriages should be imbued with heavy doses of affection and equality. Divorce grounds of cruelty or lack of support indicate that marriage was increasingly viewed as a partnership. Where a century earlier men had been granted greater discretion in their personal lives, latter nineteenth-century morality attacked such double standards. Men were not necessarily less culpable than women for their vices. Victorian morality stressed the highest standards of sexual behavior for both husbands and wives. Changing divorce codes coincided with the passage of laws restricting husbands' unilateral control over their wives' property. The passage of married women's property acts throughout the nation in the latter nineteenth century acknowledged married women's claims to property brought to or acquired in marriage. By 1887, thirty-three states and the District of Columbia gave married women control over their property and earnings (Degler 1980, p. 332).

Divorce codes including omnibus grounds such as "cruelty" (which could justify a divorce from a drunkard husband, for example) may be viewed as reflecting a Victorian American belief that women were morally sensitive and fragile, and in need of protection (Phillips 1988, p. 500). More particularly, the growing use of offenses against the intimate and emotional aspects of marriage reflected a growing belief that such things constituted matrimonial essentials. If a failure of intimacy could justify the dissolution of a marriage, then intimacy may be viewed as a core expectation of marriage.

The Twentieth Century. The first half of the twentieth century was a continuation of trends

established in the latter nineteenth century. Two world wars and the Great Depression interrupted gradually increasing divorce rates, however. During each war and during the Depression, divorce rates dropped. After each, rates soared before falling to levels somewhat higher than that which preceded these events. Sociological explanations for these trends focus on women's employment opportunities. Women's labor force participation permits the termination of intolerable unions. The separations, hastily timed marriages, and sexual misalliances characteristic of wartime were also undoubtedly factors in the post-war divorces rates. Further, the increases in divorce following these difficult times may be seen, in part, as a delayed reaction. Once the Depression or war was over, the reservoir of impending divorces broke. And finally, postwar optimism and affluence may have contributed to an unwillingness to sustain an unhappy marriage.

The second half of the century witnessed even more dramatic increases in divorce. With the exception of the peculiar 1950s (for an explanation of this anomaly, see Cherlin 1992), the trend for the second half of the 1900s was a regular and exponential growth in divorce until around 1980, at which point the increase stopped.

Though specific explanations for the increase in divorces during the twentieth century vary, several themes may be noted. First, marriage has lost much of its central economic and social significance—especially for women. For example, divorce was undoubtedly inhibited by the fact that prior to the twentieth century, custody of children was uniformly awarded to fathers (since they were legally responsible for financial support). With the acceptance of Freudian ideas of psychosexual development and similar ideas about intellectual and cognitive growth, the so-called Tender Years Doctrine became accepted practice in courts during the early 1900s which then awarded custody to mothers as regularly as they had once done to fathers. And as it became more commonplace, remarriage began to lose some of its stigma. All these changes made it possible for women to divorce their husbands if they wished. But why did so many wish to obtain divorces?

The simplest explanation is that more divorce is a consequence of higher expectations of marriage. More and more grounds for divorce are

developed as there are higher and higher expectations for what a marriage should be. In the nineteenth century, drunkenness, cruelty, and failure to provide were added to more traditional grounds of adultery and desertion. In the early twentieth century, cruelty was continually redefined to include not only physical, but mental cruelty as well.

The post-war surges in divorce created sufficient numbers of divorced persons so that the practice lost much of its stigma. The increase in divorce becomes more understandable when the loss of stigma is considered alongside the increase in women's employment since the mid 1960s. When women are employed, there is less constraint on them to remain in a marriage. But there is also less constraint on their husbands who will not be required to support their employed ex-wives after a divorce.

Since 1970, divorce has been fundamentally redefined. No-fault divorce laws passed since the early 1970s have defined as unacceptable those marriages in which couples are "incompatible," have "irreconcilable differences" or in which the marriage is "irretrievably broken." Prior to the no-fault regime, divorces required proof of a fault (crime) on the part of one spouse. The court decided whether to grant the divorce. Divorce proceedings were intentionally adversarial. Today, the non-adversarial grounds for divorce are almost entirely based on the failures of emotional essentials. Emotional marital breakdown may have been a feature of large numbers of marriages in earlier historical periods. Only now, however, is such a situation viewed as solely sufficient grounds for terminating the marriage.

DIVORCE IN THE WEST

Any theory of divorce must be able to account for the broad similarities in historical (twentieth century) trends throughout the entire Western world. These similarities exist despite notable differences in national economies, forms of government, and the role of the church. The trends are well known. There was very little divorce until the end of the nineteenth century, a slow but constant growth in divorce rates through the first half of the twentieth century (interrupted by two world wars and an international economic depression), and significant increases in divorce rates since the 1960s. The

twentieth century, in short, is when most significant changes in divorce rates occurred. And the changes noted in America were seen in most other Western nations.

Between World Wars I and II, there were widespread changes in divorce laws that reflected changing beliefs about matrimony and its essentials. The strains of war and the associated problems that produced more divorces made the practice more conspicuous and consequently more acceptable. There is no doubt one cause of divorce is divorce. When obscure, the practice was stigmatized and there was little to counter stereotypes associated with its practice. When divorce became more commonplace, it lost some of its stigma.

Social changes pertaining to women's roles are a large part of the story of divorce during the postwar era. One sign of these changes was the growth, throughout the West, of women's labor force participation. But the most conspicuous symbol of the changing role of women was the passage of suffrage legislation throughout the Western world. Before 1914, women were permitted to vote only in New Zealand, Australia, Finland, Norway, and eleven western U.S. states. In the United States, women were enfranchised in 1920. In Britain, Sweden, Germany, and many other European countries, suffrage passed soon after World War I.

Divorce laws, similarly, were altered between the wars in accordance with changing views of marriage and the role of women. The British Parliament enacted divorce reform in 1937 by significantly extending the grounds for divorce (including cruelty) and granting women new options for filing for divorce. Scotland reformed its divorce laws in 1938 by extending grounds for divorce to include failures of emotional essentials—cruelty and habitual drunkenness, for example. In 1930, the Canadian Parliament for the first time empowered judicial magistrates to grant divorce rather than requiring legislative decrees. And the Spanish divorce law of 1932 was the most liberal in contemporary Europe—providing divorce by mutual consent (Phillips 1988, p. 539). Even Nazi Germany permitted no-fault divorce by 1938 (though divorce law was aimed at increasing the number of Aryan children born).

Following World War II, divorce rates throughout the Western world stabilized after an initial increase. The low divorce rates, high fertility, and

Figure 1

SOURCE: Vital Statistics of the United States

lower age at marriage that characterized all Western nations after World War II are trends that have not been adequately explained. Whether these trends reflected the consequences of war, the effects of having grown up during the worldwide depression, or a short-term rise in social conservatism is now debated. Regardless of the cause, the decade of the 1950s is universally regarded as a temporary aberration in otherwise long-term and continuous twentieth century trends. Not until the 1960s were there additional significant changes in divorce laws or divorce rates.

The 1960s were years of significant social change in almost all Western nations. The demographic consequences of high fertility during the 1950s became most apparent in the large and vocal youth movements challenging conventional sexual and marital norms, censorship, the war in Vietnam, and educational policies. Challenges to institutional authority were commonplace. Divorce laws were not immune to the general liberalization. "Between 1960 and 1986 divorce policy in almost all the countries of the West was either completely revised or substantially reformed" (Phillips 1988, p. 562). Most such reforms occurred in the late 1960s to the late 1970s. Unlike earlier divorce law reforms, those during the post-World War II era did not extend the grounds for divorce so much as they redefined the jurisdiction over it. The passage

of no-fault divorce laws signaled a profound shift in the way divorce was to be handled.

Most significantly, divorce became the prerogative of the married couple with little involvement of the state. No-fault divorce laws do not require either spouse to be guilty of an offense. Instead, they focus on the breakdown of the emotional relationship between the spouses. These statutes typically require a period of time during which the spouses do not live together. Beyond that, evidence must be adduced to substantiate one or both spouses' claim that the marriage is irretrievably broken. The significance of no-fault divorce lies entirely in the fact that decisions about divorce are no longer the prerogative of the state or church but rather of the married couple.

The passage of no-fault divorce laws in the West is properly viewed as a response to changing behaviors and attitudes. Indeed, social science research has shown that divorce rates began to increase significantly prior to passage of such laws and did not change any more dramatically afterward (Stetson and Wright 1975).

The changes in divorce law and actual divorce behaviors in the West are a reflection of the redefinition of marriage. More vulnerable and fragile emotional bonds have replaced the economic constraints that once held spouses together. The

availability of gainful employment for women makes marriage less essential and divorce more possible. Indeed, the significant changes in women's social positions and the corresponding changes in normative expectations (i.e., gender) have been the subject of significant sociological research. These changes are recognized as fundamentally altering almost all social institutions. Marriage is no exception.

The redefinition of marriage in the latter twentieth century throughout the West reflects the profound changes in relationships between men and women that have occurred. No longer an economic institution, marriage is now defined by its emotional significance. Love and companionship are not incidents of the institution. Rather, they are essentials. Meeting these high expectations may be difficult, but sustaining them is certainly more so.

Taken together, the changes in the second half of the twentieth century may be summarized as redefining the meaning of marriage. Children are not economic assets. Spouses are not economic necessities. Marriage is a conjugal arrangement where the primary emphasis is on the relationship between husband and wife. The reasons for divorce are direct consequences of the reasons for marriage. As one changes so does the other. Since it is more difficult to accomplish and sustain matrimonial essentials, it is easier to terminate the legal framework surrounding them. Divorce has become less costly (financially, legally, and reputationally) as marriage has become more so (in terms of the investments required to accomplish what is expected of it).

CORRELATES OF DIVORCE

Sociologists have documented a number of demographic and personal characteristics that correlate with the probability of divorce. These include early age at marriage, premarital births, premarital cohabitation, divorce from a previous marriage, and low educational attainments. Social class is inversely related to divorce, yet wives' employment significantly increases divorce probabilities (see Huber and Spitze 1988 for a review).

Half of all recent marriages began with cohabitation (unmarried couples living together) (Bumpass and Sweet 1989). Repeated national studies have found that married couples who cohabited (either with each other, or with others) before marrying

have higher divorce rates than those who never cohabited (Nock 1995). The reason is still unclear. Research shows that cohabiting individuals are less committed to the idea of marriage or marital permanence. They are also less religious and tend to be drawn from lower social classes (both of which are associated with higher divorce rates) (Nock 1995). Cohabitation appears to foster (or reflect) a belief that problems in intimate relationships are solvable by ending the relationship. When such beliefs are carried into marriage, the result is higher divorce rates.

Race correlates with divorce—even after controls are imposed for socioeconomic correlates of race—with black individuals having divorce rates approximately twice those of whites. However, such large differences associated with race are recent in origin. Not until the late 1950s did significant differences in divorce, separation, and other marital statuses emerge between blacks and whites, even though a pattern of marginally higher marital disruption has been found among blacks for at least a century. Such findings suggest that the differences stem more from contemporary than historical circumstances. As Cherlin suggests, the recent changes in black Americans' family situations resemble those of other racial and ethnic groups, though they are more pronounced. The restructuring of the American economy, the decline in semi-skilled jobs, and the rise in service occupations has resulted in higher rates of black male unemployment or low wages, and better opportunities for black women. "Faced with difficult times economically, many blacks responded by drawing upon a model of social support that was in their cultural repertoire, a way of making it from day to day passed down by African Americans who came before them. This response relied heavily on extended kinship networks and de-emphasized marriage" (Cherlin 1992, p. 113).

CONSEQUENCES OF DIVORCE

For Children. A central concern of much of the recent research on divorce is how children fare. Developmental psychologists describe five ways in which marital disruption may affect children's adjustment. First, some adults and some children are more vulnerable to the stress and strain of divorce. Personality characteristics, ethnicity, or

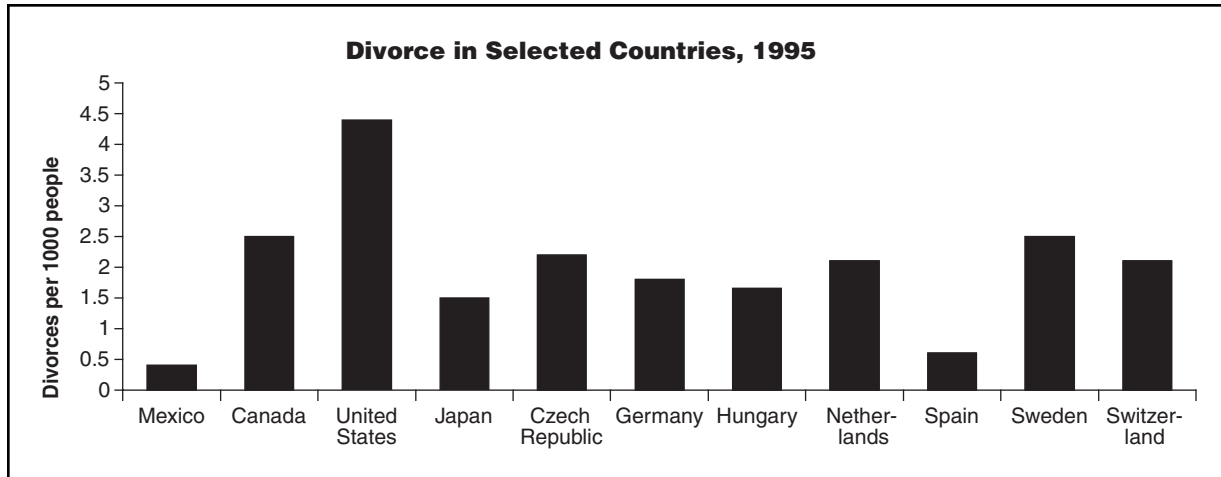

Figure 2

SOURCE: United Nations 1996 Demographic Yearbook

age for example, may make some individuals more susceptible to negative outcomes. Second, the absence of one parent, per se, may affect children's adjustment to divorce. Boys, in particular, appear to benefit from the presence of a male adult. Third, the loss of income creates many indirect problems for children, including changes in residence, school, neighborhood, and peer networks. Fourth, divorce often diminishes the custodial parent's ability to provide supportive and appropriate parenting, especially if depression follows marital disruption. And finally, negative, conflictual, and dysfunctional family relationships between parents, parents and children, and siblings are probably the most damaging consequence of divorce for children. (Hetherington, Bridges, and Insabella 1998).

Longitudinal research has shown that children who experience divorce differ from others before the disruption occurs. Cherlin showed that children whose parents were still married, but who would later divorce, showed more behavior problems and did less well in school than children whose parents would remain married (Cherlin et al. 1991).

Even after such predisruption differences are considered, divorce takes a toll in the lives of children who experience it. Divorce significantly increases the chances that young people will leave their homes due to friction with a parent, increases

the chances of premarital cohabitation, and increases the odds of premarital pregnancies or fatherhood (Cherlin, Kiernan, and Chase-Lansdale 1995). The effects of divorce in young adulthood include higher rates of unemployment and lower educational attainments. Divorce weakens young people's connections to their friends and neighbors due to higher rates of residential mobility (McLanahan and Sandefur 1994). Following divorce, many children are subjected to changes in residence, often to disadvantaged neighborhoods where peers have lower educational prospects. The lack of connections to others affects parents' ability to monitor their children. It also limits young people's knowledge about local employment opportunities.

The changed economic circumstances caused by divorce affects children in many indirect ways. The loss of available income may affect the quality of schools children attend if custodial parents move to poorer neighborhoods. The lack of income may limit children's opportunities for extracurricular activities (e.g., travel, or music lessons). The need for income often compels custodial parents to work more hours, reducing their ability to monitor children's after-school activities.

In their socioeconomic attainments, children who experienced their parents' divorce average one to two fewer years of educational attainment than children from intact homes (Krein and Beller

1988; Hetherington, Camara, and Featherman 1983). Such effects are found even after rigorous controls are imposed for such things as race, sex, years since the divorces, age at time of divorce, parental income, parental education, number of siblings, region of residence, educational materials in the home, or the number of years spent in the single-parent family. There are comparable effects of divorce on occupational prestige, income and earnings, and unemployment (Nock 1988).

White women who spent some childhood time in a single-parent family as a result of divorce are 53 percent more likely to have teenage marriages, 111 percent more likely to have teenage births, 164 percent more likely to have premarital births, and 92 percent more likely to experience marital disruptions than are daughters who grew up in two-parent families. The effects for black women are similar, though smaller. Controls for a wide range of background factors have little effect on the negative consequences of divorce. Further, remarriage does not remove these effects of divorce. And there is no difference between those who lived with their fathers and those who lived with their mothers after divorce. Experiencing parents' divorce has the same (statistical) consequences as being born to a never-married mother (McLanahan and Bumpass 1988; McLanahan and Sandefur 1994).

Such large and consistent negative effects have eluded simple explanation. Undoubtedly much of the divorce experience is associated with the altered family structure produced—in almost 90 percent of all cases a single-mother family—and the corresponding changes in family functioning. Such a structure is lacking in adult role models, in parental supervision, and in hierarchy. On this last dimension, research has shown that divorced women and their children are closer (less distinguished by generational distinctions) to one another than is true in intact families. Parent and child are drawn together more as peers, both struggling to keep the family going. The excessive demands on single parents force them to depend on their children in ways that parents in intact families do not, leading to a more reciprocal dependency relationship (Weiss 1975, 1976). Single mothers are “. . . likely to rely on their children for emotional support and assistance with the practical problems of daily life” (Hetherington, Camara,

and Featherman 1983, p. 218). In matters of discipline, single mothers have been found to rely on restrictive (authoritarian as opposed to authoritative) disciplinary methods—restricting children's freedom and relying on negative sanctions—a pattern psychologists believe reflects a lack of authority on the part of the parent (Hetherington 1972). Whatever else it implies, the lack of generational boundaries means a less hierarchical family and less authoritative generational distinctions.

The institutional contexts within which achievement occurs, however, are decidedly hierarchical in nature. Education, the economy, and occupations are typically bureaucratic structures in which an individual is categorically subordinate to a superior—an arrangement Goffman described as an “*eschelon authority structure*” (1961, p. 42). The nuclear family has been described as producing in children the skills and attitudes necessary for competition within such *eschelon authority relationships* in capitalist production and family childrearing. “The hierarchical division of labor (in the economy) is merely reflected in family life” (Bowles and Gintis 1976, p. 144–147). The relative absence of clear subordinate-superordinate relationships in single-parent families has been argued to inadequately socialize children, or place them in a disadvantageous position when and if they find themselves in hierarchical organizations (Nock 1988).

For Adults. A wide range of psychological problems has been noted among divorcing and recently divorced adults. A divorce occasions changes in most every aspect of adult life; residence, friendship networks, economic situation, and parental roles. Marriage in America makes significant contributions to individual well-being. Thus, regardless of the quality of the marriage that ends, emotional distress is a near-universal experience for those who divorce (Weiss 1979). Anxiety, anger, and fear are dominant psychological themes immediately before and after divorce. At least for a year or two after divorce, men and women report psychosomatic symptoms of headaches, loss of appetite, overeating, drinking too much, trembling, smoking more, sleeping problems, and nervousness (Group for the Advancement of Psychiatry 1980).

The emotional problems occasioned by divorce are accompanied by major changes in economic situations, as well—especially for women.

The vast majority of those involved in divorce experience a significant decline in their immediate standard of living. This problem is especially acute for women who—in almost 90 percent of cases—assume custody of children. Immediately after a divorce, women suffer an average 30 percent to 40 percent decline in their overall standards of living (Hoffman and Duncan 1988; Peterson 1989). Either in anticipation of or as a consequence of divorce, there is typically an increase in divorced women's labor force participation. Analyzing national longitudinal data, Peterson estimates that one year before the divorce decree (when most divorcing individuals are separated), women's average standard of living (total family income divided by the poverty threshold for a family of a particular size) is 70 percent of its level in the previous year. As a consequence of increased hours worked, the standard of living increases one year after divorce and by five or six years after divorce, "the standard of living of divorced women is about 85 percent of what it had been before separation" (1989, p. 48). Women who have not been employed during their marriages, however, are particularly hard-hit; the majority ending up in poverty.

Child support payments are not a solution to the economic problems created by divorce for two reasons. First, about one-quarter (24 percent) of women due child support receive none (39 percent of men awarded child support receive none). Another one-quarter receive less than the court-ordered amount. In 1991, the average amount of child support received by divorced mothers was \$3,011 per year (\$2,292 for men) (U.S. Bureau of the Census 1995). About 16.7 million, or 85 percent of the 19.8 million children in single-parent families in 1997 were living with the mother; 60 percent of whom were divorced (U.S. Bureau of the Census 1998a). Their median family income was \$22,999 compared with \$34,802 for those in single-father situations, and \$51,681 for children in households where both parents were present (U.S. Bureau of the Census 1998a). Families headed by single mothers are the most likely to be in poverty, and represent 55 percent of all poor families. In 1997, a third (31.6 percent) of all single-mother families were in poverty compared to 5.2 percent of two-parent families (U.S. Bureau of the Census 1998b). Analyzing national longitudinal data, Duncan concluded that changes in

family status—especially divorce and remarriage—are the most important cause of change in family economic well-being and poverty among women and children (1984).

Single-parent families in America have grown dramatically as a result of increasing divorce rates. And even though most divorced persons remarry, Bumpass has shown that the average duration of marital separation experienced by children under age 18 was 6.3 years and 7.5 years for whites and blacks respectively. In fact 38 percent of white and 73 percent of black children are still in a single-parent family 10 years after the marital disruption—a reflection of blacks' lower propensity to remarry and their longer intervals between divorce and remarriage (1984). The role of divorce in the formation of single-parent families differs by race. Among all single-parent white families, 25 percent are maintained by never-married mothers, 47 percent by divorced (or separated) mothers, 7 percent by never-married men, and 13 percent by divorced or separated men. Among black single-parent families, 59 percent are maintained by never-married women, 28 percent by divorced or separated women, 4 percent by never-married men, and only 3 percent by divorced or separated men. Divorce is the primary route to single-parent-hood for white mothers, whereas out-of-wedlock childbearing is for black mothers (U.S. Bureau of the Census 1998c, Table 11; 1998d).

Families headed by single women with children are the poorest of all major demographic groups regardless of how poverty is measured. Combined with frequent changes in residence and in employment following divorce, children and mothers in such households experience significant instabilities—a fact reflected in the higher rates of mental health problems among such women (Garfinkel and McLanahan 1986, pp. 11–17).

CONCLUSION

High rates of remarriage following divorce clearly indicate that marital disruption does not signify a rejection of marriage. There is no evidence of widespread abandonment of conjugal life by Americans. Admittedly, marriage rates have dropped in recent years. However, such changes are best seen to be the result of higher educational attainments,

occupational commitments, and lower fertility expectations; not a rejection of marriage per se. Rather, increasing divorce rates reflect the fact that marriage is increasingly evaluated as an entirely emotional relationship between two persons. Marital breakdown, or the failure of marriage to fulfill emotional expectations, has come increasingly to be a cause for divorce. Since the 1970s, our laws have explicitly recognized this as justification for terminating a marriage—the best evidence we have that love and emotional closeness are the *sine qua non* of modern American marriage. Contemporary divorce rates thus signal a growing unwillingness to tolerate an unsatisfying emotional conjugal relationship.

The consequences of divorce for children are difficult to disentangle from the predictable changes in household structure. Whether the long-term consequences are produced by the single-parent situation typically experienced for five to ten years, or from the other circumstances surrounding divorce is not clear. It is quite apparent, however, that divorce occasions significant instabilities in children's and mothers' lives.

Our knowledge about the consequences of divorce for individuals is limited at this time by the absence of controlled studies that compare the divorced to the nondivorced. Virtually all research done to date follows the lives of divorced individuals without comparing them to a comparable group of individuals who have not divorced. A related concern is whether the consequences of divorce reflect the experience itself, or whether they reflect various selection effects. That is, are people who divorce different from others to begin with? Are their experiences the results of their divorce, or of antecedent factors?

When almost half of all marriages are predicted to end in divorce, it is clear that marital disruption is a conspicuous feature of our family and kinship system. Divorce creates new varieties of kin not traditionally incorporated in our dominant institutions. The rights and obligations attached to such kinship positions as spouse of the noncustodial father are ambiguous—itsself a source of problems. The social institution of the family is redefined as a consequence of divorce. Entering marriage, for example, is less commonly the beginning of adult responsibilities. Ending marriage is less commonly the consequence of death. Parents

are not necessarily co-residents with their children. And new categories of “quasi” kin are invented to accommodate the complex connections among previously married spouses and their new spouses and children. In many ways, divorce itself has become a dominant institution in American society. It is, however, significantly less structured by consensual normative beliefs than the family institutions to which it is allied.

DRUG ABUSE

Drug abuse has been a major social problem in the United States for almost a century and we are now in the second decade of a continuing war on drugs. Drug abuse is a health and criminal justice problem that also has implications for nearly every facet of social life. It is a major element in the high cost of health care, a central reason for the United States's extraordinarily high rate of incarceration, and a focus of intensive education and treatment efforts. Substance abuse is an equal-opportunity problem that affects both high- and low-income persons, although its consequences are most often felt by those persons and communities that have the lowest social capital.

Substance abuse, with its connotations of disapproval or wrong or harmful or dysfunctional usage of mood-modifying substances, is a term that was developed in the United States. The more neutral term, *dependence*, is often used in other countries. *Addiction*, which formerly communicated the development of tolerance after use and a physical withdrawal reaction after a drug became unavailable, has assumed less explicit meanings. Whatever terminology is employed, there is intense societal concern about the use of psychoactive mood-altering substances that involve loss of control. This concern is manifest particularly for young people in the age group most likely to use such substances. Society is concerned that adolescents

and young adults, who should be preparing themselves for crucial educational, vocational, and other significant life choices, are instead diverted by the use of controlled substances.

The United States has the highest rate of drug abuse of any industrialized country and, not surprisingly, spends more public money than any other country to enforce laws that regulate the use of psychoactive drugs. Its efforts to control drug abuse reach out across its borders. The United States also plays a critical role in developing knowledge about substance abuse; more than 85 percent of the world's drug abuse research is supported by the National Institute on Drug Abuse.

EPIDEMIOLOGY

Information on incidence and prevalence of drug use and abuse derives from a range of sources: surveys of samples of households and schools; hospital emergency room and coroners' reports; urine testing of samples of arrestees; treatment programs; and ethnographic studies. Such epidemiological information enables us to assess drug abuse programs and decide on allocation of resources (Winick 1997).

Since World War II, the peak years for illicit drug use were in the late 1970s, when approximately 25 million persons used a proscribed substance in any thirty-day period. Overall illicit drug use has been declining since 1985. The yearly National Household Survey on Drug Abuse, which is the most influential source of epidemiology data, reported that in 1997 marijuana was used by 11.1 million persons or 80 percent of illicit drug users (Office of Applied Studies 1999). Sixty percent only used marijuana but 20 percent used it along with another illicit substance. During the 1990s, the rate of marijuana initiation among youths aged twelve to seventeen reached a new high, of approximately 2.5 million per year. The level of current use of this age group (9.4 percent) is substantially less than the rate in 1979 (14.2 percent).

Twenty percent of illicit drug users in 1997, ingested a substance other than marijuana in the month preceding the interviews. Some 1.5 million Americans, down from 5.7 million in 1985, used cocaine in the same period; the number of crack users, approximately 600,000, has remained nearly constant for the last ten years. At least 408,000

individuals used heroin in 1997, with the estimated number of new users at the highest level in thirty years.

Data on incidence and prevalence of use must be interpreted in terms of social structure. Thus, one out of five of the American troops in Vietnam were addicted to heroin, but follow-up studies one year after veterans had returned to the United States found that only 1 percent were addicted (Robins, Helzer, Hesselbrook et al. 1980). In Vietnam, heroin use was typically found among enlisted men and not among officers. Knowing such aspects of social setting and role can help in understanding the trends and can contribute to understanding the use of other substances in other situations. In any setting, the frequency of substance use, the length of time over which it was taken, the manner of ingestion, whether it was used by itself or with other substances, its relationship to criminal activity and other user characteristics (e.g., mental illness), the degree to which its use was out of control, the setting, and whether it was part of a group activity are also important.

Rates of use by subgroup can vary greatly. Thus, for example, prevalence rates of drug use are higher among males than females and highest among males in their late teens through their twenties. Over half the users of illicit drugs work full time. About one-third of homeless persons and more than one-fourth of the mentally ill are physically or psychologically dependent on illicit drugs. The first survey of mothers delivering liveborns, in 1993, found that 5.5 percent had used illicit drugs at some time during their pregnancy. A survey of college students reported that in the previous year, 26.4 percent had used marijuana and 5.2 percent had used cocaine. National Household Survey data indicate that use of illicit drugs by persons over thirty-five, which was 10.3 percent in 1979, jumped to 29.4 percent by 1991 and was 33.5 percent in 1997.

Rates of cigarette smoking are of interest because of their possible relationship to the use of other psychoactive substances. Approximately one-eighth of cigarette smokers also use illicit drugs. In a typical month in 1997, 30 percent of Americans, or 64 million, had smoked cigarettes and one-fifth of youths between the ages of twelve and seventeen, were current smokers. Almost half of all American adults who ever smoked have stopped

smoking. Drug abusers may also be involved with alcohol.

POLICY

A central contributor to current American policy toward mood-modifying drugs was the Harrison Act of 1914, which prevented physicians from dispensing narcotics to addicts (Musto 1987). The Marijuana Tax Act of 1937 and strict penalties for sale and possession of narcotics that were imposed by federal legislation in 1951 and 1966 expanded punitive strategies. An important change took place in 1971, when President Nixon—who had campaigned vigorously against drug use—established a national treatment network. Nixon was the only president to devote most of the federal drug budget to treatment; his successors have spent most of the budget on law enforcement.

In 1972, the Commission on Marijuana and Drug Abuse recommended a dual-focused policy that is both liberal and hard-line. The policy, which continues to the present, is liberal in that users who need help are encouraged to obtain treatment. But it is hard-line because it includes harsh criminal penalties for drug possession and sales. As a result, nearly two-thirds of the federal resources devoted to drug use are now spent by the criminal justice system to deter drug use and implement a zero-tolerance philosophy.

President Carter's 1977 unsuccessful attempt to decriminalize marijuana was the only effort by a national political leader to lessen harsh penalties for drug possession. Between 1981 and 1986, President Reagan doubled enforcement budgets to fight the "war on drugs." Politicians generally have felt that the traditional hard-line policy served their own and the country's best interests and there has been limited national support for legalization or decriminalization (Evans and Berent 1992).

Originating in several European countries, the policy of *harm reduction* has, during the last decade, generated growing interest in the United States as a politically viable alternative to legalization (Heather, Wodak, Nadelmann et al. 1998). It attempts to understand drug use nonevaluatively in the context of people's lives and to urge that the policies that regulate drug use should not lead to more harm than the use of the substance itself causes. A representative harm-reduction initiative

is the establishment of needle exchanges, for injecting users of heroin and other drugs, in order to minimize the possibility of HIV transmission resulting from the sharing of infected needles. The use of needles to inject illegal substances has been linked to one-third of the cumulative number of AIDS cases in the United States. In the United States, the use of federal government money for needle exchanges is prohibited, although there are approximately 1.3 million injecting drug users. Critics of these programs believe that such exchanges increase heroin use and send a latent message that it is acceptable to use drugs like heroin. Harm reductionists disagree and argue that needle exchanges lead to a decline in rates of HIV infection without encouraging use.

Another policy disagreement between America and other countries involves marijuana. In the United States many federal benefits, including student loans, are not available to those convicted of marijuana crimes. In contrast, marijuana has been decriminalized in a number of Western European countries, including Italy, Spain, and Holland. It is openly available in coffee houses in Holland, where officials believe that its use is relatively harmless and can deter young people from using heroin or cocaine. In America, marijuana is viewed by federal authorities as possibly hazardous and a potential "stepping stone" to heroin or cocaine use, and approximately 695,000 persons were arrested for its possession in 1997.

Other countries have experimented with ways to make drugs such as heroin legally available, albeit under control. Thus, in Switzerland, heroin addicts have been legally maintained. In England, methadone (a heroin substitute) can be obtained by prescription from a physician. In the United States, by contrast, an addict must enroll in a program to be able to receive methadone.

In the United States prevention of drug abuse has never been as important a policy dimension as treatment or law enforcement, in part because it requires legislators to commit resources in the present to solve a future problem. Prevention has, thus, accounted for less than one-seventh of the drug abuse budget. Because of the variety of prevention approaches and because of the American local approach to education, there are many viewpoints on how to conduct programs that will prevent young people from becoming drug users and

abusers. An information-didactic approach, often with the assistance of law enforcement personnel, has been traditional. A role-training, peer-oriented, values-clarification, alternatives, affective-education approach emerged in the 1970s, along with psychological inoculation. Addressing the social structure and family in which young people live, and targeted community action, attracted substantial support in the 1980s and 1990s.

National policy toward drug use is systematically promulgated by the Office of National Drug Control Policy (1999). The office has established the goal of reducing drug use and availability by 50 percent and reducing the rate of related crime and violence by 30 percent by 2007. It is proposed that these goals will be achieved by expanding current approaches.

Although drug abuse has been called "the American disease," physicians have had little impact on policy. Between 1912 and 1925, clinics in various states dispensed opiates to users. More recently, however, the federal government has opposed making marijuana available for medicinal purposes, even to treat persons with terminal or debilitating illnesses. Nevertheless, eleven states decriminalized marijuana possession in the 1970s and others, by referendum vote in the 1990s, have permitted physicians to recommend and patients to use marijuana medically.

CONTROL

In the United States, programs to control the supply of mood-modifying substances are intended to interdict the importation of illicit materials, enforce the laws, and cooperate with other countries that are interested in minimizing the availability of controlled substances. In addition to illicit substances (such as heroin, that has no established medical use), prescription products can be abused. These include substances such as barbiturates, that are used without medical supervision in an inappropriate manner. The problem also includes over-the-counter drug products that are not used for the purpose for which they were manufactured. Some nondrug substances like airplane model glue and other inhalants that can provide a "high" and are difficult to regulate, are also considered part of the country's substance abuse burden.

Preventing illicit drugs from entering the United States is difficult because of heavily trafficked, long, porous borders. Large tax-free profits provide incentives for drug entrepreneurs to develop new ways to evade customs barriers, process the drug for the market, and sell it (Johnson, Goldstein, Preble et al. 1985). For example, approximately seven-eighths of the retail price represents profit after all costs of growing, smuggling, and processing cocaine for illegal sale in the United States. The increasing globalization of the world economy further facilitates the international trade in illicit substances.

A key component in efforts to reduce the supply of stimulants, depressants, and hallucinogens is the Comprehensive Drug Abuse and Control Act of 1970, which established a national system of schedules that differentiated the public health threat of various drugs of abuse. This law, which has been modified over the years, classifies controlled substances into five categories, based on their potential for abuse and dependency and their accepted medical use. Schedule I products, such as peyote, have no acceptable safe level of medical use. Schedule II products, such as morphine, have both medicinal value and high abuse potential. Schedule III substances, such as amphetamines, have medical uses but less abuse potential than categories I or II. Also acceptable medicinally, Schedule IV substances, such as phenobarbital have low abuse potential, although the potential is higher than Schedule V products, such as narcotics that are combined with non-narcotic active ingredients. Conviction for violation of federal law against possession or distribution of scheduled products can lead to imprisonment, fines, and asset forfeiture.

Ever since it assumed a major role in promoting the Hague Opium Convention of 1912, the United States has been a leader in the international regulation of drugs of abuse. The United States convened the 1961 Single Convention on Narcotic Drugs and the 1971 Convention on Psychotropic Substances. Some countries, like England and Holland, subscribe to the treaties but interpret them more liberally than does the United States. The United States has also provided technical assistance, financing, and encouragement to other countries to minimize the growth of drugs such as cocaine and marijuana. Programs have been conducted in Mexico and Turkey to eradicate these

crops and related programs have been encouraged in Peru and Columbia.

Since 1930, the U.S. Treasury Department has had responsibility for drug regulation in the United States. In 1973, the Drug Enforcement Administration of the Justice Department assumed the police and control function under federal law. Each state has laws that generally parallel the federal laws on possession and distribution of controlled substances and all states have a single state agency that coordinates other programs related to drug abuse.

Regular or frequent drug users, without outside income, are likely to engage in a range of criminal activities in order to buy controlled substances. They typically engage in six times more criminal activity when using than when they are not using drugs. Urine testing of arrestees, under the federal Arrestees Drug Abuse Monitoring program, indicates that some two-thirds of those arrested in urban communities had used an illicit substance prior to arrest. It is, thus, not surprising that the rates of street crimes tend to be positively correlated with the number of illegal drug users in a community.

During the last fifteen years, both state and federal prison populations have experienced a massive increase due to the number of people convicted and jailed for selling or using drugs. Other developments contributing to the surge in the prison population include aggressive enforcement, longer sentences, the decline of parole, and mandatory sentencing procedures that provide less latitude for judges. Thus, for example, federal penalties for possession of crack, a rock-like form of cocaine that became popular in the 1980s and sells for a low price on the street, are 100 times greater than for powdered cocaine. Sellers targeting crack to urban minorities represent one of several factors that have led to a disproportionate number of young blacks in federal and state prisons, for violation of possession laws. Ninety percent of prisoners in federal prisons for crack violations are black, although twice as many whites as blacks use it.

Survey and other data consistently report that the use of mood-modifying drugs is distributed among all the socioeconomic and ethnic groups in the United States; nevertheless, arrests, convictions, deaths, and other negative outcomes of

drug use are disproportionately concentrated in specific geographic areas and population subgroups. In state prisons, blacks make up some 60 percent of the drug-law violators although they represent 12 percent of the country's population and 15 percent of regular drug users. Selective enforcement of the laws might reasonably be considered a possible contributor to such statistics.

American attitudes toward drug use have historically reflected ethnic and class-related prejudices. Thus, earlier in the twentieth century, negative attitudes toward cocaine were associated with the hostility that Southern blacks, among whom cocaine use was thought to be widespread, were believed to harbor toward whites. The public's suspicion of Chinese immigrants was a reflection of their use of opium. A number of stereotypes about marijuana reflected beliefs about its use by Mexican immigrants and some occupations that had low status at the time, such as jazz musicians.

For members of both majority and minority groups sentenced to prison, recidivism rates are high and represent one reason that the United States has higher rates of incarceration (approaching two million) than any industrialized nation. Although treatment of former drug users in prison settings has produced some promising results, treatment opportunities in prison are scarce and have not kept pace with the growth in the population of incarcerated former users. Approximately one in eight state inmates and one in ten federal inmates have taken part in treatment since their admission to prison. On a limited basis, treatment is being offered in an effort to keep offenders from returning to prison.

TREATMENT

The treatment of substance abuse has consistently been a lower priority than efforts to control drug abuse through interdiction and criminal sanctions, although cost-benefit studies have demonstrated that every dollar invested in treatment saves seven dollars in other costs. The federal government has usually spent more than two-thirds of its substance abuse budget (which now totals nearly \$20 billion) on such supply-reduction and criminal justice system strategies. Only a small minority of drug abusers have access to treatment, since health

insurers tend to discriminate against persons with substance abuse problems and there are inadequate treatment resources.

Current treatment for drug abuse, in addition to withdrawal, ranges from psychotherapeutic interventions (provided in both inpatient and outpatient settings), pharmacology agents, and various forms of milieu therapy. It frequently includes information on relapse prevention. Psychotherapy is often used in combination with other forms of treatment, and is provided both on an individual and group basis by therapists trained in medicine, psychology, social work, nursing and education. Pharmacological treatments include approaches, that substitute or block the effect of an abused substance, such as methadone maintenance for heroin (Ball and Ross 1991). Milieu therapies include a variety of residential programs where drug abusers can learn or relearn how to live substance free. Although some relatively short-term hospital-based programs exist (particularly for those with independent resources to pay for such services), the most common milieu consists of longer-term therapeutic communities such as Phoenix House, where drug users live in a setting in which they are closely monitored. The residents' progress through the several levels of the program's hierarchical social structure depends on their ability to implement the program's rules for "right living" (De Leon 1997).

Although often not considered a treatment, various fellowship groups deriving from the Alcoholics Anonymous model are widely used by drug abusers. Thus, for example, groups such as Narcotics Anonymous, Cocaine Anonymous, and parallel groups for spouses and parents of drug users exist in almost every community. Such groups, which have no professional staff and rely on the reinforcement of abstinence, support drug abusers in maintaining drug-free lives and help family members aid their drug-abusing relatives. Many treatment programs encourage their patients or clients to participate in such a twelve-step fellowship simultaneously with the treatment period or after treatment is completed.

Although substantial resources have been devoted to treatment outcome research, our knowledge of who does best in what treatment is limited. Particularly for cocaine, the use of which can lead to dependence in a short period of time, effective

pharmacological treatments are not available. A combination of strategies is often most effective especially if it recognizes that drug abuse is a chronic relapsing disorder that is likely to include multiple treatment failures on the way to an ultimately favorable outcome. Of the treatment approaches to drug abuse, milieu treatments have been among the most intensely studied. For those able to participate in such programs, they can have extremely high rates of relatively enduring positive outcomes. Whatever the treatment modality, it must include job readiness, habilitation and vocational rehabilitation, and other dimensions that will enable the former user to function effectively in the modern information-oriented community and economy.

PREVENTION

In the late 1980s, the social problems associated with drug abuse, particularly in terms of the possession and sale of cocaine in urban areas, were perceived to have reached crisis dimensions and there was a marked increase in criminal justice efforts to control substance use. Another positive response was a renewed emphasis on the prevention of drug abuse and the collateral development of broad-based community strategies designed to reduce demand for illicit drugs. Currently, such demand-reduction efforts are undergoing systematic study in several long-term longitudinal public and private programs.

There has been a transformation in views of substance abuse as we have moved from a focus on individual pathology to programs that engage community institutions. Such efforts aim to change norms about substance use through the involvement of community members and the integration of the substance-abuse programs pursued by public and private agencies. The 1990s saw the expansion of community-based programs to include a broad range of institutions, including the police and courts, the voluntary sector, as well as the media (Falco 1994). Fostered by the government's Center for Substance Abuse Prevention (part of the Substance Abuse and Mental Health Administration) and efforts of the Robert Wood Johnson Foundation, the country's largest health foundation, hundreds of communities are engaged in broad-based efforts to change the culture within

which substance abuse takes place (Saxe, Reber, HalFors, et al. 1997).

The belief that substance abuse is sustained by community norms represents an ecological approach. Environmental conditions, whether they reflect physical conditions in the community, poverty, or available health care, are thus seen as risk factors for drug use and abuse. Supporters of this view believe that what is needed are coordinated, community-wide efforts to address drug abuse at multiple levels of social organization and the collaboration of many groups. The idea that multicomponent community-action efforts can prevent drug abuse derives from earlier studies of programs designed to cope with cardiovascular disease. It is consistent with efforts to promote a variety of other health issues, but substance abuse is now a primary focus of these efforts.

The largest of these comprehensive efforts is the federal government's Community Partnership Program, which has supported over 250 partnerships. The Community Partnership Program was initiated in 1990 after the Robert Wood Johnson Foundation had begun to develop a model and sponsor broad-based community efforts. Called "Fighting Back" programs, they now provide long-term support to more than a dozen communities to develop comprehensive demand-reduction interventions. The foundation has also provided support and technical assistance to hundreds of additional communities through groups such as Join Together.

A significant element of many such prevention programs is the presence of a strong media component. The Partnership for a Drug-Free America, for example, develops and places hundreds of millions of dollars of advertising each year, and communities are encouraged to leverage local media to present anti-drug messages directed at youth. Although there is limited direct evidence of the effectiveness of media campaigns, it is likely that they reinforce education and prevention messages being delivered to youth through other means.

Schools play a central role in prevention programs, under the assumption that drug abuse will be more easily prevented if programs are started early. The goal of these programs is to provide youth with the skills to become successful adults and to teach them the community's norms and

values. There is substantial evidence that positive school experiences are linked to lower levels of drug use and conversely, that drug use is related to delinquency and problems in school.

The role of school environments in affecting adolescent substance use has been validated by specific school-based trials. In both the Midwestern Prevention Project and Project Northland, significant reductions in the prevalence of substance use by adolescents were reported (Pentz, Dwyer, MacKinnon, et al. 1989; Perry, William, Veblen-Martenson 1996). Designed for students in grades six through eight, the programs include academic curricula, along with parental and community involvement. Often, a significant mass media component is part of the effort, with a focus on correcting misperceptions about the consequences of drug use and providing alternative positive behavior. The D.A.R.E. program (Drug Abuse Resistance Education) also has been a widely used school-based prevention strategy.

Schools are not the only public institution that affect youths' likelihood to abuse drugs. The police and justice agencies, as well as the network of health and social service agencies that serve a community, have a crucial influence and prevention activities typically involve such agencies. The ability of health and social service professionals to attend to drug use is clearly important, but their role is often reactive, providing treatment rather than prevention.

One of the most important programs that has contributed to attempts by law enforcement agencies to deal with drug abuse is community policing. It represents a shift from reactive policing where the goal is to arrest offenders, to an active strategy designed to identify crime problems and work with citizens—including offenders—to avoid further difficulties. The heart of the approach is that officers get to know citizens and help them deal with minor transgressions and, in so doing, avoid serious crime. A collateral approach, widely used in the 1990s ("fixing broken windows") is designed to improve morale and confidence and stem the physical and social deterioration of communities by prompt attention to small visible manifestations of community dysfunction or decay. There is evidence that such approaches are, at least partly, responsible for declines in violent

crime, which is closely related to substance-abuse problems.

A community's resources and social institutions have a critical impact on drug use, but the attitudes and behavior of peers and family may have an even more direct influence. The affluence of a community and the quality of its schools have a substantial effect on the initiation of drug use, but their impact is mediated by adolescents' peer relationships and their interactions with significant adults in their lives. Thus, peers and parents are perhaps the most vital elements of the community context—directing or guiding youngsters' needs and desires through the obstacles in their environment. Some of the most important programs designed to address community substance abuse focus on changing peer culture and addressing family attitudes and behavior.

Parents (or other adult “guides”) arguably have the greatest potential effect on how the youngster learns to negotiate the environment as it exists (good or bad), and they can also affect the influence that the youngsters' peers exert. The use of drugs by parents significantly increases the likelihood that their youngsters will also use drugs. Although this might seem to be a clear example of youngsters modeling the behavior of their parents, the influence of parents' own use of drugs is probably more complicated. Some research suggests that it is not merely that youngsters mimic parents' behavior, but instead such modeling interacts with what they see in their peers. If both peers and parents engage in substance use, there is far greater likelihood that young people will become regular users.

The influences of peers and parents may interact in complex ways and each community is different—its resources and institutions function differently. Communities can be directed to the key levers, but there is no simple formula available to determine which activities will be most important for a particular community. What is clear, however, is that to understand and develop strategies that reduce adolescent substance abuse, it is necessary to consider the social context in which a child lives. Only by identifying the resources available within a community, the roles played by the social institutions within that community, and the behaviors and values of the individuals (parents and

children) who live in that community, can the interactions among the multiple forms and levels of influence begin to be understood.

RESEARCH

Social science research has played a critical role in the identification of the substance-abuse problem, its social consequences, and strategies to arrest the use of illicit drugs. There is now a long-standing tradition of surveys to identify drug use and attitudes toward the use of mood-modifying substances and their consequences. Surveys, such as the National Household Survey on Drug Abuse (which assesses the drug use of a random sample of U.S. residents over twelve years old) and Monitoring the Future (a school-based survey of junior and senior high school students), have each been conducted for more than two decades. Although there is considerable discussion about the validity of these surveys and how to ensure veridical data (Beveridge, Kadushin, Saxe, et al. forthcoming), there is no question that they have influenced social policy.

More recently, much of the focus of social research has shifted to assessing strategies to prevent drug use and to evaluate treatment programs. Under the auspices of the National Institute on Drug Abuse (a component of the National Institutes of Health), a variegated research program includes both biological and sociopsychological components. An emphasis of research is on assessment of programs such as D.A.R.E., the Community Partnership Program, and Fighting Back. Determining whether these programs achieve their goals of preventing substance abuse is a particularly difficult challenge. The programs are implemented differently across communities and the research design needs to separate the effects of race, socioeconomic status, and other factors from program implementation (Rindskopf and Saxe 1998).

It is also the case that antidrug programs develop loyal followings and their proponents develop a stake in showing that their efforts are successful. Thus, for example, there has been a major debate about the D.A.R.E. program and whether it is successful, with researchers claiming that the evidence suggests it is not effective. In other cases, such as the Community Partnership Program and Fighting Back, the issue has been the

availability of data that can show the effects of the program over time.

One development that will likely allow much better utilization of social research is the availability of sophisticated methodologies. Thus, for example, meta-analytic techniques are now available that permit the synthesis of data across multiple studies, allowing us to amalgamate multiple small-scale tests of programs. In addition, new analytic strategies are being developed to allow construction of multilevel statistical models. Such hierarchical linear modeling permits one to take account of the fact that programs are conducted in particular settings and facilitates the segregation of community effects from overall program effects. Qualitative ethnographic techniques have been used to track the life cycle of substance abuse and the structure of the illegal markets.

FUTURE

The war on drugs is far from being “won,” but drug abuse appears to have stabilized, with use remaining nearly constant. Two trends, that could be counterreactions, have emerged and may help to shape future use of illicit drugs. The first is the call for legalization or decriminalization of the possession of drugs such as marijuana. Several national organizations have emerged to promote this goal and to urge a harm reduction approach. The second trend is the increased licit use of mood-altering prescription substances, such as Prozac and Ritalin. Such powerful psychotropic agents are being prescribed by physicians for depression, difficulties in concentration, and similar problems. As the medical options increase, misuse of prescription drugs will likely increase and it may be more difficult to control the sale of less powerful nonprescription drugs.

ECONOMIC DETERMINISM

NOTE: *Although the following article has not been revised for this edition of the Encyclopedia, the substantive coverage is currently appropriate. The editors have provided a list of recent works at the end of the article to facilitate research and exploration of the topic.*

Economic determinism refers to a kind of causality in which an economic variable x causes a condition of behavior y . This statement of direct causality contains very little actual economic determinism. But in stating that economic condition x is the most determining factor in causing behavior y , we have a model for economic determinism that is quite common in economics and sociology. This model appears in Weber's (1979) *Economy and Society*; in his discussion of domination he states:

Nor does domination utilize in every case economic power for its foundation and maintenance. But in the vast majority of cases, and indeed in the most important ones, this is just what happens in one way or another and often to such an extent that the mode of applying economic means for the purpose of maintaining domination, in turn exercises a determining influence on the structure of domination. (p. 942)

The same model of economic determinism appears in Louis Althusser's (1970) *For Marx*, where the social formation has multiple determinants, but "the economy is determinant in the last instance" (p. 113). Neither model has the economic as a monocausal determinant of society, but economic categories, such as the economic market for Weber, clearly are part of a central structuring determination for society.

This model predates both Weber and Althusser and has its origins in eighteenth-century free market liberalism. In *The Federalist Papers*, James Madison assumes economic interests as the chief motivation of the people. In *The Wealth of Nations*, for Adam Smith it is "that in commercial society every man thus lives by exchanging, or becomes in some measure, a merchant" (1976, p. 26). For Smith people are buyers and sellers involved in production and consumption, and human behavior is an unending series of economic exchanges. Individuals pursue their own self-interest in rational ways, and their own self-interest consists of profit, which is regulated by competition in a predominantly self-regulating free market. In the pursuit of economic self-interest the individual promotes the social good, "led by an invisible hand to promote an end which was no part of his intention" (p. 477). In Smith's model an individual's pursuit of economic profit automatically structures the good for all of society.

Smith assumes an economic person who is always acting to optimize economic advantages. People here are determined by economic motives, that is, to increase profits and decrease losses.

Modern neoclassical economists, such as Milton Friedman and Gary Becker, have continued the tradition of Adam Smith. For them the only limitation on the free market model is the amount of information to which a rational actor has access. Since information is not perfect, mistakes can occur. But in the pursuit of profit a rational actor learns even from mistakes; mistakes therefore increase the amount of information that a rational actor acquires, thus increasing the chances of making correct choices in the future. Thus, the free market not only structures human behavior but determines the inevitability that these actors, in rationally pursuing profit, will acquire the information needed to produce profits continuously for themselves and to mold—even if unintentionally—the social good.

The model of economic determinism offers sociology an easily quantifiable object, a phenomenon that can be subjected to scientific procedures—observed, measured, tested, and verified. As a positivist social science, sociology requires a transhistorical and universal phenomenon such as the physical sciences have, and economic determinism provides it in economic concepts such as the market, money, the circulation of capital, and so forth. It allows sociologists to speak the language of science and to reduce all social phenomena to mathematical formulas.

All positivist social sciences use mathematical representations of social reality to understand society, and economic determinism is but one attempt at creating a scientific sociology. Still, the model has offered sociology a formula that possesses broad powers for explaining social factors and avoids problems of indeterminate multiple causes. This is what science traditionally means by lawfulness. These lawlike social categories are representations of social reality and provide a framework in which the aggregate behavior of individuals can be structured in terms of economic interests. This behavior is patterned and can be studied and subjected to scientific procedures. Thus, the model of economic determinism informs sociological analysis and research.

Exchange theory provides an example of a positivist methodology that is based on the model of economic determinism. In exchange theory, economic exchange is the determinant principle of behavior. George C. Homans, the originator of

this form of analysis, combines this economic model with a behaviorist psychology, but the economic is the determining structure. In *Social Behavior: Its Elementary Forms*, Homans states, “Human behavior as a function of its payoff: in amount and kind it depends on the amount and kind of reward and punishment it fetches” (1961, p. 13). Human relations have been reduced to the exchange and circulation of commodities. Homans assumes that a social actor is an economic person existing in a free market where individuals make rational choices to maximize profits and reduce costs. This is stated partly in the language of behavioral psychology, but the conditions of economic exchange are dominant. Thus, Homans sounds more like Adam Smith than like B. F. Skinner when he writes “we define psychic profits as rewards less costs, and we argue that no exchange continues unless both parties are making a profit” (1961, p. 61).

This model allows Homans to analyze individuals who live in a group, make numerous rational choices, and yet live a stable, patterned life. Individuals calculating their possibilities and making rational choices are led by something like Smith’s “invisible hand” to maintain group life in “practical equilibrium.”

Homans believed that his analysis was a value-neutral attempt to expand the scope of a scientifically valid sociology of human behavior. But, while exchanges are an important aspect of human interaction, the reduction of all human behavior to elementary exchanges is problematic. Homans has universalized the relations of individuals in the capitalist marketplace, relations that are historically specific and not the basis of a universal psychology of human behavior. Homans’s exchange theory is a conservative sociological theory in which pecuniary relations structure human behavior.

Another form of sociological analysis that uses the model of economic determinism is Marxist sociology. In Weber’s *The Protestant Ethic and the Spirit of Capitalism*, Marx’s analysis is called a “one-sided materialistic” interpretation (1958, p. 183). Marx provides evidence for Weber’s contention when he argues that the economic base determines the ideological superstructure. In the preface to *A Contribution to the Critique of Political Economy*, Marx writes that “the totality of these relations of production constitutes the economic

structure of society, the real foundation, on which arises a legal and political superstructure and to which correspond definite forms of social consciousness" (1970, p. 20). This famous passage, containing what is known as the base-superstructure model, became the hallmark statement for economic determinist Marxists from the Second International (Marxist Workers Congress) in 1889 to the present.

But Marx himself was not an economic determinist, even though many of his followers were. Marx theorized about a world in which human relations were subsumed under capitalist relations of production. His central concern was revolutionary change, which depended on the formation of a revolutionary class that could wage war against the dominant classes. But for Marx, class was determined not by economic conditions alone but by community and cultural conditions as well. Thus, he writes in *The Eighteenth Brumaire of Louis Bonaparte* on whether "small holding peasants" are or are not a class:

In so far as millions of families live under economic conditions of existence that separate their mode of life, their interests and their culture from those of other classes and put them in hostile opposition to the latter, they form a class. In so far as there is merely interconnection among these small holding peasants, and the identity of their interests begets no community, no national bond and no political organization among them, they do not form a class. (Marx 1963, p. 124)

This is not "economics in the last instance" but a multivalent fitting together of a series of necessary conditions. Economic conditions are insufficient, and class formation and class struggle do not occur unless community occurs as well.

Later Marxists differ from Marx on a number of issues. First, many understand the base-superstructure model as a determinant condition of class. That is, class depends exclusively on the economic base for its formation. For Marx, however, it was an insufficient condition and a "moment" in his analysis of capitalism. Furthermore, economic determinist Marxists view class struggle as a secondary phenomenon, even though it is important. Finally, many Marxists have critiqued Marx's concept of class for its inability to predict revolutionary change with scientific accuracy. Erik

Olin Wright, for instance, calls Marx's concept of class "vague" and "random"; it is much too relativistic for use as a neat, lawlike scientific formula. In his important book *Classes*, Wright preserves the Marxian tradition of the Second International and attempts to erect a positivist Marxist sociology whose propositions can be empirically verified. It is upon the base-superstructure model that Wright builds this science. As in exchange theory, Wright's model suggests that in capitalism rational actors make rational choices in pursuing their economic advantages. But Wright also attempts to build a scientific base for an analysis of class struggle, and in *Classes* he provides the causal link between capitalist exploitation and the actions of individuals in society. He does this by demonstrating that class structure is determined by property relations, a central determinant in modern society:

Class structure is of pervasive importance in contemporary social life. The control over society's productive assets determines the fundamental material interests of actors and heavily shapes the capacities of both individuals and collectivities to pursue their interests. The fact that a substantial portion of the population may be relatively comfortable materially does not negate the fact that their capacities and interests remain bound up with property relations and the associated processes of exploitation. (Wright 1985, pp. 285–286)

Economic factors are crucial for understanding the social world. But society is not reducible to economic determinants; it is too complex to be reduced to a set of economic propositions, or any single determinant set of propositions, that imply unilinear causality. Still, economic determinism is seductive because it offers a theory that has broad explanatory powers, is easily quantifiable, and can be reduced to simple mathematical formulas. Thus, it is not surprising to see it continue and expand, seemingly unaware of its limitations. For instance, George Gilder writes in *Wealth and Poverty*, "The man's earnings, unlike the woman's, will determine not only his standard of living but also his possibilities for marriage and children—whether he can be a sexual man" (1981, p. 109). The reduction of sex and marriage to economic determinants is highly problematic, both as science and as common sense. Yet generalizations about social life wholly based on economic causes persist, under the names of both science and myth. One can

restate Max Weber's warning against monocausal theories in the social sciences:

But it is, of course, not my aim to substitute for a one-sided materialistic an equally one-sided spiritualistic causal interpretation of culture and of history. Each is equally possible, but each if it does not serve as the preparation, but as the conclusion of an investigation accomplishes equally little in the interest of historical truth. (1958, p. 183)

ECONOMIC INSTITUTIONS

The analysis of economic institutions is central to the work of the classical figures of sociology—Marx, Weber, and Durkheim. These thinkers did not recognize a boundary line between sociological inquiry and economic inquiry; on the contrary, their efforts to make sense of the development of market capitalism led them to intensive analysis of market processes. Unfortunately, this thrust of sociological inquiry was largely abandoned by sociologists between World War I and the late 1960s. This was particularly true in the United States, where sociologists generally deferred to economists' claims of an exclusive mandate to study economic processes.

To be sure, there were a number of important intellectual figures during this period whose work integrated sociological and economic inquiry, but these individuals were rarely housed in sociology departments. Such economists as Thorstein Veblen, Joseph Schumpeter, and John Kenneth Galbraith have been retroactively recognized as sociologists. Similarly, the largely self-educated Hungarian scholar Karl Polanyi ([1944] 1957, 1971) is now acknowledged to have made seminal contributions

to the sociological analysis of economic institutions. Yet scholars working in the sociological mainstream either ignored economic topics or tended to incorporate the perspectives of neoclassical economics.

Since the late 1960s, however, the lines of inquiry pioneered by the classical writers have been revitalized. Sociologists working in a number of different intellectual traditions and on diverse empirical topics have developed sophisticated analyses of economic processes (Swedberg 1987). No longer content to defer to the expertise of professional economists, many of these writers have developed powerful critiques of the work of neoclassical economists (Zukin and DiMaggio 1990).

Although this body of work explores a range of different economic institutions, much of it can be understood through its analysis of the way that markets work. (Analyses of other economic institutions, such as the division of labor, money, and corporate organizations, are presented elsewhere in this encyclopedia.) In particular, an emergent economic sociological conception of market processes can usefully be contrasted with the conception of the market that is implicit in most economic writings.

THE ORGANIZATION OF MARKETS

Neoclassical economists tend to assume an ideal market situation that allows changes in prices to equilibrate supply and demand. In this ideal market situation, there are multiple buyers and sellers whose transactions are fundamentally impersonal; information on the product and the price are the only relevant variables shaping the action of market participants. Contemporary economists recognize that this ideal market situation requires a basic symmetry in the information available to buyers and sellers. When there are significant differences in information, it is likely that the resulting price will diverge from the price that would effectively equilibrate supply and demand. Nevertheless, contemporary microeconomics rests on the assumption that most markets approximate the ideal situation, including information symmetry (Thurow 1983)

The sociological view of markets is fundamentally different. It stresses the embeddedness of behavior within markets, the central role of imitation in structuring markets, and the importance of blocked exchanges. The concept of embeddedness challenges the idea that impersonality is an important feature of actual market situations. While the individual actor in economic theory is a rational actor who is able to disregard his or her social ties in the market situation, the sociological actor is seen as embedded in a network of social relations at the time that he or she engages in market transactions. This embeddedness means that a wide range of social ties exert continuing influence over how the actor will both make and respond to price signals (Polanyi [1944] 1957; Granovetter 1985).

This view has two elements. First, the individual actor is decisively influenced by social ties. For example, a consumer might choose not to do business with retailers belonging to a stigmatized ethnic group, even when their prices are lower, because members of the consumer's ethnic group genuinely believe that the products of the other group will be inferior or that contact with the stigmatized group will jeopardize one's social position. The economists' argument that such an individual has a "taste for discrimination" does not adequately capture a reality in which discriminatory behavior often occurs with very little reflection because beliefs are deeply rooted. Second, the individual actor's dependence on social ties is necessary in order for him or her to accomplish a given economic goal. As Granovetter (1985) has pointed out, a purchasing officer at a corporation might well do business with a particular supplier regardless of price considerations because of longstanding ties to that individual. These ties provide assurance that the delivery will occur in a timely fashion and the merchandise will meet established quality standards. In other words, social bonds can provide protection against the uncertainties and risks that are always involved in transactions.

The standard economic view of markets tends to ignore these uncertainties; it is generally assumed that individuals will automatically obey the

rules that make transactions possible. As Oliver Williamson (1975) has noted, this represents a profound inconsistency in economic analysis. While individuals are assumed to be self-interested, they are also expected to avoid guile and deception. In the real world, however, every transaction involves the risk that one party is deliberately cheating the other, and the more “impersonal” the transaction—that is, the less one party knows about the other—the greater the risk becomes.

This is one of the reasons that actual markets tend to develop structures and rules designed to constrain and to embed individual behavior. Although commodity markets and stock markets most closely resemble the pure markets of economic theory, in which rapid price changes serve to balance supply and demand, these markets tend to evolve complex social structures. At one level, such markets appear to be completely impersonal, in that there is no contact between buyers and sellers. On another level, however, the actual transactions are handled by a community of brokers who are well known to each other and who are expected to follow a particular etiquette for managing transactions. This structure has evolved to provide protection against unknown brokers who might prove unreliable and to assure that known brokers will be discouraged from cheating their colleagues and clients (Adler and Adler 1984; Baker 1984a; Burk 1988).

The central point, however, is that the particular ways in which market behaviors are embedded have real and significant consequences. On the one hand, embeddedness allows market processes to go forward by diminishing the opportunities for guile and deceit. On the other hand, embeddedness assures that factors besides price will influence the behavior of market participants, so it can no longer be assumed that price will automatically equilibrate supply and demand.

One of the main implications of the concept of embeddedness is that actual markets will be characterized by imitative behavior. Economists assume that each economic actor will calculate his or her preference schedule independently of all other actors. In the sociological view, however,

actors are continually making their choices in reference to the behavior of others. In deciding the price to be asked for a particular commodity, a market participant will set it in comparison with the prices of competitors (White 1981). This is one of the key reasons that in actual markets there is often less price competition than would be suggested either by economic theory or by considerable differences across firms in the costs of production.

This role of imitation plays a particularly important role in financial panics and bubbles. Panics occur when many holders of a particular kind of asset rush to convert their holdings to cash, leading to precipitous price declines. Bubbles occur when enthusiasm for a particular asset drives prices far higher than can be justified by expected returns (Kindleberger 1978). Economists have trouble explaining the behavior of individuals in most panics or bubbles because rational actors with complete information would not engage in such irrational behavior; they would understand that the underlying value of an asset is not likely to change so dramatically in a short period of time. However, actual individuals have limited information, and they cope with uncertainty by observing the behavior of their friends and neighbors. Such observation makes them quite susceptible to the collective enthusiasms of panics and bubbles.

The threat of panics is another reason that financial markets develop institutional structures to embed individual behavior. The New York Stock Exchange, for example, has an elaborate system of specialist firms who have the responsibility to smooth out the market for particular stocks. Such firms are expected to be purchasers of last resort in situations where there are too many sellers of a stock (Baker 1984b). The idea is that such action should help to reduce the likelihood of panic. While such an institutional arrangement diverges from the economists’ conception of a self-regulating market, it makes sense in the context of imitative behavior.

Furthermore, in their emphasis on the virtues of markets, neoclassical economists often suggest a vision of society as a giant bazaar in which

everything is for sale. Sociologists, in contrast, are more likely to recognize that the viability of markets depends upon a wide variety of restrictions that block certain types of exchanges. Blocked exchanges are transactions that are in violation of the law or of widely shared ethical standards (Walzer 1983). Instances of blocked exchange include prohibitions on the resale of stolen merchandise, laws that prevent government officials from selling their services to the highest bidder, and the criminalization of prostitution and the purchase of certain drugs.

More subtle blocked exchanges play an important role in structuring the economy. Lawyers are not allowed to switch sides in the middle of a civil suit in response to an offer of a higher fee by the other side. Accountants are not supposed to produce a more favorable audit in response to a higher fee (Block 1990). Loan officers at a bank are prohibited from approving loans in exchange for side payments from the applicant. The members of a corporate board of directors are supposed to place their fiduciary responsibility to the shareholders ahead of their self-interest in contemplating offers to buy out the firm. In a word, there is a complicated and sometimes shifting boundary between legitimate and illegitimate transactions in contemporary economies.

The importance of blocked exchanges sheds further doubt on arguments that markets can regulate themselves without governmental interference (Polanyi [1944] 1957). The construction of any particular market involves rules as to what kinds of exchange are open and what kinds are blocked, but the incentives to violate these rules are often quite substantial. At the same time, the incentives for market participants to police each other are often lacking. Hence, there is often no alternative to a governmental role in policing the boundary between legitimate and illegitimate exchanges. Moreover, debates about social policy are often framed in a language of individual rights that is profoundly insensitive to the importance and pervasiveness of blocked exchanges. For example, when a woman serving as a surrogate mother in exchange for a fee decides she wants to keep the baby, the issue is often debated in terms of contract law. The more fundamental issue, however, is

whether the society believes that the rental of wombs is a legitimate or illegitimate transaction (Rothman 1989).

VARIETIES OF MARKET SYSTEMS

A second important dimension of contemporary sociological work on economic institutions emphasizes the significant variations in the ways in which different market societies are institutionally organized. Against the common assumption that market societies will converge toward the same institutional arrangements, this work has used the comparative method to highlight significant and durable institutional differences. Out of this has come a rich body of literature on the wide variety of different "capitalisms" that can coexist at a particular moment in time. While there are a variety of typologies, this work has tended to identify an East Asian model, a Rhinish model that draws heavily on Germany and France, a social democratic model associated particularly with Sweden and Norway, and the Anglo-American model (Couch and Streeck 1997; Hollingsworth and Boyer 1997; Orzu et al. 1997). While researchers have identified a wide variety of differences in economic institutions, much of this work has focused on examining differences in labor markets, capital markets, and in the markets for innovation.

The study of labor-market institutions encompasses variations in how the labor force acquires basic and advanced skills; variations in how social welfare provides citizens with income in the event of sickness, disability, unemployment, retirement, and other contingencies; variations in the rights and responsibilities that employees have in the workplace; and variations in the mechanisms for matching employees with job vacancies (Rogers and Streeck 1995; Wever and Turner 1995). The point is not simply that different countries are located on different points of a continuum in terms of variables such as union density or welfare generosity. It is rather that some of these variables tend to be grouped together, so that one can identify ideal typical complexes of institutions through which societies distribute some of the costs and benefits of economic growth. For example, studies by Dore (1997) and Streeck (1997)

have sought to show how Japanese and German systems of industrial relations both differ dramatically from the Anglo-American model and work in tandem with other specific institutional features of those societies to create significant economic advantages for Japanese and German firms.

Comparative work on capital markets has generally contrasted the stock market-centered system in the United States and the United Kingdom with the bank-centered systems that have prevailed in Japan and in Continental Europe (Mizuchi and Stearns 1994; Zysman 1983). In the former firms rely primarily on stock and bond issues in impersonal markets to raise the funds required for expansion, while in the latter firms are more reliant on long-term loans from banks. This difference has important implications for corporate governance, for the size of the debt burden on corporations, for the time horizons of corporate executives, and for the openness of the economy to new entrepreneurial initiatives.

Finally, studies of the market for innovation have identified distinct varieties of what some analysts have called national innovation systems (Amable et al. 1997). This encompasses the research efforts of scientists and engineers, initiatives by government agencies to foster innovation, and the entrepreneurial activities of both public and private firms. The ways in which these elements are brought together vary significantly both in terms of the division of labor between the public sector and the private sector and the way that interactions between them are organized. Since innovation clearly weighs heavily in international economic success, some analysts have begun to examine the specific institutional features of nations that have been most effective in fostering successful innovation (Evans 1995).

This effort to identify different institutional types of capitalism has occurred during the same period in which the countries of Eastern Europe and the former Soviet Union have been making a transition from state socialism to capitalism. While some Western advisers acted as though the Anglo-American model was the only relevant model for former socialist countries to emulate, the process

of transition had the effect of deepening the awareness of the institutional variations among capitalist societies (Stark and Bruszt 1998). Hungary, for example, had to make a set of decision as to how much weight to give the stock market in corporate governance and in capital allocation. This, in turn, generated increasing interest in studies showing the important differences in the relative role of stock markets and banks in different market societies.

THE SCOPE OF MARKETS

A third important dimension of contemporary sociological work on economic institutions is a concern with the geographical scope of markets. Much of the sociological tradition has been oriented to the study of national societies or of subnational units. But an understanding of the scope of international markets calls that approach into question. Markets for raw materials, finished products, services, capital, and labor cross national boundaries and exert extraordinary influence over all aspects of social life (Swedberg 1987).

The most ambitious effort to date to chart the importance of these international markets has been the world-system theory of Immanuel Wallerstein (1974a, 1974b, 1980, 1989). Instead of using national societies as the basic unit of analysis, Wallerstein has sought to shift sociological analysis to the level of the capitalist world-system. For Wallerstein, this system is comprised of a world market and a competitive state system of divided sovereignties. Any analysis of patterns within a particular national society must begin by locating that society within the larger capitalist world-system. A nation's location at the core, the periphery, or the semiperiphery of the capitalist world-system can be expected to shape the nature of its economic and political institutions.

The existence of a single unified world market is central to Wallerstein's argument. Each nation that is part of the capitalist world-system must struggle for relative advantage in that market, and this has implications for both social relations within nations and for the political-military relations among nations. Moreover, it is a central part of

Wallerstein's project to detail the process by which various regions of the world have been incorporated into this unified world-system. The capitalist world-system began as a purely European phenomenon, but through colonization and the penetration of Western influence, this system became global. Regions that were once external to the system were progressively incorporated as peripheral areas that produced raw materials. Later-arriving nations such as the United States, Canada, and Japan moved to the semiperiphery and then to the core.

The contributions of Wallerstein and his followers have been extremely important in showing the systematic ways in which international markets shape developments within societies. The study of labor markets within the world-system, for example, has been particularly fruitful in making sense of international migrations—the massive movements of people across national boundaries—that loom so large in understanding both core and peripheral societies (Portes and Walton 1981).

Wallerstein's work, however, is vulnerable to criticism because it sometimes implies that there is a single unified world market for commodities, for labor, and for capital that operates quite similarly to the markets of economic theory. Critics have suggested that Wallerstein devotes too little attention to analyzing the specific institutional structures of global markets and that his work has not given sufficient weight to the institutional variations among capitalist societies. The response to the criticism is that the homogenizing logic of a global capitalist system will work itself out over time and will ultimately eliminate much of the variety in institutional forms.

Toward the end of the 1990s, debate over this precise issue has become increasingly important. The attention of a growing number of scholars is focused on the interactions between the varieties of market institutions at the national level and the dynamics of a global capitalist system. Particularly in discussions of "globalization" (see article in this encyclopedia), scholars ask whether there are—as Wallerstein suggests—powerful structural forces operating at the global level that are systematically

forcing all market societies to adopt Anglo-American economic institutions. One British scholar posed the question polemically by asking if there were a new type of Gresham's Law in which "bad capitalisms were driving out good" (Gray 1999).

One set of events that intensified interest in this question were the deep problems of the Japanese economy during the 1990s and the Asian economic crisis that began in Thailand in July of 1997 and spread to Malaysia, Indonesia, South Korea, and ultimately to Russia and Brazil. Enthusiasm for an East Asian model of capitalism was considerably dampened by the severity of Japan's long-term problems, by South Korea's overnight transition from success story to severe financial crisis, and by doubts that the model could facilitate sustainable growth in poorer countries such as Thailand and Indonesia. At the same time, the crisis heightened awareness that the institutions of global capitalism, especially the International Monetary Fund, were exerting powerful pressures on East Asian countries to align themselves more fully with Anglo-American ways of organizing their economic institutions. Most specifically, in the aftermath of the crisis, there were pressures on nations to shift from bank-centered finance to stock market-centered finance (Wade and Veneroso 1998).

Finally, the Asian crisis also drew attention to the power of what one observer has labeled the "electronic herd" (Friedman 1999)—the global network of traders in markets for bonds, equities, foreign exchange, and more exotic financial instruments. When significant numbers of these traders decide that a particular economy on any continent is being poorly managed, they have the capacity to precipitate a major financial crisis just by taking positions in the market that assume a depreciation of the value of the country's financial assets and currency (Block 1996). To be sure, this power is not yet universal; China and Vietnam have been able to insulate themselves from these pressures by maintaining controls on capital movements, and Hong Kong and Malaysia were successful in foiling the speculative strategies of the traders. Nevertheless, the power wielded by these traders is further evidence that the global market might be able to force steadily greater homogenization in economic institutions and practices across nations.

These same concerns extend to the more developed economies of Western Europe. Scholars have argued that the rapid movement of capital across national boundaries has fundamentally weakened the social democratic model as an alternative way of organizing market societies (Scharpf 1991). And others have begun to wonder aloud as to how long the German model can resist the pressures to abandon its particular institutions for organizing labor markets and capital markets (Gray 1999; Streeck 1997). Developments such as the cross-border merger between Daimler-Benz and Chrysler might portend German accommodation to the Anglo-American model.

The question of whether the global economy will increasingly converge to a single type of capitalism based on the Anglo-American model or whether there will be continuing diversity of the institutional forms of market societies is far from being resolved. The outcome will depend on economic and political developments over the next few decades. However, if there is convergence, the results are likely to be highly unstable unless there is significant progress in increasing the regulatory capacities of global economic institutions. If one starts from neoclassical economic premises, one can imagine that a self-regulating global economy with relatively weak international institutions could be viable. However, a sociological view of markets evokes deep skepticism about the stability of such a system (Polanyi [1944] 1957). Just as sustained economic activity within nations requires both embeddedness of markets to minimize guile and deceit and enforcement of blocked exchanges, so an increasingly integrated global economy has similar needs. Moreover, since globalization tends to weaken regulatory mechanisms at the national level, the need for effective enforcement at the global level becomes more acute.

The Asian economic crisis of 1997 and 1998 revealed that the International Monetary Fund lacks the resources and the capacity to contain international financial panics. Moreover, since the global economy lacks an effective "lender of last resort," a financial panic could lead to a cascade of failures by large financial institutions on an enormous scale. But even when the need to expand

global economic regulation is recognized, the political obstacles to the strengthening of international financial and regulatory institutions are enormous. Most national governments are extremely reluctant to cede sovereignty to international agencies. Since the same processes of globalization that increase the need for global regulation have already eroded the powers of national governments, political leaders are reluctant to limit their own authority even further. At the same time, while the United States has thrown its political and economic weight behind the forces of globalization, domestic political opposition in the United States to strengthened international agencies continues to be formidable. Hence, it appears unlikely that the globalized economy will soon have the regulatory institutions that it needs to function effectively.

FRED BLOCK

ECONOMIC SOCIOLOGY

Economic sociology constitutes its own distinct subfield in sociology and can be briefly defined as

the sociological analysis of economic phenomena. Economic sociology has a rich intellectual tradition and traces its roots to the founding fathers of sociology, especially to Max Weber and his *Economy and Society* (see Swedberg 1998). It should be noted that not only sociologists but also economists have made important contributions to economic sociology. This is particularly true for today's economic sociology, which is the result of works not only by sociologists (such as Mark Granovetter and Harrison White) but also by economists (such as Gary Becker and Oliver Williamson).

To define *economic sociology* as “the sociological analysis of economic phenomena” may seem bland and even tautological. It is therefore important to stress that it entails a definite conception of what topics may be studied by sociologists; that it implies a certain division of labor between economists and sociologists; and that it also has direct consequences for how the relationship between economic theory and sociology is conceived. That this is the case becomes very clear if we contrast this definition with two other ones that are commonly used: (1) that economic sociology primarily deals with a particular dimension of economic phenomena, namely their social dimension; and (2) that economic sociology is the study of social structures and organizations in the economy. That economic sociology deals with economic phenomena in general (our definition) means that it addresses issues not only at the periphery of the economy (such as, say, the influence of religious values on the economy or of ethnicity on entrepreneurship) but also at its core (such as the way markets operate or investment decisions are made). Sociological theory here emerges as either an alternative to economic theory or as a direct challenge to it. To look at the social dimension of economic phenomena (the first alternative definition) means, on the other hand, that sociologists only look at a limited number of economic issues, usually those that are left over once the economists have finished with their analyses. Economists may, for example, decide with the help of standard economic theory what salaries and prices are like in a certain industry, while sociologists, by looking at a factory or a work group as a social system, may

then add some additional information. Economic theory is not challenged by this type of economic sociology, since it only deals with those topics for which there is no economic theory. That economic sociology focuses on social structures or on organizations in the economy (the second alternative definition) means that a purely economic analysis may be regarded as economic sociology as long as it deals with certain topics. Why a firm rather than the market is used for a specific type of transaction may, for example, be explained by the fact that transaction costs are higher in this specific case in the market. This type of economic sociology is close to economic theory and basically dispenses with traditional sociology (although not necessarily with rational choice sociology; see, e.g., Coleman 1990).

These three ways of looking at economic sociology all have their followers. The one which emphasizes that the sociological perspective in principle can be applied to *all* types of economic phenomena is, however, the one that has been used most frequently throughout the history of economic sociology. That this is the case will become clear from the following brief overview of the field. That the two other definitions—economic sociology as the analysis of the social dimension of economic phenomena, and economic sociology as the study of social structures and organizations in the economy—also have their adherents will become obvious as well.

Since the mid-1980s economic sociology has been going through something of a renaissance in the sociological profession, not only in the United States but also in other countries. The advent of what is usually referred to as “new economic sociology” represents one of the most dynamic areas in contemporary sociology. Before the mid-1980s three separate attempts had been made to create a vigorous economic sociology, and something needs to be said about these. The first attempt was made in the early twentieth century by a group of German scholars of whom Max Weber is the most important. The second attempt was made during the same time period by Emile Durkheim and his followers in France. And the third attempt was made by some American sociologists, such as

Talcott Parsons and Neil Smelser, in the 1950s. A few words shall be said about each of these attempts before we discuss the contemporary situation.

HISTORICAL ATTEMPTS AT ECONOMIC SOCIOLOGY

The first significant attempt to create a solid economic sociology was made in Germany during the period 1890–1930 by a group of scholars who were all trained in economics. The three key figures were Max Weber, Werner Sombart, and Joseph Schumpeter. A major reason that economic sociology developed so forcefully in German-speaking academia was probably its strong tradition of historical economics. There was also the fact that toward the end of the nineteenth century Gustav von Schmoller, the leader of the historical school of economics, became embroiled in a bitter academic fight with Carl Menger, one of the founders of marginal utility analysis. By the time Weber and Sombart became active, German economics had been polarized into two camps through the so-called battle of the methods, or the *Methodenstreit*: one that was overly theoretical and one that was overly historical. The idea of “economic sociology” was conceived by both Sombart and Weber as an attempt to get out of this dead end and to function as a kind of bridge between economic history and economic theory. Economic sociology should be analytical in nature, but historically grounded. While Sombart, however, wanted economic sociology to totally replace economic theory, Weber thought differently. In his mind, a healthy science of economics (Weber used the term *Sozialoekonomie*, or “social economics”) should be broad and simultaneously draw on economic theory, economic history, and economic sociology (Weber 1949). Schumpeter basically shared Weber’s opinion, although economic theory would always rank higher in his mind than in Weber’s. The idea of such a broad-based social economics, however, never caught on.

Weber, Sombart, and Schumpeter all made a series of first-rate contributions to economic sociology. For one thing, all of them produced major studies of capitalism: Weber ([1921-22] 1978) in

Economy and Society; Sombart ([1902] 1987) in *Der moderne Kapitalismus*; and Schumpeter ([1942] 1976) in *Capitalism, Socialism and Democracy*. Weber emphasized that capitalism was becoming increasingly rationalized; Sombart was particularly interested in looking at the different historical stages of capitalism; and Schumpeter argued that modern capitalism was digging its own grave and was soon to be replaced by socialism. These visions of capitalism still dominate our thinking and are therefore of great interest. And so are many of the shorter studies by Weber, Sombart, and Schumpeter, such as Sombart’s ([1906] 1976) study of why there is no socialism in the United States, Weber’s ([1904–5] 1930) analysis of the relationship between Protestantism and the spirit of capitalism, and Schumpeter’s ([1919] 1954, [1918] 1971) two superb articles on imperialism and the tax state.

A special mention must also be made of Georg Simmel’s ([1907] 1990) *The Philosophy of Money*. This work contains an ingenious analysis of money that ranges from philosophy to sociology. No general theory of money is developed, but the author takes on a series of interesting topics, including credit, checks, and small change. Simmel should not only be credited with having made a serious attempt to develop a sociological approach of money; he was also the first sociologist to realize what an important role trust plays in economic life.

The only one to make a sustained effort to lay a theoretical foundation for economic sociology, however, was Max Weber. He did this in a chapter of *Economy and Society* (Weber [1921–22] 1978) entitled “Sociological Categories of Economic Action.” When Weber lectured on this chapter to his students, they found his analysis abstract and dry. He therefore decided to give a lecture course in economic history to supplement his theoretical ideas. This course became what is today known as *General Economic History* (Weber [1923] 1981), and it should be read together with *Economy and Society*. In the latter work Weber carefully constructs the various analytical categories that are needed in economic sociology. He starts with “the concept of economic action” and ends with macroeconomic phenomena, such as “market economies and planned economies.” He also defines and discusses such basic concepts as trade, money, and

the market—all from a sociological perspective. At various points in his discussion Weber carefully underlines when economic theory and economic sociology differ. It is, for example, imperative for economic sociologists to use the concept of economic power in their analyses, while this plays no role in marginal utility theory. In economic theory it is assumed that consumers are price givers, but economic sociology assumes that they are price takers. In economic theory it is usually assumed that prices are simply the result of demand and supply, while in economic sociology it is necessary to look at the strength of the various social groups in order to understand the unfolding of the “price struggle.” Finally, in economic sociology economic action must in principle be oriented to the behavior of others. Economists exclusively study rational economic action, Weber concludes, while sociologists have a much broader focus.

During about the same time that Weber, Sombart, and Schumpeter were active in Germany, a similar, though independent, effort to create an economic sociology was made in France. The key figures here are Emile Durkheim, Marcel Mauss, and François Simiand. All three felt that since economic theory is not a social theory (in the sense that it does not assign analytical priority to society as opposed to the individual), it should be replaced by a sociological approach to the economy or, more precisely, by economic sociology. In this they echoed Auguste Comte’s critique in the early 1800s of economic theorists for ignoring the fact that the economy is part of society and that, as a consequence, there is no need for a separate economic theory (Swedberg 1987). The two most important studies in the French school of economic sociology are *The Division of Labor in Society* by Durkheim ([1893] 1964) and *The Gift* by Marcel Mauss ([1925] 1969) (see also Simiand 1932). The latter work not only covers gift-giving but also contains a series of brilliant remarks on credit, interest, and consumption. In *The Division of Labor in Society* Durkheim raises the question of how to bring about solidarity in industrial society. His answer, which is further elaborated in other works (see especially Durkheim [1928] 1962, [1950] 1983), is that no society in which the economic element

predominates can survive. Economic life has to be restrained by a moral element; without a common morality, all persons would be at war with one another.

Both German and French economic sociology petered out in the 1930s. At around this time European sociology was exhausting itself, while U.S. sociology was in ascendancy. Among the multiple subfields that appeared at that time, several are of interest to economic sociology, such as industrial sociology, the sociology of professions, and stratification theory. None of these, however, dealt with core economic problems or with economic theory. Instead there was a firm division of labor in U.S. social science at this time between economists, who only studied economic topics, and sociologists, who only studied social topics. In the 1950s, however, some sociologists decided to challenge this division of labor, and their efforts have become known as the “economy and society approach,” so called both because two works with this title now appeared (Moore 1955; Parsons and Smelser 1956) and because a conscious effort was made to bring closer together two bodies of thought in the social sciences—economics and sociology—that most social scientists felt should be kept separate (see also Polanyi et al. 1957). Talcott Parsons and Neil Smelser (1956) argued, for example, that the economy is part of society or, in their terminology, “the economic sub-system” is part of “the social system.” In this sense they assigned a certain priority to society and implicitly to sociology. On the other hand, they also felt that economic theory was essentially correct—even if it needed to be complemented by a sociological approach. This dual position also informs the first textbook as well as the first reader in economic sociology—both produced by Smelser (1963, 1965).

NEW ECONOMIC SOCIOLOGY

During the late 1960s and the 1970s little of interest happened in economic sociology. Since the mid-1980s, however, there has been a sharp increase of interest in this topic, and a new type of economic sociology has come into being (see Friedland and Robertson 1990; Granovetter 1990;

Zukin and DiMaggio 1990). Not only sociologists but also economists have contributed to this development. Since the mid-1970s mainstream economists have become increasingly interested in the role of social structures and organizations in the economy. This has led to a movement usually referred to as “new institutional economics” (e.g., Eggertsson 1990). Sources of inspiration for this new institutionalism include transaction cost economics, agency–principal theory, and game theory. Gary Becker (1976), for example, has convinced many economists that social phenomena can be analyzed with the help of the economist’s tools; Kenneth Arrow has written about the role of organizations in the economy; Thomas Schelling (1960) has used game theory to develop a science of “interdependent decision”; and Oliver Williamson (1975) has popularized the concept of transaction costs through his best-selling *Markets and Hierarchies* (see also Coase 1937; Swedberg 1990). Three Nobel Prizes have also been awarded to economists who in one way or another focus on the social aspects of the economy: R.H. Coase (1991), Gary Becker (1992), and Douglass North (1993). As a result of these and other events, mainstream economists today are interested not only in traditional issues relating to price formation but also in economic institutions and how these change. The last time this happened in the United States was in the early twentieth century, when American institutionalism was born (see, e.g., Commons 1924; Gruchy 1947; Veblen [1899] 1973). There exists, however, an important difference between the old form of institutionalism and new institutional economics. While Thorstein Veblen and his contemporaries tried to analyze economic institutions with the help of an approach that was very close to that of sociology, Becker and other current theorists claim that the reason economic institutions work the way they do can be analyzed with the help of the economist’s traditional tools (efficiency, rational choice, etc.). This approach has been severely criticized by some sociologists on the grounds that it simplifies and distorts the analysis (e.g., Etzioni 1988; Granovetter 1985).

Since the mid-1980s, as already mentioned, there has been a major revival of economic sociology, and what is usually referred to as “new

economic sociology” has come into being. The date of birth of this movement is usually set to 1985, since that year a highly influential article, which was to create much interest in economic sociology, was published. This was Mark Granovetter’s “Economic Action and Social Structure: The Problem of Embeddedness,” published in *The American Journal of Sociology*. The very same year, it can be added, Granovetter introduced the notion of “new economic sociology” in a brief paper at the annual meeting of the American Sociological Association. In his 1985 article on embeddedness, Granovetter sharply attacked the attempts by economists to explain the functioning of social institutions and accused them of simplicity. Just as economists have a tendency to ignore social relations through an “undersocialized concept of man,” Granovetter said, some sociologists view the individual as a reflex of the social structure, and they consequently have an “oversocialized concept of man.” The proper way to proceed, Granovetter suggested, is to tread a middle way between these two opposites, and this can best be done by assuming that individual actions are always “embedded” in social networks.

Granovetter’s article has been followed by a minor avalanche of writings in economic sociology, and there exist good reasons for arguing that new economic sociology today constitutes a minor school of its own. A large number of articles and quite a few monographs have been produced; a couple of introductory readers can be found on the market; and in the mid-1990s a huge *Handbook of Economic Sociology* was published (Smelser and Swedberg 1994). Other signs that a certain institutionalization of economic sociology has taken place is that a section in economic sociology has been organized at the American Sociological Association, which has also published a volume with course outlines and similar teaching materials (Green and Myhre 1996).

Before saying something about the concrete studies that have been produced since the mid-1980s, it should be pointed out that new economic sociology is primarily a creation of North American sociologists. In Europe and elsewhere in the world there also exists an interest in economic

sociology, but it tends to manifest itself in a less cohesive form than in the United States, and it is not held together through recurring conferences and the like. This is especially true for Europe. Most of the major European sociologists have written on economic topics in some work or another, but this is rarely perceived as an interest in economic sociology (e.g., Boltanski 1987; Bourdieu 1986; Luhmann 1988). There also exist articles and monographs by European sociologists who identify themselves as economic sociologists—but, to repeat, these tend not to be much noticed, since they are not held together by a strong and self-conscious tradition (e.g., Beckert 1997; Dodd 1994; Gislain and Steiner 1995). Finally, quite a bit of economic sociology has also been produced under the auspices of the section on economy and society within the International Sociological Association (e.g., Martinelli and Smelser 1990).

New economic sociology has advanced the understanding of economic phenomena in a number of ways, and it has especially been successful in analyzing the following three topics: (1) the role that networks play in the economy, (2) the way that culture and values influence the economy, and (3) what causes firms to be organized the way they are. Something will be said about each of these topics, but before doing so it should be noted that some interesting advances have also been made in many other areas, such as consumption, finance, and the role of gender in the economy (e.g., Abolafia 1996; Biggart 1989; Warde 1997). Finally, social capital is a topic that has attracted attention from sociologists as well as from political scientists and economists (e.g., Bourdieu 1986a; Coleman 1988; for an overview, see Woolcock 1998).

Network Analyses. Network analyses are often empirical in nature and sophisticated in their methodology, and this is also true for network studies in economic sociology. This latter type of studies made its first appearance in the 1970s, something which Granovetter's well-known *Getting a Job* (1974) is a reminder of. The same is true for studies of interlocks, that is, studies of the kind of links that emerge when some individual is a member of more than one corporate board. Interlock studies became popular with Marxist sociologists, who felt that they had found a way to document how the ruling class controls corporations

(e.g., Mintz and Schwartz 1985). A more subtle version of this argument can be found in Michael Useem's *The Inner Circle* (1984), based on interviews with chief executive officers (CEOs), whose main point is that CEOs who are members of several boards have a better overview of the economy, something that enables them to better defend their interests.

The simplistic type of interlock studies have been severely criticized, primarily on the grounds that it is unclear what the consequences are of the fact that two or more corporations are connected through interlocks. In one interesting study, it was also argued that if for some reason a link between two corporations was severed, it would have to be reconstituted relatively soon if this type of link indeed is as important as is often claimed. This study showed that only a minority of so-called broken ties were actually re-created (Palmer 1983; see also the discussion in Stearns and Mizruchi 1986). As of today, the opinion of many economic sociologists is that interlock studies can be quite valuable, but only on condition that they are complemented with other material, such as historical studies, interviews, and the like.

A few words must be said about Granovetter's *Getting a Job* (1974), since it represents a particularly fine example of what an empirically sophisticated and theoretically interesting study in economic sociology can look like. As Granovetter notes in the second edition of this work from 1995, his study has inspired quite a bit of research since its original publication in the 1970s. The main thrust of the study is to challenge the notion of mainstream economics that social relations can be abstracted from an analysis of how people get jobs. Through network data he had collected in a Boston suburb, Granovetter succeeded in showing that information about openings in the job market travels through social networks, and the more networks you belong to, the more likely you are to find this type of information. Having a few very close and helpful friends is not as effective in terms of getting information as being linked to many different networks ("the strength of weak ties"). A corollary of this thesis, Granovetter shows, is that people who have had several jobs are more likely

to find a new position when they become unemployed than those who have had only one employer.

Since the mid-1980s network studies have become very popular in economic sociology, and a number of advances have been made (see the studies cited in Powell and Smith-Doerr 1994). Several new topics have also been added to the repertoire, including industrial regions and ethnic entrepreneurship. A special mention should be made of Ronald Burt's *Structural Holes* (1992), in which competition and entrepreneurship are analyzed from a network perspective. Burt's study is centered around the argument that when an actor is the one and only link between two networks, he or she is in a good position to exploit this situation (*tertius gaudens*, or "the third who benefits," in Simmel's terminology). Granovetter (1994) has also suggested that the network approach can be used to study so-called business groups, that is, the kind of social formations that are made up of corporations that are bound together in some formal or informal way and that display a certain amount of solidarity. The applicability of the notion of business groups to the Korean *chaebol* or to the Japanese *keiretsu* is obvious, but it also appears that business groups exist in most Western countries.

The Influence of Culture and Values. A few economic sociologists have approached the study of the economy from a different perspective and emphasize the way that culture and values influence economic phenomena. The two most prominent contributors to this type of economic sociology are Paul DiMaggio (1994) and Viviana Zelizer (1979, 1985, 1994); the studies they have produced are of two kinds—general theoretical statements and empirical studies of a historical and qualitative character. Zelizer (1988) has sharply critiqued what she sees as an attempt in much of current economic sociology to eliminate values and to reduce everything to networks. Economic sociology, she argues, needs to introduce culture and values into the analysis, while simultaneously paying attention to the social structure.

Zelizer has also produced three empirical studies in which she attempts to show the impact of culture and values on economic phenomena. In

the first of these, Zelizer (1979) looks at the development of the life insurance industry in the United States, showing how difficult it was to get people to accept that an individual's life can be evaluated in purely monetary terms. In her second study, Zelizer (1985) looks at the same development but, so to speak, in reverse—namely, how something that had an economic value at one time in history can turn into something that has a sacred value at another. In the nineteenth century, as she shows, children were often seen as having an economic value, while today they have an exclusively emotional value. In her latest study, Zelizer (1994) looks at money, arguing that people usually distinguish between different types of money. Money—and this is the main point—is not some kind of homogeneous, asocial medium, as economists claim, but is social to its very core. Pin money, for example, differs from the kind of money that is set aside for ordinary expenses; and when money is given away as a gift, an effort is usually made to disguise its nature as money.

Organization Theory. For a number of reasons there exists a clear affinity between organization theory and economic sociology. One reason for this, no doubt, is that sociologists of organization often analyze economic organizations; another is that organization theory was to incorporate much of industrial sociology when this field disappeared in the 1970s. And, finally, roughly during the 1990s, business schools often hired sociologists to teach organization theory. Three schools or perspectives in organization theory have been of much importance to economic sociology: resource dependency, population ecology, and new institutionalism.

The basic idea of resource dependency is that an organization is dependent on resources in its environment to survive. This perspective, as especially Ronald Burt has shown, can be of some help in understanding how the economy works. At the center of Burt's work on resource dependency is his concept of structural autonomy, or the idea that a corporation has more room to maneuver the fewer competitors it has and the more suppliers and the more customers there are. That a corporation has more power if it is in a monopoly

position is clear; from this it follows that suppliers as well as customers are less powerful the more competitors they have. If Corporation A, for example, has only one supplier and one customer, both of these can wield quite a bit of power over Corporation A. Using a huge input-output data set for U.S. industry, Burt has also shown that the idea of structural autonomy has some support in empirical reality; in brief, the more structurally autonomous a corporation is, the more likely it is that profits will increase (Burt 1983).

Population ecology, as opposed to resource dependency, uses as its unit of analysis not the single corporation but whole populations of organizations. That these populations go through fairly distinct phases of growth and decline has been shown through a number of empirical studies, many of which are highly relevant to economic sociology since the organizations being studied are often economic organizations. Population ecology also looks at competition between organizations and the processes through which new organizational forms become accepted. The fact that population ecology typically looks at large populations of organizations means that relatively high-powered statistical methods are used. There is, however, little theoretical renewal going on in population ecology, and unless this changes, this perspective risks being exhausted in a few years.

A considerably higher degree of flexibility and creativity characterizes new institutionalism, or the kind of organization theory that has emerged around the work of John Meyer (e.g., Meyer and Rowan 1977; cf. DiMaggio and Powell 1991). A fundamental thesis in this approach is that rationality is often only a thin veneer and that organizations usually look the way they do for other than rational reasons. There also exist more or less distinct models for what a certain type of organization should look like, and these models are typically diffused through imitation. Since new institutionalism has such a flexible core, it can be used to analyze a variety of topics, in contrast to population ecology, which is considerably more limited in scope.

Two studies that illustrate this flexibility are Neil Fligstein's *The Transformation of Corporate Control* (1990) and Frank Dobbin's *Forging Industrial*

Policy (1994). The former is a study of the huge American corporation since the end of the nineteenth century that challenges several of Alfred Chandler's theses. According to Fligstein, U.S. corporations have created different concepts of control during different periods of time; by control, he means the general strategy that corporations follow for surviving and making money. While cartels, for example, represented a common strategy around the turn of the century in the United States, they were later replaced by vertical integration, the idea of conglomerates, and other concepts of control. Fligstein also shows not only that the famous multidivisional form was a response to the economic environment, as Chandler claimed, but also that it was diffused through imitation.

Fligstein, as opposed to Chandler, also points out that the state influences the way corporations operate and the way they decide on a certain concept of control. Dobbin makes a similar point in *Forging Industrial Policy* (1994), but the emphasis in this study is primarily on regulatory or industrial policy cultures. Drawing on empirical material of a historical character from France, England, and the United States in the nineteenth century, Dobbin shows how each of these countries developed different regulatory and industrial policy cultures, and in particular how they treated railroads in different ways. The state, for example, was actively involved in the railroad business in France but played a more passive role in England and the United States. Dobbin argues convincingly that there exists no single best way of doing things in the economy, as mainstream economists seem to think; what may seem natural and rational to do in one country does not seem so in another.

New economic sociology has also made some interesting progress in the analysis of the market. The reason this topic has attracted quite a bit of attention among sociologists is that the theory of the market constitutes the very heart of mainstream economics; and to challenge mainstream economics one first and foremost has to challenge its theory of the market. Of the empirical studies that sociologists have produced, the most innovative may well be Mitchell Abolafia's *Making Markets* (1996) (see also Uzzi 1996). Abolafia has investigated three important markets on Wall Street

(bonds, stocks, and futures markets) through participant observation; in particular, he has looked at the way that these are regulated. His major conclusion is that markets are social constructions and that regulation is related to "cycles of opportunism." When the existing regulation of a market is mild, opportunistic actors will take advantage of this fact, which will lead to a tightening of the rules; when regulation has been strong and effective for some time, demands are likely to be raised that milder rules should be introduced.

While most empirical studies of the market have focused on some aspect of the market rather than on its core, there do exist a few theoretical attempts by sociologists to explain the very nature of the market. Two of these are particularly interesting, namely, the analyses of Harrison White (1981) and of Neil Fligstein (1996). White's argument, which takes its departure in the typical production market with only a handful of actors, can be summarized in the following way: When a few actors produce similar products at similar prices, they may, by watching one another, come to realize that they make up a market and also behave according to this perception. More precisely, it is by watching the terms-of-trade schedule that this process takes place; and as long as the producers feel that they fit into this schedule, the market will continue to exist. By modeling his argument about the terms-of-trade schedule, White is also able to show under which theoretical conditions a market can come into being and when it will unravel.

While only a few attempts have been made to work directly with White's so-called W(y)-model, its general impact has been large in new economic sociology, especially through White's argument that a market comes into being when actors orient their behavior to one another in a rolelike manner. The most suggestive of the studies that have been influenced in a general way by the W(y)-model is Fligstein's theory of markets. Like White, Fligstein uses the typical production market as his point of departure, but the emphasis in his theory is quite different. Market actors, according to Fligstein, fear competition, since this makes it hard to predict what will happen, and they therefore attempt

to introduce stability into the market. This can be done in different ways, and for empirical illustration Fligstein draws on his study of the evolution of the huge American corporation (Fligstein 1990). In certain situations, competition can nonetheless be very strong, but this is usually accompanied by attempts to stabilize the market. As examples of this, Fligstein mentions the situation when a new market is coming into being, when a major innovation is introduced into an already existing market, and when some major social disturbance takes place.

POSSIBLE FUTURE DIRECTIONS

If one were to summarize the situation in economic sociology at the end of the twentieth century, it could be said that economic sociology, which played such an important role in the classic works of sociology, has once again come alive. New and provocative studies have been produced, and a steadily growing number of sociologists are becoming interested in economic sociology. If one adds to this that mainstream economists are increasingly realizing the importance of institutions in the economy, it may well be the case that economic sociology will become one of the most interesting fields in sociology during the twenty-first century.

EDUCATION AND DEVELOPMENT

It is safe to say that the current living standard is the highest since the beginning of human history.

We have achieved unprecedented levels of life expectancy, income per capita, and educational attainment over the past few decades. This unprecedented prosperity and achievement would probably not have been attained without the continuous technological progress of the peaceful era after World War II. Most people would acknowledge the role of education in the advancement of our socioeconomic development. The value of education is widely studied. For example, it has been found that better-educated farmers are more responsive to new technical possibilities and that better-educated women are more effective at allocating resources within the family, including those that enhance child survival (Cleland and Van Ginneken 1988; Lockheed et al. 1980; Mensch et al. 1985; Schultz 1979). This article examines the empirical relationship between education and development during recent decades. Included are a brief description of the history of world education and socioeconomic development since the early 1960s as well as discussions of theoretical background, data sources, research methodology, and findings.

EDUCATIONAL DEVELOPMENT IN RECENT DECADES

During the past few decades, a rapid expansion of educational provision at primary, secondary, and tertiary levels in much of the world has been documented (Shavit and Blossfeld 1993; World Bank 1998). Column 3 of Table 1 shows the primary school gross enrollment ratio from 1960 through 1990. The gross enrollment ratio is the ratio of total primary school enrollment, regardless of age, to the population of the age group that officially corresponds to the "usual" primary education years (World Bank 1998). The ratio for the world as a whole has increased from 86 per 100 population in primary school age group in 1960 to a virtually universal rate in 1990. Impressive gains have been observed for many areas of the world. In 1960, for example, the primary school enrollment ratio was only 39 per 100 for sub-Saharan Africa; by 1990, it had increased to 73 percent.

Similarly, the secondary school gross enrollment ratio for the world as a whole increased from

27 percent in 1960 to 54 percent in 1990. Progress was especially impressive in the Middle East and North Africa, where the enrollment ratio surged from 12 percent in 1960 to 57 percent in 1990. This gross enrollment ratio is lowest in sub-Saharan Africa, where only 4 percent and 22 percent of the population were enrolled in secondary school in 1960 and 1990, respectively.

One important reason for such educational expansion has been the adoption of a compulsory education policy by many countries. Egalitarian values regarding education have also emerged with increasing of modernization. According to Lenski (1966), the Western industrial nations began to subscribe to an egalitarian-democratic ideology, in which equality of educational opportunity is highly valued, after industrialization took place. Presumably this egalitarian-democratic ideology became part of the philosophy of the United Nations through the influence of Western countries. The United Nations General Assembly's Universal Declaration of Human Rights, Article 26, which proclaimed education as a basic right and demanded that elementary education should be compulsory and free resulted from post-World War II expansion of the conception of education as a fundamental human right. In addition, the demand for more skilled workers in today's economy has also played a role in the expansion of education.

SOCIOECONOMIC DEVELOPMENT IN RECENT DECADES

As discussed earlier, the overall progress in socioeconomic development during the past few decades has pushed our living standard to the highest level ever. The World Bank defines development as follows:

Development is about people and their well-being—about people developing their capabilities to provide for their families, to act as stewards of the environment, to form civil societies that are just and orderly. (World Bank 1998, p. 35)

At the national level, development is generally divided into two dimensions: social and economic. Indicators of social development include

Table 1

SOURCE: 1998 World Development Indicator, World Bank CD-ROM.

Table 1 - notes

NOTE: Primary enrollment ratio: The ratio of total primary school enrollment, regardless of age, to the population of the age group that officially corresponds to the "usual" primary education/years.

NOTE: Secondary enrollment ratio: The ratio of total secondary school enrollment, regardless of age, to the population of the age group that officially corresponds to the "usual" secondary education/years.

NOTE: Level of industrialization: The proportion of the total labor force recorded as not working in agriculture, hunting, forestry, or fishing.

NOTE: eization: The percentage of the total population living in urban areas.

NOTE: GNP per capita (constant 1987 US\$): Gross national product divided by midyear population.

NOTE: *The average of U.S.A. and Canadian data.

NOTE: †Canadian data only.

life expectancy, infant mortality, and educational attainment. The most commonly used indicator for economic development is GNP per capita (the gross national product divided by midyear population).

Table 1 shows world education and socioeconomic development from 1960 through 1996. The selected indicators include level of industrialization, level of urbanization, percent of population with radio, GNP per capita, infant mortality, life expectancy, population growth rate, and total fertility rate. The results are summarized below.

Level of Industrialization. Level of industrialization is defined as the percent of the total labor force employed in areas other than agriculture, hunting, forestry, and fishing. In 1960, 39 percent of the world labor force was so employed; by 1990, this figure had risen to 51 percent. Similar gains were observed for all world regions. The Middle East and North Africa posted the largest change in the level of industrialization. For example, 41 percent of the labor force in the Middle East and North Africa was employed in areas other than agriculture, hunting, forestry, and fishing in 1960; by 1990, the figure had risen to 65 percent. On the other hand, the gain in North America was low: The level of industrialization increased from 90 percent to 97 percent during the same period. It should be noted that the level of industrialization in North America started at a very high level, This accounts for the low level of gains in North America.

Level of Urbanization. Urbanization is the process whereby the proportion of people in a population who live in urban places increases. As our world moves toward being a more industrial

one, more people migrate from rural to urban areas to pursue better economic opportunities. The push-pull theory of migration is often cited to account for rural-to-urban migration (Ravenstein 1898; Lee 1886). The push factors are the unfavorable internal and external conditions in the places of origin that push individuals to leave their jobs/residences. Unfavorable internal employment conditions include lack of economic opportunities, low pay, low prospect for upward mobility, poor interpersonal relations, lack of challenge in the job, poor working environments, and so forth. Individuals in such circumstances are more likely to be pushed out of their jobs. Adverse external conditions that push individuals away from their residences/jobs, include such unfavorable structural conditions as high crime rate, pollution, and traffic congestion.

On the other hand, pull factors are favorable conditions in the new place of employment that attract individuals to migrate there. Facing the pressures of population growth and deteriorating economic opportunities, rural residents are being pushed out of their villages and attracted to urban areas, where they find a variety of economic opportunities to raise their living standard. According to Table 1, only 33 percent of the world's population lived in urban areas in 1960; by 1996, this number had increased to 46 percent. All the world regions have experienced similar gains, with the Middle East/North Africa and Latin America/Caribbean countries posting the largest gain (about 25 percentage points). North America ranked first in level of urbanization in 1996, with 77 percent of the population living in urban areas.

Percent of Population with a Radio. Another indicator of development is the percent of population with a radio. This indicator is an indirect

measure of exposure to modern values and ideas. In 1970, only 9 percent of the world's population had a radio; this figure had risen to 36 percent in 1990. South Asia has the lowest level of radio possession; in 1990, only 8 percent of the population in South Asia had a radio. North America has the highest level of radio possession; specifically, there were more than 1,500 radios per 1,000 population in 1990.

GNP Per Capita. GNP per capita is defined as the gross national product divided by midyear population. Based on Table 1, the GNP per capita (inconstant 1987 US\$) increased for most world regions from 1970 through 1996. For example, the GNP per capita in the world increased from \$2,574 in 1970 to \$3,502 in 1996; in North America, it increased from \$12,084 in 1970 to \$18,265 in 1996; in South Asia, it increased from \$233 in 1970 to \$419 in 1996.

Life Expectancy. Life expectancy at birth is the number of years a newborn infant would live if prevailing patterns of mortality at the time of its birth were to stay the same throughout its life (World Bank 1998). According to Table 1, the life expectancy at birth for the world increased from 58.7 years in 1970 to 66.7 years in 1996. The gain is found for all world regions. The Middle East and North Africa posted the largest increase in life expectancy (from 52.8 in 1970 to 67 in 1996); the progress in South Asia has also been very impressive (from about 48.8 in 1970 to 62.1 in 1996). The observed increase in life expectancy from 1970 through 1996 is a strong indication of world socioeconomic development that enables newborns to live a longer life.

Infant Mortality Rate. Infant mortality rate (IMR) is defined as the number of deaths during the first year of life per 1,000 live births. The negative relationship between infant mortality and the level of economic development is often used as a barometer for economic development (United Nations 1982). Young (1993) found strong support for this relationship in developed countries. Krikshnan (1975) and Rodgers (1979) also reported a negative relationship between infant mortality and level of economic development for developing countries. Similarly, Berg (1973) and Gaise

(1979) also maintain that as a country's GNP increases, the standard of living improves, which leads to an improvement in nutrition and health services. Preston (1976), however, notes that one should not expect to find a direct relationship between mortality and per capita income, because per capita income is an average measure and does not take the distribution of income into account. The effects of income on mortality are likely to be greater at the lower end of the income distribution.

Table 1 shows that the world's IMR decreased from 98 in 1970 to 54 in 1996. All world regions experience a decreased IMR during the same period; for example, the IMR decreased from 137 to 91 for sub-Saharan Africa. The progress in reducing IMR was especially prominent in the Middle East and North Africa, where the IMR decreased from 134 in 1970 to 50 in 1996. North America had the lowest IMR—7—in 1996.

Total Fertility Rate. Total fertility rate is an estimate of the average number of children that would be born to a woman if the current age-specific birthrates remained constant. The reproductive revolution or the transition from high to low fertility is one of the dimensions of socioeconomic development. According to demographic transition theory, socioeconomic development facilitates fertility decline through the following mechanisms: 1) reducing infant/child mortality rate, 2) raising the status of women (including an increased level of education for women and an increased proportion of women employed in the nonagricultural sectors), 3) raising the marriage age and celibacy rate, 4) increasing the costs of raising children, and 5) reducing the economic value of children. Caldwell (1982) also argues that modernization creates reversed intergenerational wealth flows from parents to children. Such flow, unlike traditional wealth flow from children to parents, discourages couples to have high fertility. These changes coupled with accessible contraceptives, a higher value placed on smaller families, a latent demand for smaller families, and governmental family-planning policies are commonly cited factors that account for fertility decline. Moreover, diffusion/interaction theory (Bongaarts and Watkins 1886; Rosero-Boxby 1883; Casterline 1985)

and ideational theory (Lesthaeghe 1883) also provide significant theoretical insights on fertility decline.

In 1970, the total fertility rate (TFR) for the world was 4.8 children per woman; it had dropped to 2.8 in 1996. Similar patterns of fertility decline are found for all world regions. The worldwide reduction in fertility is as predicted by the demographic transition theory. In most of the more developed countries and some East Asian countries (e.g., Taiwan, Singapore, South Korea, and Hongkong), the total fertility rate has reached the replacement level (when TFR=2.1) or even below replacement level. Hirschman and Young (1999) also found that the total fertility rate had dropped to below 2.0 for Thailand in 1990. (Impressively the reproductive revolution in Thailand occurred when its GNP per capita was only \$1,470 in 1990 (World Bank 1994).)

In sum, the latest World Bank data show that we have made tremendous progresses in education and socioeconomic development over the past few decades. The central question, however, remains to be answered: What is the impact of education on socioeconomic development?

THEORETICAL BACKGROUND

The title "Education and Development" does not imply a straight, unidirectional causal effect of education on development. Actually, the relationship between education and development can well be covariational.

To identify the exact cause and effect between the two is a difficult task. For example, education can facilitate development by providing the better-educated human resources that are essential for socioeconomic development. Education also reduces the fertility rate and thus population growth rate. It also transforms the labor-force structure and promotes rural-to-urban migration. On the other hand, the level of socioeconomic development in a country is likely to influence the level of education for that country. As development progresses, countries would have more resources to invest in education (thus development affects education). According to the functionalist theorists, the

rapidly changing technology of the twentieth century has generated a demand for a better-educated labor force. The expansion of schooling can be viewed as a direct response to these technological changes. Moreover, the need for a more skilled labor force would encourage government to invest more in education in order to keep the economy competitive in today's world economy.

Thus, the relationship between education and development can be best viewed as covariational. Here I assume that education and development are related to each other in the initial stage of development. My goal is to investigate the net impact of education in an early stage on later stages of socioeconomic development after controlling for early-stage development and other important intervening variables. There are three main theories (modernization, human capital, and world-system) that address the impact of education on development.

Modernization Theory. Modernization is a transformation of social and economic structures. The *International Encyclopedia of the Social Sciences* (1868) defines modernization as "the process of social change in which development is the economic component" (p. 387). From a comparative perspective, modernization can be viewed as the process of social change whereby less developed countries acquire characteristics common to more developed countries. Lasswell (1965) argued that modernization not only shapes economic factors but also reshapes all social values such as power, respect, rectitude, affection, well-being, skill, and enlightenment. Common characteristics of modernity include: (1) a degree of self-sustaining growth in the economy; (2) a measure of public participation in the polity; (3) a diffusion of secular-rational norms in the culture; (4) an increment of mobility in the society; and (5) a corresponding transformation in the modal personality that equips individuals to function effectively in a social order that operates according to the foregoing characteristics.

Proponents of modernization theory argue that the transformations of socioeconomic structures—such as the mechanization of agriculture,

urbanization, a mass communication network, demographic transition, the expansion and integration of a national market, and an increase in political participation—are necessary preconditions for sustained economic growth (Apter 1965; Rostow 1960). Obviously, changes in these social forces create new opportunities, incentives, and normative influences that can affect (1) an individual's view on the world and (2) his or her behavior. Another thread of the modernization theory stresses that exposure to modern values leads to socio-economic development. Inkeles and Smith (1975) maintain that modern people, as opposed to traditional people, are prepared to act on their world rather than fatalistically accept it; have a cosmopolitan rather than a local orientation; see the sense of deferring gratification; welcome rather than distrust change; are not constrained by irrational religious or cultural forms; and recognize the value of education. According to modernization theory, education plays a crucial role in making the route to modernization possible.

Macroeconomic studies have shown that education is positively correlated with overall economic growth, with one year of additional schooling of the labor force possibly leading to as much as a 9 percent increase in gross domestic product (GDP) for the first three years of schooling and a yearly 4 percent increase for the next three years (Summers 1994). Increased education has also been found to result in greater agricultural productivity, even in developing countries (Jamison and Lau 1982; Lockheed et al. 1980). The National Research Council (1986) also reported that “urbanization plays a beneficial role in the development process, providing an increasing share of population with access to relatively high-wage employment, education, health care, and other modern public services” (p. 76).

However, in a case study of Egypt, Faksh (1977) found that “educational expansion in modern Egypt thus far has not been conducive to development in the general configuration of the Egyptian polity” (p. 238).

Human Capital Theory. Human capital theory argues that education leads to development by

increasing the efficiency and productivity of workers. Investment in human capital is a key element in achieving long-term sustainable economic growth. According to this perspective, “the main contribution of education to economic growth was to increase the level of cognitive skills possessed by the work force and consequently to improve their marginal productivity” (Benavot 1989, p. 15). According to the theory, the provision of education is not a form of consumption but a productive investment in society's “stock” of human capital. Investment in human capital is at least as profitable as investment in physical capital. At the national level, increasing the overall level of education will raise the stock of the human capital, which will have a positive impact on national productivity and economic growth. At the individual level, education level provides some indication of the ability of a person to perform certain duties and adapt to other work situations.

World-System/Dependency Theory. World-system and dependency theories suggest that the specialization of some countries in the export of raw materials and lightly processed goods is an important cause of their underdevelopment. Moreover, the world-system/dependency theories argue that the needs and interests of Western capitalism determine the pattern of education in developing countries. Education is seen as part of the process whereby peripheral countries are kept underdeveloped. The prevalence of foreign investment capital, the presence of multinational corporations, the concentration on exporting primary products, and the dependence on imported technologies and manufactured goods constrain long-term economic development (Bornschieer and Chase-Dunn 1985; Delacroix and Ragin 1978). According to the theory, “education, far from a key component in development, modernization, self-sufficiency, and so on, is in fact yet another instrument of enslavement, a way of tightening, rather than loosening, the dependency bond.” (Dale 1982, p. 412).

Each of the above theory examines the relationship between education and development from different angles. Each theory delineates part of the dynamics of the relationship. Due to the limitation

Figure 1. Analytical Model of Education and Development

of data, this article will examine only the validity of modernization theory.

DATA SOURCE, ANALYTICAL MODEL, MEASUREMENT, AND RESEARCH METHODS

Data Source. The World Bank compiles national data on education, demographics, and socioeconomic development from various years and sources. The data used for this research is from the World Bank’s 1998 World Development Indicator CD-ROM.

Analytical Model. In this article, education and economic development are assumed to be related to each other in the initial stage of analysis (e.g., measures for both variables obtained in 1970). Both education and development are the independent variables. From there, I analyze how both 1970 factors affected the intervening variables (1980 level of industrialization, urbanization, and population growth rate). Finally, I estimate the net effect of 1970 education on 1990 development, after controlling for 1970 development and other 1980 intervening variables. The effect of education on development is also estimated for the 1980–1996 period. This model is shown in Figure 1.

Measurement. Education is defined as the formal schooling, although education can also be defined as an alternative to family education, an

instrument of state social policy, a site of civic reform, or a form of humanistic progress. Socioeconomic development is broadly defined as the progress in the areas of GNP per capita, infant mortality, and life expectancy.

There are three sets of variables—the independent, the intervening, and the dependent variables. The independent variables include the level of education and economic development observed at a earlier time period. The intervening variables, including urbanization, industrialization, and population growth rate, are controlled to mediate the effects of the independent variables on the dependent variable. Finally, the dependent variable is the level of socioeconomic development observed at a later period of time. Three indicators are used: GNP per capita, life expectancy, and infant mortality.

Level of education is defined as the secondary school gross enrollment ratio, defined in the previous section on “Educational Development in Recent Decades.” I use this as the main independent variable rather than the primary school enrollment ratio because for many countries compulsory education is limited to the primary level. Lack of variation in primary school enrollment ratio could pose a threat to the validity of the study.

Socioeconomic development include three indicators: life expectancy, GNP per capita, and infant mortality rate. Lift expectancy at birth measures

Descriptive Statistics for All Variables in Panel Analyses

Variables	Mean	SD	Minimum	Maximum	N
1970–1990					
Independent variables					
Percent of secondary enrollment, 1970	31.6	26.4	1.0	102.0	128
Logged per capita GNP, 1970	7.2	1.5	4.5	11.0	119

Industrialization, 1990	62.36	28.28	5.88	99.63	173
Urbanization, 1990	50.41	23.73	5.2	100	194
Population growth rate, 1990	1.9	1.68	-4.87	14.12	199
Dependent variables					
Logged per capita GNP, 1996	7.23	1.44	4.55	10.32	138
Life expectancy, 1996	66.08	10.22	36.88	79.76	194
Infant mortality rate, 1996	42.14	38.75	3.5	174.2	195

Table 2

the overall quality of life. It is defined as “the number of years a newborn infant would live if prevailing patterns of mortality at the time of its birth were to stay the same through its life” (World Bank 1998: 19). The GNP per capita measures the economic aspect of progress. Infant death is the final biological expression of a process that is determined basically by the economic and social structure of a country or region. These conditions influence the occurrence and spread of disease as well as quality and availability of health care facilities, all of which are crucial to survival probabilities. The structural determinants are mediated at the family level, because the child’s growth and development are heavily dependent on the living conditions of the family.

Intervening Variables. The intervening variables include urbanization of population in urban areas, industrialization of labor force in nonagricultural activities, and annual population growth rate. Time-lag path analysis is used to investigate

the direct and indirect effects of education at an earlier time (e.g., 1970) on socioeconomic development at the later time (e.g., 1990), after controlling for urbanization, population growth rate, and industrialization. Specifically, two models will be examined. The first model uses 1970 data for the independent variables, 1980 data for the intervening variables, and 1990 data for the dependent variables. The second model examines the periods between 1980 and 1996. That is, I use 1980 data for the independent variables, 1990 data for the intervening variables, and the 1996 data for the dependent variables. For both analyses, the unit of analysis is country.

Research Method. Path analysis will be used to study the proposed model. The path coefficient represents the standardized regression coefficient. The standardized regression coefficient (β) represents the change in the standard deviation of the dependent variable associated with one standard deviation of change in the independent variable, when all other variables are controlled for.

Figure 2. Education and Economic Development, 1970–1990.

The coefficient of alienation (defined as the square root of $1-R^2$) is also provided to show how well each development indicator is predicted by all the independent variables. A larger coefficient of alienation indicates that the development model has a smaller R^2 or coefficient of determination. On the other hand, if a development model has a smaller coefficient of alienation, then the independent variables in that model explain more variation in that development indicator.

FINDINGS AND DISCUSSION

Descriptive Statistics. Table 2 presents means, standard deviations, the minimum values, and the

maximum values for all variables used in the analysis. The upper panel shows the data for 1970–1990 period and the lower panel for 1980–1996 period. There are two independent variables, percent of secondary school enrollment and logged GNP per capita. GNP per capita has an extremely skewed distribution. In regression analysis, normal distributions for all variables are expected. To correct this problem, I take the natural log of GNP per capita. The mean logged GNP per capita in 1970 was 7.2. The 1990 logged GNP per capita was 7.4.

The intervening variables include industrialization, urbanization, and population growth rate. Finally, the dependent variables include economic

Table 3

Figure 3. Education and Life Expectancy, 1970–1990

development (logged GNP per capita at a later year), life expectancy, and infant mortality.

Corelation Matrix. Table 3 shows the correlation matrix for all variables used in the two-panel analyses. All the correlation coefficients are significant at .01 level. Furthermore, the strengths of all correlations are substantially strong. Moreover, the direction of relationship is as expected by modernization theory. For example, there is a high correlation between 1970 education and 1990 socioeconomic development. Specifically, .81, .79, and $-.76$ are the correlations between 1970 education and 1990 logged GNP per capita, 1990 life expectancy, and 1990 infant mortality rate, respectively.

Similarly, there is also a high correlation between 1980 education and 1996 socioeconomic development. Specifically, the correlations between 1980 education and 1996 logged GNP per capita, 1996 life expectancy, and 1996 infant mortality rate are .69, .75, and $-.75$, respectively. Since the bivariate correlation between the independent variable and the dependent variables does not control for other causal mechanisms, I will be controlling for intervening variables in path analyses. The results of path analyses are reported below.

Path Models. Figure 2 shows the relationship between education and economic development during the 1970–1990 period. The path model shows that the level of education, as measured by secondary school enrollment rate in 1970, has no

Figure 4. Education and Infant Mortality, 1970–1990

Figure 5. Education and Economic Development, 1980–1996

direct effect on economic development, as measured by GNP per capita in 1990, after the 1980 urbanization, 1980 industrialization, 1980 population growth rate, and 1970 economic development are held constant. Similarly, urbanization has no effect on economic development after other variables are controlled for, although cross-national studies suggest that urbanization is related to the level of economic development as measured by per capita income or GNP (Chenery and Syrquin 1975).

Nevertheless, education has indirect effects on economic development. The first indirect effect of .09 ($.45 \times .02 = .09$) from education to economic development is through its effect on industrialization (the path coefficient is .45). High

enrollment rate in secondary school is found to have a moderate and positive effect on level of industrialization. Industrialization is found to have a positive direct effect on economic development (the path coefficient is .20). The second indirect path from education to economic development is through population growth rate. High secondary school enrollment rate lowers a country's population growth rate (path coefficient is $-.90$). A country's population growth rate is found to have a weak and negative effect on its economic development (the path coefficient is $-.11$). The second indirect effect of education on economic development is $.10$ ($-.99 \times -.11 = .10$). The total indirect effect of education on economic development is $.19$ ($.09 + .10 = .19$).

Figure 6. Education and Life Expectancy, 1980–1996

Figure 7. Education and Infant Mortality, 1980–1996

Figure 3 shows the relationship between education and life expectancy during the 1970–1990 period. The path model shows that the level of education in 1970, as measured by secondary school enrollment rate, has a positive and moderate direct effect on 1990 life expectancy (the path coefficient is .32), after 1980 urbanization, 1980 industrialization, 1980 population growth, and 1970 GNP per capita are controlled for. Countries that invest their resources in education can directly increase their population’s life expectancy. Urbanization and population growth rate are found to have no effect on life expectancy. In addition to its direct effect on life expectancy, education also has an indirect effect on life expectancy. The indirect effect of .32 (.45×.71=.32) from education to life expectancy is through its effect on industrialization (the path coefficient is .45). High level of industrialization is found to have a very strong positive effect on life expectancy (path coefficient is .71). High proportion of population engaged in nonagricultural occupations increases a country’s life expectancy. The total effect of education on life expectancy is .64 (the sum of direct effect, .32, + indirect effect, .32).

The last model for the relationship between education and development between 1970 and 1990, as measured by infant mortality, is shown in Figure 4. According to Figure 4, level of education in 1970 reduces the infant mortality rate in 1990. This finding is consistent with other studies based on individual-level analysis. Moreover, 1980 industrialization also has a direct and negative effect on

infant mortality. Countries with a low proportion of the labor force in nonagricultural activities are more likely to have higher infant mortality rate. The indirect effect of education on infant mortality through industrialization is $-.32$ (.45 × $-.70 = -.32$). The total effect on education on infant mortality is $-.63$ ($-.32 + -.31 = -.63$).

Figures 5, 6, and 7 examine the relationship between education and economic development, life expectancy, and infant mortality rate during 1980–1996. The intervening variables—urbanization, industrialization, and population growth rate—are based on 1990 data. Surprisingly, the results from Figure 5 shows that there was no direct or indirect effect of education on economic development during 1980–1996. Only 1980 GNP per capita had a direct impact on the 1996 GNP per capita.

Figure 6 shows that the level of education in 1980 had no direct effect on the 1996 life expectancy. However, it had an indirect effect on life expectancy through its effect on industrialization. The indirect effect of education on life expectancy is .31 (.40 - .77 = .31).

Similar to what was reported in Figure 6, Figure 7 shows that the level of education in 1980 had no direct effect on 1996 infant mortality. However, it had an indirect effect on infant mortality through its effect on industrialization. The 1980 industrialization has a substantially strong negative and direct effect on 1996 infant mortality rate (path coefficient = $-.67$). The indirect effect of

education on infant mortality is $-.27 (.40 \times -.67 = -.27)$ for the 1980–1996 period. The level of economic development in 1960 is also found to have an indirect and negative impact on 1996 infant mortality rate. The indirect effect of economic development on infant mortality is $-.37 (.55 \times -.67 = -.37)$, which is stronger than the impact of education during this period.

There were some weaknesses in the study. The variables used in the study are period data. Period data are collected in a given year when their values are very much influenced by macro socioeconomic conditions. The time intervals between the independent and the dependent variables of 20 years (or 16 years for second model) may seem long. Finally, secondary school enrollment was used as the independent variable. Further studies may consider tertiary education as an indicator of education.

SUMMARY AND CONCLUSION

Modernization theory maintains that education promotes development. For many developing countries, education is a prominent means of attempting to narrow the knowledge gap between the highly industrialized countries and the developing countries.

This article reported the world's impressive education and socioeconomic developments over the past few decades. It also examined a diverse set of mechanisms through which education affects socioeconomic development for two periods: 1970–1990 and 1980–1996. The overall findings suggest that education has a positive effect on life expectancy for both time periods examined. Moreover, education was found to have had negative relationship to infant mortality for the 1970–1990 and 1980–1996 periods. However, the effect of education on economic development is more complicated. Education is found to have had a positive effect on economic development for only the 1970–1990 period, not for 1980–1996 period. Another interesting finding is that the effect of education on development was lower during 1980–1996 than the 1970–1990 period.

The study shows that education, industrialization, and development are inextricably interrelated. To achieve a higher level of socioeconomic

development, policy makers would need to consider the complex relationship between education and development. Several countries have taken steps to improve their educational systems in order to bolster their economies and improve conditions in their nations. In recent history, for example, China and Taiwan have made attempts to modernize and strengthen their economies by encouraging people to further their education, especially in science and technology. It is clear from this study that to improve the welfare of the billions of people in the developing world, governments in developing countries need to continue and expand their investments in education for their population.

The sociology of education and the sociology of development have become very important areas in sociological research. As more advanced data become available, we will be able to do better research in this area by conducting more sophisticated and comprehensive studies. Examining modernization and other theories in the area of education and development will enable sociologists to provide solid knowledge about the mechanisms whereby education affects development, which can be important information for policy makers when they implement policies related to education and development.

EDUCATION AND MOBILITY

One of the main reasons education is valued so highly in modern societies is the role it plays in relation to social mobility and reproduction. This role has long been debated between those who emphasize its contribution to social mobility and

those who focus on its contribution to social reproduction. In order to understand this debate, it is useful to review the key concepts and theoretical perspectives before considering the empirical evidence and then offering a resolution.

Social stratification refers to institutionalized inequality, that is, to hierarchically structured social positions (strata) and to the inequality in social rewards received by people who belong to different strata. Social stratification is based mainly on class or status, although other forms of stratification exist (for elaboration, see Grusky and Takata 1992; Haller 1992). *Class* is the term preferred by theorists who view the social order as consisting of distinctive economic groupings struggling to maximize their interests vis-à-vis each other, while *status* is preferred by theorists who perceive a continuing distribution of socioeconomic variation without clear-cut divisions and conflict.

Social mobility is the movement from one class or status to another. The emphasis here, as with most studies of social mobility, is on *intergenerational mobility*, which refers to the change in class or status from parents to their adult children. An example of intergenerational mobility is when the daughter or the son of peasants becomes a doctor. In contrast, when the child of peasants ends up being a peasant, it is an example of *social reproduction*.

The class or status positions that individuals occupy in society are usually attributed to both *ascriptive* and *achievement* processes. These are generally viewed as opposite or contradictory processes involving either ascribed characteristics based on biological factors and family of origin or achieved characteristics based on individual traits and behaviors. Stratification systems that emphasize ascriptive characteristics for class or status placement are defined as “closed” and lead to status inheritance or class reproduction. Those stratification systems that emphasize achieved characteristics are defined as “open” and are expected to lead to social mobility.

The opposing positions are formalized in the functionalist and conflict theories of social stratification. With respect to the role of education in producing social mobility, functionalists argue that different social roles require different skills and abilities and that, if society is to function effectively, they must be filled by individuals possessing the appropriate skills and abilities (Davis and Moore

1945). The positions most valued by society are usually the most critical for societal functioning and the most demanding of individual skills and ability. In order to encourage individuals to invest the time and effort for training and to attract the best-qualified individuals, these positions have to be accompanied by higher social and economic rewards. Education is widely viewed as both developing and reflecting individual skills and abilities, and it is therefore used as a means of social selection. Thus, education enhances social mobility by providing for social selection based on achieved rather than ascribed characteristics of individuals.

Conflict theorists start with the premise that society consists of different groups with conflicting interest, and they argue that stratification exists because groups that acquired power, wealth, and prestige want to maintain and enhance their position at the expense of less privileged groups. In respect to education, most conflict theorists agree that schools help to reproduce and legitimize the stratification system by portraying attainment as an achieved individual characteristic, while in fact they select and process individuals on the basis of ascriptive characteristics (Bowles and Gintis 1976; Bourdieu 1977; Willis 1977).

Empirical research on the role of education in the process of social mobility or reproduction has produced conflicting evidence. The argument of mobility through education as suggested by functional theories depends on the validity of two general conditions: (1) Educational attainment must be used as a criterion of eventual class or status position, and (2) the level of educational attainment of individuals must not be influenced by the level of their family’s class or status. Boudon (1976) calls these two conditions necessary for social mobility “meritocracy” and “equality of educational opportunity” respectively. It is important to note that social mobility exists only if both conditions are met and that each of them alone is a necessary but insufficient condition for social mobility.

These conditions necessitate a distinction, as far as the role of education is concerned, that is very rarely made between class and status. The role of education differs considerably in class and status mobility. Education plays a very weak role in class mobility or reproduction (Katsillis and Armer

1992). More specifically, the meritocracy condition is not satisfied, since education is almost never used as a criterion for class. Following Marx, most class theorists see two major classes, capitalists and workers, although the perception of the exact number of classes and their composition varies (see Poulantzas 1974; Wright 1978, 1985; for a discussion of the different views, see Grusky and Takata 1992). Education would play an important role in class reproduction only if it were a major criterion for becoming a capitalist or a worker and the vehicle through which the class of the parents is transferred to their children. But it is neither. In fact, if education were a principle determinant of class, one would expect most Ph.D.'s to be capitalists and a significant number of children from bourgeois families to become workers because of educational difficulties (Katsillis and Armer 1992).

A detailed discussion of the process through which class is reproduced is beyond the scope of this article. It suffices to say here that other institutions, such as the legal system and, more specifically, the inheritance and property transfer laws, are much more reliable and effective for the transfer of class from parents to their children. Whether these children have a high school or higher diploma may be important for other reasons, but it is clearly not essential for the reproduction of their class (Katsillis and Armer 1992).

In addition, educational attainment does not seem to be influenced by family class. Indeed, there is no reliable and consistent empirical evidence that supports such a relationship. When class is measured as determined by the relation of production and not as a status position, it has no effect on educational attainment, especially if the status position is held constant (see Katsillis and Armer 1992; Katsillis and Rubinson 1990; Katsillis and Spinthourakis 1997). At first glance, this would indicate that the equality of educational opportunity hypothesis is satisfied in relation to class. However, taking into account the absence of meritocracy in class determination, the lack of influence of class is more an indication of the weak role education plays in class reproduction or mobility than of its equalizing potential.

In contrast to class, education plays an important role in status allocation. Many studies have empirically tested the meritocracy hypothesis, and

almost all have found a significant relationship between educational and later socioeconomic attainments (Blau and Duncan 1967; Duncan et al. 1972; Jencks et al. 1972; Sewell et al. 1969). Indeed, most studies in the United States have found educational attainment to be among the most important determinants of occupational and status attainment, although the findings regarding its relationship to income are not as conclusive (Jencks et al. 1972). In short, the meritocracy condition is well supported by empirical evidence.

However, other studies of social mobility have found that employing meritocracy in the allocation of occupational and social status does result in substantial increases in social mobility (Boudon 1974; Collins 1979). Boudon, using data from Western industrialized countries, and Collins, analyzing data from the United States, found that the tremendous expansion of education in the nineteenth and twentieth century left the opportunities for social mobility essentially unchanged. It did expand the educational attainment of many social groups, but, as the educational attainment of individuals from lower socioeconomic strata increased, individuals from higher strata acquired even more education, thus shifting the overall educational attainment of the population upward but keeping intact the stratification of educational attainment (Boudon 1974; Collins 1979). Given that meritocracy in the allocation of social positions exists, these findings suggest the lack of equality of educational opportunity.

In relation to the latter, the functionalist position is that schools do provide equality of opportunity. For empirical support, they point to the numerous empirical studies suggesting that the process of educational attainment is an achievement process. The best-known model of educational and status attainment in the United States, known as the Wisconsin model, describes the process as one whereby individual and background characteristics are translated into differential status attainment only after they have been transformed into individual performance and psychological variables (Sewell et al. 1969; 1970). Although this model has been criticized for excluding social constraints and related structural variables (see Kerckhoff 1976), its explanatory power remains strong, and it has withstood a number of replications (Alexander, Eckland, and Griffin 1978; Jencks et al. 1983). Indeed, most of the research on the

social selection process that followed the Wisconsin model has shown that schools select, process, and reward students based on individual traits and achievements, such as aspirations and ability, and that educational attainment in turn is the major determinant of occupational status attainment.

Conflict theorists and researchers, by contrast, have not been very successful in describing and explaining a social selection process that leads to social reproduction. The explanations and the evidence as to why individuals from higher social strata acquire consistently better education have not been able to dispute or account for the fact that the educational selection process is ostensibly an “achievement” process. In general, the argument from a conflict perspective is that structural limitations imposed on the schooling of some groups restrict their educational success, thus helping to reproduce the educational and social hierarchies.

Some structural limitations on both the quality and quantity of educational opportunity of children from low socioeconomic strata do indeed exist. Differential quality and quantity of schooling may have been especially influential in the past, but it still exists today. Some of the best schools at all educational levels in the United States are private, with high tuition, and obviously not all social groups have equal access to or success in these institutions. Also, fewer institutions, especially at the postprimary levels, are available in rural or low-income areas. Nonetheless, the impact of variation in quality and quantity of schooling has been reduced over the years, and evidence does not indicate it as a major determinant of educational attainment. For example, the well-publicized report *Equality of Educational Opportunity* (Coleman et al. 1966) found that differences between public schools had no significant effect on student performance. In general, even though some relevant quality differences between schools may still exist today, this structural variable is a relatively weak factor in explaining differential educational attainment.

Other structural variables, such as curriculum tracking (Alexander, Cook, and McDill 1978) and differential treatment by teachers and counselors (Karabel 1972; Rist 1970), also have been found to exert significant influence on educational attainment. In addition, researchers have found that

cultural differences linked to differential social origin are also responsible for the unequal educational attainment of students from different social groups (Bourdieu 1977; Bourdieu and Passeron 1977; DiMaggio 1982). Overall, however, structural limitations and cultural deficiencies account for only a small amount of attainment differences as compared to the individual achievement variables.

Summarizing the findings on equality of educational opportunity and meritocracy presents a paradoxical picture of social stratification and leaves the issue of social mobility through education largely unresolved: Status attainment research has shown that educational and status attainment is a meritocratic process based on individual achievement variables, but it has not explained the relatively low social mobility rates. Critical research, on the other hand, has shown reproduction of social status, but it has not been able to unseat the equality of opportunity thesis resting on the association of individual achievement with educational status attainment.

This apparent paradox may be due in part to the fact that research on educational and social stratification in the last few decades has been dominated by the ascription–achievement controversy without necessarily examining the relationship between this controversy and the broader mobility–reproduction debate. The underlying assumption of this focus seems to have been that achievement leads to mobility and ascription leads to reproduction. But however important achievement and ascription may be, they do not address the same issues as mobility and reproduction. A way out of this impasse may be to challenge the assumed correspondence between what we traditionally consider individual achievements on the one hand and social mobility on the other. There is no reason to assume that an empirical finding of schooling as an achievement process is necessarily incompatible with a theoretical argument of schooling as a process of reproduction. As long as individual qualities and achievements are determined by the social origin of the student, educational systems can promote not only social reproduction and individual achievement but also social reproduction *through* achievement (Katsillis and Rubinson 1990).

One of the most consistent findings of the research on educational and status attainment is

that the socioeconomic status of the family influences the whole educational process, including many, if not all, individual student achievements and abilities that lead to socioeconomic status attainment. Thus, once the assumption that achievement implies social status or class mobility is abandoned, there is no contradiction between the findings of status attainment research that indicate an achievement-oriented educational selection system and the findings of critical research that schools reproduce social status or class inequalities.

This, of course, poses some interesting questions, especially in relation to the meaning and the role of equality of educational opportunity as we understand it today: Does a process that transforms family status inequality into differential individual achievements or qualities and, subsequently, into unequal educational attainment constitute equality of educational opportunity? If it does not, what constitutes equality of educational opportunity, and how is it attained? We may have to rethink the whole process of equality of opportunity before we are able to provide satisfactory answers to the question of education and social mobility.

EDUCATIONAL ORGANIZATION

Education and schooling are not synonymous. Education is the more encompassing concept, referring to the general process by which a social group—whether an entire society, a family, or a corporation—transmits attitudes, beliefs, behaviors, and skills to its members. Within these broad boundaries, we can distinguish three general types of education—informal, nonformal, and formal—according to the location of instruction, the characteristics of the teachers, the methods of instruction, and what is learned.

Informal education takes place in the context of everyday life, and the educators include family members, peers, workmates, and the mass media. Formal education or schooling, meanwhile, takes place outside the family in institutions that specialize in education, is conducted by teachers who are not students' intimates and whose principal occupation is education, and stresses learning more through verbal and written description and guided inquiry than through observation and imitation. Finally, nonformal education—which takes

such forms as on-the-job training, agricultural extension programs, and family-planning outreach programs—is more organized than informal education but has aims that are more specific and short term than those of formal education.

Virtually all societies utilize all three forms of education, but they differ in the relative predominance of these forms. In nonindustrialized societies, informal education dominates, with formal and nonformal education only marginally present. But in industrialized societies such as the United States, formal education rivals, if not exceeds, nonformal and informal education in importance and the use of society's resources. However, this is not to say that such agencies of informal education as the mass media do not have very profound effects. The ubiquity of the modern mass media and the fact that they are now held in relatively few hands allow them to widely and deeply shape many of our beliefs, attitudes, and behaviors (Bagdikian 1990; Herman and Chomsky 1988).

THE STRUCTURE OF NATIONAL SCHOOL SYSTEMS

School systems across the world are converging more and more in structure and content (Meyer, Kamens, and Benavot 1992; Meyer, Ramirez, and Soysal 1992). Yet school systems still differ considerably, even among countries comparable in economic development. One key axis of variation is relative size. Nations greatly differ in the proportion of their total population, especially the young, enrolled in school. For example, in 1994 the proportion of youth of secondary school age enrolled in school averaged 94 percent across twenty-one advanced industrial societies (sixteen European countries, the United States, Canada, Japan, Korea, and Australia). But the average percentage was 55 percent for eighteen less developed Asian countries (excluding Japan, Korea, Taiwan, Hong Kong, and Singapore) and 32 percent for fifteen African countries (U.S. National Center for Education Statistics 1997).

Clearly, differences in wealth and degree of industrialization explain a major part of this variation. But even when we control for these factors, we still find enormous differences among societies in the structure of their school systems.

Economically Advanced Countries. Even economically advanced societies differ greatly in how their school systems are governed and how their students' school careers are structured. Nations differ greatly in how much control the national government exercises over how schools are financed and operated. There are several countries that lodge governance primarily at the subnational or provincial level, such as the United States, Canada, and Germany. But most advanced societies vest control in a national central educational authority, usually a national Ministry of Education. For example, the Japanese Ministry of Education provides most of the funding for schooling, determines national curriculum requirements (the subjects to be taught and the depth in which they are to be covered), selects lists of acceptable text books, sets standards for teacher training and certification, and administers the 166 or so public universities. To be sure, local prefectural boards establish or close schools, hire and supervise teachers, and plan the curriculum. But they do all this within parameters set by the national ministry, which can veto their decisions (Kanaya 1994).

Nations with strongly centralized school governance leave much less room for local control and therefore for local variation in the content and structure of schooling. But the flip side of the coin is that such nations also suffer from much less inequality in school spending across localities and—because of class and racial segregation in housing—across social classes and races.

School systems in advanced industrial societies vary also in the structure of students' careers; that is, the timing of career selection and therefore curricular differentiation; the proportion of secondary students specializing in vocational studies; the strength of the tie between vocational training in secondary school and labor-market outcomes; the proportion of students entering and graduating from higher education; and the degree of differentiation within higher education, including whether there is an elite sector with privileged ties to elite public and private jobs (Brint 1998; Hopper 1977). The United States and Germany are nearly polar opposite on virtually all these dimensions.

The United States puts off occupational selection until very late. The main branching point comes after high school, when a student decides

whether to go to college, which college to enter, and later what field to major in. As a result, U.S. high schools have a weak connection to the labor market. Because of this, many current educational reforms—such as school-to-work partnerships between schools and employers—are directed toward enhancing the connection between secondary school curricula and labor market opportunities.

Meanwhile, the proportion of students entering and graduating from higher education is huge. In 1996, 65 percent of high school graduates (or about 58 percent of all college-age youth, given a dropout rate of about 11 percent) entered higher education. According to the High School and Beyond Survey, about one-quarter of college entrants eventually receive a baccalaureate degree or higher and another one-fifth receive a one- or two-year certificate or degree. These figures for college entrance and graduation are about double those for Germany (Organization for Economic Cooperation and Development 1998; U.S. National Center for Education Statistics 1997). Because so many U.S. students go on to college and because student selection occurs to a great extent within college, U.S. higher education institutions are quite varied in curriculum, prestige, and student-body composition (see below).

Germany, meanwhile, has a very different school system. Student selection occurs at age ten, when students are divided between academic high school (Gymnasium) and two types of vocational secondary schooling (Realschule and Hauptschule). At age fifteen students graduate from the vocational high schools into either more advanced vocational schools or apprenticeship programs combining on-the-job and classroom training. Both are strongly connected to specific employment. Meanwhile, graduates of the Gymnasium go on to take the Abitur exam, which determines if they will be allowed into university. All told, only one-quarter of German students enter the university and only 15 percent get university degrees (Brint 1998; Organization for Economic Cooperation and Development 1998).

These differences in student careers fundamentally shape educational outcomes. A tightly coupled school career system, in which test results largely determine admission to the best schools and graduation from them in turn strongly shapes

job placement, will tend to produce students who work hard at their schooling and their exam performance, as is the case in Japan (Brint 1998; Rohlen 1983). But the effects of school structure reach further. School systems that have small, highly selective higher educational sectors with little or no distinctions made among universities, as in the case of Germany, will tend to generate greater class consciousness and solidarity. In contrast, schools systems with large, internally heterogeneous higher education sectors, such as in the United States, foster weaker class consciousness (Brint 1998).

Economically Less Developed Countries. Economically less developed countries (LDCs) vary greatly as well in the size and structure of their school systems. For example, in Africa, the ratio of secondary school students to the secondary-age population ranges from 7 percent in Mozambique to 77 percent in Egypt (U.S. National Center for Education Statistics 1997). In addition, LDCs vary greatly in how socially exclusive their higher education systems are; for example, in 1985 the proportion of postsecondary students who are female ranged from 24 percent in sub-Saharan Africa to 52 percent in the Caribbean (Ramirez and Riddle 1991).

A major source of this diversity in size and structure is, of course, differences in degree and form of economic development even among less developed societies. But other factors also play an important role in causing this variation. Though most LDCs were at some point colonies or protectorates of one of the European powers or the United States, this colonial inheritance was not homogeneous. For example, the British and French colonial heritages were quite different, rooted in the different educational and political systems of those two countries. British colonies typically had higher rates of college attendance and lower rates of grade repetition than French colonies, echoing the differences between their colonial masters' own school systems (Brint 1998). Furthermore, the nature of the political elites—whether enthusiastic modernizers as in Turkey or Iraq or conservatives as in Saudi Arabia—has made a difference in how much emphasis they put on expanding the school system (Brint 1998).

Despite these variations, educational systems in economically less developed countries (LDCs)

do exhibit considerable homogeneity in structure. A lack of resources has tended generally to force a lower level of educational provision (Brint 1998). In addition, many LDCs share a common colonial inheritance; for example, across the former British colonies in Africa and the Caribbean, secondary education remains dominated by the British “O-level” and “A-level” examinations (Brint 1998). Moreover, modernizing movements of quite various ideological stripes have seen education as a way of creating loyalty to and solidarity with their new ideas (Brint 1998; Meyer, et al. 1992). Finally, the World Bank has been playing a homogenizing role by strongly urging particular reforms (such as emphasizing primary over tertiary education and deemphasizing vocational education) on nations applying for loans (Brint 1998).

A CLOSER LOOK AT THE STRUCTURE OF THE U.S. SCHOOL SYSTEM

As noted above, the U.S. school system is quite unlike that of most other advanced industrial societies. The United States is virtually unique among advanced societies in that education is not mentioned in the national constitution and educational governance is not lodged with the national government (Ramirez and Boli-Bennett 1982). Instead, schooling in the United States is a state and local responsibility. Consequently, the United States has more than fifty separate sovereign educational authorities.

The United States has no national universities (except for the military academies and a few other specialized institutions). There is no required national exam for university entrance. While the Scholastic Assessment Test (SAT) and the American College Testing (ACT) exam are widely used, they are privately operated and individual colleges decide whether and how their results will be used.

The connection between educational credentials and workplace opportunities is comparatively weak in the United States (Collins 1979). Of course, for some occupations, the connection is quite strong, with a standardized curriculum preparing graduates for licensing examinations. But for most college graduates, the connection between their college major and their work careers is tenuous at best. Significant labor-market advantages go

to those who attend and graduate from college, but the school system has relatively weak connections to most occupational sectors. Recent reforms, such as the 1994 federal School-to-Work Act, aim to tighten the links between secondary and postsecondary training and the labor market (Van Horn 1995). But it will take many years of such efforts before the United States even approximates Germany or Japan in the closeness of linkage between school and work.

These structural features have created an educational system in the United States that is wide open and characterized by very high enrollments and great student and institutional diversity. We make available a seat in some college somewhere for virtually everyone who wants to attend. Consequently, our secondary education system is less decisive than in most other countries, as “second-chance” opportunities abound. Secondary school students do not have to make hard decisions about their educational futures until quite late, often in college.

In order to better understand these unusual features of the American system, let us examine the structure of U.S. education in greater detail.

Elementary and Secondary Education. All elementary and secondary (K–12) school districts operate within the confines of the relevant state education law, which specifies requirements for graduation, certification of teachers, and so forth. State governments also provide on average about 47 percent of public school funding, with most of the rest coming from local taxes (U.S. National Center for Education Statistics 1997).

Private schools, too, must conform to state education law, but they are less restricted than are public schools. For example, in most states, the regulations governing teacher certification are less strict if one teaches in a private school than a public school. It is almost entirely up to the private school and its sponsors to generate financial support. No tax-derived funds may be used to support private K–12 schooling unless special conditions are met (for example, private schools may receive public aid if they enroll handicapped students). Interestingly, public aid flows much more easily to private colleges. They can receive student financial aid, grants to build academic facilities, and grants

and contracts to conduct research and run academic programs.

The operation of public education at the elementary and secondary levels largely rests with the local school district. In 1995–1996 there were about 16,000 separate school districts in the nation, each with its own school board, superintendent, and schools (U.S. National Center for Education Statistics 1997). Although smaller school districts have often been consolidated into larger ones, many states still have hundreds of separate districts. School district boundaries are usually coterminous with local political boundaries, but elected school boards are rarely identified with a political party. Localities provide about 46 percent of public school funding (U.S. National Center for Education Statistics 1997).

This reliance on local revenues derived from property taxes generates great disparities in per-pupil spending across property-rich and property-poor districts. Though states have increased their share of educational expenses, largely due to legal challenges to relying on local property taxes for funding, spending disparities have decreased only a little. The poorest districts do have more money to spend, but rich districts have increased their tax levels in order to maintain their spending lead (Ballantine 1997).

An important consequence of the U.S. pattern of considerable local control is that local concerns are more likely to be reflected in school policies and practices than is common in countries with more centralized educational systems. Citizens elect local school boards and frequently vote on budgets, property tax rates, and bond issues. Moreover, parents exercise considerable informal political power through parent–teacher associations, informal conferences with school teachers and administrators, and decisions about whether to send their children to a particular school or not. (See the section below on modes of influence over schools.)

Despite the absence of strong national control, U.S. elementary and secondary schools do share many similarities across the country. One reason is that the federal government does exercise a homogenizing influence through its policy recommendations and funding for particular programs. In addition, national professional associations of educators and regional nongovernmental

accrediting agencies provide common definitions across states and localities of what constitutes good educational practice. Also, college admissions requirements, though they vary across colleges, are similar enough to influence the course offerings of secondary schools. Moreover, textbook writers and publishers, who provide instructional material for schools nationwide, influence what is taught and often how it is taught by marketing the same instructional materials nationwide (Apple 1986). Finally, the high geographic mobility of students and teachers has helped reduce the isolation and consequent diversity among schools.

Across the United States, formal public schooling generally begins at age six, but enrollment in preschool and kindergarten is widespread and growing. In 1995 about 61 percent of three- to five-year-olds were enrolled part time or full time in nursery schools or kindergartens (U.S. National Center for Educational Statistics 1997).

Elementary schools are smaller than secondary schools. They are also less differentiated internally, in that all students are exposed to essentially the same subject matter by their "home room" teacher. However, within the home room, teachers often do divide students into different groups that are supposed to learn the same material at different speeds. This within-class differentiation is often termed "ability grouping," but in actuality test scores are often only a weak predictor of group assignment. Nonetheless, this grouping by putative aptitude is an important source of later class and, less so, racial differences in achievement (Dougherty 1996).

While elementary schools are generally alike in organization and curriculum, they differ widely in student composition. Because they draw from neighborhoods differing in class and racial composition, they end up differing from each other in student composition.

Secondary schooling begins around age thirteen. For the most part, U.S. secondary schools are "comprehensive"; that is, intended as much for those who will not attend college as for those who will. The comprehensive high school provides college preparation, vocational education, and general secondary education under one roof (Clark 1985; Krug 1964, 1972).

The comprehensive nature of U.S. secondary schools is fairly atypical, for the usual pattern abroad is to have separate academic and vocational high schools. For example, in Germany, academic and vocational training is assigned to separate secondary schools, with nearly half of all students entering the latter (Brint 1998).

The United States is also atypical among industrialized societies in awarding secondary school diplomas qualifying their holders for college entrance solely on the basis of the number and kinds of courses taken. Most other countries require passage of a national exam to receive a degree that qualifies one for university entrance (Brint 1998). To be sure, seventeen U.S. states do use minimum-competency examinations for awarding high school degrees (Airasian 1987; U.S. National Center for Education Statistics 1997), but the country still does not have a European-style national examination that alone determines university entrance.

The exceptional devotion of the United States to comprehensive schooling is traceable to two factors. The strong local role in educational governance in the U.S. system makes it more likely that the demands of non-college-goers will be listened to. Moreover, the heterogeneity of the U.S. population has made social integration a more pressing concern than in most European societies. This is evident in the words of the highly influential 1918 report, *Cardinal Principles of Secondary Education*: "The comprehensive school is the prototype of a democracy in which various groups have a degree of self-consciousness as groups and yet are federated into a larger whole through the recognition of common interests and ideals. Life in such a school is a natural and valuable preparation for life in a democracy" (National Education Association 1918, p. 26).

While U.S. comprehensive schooling may have been successful in its aim of social integration, its diffuse character has also been widely criticized. As many recent critics have noted, the variety of curricular goals and educational and social purposes served by U.S. secondary schools blurs their academic mission. When large proportions of students are not particularly academically inclined, the rigor and sense of purpose necessary to motivate student effort are missing. Moreover, the huge size of many U.S. schools makes them impersonal and hard put to maintain the involvement

and commitment of students (Cusick 1983; Goodlad 1984; Powell et al. 1985; Sizer 1985).

While the U.S. school system is much less differentiated than is typical abroad, U.S. secondary schooling is by no means entirely undifferentiated. To begin with, there is an extensive private sector. Ten percent of all U.S. K-12 students attend private schools. These schools vary enormously, from individual Montessori schools, Christian academies, and elite private schools to city-wide systems of Catholic parochial schools. While small in numbers and enrollments, the elite private schools, which are variously termed "prep" or "boarding" or "country day" schools, carry great prestige and importance. Most areas of the United States have elite schools, but the most famous are the boarding schools of New England, such as Phillips Exeter, Choate/Rosemary Hall, Groton, Hotchkiss, and St. Paul's. These schools have enrolled such famous Americans as Franklin D. Roosevelt, John F. Kennedy, Adlai Stevenson, George Bush, and Nelson Rockefeller. The importance of these schools lies not only in the fact that they heavily enroll the sons and daughters of the upper and upper-middle classes, particularly those of long-established wealth and prominence, but also in the fact that they provide their students with privileged access to the top universities and, in turn, corporate and governmental leadership (Cookson and Persell 1985; Hammack and Cookson 1980).

But it is not just the public/private divide that provides differentiation within the U.S. system. Even the comprehensive public high schools provide alternatives within their walls in the form of different curricular groupings (college prep, vocational, and general) and courses at different levels of rigor. However, this phenomenon, typically termed "tracking," has been criticized as a significant source of class and racial inequality in educational attainment (Dougherty 1996). Consequently, a movement has developed to "detrack" schools by eliminating grouping and instead relying on "cooperative learning" within mixed-ability classrooms (Oakes and Lipton 1992; Wells and Oakes 1996).

In addition to different tracks, most U.S. urban school districts maintain specialized vocational and academic secondary schools. For example,

Boston, New York, Philadelphia, and San Francisco have maintained old and distinguished academic high schools such as Boston Latin.

Since about 1970, most urban school systems have introduced a wide variety of programs in order to meet demands for more choice, retain middle-class white students, and better motivate students (Dougherty and Sostre 1992). New York City provides a good example of how highly differentiated some urban school systems have become. The city does have a large number of general "academic/comprehensive neighborhood schools." However, within many of these schools, there are "academies" or other magnet programs, which are operationally independent and have some freedom to select their students from wider attendance areas. In fact, there are about fifty small alternative high schools that offer special curricular emphases and that are open to students citywide. New York City also has a variety of vocational schools. Special "educational opportunity" high schools are organized around vocational themes (such as health, business, or aviation) and have the right to select their students. On the other hand, there are also ordinary vocational schools that have no particular focus and have open admissions. Finally, the city boasts four very well-known college preparatory schools, such as the Bronx High School of Science, that grant entry solely on the basis of an examination or audition (Board of Education of the City of New York 1997).

In recent years, a new form of differentiation has arisen within the public schools: "charter schools." Since 1991, more than thirty-five states have passed legislation making these schools possible, and perhaps more than 1,000 of them are now operating. Once granted a "charter" by the state or other designated authority, these schools operate independently of many existing school regulations but are financed by funds that would otherwise go to the districts. Charter schools are accountable to the chartering authority, and the renewal of their charter depends on meeting the goals set forth in their mission statement. The idea behind these schools is to free public school parents, teachers, and administrators to create schools that "break the mold" of existing schools and, by competing with existing public schools for students, force them to improve their performance and attractiveness. Moreover, many charter advocates have seen charter schools as a way of meeting

the growing parental demand for choice—among not only affluent white parents but also working-class minority parents—but keeping it from tipping into a demand for vouchers to allow student to attend private schools. Beyond these commonalities, charter schools are very diverse in size, mission, student composition, and sponsorship. And because of this variation and their youth, it is unclear what impact charter schools will ultimately have. The jury is still out on whether they will enroll more than a fraction of public school students, successfully “routinize the charisma” of their founders after those founders move on, significantly enhance the performance of their students, and effectively stimulate regular public schools to improve. Many fear that charter schools may simply cream off the most advantaged students and leave the regular public schools more segregated and academically impoverished than ever (Cobb and Glass 1999; Manno et al. 1998; Wells et al. 1999).

Higher Education. As with the K–12 system, the U.S. higher education system is also quite unusual. It is much larger than, and organized very differently from, most other nations’ systems. As of 1995, the United States had 3,706 institutions of higher education enrolling 14.3 million students in credit-bearing courses, which corresponded to about 35 percent of the population age 18–21 (keeping in mind that many college students are older than twenty-one). In addition, there were some 6,300 noncollegiate postsecondary institutions enrolling 850,000 students (U.S. National Center for Education Statistics 1997). All these numbers are much larger than those for comparable advanced industrial societies.

Given their number, it is not surprising that American colleges are quite varied. This variation can be usefully categorized along three axes: control, degrees and programs offered, and student-body composition.

U.S. colleges are legally owned by a wide variety of bodies. Some 1,700 colleges are public, owned by local, state, and federal governmental bodies. They account for 45 percent of all colleges but 78 percent of all college enrollments. Meanwhile, about 2,000 colleges are private, owned either by religious groups, profit-making corporations, or nonsectarian, non-profit-making boards. The nonsectarian, nonprofit private institutions

include both many of the most prestigious doctorate-granting universities in the world and many small, undistinguished liberal arts colleges (U.S. National Center for Education Statistics 1997).

The U.S. Department of Education distinguishes five kinds of colleges according to the degrees and programs that they offer. The first group is the 171 “doctoral” institutions that offer doctoral and professional programs and produce a large number of graduates with either Ph.D.’s or medical and dental degrees. “Comprehensive” institutions, numbering about 420, make up the second category. They offer graduate programs but graduate few people with doctoral or medical degrees. Rather, they specialize in undergraduate, master’s, and law programs. Quite often these institutions are former teacher-training colleges that broadened into general liberal arts schools and added graduate programs. The nearly 700 “general baccalaureate” or “liberal arts” colleges emphasize undergraduate education and have very few, if any, graduate programs. “Specialized” colleges, which number about 600, emphasize one field, such as engineering or the arts, and offer either a baccalaureate or postbaccalaureate training. Finally, the nearly 1,500 “two-year colleges” specialize in two-year associate’s degrees, one-year vocational certificates, and noncredit training. They enroll not only college-age students seeking academic or vocational training but also older adults seeking job retraining, skills upgrading, or avocational knowledge (Cohen and Brawer 1996; Dougherty 1994).

U.S. higher educational institutions also differ in their student-body composition. As one moves from universities to four-year colleges to two-year colleges, the proportion of students who are male, white, upper-class, or academically high-performing drops. In addition, some colleges serve distinct student populations; for example, nearly 200 colleges are single-sex and nearly 100 are all-black (U.S. National Center for Education Statistics 1997).

MODES OF INFLUENCE OVER SCHOOLS

The governance of education has been a repeated motif in our discussion above. We would now like to discuss it in greater detail. So far, in our discussion of control we have focused on political authority, whether exercised by national, state, or

local governments or the citizens that elect them. But political authority is only one of several, often contradictory, mechanisms of influence over U.S. schooling. Also operative are market competition, bureaucratic power, professional authority, and ideological formation (Weiss 1990).

Political Authority. Political authority is vested in the various elected bodies of government and ultimately in the citizenry. State governors, legislatures, and boards of education control the schools through state funding (which amounts to nearly half of all public school revenues) and through laws specifying minimum curriculum and graduation requirements, the minimum length of the school day and year, required facilities, standards for teacher education and certification, standards for school plant, school district lines, and so forth (Campbell et al. 1990; Wirt and Kirst 1992).

However, state governments delegate political authority over the day-to-day operation of schools to local schools boards elected by local citizens. These local boards in turn have the power to hire and supervise district superintendents and school principals. The boards also vote on the school budget, the local tax rate (though usually subject to voter referendum), curriculum, teaching, facilities standards beyond state minimal, and the rules for hiring and supervising teachers (Campbell et al. 1990; Wirt and Kirst 1992).

The federal government, meanwhile, only contributes about 7 percent of K-12 public school revenues, mostly in the form of categorical aid (discussed below under "Market Competition"). However, through the federal courts, the federal government has had a profound effect on school policies involving the treatment of pupils, particularly women, racial and linguistic minorities, and the handicapped. Moreover, as will be discussed below, the federal government has also exercised great ideological power (Campbell et al. 1990; Wirt and Kirst 1992).

Citizens, finally, exert political authority. Very frequently they vote on who will represent them on a school board or in state office. They also exercise direct democratic control by voting on tax rates and bond issues through local and state referenda and initiative elections. And in states such as California and Washington, it has become commonplace for voters to vote on school policies

such as affirmative action in student admissions and teacher hiring (Wirt and Kirst 1992).

However legitimate and powerful political authority is, it can also be ineffective, particularly in a highly decentralized political system such as that of the United States. When a host of different government bodies impose multiple, often conflicting, mandates on schools, the effectiveness and authority of any one given political body is undermined (Weiss 1990).

Market Competition. Market control is less coercive than political authority. Schools can refuse to act in the way a market actor wishes, but that actor achieves compliance by supplying or denying resources that the school values and that the school cannot easily acquire from alternative sources (Pfeffer and Salancik 1978). These resources include funds, students, teachers, and jobs. Market control is particularly obvious in the case of private schools, which usually do not have a guaranteed clientele or funds and must recruit new students every year. But public schools also face market competition. In fact, market control over public schooling is steadily rising with the current vogue for school choice, charter schools, performance-based funding, and other means of making public schools more "accountable."

Students and their parents exercise market control over schools through their decisions about which schools to attend (Spicer and Hill 1990; Weiss 1990). If many middle-class students desert a school district, it loses state funding, which is largely enrollment-driven. Moreover, local tax revenues may also decline. Real estate values are strongly affected by perceptions of the quality of local schools, and these perceptions are in turn shaped by how many middle-class and white students attend a school. But even if school revenues are not affected, the desertion of middle-class students can still affect schools by impinging on teachers' perceived quality of work. Teachers usually clamor for better-prepared students, and a loss of middle-class students can lead the better teachers to themselves desert a particular school.

In order to retain students, particularly middle-class white ones, school districts adopt a variety of expedients. They create "gifted" programs or "magnet" schools that attract such students not only by offering superior academic resources but

also by largely segregating them from working-class and nonwhite students (Metz 1986; Wells 1993).

School competition for students has risen in the 1990s. It used to be that the main choices parents had available were between sending their children to public or private schools or between living in one school district versus another. But competition for students has increased with the advent of greater choice within the public schools in the form of magnet schools, charter schools, and interdistrict choice plans (Cookson 1994; Metz 1986; Wells 1993).

Students and their parents exert market power not only over schools overall but also over the classrooms within them. Student decisions about whether to take one or another course or whether or not to actively participate in class deeply shape the character of teaching and learning within classrooms. In order to attract students and then motivate them to work hard and actively participate, teachers often resort to such devices as giving students more choice over course selection or course content, making course content less abstruse and technical (more "relevant"), reducing academic demands, and grading less stringently (Powell et al. 1985; Weiss 1990).

But teachers themselves are also market actors. Teachers can choose whether to go to work for one or another district or, if they have enough seniority, work at one school versus another in the same district. Hence, school districts compete to hire and retain teachers, particularly if they are in fields such as math and science, where qualified teachers are scarce. Moreover, teachers have shaped the schools through their collective capacity to withhold their labor through unions. With the rapid growth of teacher unions since the early 1960s, teachers have been able to secure considerably higher salaries and greater voice in how schools run than they had before (Campbell et al. 1990; Kerchner et al. 1993).

Business also shapes schools through market control. For one thing, business controls jobs. Schools compete to place their students in good jobs because a good placement record can be used in turn to attract students. In order to get their students placed in good jobs, schools inculcate the kinds of skills, attitudes, and behaviors that business is looking for in new workers (Brint and

Karabel 1989). In fact, business's influence based on its role as future employer of students has been institutionalized in the form of a myriad of business/school or school-to-work "compacts" or "partnerships" in which formal links are established and schools receive resources and job placements in return for greater responsiveness to business opinions about the desirable content of education (Gelberg 1997; Van Horn 1995).

In addition, business along with foundations and government influence schools through discretionary funding. Almost all business and foundation aid and most federal aid to schools takes the form of categorical grants. These funds will flow to a school only if it successfully competes with other schools to demonstrate that it is willing and able to engage in actions that the funder wishes to encourage. Moreover, this avenue of market control is increasing, as state governments establish not only more categorical grant programs but also performance funding, in which a certain portion of state formula aid is conditioned on meeting certain performance targets.

Market competition can be a very powerful control device, but it is also less effective than its evangelists believe. For example, greater student choice may not cause the deserted schools to change. The schools may not know why students are leaving, and the loss of funds, good students, and good teachers may impede its capacity to improve. Moreover, even if schools do react, they may get the wrong cues because students and their parents make bad choices due to lack of good information (Weiss 1990). Similarly, categorical aid often fails to accomplish its purpose. What schools do to secure the aid may bear little resemblance to how the aid is actually used. This has been a perennial problem with federal Title I funding for high-poverty schools. It often does not end up benefiting the students to which it is ostensibly targeted (Somini 1999).

Bureaucratic Power. Schools are bureaucratic organizations. They have explicit goals. Their work is done through a division of labor involving specialized jobs. There is a chain of command, with explicit differences in the authority of members according to their place in the organizational hierarchy. The members' actions are largely governed by formal rules and a norm of professionalism (impersonality). Organizational decisions are

recorded through explicit and voluminous records. And personnel decisions are supposedly governed by merit (Bidwell 1965).

Within this bureaucratic structure, administrators—such as district superintendents or college presidents, school principals or deans—exercise great power. They create jobs and define their responsibilities, establish organizational rules, allocate scarce resources (money, space, staff, etc.), order specific actions, referee conflicts among subordinates, and hire and supervise subordinates (Campbell et al.; Weiss 1990).

Historically, teachers have been objects of administrative power. But increasingly, they themselves are participating in the exercise of administrative duties. The movement for school-based management has given teachers the potential to exercise greater power over how schools are run, though it is still not clear to what extent this has become a reality. In numerous communities, school councils have been set up that include teacher members. These councils have the authority to exercise considerable voice over such things as a school's budget, teacher hiring (what areas to hire in and whom to recommend to the district), and student discipline rules (Kerchner et al. 1993; Mohrman et al. 1994). However, this authority is often not exercised in practice. Between principal resistance to sharing authority and teacher reluctance to assume it, school councils often end up exerting much less authority than authorized.

Bureaucratic control had become perhaps the dominant form of school control by the end of the Progressive era. But despite its power, bureaucratic control does not handle localized, specific situations well. The general orientation of bureaucratic rulemaking is toward general prescriptions because the aim is to circumscribe the discretion of organizational staff (Weiss 1990). However, student-centered education—particularly in a highly diverse, politically decentralized society such as the United States—often does not fit easily within bureaucratic universalism.

Professional Authority. However bureaucratic schools are, they are also professional organizations because teachers make up such a large portion of the labor force and administrators are invariably former teachers. The main fount of professional authority lies in the fact that effective teaching requires the exercise of discretion—how

teachers are to interact with students cannot be prescribed—and teachers largely monopolize the knowledge necessary to correctly exercise that discretion. Teachers use their professional authority to strongly shape curriculum, student evaluation, student discipline, proper classroom practices, and teacher training (Weiss 1990).

Nonetheless, teacher professional authority has always been uncertain and contested. This authority is at its apex in the classroom and fades as one goes up the bureaucratic hierarchy (Metz 1978; Weiss 1990). The weakness of teachers' claims for professional power and autonomy results from several factors. The majority of teachers are women, giving teaching less status than more male-dominated professions. Also, because of the unique complexity of the teacher–student relationship, teachers are less able to deliver consistent results than members of professions such as medicine and engineering. Finally, teachers must coexist with a powerful and numerous body of competitors for influence over students; namely, parents. (We discuss teacher–parent struggles for control below.) In the face of these limits to professional authority, teachers have increasingly resorted to market control, in the form of unionism, in order to bolster their influence over the schools.

Ideological Formation. Various actors can shape schools by the power of their ideas; that is, by their successful socialization of educational policy makers to certain values and beliefs (Weiss 1990). This ideological power has been strongly used by the federal government. Repeatedly, it has stimulated schools to take action by focusing attention on certain problems or offering exemplary solutions. One of the most notable examples has been the educational “excellence” movement of the 1980s and 1990s, which was strongly accelerated—though not really sparked—by the report of the National Commission on Excellence in Education, *A Nation at Risk* (1983). Within a year of its publication, many states and localities established commissions similar to the National Commission and passed laws implementing its recommendations. On a more global level, the power of ideological persuasion can be seen in the unusual homogeneity across the world in how nations have pursued the expansion and centralization of their educational systems. In large part this commonality of action is rooted in widespread support for a model of societal modernization that emphasizes

national unification and development by means of the mass mobilization of citizens through a unified school system (Ramirez and Boli 1982).

Once established, ideological control can be extremely powerful and durable. Its main limitation is that it usually takes a long time to establish. And unlike the other forms of power, it is particularly dependent on the willing acquiescence of those who would be influenced (Weiss 1990).

Conflict Between Various Modes of Control.

Many actors attempting to influence the schools utilize—wittingly or unwittingly—several of these modes of control. For example, state governments use political authority, market competition (through categorical aid), and ideological persuasion to get school personnel to act in certain ways. These different modes of influence can often yield great power if they are effectively meshed. But quite often they contradict each other.

Assertions of bureaucratic authority have been met by counterclaims by teachers in the name of professional authority or market control. Teachers have resisted state and local expansions of bureaucratic authority by mobilizing professional associations (for example, the National Council of Teachers of Mathematics) to shape the content of state curriculum standards (Massell 1994; Ravitch 1995). But because assertions of professional authority are often resisted, teachers have resorted as well to market control, in the form of teacher unionism.

But these assertions of power by teachers and by local and state school bureaucrats have in turn provoked democratic counterclaims by groups representing conservative parents concerned about parental prerogatives over education. These groups have strongly criticized teacher unionism and various curricular and pedagogical innovations advocated by teacher professional associations at the national, state, and local levels. These controversial innovations have included not only sex education and values clarification but also state content, performance, and evaluation standards. In California and Pennsylvania, parents associated with such New Right groups as Citizens for Excellence in Education, Focus on the Family, and Eagle Forum have vociferously attacked statewide goals and standards, performance-based assessment, whole-language instruction, and conceptually oriented math education. These groups reject such

curricular and pedagogical reforms as ineffective and unwarranted educational experimentation on children that undermines parental prerogatives to determine the content of their children's education (Boyd et al. 1996; Kirst and Mazzeo 1995).

Interestingly, there has been little conflict between market control and democratic authority. For example, inadequate critical attention has been devoted to business/school partnerships and the question of how compatible are business desires and public interests in schooling. This absence of scrutiny may be due to the weakness of the socialist tradition in the United States. Because of this weakness, democracy and the market are seen in the popular mind as largely compatible. Both voting and buying tend to be seen similarly, as decisions by atomized actors operating on the basis of narrow self-interest. Public discussion and the public interest tend to be seen as no more relevant to voting than to buying. As a result, efforts to increase market competition within schooling through such devices as vouchers and charter schools are often portrayed in the U.S. as democratic innovations—because they “empower” individuals—whereas in Europe there is much more hesitation to equate consumer choice and citizen sovereignty (Whitty et al. 1998).

CONCLUSION

The sociology of U.S. schooling can benefit enormously from keeping in mind several features of that system. The educational system goes well beyond the schools to include such other institutions as families, the mass media, employers, and churches. Even when we focus on the schools, it is important to keep in mind that the U.S. school system is highly unusual compared to those in other advanced industrial societies. And when we turn to control of the U.S. system, we need to look beyond political authority to also consider other, often contradictory, mechanisms of influence over the schools: market competition, bureaucratic decision making, professional authority, and ideological formation.

EMOTIONS

Emotions arise in individual experience, frequently with noticeable physiological signs, such as a racing heart, flushed or pallid face, tense gut, cold hands, and so forth, and thus may seem an unsuitable topic for sociological examination. This attitude, however, reckons without the incontrovertible facts that *most human emotions result from real, imagined, recollected, or anticipated outcomes of social interaction* and that interaction is the fundamental stuff of sociological analysis. Thus emotions are empirically linked to the social by virtue of their being a consequence of involvement in interaction. But emotions are also precursors of the social, by virtue of their mobilizing energy and motivation for the accomplishment of major social tasks, not the least of which is social solidarity itself.

Although emotions are thus important features of social life, they have had a varying place in the history of sociology. Early recognized as important by the great founders of the field—Marx, Durkheim, Weber, and Simmel—emotions declined in importance after the 1920s, as behavioral and cognitive approaches came to the fore in the social sciences. (Although these two approaches are thoroughly antagonistic to each other, they have agreed that emotions are irrelevant or unamenable to sociological analysis.) Resurrected after a long hiatus, emotions have once again come into their own and are now recognized both as exerting causal effects as well as serving as important results of social endeavors.

This article covers both early and present-day approaches to what has come to be known as the sociology of emotions and examines the role of emotions as both independent and dependent variable.

THE PLACE OF EMOTIONS IN NINETEENTH-CENTURY SOCIOLOGY

In the great effort to topple the entrenched structures of monarchy and clergy in eighteenth-century Europe, a signal weapon was *reason*. By virtue of the application of reason to traditional modes of thought and conduct, philosophers and political theorists concluded that the dominion of kings and priests was falsely premised and that all men were created equal. That reason alone could lead to such a startling conclusion for that day was the result of the conquest by reason in another domain, namely natural science. In astronomy, physics, chemistry and biology, the work of reason had accomplished transformations of thought and understanding of a revolutionary nature. The success of reason here gave social thinkers confidence that reason applied to social life would produce results equally significant. And, indeed, it did in form of the upheavals that culminated in the American and French Revolutions.

What had been only thought was put into practice and the tradition of a thousand years swept away. In the ensuing years, reason was enshrined, a new god replacing the old ones that had been discarded. But as this occurred, a counterrevolutionary ideological process was getting under way. In England, Thomas Burke, at first

partial to the aims of the French Revolution, recoiled in horror at its excesses—reason had run amok, with a degree of passion and emotion that was terrifying. Burke argued that society was not amenable to quick constructions or reconstructions. Rather, a slow accretion of time-tested ways that ultimately refined the social rules and customs was the only reliable method for attaining a safe, stable, and satisfactory social order. Opposing the worship of reason, Burke posed rather the validity of an emotional basis for social solidarity. Longstanding mores garnered emotional support and, by virtue of this, violent social change, with its attendant upheaval, was averted.

Burke's conservative message, which rejected the application of reason to social forms, was to lie fallow for a century, until it was resurrected in a more systematic sociological way by Émile Durkheim. In the interim, Karl Marx, also an exponent of reason in the reorganization of society, had propounded his comprehensive historical theory of the growth and decay of societal organization. Yet in developing his understanding of how society, particularly capitalist society, works, Marx ([1842–1844] 1971, [1867] 1967; Engels [1846] 1947) also produced a paradigm for how to examine emotions sociologically. His approach remains important today, even if the specific political and ideological interests of Marxism are no longer attached to it.

Marx propounded the view that forms of social organization—feudalism, capitalism, socialism—were products of such factors as technology and the division of labor, which he termed the *mode of production*, and certain forms of authority and property rights, which he termed the *relations of production*. A given historical mode of production gave rise, for Marx, to a necessary set of relations of production. In feudal times, the relatively primitive technology required a great deal of hand labor, as exemplified in craft production, where producers owned their tools, their raw materials, and the products of their labor. Property rights and social relations were in line with the division of labor made possible by the technology of the time.

After the Industrial Revolution, with its relatively advanced technology, a new form of division of labor and property rights emerged. The factory

system entailed labor sold by its owners, the workers, as if it were any other commodity. Factory workers owned neither the tools, the raw materials, nor the products of their labor. Thus a new set of property and authority relations came into existence because of the more advanced technology and the division of labor this enabled.

Here Marx looked closely at the horrible conditions of early entrepreneurial capitalism. The principal, although not the only, defect of capitalism was that workers were reduced to a state of what Marx called “immiseration,” a condition fostered by subsistence wages. Poor housing, poor food, poor health, and impoverishment of spirit were the common lot of factory workers. Beyond this was the state of “alienation,” a concept Marx adopted from the work of philosopher Georg Frederick Hegel. Hegel had reflected on the sad fate that befell human effort, which, once crystallized in material objects, exists separately and apart from the individual who exerted it and, in this sense, was alienated from its producer. Marx used this concept to forge a theory of emotional consequences for workers under capitalism.

The primary form of workers’ alienation was the fundamental experience of chagrin, bitterness, and resentment because of the loss, or alienation, of the product of their labor to the capitalist, who did not labor or produce anything. According to Marx, this was the main emotional result of a system in which those who produced things were not the same ones who owned them.

A second form of alienation resulted from the boring and mentally numbing tasks of factory-based production. Instead of the inherent satisfactions of earlier craft forms of work, workers in modern industry, with its extensive division of labor, obtained little pleasure from their largely repetitive tasks.

A third form of alienation was the emotional isolation and competitive envy of others: both owners and fellow workers. This led to the breakdown of solidarity and community, the comfortable sense of belonging to a group in which one was an accepted member. Melvin Seeman (1959) translated Marx’s forms of alienation into five elements: (1) powerlessness, or a feeling that one had no control over one’s fate; (2) meaninglessness,

or a sense of confusion about the value and significance of one’s efforts; (3) self-estrangement, or a feeling of distance between what one felt oneself to be and what one was required to do at work; (4) isolation, or the longing for a sense of connection with others; and (5) normlessness, or the feeling that one’s efforts lacked aim or goal.

Even if Marx’s critique of capitalism is ignored, it is important to recognize his innovation in sociological analysis, what today we would call social psychology; that is, how social organization affects individual variables. In Marx’s case view, how the social patterns by which labor is organized and its benefits distributed affects emotions. This mode of analysis, designated by the term *social structure*, is one of the two main types of approach to the analysis of emotions in current sociology. The other, designated as *culture*, was fostered by the work of Max Weber.

Although he recognized the power and utility of Marx’s social structural analysis of capitalism and its emotions, Weber cast a different light on the process and examined different emotions. In his most famous work, *The Protestant Ethic and the Spirit of Capitalism*, Weber ([1904–1905] 1958) engaged Marx in an intellectual battle over who better understood the historical processes that led to capitalism. According to Marx, the economic infrastructure of society—the mode and relations of production—gave rise to the superstructures of society; namely, the way in which other institutions, such as the family, religion, politics, art, and so on, were organized. Further, Marx contended that the infrastructure even determined ideas. And here Weber demurred. Instead, Weber sought to show that capitalism was the product of a distinct set of religious ideas, along with the emotions that those ideas fostered.

For Weber, the crucial ideational matrix for capitalism was the Calvinist doctrine of predestination. This is the view that salvation in the religious sense is determined for everyone prior to birth. Some, the elect, are destined to be saved and the remainder, doomed to eternal damnation. According to this doctrine, there is nothing one can do to change one’s fate—no action, no amount of devotion can change one’s predestined fate. For many today, this seems like an odd doctrine, and many wonder how it could have held sway. But in

Geneva and other places where Calvinism reigned for a while, the belief was of the utmost importance, since it spelled out the possible eternal fate of one's soul.

Weber conjectured that such a doctrine must have been accompanied by some powerful emotions, mainly a terrible anxiety. At this point, Weber argues, a reaction formation of necessary optimism intervened to forestall despair. Calvinists came to believe that somehow, contrary to doctrine, they might change a dire fate by the most faithful and dedicated service to God's commandments. One of the most important ways in which to do this was in one's God-given *Beruf*, or vocation; that is, one's life's work, whether it be as a farmer, artisan, merchant, and so forth. Pursuing one's daily work in so dedicated a fashion would perhaps avert the severity of a predestined fate.

But such religiously and emotionally driven attention to one's occupation brought an unsought consequence: It led to worldly success. This in itself, despite doctrinal objections, seemed like a divine signal. Those who succeeded in worldly pursuits began to see this as a hopeful sign that they were among the elect. And, if this were so, then even greater worldly success would ensure that prognosis. Given that Calvinism also inveighed against material display, it led the successful to plow their profits back into their work. In other words, said Weber, it led to the routine practice of the capitalist method of doing business, thus giving rise to that historic form of entrepreneurship. In Weber's view, anxiety and a form of coping with it were central to the emergence of capitalism.

In the terms of the present-day sociology of emotions, Marx originated an approach based on *social structure*, while Weber fostered an approach based on *culture*. The effects of this distinction will be elaborated below.

Émile Durkheim also entered the debate against Marx, but on a different front from Weber. Marx had viewed religion as an opiate, offering hope to and dulling the pain felt by workers who suffered from the extremes of dislocation and poverty, especially during the early stages of capitalism. Marx supposed that when socialism conquered, it would obviate the need for religious belief and practice. Durkheim ([1915] 1965) viewed this as a

form of ultrarationalism and sought to uncover the universal wellsprings of religion, which, he believed, would flourish regardless of what form society took. In order to investigate religious phenomena at their simplest—and hence most likely to prove universal—Durkheim examined the religion of Australian Aborigines, a group that appeared to be about as primitive as one could find according to nineteenth-century understanding.

First Durkheim proposed a distinction between religious behavior and everyday behavior, the sacred and the profane. He saw the two as segregated by time and place as well as by behavior. Among the Aborigines, the sacred emerged during clan gatherings, with the worship of totems—animals that stood for the clan and with whom clan members identified. Worship was a matter of ritual practice involving highly emotional activities—rhythmic chanting, frenetic dancing, sexual intercourse—with individuals giving over emotional control to the impulses of the moment. Durkheim reasoned that in these moments of heightened emotional arousal, individuals felt themselves to be in the grip of forces greater than themselves, providing a sense of the presence of something greater than any single individual—a spirit, a god. But Durkheim argued that the only supra-individual entity present was the group itself; that is, the co-presence of the members of the group, giving themselves over to strong emotions, provided the sense of a superior force. In worshipping that force, group members were, unwittingly, worshipping the group itself.

Durkheim generalized this point, arguing that ritual conduct, with its element of emotional arousal, leads to a sense of solidarity among those who engage in the ritual. Thus, religious ritual, far from representing the dead hand of the past, as Marx would have it, enabled group members to cleave to each other and make group continuity possible. This is true, said Durkheim, even when the shared emotion is sadness. Indeed, in examining funerary rites, he showed that coming together on the death of a group member stirred up emotions that transcended the sadness itself. Remarkably, a feeling of strength and renewed vitality emerged from the co-presence of other mourners. Emotions, thus, are not merely individual phenomena; they are crucial to the existence of human groups.

Society itself is possible only because its members periodically share emotions, whether elation over great victory or sadness over great loss.

EMOTIONS IN MODERN PERSPECTIVE

Although present-day sociologists of emotions treat them differently in many ways than did the founders of the field, they nonetheless hue close to the main insight of the founders; namely, that emotions are socially constituted. This means several things.

First, emotions emerge from episodes of interaction in which valued outcomes are at stake. Second, emotions have a socially normative component. Thus, when one's emotions deviate from the normative emotional prescription, there is some constraint to adjust one's emotions to what is normatively specified. Third, over time, as social conditions change, emotional requirements change as well. New conditions mean a somewhat new recipe for emotional life.

In the present-day sociology of emotions, two major sociological traditions converge on the social constitution of emotions, but they do so in different ways. The *social structural* approach examines emotions as direct products of social interaction and its outcomes. For example, insult leads to anger; deflated ego leads to shame; threat leads to fear; and so on. In each case, the end result of the social interaction is experienced as an emotion.

By contrast, the *cultural* approach looks mainly at the regulation of emotional expression by social rules. For example, we are enjoined to be happy at weddings, sad at funerals, angry at injustice, and so on. In each case, the individual who is emotionally out of line with what is expected in the situation confronts the possibility of emotional deviance.

The social structural and the cultural approaches form the main body of work in the modern sociology of emotions, and we discuss each in turn.

Social Structural Approaches. The earliest modern sociologist of emotion was Erving Goffman (1959, 1967, 1981), a transitional figure between the works of the founders, especially Durkheim, and later approaches. He focused powerfully on

ordinary conversation as one of the main settings of social interaction. In the social interaction we call conversation, he found high emotional drama. Although conversation most often proceeds without conscious reflection about it by the participants, a conversation has only to break down to receive considerable and sometimes perplexed attention. Goffman saw that conversation actually comprises a miniritual, much in the manner Durkheim described, and that a successful conversation is like a successful ritual: Everyone plays a necessary prescribed role, even if the exact content of the role is not prescribed. In a successful conversation, participants experience a degree of self-realization that produces the kind of satisfaction that ensues from a whole-hearted and authentic participation in a religious ritual. Indeed, there is a similar sacred aspect to conversation, with the most important sacred object on display being the participant's self. In conversation, that self is accorded a due reverence by other participants or is demeaned by them.

Goffman proposed that in a conversation every actor offers a "line" about him- or herself, one which the other participants are expected to take at face value. For example, one has just been promoted to a higher position, or one has sacrificed dearly for a loved one, or one has learned how to play a Bach partita, and so on. If one carries off the line in the conversation such that others confirm one's projected persona, one feels confident and self-assured. But if one stumbles conversationally and the projected self becomes noncredible, then embarrassment ensues. Unless the actor has what Goffman calls "poise," which is the ability to mask one's embarrassment, the conversation falters.

Since conversation by its nature is interactional, other participants must cooperate in sustaining the viability of the conversational interaction. Except in unusual circumstances, Goffman saw in ordinary talk a precarious social order that is supported by the emotions of the participants, requiring their cooperation and emotional sensibility to succeed. The social order of ordinary talk is an instance of social order in general. Although Goffman did not pursue the larger questions of social order in society, his point about the emotional underpinnings of the micro order was extended to the social macro order, especially in the

formal precedence orders of social power and status. Randall Collins and Arlie Russell Hochschild examined this question in the domain of stratification.

Stratification is the division of the social order into a hierarchy of power, status, and benefits. Some individuals have more and some have less of these desirable attributes and commodities. Since so many life chances are tied up in the stratification order, it is understandable that emotions are focal here, too.

According to Collins (1975, 1981, 1990), social systems, whether large or small, are arenas of conflict in which power, status, and benefits are sought by the participants. In modern societies, the main field of conflict is in organizations devoted to work. Here there are order-givers and order-takers, whose daily interactions are fraught with emotional consequences. Relative to order-takers, order-givers are secure, confident, and charged with emotional energy. This is because they are at the head of organizational units that support their initiatives and legitimate their orders. Order-takers, on the other hand, are relatively resentful, indifferent, and alienated. They are under constraint from the organizational coalitions headed by the order-givers; they will be punished if they do not obey.

Following Durkheim's model, Collins views the daily interactions of order-givers and order-takers as a ritual in which the former display their social value by providing information, evaluating the performances of others, and mobilizing the morale and energies of group members. The order-takers are the objects of the ritual, which is intended to arouse them to the same pitch of organizational commitment experienced by the order-givers. But since the order-givers, as the main beneficiaries of the system of organizational stratification, are most aroused in the ritual, they are most likely to cleave loyally to the symbols of the organizations they represent. As beneficiaries of far less, order-takers are also aroused—but with different emotions that are less conducive to good feelings, high energy, and loyal commitment.

Hochschild (1979, 1983) examined some of the emotional accompaniments of labor in service organizations. In an exemplary study of airline flight attendants, she found these workers to be

often conflicted in their emotions. Although they were trained specifically to do what Hochschild called emotional labor—namely, to cater to passengers' expectations in situations of high time and space constraints, as well as passengers' sometimes impolite or obstreperous behavior—flight attendants' own emotions had to be suppressed. Insulted by a passenger, they were required to suppress anger; disgusted by a passenger's conduct, they were required to overlook their own emotion; and so on—all in the service of not alienating customers. According to Hochschild, this left many of the flight attendants emotionally numb from the overpractice of emotion suppression. Hochschild generalized these findings to the service economy at large, where most of the occupations that require emotional labor are staffed disproportionately by women.

Taking a broader perspective on social structure, Theodore Kemper (1978, 1987, 1989, 1990) proposed that most emotions could be examined as resultants of interaction outcomes in two dimensions; namely, power and status. Power is a relationship in which one actor compels another actor to do something the latter does not want to do. This entails the employment or threat of employment of a variety of noxious stimuli—from physical and verbal violence, through withholding of deserved rewards, to subtle manipulations such as lying and deception. Power is exercised pandemically, whether in informal social interactions or in organizations that carry out the broad work of society.

Status (or status-accord), on the other hand, is a social relationship in which actors voluntarily provide rewards and gratification to other actors. Coercion plays no part here. Status-giving is the basis of true social solidarity, and individuals who voluntarily share membership with each other in a social group are normally motivated to provide each other with the benefits of status, the ultimate degree of which is love.

Kemper proposed that outcomes of interaction in power and status terms give rise directly to emotions. For a sense of how this works, it is important to see that a relatively simple model of social relational outcomes suffices for the analysis. Every relational exchange takes place along the dimensions of power and status. For each actor,

the outcomes can be: an increase in power and/or status, a decline, or no change. This produces 12 possible outcomes (2 actors \times 2 dimensions \times 3 results), but only 4 of these will actually occur, namely a power and status outcome for each actor A. Emotions will flow from these.

In the power dimension, the available evidence suggests that actor A loses power or actor B gains it, the emotional outcome for actor A is some degree of fear or anxiety. If actor A gains power and/or actor B loses it, the emotional outcome for actor is likely to be a sense of security. In the status domain, the outcomes are a bit more complex. If actor A gains status, he is likely to feel contented, satisfied, and happy. If actor A loses status, the emotional outcome depends on the felt sense of agency: Who was ultimately responsible for the status loss? If actor B is held culpable, the emotional result is anger. If the self is held culpable, the emotional result is shame or, more seriously, depression, if actor A feels that the situation is irremediable.

When the situation is one in which actor A gives status to actor B, we may expect satisfaction and contentment on the part of actor A. When actor A withholds or withdraws status from actor B, several emotional outcomes are possible. If actor B is deemed responsible (“deserving” this treatment), the result is likely to be satisfaction of a self-righteous kind on the part of actor A. If actor B was not responsible (not “deserving” the treatment), then two emotions are possible, either singly or jointly. If actor A deems that he or she did not live up to his or her character standing—that is, the amount of status with which he or she is generally credited by others as deserving—he or she will feel shame. On the other hand, if actor A concentrates on the harm or hurt he or she did to actor B, guilt is likely to ensue. In the instance of shame, actor A recognizes that he or she has acted in such a way as not to deserve the status he or she has been accorded. In the case of guilt, actor A recognizes that he or she has used an excess of power against actor B.

Some aspects of emotion also follow from anticipations that are either confirmed or disconfirmed by subsequent interaction. Thus, the actor who anticipated losing power but did not should feel especially secure. The actor who did

not anticipate receiving status but received it is likely to feel especially pleased. In general, disconfirmations of expectations tend to exert a multiplier effect on the emotions that would ordinarily be felt from the power–status outcome in the situation.

Kemper’s approach to emotions through power and status analysis also allows a social relational perspective on love and on its frequently confused near-relation, liking. Kemper defines a love relationship as one in which at least one actor gives or is prepared to give extreme amounts of status (for terminological purposes, status is equated with affection) to another actor. The definition includes nothing about power, but since power is a feature of all relationships, including it allows for seven different ideal-typical love relationships: (1) *Adulation*, in which one actor gives or is prepared to give extreme affection to another who may not even know of the other’s existence. Neither actor has or uses power. (2) *Ideal love*, in which each actor gives or is prepared to give extreme amounts of affection to the other. Neither actor has or uses power. (3) *Transference* or *mentor love*, in which each actor gives or is prepared to give extreme amounts of affection to the other, but one of the actors also has a great deal of power over the other. This pattern is prevalent in ideal teacher–student, therapist–client, or mentor–mentee relationships, in which the former in each case is the one with power over the latter. (4) *Romantic love*, in which each actor gives or is prepared to give extreme amounts of love to the other, but each actor also has a great deal of power over the other. This is the kind of relationship in which each can suffer intensely from the real or imagined withdrawal of affection by the other. (5) *Unfaithful love*, in which only one actor gives or is prepared to give extreme amounts of affection to the other, but both actors have a great amount of power. Infidelity is a case of this kind of relationship; the betrayer has withdrawn affection from the betrayed, although the betrayed still has a great deal of power, which is why most infidelities are kept secret. (6) *Infatuation* or *unrequited love*, in which one actor gives or is prepared to give extreme amounts of affection to the other but has no power, while the other actor gives no affection but has a great deal of power. (7) *Parent–Infant Love*, in which the parent gives extreme amounts of affection to the infant and the

infant gives nothing in return, while the parent has a great deal of power and the infant has none. These seven relationships can also be represented visually in a two-dimensional space according to their power and status (affection) locations (See figure 1).

Kemper (1989; and Reid 1997) distinguishes love from liking as follows: one feels love for another when the other’s qualities match one’s standards to an extremely high degree. It does not matter what the standards are; they may be trivial (e.g., he dresses well; she dances well) or they may be profound (e.g., he is a noble man who would

risk his life to preserve others; she is compassionate woman whose concern is with the well-being of others). In either case, if one has standards that are met by these qualities in the other, then it is likely that feelings of love will be induced. Ordinarily, more than one standard must be met by the qualities of the other in order for love to bloom. No small standard in Western culture is appearance, which often dominates all others, at least among the young. Love thus has to do with the qualities of the other and how they match our standards.

Liking, on the other hand, according to Kemper, is the pleasant feeling that arises when the other

gives us status or affection. Liking requires that the other act well toward us; love has no such requirement, as shown by such types (above) as adulation, unfaithful love, infatuation or unrequited love, and parent-child love. In each of these, one party loves another who gives no affection in return. In love this is possible; in liking, it is not.

Kemper's use of power and status is matched by Heise (1979) and his colleagues (Smith-Lovin and Heise 1988; MacKinnon 1994) in another structural approach to emotions known as affect control theory (ACT). Heise's model of interaction and emotions stems from a linguistic paradigm, most notably the semantic differential (SD), which purports to get at fundamental categories of meaning in the use of language. Supported by many cross-cultural studies, the proponents of the SD have found three fundamental dimensions: potency (power), evaluation (status), and activity. Kemper does not include activity in his approach to emotions, although it has a place in a more general social organizational framework as standing for technical activity in the division of labor.

Working with the potency, evaluation, and activity dimensions, Heise and his colleagues have developed a mathematically sophisticated set of formulas to predict a variety of outcomes, including emotions. First, common language terms—nouns, verbs, adjectives—are rated by samples of respondents for their potency, evaluation, and activity standing. For example, the term *father* may stand relatively high on each of these; on the other hand, the term *criminal* may stand high on potency and activity but low on evaluation. Heise has compiled a large dictionary of such terms whose potency, evaluation, and activity values can be entered into complex regression equations to predict emotions.

The basic notion in ACT is that individuals behave so as to maintain their fundamental identity. If something has occurred—whether action by oneself or another—that questions the validity of that identity, an emotion results. For example, a parent may usually be loving to his or her child, but if the parent acts out of character by behaving cruelly or indifferently to the child, there is a felt need to reequilibrate the relationship and reclaim the identity of loving parent. The emotion, whether it is shame or guilt, provides some of the

motivational energy to repair the relationship and maintain the fundamental identity.

In some examples of how this works, Heise and his colleagues found that when a father serves a son, the father's emotions were predicted to be pleased, contented, and relieved, while the son's emotions (the emotions of the recipient of interaction can also be predicted) were predicted to be amused, light-hearted, and euphoric. If a judge sentences a gangster, the judge's emotions were predicted to be contented, relieved, and proud, while the gangster's emotions were predicted to be uneasy and awestruck. Several emotions are usually generated by the ACT equations because they have approximately equal value in potency, evaluation, and activity terms for the given situation.

Heise has examined complex instances in which an individual is observed to perform an act and reveal a number of emotions. How others will judge the actor is predicted to be based on the emotions the focal actor reveals. For example, when a man kisses a woman, if he is cheerful, he is identified as a gentleman, pal, or mate, identities that gain significantly in evaluation, with some loss in the potency dimension. On the other hand, if he kisses a woman and manifests disgust, he is identified at a much lower evaluation level, but with his potency remaining unchanged. If he displays nervousness, he is identified as having lower standing in both evaluation and potency.

Heise's method also allows for a distinction between emotions and moods. For example, if a father ignores a son, the father is predicted to feel unhappy. ACT now predicts that the father will act to reinstate his identity as a father who does not ignore his son. In contrast to the father who became unhappy over his act, there is the unhappy father, a fundamental identity combining a social position with an emotion. Heise identifies this as a mood. According to ACT, moods give rise to consistent behavior; for example, the unhappy father might neglect or attack the son.

In all, the structural theorists of emotion are concerned with predicting emotions from the social locations and relationships of actor. This assumes that there is a natural (or pancultural) universal reaction to certain kinds of social relational outcomes. For example, insult evokes anger. One

of the most important differences between the social structural and cultural approaches (to be discussed next) hinges on whether this assumption is correct.

Cultural Approaches to Emotions. In contrast with the social structural view of emotions as direct results of social relations between actors, the cultural approach inserts an intervening stage; namely, the normative definition of situations and the specification of what emotions are appropriate in them. Hochschild proposes that these “feeling rules” define and regulate the expression of emotion. Examining emotions from this perspective leads to a strong emphasis on the study of how emotions are managed so that they conform with the normative requirements of given situations. Culturally oriented sociologists of emotion are also concerned with how emotions contribute to social order. Guilt and shame are significant emotions for this purpose.

The cultural approach to emotions is partial to cognitive and idealist models, since these concern themselves with mental processes that come to determine emotions. The fundamental source of the cultural approach is *symbolic interactionism*. In this school, whose prime practitioner and exemplar was George Herbert Mead (1934), the fundamental notion is that virtually nothing, not even mind or self, precedes social interaction. Thus social interaction actually constitutes or constructs these fundamental categories.

Mead proposed that after some cooperative interactions with another person, we have the capacity to call up in ourself the probable reaction of the other to any proactive behavior of our own. This is based on the recollection of the pattern of interactions with the other when one or another behavior on our part elicited one or another response on the part of the other. The ability to recapitulate all this in our head prior to any actual behavior is what Mead termed *mind* and the process, *thinking*.

Having derived mind from prior social interaction, Mead went further and located the origin of the self in the same kinds of interactive encounters with others. In Mead’s terms, we become capable of putting ourself in the place of the other and looking at ourself as if we were an object. This

mental operation provides us with a sense of self—our identity—as derived from the perspective of another. The actual self of the individual is some composite of the many selves that are available when one takes the perspective of the many others with whom one interacts.

The most widely known approach to emotions from the symbolic interactionist perspective is offered by Hochschild (1979, 1983). She posits that emotions arise in a somewhat natural way in situations or frames. But the emotion is then subjected to examination as more or less appropriate from the perspective of the normative borders of the situation. Expressed as “feeling rules,” the norms specify the required emotions in given frames: happy at birthday parties, sad at funerals, and so on. Because most people react emotionally to situations in more or less the ways that the rules require, they are rarely conscious of the rules. But should there be a discrepancy between the emotion and the rule, there is a sense of discomfort and a felt pressure to adapt. Hochschild offers a number of likely strategies that are used to manage one’s emotions in such emotionally deviant situations. Principally, one may engage in either surface or deep acting. In the former, one puts on the manifest signs of the emotion even if one does not authentically feel it; for example, smiling at the host of a party, despite the fact that one despises him. In deep acting, the individual actually tries to evoke the prescribed emotion.

For Hochschild, emotion essentially results from a discrepancy between what we perceive and what we expected. The inchoate feeling is labeled by cultural fiat as anger, fear, shame, and so on, and this provides a reservoir of cultural associations with the significance, meaning, implications, and so on of having such an emotion. These may ramify into modifying or seeking to change the emotion. Thus culture, the aggregate of normative understandings derived from others, intervenes early in the emotion process, leading to the judgment that emotion is a social construction. For example, shame is constructed from five perceptions: motive (I want to do right); possession (I have done wrong); value (I disapprove); agency (I am the cause of the event); and self-agent relations (the audience for my act is better than I am).

Hochschild’s (1983) widely cited study of emotion management among airline flight attendants

has led to a significant body of research that has focused on the *emotional* effects of managing emotions. These studies are reviewed by Morris and Feldman (1996) and Gibson (1997).

Peggy Thoits (1990) has taken Hochschild's ideas on emotion management to another level. In her view, emotions are comprised of four elements: situational cues, physiological changes, expressive gestures, and an emotion label. These are so connected in memory and behavior pattern that the elicitation of one evokes the others. Thoits proposes that when emotions and feeling rules are discrepant, the actor can manage this through either cognitive or behavioral manipulation of the four elements of emotion. For example, one can withdraw when a deviant emotion is felt (behavior-situational), or one can exercise or take drugs to change the physiological base of the emotion (behavior-physiological), or one can redefine the situation so that its implication for emotion changes (cognitive-situational), and so on.

Thoits also expands Hochschild's notion of emotional deviance through proposing four situations that might dispose toward it: multiple role occupancy, subcultural marginality, role transition, and rigid rules governing ongoing roles or ceremonial occasions. Thoits also proposes that a deviant emotion not only violates the feeling rules but also includes emotions that are too prolonged, too intense, or directed at the wrong target. Yet even deviant emotions may become legitimate if they are widely shared, thus leading to a change in social norms. An example is the change in national sentiment brought about by the protests of the antiwar movement during the Vietnam period.

In another fundamentally symbolic interactionist approach to emotions, Clark (1997) examines sympathy, an emotion treated importantly by Adam Smith ([1759] 1853) in his *Theory of Moral Sentiments*. Clark sees sympathy as a pervasive emotion, making society possible, for without it there would be no "social glue." Indeed, since sympathy is so important, "sympathy entrepreneurs," emerge to facilitate the evocation and display of this emotion. These are voluntary organizations designed to mobilize sympathy for specific victims (for example, Mothers Against Drunk Driving [MADD]) or commercial organizations, such as greeting card companies, that facilitate expressions of sympathy by large publics. Clark also sees what she refers to

as "sympathy margins" as regular features of social relationships. These are earned credits, so to speak, that enable individuals to call on the understanding, sympathy, and forgiveness of others when they are caught out, or caught short, or have otherwise become hapless victims.

Steven Gordon (1981) is another exponent of the social constructionist view of emotions. Although he acknowledges that emotions per se are elemental and biological, he contends that shortly after childhood they are culturally transformed into what he calls "sentiments." For example, the elemental emotion of anger is converted into such sentiments as resentment, righteous indignation, moral outrage, and so on. This is presumed to be the fate of all emotions. Since sentiments are socially formed, they can be invented or even abandoned.

Gordon stands within the tradition of Norbert Elias (1978a, 1978b), who offered an insightful historical perspective on the emergence of the emotion of shame as an important feature of social relations between different social classes. Elias examined especially the relations between the rising bourgeoisie of the fifteenth and sixteenth centuries and the aristocrats who disdained them. In many instances the nobility, seeking to insulate itself from the incursions of lower-status merchants and traders, refined their practices in the execution of common daily chores involving dining, self-cleansing, toilet functions, and so on. Those who could not match the newly defined limits of gentility were exposed to ridicule and shaming. For a long historical period, the aristocracy were the arbiters of manners, that is, what passed for acceptable social conduct. Those who were ill trained in the ultrarefinements thus properly felt shame.

Although symbolic interactionism has been used to refute the idea of fixity in the domain of emotions, Susan Shott (1979) and Thomas Scheff (1979, 1988, 1994, 1997) have also employed it to show how emotions underlie social order and stability. The fact that pattern and predictability exist in much of social life, rather than chaos and randomness, poses one of the longstanding problems in sociological analysis. It is generally acknowledged that the reverse side of social order is social control, indicating that society manages somehow to instill in individuals a propensity to comply with required social forms and that deviance from

these forms, though greater in some periods than in others, is actually quite limited. How is this accomplished?

There are two main answers to the question, and both of them turn on emotion. First, social order may be imposed by dominant and powerful groups. Their tactic is to evoke fear for nonconforming behavior. Although it has been argued by some, such as Talcott Parsons, that such regimes cannot be stable in the long run, in the short run they can have remarkable sticking power. Decades or even centuries may elapse before a feared government is overthrown.

The second ground for social order entails acceptance of the existing pattern of things. And here sociologists have split on what is accepted. On the one hand, social order can flow from belief in the validity of the social norms. One pays one's taxes, serves in the armed forces, does not steal even when there is an opportunity to do so undetected, and so on because the rules are deemed valid and it feels morally right to abide by them. A second view, which has come to prominence, is that underlying social order is an emotional order. Without an emotional basis, social order would not be possible.

Attacking the question from a symbolic interactionist perspective, Shott proposes a set of "role-taking emotions" that are central to social control: guilt, shame, embarrassment, pride, and vanity. Each of these involves the central symbolic interactionist mechanism of putting oneself in the place, or taking the role, of the other person and thereby evoking his or her perspective. The result of such role-taking can be an emotion directed toward the self, because it evokes in the self the judgment that others are making about the self. Guilt involves the self- and (presumed) other-judgment of "moral inadequacy." Shame entails the self- and (presumed) other-rejection of an "idealized self-image." Embarrassment arises from the realization that others view one's self-presentation as "inept." Pride comes from placing oneself in the position of others and regarding oneself with approbation; vanity is a reduced form of this, in that one is not sure of other's approval.

These emotions (with perhaps the exception of vanity) operate homeostatically. Individuals are moved to reduce the incidence of such unpleasant emotions as guilt, shame, and embarrassment and

increase the incidence of pleasant emotions such as pride. How is this done? Obviously, one avoids the unpleasant emotions by avoiding conduct that would earn the disapprobation of others. One gains pleasant emotions by engaging in conduct of which others approve. In general, the emotions fit one into the moral requirements of others, who are themselves governed by the same set of pre- and proscriptions for social conduct.

Shott suggests that the role-taking emotions are an inexpensive way for society to obtain social order, since they make each person his or her own guardian in ensuring that the emotional tone of one's life remains, on balance, more pleasant than painful. Where such self-control fails, the prospects of social order are not entirely dim, for the emotions that ensue—guilt, shame, or embarrassment—motivate reparative action to reequilibrate the social order as well as others—therefore, one's own—opinion of oneself. Thus, guilt and shame have been shown to increase compensatory altruism toward others, and embarrassment has been shown to evoke compensatory supererogation or attainment as a way of reequilibrating the judgments of others about the self to return to a positive balance.

Finally, Shott proposes a role-taking emotion that is not reflexive, in that it does not pertain to a judgment of the self. This is empathy, which allows one to feel what the other person in the situation is feeling, or what one would likely feel if one were in the place of the other person. Empathy makes any emotion vicariously accessible. Where the emotion reveals the other to be in a socially vulnerable place, one has the embodied sense of the need that other has for social rescue, and the likelihood of engaging in that rescue is enhanced. Thus empathy allows for the evocation of solidarity with others and the preservation of social order through protective behaviors that take up the slack when others are unable to act suitably in their own behalf.

Scheff is also concerned with social order, but he focuses on shame and pride as the ne plus ultra emotions in this regard. He takes a cue from Charles Horton Cooley's ([1902] 1922) famous looking-glass metaphor: "Each to each a looking glass, reflects the other that doth pass" (p. 184). Cooley asserted that pride and shame were the emotional engines for getting individuals to conform to the requirements of their fellow members

in society. Scheff proposes that individuals are continuously in a state of either pride or shame. But then the question arises as to why, if these emotions are so important, there is so little evidence of them.

Scheff proposes that shame is a recursive emotion. That is, once present it has a tendency to evoke more shame, or even anger, over the fact that one is ashamed. This can lead to a spiral of emotion about emotion about emotion . . . that leads to both an inability to escape the emotion and a tendency to hide it from others—a frequent response when coping with shame. This hiddenness, proposed as a defining feature of shame, ties in with the work of Helen Block Lewis (1971), whose intensive analysis of psychotherapy protocols revealed two types of “unacknowledged” shame: *overt, undifferentiated shame* and *bypassed shame*. The former is manifested by painful feelings and self-derogation (“I am stupid, foolish, feckless, incompetent,” and the like). Often this is accompanied by stammering, unnecessary word repetition, averted gaze, and declining audibility of speech. Both the verbal, paralinguistic and proxemic forms are means of hiding the self from the evaluating gaze of others.

Bypassed shame, on the other hand, leads to covert such symptoms as obsessive focusing on the episode that evoked the inadequate response, as if the replay could retrieve the lost status. Thought and speech are hyperactive, actually preventing one from participating with others in the natural rhythm of conversational flow. Both types of shame share the common characteristic of low visibility, thus demonstrating the power of shame as the emotional foundation of social control. Only those with sufficient self-esteem can acknowledge their shame and thus discharge it. But self-esteem itself, as proposed by Mead, derives from the good opinion of others, which itself arises when one conforms to their normative requirements; that is, when there has been social control.

This formulation, implying catharsis in the discharge of shame, ties into Scheff’s work on the problem of undischarged emotions. Scheff proposes that catharsis of these residual emotions can only occur in properly “distanced” settings. Here Scheff adopts the concept of “aesthetic distance,” employed by Bullough in his analysis of drama. According to Bullough (1912), an audience can

experience a dramatic presentation in various ways according to its emotional distance from what appears on stage. Too little distance involves the audience so deeply that it forgets it is merely watching a play and wants to mount the stage in defense of the hero. Too much distance leaves the audience uninvolved, indifferent to whatever murder or mayhem may be happening on stage. Optimum, or aesthetic, distance, like the last of Goldilocks’s porridge bowls and beds, is “just right,” providing a comfortable level of emotional arousal that leads to the “purgation of pity and terror,” which according to Aristotle was the aim of drama.

In a similar vein, Scheff proposes that troublesome residual emotions may also be purged in social settings where there is optimum distance. To do so, he suggests, requires that the expressive emotional content be retrieved (for example, crying, trembling, sweating), but in a context in which the individual can be both participant and observer of his or her own emotional display. When these conditions for emotional aesthetic distance are met, catharsis occurs. This is signaled by an anomalous emotional outcome: even though the residual emotion may be unpleasant, discharging it is not unpleasant, and there is a succeeding state of clarity of thought, relaxation, renewed energy or exhilaration. Although the catharsis paradigm is somewhat different from the social control paradigm, the two are joined in that unacknowledged shame, which is not discharged, often leads to spirals of emotion (e.g., anger over shame over fear) that incapacitate individuals in their social interactions, leading sometimes to violent outbursts that break through all the bonds of social control.

Robert Thamm (1992) builds a theory of emotions on the foundations of Talcott Parsons’s and Edward Shils’s scheme for a general theory of action. In their formulation, social actors are linked in reciprocal forms of action and response through expectations and sanctions. In social settings, individuals have expectations of each other, and in light of those expectations they reward or fail to reward each other’s behavior. From each actor’s perspective, according to Thamm, this leads to four questions: (1) Is the self meeting expectations? (2) Is the self receiving rewards? (3) Is the other meeting expectations? (4) Is the other receiving rewards? These constitute a social matrix for

the production of emotions. As the answers to these questions vary from yes (+) to no (-) to don't know (0), different emotions result. A given state of the system of self and other's expectations and sanctions can be coded by a pertinent series of pluses, minuses, and zeros. For example, if the answer to all four questions is yes, the coding is [++++]; if the answer to all four is no, the coding is [----]; if the answer to the first two is yes and the last two is no, the coding is [++--].

Based on the permutations of the many possible states of the expectations-sanctions system, Thamm hypothesizes a variety of emotional resultants. For example, when the self meets expectations [+000], the self feels pleased with itself. When the self does not meet expectation [-000], the self feels disappointed with itself. When the other does not meet expectations [00-0], the self feels disappointed in the other. When the self meets expectations but is not rewarded [+00], the self feels powerless. When the other does not meet expectations, so that the self is not rewarded [0--0], the self feels anger at the other. Many additional hypotheses follow from the variations along the spectrum of expectations-sanctions possibilities.

The reliance of the cultural approach to emotions on mental structions susceptible to socialization and variable according to historical conditions of change, directly conflicts with at least some elements of the social structural position. The latter places more emphasis on universal situational determinants of emotion and on some biological mechanisms that articulate with the situation-emotion nexus. Kemper (1987) has attempted to reconcile some of the opposing views through a syncretic analysis, focusing on the issue of primary and secondary emotions.

Kemper proposes that a large body of cross-cultural, phylogenetic, autonomic, social relational, and classificatory evidence leads to a model of four primary emotions: fear, anger, sadness, and joy (or nominal variants of these). Since there are additional emotions, the question is: What is their source? Kemper proposes that emotions beyond the primary ones may arise from a specific pattern of socialization in which a social definition and label are applied to a situation in which one of the primary emotions is being felt. For example, pride may be derived from socialization to the idea of self-regard for accomplishment in a context of joy.

Shame may result from socialization to the idea of self-rejection in a context of anger. And guilt may derive from socialization to the idea of self-rejection for what is defined as a morally wrong action in the context of fear. The primary emotion contexts are important because they provide the autonomic, therefore specifically emotional, underpinnings of the secondary emotions. The cultural components, such as situational definitions and emotional labels, are important because they help the person differentiate and ascribe the feeling to particular social and behavior contexts.

Gibson (1997) offers a different approach to the reconciliation of the structural and cultural approaches to emotions by incorporating aspects of both in his model for feeling and expression of emotions in organizations. Both structural conditions and display rules operate to instigate and control emotions in organizational contexts.

REASON AND EMOTION

One of the longest-standing problems in the study of emotions is the relationship between emotions and reason. This question has engaged two millennia of philosophers and psychologists, including Aristotle, Aquinas, Spinoza, Hume, and Freud. Sociologists are latecomers here, but have substantially and persuasively claimed that reason is not an isolated domain of human action, but is imbued with emotion (Kemper 1993), a point that a sociological approach makes particularly clear.

Max Weber ([1922] 1947) set the stage by distinguishing between *Zweckrational*, or expedient action, and at least two types of emotional action: *Affectuel*, or impulsive action, and *Wertrational*, or value-oriented action. But he did little to develop the relationship between the two emotional types and the strictly expedient type. The latter is the prototypical action of economic theory, where means are examined and selected to attain the best possible outcome. In the economic version, money is the usual yardstick for the efficacy of the decision based on expediency. Other considerations are treated more or less as "noise," disturbing the adequacy of the model. The sociological version of this economic approach is rational choice theory.

In a radical confrontation with rational choice theory, Collins (1993) throws down the gauntlet to

economically based theories. He argues that the main preference order is based on emotional currency, namely emotional energy (EE) which is acquired in successful interactions with others (see earlier description of Collins' work). The good feelings—confidence and enthusiasm—that individuals derive from participation in interaction are the *summum bonum*, and this is what individuals are attempting to maximize in their so-called rational choices, regardless of what the currency may appear to be—money, status, practical or aesthetic enjoyment of material goods, and so on.

Lawler and Thye (1999) approach the rational choice issue through the window of social exchange theory, in which self-interested actors are trying to obtain something of value from other self-interested actors. They examine the *context* of exchange, which ordinarily will have a certain emotional tone and emotional requirements, the *processes* of exchange, which may make actors feel satisfied, excited, or otherwise emotionally aroused, and the *outcome* of exchange at which point actors may feel gratified or angry, prideful or crestfallen. In a useful schematic formulation, Lawler and Thye organize the context, process, and outcome features of exchange according to six different mainly sociological approaches to the study of emotions. For context, the *cultural-normative* approach (Hochschild 1979) and the *structural-relation* approach (Collins 1975, Kemper 1978); for processes, a psychologically oriented *social-cognitive* approach (Bower 1991) and a *sensory-informational* approach (Heise 1979); and for outcomes, a *social attribution* approach (Weiner 1986) and a *social formations* approach (Collins 1981 and Lawler and Yoon 1998). This schematic formulation enables analysts to move easily into the examination of motions in social exchange situations.

EMOTIONS AND MACROPROCESSES

Most sociological examinations of emotion are social-psychological; that is, social structures, processes, or outcomes of these are seen to produce emotions in the individuals involved, with emotions differing according to where in the structure, process, or outcome the individual stands. Jack Barbalet (1998) provides an important exception to this social-psychological approach, conceiving of emotion as integral to social relations and social

processes themselves. Emotion is felt by individuals—this cannot be escaped—but as an aspect of societal patterns of social organization in terms of class, gender, race, and the like. This leads to another perspectival difference: Most sociological approaches to emotion examine social processes and social relations as the independent variables—they cause or produce emotions. Barbalet reverses this and examines how emotions cause or produce social processes and social relations. Furthermore, this is conceived at the macro level, engaging societal, as opposed to interpersonal, processes.

For example, working-class individuals might be expected to harbor social resentment against those who are better off, but such resentment is scant in the United States and has led to no effective political movements. Following Bensman and Vidich (1962), Barbalet tries to explain this in part by locating different sectors of the working class in different places in normal trade cycles in capitalist societies. A dynamic economy contains both expanding (e.g., computers) and contracting (e.g., textiles) industries, and workers in the different industries cannot be expected to experience the same emotions, thus vitiating any theory or program that views workers in a monolithic way.

In another venture into the macrosociology of emotions, Barbalet examines the emotion, mood, or feeling of confidence as an important feature of social process. Particularly in the business community, confidence is a necessary condition of investment. Indeed, in Barbalet's view, confidence dominates even rational calculation. This is because rational business planning is limited by the fact that it is future-oriented and the information that rational assessment requires is unavailable—it can only unfold in the future. Therefore, to undertake action under conditions of limited rationality, the business community must rely on its intuition that investment will be profitable. Put otherwise, it must have confidence. Government is an important constituent of the situation, sometimes enhancing and sometimes depressing business confidence. Barbalet proposes that what differentiates these effects of government policy is whether they reflect "acceptance and recognition" of the business community. For example, government spending on infrastructure or the bailout of the savings and loan industry reflect such appreciation. On the other hand, business interests feel slighted when the government proposes strict policies to

reduce global warming, and business confidence falls accordingly. In both examples—those of the working class and business—the emotions are aggregated products of many individuals that then act as a discrete force in society.

In an unusually strong entry of a macrosociological approach into the domain of emotions, Jasper (1998) and Goodwin and Jasper (1999) have argued for the overlooked importance of emotions in the understanding of large scale social movements. Social movements, they argue, are awash in emotions. Anger, fear, envy, guilt, pity, shame, awe, passion and other feelings play a part either in the formation of social movements, in their relations with their targets who are either antagonists or possible collaborators, and in the lives of potential recruits and members. Without the emotions engaged in movement environments, dynamics, and structure it would be hard to explain how social movements arise, amass critical levels of support, maintain such support in long enduring campaigns in the face of often intense opposition, and provide means for recruiting and sustaining supporters, both as active members and as favorably disposed publics and bystanders. Understanding the dynamics of emotions thus clarifies social movement dynamics.

CONCLUSION

The sociology of emotions has a long history but only a short recent life. It is a diverse speciality, reflecting many of the axial divisions that currently rend the field, but one that lends itself to the illumination of a large number of problem areas from the micro to the macro level. The main requirement for the present-day sociology of emotions is, as Peggy Thoits (1989) has argued, to pursue empirical support for its many theories. Only in this way will it become clear in which direction theory can most fruitfully go.

THEODORE D. KEMPER

ENVIRONMENTAL EQUITY

The scientific study of the social distribution of environmental impacts has quickly become an important area of inquiry within environmental sociology. Scholarly interest in this topic—which has been referred to as environmental justice,

environmental equity, or environmental racism—does not derive from formal theories of differential environmental impacts, but rather has been inspired by the rapidly evolving environmental justice movement. Sociologists have studied both the social movement itself and the claims of environmental inequity made by the movement's proponents. The study of environmental justice has important implications for other areas of sociology, including stratification, race relations, sociology of health, and the study of social movements.

THE ENVIRONMENTAL JUSTICE MOVEMENT

Origins of the Movement. In the summer of 1978, the state of New York finally acknowledged what the residents of Love Canal had suspected for some time—that some of the 21,000 tons of chemical waste that had been dumped into an abandoned canal between 1942 and 1952 were now leaking into the basements of nearby homes and percolating into the playgrounds of the elementary school that had been built directly above the filled canal (Levine 1982). The situation presented “great and imminent peril to the health of the general public residing at or near the site,” according to the New York state commissioner of health (as quoted in Levine 1982, p. 7). This announcement galvanized the concerns and suspicions of many residents of this working-class community, who for years had endured bad smells, mysterious sinkholes, skin irritations, respiratory problems, spontaneous abortions, and birth defects. Soon after this announcement, the private concerns of individual people began to develop into an organized social protest that pressured the state and federal governments to take action to protect the health, safety, and property of the citizens.

The events at Love Canal continued to make national headlines for the next two years. In 1979, before the media or the public could forget about environmental health risks, an accident occurred at the Three Mile Island nuclear power plant near Harrisburg, Pennsylvania (Walsh 1981). Large quantities of radioactive gas and water were released, and over 100,000 residents within a 15-mile radius of the plant were evacuated. Overnight, public support rallied behind local anti-nuclear groups that had previously been viewed as radical.

Soon after, grassroots anti-toxics movements began to proliferate in the United States. In addition to the media attention given to Love Canal and Three Mile Island, a number of other factors set the stage for the emergence of these movements. The growing popularity of the mainstream environmental movement and books such as Rachel Carson's *Silent Spring* (1962) had made much of the public aware that there were health hazards surrounding man-made chemicals, that citizens could be exposed to them unknowingly, and that technical and political solutions to such problems were not readily available (Cable and Shriver 1995; Freudenberg and Steinsapir 1992; Szasz 1994). In addition, problems associated with the unsafe disposal practices used during the post-World War II industrial boom began to surface at this time, causing increasing discovery of new toxic contamination problems.

Racial issues quickly became central to the environmental justice movement. The first environmental justice protest organized by African Americans took place in 1982 in Warren County, North Carolina, where the state proposed to build a landfill for the disposal of hazardous polychlorinated biphenyls (PCBs) that had been illegally dumped in 14 different North Carolina counties (Bullard 1994). This was a poor, mostly black, rural community. Why had this community been chosen to receive the landfill? Local residents believed that race was a deciding factor. They called upon black civil rights leaders for support, and a protest was organized. Although the landfill was eventually constructed, the Warren County protest was a landmark in the history of the environmental justice movement. Since then numerous other communities of color, primarily African American, Hispanic, and Native American, have become active in the environmental justice movement (for examples, see Bullard 1993 or Hofrichter 1993).

The formation of local-level anti-toxics movements has tended to follow a general pattern (Cable and Benson 1993; Cable and Shriver 1995). The first stage is the recognition that there is a local toxics hazard. Often, this recognition is a result of health problems among members of the community. Thus it is frequently women, particularly housewives, who are the first to become involved with toxics issues, since they are most likely to take responsibility for the health of the family (Krauss 1993; Brown and Masterson-Allen

1994). Once a toxics problem is perceived by community members, they typically turn to official administrative and regulatory bodies for correction of the problem. The results are usually disappointing, and residents often come to believe that these institutions actually serve the interests of polluters more than the interests of residents (Bullard 1994; Cable and Benson 1993; Krauss 1989; Levine 1982; Molotch 1970). A sense of injustice, and often a deep sense of betrayal, develops among local activists, and they begin to pursue alternative means of social control through social movement organizations.

Most anti-toxics movements emerge in poor, working class, or minority communities (Brown and Masterson-Allen 1994; Freudenberg and Steinsapir 1992). Many activists and analysts alike argue that this is due to the disproportionate share of toxic pollution borne by these communities (Austin and Schill 1991; Bullard 1994). More affluent communities have more resources to draw on—including adequate funding, an educated membership, access to professional advice, and social networks that overlap with local power structures—and thus they are better able to control pollution problems through the political and regulatory processes (Hurley 1995; Molotch 1970).

The notion that less powerful communities have been targeted for polluting facilities was further reinforced by the widespread circulation among the grassroots community of a report written by the consulting firm Cerrell Associates, Inc. for the California waste industry. The report recommended that waste incinerators would most easily be sited in communities least likely to generate political resistance (i.e., communities that have populations that are older, more conservative, less educated, and have lower average incomes) (Cerrell Associates, Inc. 1984; Cable and Shriver 1995).

Relationship to Mainstream Environmental Groups. The environmental justice movement differs significantly from the “mainstream” environmental movement in terms of its membership, values, and tactics. The mainstream environmental movement has focused primarily on issues of conservation of natural resources and preservation of natural beauty. Membership in mainstream environmental organizations grew rapidly in the United States from 1960 to 1990, with three groups—the Sierra Club, the National Wildlife

Federation, and the National Audubon Society—each claiming more than 500,000 members (Mitchell et al. 1991). Mainstream environmental groups have professional staffs, generate funds through large foundation grants and membership dues, and work primarily within the system by using lobbying and litigation to influence government action.

Mainstream environmentalism has often been characterized as an elite movement. Early studies supported this general view when they found the greatest support for environmental causes among people who are young, white, well-off, urban, well-educated, and politically liberal (Buttel 1979; Buttel and Flinn 1974; Kreger 1973; Morrison et al. 1972). Some more recent research has confirmed these findings (Jones and Dunlap, 1992). However, one longitudinal study suggests the well-educated and well-off were simply the first to embrace environmentalism (Kanagy et al. 1994).

There has been some debate about the role of race in mainstream environmentalism. It has been common for social scientists to assume that African Americans will be less supportive of environmentalism than whites, but most evidence suggests that when it comes to environmental concern, there is no significant difference between blacks and whites (Jones and Carter 1994). Blacks *are* less likely, however, to be involved in mainstream environmental action (Taylor 1989; Mohai 1990). One explanation for this lag in environmental action is that blacks are more likely to experience a variety of stressors which detract from their ability to act upon environmental concerns. As Robert Bullard put it: “Decent and affordable housing, for example, is a top environmental problem for inner-city blacks” (1994, pp. 10–11).

In contrast to mainstream environmentalism, environmental justice movements tend to develop in poor, working class, or minority communities (Brown and Masterson-Allen 1994; Freudenberg and Steinsapir 1992). The two movements also have different goals—concerns about local health threats are central to the environmental justice movement. Protests often focus on pollution-generating facilities, such as factories, landfills, toxic waste dumps, incinerators, or nuclear power plants. Participants in these movements are generally people who believe they are personally at risk from the

facility. Thus, at least initially, these protests are generally grassroots-generated, and locally focused.

This focus on local issues has prompted some members of the mainstream environmental movement to charge that environmental justice activists are mere “NIMBY” (Not In My BackYard) protesters (Freudenberg and Steinsapir 1992). They accuse environmental justice activists of lacking concern for the environment in general and of acting out of pure self-interest. In turn, environmental justice activists have accused the mainstream environmental movement of representing elite interests and being content to let disadvantaged groups bear the toxic burden of modern affluence. As relative newcomers to environmental activism, members of the environmental justice movement have generally been disappointed with the lack of assistance given their cause from the larger, more established environmental groups (Bullard and Wright 1992; Taylor 1992).

Grassroots environmental protests have tended to use different tactics than the mainstream environmental groups. They typically lack the funds or the political clout to lobby and negotiate with elites. Thus they are more likely to use disruptive and attention-getting tactics, such as public protests, sit-ins, letter writing campaigns, and attendance at public hearings (Bullard 1994). In one extreme example, a group of residents in Love Canal took an EPA official hostage for several hours in an effort to generate media attention (Levine 1982). Environmental justice groups have also made use of the courts, primarily through tort actions that seek reparations for damage to health and property.

These differences between the two movements have had conflicting implications for social movement theory. The elite membership of mainstream environmental groups has often been viewed as support for *resource mobilization theory*. This theory proposes that the emergence of social movements has little to do with the existence or extent of grievances experienced by movement participants. Grievances are a given, everyone has them, and the development of active social movements depends upon the availability of resources available to particular groups of people to advance their causes (McCarthy and Zald 1977). In contrast, the environmental justice movement is based on grievances and is comprised of members with relatively

little resources. Current social movement theory appears inadequate to explain the environmental justice movement (Brown and Masterson-Allen 1994; Masterson-Allen and Brown 1990; Walsh 1981; Walsh et al. 1993).

Expansion of the Environmental Justice Movement. The environmental justice movement has evolved beyond its origin in the late 1970s as a collection of isolated local protests. Regional coalitions, such as the Southern Organizing Committee and the Southwest Network for Environmental and Economic Justice, have formed to facilitate the sharing of ideas, resources, and networks among geographically dispersed groups. A number of national support organizations have also been formed, most notably the Citizen’s Clearing House for Hazardous Waste (led by Lois Gibbs of Love Canal) and the National Toxics Campaign Environmental Justice Project (Moore and Head 1993). These organizations provide resources and information to smaller groups, and have conducted their own organizing and lobbying campaigns at the national level. Activists have also connected with the academic community, and a number of research and support centers for environmental justice have been established. These include the Environmental Justice Resource Center at Clark Atlanta University in Atlanta and the Deep South Center for Environmental Justice at Xavier University in New Orleans, among others (Wright 1995). Members of the environmental justice movement have increasingly sponsored meetings and panels that bring together activists, scholars, and the media.

Institutional responses to the environmental justice movement have also increased at the national level. In 1992 the Environmental Protection Agency established an Office of Environmental Equity (Cutter 1995). In 1994, President Clinton signed Executive Order 12898, which requires every federal agency to adhere to principles of environmental justice in its operations (Clinton 1994). The issue of racial disparity has allowed activists to file administrative complaints under Title VI of the 1964 Federal Civil Rights Act.

A New Worldview—Ecological Democracy. Many scholars have noted the profound change in worldview that often results from individual participation in the environmental justice movement. As noted earlier, environmental justice activists

often become disillusioned with the ability of the government to protect them from toxic contamination. This change is often conceived as a reframing of the toxics problem: what was initially perceived as an isolated technical or regulatory problem is now seen as a larger social issue involving the relative power of corporations and citizens, the role of the state, and conceptions of social justice (Capek 1993; Brown and Masterson-Allen 1994; Cable and Shriver 1995). Capek (1993) argues that, especially for black communities, the civil rights movement provided a “master frame” which legitimated the quest for environmental equality and permitted critical analysis of the social structure that created the inequity.

This new, broader perspective now dominates discourse on the causes of environmental inequity. As Heiman (1990) puts it, the Not In My BackYard perspective has become the Not In Anybody’s BackYard critique. When challenged as to where hazardous facilities should be located, rather than try to locate them in someone else’s backyard, environmental justice activists have responded by questioning the assumption that such facilities are a public good that must be sited somewhere. “The not-in-anybody’s-backyard stand forces the debate away from the suitability of specific waste treatment facilities of locations, and toward a more fundamental reassessment of the propriety of a production system under private control where, in the quest for profit, the public is exposed to known risks” (Heiman 1990, p. 361).

This new perspective was expressed in the *Principles of Environmental Justice*, a document created in 1991 by a group of activists at the People of Color Environmental Leadership Summit. Among the 17 principles adopted are these:

1. Environmental Justice affirms the sacredness of Mother Earth, ecological unity and the interdependence of all species, and the right to be free from ecological destruction. 3. Environmental justice mandates the right to ethical, balanced and responsible uses of land and renewable resources in the interest of a sustainable planet for humans and other living things. 5. Environmental justice affirms the fundamental right to political, economic, cultural and environmental self-determination of all peoples. 6. Environmental justice demands the cessation of the production of all toxins,

hazardous wastes, and radioactive materials, and that all past and current producers be held strictly accountable to the people for detoxification and the containment at the point of production. 7. Environmental justice demands the right to participate as equal partners at every level of decision-making including needs assessment, planning, implementation, enforcement and evaluation. (Reprinted in Hofrichter, 1993, pp.237–239)

In searching for the causes of environmental inequity, many analysts—academics and activists alike—have come to see issues of environmental justice as a result of an inherent contradiction within the liberal democratic capitalist state (Cable and Benson 1993; Hamilton 1993; Heiman 1990; Krauss 1989; see also O’Connor 1973). The essence of this argument is that the state is charged with two conflicting goals: to further the accumulation of capital and profits for private industry; and to protect the interests of individual citizens and communities. Particularly in terms of environmental regulation, these two goals are at odds because environmental regulations protect citizens from industrial externalities at the expense of profits.

This line of reasoning is compatible with that of social ecologists and eco-Marxists. For example, Faber (1998) states:

The roots of America’s ecological problems and injustices are grounded in the expansionary dynamics of the global capitalists system To sustain the process of capital accumulation and higher profits in the new global economy, American capital is increasingly relying on ecologically and socially unsustainable forms of production. . . . In so doing, America’s corporate ruling class, the 1 percent of the population that owns 60 percent of all corporate stock and business assets, is serving its own narrow material interests at the expense of the environment, communities, and the health of working people. The reason is that corporate expenses related to human health and environmental quality do not typically increase labor productivity (hence potential profits) sufficiently to outweigh such expenditures. . . . It costs capital and the state much less to displace environmental health problems onto people who lack health care

insurance, possess lower incomes and property values, and as unskilled or semiskilled laborers are more easily replaced if they become sick or die. In this sense, environmental inequalities in all forms, whether they be class, race, gender, or geographically based, are socially constructed features grounded in the systemic logic of capitalist accumulation. (pp. 2–5)

The emergence of this theoretical model of environmental justice has inspired some writers to call for a restructuring of society and a return to basic principles of democracy. They reject the false contradiction between individuals rights and social goods. In particular, they are challenging corporate power and control over production decisions (Pullido 1994; O'Connor 1993; Hamilton 1993). They favor a new social contract with the state to create an economic democracy in which decision making is decentralized. For example, O'Connor (1993) states:

For the people to regain their sovereignty and restore their environment, fundamental changes in the structure of government are required that permit effective discussion, debate, and decision making. Every citizen, regardless of wealth, should be given an equal opportunity to bring ideas to stop environmental decline directly to the American people. In addition, each citizen will need new rights, in relation to polluting or poisonous industries, in order to allow citizens an opportunity to protect themselves and their communities from the everyday abuses of economic power, against which no level of regulation or conventional governance can fully protect them. (p. 52)

Global Issues in Environmental Justice. The global dimensions of environmental justice issues have been receiving increased attention. Third World environmental problems, particularly natural resource depletion, have generally been viewed by established international authorities (particularly the United Nations) as the result of insufficient development and a lack of advanced technology (World Commission on Environment and Development, 1987). Alternatively, however, critical scholars see Third World environmental problems as the legacy of colonialism and continuing exploitation of the periphery by core nations (Esteva 1992; Harvey 1997; Redclift 1987; Sachs 1997; Weissman 1993). Plans to promote development

in the Third World often involve large-scale construction projects (often funded by the World Bank) that cause large-scale destruction of natural resources such as forests, rivers, farmlands, or native species. Agyeman and Evans (1996) explain the situation this way:

The well-entrenched belief endemic to Northern societies is that the extant economic and social conditions of many Southern societies legitimately permit commercial behaviour that would not be accepted in the North, often justified in terms of bringing employment to areas of no work. However, the implicit, unstated position is fundamentally racist, in that such commercial behaviour is deemed as appropriate for black people whereas it is inappropriate for white people. It is far away from the economic power centres of the North, and any local representations concerning pollution or environmental degradation are likely to be muted for fear of unemployment. (pp. 74–75)

A case in point is the Union Carbide pesticide factory near Bhopal, India that released a cloud of poisonous gasses in 1984, killing an estimated 6,600 people and injuring as many as 600,000. Such a massive facility probably could never have been sited in a Northern country, and it would have required much more expensive safety measures.

The involvement of U.S. environmental groups in Third World environmental issues has been strongest in the protection of forests and natural habitat, and has generally involved mainstream environmental groups and other organizations dedicated to global justice and equity (Keifer and Benjamin, 1993). One popular intervention is the debt-for-nature swap, in which a Northern environmental group pays a portion of a Third World country's debt on the condition that the recipient nation will establish a nature preserve or other conservation program. These types of programs are increasingly resented by the nations of the South, who view them as paternalistic extensions of the North's colonial control that interfere with local self-determination. One alternative that has been developed is the debt-for-Indian-stewardship swap, in which indigenous people gain control over parcels of land in exchange for debt relief (Alston and Brown 1993).

The export of toxic waste to Third World nations has also become a major political issue. As the cost of disposal rises, facilities in the United States and Western Europe are increasingly looking for new locations to dispose of their wastes. For example, a ton of waste that costs \$200 to store in the United States will cost \$40 to dispose in Benin (Mpanya 1992). About half of all African nations have been approached by Western interests to serve as dump sites. At least 25 African nations have agreed, motivated by payments of \$10 to \$25 million that can be used to make payments on international debt. There have also been several rather widely publicized cases (and probably many undiscovered cases) where toxic waste has been imported into Third World countries under false pretenses, often labeled as fertilizer or construction material. For example, 4,000 tons of toxic incinerator ash from Philadelphia were unloaded on a beach in Haiti, falsely labeled as fertilizer. The attempt to repatriate the toxic ash has dragged on for years (Bruno, 1998).

The economic logic of these practices was revealed in a leaked internal World Bank memo, written in 1991 by then chief economist Lawrence Summers, which was subsequently published in *The Economist* (September 8, 1992). It reads in part:

Just between you and me, shouldn't the World Bank be encouraging more migration of the dirty industries to the LDC's (Lesser-Developed-Countries)? I can think of three reasons: 1) The measurement of the costs of health-impairing pollution depends on the foregone earnings from increased morbidity and mortality. From this point of view a given amount of health-impairing pollution should be done in the country with the lowest cost, which will be the country with the lowest wages. I think the economic logic behind dumping a load of toxic waste in the lowest-wage country is impeccable and we should face up to that. 2) The costs of pollution are likely to be non-linear as the initial increments of pollution probably have very low cost. I've always thought that underpopulated countries in Africa are vastly under-polluted; their (air pollution) is probably vastly inefficiently low compared to Los Angeles or Mexico City. Only the lamentable facts that so much pollution is generated by non-tradable industries (transport, electric generation) and that the unit transportation costs

of solid waste are so high prevent world welfare-enhancing trade in air pollution and waste. 3) The demand for a clean environment for aesthetic and health reasons is likely to have very high income elasticity. The concern over an agent that causes a one in a million change in the odds of prostate cancer is obviously going to be much higher in a country where people survive to get prostate cancer than in a country where under-5 mortality is 200 per thousand. Also, much of the concern over industrial atmosphere discharge is about visibility of particulates. These discharges may have little direct health impact. Clearly trade in goods that embody aesthetic pollution concerns could be welfare enhancing.

In an attempt to address the problem of increasing toxic exports, the United Nations organized a convention held in Basel, Switzerland regarding the international movement of toxic waste. In 1989, 118 nations signed the Basel Convention on the Control of Transboundary Movements of Hazardous Waste and their Disposal. The Basel Convention prohibits the transfer of toxic wastes from member nations of the Organization for Economic Cooperation Development (OECD—an organization comprising the most industrialized and developed nations in the world) to non-OECD countries. However, many nations, including the United States, have yet to ratify the treaty and make it the law of the land. Furthermore, other international agreements, particularly international trade agreements such as the North American Free Trade Agreement (NAFTA) and the General Agreement on Tariffs and Trade (GATT) actually make it more difficult for individual nations to restrict the flow of toxic substances across their borders, since such restrictions can present impediments to free trade.

EMPIRICAL RESEARCH ON ENVIRONMENTAL EQUITY

Research Findings. For many environmental justice activists, the existence of inequitable environmental impacts along race and class lines is a reality. For sociologists and other scholars, however, the nature and extent of these inequities needs to be established through systematic and objective research. The protest against the Warren County landfill (described above) launched the current

interest in empirical investigation into claims of disproportionate siting of environmentally hazardous facilities in disadvantaged communities. One of the activists involved in the Warren County protest was Congressman Walter E. Fauntroy, who initiated a study by the General Accounting Office (GAO) of hazardous landfill siting in the South (GAO 1983). The GAO study, though limited in scope and analysis, found a relationship between the siting of landfills and the racial and economic characteristics of residents in surrounding communities. A more comprehensive study, also in response to the Warren County protest, was conducted by the Commission for Racial Justice of the United Church of Christ (United Church of Christ 1987). This study analyzed the presence of hazardous waste treatment, storage, and disposal facilities (TSDFs) in all zip codes in the United States, and concluded that racial composition was the strongest predictor of the presence of a TDSF. This study was circulated widely within the civil rights community and is considered to be the seminal investigation into racial bias in environmental risk. Interestingly, as Szasz and Mueser (1997) point out, the United Church of Christ analysis was not the first study of environmental justice. A number of investigations conducted in the 1970s, which focused more on social class than on race, had already found disparities in exposures to environmental risks, but these studies were largely ignored by the social science community. It took the politicizing force of the charge of racism to get scholars to take up serious investigation of the distribution of environmental hazards.

Since the United Church of Christ report, research on this topic has grown rapidly. Most studies, with some significant exceptions, have reported some type of social disparity in the distribution of environmental hazards. (See Szasz and Meuser 1997 for a comprehensive review of environmental justice research.) Higher levels of environmental hazards in places with lower socioeconomic status have been found by the United Church of Christ (1987), Burke (1993), Pollack and Vittas (1995), Been (1997), Boer et al. (1997), Brooks and Sethi (1997), Ringquist (1997), Kreig (1998), and Daniels and Friedman (1999). Similar findings for minority communities have been reported by the United Church of Christ (1987), Burke (1993), Zimmerman (1993), Perlin et al. (1995), Pollack

and Vittas (1995), Been (1997), Boer et al. (1997), Brooks and Sethi (1997), Ringquist (1997), Kreig (1998), Stretesky and Hogan (1998), and Daniels and Friedman (1999). Research by Anderton et al. (1994; 1997), Bowen et al. (1995), and Cutter et al. (1996), however, found no significant evidence of race or class disparity in the distribution of environmental hazards.

Methodological Issues. It is important to note that the studies mentioned above have used a variety of different research designs, and thus are not entirely comparable. For example, researchers have studied a wide range of geographic locations, ranging in size from the entire United States to a single metropolitan area, and results from one location may have little bearing on the situation in others. Furthermore, some of these differences in design point to important methodological issues that need to be considered in evaluating environmental equity.

One of the most important methodological issues involves the conceptualization and measurement of pollution. What constitutes a hazard? A wide variety of environmental risks have been discussed in the literature, including lead poisoning, pesticide exposure, toxic fish consumption, occupational hazards, nuclear facilities, municipal landfills, hazardous waste sites, and industrial emissions. Empirical research to date has most often used data on three types of hazards: hazardous waste treatment storage and disposal facilities (TSDFs) (United Church of Christ 1987; Anderton et al. 1994; Cutter et al. 1996; Been 1997; Boer et al. 1997); Superfund sites or other sites known to be contaminated with hazardous wastes (Anderton et al. 1997; Cutter et al. 1996; Kreig 1998; Stretesky and Hogan 1998; Zimmerman 1993); and data on industrial toxic releases from the EPA's Toxics Release Inventory (TRI) (Burke 1993; Bowen et al. 1995; Brooks and Sethi 1997; Daniels and Friedman 1999; Perlin et al. 1995; Pollack and Vittas 1995; Ringquist 1997). The focus on these particular environmental hazards stems partially from the seriousness of their potential impacts on human health, but it is also due to the simple fact that there are publicly available data for these hazards.

The extent of the risk posed by these forms of pollution is an important variable that sociologists have yet to fully address. Some researchers have

tried to take this issue into account by measuring the distance of resident populations from the hazard (Pollack and Vittas 1995), and others have included data on the toxicity of released chemicals in their analyses (Bowen et al. 1995). However, we still have relatively little information about exposure pathways and the risks to health that result from the environmental hazards under study. Epidemiologists, statisticians, and others have reported associations between the proximity of various environmental hazards and heightened morbidity and mortality (e.g., Geschwind et al. 1992; Kelsall 1997), but there are currently many more questions than answers about the mechanisms by which pollutants cause disease, the dose-response relationships involved, and potential synergistic effects (National Research Council 1991). These issues, although outside the domain of sociological inquiry, are highly relevant to the study of environmental equity, since adverse health outcomes lie at the core of citizen concerns about environmental contamination.

Another methodological issue involves a controversy in the literature concerning the appropriate geographic unit for the study of environmental equity. Some analysts have declared that, due to their smaller size, census tracts or block groups are more appropriate than zip codes, counties, or regions (Anderton et al. 1994; Bowen et al. 1995; Cutter et al. 1996). They suggest that findings of racial inequity such as that found in the United Church of Christ study are the result of an ecological fallacy resulting from the use of too large a geographic unit. Large units can mask significant heterogeneity in the distribution of residents, hazards, or both. Whether the ecological fallacy has played a role in findings of environmental inequity is still unresolved, as attempts to address the issue have been inconclusive. Bowen et al. (1995) claimed to compare two geographic levels in their study of environmental equity in Ohio, however, they analyzed first all counties in Ohio and then census tracts only in Cuyahoga County. Thus it is impossible to know if differences between the two levels were due to the unit of analysis or the area of study. Cutter et al. (1996) studied environmental justice in South Carolina at the county, tract, and block group levels. While they did observe that bivariate relationships changed significantly across geographic units, they found little evidence of

environmental inequity in South Carolina at any level, and thus no evidence of the ecological fallacy.

Future Directions. Evidence is mounting that disparities do exist in the distribution of environmental hazards according to race and class. But there is still much to know with regard to which groups of people are exposed to which hazards. As noted above, there are many types of environmental hazards and they may have very different distributions and impacts.

Perhaps the most significant question raised by this line of research is the question of process. How have disadvantaged communities come to be associated with greater environmental risks? Which came first—are hazardous facilities sited in already disadvantaged communities, or do poor and minority residents tend to settle near already existing facilities? This question is particularly significant because the answers may have important implications for policies intended to remedy inequities. Szasz and Meuser (1997) suggest six possible scenarios, ranging from overt discrimination in the siting process to market rationality. Most of the empirical research has been cross-sectional in design, and thus cannot address this important issue. One major barrier has been the lack of good historical data on environmental hazards. A few longitudinal studies have been conducted, but the results have been inconclusive (Been 1994; Been 1997; Oakes et al. 1996). Evidence about process from case studies of polluted communities, while perhaps not generalizable, suggests the operation of complex reciprocal processes (Hersch 1995; Hurley 1995). Traditional heavy industry in Pittsburgh, Pennsylvania and Gary, Indiana, for example, appears to have been located in places near raw materials and transportation. Initially, the lack of transportation meant that more-affluent white workers lived closer to the factories. Over time, a number of processes brought African Americans and poor whites into closer proximity to pollution. Improved transportation and affluence, combined with housing segregation, allowed middle-class whites to move away from the factories into new housing on the suburban fringe, while blacks moved into downtown locations. As the cities grew and environmental regulation increased, it became necessary to locate sites for the disposal of wastes. Affluent communities with more political clout were able to keep such facilities outside their

borders. Less advantaged communities were more vulnerable to the siting of waste facilities due to a lack of effective zoning regulations, a reluctance to protest anything that might bring jobs, and a lack of information about the types of facilities that were being proposed for construction.

This question of process points to the need to establish links between existing sociological theories and the issues raised by the environmental justice movement regarding the distribution of environmental impacts. What larger social forces have had a role in producing these outcomes? As noted above, some scholars have begun to link environmental inequities to general theories of capitalist production. In order to demonstrate the relevance of these ideas (or other theories, for that matter) to environmental justice, more specific mechanisms of inequity must be identified. Several factors have been suggested, including housing discrimination, the market dynamics of land values, occupational segregation, and procedural inequities in environmental regulation. Hopefully, future research will begin to address these challenging issues.

ENVIRONMENTAL SOCIOLOGY

Environmental sociology is a relatively new area of inquiry that emerged largely in response to increased societal recognition of the seriousness of environmental problems. Many areas of sociology have similarly arisen as a result of societal attention to problematic conditions, including poverty and inequality, racial and gender discrimination, and crime and delinquency. Environmental sociology is unique, however, in that sociological attention to environmental problems had to overcome strong disciplinary traditions that discouraged giving attention to nonsocial conditions such as environmental quality. Consequently, the growth of sociological work on environmental issues has been accompanied by a critique and reassessment of core sociological assumptions and practices, with the result that environmental sociology has a somewhat ambivalent stance toward its parent discipline.

We begin with a brief examination of the nature and evolution of environmental problems, in order to clarify the kinds of issues that are of concern to environmental sociologists. Then we describe the emergence of societal attention to environmental problems, highlighting sociological work on environmental activism and related topics. Next we describe sociology's response to the increased salience of environmental problems, including the development of environmental sociology as an area of inquiry as well as its critique of mainstream sociology's neglect of environmental issues. Then we review some important emphases of the field, including analyses of the causes of environmental problems, examinations of the social impacts of these problems, and analyses of

solutions to such problems. We end with a brief overview of recent trends and debates in the field.

SOCIETAL-ENVIRONMENTAL INTERACTIONS AND THE EVOLUTION OF ENVIRONMENTAL PROBLEMS

Environmental sociology is typically defined as the study of relations between human societies and their physical environments or, more simply, "societal-environmental interactions" (Dunlap and Catton 1979). Such interactions include the ways in which humans influence the environment as well as the ways in which environmental conditions (often modified by human action) influence human affairs, plus the manner in which such interactions are socially construed and acted upon. The relevance of these interactions to sociology stems from the fact that human populations depend upon the biophysical environment for survival, and this in turn necessitates a closer look at the functions that the environment serves for human beings.

Three Functions of the Environment. The biophysical environment serves many essential functions for human populations, as it does for all other species (Daily 1997), but three basic types can be singled out. First, the environment provides us with the resources that are necessary for life, ranging from air and water to food to materials needed for shelter, transportation, and the vast range of economic goods we produce. Human ecologists thus view the environment as providing the "sustenance base" for human societies, and we can also think of it as a "supply depot." Some resources, such as forests, are potentially renewable while others, like fossil fuels, are nonrenewable or finite. When we use resources faster than the environment can supply them, even if they are potentially renewable (such as clean water), we create resource shortages or scarcities (Catton 1980).

Second, in the process of consuming resources humans, like all species, produce "waste" products; indeed, humans produce a far greater quantity and variety of waste products than do other species. The environment must serve as a "sink" or "waste repository" for these wastes, either absorbing or recycling them into useful or at least harmless substances (as when trees absorb carbon dioxide and return oxygen to the air). When land

was sparsely populated and utilization of resources was minimal, this was seldom a problem. Modern and/or densely populated societies generate more waste than the environment can process, however, and the result is the various forms of “pollution” that are so prevalent worldwide.

Humans, like other species, must also have a place to exist, and the environment provides our home—where we live, work, play, travel, and spend our lives. In the most general case, the planet Earth provides the home for our species. Thus, the third function of the environment is to provide a “living space” or habitat for human populations. When too many people try to live in a given space, the result is overcrowding, a common occurrence in many urban areas (especially in poorer nations). Some analysts suggest that the entire planet is now overpopulated by human beings, although efforts to determine the number of people the Earth can support has proven to be difficult and contentious (Cohen 1995).

When humans overuse an environment’s ability to fulfill these three functions, “environmental problems” in the form of pollution, resource scarcities, and overcrowding and/or overpopulation are the result. However, not only must the environment serve all three functions for humans, but when a given environment is used for one function its ability to fulfill the other two is often impaired. Such conditions of functional competition often yield newer, more complex environmental problems.

Competition among environmental functions is especially obvious in conflicts between the living-space and waste-repository functions, as using an area for a waste site typically makes it unsuitable for living space. When an area is used as a garbage landfill or hazardous waste site, for example, people don’t even want to live near it, much less on it (Freudenburg 1997). Likewise, if hazardous materials escape from a waste repository and contaminate the soil, water, or air, the area can no longer serve as a supply depot for drinking water or for growing agricultural products. Finally, converting farmland or forests into housing subdivisions creates more living space for people, but it means that the land can no longer function as a supply depot for food or timber (or as habitat for wildlife).

The Evolution of Environmental Problems. Understanding these three functions played by the environment provides insight into the evolution of

environmental problems, or the problematic conditions created by human overuse of the environment. In the 1960s and early 1970s when awareness of environmental problems was growing rapidly in the United States, primary attention was given to air and water pollution and to litter—problems stemming from the environment’s inability to absorb human waste products—as well as to the importance of protecting areas of natural beauty. The “energy crisis” of 1973 highlighted the dependence of modern industrialized nations on fossil fuels and raised the specter of resource scarcity in general. The living-space function came to the forefront in the late 1970s when it was discovered that a neighborhood in Niagara Falls, New York, was built on an abandoned chemical waste site that had begun to leak toxic materials. Love Canal came to symbolize the growing problems of using an area as both waste repository and living space.

New environmental problems continually emerge, the result of humans trying to make incompatible uses of given environments. Global warming is an excellent example. It is primarily a consequence of a rapid increase in carbon dioxide in the Earth’s atmosphere produced by a wide range of human activities—especially burning fossil fuels (coal, gas, and oil), wood, and forest lands. This buildup of carbon dioxide (CO₂) traps more of the Sun’s heat, thus raising the temperature of the Earth’s atmosphere. While global warming results from overuse of the Earth’s atmosphere as a waste site, the resulting warming may in turn produce changes that make our planet less suitable as a living space (not only for humans, but especially for other forms of life). A warmer climate may also affect the Earth’s ability to continue producing natural resources, especially food supplies (Stern et al. 1992).

These examples of how human activities are harming the ability of the environment to serve as our supply depot, living space, and waste repository involve focusing on specific aspects of particular environments (e.g., a given river’s ability to absorb wastes without becoming polluted). However, it is increasingly recognized that the health of entire ecosystems is being jeopardized as a result of growing human demands being placed on them. An *ecosystem* is an interacting set of living organisms (animals and plants) and their nonliving environment (air, land, water) that are bound together

by a flow of energy and nutrients (e.g., food chains); it can range in size from a small pond, to a large region such the Brazilian rainforest, to the entire biosphere—the Earth’s global ecosystem (Freese 1997). Technically, it is not “the environment” but “ecosystems” that serve the three functions for humans—and for all other living species.

Exceeding the capacity of a given ecosystem to fulfill one of the three functions may disrupt not only its ability to fulfill the other two but its ability to continue to function at all. As a recent U.S. Environmental Protection Agency (EPA) report notes, “Ecological systems like the atmosphere, oceans, and wetlands have a limited capacity for absorbing the environmental degradation caused by human activities. After that capacity is exceeded, it is only a matter of time before those ecosystems begin to deteriorate and human health and welfare begin to suffer” (EPA Science Advisory Board 1990, p. 17). Human overuse of ecosystems thus creates “ecological disruptions” that become “ecological problems” for humans. As more and more people require places to live, use resources, and produce wastes, it is likely that ecological problems will worsen and that new ones will continue to emerge.

The notion that human societies face “limits to growth” was originally based on the assumption that we would run out of natural resources such as oil, but nowadays it is recognized that the ability of ecosystems to fulfill any of the three necessary functions can be exceeded. Ozone depletion, for example, stems from exceeding the atmosphere’s limited ability to absorb chlorofluorocarbons (CFCs) and other pollutants. Thus, it is not the supply of natural resources per se, but the finite ability of the global ecosystem to provide us with resources, absorb our wastes, and still offer suitable living space (all of which, as we have seen, are interrelated) that constrains human societies. The emergence of problems such as ozone depletion, climate change, species extinction, and rainforest destruction are indications that modern societies may be taxing the limits of the global ecosystem (see, e.g., Daily 1997).

This brief sketch of the nature and evolution of environmental problems reveals the rich subject matter studied by environmental sociologists. While broadly construed as the study of relations

between human societies and their physical environments, the field focuses primary attention on the ways in which modern societies are altering their environments and the ways in which such alterations eventually create problematic conditions for our societies—as well as the ambiguities and controversies involved in assessing and responding to these alterations and impacts (Hannigan 1995). Despite improvements in specific environmental problems, such as urban air quality and the quality of many streams and lakes, in the last quarter of the twentieth century, newer and often more serious environmental problems—often affecting wider geographic areas—have continued to emerge as greater effort is made to monitor the quality of the environment. Consequently, it seems safe to assume that environmental sociology will have no shortage of subject matter in the foreseeable future.

SOCIETAL RESPONSE TO ENVIRONMENTAL PROBLEMS

Environmental concerns first attained considerable prominence in the United States with the rise of the progressive conservation movement in the late 1800s and early 1900s in response to reckless exploitation of the nation’s resources. This movement included both “utilitarians” like Gifford Pinchot, who sought to manage natural resources such as forests wisely to ensure their continued availability, and “preservationists” like John Muir, who sought to preserve areas of natural beauty for their own sake. Although these two factions eventually came into conflict, their joint efforts led to legislation establishing national parks and agencies such as the U.S. Forest Service while also spawning organizations such as the Sierra Club and National Audubon Society.

These “conservation” organizations and agencies continued to exist and grow periodically throughout the first half of the twentieth century, but they did not become highly visible until the 1950s and 1960s, when preservationist organizations such as the Sierra Club achieved renewed visibility by fighting for the protection of areas of natural beauty such as the Grand Canyon (which had been threatened by damming). The older preservationist concern with natural areas gradually coalesced with concerns about issues such as

pesticide contamination—publicized by Rachel Carson's *Silent Spring*—and air and water pollution and other urban-based problems (Taylor 1997). These newer “environmental” problems tended to be more complex in origin (often stemming from new technologies), and had delayed, complex, and difficult-to-detect effects that were consequential for human (as well as nonhuman) health and welfare. Encompassing pollution and loss of recreational and aesthetic resources, and ultimately the consequences of overusing all three functions of the environment, such problems were increasingly viewed as threats not only to “environmental quality” but to our “quality of life” (Dunlap and Mertig 1992).

By the late 1960s the older conservation movement had evolved into a modern “environmental movement,” as traditional conservation organizations joined with newer, multi-issue organizations, such as the Natural Resources Defense Council and Environmental Defense Fund, to pursue a wide range of environmental goals. The transformation from conservationism to environmentalism—symbolized by celebration of the first “Earth Day” in 1970—is reflected by the growth of an “environmental” discourse that largely supplanted the older conservation/preservation discourses (Brulle 1996) as well as by the explosive growth of both local and national environmental organizations concerned with a wide range of issues in the 1970s (McLaughlin and Khawaja 1999). With a reported 20 million participants, “E-Day” not only launched the contemporary environmental movement but mobilized a far greater base of support for environmentalism than had ever been achieved by the earlier conservation movement (Dunlap and Mertig 1992).

Environmental sociologists quickly tried to explain the emergence of the modern environmental movement. Besides highlighting the crucial roles played by older conservation organizations (such as the Sierra Club) in mobilizing public support, they pointed to the following factors: growth of scientific knowledge about problems such as pesticides and smog; intense media coverage devoted to incidents such as the 1969 Santa Barbara oil spill; rapid increase in outdoor recreation that brought more and more people into direct contact with threatened environments; widespread post-World War II affluence that stimulated increasing concern with quality of life over

more materialistic pursuits; and, finally, the general climate of social activism that grew out of the civil rights, anti-Vietnam War and student-power movements (see, e.g., Morrison et al. 1972). More recent analyses have emphasized the decline of class politics and materialist concerns and the subsequent emergence of new social movements devoted to quality-of-life goals as the broad socio-cultural context in which environmentalism developed (e.g., Buttel 1992).

The last three decades of the twentieth century have seen enormous changes in the nature of environmentalism, often chronicled by sociologists. The large national organizations, like the Sierra Club, constituting the core of the “environmental lobby” have remained strong, but their limited ability to produce effective results and the continual emergence of new issues that escape their purview have resulted in the emergence of numerous alternative strands of environmental activism. The result is that environmentalism is far more diverse than in the older days of the utilitarian-preservationist bifurcation (Dunlap and Mertig 1992). A major divide is that between the national organizations and the burgeoning number of local, grassroots groups that are typically concerned with hazardous conditions in their communities. A particularly potent form of grassroots activism has arisen in response to evidence of environmental racism, or the disproportionate location of hazardous facilities in minority communities, and the “environmental justice” movement spearheaded by people of color is the result (Taylor 1997). A variety of other splinter groups, including radical environmentalism (exemplified by the direct-action tactics pursued by Earth First!), deep ecology (a biocentric philosophy urging the equality of all forms of life), and ecofeminism (which links environmental degradation to the exploitation of women), along with the increasing internationalization of environmental organizations, make the contemporary environmental movement a highly complex entity (Brulle 1996).

Regardless of its historical causes, the establishment and continued existence of a viable environmental movement has ensured that environmental issues remain on the nation's policy agenda. Several pieces of landmark legislation aimed at protecting and improving environmental quality were passed in the late 1960s and early 1970s, including the National Environmental Policy Act

requiring environmental impact assessments and establishment of the Environmental Protection Agency. Despite some ups and downs, environmental quality has remained a major national goal for the last three decades of the twentieth century, with new concerns continually emerging—often in response to specific “crises” such as the *Exxon Valdez* oil spill in Alaska.

The environmental movement has been widely criticized for failing to halt environmental degradation in our nation (and the world). Nonetheless, compared to other social movements, environmentalism has clearly been one of the most influential movements of the last half of the twentieth century, ranking with the women’s movement, civil rights movement, and peace/antiwar movements as having changed the contours of contemporary life. Environmental concerns are now institutionalized throughout our society, not only in government laws and agencies, but in the form of environmental education (K–12) and college-level environmental studies, environmental reporters and news beats among major media, environmental affairs offices within major corporations, the growing involvement of mainstream religions with environmental problems, and a reasonably well funded and institutionalized discipline of environmental science. To these institutional indicators one can add cultural changes such as the emergence of an environmental discourse throughout society, including advertising; the ubiquity (if not effectiveness) of recycling and the gradual growth of green consumer behaviors; and the normative disapproval of outright assaults on environmental quality whether by governments or industry. Despite the intermittent emergence of open opposition to environmentalism—as represented by the current “wise-use” movement that seeks to lift governmental restrictions on use of natural resources (Switzer 1997)—the overall trends toward “environmentalization” validate claims that we are witnessing a “greening” of society at both the institutional and cultural levels (Buttel 1992).

DISCIPLINARY RESPONSE: THE BIRTH OF ENVIRONMENTAL SOCIOLOGY

Although there was scattered sociological attention to natural resource issues prior to the 1970s, environmental sociology developed in that decade

as sociology’s own response to the emergence of environmental problems. At first sociologists tended to pay more attention to societal response to environmental problems than to the problems themselves. As noted earlier, analyses of the environmental movement were popular, as were studies of public attitudes toward environmental issues. Prime topics included identifying the social sectors from which environmental activists were drawn and the social bases of pro-environmental attitudes among the general public (Dunlap and Catton 1979). Broader analyses of the ways in which “environment” was being constructed as a social problem, and the vital roles played by both activists and the media in this process, also received attention (Albrecht 1975). In addition, rural sociologists conducted a growing number of studies of natural resource agencies, while other sociologists examined environmental politics and policy making. In general, sociological work on environmental issues typically employed perspectives from the larger discipline to shed light on societal awareness of and response to environmental problems. In today’s parlance, these initial efforts largely involved analyses of aspects of the “social construction of environmental problems” and represented what was termed a “sociology of environmental issues” (Dunlap and Catton 1979).

As sociologists paid more attention to environmental issues, a few began to look beyond societal attention to environmental problems to the underlying relationships between modern, industrialized societies and the physical environments they inhabit. Concern with the causes of environmental pollution was supplemented by a focus on the social impacts of pollution and resource constraints. In some cases there was explicit attention to the reciprocal relationships between societies and their environments, or to the “ecosystem-dependence” of modern societies (Dunlap and Catton 1994). These concerns were bolstered by the 1973–1974 “energy crisis,” as the interrupted flow of oil from Arab nations generated dramatic and widespread impacts and vividly demonstrated the vulnerability of modern industrial societies to an interruption of their fossil fuel supplies and—by extension—to natural resources in general (Rosa et al. 1988). Sociologists were quick to respond with numerous studies of the impacts, particularly the inequitable distribution of negative ones, of energy shortages (Schnaiberg 1975).

Sociological interest in the impacts of energy and other resource scarcities accelerated the emergence of environmental sociology as a distinct area of inquiry by heightening awareness that “environment” was more than just another social problem, and that environmental conditions could indeed have societal consequences. Studies of the societal impacts of energy shortages thus facilitated a transition from the early “sociology of environmental issues” to a self-conscious “environmental sociology” focused explicitly on societal–environmental relations. In retrospect, it is apparent that this concern also contributed to a rather one-sided view of such interactions, however, as the effects of resource constraints on society received far more emphasis than did the impacts of society on the environment (something that has been rectified in more recent research on the causes of environmental degradation).

The nascent environmental sociology of the 1970s was quickly institutionalized via formation of interest groups within the national sociological associations. These groups provided an organizational base for the emergence of environmental sociology as a thriving area of specialization and attracted scholars interested in all aspects of the physical environment—from environmental activism to energy and other natural resources, natural hazards and disasters, social impact assessment, and housing and the built environment (Dunlap and Catton 1983). The late 1970s was a vibrant era of growth for American environmental sociology, but momentum proved difficult to sustain during the 1980s, as the Reagan era was a troublesome period for the field and social science more generally. Ironically, however, sociological interest in environmental issues was beginning to spread internationally, and by the late 1980s and the 1990s environmental sociology was not only reinvigorated in the United States but was being institutionalized in countries around the world and within the International Sociological Association (Dunlap and Catton 1994).

The resurgence of environmental sociology in the United States and its emergence internationally benefited from key societal events. Publicity surrounding Love Canal and other local environmental hazards stimulated interest in the impacts of such hazards on local communities, while major accidents at Three Mile Island, Bophal (India), and

Chernobyl dramatized the importance of technological hazards and helped generate sociological interest in the environmental and technological risks facing modern societies (Short 1984). More recently, growing awareness of global environmental problems such as ozone depletion, global climate change, and tropical deforestation have served to enhance sociological interest in environmental problems—particularly at the global level (Dunlap and Catton 1994).

ENVIRONMENTAL SOCIOLOGY AND THE LARGER DISCIPLINE

As previously noted, early sociological work on environmental issues typically involved application of standard sociological perspectives drawn from social movements, social psychology, social problems, and so forth to empirical work focusing on societal response to environmental issues. Efforts to theorize about environmental matters were rare, and they tended to involve demonstrations of the utility of established theoretical perspectives, such as Parsonian theory, for viewing environmental issues rather than asking whether such perspectives were adequate for understanding the relations between modern societies and their biophysical environments (Klausner 1971). Since sociologists interested in theorizing about the relations between modern societies and their environments found little guidance from the larger discipline, they drew heavily upon other disciplines, such as general ecology (Catton 1976), or combined ecological and sociological insights in order to develop new theoretical perspectives (Schnaiberg 1975).

Unlike the larger society, in the 1970s mainstream sociology was remarkably oblivious to the relevance of environmental matters. This disciplinary blindness stemmed from a long period of neglect of such matters stimulated by both societal developments and disciplinary traditions. The Durkheimian emphasis on explaining social phenomena only in terms of other “social facts,” plus an aversion to earlier excesses of biological and geological “determinisms,” had led sociologists to ignore the physical world. These disciplinary traditions were further strengthened by sociology’s emergence during an era of unprecedented growth and prosperity, when limits to resource abundance and technological progress were unimaginable, and increased urbanization, which reduced

direct contact with the natural environment. With modern, industrialized societies appearing to be increasingly independent of the biophysical world, sociology came to assume that the exceptional features of *Homo sapiens*—language, technology, science, and culture more generally—made these societies “exempt” from the constraints of nature. Thus, the core task of sociology was to examine the uniquely social determinants of contemporary human life (Dunlap and Catton 1979, 1983). In short, mainstream sociology offered infertile ground for planting sustained interest in the relations between societies and their biophysical environments.

It is not surprising, therefore, that efforts to establish environmental sociology as a legitimate and important area of inquiry included criticism of the larger discipline’s blindness to environmental matters. Indeed, efforts to define and codify the field of environmental sociology were accompanied by explication and critique of the “human exemptionalism paradigm” (HEP) on which contemporary sociology was premised. While not denying that human beings are obviously an exceptional species, environmental sociologists argued that our special skills and capabilities nonetheless failed to exempt us from the constraints of the natural environment. Consequently, it was argued that the HEP needed to be replaced by a more ecologically sound perspective, a new ecological paradigm (NEP), that acknowledges the ecosystem-dependence of human societies (Catton and Dunlap 1978, 1980). It was further argued that much of environmental sociology, particularly examinations of the relations between social and environmental factors (as opposed to analyses of the social construction of environmental issues), entailed at least implicit rejection of the HEP with its assumed irrelevance of nonsocial phenomena to modern societies (Dunlap and Catton 1979, 1983).

The call for revision of mainstream sociology’s dominant paradigm, and particularly the urging of adoption of an ecological perspective, has been a controversial feature of environmental sociology. While regarded as a core element of the field’s commitment to ensuring that the material bases of modern societies are no longer neglected by sociology, the argument has been criticized for deflecting efforts to utilize classical and mainstream theoretical perspectives in environmental sociology (Buttel 1996, 1997). Fortunately, debate about the

need for an ecological perspective versus the relevance of mainstream sociological theories has taken a new turn in recent years, as several environmental sociologists have independently begun to develop ecologically informed versions of classical theoretical perspectives. Efforts to develop “green” versions of Durkheimian, Weberian, and especially Marxian macro-sociologies as well as micro-level perspectives, such as symbolic interactionism, bear the fruit of integrating an ecological paradigm with classical theoretical traditions (see Foster 1999 and references in Dunlap 1997).

Increasing awareness of the societal significance of ecological conditions has not only stimulated efforts to develop greener sociological theories but also opened the floodgates of empirical research on societal–environmental relations. Studies such as those conducted by Freudenburg and Gramling (1994) on oil development in coastal waters, which convincingly show how development depends on *both* environmental conditions and social forces, and by Couch and Kroll-Smith (1985) on community hazards, which demonstrates the differing impacts of natural versus human-made disasters, clearly violate the disciplinary tradition of ignoring all but the social causes of social facts (as do many of the studies to be reviewed later).

While the empirical thrust of environmental sociology thus represents at least implicit rejection of mainstream sociology’s “exemptionalist” orientation by continually demonstrating the relevance of environmental factors in modern, industrialized societies, the situation regarding adoption of an ecological paradigm or perspective is less clear. Some environmental sociologists follow Catton’s (1980) lead in applying ecological theory and concepts to human societies (e.g., Fischer-Kowalski 1997), and others employ an ecological perspective as an “orienting strategy” that encourages them to raise questions about issues such as the long-term sustainability of current consumption patterns in the wealthy nations (Redclift 1996). However, some environmental sociologists express caution regarding the utility of ecological *theory* as a guiding framework for environmental sociology (Buttel 1997) or disavow its utility altogether (Macnaghten and Urry 1998). These differing orientations stem from the inherent ambiguities involved in applying concepts and findings from general ecology to human societies (Freese 1997)

as well as differences of opinion about the roles of paradigms versus theories in empirical inquiry.

SOME CURRENT RESEARCH EMPHASES

Over the last three decades of the twentieth century, sociological research on environmental issues has focused on a wide range of topics, and we cannot begin to do justice to the full body of work by environmental sociologists. Fortunately, several existing reviews and compilations provide fairly comprehensive overviews of this research, covering the 1970s (Dunlap and Catton 1979), 1980s (Buttel 1987; Rosa et al. 1988), and 1990s (Buttel 1996; Dunlap and Catton 1994; Redclift and Woodgate 1997). Consequently, we limit our attention to sociological work on three particularly important theoretical and policy-relevant topics: the causes of environmental problems, the impacts of such problems, and the solutions to these problems.

Causes of Environmental Problems. Given that environmental sociology arose largely in response to increased recognition of environmental problems, it is not surprising that a good deal of work in the area has been devoted to trying to explain the origins of environmental degradation. Much of the early work, however, was devoted more to analyses and critiques of the rather simplistic views of the causes of environmental degradation that predominated in the literature rather than original studies. The need for such analyses stemmed from the fact that the predominant conceptions of the origins of environmental problems tended to emphasize the importance of single factors such as population growth (emphasized by Paul Ehrlich) or technological development (stressed by Barry Commoner), rather than recognizing the multiplicity of factors involved, and also ignored or simplified the distinctively social causes of environmental degradation. In this context, environmental sociologists tended to explicate the competing range of explanations (Dunlap and Catton 1983) and to criticize the most widely accepted ones for their shortcomings (Schnaiberg 1980).

The most powerful sociological critique of common conceptions of the origins of environmental problems in general, and those by biologists such as Ehrlich and Commoner in particular, was provided by Schnaiberg (1980). Schnaiberg

criticized Ehrlich's view by noting the enormous variation in environmental impact between populations of rich and poor nations as well as between the wealthy and poor sectors within individual nations, emphasized that population growth is interrelated with factors such as poverty—which induces poor people to have more children for work-force and security reasons. Similarly, Commoner's perspective was criticized for viewing technology as an autonomous force, ignoring the degree to which technological developments are driven by political and especially economic forces—particularly the need for profit and capital accumulation.

Besides demonstrating the oversimplification involved in attributing environmental degradation to either population or technology, Schnaiberg also critiqued a third factor widely mentioned as a cause—the wasteful lifestyles of consumers. In particular, Schnaiberg distinguished between the production and consumption spheres of society, arguing that the former is the more crucial contributor to environmental degradation. Attributing environmental degradation to the affluence of consumers ignores the fact that decisions made in the production realm (e.g., as to what types of transportation will be available to consumers) are far more significant than are the purchasing behaviors of individual consumers. Consequently, Schnaiberg emphasized the “treadmill of production,” or the inherent need of market-based economic systems to grow and the powerful coalition of capital, state, and labor supporting such growth, as the most fundamental contributor to environmental degradation.

While Schnaiberg's analysis, which he has continued to update and refine (see, e.g., Schnaiberg and Gould 1994), has become highly influential within environmental sociology (Buttel 1987, 1997), it has proven difficult to translate into concrete empirical research beyond local case studies of organized opposition to treadmill processes (Gould et al. 1996). Consequently, a new generation of sociological analysts, while cognizant of Schnaiberg's insights, have adopted a broader framework for investigating the causes of crucial environmental problems, particularly pressing global problems.

Ironically, one line of this new work has involved revisiting the Ehrlich–Commoner debate over the relative importance of population and

technological factors in generating environmental degradation. As their debate progressed, both sides realized that they could not totally ignore the other's preferred cause, or more distinctively social factors, and the debate became encapsulated in differing interpretations of a simple formulation known as the "IPAT" equation. Both Ehrlich and Commoner came to agree that environmental impact = population \times affluence \times technology, although debate continued over which factor on the right side of the equation had the most impact on environmental degradation (for more on this debate, see Dietz and Rosa 1994; Dunlap et al. 1994).

In recent years environmental sociologists have begun to reassess the IPAT model's utility, particularly as a means of examining the crucial causal forces generating global-level environmental problems such as tropical deforestation and global climate change. Taking into account earlier critiques of the IPAT model, Dietz and Rosa (1994; see also Rosa and Dietz 1998) have proposed a major revision that they label "STIRPAT," for "stochastic impacts by regression on population, affluence and technology." Whereas IPAT is an accounting equation that assumes direct proportionality between impact and each of the other three factors, such that a 10-percent increase in population (or technology or affluence) is assumed to produce a 10-percent increase in impact, STIRPAT treats such linkages as hypotheses to be tested. In addition, it allows both for decomposition of the individual factors (e.g., population size versus growth rate) in the model and the consideration of cultural, institutional, and political factors as additional sources of environmental impact.

While the STIRPAT model can be applied to any environmental impact, the initial application has been to global climate change, where the basic model was used to estimate CO₂ emissions (Dietz and Rosa 1997). Two interesting results emerged: First, diseconomies of scale apparently exist at the largest population sizes, as countries with the largest populations (e.g., China and India) have a disproportionate impact on CO₂ loads. Second, the results also replicated recurrent findings by economists that suggest the existence of an environmental Kuznets curve. Economists argue in these studies that as affluence increases, environmental impact per unit of affluence decreases, producing an inverted U curve, or a Kuznets curve, named as the relationship between development

and inequality posited by Simon Kuznets (see Dietz and Rosa 1997 for citations).

A related sociological study, involving a longitudinal analysis of national CO₂ emissions, challenges the economists' faith that economic development will lessen environmental impacts because of the Kuznets curve. Roberts and Grimes (1997) conclude that since the energy crisis of the 1970s, affluent nations have become more carbon-efficient, producing more gross national product per unit of CO₂ emissions, but that the carbon efficiency of middle-income nations has gone down slightly and that of the poor nations has dropped substantially. Consequently, the poorest nations are locked into a pattern of high and even increasing environmental impact per unit of affluence, while wealthy nations may indeed follow the patterns proposed by development theorists. If true, this challenge to development theory suggests that the continued development of poor but populous nations like China and India will lead to increasing levels of CO₂ and other pollutants rather than the pattern observed in wealthy nations.

Tropical deforestation is another global-level problem that has attracted increasing attention by environmental sociologists seeking to understand its causes. A series of studies by Rudel and colleagues (see Rudel and Roper 1997) employ a variety of theoretical models encompassing population, technology, and affluence (the components of the IPAT and STIRPAT models) as well as a wide range of both national and international social-structural variables such as level of inequality, urbanization, and international debt. These studies typically find a significant impact of population growth in general, and patterns of rural versus urban growth in particular, on deforestation rates, but these effects are moderated by a wide range of environmental conditions and social-structural factors. Importantly, but not surprisingly, Rudel finds that deforestation is partly a function of the size of nations' forests and the topography of forest land as well as political and economic decisions to invest capital in forestry, levels of economic development, and international indebtedness.

Sociological studies of global-level problems such as deforestation and emissions of greenhouse gases, both of which directly contribute to global climate change, are yielding important findings as well as conceptual and methodological strategies

for developing a better understanding of the driving forces producing global environmental change and other environmental problems (Rosa and Dietz 1998). As such, they represent an important supplement to natural-science research programs on these topics.

Impacts of Environmental Problems. As noted earlier, environmental sociology was just emerging at the time of the 1973–1974 energy crisis, and it is not surprising that a good deal of effort was made to identify real as well as potential social impacts of energy and other natural resources in this early period of the field. While diverse impacts, from regional migration to consumer lifestyles, were investigated, heavy emphasis was placed on investigating the “equity” impacts of both energy shortages and the policies designed to ameliorate them (Rosa et al. 1988). A general finding was that both the problems and policies often had regressive impacts, with the lower socioeconomic strata bearing a disproportionate cost due, for example, to rising energy costs (Schnaiberg 1975).

Equity has been a persistent concern in environmental sociology, and researchers gradually shifted their attention to the distribution of exposure to environmental hazards (ranging from air and water pollution to hazardous wastes). Again, a persistent finding has been that exposure to environmental hazards is generally negatively correlated with socioeconomic status. A growing number of studies have also found that minority populations are disproportionately exposed to environmental hazards, in part because of their lower-than-average socioeconomic levels but perhaps also because of conscious decisions to locate hazardous sites in minority communities. Such findings, which a few recent studies have challenged, have led to charges of “environmental racism” and efforts to achieve “environmental justice.” At a broader level, international equity is attracting the attention of environmental sociologists, who are investigating the export of polluting industries from wealthy to poor nations, the disproportionate contribution of wealthy nations to many global-level problems, and the consequent hurdles these phenomena pose for international cooperation to solve environmental problems (Redclift and Sage 1998).

Sociologists have not limited themselves to investigating the equity impacts of environmental

problems, and studies of communities exposed to technological or human-made hazards (such as Love Canal) offer particularly rich portrayals of the diverse impacts caused by discovery of community hazards. Whereas natural hazards—such as floods, hurricanes, and earthquakes—have been found to result in a therapeutic response in which communities unite in efforts to help victims, repair damage, and reestablish life as it was before the disaster struck, technological disasters have been found to have very different impacts (Freudenburg 1997). Although a putative hazard often appears obvious to those who feel affected by it, the ambiguities involved in detecting and assessing such hazards often generate a pattern of intense community conflict. Unlike those affected by natural hazards, the “victims” often find themselves at odds not only with public officials but also with other residents who fail to acknowledge the seriousness of the hazard (for fear of economic loss in terms of property values, jobs, etc.). In many cases, such conflicts have resulted in a long-term erosion of community life as well as exacerbation of the victims’ personal traumas stemming from their exposure to the hazards (Couch and Kroll-Smith 1985).

Solutions to Environmental Problems. As was true for the causes of environmental problems, early work by environmental sociologists interested in solutions to these problems often involved explications and critiques of predominant approaches. Early on Heberlein (1974) noted the predilection of the United States for solving environmental problems via a “technological fix,” or developing and applying new technologies to solve problems such as air and water pollution. Understandably popular in a nation with a history of technological progress, such a solution is appealing because it avoids mandating behavioral and institutional change. Unfortunately, solving problems with new technologies sometimes creates even more problems, as illustrated by attempts to solve energy shortages with nuclear power. Consequently, as the seriousness and pervasiveness of environmental problems became more obvious, attention was given to a variety of “social fixes,” or efforts to change individual and institutional behaviors.

Expanding on Heberlein’s analysis, other sociologists (e.g., Dunlap et al. 1994) have identified three broad types of social fixes, or implicit policy

types: (1) the cognitive (or knowledge) fix, which assumes that information and persuasion will suffice to produce the necessary changes in behavior, illustrated by campaigns encouraging energy conservation and recycling; (2) the structural fix, which relies on laws and regulations that mandate behavioral change, reflected in highway speed limits or enforced water conservation; and (3) the intermediary behavioral fix, which employs incentives and disincentives to encourage changes in behavior, as illustrated by pollution taxes (penalties) and tax credits (rewards) for installing pollution-abatement technology (see Gardner and Stern 1996 for a more refined typology of policy approaches and detailed examples of each).

Environmental sociologists, in conjunction with other behavioral scientists, have conducted a range of studies that bear on the efficacy of these differing strategies for solving environmental problems, ranging from field experiments to test the effectiveness of information campaigns in inducing energy and water conservation to evaluations of alternative strategies for generating participation in recycling programs (see Gardner and Stern 1996 for a good summary). A noteworthy sociological study was Derksen and Gartrell's (1993) investigation of recycling in Edmonton, Alberta, which found that individuals' level of environmental concern (and, by implication, knowledge about the importance of recycling) was not as important in predicting recycling behavior as was ready access to a curbside recycling program. While sociologists have conducted numerous field experiments and evaluations of community environmental programs, typically investigating the efficacy of one or more of the above-noted "fixes," they have generally left examinations of national and international environmental policy making to political scientists and economists. However, sociologists have begun to pay attention to efforts to negotiate international agreements to achieve reduction of greenhouse gases (Redclift and Sage, 1998), and we expect more sociological work along these lines.

CURRENT TRENDS AND DEBATES

As the foregoing illustrates, environmental sociology not only emerged in response to societal attention to environmental problems but has focused much of its energy on understanding these problems, especially their causes, impacts, and

solutions. The field has proved to be more than a passing fad, becoming well institutionalized and also increasingly internationalized. But in the process, fundamental assumptions that once served to unify the field—agreement over the reality of environmental degradation; diagnoses of such degradation as inherent to modern, industrialized societies; and the sense that mainstream sociology was largely blind to the significance of environmental matters—have become matters of debate (Buttel 1996, 1997).

The emergence of environmental problems provided the *raison d'être* for environmental sociology, and the seriousness of such problems was seldom challenged. While environmental sociologists from the outset paid attention to ways in which claims about environmental conditions are socially constructed and become the subject of societal conflict (e.g., Albrecht 1975), such efforts seldom questioned the objective existence of environmental problems. In recent years, however, environmental sociology has felt the effects of the larger discipline's turn toward more cultural and interpretative orientations. A growing number of scholars, particularly in Europe, have not only highlighted the contested nature of claims about environmental problems but—in the postmodern tradition—concluded that there is no reason for privileging the claims of any parties to these debates, including those of environmental scientists as well as activists (Macnaghten and Urry 1998).

Such work has led to the emergence of a strong constructivist/interpretative orientation in environmental sociology that challenges the objectivist/realist perspective that has traditionally been dominant. Whereas the realist orientation assumes that the environment is a biophysical entity existing independent of humans, thereby providing the setting for study of human-environment interactions as the core of environmental sociology, the constructivist orientation leads its adherents to adopt an agnostic view of such interactions, preferring instead to examine knowledge claims—and the social forces they reflect—about these interactions (Macnaghten and Urry 1998). These competing perspectives can be readily seen in sociological work on global environmental change (GEC), where those in the realist camp have sought to complement natural-science research by examining, for example, societal processes leading to tropical deforestation

and greenhouse gas emissions (noted previously), while constructivists have highlighted the uncertainties in scientific evidence for GEC and the social, political, and historical forces that have made GEC a central topic of scientific and policy-making interest (see Rosa and Dietz 1998). These differing orientations have led to debate among environmental sociologists, with realists pointing to shortcomings of the constructivist approach (Dickens 1996; Murphy 1997) and constructivists demonstrating the utility of their perspective (Hannigan 1995). Fortunately promising syntheses of constructivist and realist perspectives are beginning to emerge (Rosa 1998).

Another source of debate is the inevitability of continued environmental degradation, particularly on the part of advanced, industrialized nations. Whereas environmental sociologists have traditionally seen the drive toward capital accumulation inherent in such societies as making environmental degradation inevitable (as epitomized by Schnaiberg's "treadmill of production" argument), European scholars have increasingly suggested that this may not be the case. Obvious successes in environmental amelioration within advanced European nations have led them to build upon economic models of "industrial ecology," which suggest that modernization of industrial processes can permit production with ever-decreasing levels of material input and pollution output, heralding a new era of "ecological modernization" (Spaargaren and Mol 1992).

This perspective not only adopts a more sanguine image of the future of industrialized societies but, as Buttel (1996, 1997) notes, involves a shift in focus for environmental sociology: from a preoccupation with the origins of environmental degradation to efforts to explain the institutionalization of environmental amelioration (via technological innovation, policy incentives, pressures from citizens' groups, etc.). While representing an important complement to traditional perspectives in the field and building on larger sociological debates about the future of "modernity," ecological modernization is vulnerable to criticism. First, its development in northern Europe leads to concerns that ecological modernization is not applicable to less wealthy and technologically disadvantaged nations. Second, although nations such as the Netherlands have made considerable advances

in protecting their own environments, their import of natural resources and export of pollution creates a large "ecological footprint" well beyond their borders (Wackernagel and Rees 1996). Finally, even if continual progress is made in creating cleaner, more efficient production processes, these gains may be offset by continued economic growth and consumption and consequent increased demand for materials and energy (Bunker 1996).

The trends toward adoption of more constructivist/interpretive frameworks and models of ecological modernization are related to a third trend in environmental sociology—the ongoing reassessment of its relationship to the larger discipline. As noted earlier, the emergence of environmental sociology was marked by criticism of mainstream sociology's neglect of the ecosystem-dependence of modern, industrialized societies and consequent inattention to the challenge posed by environmental problems. This critical orientation led many environmental sociologists to look to other disciplines (such as ecology and environmental science) for guidance and probably contributed to a somewhat insular perspective vis-à-vis mainstream sociology.

But in the 1990s environmental problems, particularly global-level threats like climate change, have caught the attention of growing numbers of eminent sociologists, such as Giddens (1990), who have recognized that such problems cannot be ignored in analyses of the future course of industrial societies. Greater interaction between environmental and mainstream sociology has resulted, and the penetration of currently fashionable perspectives, such as cultural/interpretive frameworks and theories of the nature of late modernity into environmental sociology has followed—as exemplified by the popularity of the constructivist and ecological modernization perspectives. This is resulting in considerable debate and self-reflection among environmental sociologists, something that a maturing field can afford. Hopefully, environmental sociology will emerge with renewed relevance to the larger discipline of sociology as well as continued relevance to societal efforts to ensure an ecologically sustainable future for humankind.

EPIDEMIOLOGY

Epidemiology is the study of the distribution of disease and its determinants in human populations. Epidemiology usually takes place in an applied public health context. It focuses on the occurrence of disease by time, place, and person and seeks to identify and control outbreaks of disease through identification of etiological factors. Its approach is to identify associated risk factors and then work back to causes.

Historically, the focus of epidemiology was on large outbreaks, usually of infectious disease. The substance and methods of epidemiology have been applied to most forms of acute and chronic disease and many other physical and mental health conditions. Along with the broadening of the subject matter of epidemiology has come more focus on its methods. Along with the specialization of

epidemiological methods has come the professional identification of persons as epidemiologists. In this entry, we address the origins, methodology, current topics, and professional issues related to epidemiology.

PROFESSIONAL ROLE

Epidemiology is the professional identification of an increasing number of persons who have received specialized training in departments of epidemiology in schools of public health. Many complete approved courses of study at the master's or doctoral level leading to an M.P.H., Dr. P.H., or Ph.D. with epidemiology as an area of concentration. Some schools offer the M.P.H. to physicians after an abbreviated course of study. Like most other developing professions, graduate epidemiologists are protective of their professional identification and would seek to differentiate their professional credentials from those who have found their ways to epidemiological roles from other educational backgrounds. The problem in this developing professionalism is how to define a unique intellectual content or theory of epidemiology, when the applied nature of the discipline demands that the latest theories and methods of investigating disease be incorporated into any ongoing investigation.

ORIGINS

Langmuir (Roeché 1967, p. xiii) traces the origins of epidemiology as far back as Hypocrites' report of an outbreak of mumps among Greek athletes, but the written history of mankind is full of major outbreaks of disease, which the practitioners of the time attempted to control with methods ranging from folk remedies and the available medicine, to religion and witchcraft, and even to civil and sanitary engineering. It was the careful and scientific observation of these outbreaks that led to the development of modern epidemiology.

Perhaps the most famous early epidemiological inquiry was John Snow's careful observation of the house-by-house locations of incident cases of cholera during epidemics in London in the 1840s and 1850s. Snow's correlation of new cases with some water supply systems, but not others, changed the conventional medical wisdom about how cholera was spread and did so before the microbial nature

of the disease was discovered. Roeché's *Annals of Epidemiology* provides a number of examples of the application of epidemiological methods in relation to local outbreaks in the earlier part of the twentieth century. More recent well-known investigations have included those relating to Legionnaires' disease and AIDS.

Epidemiology as a discipline has grown along with the many associated disciplines of public health and medicine. Microbiology has identified the organisms and modes of transmission for many infectious diseases. Biochemistry, physiology, virology, and related basic medical sciences have provided the scientific background to support the development of the epidemiology of infectious disease. Other sciences ranging from genetics to sociology have contributed to the various specializations within epidemiology, which are broadly classified as infectious disease, chronic disease, cancer, cardiovascular disease, genetic, perinatal, reproductive, oral, occupational, environmental, air pollution, respiratory, nutritional, injury, substance abuse, psychiatric, social, and health care epidemiology as well as pharmaco-epidemiology.

A CONCEPTUAL PARADIGM

A typical paradigm in epidemiology focuses on the interaction of: host, agent, and environment. The host is typically a person but is sometimes another species or organism which provides a reservoir of infection that is subsequently transmitted to humans. In the presence of an epidemic, one tries to understand the characteristics of the host that provide susceptibility to the epidemic condition. Characteristics that are frequently considered are: (1) genetic characteristics; (2) biological characteristics, such as immunology, physiology, and anatomy; (3) demographic characteristics, such as age, sex, race, ethnicity, place of birth, and place of residence; (4) social and economic factors, such as socioeconomic status, education, and occupation; and (5) personal behaviors, such as diet, exercise, substance use, and use of health services.

The agents in this paradigm have classically been rats, lice, and insects. They may be biological, such as viruses or bacteria, as is the case in most infectious disease epidemiology. Typhus, cholera, smallpox, the Ebola virus, Legionnaires' disease, and AIDS follow this model. Chemical agents have also contributed to significant epidemics. Some

have been physiological poisons such as the mercury once used in hatmaking, lead in old paint, water pipes, or moonshine liquor; others have been carcinogens such as tobacco or PCBs found as a contaminant in oil spread on roads. Recent focus has been on alcohol and other drugs of abuse. Other physical agents have included asbestos, coal dust, and radioactive fallout. Guns, automobiles, and industrial equipment are also agents of injury and mortality. Sometimes the “agent” has been a nutritive excess or deficiency, demonstrated in Goldberger’s 1915 discovery that a deficiency of niacin, part of the vitamin B complex, causes pellagra. Similarly, stress and other elements of lifestyle have been investigated as contributors to cardiovascular disease. An element in the consideration of agents is the degree of exposure and whether the agent alone is a necessary or sufficient cause of the disorder.

The third element of this paradigm is the environment, which may promote the presence of an agent or increase host susceptibility to the agent. Many elements of the environment may be relevant to the disease process, including (1) the physical environment, such as climate, housing, and degree of crowding; (2) the biological environment, including plant and animal populations, especially humans; and (3) the demographic and socioeconomic environments of the host.

At the core of this simple paradigm is the potential for multiple paths of causation for an epidemic. Rarely is a single cause sufficient to ensure the onset of a disease or condition. Thus the approach considers alternative modes of transmission, such as the influence of a common agent versus transmission from host to host. For many agents there is an incubation period, with delayed onset after “infection” or contact with the agent. Further, exposure may lead to a spectrum of disease with variation in the type and severity of the response to the agent. An important element to observe in any outbreak is *who* is not affected and whether that is due to immunity or some other protective factor.

METHODOLOGY

Field Methods. The historical method of epidemiology began with the observation that an epidemic was present, with the initial response

beginning with “shoe leather” investigation of who was affected and how. The initial approach focused on identified cases and their distribution over time and place, leading to a methodology that was often able to discern the risk factors for a disease even before a particular pathogen could be identified. The description of cases in terms of geography and environment as well as various demographic characteristics and exposures remains at the core of epidemiology.

Essential complements to epidemiologic field methods are careful clinical observation, measurement, and classification of the disorder, as well as laboratory identification of any pathogens and identification of potential risk factors for the observed disorder. This methodology is drawn from the methods of associated fields such as pathology, bacteriology, virology, immunology, and molecular genetics. Efforts at classification of pathogens have been augmented by the collection of libraries of reference specimens from past outbreaks.

A problem with the investigation of known outbreaks is that many types of epidemic may develop unobserved until a significant proportion of the population is affected. This has led to the development of surveillance strategies. Among these have been the reporting of multiple causes on death certificates and the mandatory reporting to the health department of many communicable diseases, such as tuberculosis and sexually transmitted diseases. The early detection and reporting of outbreaks make various public health interventions possible. Statistical analysis of mortality and morbidity has become a major component of the public health systems of most countries.

Case Registers. An extension to this approach involves case registers, in which identified mortality or morbidity is investigated and compiled in a statistical database, with subsequent investigation of the detailed context for each case. Case registers for particular types of diseases typically identify a case and then collect additional information through review of medical charts and direct field investigations and interviews. Although not as detailed as most case registers, large databases of treated disorders are gathered by various funders or providers of health services. These include the Health Care Finance Administration (Medicare and Medicaid) and various private insurance companies.

The systematic analysis of large databases, whether case registers or those of administrative agencies, makes it possible to monitor the prevalence of various conditions and to detect increases in prevalence or outbreaks long before they would be detected by individual clinicians. Analyses of mortality and morbidity are presented by most public health agencies. Typical methods include the presentation of rates of disorder, such as the number of cases per 100,000 population for geographic and demographic subpopulations. Analyses might ask whether rates are higher in one place compared to another, for a particular birth cohort, or for persons of a particular socioeconomic status. Such comparisons may be crude or adjusted for factors such as age and sex, which may bias such comparisons. Sometimes the analyses provide detailed age- and sex-specific comparisons or breakouts by other risk factors. Yet this approach is dependent on people with diseases being identified through the health system.

Prevalence Surveys. In order to discover the true prevalence of various conditions and risk factors, it is possible to conduct sample surveys of the population of a country or other geographic unit. This approach avoids potential reporting bias from the health care system and can identify conditions that might not otherwise be recognized or reported. Typically a representative sample of persons would be interviewed about their health, and sometimes various examinations or tests would be administered. Large comprehensive surveys of health and nutrition are conducted regularly by the National Center for Health Statistics. More specialized surveys of particular conditions such as blood pressure, substance use, and mental health have been conducted by federal, state, and private agencies. Because participation in most such surveys is voluntary, investigative procedures are usually limited to interviews and test procedures with little discomfort or risk. The limitation of prevalence surveys is that they are expensive and may have respondent selection biases. On the other hand, they have great potential for collecting detailed information about disorders and potential risk factors.

Case-Control Studies. The case-control method is used extensively in epidemiology. This approach typically starts with a sample of cases of a particular disorder and identifies one or more samples of persons who appear similar but who do

not have the disorder. Careful comparison of the groups has potential for identifying risk factors associated with having the disorder or, alternatively, factors that are protective. The most important issue in designing case-control studies is the designation of an appropriate control group in such a way that the process selecting controls neither hides the real risk factors nor pinpoints apparent but false ones. Control groups are frequently designated by geographic or ecological variables and are often matched on individual characteristics such as age and sex. These methods are somewhat similar to those used in natural experiments, in which two groups differ on one or more risk factors and the rates of disorder are compared, but the case-control method starts with identified cases.

Cohort Studies. Unlike the prevalence survey and most case-control studies, which are cross-sectional or retrospective in nature, a cohort study endeavors to identify groups of persons who do not have the disorder or disorders in question and then follows them prospectively through the occurrence of the disease, with ascertainment of factors likely to contribute to the etiology of the disease. Such studies may start with a general sample of the population or may select groups based on the presence or absence of hypothesized risk factors prior to onset of the disorder. They then follow the samples for incident disorder. Unlike cross-sectional studies, cohort studies provide the possibility of determining causal order for risk factors and thus avoid the possibility that apparent risk factors are simply consequences of the disease. The main problem with true cohort studies is that they must last as long as it takes for the disease to develop, which may even take longer than the working life of the investigator. Sometimes, however, cohorts can be found that have been identified and assessed historically and thus can be compared in the present. Examples may be insurance groups, occupational groups, or even residents of certain areas. Then the task is to gather the information on exposure and relate it to health outcomes.

Experimental and Quasi-Experimental Methods. A true experiment is dependent on random assignment of persons or groups to conditions, but one would hardly assign a person to a condition known to produce a serious disease. Nonetheless, there are research designs that approximate

true experiments. The most direct is an intervention study in which an intervention that cannot be provided to everyone is provided to one group but not another—or provided to the alternative group at a later time. A quasi-experimental design would identify a group that has been exposed to a risk factor and compare it to another that has not. If the factors that govern the initial exposure appear to be truly accidental, then the quasi-experiment may be nearly as random as a true experiment. In such circumstances or in true randomization, one can determine the effect of the risk factor on outcomes with little risk of the outcome determining the status of the risk factor.

Alternative Methods. There are a number of research designs found in epidemiology. Those presented above are typical but certainly not exhaustive of the alternatives. At the core of nearly all of these methods, however, is the identification of factors associated with the incidence or prevalence of particular types of disorder.

CURRENT ISSUES

In recent epidemiological literature there has been some concern about the future development of epidemiology. A part of this discussion focuses on the basic paradigm being used and whether it has shifted from an ecological approach consistent with the spread of infectious disease and related pathogens to individual risk factors that are more closely related to the current emphasis on chronic diseases. The growing influence of molecular and genetic methods increases this tendency. It has been suggested that this focus on individual and proximate causes blames the individual rather than fixing the prior cause. Some authors have suggested that epidemiology should regain its public health orientation by focusing more on ecological issues affecting the risk status of groups rather than on individual-level factors, and one suggested that the primary focus should be on fighting poverty. A more integrative approach has been suggested by Susser and Susser (1996a, 1996b), who criticize the field for continuing to rely on a multiple risk factor “black box” approach, which is of declining utility, in favor of an approach that encompasses multiple levels of organization and causes from the molecular to the societal.

A second area of concern, identified by Bracken (1998), is the relationship of epidemiology to corporate litigation when various rare disorders are related to sources of risk such as cellular telephones, breast implants, and the like. The issue is the extent to which epidemiologists can provide risk information to journalists and the public without undue burden from unbridled discovery and from the inconsistencies of findings of rare exposures related to rare diseases.

A third issue appears to be the search for professional identity in a discipline that has applicability across the full range of health professions, human and otherwise. The professional positions identified in a 1999 Internet search indicated that there is a continuing market for persons with epidemiological training but that these positions are distributed widely in departments supporting specific disciplines or located in various public health settings. Thus the job titles are often designated in a hyphenated form, such as psychiatric-epidemiologist, cancer-epidemiologist, and genetic-epidemiologist. For a more complete introduction to the principles and methods of epidemiology see Kleinbaum, Kupper, and Morgenstern (1982), Littlefeld and Stolley (1994), or MacMahon and Trichopoulos (1996).

CHARLES E. HOLZER, III

EPISTEMOLOGY

The term *epistemology* is used with two separate meanings according to different cultural traditions. In English-speaking countries, epistemology denotes the philosophical theory of knowledge in general: in this sense, it includes themes and problems such as the question of the possibility of valid knowledge, the analysis of the nature of such validity, the foundation of knowledge on reason or on experience and the senses, the analysis of different types of knowledge, and the limits of knowledge. In continental Europe, the above issues are considered part of the field of the more general discipline of *gnoseology* (*gnoséologie* in French, *gnoseologia* in Italian and Spanish) or *theory of knowledge* (*Erkenntnistheorie* in German), whereas the aim of epistemological inquiry is restricted to scientific knowledge.

In this second sense, with particular respect to social sciences (and sociology, in particular) the fundamental epistemological question becomes: “Is it possible to acquire any valid knowledge of human social reality? And, if so, by what means?” As these questions show, epistemological issues are inescapably interconnected with methodological problems; however, they cannot be reduced to simple technical procedures and their validity, as a long empiricist tradition among sociologists has tried to do. A full epistemological awareness, from a sociological point of view, should cope with at least four main issues:

1. Is the nature of the object of social sciences (i.e., social reality) fundamentally different from that of the object of natural sciences (i.e., natural reality)?
2. Consequently, what is the most appropriategnoseological procedure with which to study and understand social reality?
3. Are we sure that the particular knowledge we get by studying a particular social reality can be generalized?

4. What kind of causality can we postulate between social events, if any?

Historically, the various sociological traditions or schools have answered these four questions differently. We shall trace them by following the three main epistemological debates that took place between three pairs of opposing schools of sociological and epistemological thinking: positivism versus historicism, logical empiricism versus dialectical theory, and realism versus constructivism.

POSITIVISM VERSUS HISTORICISM

At the beginning of the nineteenth century, the discipline of sociology originated as the positivistic science of human society and aligned itself against metaphysical and philosophical speculation about social life. This, according to Auguste Comte, the founder of sociology, implied the straight application of the scientific method used in physics and the other natural sciences to the analysis of human society. His *social physics* (Comte 1830–42) is the expression of the new culture of the Industrial Revolution and of its practical ambition of a totally planned social life. Comte’s positivistic doctrine is organic and progressive and holds a naive faith in the possibility of automatically translating scientific knowledge of the laws of society into a new harmonious social order.

The uncritical assumptions of Comte as to the reliability and universal applicability of scientific method were at least partially tempered by John Stuart Mill, who considered illiberal and doctrinaire Comte’s idea that, once sociological laws are established by the same scientific method of natural science, they can no longer be questioned. Mill objected that scientific knowledge never provides absolute certainties, and he organically settled the British empiricist tradition in his *A System of Logic, Ratiocinative and Inductive* (1834). Starting from the epistemological positions of David Hume, Mill considered knowledge as fundamentally grounded on human experience, and the induction as its proper method. The possibility of inductive generalization is based on the idea of regularity and uniformity of human nature, ordained by laws; and even social events are correlated in the form of empirical laws, which we can understand using the scientific method, considered as a formal logical structure independent from human subjectivity.

The individualistic and liberal features (based on utilitarian ethics) of British positivism were particularly evident in Herbert Spencer, who opposed to Comte's organicistic view of society the greater importance of the particular with respect to the organic whole. His central focus on the concept of evolution supplied him with a synthetic perspective with which to study reality as a whole, using the analogy of biological and inorganic evolution to consider social evolution (1876–1896). However, the most complete development of a positivistic epistemology in sociological thought is certainly contained in Emile Durkheim's work *Les règles de la méthode sociologique* (1895). What he terms *faits sociaux* (social facts) can be characterized according to four criteria: two of the criteria are related to the subjects observed, whereas the other two are concerned with the sociologist observing them.

The first criterion considers the social facts as a reality external to the individual conscience: social institutions have their own life independent from individual life. The second criterion is that this external, objective nature of social facts consequently confers upon them a normative, coercive power over the individual: these social facts impose themselves on him, even without his will. Morals, public opinion, law, customs are all examples of this. These two features of social facts require, on the part of the social scientist observing them, the observance of two further qualifying criteria. Firstly, they should be considered as "things," that is, they should be studied as an external, objective reality, separate from the individual consciousness. Secondly, consistent with their nature, social facts can be explained only by other social facts: the nature of social causality is specific, and can be reduced neither to psychological causes of individual behavior, nor to biological causality, as Spencer's evolutionism suggested. The emerging nature of social phenomena from the level of psychological and biological phenomena grounds their autonomous, distinct reality: this, in turn, constitutes the specific field of sociology and of the other social sciences. To explain social phenomena, sociology should adopt a unilinear concept of causation: the same effect always corresponds to the same cause. Any plurality of causes, according to Durkheim, involves the impossibility of sorting a scientific principle of causality.

In sum, we can say that the classic positivistic paradigm of sociology is characterized by the recognition of the specific nature of social facts as emerging from the other spheres of reality. However, this implies an idea of sociology as a naturalistic science of society, using the same methods already applied with success in natural sciences (*methodological monism*), and grounded on experience as perceived by the senses and generalized on the basis of universal human nature (*induction*). Finally, a proper explanation of social facts should take into account only one cause for each effect (*mono-causal determinism*).

A serious challenge to this epistemological view of sociology came from the German Historical School: the debate about the method (*methodenstreit*) which took place in Germany during the last decades of the nineteenth century is the first example of epistemological debate in sociological history. It started with Wilhelm Dilthey, the major representative of German historicism, who argued against Comte and Mill's proposal of introducing the methods of physics into the "moral sciences." What he termed "spiritual sciences" (*Geisteswissenschaften*) were of a radically different type from the natural sciences and therefore they could not share the same method (Dilthey 1833). In fact, their objects were states of mind, spiritual experiences that could be apprehended only by means of an "empathic understanding" (*Verstehen*): "we explain nature, we understand psychic life" (*ibid.*). In the first phase of Dilthey's thought, this understanding, on which the sociohistorical nature of the spiritual sciences is grounded, was not considered to be mediated by sense perception, but rather as producing a direct and immediate intuitive knowledge-by-acquaintance. In the second phase of his thought (1905), however, he believed that psychic life was not immediately understandable, but would require the hermeneutic interpretation of its objective displays in cultural life. In any case, his distinction between the aim of natural sciences (to explain *erklären* data by means of external senses) and the scope of human sciences (to understand *verstehen* through an intrapsychic experience) was posited as a long-lasting distinction in the social sciences.

Wizhelm Windelband and Heinrich Rickert, two other adherents of German historicism, criticized Dilthey's distinction between nature and

spirit and the related sciences, since they considered human knowledge as always a spiritual activity, without regard to its *object*. In its place, they proposed a distinction based on the *form* and on the different type of *methods* used: whereas the *idiographic* method is a description of singular events, the *nomothetic* method is concerned with the inquiry of regularities and general laws (Windelband 1894). The first type of procedure is typical of—though not exclusive to—the *sciences of the particular*, the sciences of culture that, being historical, had to interpret and understand the individual character of the historical event; the second type of method is more typical of the *sciences of the general*, natural sciences that are aimed at establishing general laws. Knowledge is always a simplification of reality, which is a heterogeneous continuum (*eterogenes Kontinuum*); knowledge can either proceed by making a homogeneous *Kontinuum*, as the natural sciences do, or by sectionalizing a portion of heterogeneous *Diskretum*, such as the sciences of culture do. Rickert (1896) further developed the necessity of referring to values as a foundation for sociohistorical knowledge: the sciences of culture (*Kulturwissenschaft*) are not idiographic disciplines only, they should also refer to *value relevances* (*Wertbeziehung*) if they want to understand the actual meaning of sociohistorical events.

The most significant attempt to reconcile the two antitheses (understanding/explanation and idiographic/nomothetic) has been carried out by Max Weber, the founder of German sociology, who was profoundly influenced by German historicism, although critical of its idealistic orientation. In his methodological essays (1904–17) and in subsequent works, Weber undertakes an inquiry into the nature and validity of methods used in the social sciences and presents a general epistemological framework for his *interpretive sociology* (*Verstehende Soziologie*). He argued in particular for the necessity of when investigating social actions, 1) resorting to an *interpretive understanding*, which is not separated by *causal explanation*, 2) while avoiding *value judgements*, establishing *value relevances* (*Wertbeziehungen*) of the subject matter as criteria for its cultural importance and scientific pertinence, and 3) preserving the social and cultural uniqueness of the historical event, using the *ideal-type* methodology. These three points constitute

Weber's main elaboration of the epistemological tenets of German historicism.

With regard to the first point, Weber criticized Wilhelm Wundt and George Simmel (who were influenced by Dilthey), who reduced socio-historical knowledge to psychological understanding, since this position cannot support an objective knowledge: to properly understand a socio-historical event requires establishing some relations of cause and effect in order to test our interpretive comprehension. Therefore, Weber conceived an idea of sociology as both a generalizing, nomothetic and interpretive, idiographic science, arguing for the complementarity of interpretive understanding and causal explanation: that is, a researcher's personal understanding should be balanced by empirical and statistically established regularities of scientific explanation (1913).

Secondly, Weber distinguishes *value judgements*, based on personal faith and belief, and *fact judgements*, based on science. Scientific knowledge cannot be neutral, in the sense that the values of the researcher inevitably influence his choices of relevance—the specific selection of problems and focus. However, it can be *nonevaluative* and *objective* in the sense that, once its priorities have been selected according to the researcher's personal values, the researcher should proceed by testing empirical evidence supporting his hypotheses, thus expressing fact judgements only.

Finally, the ideal-type concept was employed by Weber to explain certain unique historical events using a model of *plural causality*: a singular event is always the effect of a multiplicity of historical connections. The problem becomes, in the infinite flow of events, to sort out the proper model of factors that under certain conditions and at a certain time can *probably* explain that effect. This also implies a *probabilistic* idea of causation, which gets beyond the deterministic approach typical of positivistic unilinear causation by a model of plural probabilistic-causal connections.

LOGICAL EMPIRICISM VERSUS DIALECTICAL THEORY

The epistemological legacy of German historicism—with its *dualistic* approach to the relationship between social and natural sciences, its preferential bias for a gnoseological model based on

interpretive understanding, and its *probabilistic* model of *multiple causality*—has undoubtedly influenced a significant part of contemporary twentieth century sociology, such as the School of Chicago (Park's contacts with Windelband and Simmel are well known) and, more strongly, the later interpretive sociology (through Weber and Simmel) and the phenomenological tradition in sociology (through Schutz). Its impact is manifest even in the antipositivistic methodological choices of many sociologists as different as Pitrim Aliksandrovič Sorokin (1959) and Charles Wright Mills (1959). Altogether, these different currents answer negatively the epistemological question about the possibility of acquiring knowledge of human social reality by means of empirical data alone. They reject the methodological unity of the natural and social sciences and do not accept the straight application of the scientific method to sociological analysis. When researchers undertake empirical research, they resort to methodological perspectives that result from the researcher's epistemological choices: they tend to reject technical terminologies and statistical quantification, to privilege common-sense conceptualization and language, and to take the point of view of the social actor instead of that of the researcher and of the scientific community. Qualitative methodologies of this kind are also favored by those microsociologies—such as symbolic interactionism, ethnomethodology, and sociologies of daily life of different varieties—that have not been directly influenced by the idealistic and antipositivistic tenets of the German historicism. Although seldom explicitly stated, their epistemological foundations, which tacitly direct their choice of methods and tools of social research, are mostly consonant with those of interpretive and phenomenological sociologies.

The large majority of sociologists, however, followed an empirical-quantitative approach and accepted the scientific method borrowed from natural sciences as the appropriate and valid method of social sciences. The positivistic epistemological foundations of this *mainstream* sociology are quite evident in its most significant representatives Lazarsfeld and Lundberg, and in their utilization of the *social survey* as the main research tool of sociological inquiry. Lazarsfeld, in particular, although reluctant during his work at Columbia University to directly tackle epistemological issues

while preferring practical empirical research, was well known for his neo-positivistic convictions (Gallino 1973:27), which were rooted in his mathematical and psychological background within the Vienna philosophical movements of the post-World War I period.

In fact, during the twenties and thirties of the twentieth century, a new group of positivists, the so-called “Vienna Circle,” arose in the Austrian capital, profoundly influenced by the work of the physicist Ernst Mach, the pioneers of mathematical logic Gottlob Frege, Bertrand Russell, Alfred North Whitehead, and Ludwig Wittgenstein, and by the French *conventionalism* of Pierre Duhem and Jules-Henri Poincaré. Mach considered science not a fact-finding but a fact-related activity: it cannot claim to discover the absolute truth about reality, since its laws are not absolute but, at best, “limitations of possibilities.” Russell, among the pioneers of mathematical logic, attempted a logical foundation of mathematics that considers the element of necessity present in both disciplines. This can be considered as the basis of the logical structure of thinking. Finally, Duhem and Poincaré suggested an idea of scientific theories as being purely hypothetical and conventional constructions of the human mind.

On these premises, the main representatives of the “Vienna Circle”—Moritz Schlick, Rudolf Carnap, and Otto Neurath—preferred the label of *logical empiricism* or *neopositivism* to distinguish themselves from classical positivism, since they discarded its sensist view—the idea that knowledge originates from experience gained only through the senses, and from the observation and verification of that experience. They rejected direct observation of experience as the only means of hypothesis testing, and they considered verification as “testability in principle.” In this way, they accepted theoretical constructs without direct empirical referents as meaningful. They renewed empiricism on the new basis of the logical analysis of language: in fact, they argued that linguistic statements can be shown to be true or false by appeal to both logic and experience, and that both means, being factual, can be considered meaningful.

Logical empiricism still maintained some fundamental epistemological tenets of classical positivism, however, such as the idea that only empirically verifiable knowledge was meaningful, that

science was a cumulative process based on induction, that the method of physics was the method of all sciences including social sciences (*methodological monism*), and that the discovery of natural and general laws was the fundamental aim of any science. The criticism of Karl Popper was aimed at most of these foundations and reversed them in a sort of *negativism* (Cipolla 1990). Since his first major publication (Popper 1934), the Austrian philosopher formulated his tenets in opposition to the main assumptions of the neopositivist: first and foremost, the *induction* as an appropriate method to infer general laws from the observation of a singular case. He argued that one case is enough to demonstrate the falsity of induction and that verification always depends on observational theories that are often derived from substantially the same theory from which hypotheses under test have been deducted, making their test logically inconclusive. Popper dropped the notion of *verification* itself in favor of that of *falsification*, and proposed a *hypothetic-deductive* method, based on the assumption that a hypothesis can be definitely considered false if it fails an adequate test, while if it is congruent with data this does not necessarily mean it is true. In any case, Popper argued that a theory is maintained as true only provisionally, and it always remains a conjectural hypothesis that can be confuted in the future. In this way, scientific knowledge is never a closed, completed system, but always remains open to new possibilities. And even though Popper believed in the *methodological monism*—the unified theory of method—this is not absolute but conjectural, critical, and subject to falsification (1963).

A substantial refusal of *methodological monism* is represented by the Frankfurt School with its “critical theory of society” that advocates the necessity of the dialectical method in sociology. Its epistemological tenets are derived partly from Weber’s thought on Western reason and rationalization and partly from the young Hegel-influenced Marx of the *Philosophical-Economical Manuscripts* of 1844. It was also strongly influenced by the two critical Marxists Lukacs and Korsch and by the psychoanalysis of Freud. Dialectical epistemology implies:

1. The *holistic* approach, that is, the necessity of considering the totality in order to understand the parts, which are mediated by totality.

2. The denial of the separation of history and sociological theory in order to grasp the dialectical process of change.
3. A demystifying attitude in undertaking critical analysis of society and of the irrationality of Enlightenment reason once it has become purely instrumental and separated from its goals, that is, when it’s become a pure means of domination over men and society.

In 1961 the second most significant debate in the history of sociological epistemology took place at Tübingen between Theodor Adorno and Jurgen Habermas (two of the most prominent representatives of the Frankfurt School) on one side and Karl Popper and Hans Albert on the other (Adorno et al. 1969). The neopositivistic epistemology of the latter two was strongly questioned by the former two, who criticized its dialectic nature and who considered it a sort of logical formalism without any connection with its contents and that was incapable of understanding the social reality. The aim of sociology is to go beyond apparent phenomena, to grasp social contradictions and conflicts by interpreting society as a totality. This implies a refusal of the individualistic approach of positivism, of its *monism* with regard to the scientific method, of its measurement and *quantification* of social reality. Beyond Popper and Albert, the actual target of the Frankfurt scholars was the American school of sociology, whose positivistic analytical framework (theoretical categories and their translation into research tools) was considered an ideological reflection of the domination structures in the late capitalistic society.

REALISM VERSUS CONSTRUCTIVISM

Since the 1960s, logical empiricism, under criticism from many sources, has dissolved in a plurality of *postpositivistic* approaches, whose common denominator is a reformulation of positivistic tradition. This allows them to be grouped under the label of *scientific realism*, which asserts the absolute or relative independence of the reality under scientific scrutiny from the human researcher studying it. This, in turn, is based on the fundamental distinction between the objectivity of the reality observed and the subjectivity of the scientific observer studying it. The common tenet of realisms

of all types is that the observer does not belong to the reality he observes; by means of his techniques of scientific inquiry, he should avoid any involvement and influence on reality, maintaining a neutral position. In this way, the subjectivity of the observer is limited to his “discovery” of the objective reality.

One of the first attacks on the neopositivistic legacy was by Willard Van Ormand Quine (1952), who proposed a holistic view of knowledge, considered as a field of forces whose limiting conditions are constituted by experience. In turn, Mary Hesse (1974) considered scientific language as a dynamic system whose continuing growth is due to metaphorical extension of the natural language. Thomas Kuhn (1962) greatly contributed to the growing consciousness of the reality of scientific change by analyzing its actual historical development, challenging the common-sense concept of science as a purely rational enterprise. Taking scientific practice into account, he showed how it is usually ruled by a *paradigm*, a world view, legitimized by the scientific community, that remains dominant until a new paradigm replaces it.

Paul K. Feyerabend, with his “methodological anarchism” (1975), proposed a paradoxical and extreme view of science. In Feyerabend’s view, the scientific method remains the only rational procedure for deciding and agreeing upon which theory is more adequate to describe and explain a state of affairs in the natural as well as in the social worlds. Of course, rationality depends on common premises and procedures: the advantage of accepting them is great because it is through them that intersubjectivity is achieved. Scientific objectivity resides neither in the object of knowledge, as classical positivism maintained, nor in the subject, as idealists tend to believe, but rather in the intersubjectivity that results when researchers adopt the same procedures and accept the premises on which those procedures are based. It is the reproducibility of the methods, techniques, and tools of scientific research that secures the replicability of results. And their reproducibility is due largely to their being public procedures, easily scrutinized and reapplied. The results of the research in the natural sciences may be more objective than those in the social sciences, but this is due to the standardization and publicity of procedures in the natural sciences. There is no ground for supposing that

natural sciences possess a special objective attitude, while social scientists possess a value-oriented attitude. The problem is that many research procedures in the social sciences are not reproducible, because they often reflect a private state of mind communicated through linguistic expression full of connotative meanings, often not shared by all in the research community.

The *critical realism* of Roy Bhaskar (1975) proposes an ontology based on the distinction of three spheres: the *real*, the *actual*, and the *empiric*, arguing in favor of the existence of structures or hidden mechanisms that can work independently from our knowledge, but whose power can be empirically investigated both in closed and open systems. This realistic view of science is supported also by Rom Harré (1986), who stresses the role of models in the development of theory. The new realists also suggest a *relational paradigm* for sociology in order to overcome the traditional antinomy between structure and action by a theory of *structuralization* (Giddens 1984) and by a *transformative model of social activity* (Bhaskar 1989). According to this new paradigm, the social structure should be considered as both the omnipresent condition and the continuously reproduced outcome of the intentional human action. This view is shared by the *applied rationalism* of Pierre Bourdieu, who systematically applies relational concepts and methodically compares his theoretical models with the empirical material that is the result of different research methodologies (Bourdieu et al. 1973). The critical view of science taken by the new realists, joined with their transformative conception of social reality, has produced a *critical naturalism* that considers both the positivist and the historicist traditions as dependent on the same positivistic conception of the natural sciences. This critical naturalism holds that, in actuality, both the human social life and the natural life are liable to scientific explanation, although of a different kind (Bhaskar 1989).

This realistic view has been seriously challenged in the 1980s and 1990s by the *constructivistic movement*, giving rise to the third, and still ongoing, epistemological debate in the history of sociology. Constructivism proposes the unification of the objective reality observed with the subjective reality of the observer. The rationale is that the reality investigated and the science used to investigate it have an equally subjective origin, which

implies that the reality observed “depends” on the observer. This does not mean that constructivism denies the actual existence of an autonomous reality from the observer, but rather that an “objective” representation of this external reality by scientific knowledge is not possible. All that can be said about reality is inevitably a “construction” of the observer (von Foerster 1984), who, in turn, being part of this reality, is a “black box” whose internal components are unobservable. Therefore, even for the constructivists, reality is an elusive objectivity, with its autonomous existence which cannot be reduced to a simple subjective and arbitrary experience. What is “constructed” is the knowledge and not the reality (Von Glasersfeld 1987).

There are different types of constructivism. The most radical (Von Glasersfeld 1995) maintains that nothing can be said even by the observer, apart from the trivial verification that he observes. An unknowable observer faces an unknowable reality. A more moderated type of constructivism considers still possible a theory of the observer, even though it denies the same possibility for the reality observed (Maturana 1988). And finally, there is a constructivism which accepts both a theory of the observer and of the observed, considering them as mental systems (Luhmann 1990).

TOWARDS AN INTEGRATED AND PLURALISTIC PARADIGM

As the current debate between realism and constructivism shows, the positions only appear distant. Especially when they move from the more abstract theory to the empirical research, the respective positions become more ambiguous, vague, and overlapping. Moreover, there are clear indications that the old cleavages between positivistic and interpretive sociologies may slowly fade away. Even though quantitative research techniques appear more precise and rigorous—with their standardization and reproducibility features—than qualitative methods, it is difficult to justify using quantification for all types of sociological data. Many sociologists believe that not all aspects of social phenomena could be subject to the rules of quantification. And most of them start out thinking that quantitative and qualitative methods and techniques are complementary. Yet, such an integrated and pluralistic methodology needs to be justified by an explicit epistemology. Therefore,

the times seem ripe for a new epistemological foundation of an emerging integrated and pluralistic methodology, even though a few attempts have been made towards this goal.

The first attempt was the *ecological paradigm* of Gregory Bateson (1972). Strongly influenced by his participation in the 1940s in the interdisciplinary research group on cybernetics composed of Von Neumann, Shannon, Von Foerster, and Wiener, among others, he then organized all his subsequent work in different fields around a few central cybernetics concepts, including schismogenesis, circular communication, and feedback. On the ground of this new theoretical perspective, he built up an epistemology aimed at getting beyond the boundaries between the internal and the external components of the observer, the “mind,” conceived as a network of founding relationships. In this process, the identity of the observing subject is dissolved into its ecological environment, in the relationship between subjective meanings, action, and action objective. Even though Bateson’s epistemology precedes the debate between realism and constructivism, it has clearly inspired most of the constructivistic approach.

A second attempt, historically, can be traced in Edgar Morin’s attempt to set up a new general method (Morin 1977, 1980, 1986), which can be applied in every field of knowledge according to a methodological *plurivers*. In this way, he tries to overcome the shortcomings of the traditional scientific paradigm, which he considers *disjointed*, *reductive*, and *simplified*, since it does not take into account the complexity of reality. The *multidimensional* character of reality is precisely the starting point of his very comprehensive attempt to found a new epistemology based on the *auto-eco-organizing* principle. An attempt, however, which for the most part is affected by a biologicistic bias, seems quite inappropriate for the social sciences.

Finally, Costantino Cipolla has proposed a new *correlational* paradigm based on an *epistemology of tolerance* (Cipolla 1997) which prefers an “inter-” and “co-” perspective linking together and integrating the traditionally opposite epistemological poles in an attempt to reassemble them into a new pluralistic approach. Closer to the sociological tradition of the first two attempts, this new correlational paradigm takes into account the reasons of both the realists and the constructivists

and focuses its attention on the connection, the relation, and the link between the objective reality and the subjective observer in order to avoid any absolutism of either of the poles. It is starting from this bivalent conception of reality—which considers reality as both autonomous in itself and “constructed” by the subject, who is in turn the outcome of the real social forces, so that each pole is considered only partially autonomous and strictly interconnected with the other—that it should be possible to re-found the sociological epistemology on the ground of the methodological research questions of the discipline, in recognition of the fundamental ambivalence of reality and of the need of an *adductive* procedure as a “double movement” between induction and deduction, particular and general, theoretical hypotheses and social reality beyond any self-contained reductivistic monism.

COSTANTINO CIPOLLA
GUIDO GIARELLI

EQUALITY OF OPPORTUNITY

Equality of opportunity refers to the fairness of processes through which individuals with different backgrounds or from different social groups reach particular outcomes, such as educational or occupational goals. Sociologists have developed several alternative approaches to defining and assessing equality of opportunity in each outcome domain, including trends in demographic gaps, residual differences after relevant qualifications are taken into account, process differences in the variables linking individual attributes to outcomes, and structural differences in the barriers encountered in preparing for, learning about, or obtaining particular educational or occupational achievements. Each approach has advantages and disadvantages for particular scientific, policy, and practical purposes.

TRENDS IN DEMOGRAPHIC GAPS

Equality of opportunity is usually judged with reference to major demographic groupings, such as race, sex, or socioeconomic status. When there are significant changes over an extended period of time in educational or occupational outcome gaps for major subgroups, inferences may be made that changes in opportunity structures underlie the trends. This argument is best made when confidence is high on the accuracy of the outcome trend data, the timing of changes in outcomes and specific opportunity processes can be matched, and other subgroup differential changes in personal resources can be discounted as nonexistent or following a different time sequence.

In education, changes in racial/ethnic gaps in achievement scores and college attendance rates have been subjected to trend analyses to pinpoint opportunity processes. The test score gap showing higher average achievement in basic skills by white students compared to African-American students has shown a significant narrowing since the 1970s, although the convergence may have stalled or begun to reverse on some tests by the end of the century (Jencks and Phillips 1998). Since the largest gains during this period occurred for African-American students who entered school between the late 1960s and late 1970s, particularly in the South, some have credited the antipoverty legislation and school desegregation enforcements of

the time aimed at increasing educational opportunities for minorities. Trends in college entry among gender and racial/ethnic groups show interesting patterns in recent decades that invite explanations of changing opportunities for selected groups. After a long-term upward trend from the 1940s to the mid 1970s, when college entry increased more for African Americans than whites to narrow the gap in educational attainments, college entry actually declined among African-American high school graduates from the mid 1970s to the mid 1980s, with some signs of recovery in black initial college enrollments in the 1990s that still did not match the progress of whites during the same period. Careful analyses to match various contemporaneous changes to the college entry trends through the 1980s ruled out most changes in personal resources, such as family income and academic achievement, although modifications in college financial aid policies from grants to loans in the face of rapidly rising college costs may account for minority college entry declines (Hauser 1993).

Racial/ethnic gaps in college degree attainments, after gradually closing for successive decades, still remain very large and recently also have begun to grow even larger. The number of African-American recipients of either bachelor or advanced degrees has actually declined since the beginning of the 1980s, which can be tied to numerous inequalities of access and support in the American education system across the grades and the court-inspired decline of racial considerations in the admissions policies of some colleges (Miller 1995; Orfield and Miller 1998).

Economic changes over recent decades in the distribution of income have also been subjected to trend analyses. Income inequality as measured by the gaps in the percentage of annual income held by different social groups, such as the top fifth versus bottom fifth of the population, showed moderate improvements, with only small periods of slight reversals over the years following World War II through the end of the 1970s. But the period since 1980 has been one in which income inequality increased sharply, sometimes called the shrinking middle class, as the rich got richer, acquiring a higher percent of total income, while productivity growth eliminated jobs or decreased earnings for many less educated workers (Levy,

1995). Numerous factors have been associated with recent trends, including reduced access to employment opportunities due to the movement of jobs from many urban locations where poor minority workers live (Wilson 1996).

RESIDUAL DIFFERENCES IN EQUALITY OF OPPORTUNITY

Even when major outcome gaps are observed, the issue remains whether individuals from major population subgroups have had the same chances to achieve educational or occupational success, assuming that they possess the same distributions of personal attributes to qualify for success. Because any initial average outcome gaps between subgroups can be due to unequal possession of relevant qualifications, as well as to unfair access to the opportunities that link qualifications to achievements, it is necessary to take into account differences in personal qualifications before deciding that unequal opportunities exist.

Researchers have frequently tested for inequalities of opportunity by estimating the residual gap between the educational or occupational success of selected race, sex, or social-class groups after individual differences in relevant credentials or competencies and educational or labor market locations have been statistically controlled for. The usual methodology is to estimate a prediction equation or to use other methods of standardization for selected individual resource variables that permit a researcher to compare the actual group difference in an educational or occupational outcome with the residual gap that would be expected if one group's productivity resources were replaced by the average resources of the other group (Farley and Allen 1987, Chap. 11). For example, the actual average difference in annual earnings of African-American and white workers in the North would be compared against the residual earnings gap when one assumes that African-American workers' resources (such as education and labor-market experience) deliver the same rate of return in earnings as that experienced by white workers. Some problems are inherent in this approach, including the risk of overestimating the residual gap if some important qualification variables are omitted or poorly measured and the chance of underestimating the residual gap when some groups

are deprived of relevant qualifications due to earlier unequal opportunities not reflected in the estimation methodology. Nevertheless, several important residual race, sex, or social-class gaps have been identified for various important educational and occupational outcomes. However, these gaps are often associated with some subgroups but not others, and some gaps have been changing more rapidly than others in recent years.

Numerous national and regional studies have been conducted since the 1960s to estimate the inequality of job opportunities, including research that examines residual subgroup differences in unemployment rates, occupational distributions, and dollar returns from holding a job. Studies of race, sex, and social-class residual gaps in earnings and income of employed workers have been particularly noteworthy, with more than twenty-five major national studies having been published since 1965 (Farley and Allen 1987).

The research on earnings gaps that estimates the "cost of being black" due to inequality of job opportunities has contrasted the experiences of male and female workers and reported the continuing but declining significance of race. After taking into account differences in educational attainment, age or years of potential labor-market experience, hours of work, and regional location, large residual gaps in earnings are found between male African-American and white workers, with African Americans earning 10 to 20 percent less than comparable whites in various regions and at various educational levels. Women continue to earn much less than men of the same race with similar educational credentials, but the residual race gap for women is no longer the same as reported for men. In 1960, African-American women earned less than white women at all educational levels except college graduate, but this gap had been eliminated or reversed by 1980, when college-educated African-American women actually reported greater earnings, largely because of greater hours of employment. The residual race gap in earnings for employed workers also appeared to grow somewhat smaller, for men between 1960 and the 1990s, but it still remains between 10 and 15 percent at all educational levels.

At the same time, evidence is mounting that racial gaps in rates of unemployment are significant and have been growing worse since the 1960s

for African-American men in most age and education categories; they are especially severe for unmarried young African-American men in the North who have limited educational attainments (Farley and Allen 1987, chaps. 8–11; Jaynes and Williams 1989, Chap. 6). While the economic boom period in the 1990s benefited the average employment prospects and median incomes of all race/ethnic and gender groups, the lower levels of the income distribution and the poorly educated did not keep pace and actually fell behind in some of these years.

Race inequalities of accumulated wealth have also been investigated after statistically taking into account factors that affect how individuals encounter financial opportunity structures. Measured by either the net worth of a household total assets less any debts or as net financial assets that exclude equity accrued in a home or vehicle that is more difficult to convert into other resources, very large racial differences are found in wealth that have grown even larger in recent years. The average black family held \$3,779 in mean net worth in 1967, which rose to \$19,736 in 1984 and \$23,818 in 1988, in comparison to the average white family's mean net worth, which stood at \$20,153, \$76,267, and \$95,667 for the same time periods, for a race gap that widened by \$40,000 during these years and reached \$71,849 by 1988. After controlling for differences in age, annual household income, household composition, and professional and self-employed status, nearly three-quarters of the racial gap is left unexplained. Institutional and policy factors that may account for the residual race differentials in wealth include mortgage loan and interest rate practices, evaluation of different neighborhoods, and various inheritance mechanisms whereby status and resources can be transmitted across generations (Oliver and Shapiro 1995).

Inequalities of educational opportunity have been examined by estimating residual race, sex, or social-class gaps in outcomes net of initial resources, especially for college enrollment and completion rates. Among the earliest evidence of a social-class gap in college attendance net of academic ability is data from the 1960s showing that even after controlling on standardized test performance, students from lower categories of socioeconomic status are much less likely to enter college

within five years of high school graduation. The talent loss due to unequal social-class background was estimated to be 50 percent of top-ability students who do not enter college from the lowest socioeconomic quartile, compared with a loss of only 5 percent of high-ability students from the highest socioeconomic quartile (U.S. Department of Health, Education and Welfare 1969). The importance of social-class factors for educational equity was reinforced by extensive research on Wisconsin high school students that included measures of race as well as student achievement on standardized tests. Social-class disparities in educational attainment net of academic ability were again in evidence, as it was reported that top-ability students were only half as likely to attend college or to graduate from college if they came from the lowest quarter, rather than the highest quarter, in socioeconomic status (Sewell and Hauser 1980). These studies also estimated that observed African-American–white differences in years of educational attainment can largely be accounted for by social-class differences between the racial groups.

However, race differences in students' achievement test performance are not so well explained by socioeconomic status alone. A study of seven national probability samples of adolescents from 1965 to 1996 described trends in black–white test score gaps after adjustments had been made for social class, family structure, and community variables. About a third of the test score gap is accounted for by racial differences in social class, so a major race gap remains in adjusted test scores; this gap has narrowed somewhat since 1965, although the rate of closure seems to have decreased or reversed since 1972. Group differences at the extremes of the distribution reveal contrasting gaps and the importance of social-class factors. Social-class-adjusted differences at the bottom of the distribution are closing more rapidly, especially in reading, but differences at the top of the achievement distribution are large and they are neither improving over time nor due to relative changes in social class (Hedges and Nowell 1999). This supports that argument that gaps in test scores are due to factors other than social class and family structure, such as discrimination, residential segregation, and the quality of schooling available to African Americans (Jaynes and Williams 1989).

PROCESS DIFFERENCES IN OPPORTUNITIES

Another approach to assessing equality of opportunity is to compare the attainment processes that link personal resources or investments to educational or occupational achievements for different social groups. Opportunities can be defined as unequal when the major avenues to advancement used by one group are not as effective for another. Researchers have frequently reported attainment process differences in the degree to which various population subgroups have been able to capitalize on advantages of family background or have experienced a high rate of return on investments in building relevant competencies or credentials. Some of this work has been criticized for possible shortcomings of methodology and interpretation.

Studies of social-group differences in an attainment process are important because they help to estimate the long-run prospects for closing existing achievement gaps (Featherman and Hauser 1978, Chap. 6). The prospects are positive if each subgroup has access to an attainment process that will translate improvements of personal and family resources into achievement outcomes, especially when programs and policies are available for investments in upgrading resources of groups that at present are weak. But if some groups are lagging in relevant skills and credentials, and are exposed only to attainment processes that provide poor returns in comparison with other groups, then the prospects are dim for closing existing gaps.

Studies of general social mobility processes have identified the special problems of African American males in translating any advantages from the family of origin into attainments in their own adult lives. For the white male population in this country, clear intergenerational processes have been evidenced in which sons can build upon a middle- or upper-class family background, as shown by the strong relationship between father's and son's occupational status for whites over many recent decades. In contrast, through the 1960s, African-American males have not been as able to capitalize on any family advantages in building their occupational careers, as shown by the weak relationship for intergenerational mobility and the frequency with which substantial proportions of African-American males from nonmanual or white-collar households are downwardly mobile

and unable to benefit from their family advantages. There is some indication that since the 1970s race differences for males in the opportunities to benefit from any inheritance of family social-class advantages have closed (Farley and Allen 1987; Featherman and Hauser 1978.)

Race differences in the processes of school effects on achievement have been reported in two national studies by the sociologist James S. Coleman and his research coworkers. In a 1966 national study of public schools, differences in school resources and learning environments were found to have larger average effects on African-American students' achievement than on white students' achievement (Coleman et al. 1966). The result was interpreted as a differential sensitivity of disadvantaged students to school improvements, because these students from poor families relied more on good schools for their development of academic skills. A similar race difference in educational processes was found in the 1980s with national data from public and private high schools (Coleman and Hoffer 1987). African Americans, Latinos, and students from low socioeconomic backgrounds were found to do better in Catholic schools than in public high schools, in terms of both higher test scores and lower dropout rates. It was argued that these students especially benefited from the greater academic demands that can be enforced by the sense of community established by Catholic schools, which compensates for family disadvantages of many of these students. Again, minority and disadvantaged students were found to be more responsive to changes in school environments that have effects on high school students' achievement and completion rates. Other researchers have questioned the recent results on the grounds that key student/family self-selection variables were not controlled in the analyses of public-Catholic school differences and that the sizes of the race interaction effects were not impressive by conventional statistical standards (Alexander and Pallas 1985; McPartland and McDill 1982).

Research has indicated that race inequalities are currently much less evident in educational attainment processes than in occupational attainment processes. Analyses using appropriate statistical tests of the processes that yield important educational achievements—such as additional years of schooling and scholastic outcomes, including

grades and test scores—have found great similarities between African Americans and whites (Gottfredson 1981; Wolfle 1985). Thus, not only have African-American-white differences in the frequency of high school graduation and college education been diminishing, the processes that link social background and school input variations to educational achievements have become very similar for African Americans and whites. At the same time, race gaps in school test scores have been closing more slowly, and serious disparities persist in the level of financing and concentration of single-race and disadvantaged student bodies in schools attended by racial minorities, even though education attainment processes would translate improvements of such inputs into attainments for African Americans (Jaynes and Williams 1989).

However, major race and sex differences continue in the occupational domain regarding both the processes of attainment and the gaps in achievement. Labor-market disparities by race and sex are much more apparent than differences in educational opportunities, but the disparities are exhibited in complex patterns or processes according to individuals' social-class position, labor-market location, career stage, and other factors (Farley and Allen 1987; Featherman and Hauser 1978; Jaynes and Williams 1989; Wilson 1987). The chances are equally good for African Americans and whites of each sex who are highly educated to gain entry to good jobs, but advancement opportunities to higher positions at later career stages are more likely to be missed by African Americans. At the same time, African-American male workers with less advanced credentials are much more likely to have periods of unemployment or reduced hours, and to be paid less when employed, than white males with equivalent years of schooling. The greatest race discrepancies are observed for poorly educated young African-American males, who are much more likely than comparable whites to be unemployed, to have dropped out of the labor force, or to report no annual earnings. William J. Wilson (1980) has developed a theory of the "declining significance of race" that considers the growing social-class gaps within the African-American population in occupational success, as well as the special difficulties faced by poorly educated African-American males in urban racial ghettos, whom he views as "the truly disadvantaged" (Wilson 1987).

STRUCTURAL BARRIERS TO EDUCATIONAL OPPORTUNITIES

While careful studies of residual differences and attainment process differences can document the existence of unequal opportunities, other research is required on specific interactions and practices in schools or labor markets to understand the actual barriers that unfairly inhibit individuals because of their sex, race, or social-class position. For education, research on differential access to specific components of schooling, studies of tracking and grouping policies in elementary and secondary schools, and examinations of financial aid practices in higher education have identified some specific structural barriers in educational opportunities.

A landmark study was conducted in response to a congressional request under the 1964 Civil Rights Act and published in 1966 with the title *Equality of Educational Opportunity*. Also known as the "Coleman Report," after the sociologist James S. Coleman who directed the research, it was both influential and controversial for the way it examined educational opportunities and for its major findings (Coleman et al. 1966). Based on a large national survey of students and schools at both elementary and secondary levels, the Coleman Report collected the most comprehensive data available at that time on equity issues in education. It was not satisfied to compare only the average school input resources experienced by different race and ethnic groups—such as textbooks, libraries and laboratories, per pupil expenditures, teacher qualifications, or class size. The Coleman Report also considered race and ethnic differences on student outcomes as measured by standardized tests in major subjects, and asked how different school components contributed to student learning, in order to weigh inequalities of school inputs by their importance for student outcomes. The simultaneous examination of school inputs, student outcomes, and their relationships to one another had not been attempted before in assessing equity issues, and the published results have been a continuing source of reanalysis and reinterpretation.

The Coleman Report did find large differences in test scores between white and most racial and ethnic minority groups that existed from the time students began school and were not reduced,

on the average, as students moved from grade 1 to grade 12. These differences in student outcomes could not be explained by variations in the school input factors measured by the Coleman Report surveys, because within each region no great disparities of school inputs appeared for different racial and ethnic groups, and these factors did not relate strongly to student outcomes in any case after family background and social-class factors were statistically controlled. In fact, when school factors were combined into three clusters for analysis—(1) instructional materials and resources, (2) teacher and staff characteristics, and (3) student body composition—the most important component in accounting for variations in student test scores net of family background was the attributes of fellow students. Thus, the large observed group differences in student outcomes were not found to be accounted for by existing variations in conventional school and teacher components, although attending a school with fellow students who were college-bound did seem to make a positive contribution to the learning environment.

Subsequent investigations have shown that improvements in school factors, such as smaller class size, better-qualified teachers, and well-directed extra resources, can actually make a significant difference for student learning (Burtless 1996; Jencks and Phillips 1998). But the general picture drawn by the Coleman Report has been confirmed of an educational system that does little to reduce the large racial and ethnic differences in academic test scores with which students begin elementary grades (Jencks et al. 1972; Puma et al. 1997).

The Coleman Report data did not measure within-school differences in educational resources and learning environments, and consequently was unable to analyze major barriers to equal opportunities from specific internal school practices, such as tracking and ability grouping. Other research has shown that when students are tracked into separate programs or separate courses according to their earlier test scores or grades, those in the lower-level groups are likely to encounter serious barriers to their educational growth and progress. Lower tracks and lower-level courses have been shown to offer weaker educational resources, such as fewer expert teachers and poorer educational climates with lower academic expectations, that can lead to lower average student achievement test scores and decreased probabilities of completing

high school and continuing education in college (Gamoran 1986; Hallinan 1988; Oakes 1985). Tracking is now seen as a major barrier to equal educational opportunities because tracking and ability grouping are very common practices in American schools, and minorities and socioeconomically disadvantaged students are much more likely to be assigned to the lower-level programs and courses within their schools (Oakes 1985).

Moreover, the educational resources available at the school level are thought to be more unequal for minorities and disadvantaged students at the present time than they were found to be in the 1966 Coleman Report assessments (Smith and O'Day 1991). Since the 1960s, demographic trends have created greater concentrations of poverty in large urban schools, and changes in funding support for public education in central city districts have reduced those districts' relative ability to purchase adequate classroom supplies and materials, and to recruit and retain highly qualified teachers. In addition, trends in school desegregation, which produced increasing numbers of racially mixed schools with improved learning environments for minorities because of court decisions from 1954 through the 1970s, were reversed in the late 1980s and early 1990s, when school segregation grew in most regions and in the nation as a whole (Orfield and Eaton, 1996). Consequently, school-level barriers to equal educational opportunities have worsened since the 1960s, because the changing urban demographics and negative fiscal trends have dramatically altered the student body composition and the quality of the teaching staff that the Coleman Report found to be the most important factors of a good school.

Barriers have been identified in college educational opportunities, which also may have gotten worse, especially for African-American males, in recent years. Minorities have long been underrepresented as students at four-year colleges, in scientific major fields, and in obtaining advanced degrees (Trent and Braddock 1987). Some of these gaps had been closing through the 1970s, but since that time, uniform progress is no longer evident and some actual downturns in minority enrollments and attainments have been recorded (Jaynes and Williams 1989; Miller 1995; Wirt et al. 1998). African-American and Latino students often encounter special problems in pursuing college

programs because of insufficient social and academic support on campus or inadequate prior educational experiences (Green 1989). Recent reversals in minority enrollments have been explained by increasing tensions related to race and ethnicity on some college campuses and to changes from grants to loans in many financial assistance programs which poor students are less likely to receive or use (Blackwell 1990).

STRUCTURAL BARRIERS TO OCCUPATIONAL OPPORTUNITIES

To help account for residual sex or race gaps in job success and in the career attainment process, research has identified specific structural barriers to sex equality and to racial equality in occupational opportunities.

Studies of the large average earnings differences between men and women workers show that very large gaps remain after statistically controlling on individual differences in input variables such as education and experience, but these gaps are substantially reduced by adding measures of each person's occupation or occupational group. This result indicates that sex gaps in earnings have much of their source in the extreme job segregation by sex in the American labor market—many occupations are primarily filled by women or primarily filled by men—and the wage levels are much lower for “female” occupations (Treiman and Hartmann 1981). Since fully two-thirds of men and women would have to change jobs to achieve similar representation of each sex across occupations, full enforcement of antidiscrimination laws against unequal pay for men and women in the same occupation can achieve only modest improvements in wage differentials by sex. Other suggested approaches to reducing sex segregation of jobs and associated wage gaps—such as enriching the socialization experiences toward a wider range of career exposures for children and youth of both sexes, or incorporating policies of “comparable worth” that establish wage rates by job features, irrespective of sex or race of incumbents (Hartmann 1985; Marini 1989)—have not yet made large inroads.

To specify how occupational opportunities continue to be unequal for racial or ethnic minorities, research has identified structural barriers at each stage of the occupational career process.

Barriers can appear at the job candidate stage, when employers are recruiting the pool of candidates for job openings; at the job entry stage, when an individual is actually selected to fill a vacancy; and at the job promotion stage, when transfers are made within a firm to fill spots at higher levels (Braddock and McPartland 1987; Feagin and Feagin 1978; Marini 1989).

At the job candidate stage, qualified minorities of either sex may fail to learn about many desirable job openings because they are excluded from useful social networks that provide others with information about and contacts for particular employment opportunities. Employers find job candidates more frequently from walk-ins and friends of current employees (the result of informal social networks) than any other recruitment means for lower- and middle-level jobs. The social contacts used by many minorities are racially segregated networks that on the average are not as well tied to good job information as the social networks available to whites. This barrier to equal opportunities at the job candidate stage is partially kept in place by the continued racial segregation of the schools and neighborhoods that create many social networks and by the underrepresentation of minorities in the upper levels of firms, where informal information for friends and relatives about job openings is often best acquired (Crain 1970; Rossi et al. 1974).

At the job entry stage, otherwise qualified minorities are often not selected because of barriers of statistical discrimination and information bias. Employers who do not wish to invest much to obtain extensive information about job applicants will often use a group identifier, such as sex or race, in hiring decisions when they believe that traits on which subgroups may differ statistically predict job performance. For example, such “statistical discrimination” can occur when an employer selects a white over a minority applicant for a job requiring good academic skills, based on a belief in average racial group differences on academic test scores rather than on actual individual candidates' differences in academic skills shown on tests administered or obtained by the employer during the screening process (Bielby and Baron 1986; Braddock et al. 1986; Thurow 1975).

Even when qualification data from individuals are relied upon in hiring decisions, other barriers

to equal opportunities occur due to “information bias” of data on minority candidates. References and recommendations from school or employment officials for African-American applicants may be viewed as less credible by white employers who are less familiar with an African-American school, a member of the African-American clergy, or an African-American firm, or who may be more wary of information provided by minority sponsors due to stigmas or stereotypes attached to these sources. Similarly, minority job applicants who grow up in communities that have high youth unemployment rates will be less able to satisfy prospective employers’ interests in previous employment experiences and references (Braddock and McPartland 1987).

At the job promotion stage, minorities may face unfair barriers due to internal recruitment methods or because they are poorly positioned within internal labor markets. However, findings from a national study indicate the potential benefits to minorities of seeking internal promotions: The average pay differential between African-American and white workers is less for jobs filled from inside a firm than for jobs filled from outside for individuals of the same sex and education level, suggesting that unfair selection is reduced when employers process information on applicants’ actual job performance within their firm. On the other hand, the same study showed that unless an internal vacancy is widely advertised within a firm, whites are more likely to be sought out for available promotions (Braddock and McPartland 1987). Moreover, research has shown that minorities are less likely to have entered a firm on a career ladder that ordinarily leads to promotion opportunities, so they may never be eligible to compete for advancement through an internal labor market (Rosenfield 1980).

POLICIES AND PRACTICES

Governments and courts have established policies and practices in recent decades that are intended to eliminate race and sex discrimination and to ensure equality of opportunity. These range from the 1954 Supreme Court decision against segregated schools to the civil rights legislation of the 1960s and the executive orders to establish affirmative action guidelines in employment (Burstein 1985; Jaynes and Williams 1989). However, in the

final decades of the twentieth century, major court decisions have stepped back from considerations of race in school attendance patterns, college admissions policies, and employment selection practices (Orfield and Eaton 1996; Orfield and Miller 1998). At the same time, the expectation of high performance in elementary and secondary schools by students regardless of race or ethnicity has become widespread national and state policy, as a common-core academic curriculum is being mandated for all learners. It has yet to be determined how testing of students will combine with higher standards to influence access to educational opportunities and the gaps in dropout rates and achievement scores.

Although it is difficult to distinguish the effects of one governmental action from those of another in improving the life chances of women and minorities, clear advances have been made that can be attributed to the combined impacts of various public policies for equal rights. For example, from 1970 to 1990 the race gaps in academic test scores of schoolchildren decreased between 25 and 50 percent for different age groups (Smith and O’Day 1991). Reductions in the race gaps in terms of years of school completed have been dramatic, especially among female students. Greater equity is also evident in some labor-market behaviors, including the distribution of occupations by race within sex groups. On the other hand, inequalities in the distribution of income have grown in recent years, with a much higher share going to the top earners; average racial improvements are not evident in employment rates and income levels of adult males; some stagnation or reversals have occurred in upward trends of minority test scores and college attainment rates; and extensive racial segregation of housing and schooling remains a dominant feature of American life. The increasing diversity of minority groups in this country will amplify issues of equality of opportunity that concern language and cultural background differences in the population (Harrison and Bennett 1995).

Controversy continues to accompany further efforts to sustain current policies and to institute new practices for equal opportunities. The differences are most evident on whether outcome-based policies are required to overcome systemic barriers—for instance, affirmative action programs that use guidelines and timetables—or whether efforts

should concentrate only on intentional discrimination or on specific aspects of the processes that inhibit equal rights (Levinger 1987).

ETHICS IN SOCIAL RESEARCH

The immediacy of subject matter in social science underscores the importance of ethical issues in research by social scientists. This is particularly true in sociology. A rather small percentage of sociologists use historical documents or cultural products as data. The majority rely upon interviews with actively cooperating subjects, records relating to persons still living or recently alive, unobtrusive observation of live actors, or participant studies within interacting groups. Sociological research typically focuses on relatively large study populations and poses questions relevant to many dimensions of individual and social life. Both the process and application of sociological inquiry may conceivably affect large numbers of subjects in an adverse manner. Thus, the question of "right" and "wrong" in research has been a continual (though not always powerful or explicit) concern within the profession.

Ethics may be conceptualized as a special case of norms governing individual or social action. In any individual act or interpersonal exchange, ethics connotes principles of obligation to serve values over and above benefits to the people who are directly involved. Examination of ethical standards in any collectivity provides insights into its fundamental values; identification of ethical issue provides clues to its basic conflicts. This is as true of sociology as a profession as it is of other social systems.

The most abstract and general statements about ethics in sociological literature reflect broad agreement about the values that social inquiry should serve. Bellah (1983) writes that ethics constitutes an important, though typically implicit, topic in the thinking of sociology's founders (such as Durkheim and Weber) and leading modern practitioners (such as Shils and Janowitz). Even while consciously striving to distinguish their emerging discipline as a science free of values and moralizing, the early sociologists appeared to have a distinct ethical focus. The discipline's founders implied and sometimes stated that sociology necessarily involved ethical ends, such as identification of emerging social consensus or the development of guidelines for assessing social good. Modern sociologists have emphasized improvement of society's understanding of itself as the discipline's principal ethical end, as opposed to determining a specific direction or developing technology for social change. In the broadest sense, contemporary sociologists seem to consider the raising of consciousness as quintessentially ethical activity and social engineering by private or parochial interests as ethically most objectionable. In the phraseology of Edward Shils, this means contributing to "the self-understanding of society rather than its manipulated improvement" (Shils 1980, p. 76).

Dedication to advancement of society's understanding of itself through diverse scientific approaches may comprise the fundamental ethic of sociology. A *Code of Ethics* published by the American Sociological Association (ASA) in 1989 (American Sociological Association 1989) gave concrete expression to this ethic. Concentrating primarily on research, the *Code of Ethics* emphasized three specific areas of concern: (1) full disclosure of motivations for and background of research; (2) avoidance of material harm to research subjects, with special emphasis on issues of confidentiality;

and (3) qualifications to the technical expertise of sociology.

The first area appeared concerned primarily with a fear among sociologists that agencies of social control (such as military or criminal justice units) may seek intelligence under the guise of social research. Thus, the code advised sociologists not to "misuse their positions as professional social scientists for fraudulent purposes or as a pretext for gathering intelligence for any organization or government." The mandate for disclosure has implications involving relations among professionals, between professionals and research subjects, and between professionals and the public. Another provision of the code read, "Sociologists must report fully all sources of financial support in their publications and must note any special relation to any sponsor." (p. 1)

The second area of concern in the code placed special emphasis on assurance of confidentiality to research subjects. It stressed the need for extraordinary caution in making and adhering to commitments. As if to recognize the absence of legal protection for confidentiality in the research relationship and to mandate its protection nevertheless, the code stated: "Sociologists should not make any guarantees to respondents, individuals, groups, or organizations—unless there is full intention and ability to honor such commitments. All such guarantees, once made, must be honored" (p. 2).

As a subject of professional ethics, the third area is extraordinary. Provisions mandating disclosure of purpose and assurance of confidentiality might appear in the code of ethics of any profession dealing regularly with human clients or subjects. But it is surprising to find, as a provision in the 1989 ASA *Code of Ethics*, the mandate that sociologists explicitly state the shortcomings of methodologies and the openness of findings to varying interpretation. The following quote illustrates provisions of this nature:

Since individual sociologists vary in their research modes, skills, and experience, sociologists should always set forth ex ante the limits of their knowledge and the disciplinary and personal limitations that condition the validity of findings. To the best of their ability, sociologists should . . . disclose details of their

theories, methods and research designs that might bear upon interpretation of research findings. Sociologists should take particular care to state all significant qualifications on the findings and interpretations of their research. (p. 2)

Themes in the 1989 *Code of Ethics* dealing with disclosure and confidentiality reflect widely shared values and beliefs in the profession. Historically, sociology has stood out among the learned professions as critical of the authority of established institutions such as governments and large business firms. But propositions about the limitations of theories and methodologies and the openness of findings to varying interpretation suggest conflict. In the late twentieth century, sociological methodologies encompassed both highly sophisticated mathematical modeling of quantitative data and observation and theory building based entirely on qualitative techniques. Acknowledgment of the legitimacy of these differences in an *ethical* principle reflects a strenuous attempt by sociology as a social system to accommodate subgroups whose basic approaches to the discipline are inconsistent with each other in important respects.

A more recent formulation of the ASA *Code of Ethics*, published in 1997 (American Sociological Association 1997), restates the basic principals of serving the public good through scientific inquiry and avoiding harm to individuals or groups studied. But a shift in emphasis appears to have occurred. The 1989 *Code* explicitly cited the danger of governmental or corporate exploitation of the sociologist's expertise. The 1997 *Code*, though, stresses ethical challenges originating primarily from the researcher's personal objectives and decisions.

The 1997 *Code of Ethics*, for example, contains a major section on conflict of interest. According to this section, "conflicts of interest arise when sociologists' *personal or financial* interests prevent them from performing their professional work in an unbiased manner" (p. 6; emphasis added). A brief item on "disclosure" asserts an obligation by sociologists to make known "relevant sources of financial support and relevant personal or professional relationships" that may result in conflicts of interest vis-a-vis to employers, clients, and the public (p. 7).

The two most extensive sections in the 1997 *Code* are those on confidentiality and informed consent. The directives addressing confidentiality place extraordinary responsibility on the individual sociologist. Pertinent language states that "confidential information provided by research participants, students, employees, clients, or others is treated as such by sociologists *even if there is no legal protection or privilege to do so*" (emphasis added). The *Code* further instructs sociologists to "inform themselves fully about all laws and rules which may limit or alter guarantees of confidentiality" and to discuss "relevant limitations on confidentiality" and "foreseeable uses of the information generated" with research subjects (p. 9). It is recommended that information of this kind be provided at the "outset of the relationship." Sociologists are neither absolutely enjoined from disclosing information obtained under assurances of confidentiality nor given clear guidance about resolving pertinent conflicts. The *Code of Ethics* states:

Sociologists may confront unanticipated circumstances where they become aware of information that is clearly health- or life-threatening to research participants, students, employees, clients, or others. In these cases, sociologists balance the importance of guarantees of confidentiality with other priorities in [the] Code of Ethics, standards of conduct, and applicable law. (p. 9)

The section on informed consent, the most extensive in the 1997 *Code of Ethics*, reflects a frequent dilemma among sociologists. The basic tenets of informed consent as stated here approximate those in all fields of science. Obtaining true consent requires eliminating any element of undue pressure (as might occur in the use of students as research subjects) or deception regarding the nature of the research or risks and benefits associated with participation. In social research, however, statement of the objectives of an investigation may affect attitudes and behavior among research subjects in a manner that undermines the validity of the research design. Recognizing this possibility, the *Code* acknowledges instances when deceptive techniques may be acceptable. These include cases where the use of deception "will not be harmful to research participants," is "justified by the study's prospective scientific, educational, or applied value," and cannot be substituted for by alternative procedures (p. 12).

A review of historical developments, events, and controversies of special importance to sociologists in the decades preceding the 1989 and 1997 *Codes of Ethics* promotes a further appreciation of the concerns they embody. Perhaps the most far-reaching development in this era was the introduction of government funding into new areas of the sociological enterprise. In sociology, as in many areas of science, government funding provided opportunities to expand the scope and sophistication of research, but it created new ethical dilemmas and accentuated old ones.

Increased government funding created interrelated problems of independence for the sociological researcher and anonymity for the research subject. A report by Trend (1980) on work done under contract with the U.S. Department of Housing and Urban Development (HUD) illustrates one aspect of this problem. Possessing a legal right to audit HUD's operations, the General Accounting Office (GAO) could have examined raw data complete with individual identifiers despite written assurances of confidentiality to the subjects by the research team. Sensitivity on the part of the GAO and creativity by the sociologists averted an involuntary though real ethical transgression in this instance. But the case illustrates both the importance of honoring commitments to subjects and the possibility that ethical responsibilities may clash with legal obligations.

Legal provisions designed explicitly to protect human subjects emerged in the 1970s. Regulations developed by the U.S. Department of Health and Human Services (DHHS) require that universities, laboratories, and other organizations requesting funds establish institutional review boards (IRBs) for protection of human subjects. The 1997 ASA *Code of Ethics* makes frequent reference to these boards as a resource for resolution of ethical dilemmas.

Sociologists, however, have not always expressed confidence in the contributions of IRBs. One commentary (Hessler and Freerks 1995) argues that IRBs are subject to great variability in protecting the rights of research subjects at the local level. Others contend that deliberations of these boards take place in the absence of appropriate standards or methods of analysis. The expertise and concerns of IRBs may not apply well to

actual risks posed by sociological research methods. Biomedical research, the primary business of most IRBs, potentially poses risks of physical injury or death to the research subject. Except in extraordinary circumstances, sociological techniques expose subjects at worst to risks of embarrassment or transient emotional disturbance. IRB requirements often seem inappropriate or irrelevant to sociology. In the words of one commentator, the requirement by IRBs that researchers predict adverse consequences of proposed studies encourages sociologists to engage in exercises of "futility, creativity, or mendacity" (Wax and Cassell 1981, p. 226).

Several instances of highly controversial research have helped frame discussion of ethics among sociologists. Perhaps most famous is the work of Stanley Milgram (1963), who led subjects to believe (erroneously) that they were inflicting severe pain on others in a laboratory situation. This experiment, which revealed much about the individual's susceptibility to direction by authority figures, was said by some to present risk of emotional trauma to subjects. Milgram's procedure itself seemed to duplicate the manipulative techniques of authoritarian dictators. Distaste among sociologists for Milgram's procedure helped crystallize sentiment in favor of public and professional scrutiny of research ethics.

The Vietnam era saw increasing suspicion among sociologists that government might use its expertise to manipulate populations both at home and abroad. A seminal event during this period was the controversy over a U.S. Army-funded research effort known as Project Camelot. According to one commentator, Project Camelot aimed at ascertaining "the conditions that might lead to armed insurrections in . . . developing countries so as to enable United States authorities to help friendly governments eliminate the causes of such insurrections or to deal with them should they occur" (Davison 1967, p. 397). Critical scrutiny by scholars, diplomats, and congressional committees led to cancellation of the project. But provisions in the 1989 *Code of Ethics* on disclosure and possible impacts of research clearly reflect its influence.

The end of the Cold War and increasing litigiousness among Americans may help explain the shift in emphasis between the 1989 and 1997

ASA *Codes of Ethics*. As noted above, the later *Code* appears to emphasize ethical issues facing sociologists as individuals rather than as potential tools of government and big business. Many sociologists have stories to tell about actual or potential encounters with the legal system over the confidentiality of data obtained from research subjects. The visibility and frequency of such encounters may have helped shape the 1997 *Code's* section on confidentiality.

The most celebrated confrontation of a sociologist with the law involved Rik Scarce, who was incarcerated for 159 days for refusing to testify before a grand jury investigating his research subjects. Scarce's case is described by Erikson (1995):

Scarce found himself in an awful predicament. He was engaged in research that rested on interviews with environmental activists, among them members of the Animal Liberation Front. One of his research subjects came under investigation in connection with a raid on a local campus, and Scarce was ordered to appear before a grand jury investigation. He refused to answer questions put to him, was found to be in contempt, and was jailed for more than five months.

Some evidence suggests that the institutional structure surrounding social research has proven an uncertain asset in personal resolution of ethical issues such as Scarce's. The 1997 ASA *Code of Ethics* advises sociologists confronting dilemmas regarding informed consent to seek advice and approval from institutional review boards or other "authoritative [bodies] with expertise in the ethics of research." But IRBs typically serve as reviewers of research plans rather than consultative bodies regarding issues encountered in execution of research; the phrase "authoritative [bodies] with expertise in the ethics of research" has a vague ring. Lee Clark's (1995) description of his search for guidance in responding to a law firm's request for his research notes illustrates the limitations of IRBs and related individuals and agencies:

. . . I talked with first amendment attorneys, who said academic researchers don't enjoy journalists' protections. . . . I was told that if I destroyed the documents, when there was reason to expect a subpoena, then I would be held in contempt of court. I talked with ASA officials and the chair of ASA's Ethics Committee, all

sympathetic but unable to promise money for an attorney. They were equally certain of my obligations according to the Ethics Code. . . . I talked with lawyers from Stony Brook [where Clark had performed his research], who told me that the institution would not help. Lawyers for Rutgers, where I was . . . employed, said they wouldn't help either.

In all human activity, individuals ultimately face ethical issues capable of resolution only through personal choice among alternatives. But increasingly, sociologists seem to face these choices unaided by distinct guidelines from their profession. This default to personal responsibility derives in part from the ambiguity in two philosophical principles widely encountered in sociological discourse, utilitarianism and moral relativism.

As an ethical principle, utilitarianism seems to provide a convenient rule of making decisions. The prevailing morality among modern cosmopolitans, utilitarianism applies the principle of the greatest net gain to society in deciding questions of research ethics. This perspective places emphasis on degrees of risk or magnitude of harm that might result from a given research effort. Under this perspective, Project Camelot (cited above) may have deserved a more favorable reception. Davison (1967) suggests that completion of the project would probably not have caused appreciable harm. He comments:

If past experience is any guide, it would have contributed to our knowledge about developing societies, it would have enriched the literature, but its effects on this country's international relations would probably have been tangential and indirect. (p. 399)

Several well-known and ethically controversial studies may be justified on utilitarian grounds. Among the best known is Laud Humphreys's study of impersonal sex in public places (1975). Humphreys gained access to the secret world of male homosexuals seeking contacts in public restrooms by volunteering his services as a lookout. Despite its obvious deception, Humphreys's work received the support of several homophile organizations (Warwick 1973, p. 57), in part because it illustrated the prevalence of sexual preferences widely considered abnormal. In his study of mental institutions, Rosenhan (1973) placed normal (i.e.,

nonpsychotic) observers in psychiatric wards without the knowledge or consent of most staff. His study generated highly useful information on the imperfections of care in these institutions, but the deception and manipulation of his subjects (hospital staff) are undeniable.

As a rule for making decisions, though, utilitarianism presents both practical and conceptual problems. Bok (1978) points out the difficulty in estimating risks of harm (as well as benefits) from any research activity. The subtle and uncertain impacts of sociological research techniques (as well as associated findings) make prospective assessment of utilitarian trade-offs extremely problematical. Many traditional ethical constructs, moreover, contradict utilitarianism, implying that acts must be assessed on the basis of accountability to abstract principles and values (e.g., religious ones) rather than the practical consequences of the acts themselves.

Moral relativism provides some direction to the uncertainty implicit in utilitarianism. This principle assumes that "there are no hard and fast rules about what is right and what is wrong in all settings and situations" (Leo 1995). Under this principle, ethical judgment applies to ends as well as means. Moral relativism might provide ethical justification for a sociologist who, believing that the public requires greater knowledge of clandestine police practices, misrepresents his personal beliefs or interests in order to observe these practices. The very relativism of this principal, however, invites controversy.

The 1997 ASA *Code of Ethics* restates the profession's fundamental ethic as striving to "contribute to the public good" and to "respect the rights, dignity, and worth of all people" (p. 4). Regarding research activity, the *Code* places primary emphasis on informed consent, protection of subjects from harm, confidentiality, and disclosure of conflicts of interests. But the *Code*, the institutional milieu of sociology, and the practical conditions under which sociological research takes place preclude strong direction for individuals in the ethical dilemmas they encounter.

ETHNIC CLEANSING

See Genocide.

ETHNICITY

Ethnicity is a salient feature of numerous societies throughout the world. Few societies are ethnically

homogeneous, even when they proclaim themselves to be. Consequently, ethnicity has been a preoccupation of sociologists since the early days of the discipline (although more so in the United States than elsewhere).

Yet there is not complete agreement on how the subject should be defined. In the past, it was common to highlight cultural difference as an essential feature of ethnic distinctiveness (see, e.g., van den Berghe 1967). Recently, this has lost favor on the grounds that cultural differences may vary from one setting to another and from one historical period to another. Following an approach attributed to Frederik Barth (1969), recent definitions have therefore focused on the existence of a recognized social boundary. But still among the most useful definitions is the classic one of Max Weber ([1922] 1968): An ethnic group is one whose members “entertain a subjective belief in their common descent because of similarities of physical type or of customs or both, or because of memories of colonization and migration” Weber adds insightfully, “It does not matter whether or not an objective blood relationship exists” (p. 389).

Despite definitional disagreements, there is general recognition that a number of characteristics appear as hallmarks of ethnicity; not all of them will be present in every case, but many will be. They include features shared by group members, such as the same or similar geographic origin, language, religion, foods, traditions, folklore, music, and residential patterns. Also typical are special political concerns, particularly with regard to a homeland; institutions (e.g., social clubs) to serve the group; and a consciousness of kind, or sense of distinctiveness from others (for the full listing, see Thernstrom et al. 1980, p. vi).

There is controversy over whether race should be viewed as a form of ethnicity. In this context, “race” should not be understood as a bundle of genetically determined traits that of themselves generate social differences—a view that has been repudiated by the vast majority of social scientists—but as a kind of social classification used by members of a society. Many scholars distinguish between ethnicity and race. For example, Pierre van den Berghe (1967) defines race as a social classification based on putative physical traits and ethnicity as a classification based on cultural ones

(see also Omi and Winant 1994). The contrast between the two can also be formulated in terms of volition vs. external constraint, with racial categories seen as more imposed by outsiders and ethnic ones as more claimed by the group members themselves (see, e.g., Waters 1990). But equally commonly, race is seen as a variant of ethnicity: A racial group is, then, an ethnic group whose members are believed, by others if not also by themselves, to be physiologically distinctive. This is the approach adopted in this article for several reasons. Not only do racial groups typically have the characteristics of ethnic groups (e.g., cultural distinctiveness), but many seemingly nonracial ethnic groups may also be believed to possess some distinctive physical features (e.g., the olive skin tone of Italians). The distinction between the two types of groups is therefore not hard and fast, a conclusion that is underscored by the historical transmutation of some racial groups into nonracial ones, for example, the Irish (Ignatiev 1995; Roediger 1991).

Sociologists recognize that the imprint of history on the contemporary ethnic relations of any society is deep, and this gives rise to another distinction that is potentially central to any discussion of ethnicity. It pertains to the mode of entry of a group into a society, and it has been formulated by Stanley Lieberson (1961; see also Blauner 1972) in terms of the situation that obtains just after contact between an indigenous group and one migrating into an area. One possibility is that the migrant group dominates, typically through conquest (often aided by the introduction of new diseases)—this is exemplified in the contacts between indigenes and European settlers in Australia and the United States. The other is that the indigenous group dominates, as occurred during the century of mass immigration (1830–1930) to the United States. The crux of the matter here is whether a group is incorporated into a society through force or through more or less voluntary migration. Lieberson argues that a group’s mode of entry is fateful for its trajectory of development in a society, and this is amply borne out in the literature on ethnicity.

Stated in very broad terms, three approaches have dominated the sociological study of ethnicity; a fourth and much newer one appears to hold the promise of eventual parity with them. Of the older

approaches, one, the *assimilation* perspective, focuses on social processes and outcomes that tend to dissolve ethnic distinctions, leading to the assimilation of one ethnic group by another or by the larger society. The second approach could be labeled as *stratification*. As the name implies, it addresses the origins and consequences of inequalities of various kinds among ethnic groups. The third approach focuses on *ethnic-group resources*, and encompasses processes, such as mobilization and solidarity, by which the members of ethnic groups attempt to use their ethnicity to compete successfully with others. The newest approach is a *social constructionist* one. It stems from the recognition that ethnic boundaries are malleable and is concerned with the ways by which such boundaries are created, maintained, and transformed.

No one of these approaches could be described as preeminent; each is a major presence in contemporary research on ethnicity and has shown that it has something to contribute. Other approaches are possible but are not as theoretically and empirically developed as these four. One other approach seeks a basis for ethnicity in sociobiology, viewing it as a form of genetic nepotism, a generalization of the universal tendency among animals to favor kin. van den Berghe (1981) has been an exponent of such an approach, but as yet no body of evidence has been developed to distinguish it from more sociological approaches; other sociologists have not followed his lead. Ethnicity has also been viewed as “primordial,” deriving from deeply seated human impulses and needs that are not eradicated by modernization (Isaacs 1975). But this viewpoint has not led to sociologically interesting research, and it has lacked exponents in recent decades. Another attempt, stemming from “rational choice theory” (Banton 1983; Hechter 1987), seeks to explain ethnic phenomena in terms of the efforts of individuals to maximize their advantages (or, in technical language, utilities). Research using rational choice theory is still too immature to draw up a meaningful balance sheet on it.

The assimilation approach has deep roots in classical social theory as well as in American sociology, where it is often traced to Robert E. Park’s 1926 formulation of a race relations cycle of “contacts, competition, accommodation, and eventual assimilation” (quoted from Park 1950, p. 150; cf. Lal 1990). The canonical statement of the assimilation approach is by Milton Gordon (1964; for an

updated revision, see Alba and Nee 1997). Although Gordon was addressing the role of ethnicity in the United States, his formulation is so general that it can be readily applied to other societies. At the heart of his contribution is the recognition that assimilation is a multidimensional concept. He distinguished, in fact, among seven types of assimilation, but the critical distinction lies between two of them: acculturation and structural (or social) assimilation. *Acculturation* means the adaptation by an ethnic group of the cultural patterns of the dominant, or majority, group. Such acculturation encompasses not only external cultural traits, such as dress and language, but also internal ones, such as beliefs and values. Gordon (1964) theorized that acculturation is typically the first of the types of assimilation to occur and that the stage of “acculturation only” may continue indefinitely” (p. 77)—hence the importance of the second assimilation type, structural assimilation. *Structural assimilation* is defined by Gordon to mean the entry of an ethnic group’s members into close, or primary, relationships with members of the dominant group (or, at least, with ethnic outsiders). The cardinal hypothesis in Gordon’s (1964) scheme is that structural assimilation is the key that unlocks all other types: “Once structural assimilation has occurred . . . all of the other types of assimilation will naturally follow” (Gordon 1964, p. 81). Once structural assimilation occurs, the way is open to widespread intermarriage, an abating of prejudice and discrimination, and the full participation of ethnic-group members in the life of a society.

Gordon discussed certain models, or theories, of the assimilation process (they might also be described as ideologies because of their value-laden character). Although these were, again, developed for the U.S. context, Gordon’s discussion is so lucid that the models have passed into more general application. One is labeled as “Anglo-conformity” by Gordon, and it describes an assimilation that is limited to acculturation to the behavior and values of the core ethnic group, taken to be Protestants with ancestry from the British Isles in the American context. A second model is that of the “melting pot.” It envisions an assimilation process that operates on cultural and structural planes. One outcome is a culture that contains contributions from numerous ethnic

groups and is adopted by their members. A parallel outcome on a structural plane is a pattern of widespread marriage across ethnic lines, in which the members of all ethnic groups participate and which leads ultimately to population made up of individuals of quite intermixed ancestry. The melting-pot idea corresponds with some popular notions about U.S. society, but so does the last model explicated by Gordon—namely, “cultural pluralism.” Cultural pluralism corresponds with a situation in which ethnic groups remain socially differentiated, often with their own institutions and high rates of in-group marriage, and retain some culturally distinctive features. It is, in fact, an apt description of many societies throughout the world.

Urban ecology, dating back to the origins of the Chicago School of American sociology, is quite compatible with the assimilation approach. A core tenet of this tradition is that the spatial separation of one group from another mirrors the social distance between them and changes as this does. This ultimately implies a model of *spatial assimilation* (Massey 1985), according to which residential mobility follows from the acculturation and socioeconomic mobility of ethnic-group members and is often an intermediate step on the way to more complete—that is, structural—assimilation. The model envisions an early stage of residential segregation, as the members of ethnic groups—typically, immigrants and their children—are concentrated in urban enclaves, which frequently results in the displacement of other groups. But as the members of an ethnic group acculturate and establish themselves in the labor markets of the host society, they attempt to leave behind less successful co-ethnics and to convert socioeconomic and assimilation progress into residential gain by “purchasing” residence in places with greater advantages and amenities. This process implies, on the one hand, a tendency toward dispersion of an ethnic group, opening the way for increased contact with members of the ethnic majority, and, on the other hand, greater resemblance in terms of residential characteristics between successful ethnic-group members and their peers from the majority group.

The assimilation perspective has been successfully applied to American ethnic groups derived from European immigration. In a review of the evidence, Charles Hirschman (1983) documents the abating of ethnic differences in the white

population in terms of socioeconomic achievement, residential location, and intermarriage. To cite some representative research findings, Stanley Lieberson and Mary Waters (1988), comparing the occupations of men of European ancestry in 1900 and 1980, find a marked decline in occupational concentrations, although these still show traces of the patterns of the past. These authors and Richard Alba (1990) also demonstrate the great extent to which interethnic marriage now takes place within the white population: Three of every four marriages in this group involve some degree of ethnic boundary crossing. The assimilation perspective as applied to European Americans has not been without its critics; Andrew Greeley (1971) has done the most to assemble evidence of persisting ethnic differences.

There can be no doubt that African Americans do not exemplify the patterns expected under the assimilation perspective (e.g., Massey and Denton 1993). A question that now motivates much debate and research is the degree to which the assimilation patterns will be found among contemporary immigrants and their descendants (see Alba and Nee 1997; Portes and Rumbaut 1996). It is too early to answer the question, but reflecting on the potential differences between past and contemporary immigrations, Portes and Zhou (1993) have added a new concept to the ethnicity arsenal—namely, *segmented assimilation*, which acknowledges that the strata of American society into which individuals assimilate may vary considerably. In their view, the children of dark-skinned, working-class immigrants who grow up in the inner city are at great risk of assimilating into the indigenous lower class and thus experiencing assimilation with little or no upward mobility.

Much of the evidence on assimilation and ethnic change is derived from cross-sectional studies rather than those done over time; the latter are difficult to conduct because of the limited availability of comparable data from different time points. Cross-sectional analyses involve some dissection of an ethnic group into parts expected to display a trajectory of change. One basis for such a dissection is generational groups. *Generation* here refers to distance in descent from the point of entry into a society. (By convention, generations are numbered with immigrants as the “first,” so that their children are the “second,” their grandchildren are

the “third,” etc.) Generally speaking, later generations are expected to be more assimilated than earlier ones. Another basis for dissection is *birth cohorts*, defined as groups born during the same period. Cohort differences can provide insight into historical changes in a group’s position. Both kinds of differences have been used to study ethnic changes in the United States (for an application of the generational method, see Neidert and Farley 1985; for the cohort method, see Alba 1988).

The second major approach to the study of ethnicity and race, labeled above as “stratification,” is considerably less unified than the assimilation approach, encompassing quite diverse theoretical underpinnings and research findings. Yet there are some common threads throughout. One is an assumption that ethnic groups generally are hierarchically ordered: There is typically a dominant, or *superordinate*, group, which is often described as the *majority* group (even though in some societies, such as South Africa, it may be a numerical minority of the population). There are also *subordinate* groups, often called *minorities* (although they may be numerical majorities). Second, these groups are assumed to be in conflict over scarce resources, which may relate to power, favorable occupational position, educational opportunity, and so forth. In this conflict, the dominant group employs a variety of strategies to defend or enhance its position, while minority groups seek to challenge it. Often, the focus of the stratification approach is on the mechanisms that help preserve ethnic inequalities, although there has also been some attention to the means that enable minorities successfully to challenge entrenched inequality.

One tradition in ethnic stratification research has looked to mechanisms of inequality that are rooted in ideologies and outlooks that are then manifested in the behavior of individuals. This is, in fact, a common meaning for the word *racism*. A longstanding research concern has been with *prejudice*, which is generally defined as a fixed set of opinions, attitudes, and feelings, usually unfavorable, about the members of a group (Allport 1954). Prejudice is frequently an outgrowth of *ethnocentrism*, the tendency to value positively one’s own group and denigrate others. It can lead to *discrimination*, which is a behavior: the denial of equal treatment to a group’s members, exemplified by the refusal to sell homes in certain neighborhoods to minority-group members. The investigation of

prejudice was one of the early testing grounds for survey research. In the United States, this research uncovered a dimension of *social distance*, expressing the specific gradations of social intimacy the majority is willing to tolerate with the members of various ethnic groups (Bogardus 1928). Recent research has revealed a paradoxical set of changes: on the one hand, a secular decline in traditional prejudice, most notably the prejudiced attitudes and beliefs held by whites about blacks; on the other, little increase in support for government policies that implement principles of racial equality (Schuman et al. 1998). This divergence has led many scholars to theorize about the emergence of modern forms of prejudice, exemplified by the concept of *symbolic racism* (Kinder and Sears 1981).

However persuasive as explanatory factors prejudice and discrimination may appear to the layperson, sociologists have in recent decades more and more neglected them in favor of *institutional*, or *structural*, mechanisms of inequality (see, e.g., Bonilla-Silva 1997). One reason for this shift has been skepticism that prejudice and individual-level discrimination by themselves are adequate to account for the depth and durability of racial and ethnic cleavages in industrial societies, especially since these purported explanatory factors have seemed to decline in tandem with rising educational levels. (However, the emphasis on structural mechanisms can itself be faulted for neglecting the ideological component in racism.)

One expression of the focus on structural factors has been the notion of *institutional racism* (Blauner 1972). According to it, inequality among racial and ethnic groups depends not so much on individual acts of discrimination as it does on the workings of such institutions as the schools and the police, which process and sort individuals according to their racial and ethnic origins and ultimately impose very different outcomes on them. An assumption of this approach is that this sort of discrimination can occur on a wide scale without equally widespread prejudice. Indeed, it may even be possible without any discriminatory intent on the part of individuals in authority; an example would be educational tracking systems, which sort students according to racial background based on culturally and socially biased cues that are presumed by teachers and administrators to be related to intellectual ability. Studies deriving from the notion of institutional racism have in fact provided

some compelling analyses of the perpetuation of inequalities (on education, see Persell 1977), although they also can easily descend into controversy, as when any unequal outcome is declared to indicate the operation of racism.

A crucial arena in which both institutional and individual forms of racism operate to produce inequality is that of residence. Residential segregation is probably the most prominent indicator of the persisting importance of race in the United States; and it is critical to many other inequalities because life chances, especially for children, vary sharply across neighborhoods, which differ in many ways, from the qualities of the housing and schools they contain to the risks that their residents will be victims of crime. Decades of research with highly refined data and measures, such as the well-known Index of Dissimilarity, have shown that levels of neighborhood segregation by race are quite high and, at best, moderating very slowly (Farley and Frey 1994; Massey and Denton 1993). The pattern in many American cities can be described as one of *hypersegregation*, in the sense that the overwhelming majority of African Americans reside in large, consolidated ghettos containing virtually no whites and few members of other groups (Massey and Denton 1993). Residential segregation is not much explained by the economic inequalities between whites and blacks. So-called audit studies, involving matched pairs of white and black housing applicants, reveal considerable outright discrimination in the housing market. While whites are now more willing than in the past to accept blacks as neighbors, it appears that their tolerance is usually limited to small numbers. Contemporary segregation is also the consequence of government policies, past and present. The policies of the Federal Housing Administration, which effectively led in the 1930s to the modern mortgage instrument but were biased against mortgage lending in areas with many black residents, have had an enduring impact of American residential patterns, reflected in the division between largely white suburbs and largely nonwhite cities. (For a thorough discussion of the mechanisms behind segregation, see Massey and Denton 1993.)

A major theme in the stratification approach is the often complicated relationship, or interaction, between ethnicity and social class. One viewpoint is that ethnicity is, to some degree at least, a

manifestation of deeply rooted class dynamics. This has led to analyses that emphasize the economic and material foundations of what appear superficially to be cultural and ethnic distinctions. Analyses of this type have sometimes been inspired by Marxism, but they are hardly limited to Marxists. For example, Herbert Gans ([1962] 1982), in an influential analysis of second-generation Italians in a Boston neighborhood, argued that many of their distinctive traits could be understood as a function of their working-class position, which was not greatly changed from the situation of their southern Italian ancestors. In a related vein, Stephen Steinberg (1989) argues that cultural explanations of ethnic inequalities, which impute “undesirable” characteristics to some groups and “desirable” ones to others, are often rationalizations of economic privilege.

It is sometimes argued that inequalities that once rested on an ethnic basis now rest primarily on one of class. An important, if controversial, instance is William J. Wilson’s (1978, 1987) claim of a “declining significance of race” for American blacks. One part of Wilson’s argument focuses on an increasing socioeconomic division within the black population. This is held to result from the increasing opportunities available to young, well-educated African Americans since the 1960s. However, while improvements have been registered for a minority of the group, the lot of the black poor has not improved—it has even worsened. Wilson describes their situation as one of an *underclass*, which he defines in terms of isolation from the mainstream economy and society. His explanations for the emergence of the underclass are structural, not individualistic, and include the spatial concentration of the black poor in run-down urban neighborhoods, which have been stripped of their institutional fabric and middle-class residents, and the exodus of suitable job opportunities from central cities to suburbs and Sunbelt areas. In opposition to Wilson, others have argued that the emergence of underclass ghettos is better understood as a consequence of racism, as exemplified in residential segregation (e.g., Massey and Denton 1993).

An economic approach has also been used to explain ethnic conflict, which is seen as an outgrowth of the conflicting material interests of different ethnic groups. An exemplar is provided

by the theory of the ethnically *split labor market* (Bonacich 1972). Such a labor market develops when two ethnically different groups of workers compete (or could compete) for the same jobs at *different costs to employers*. It is typical in such situations for the higher-priced group of workers to have the same ethnic origins as employers, and therefore for the lower-priced group to be ethnically different from both. Nevertheless, it is in the interest of employers to substitute lower-priced workers for higher-priced ones wherever possible, despite the ethnic ties they share with the latter. Intense ethnic conflict can therefore develop between the two groups of workers, as the higher-priced group seeks to eliminate the threat to its interests. Two strategies may be employed: exclusion of the lower-priced group (for example, through legal restrictions on the immigration of its members) or creation of a caste system, that is, the limitation of the lower-priced group to a separate sphere of undesirable jobs. Split-labor-market theory has been applied to black–white relations in South Africa and the United States.

Yet, even in terms of a strictly economic approach, the precise genesis of the conflict between different ethnic groups of workers is open to question, and the theory of *segmented labor markets* draws another picture (Piore 1979). This theory divides the economies and labor markets of advanced capitalist societies into a primary sector, which contains relatively secure, well-paid jobs with decent working conditions and the opportunity for advancement, and a secondary sector, made up of insecure, dead-end jobs at low wages. Regardless of their class position, workers from the dominant group prefer to avoid jobs in the secondary sector, and usually they can manage to do so. Even unemployment may not be sufficient to force them into the secondary sector, since the benefits and resources available to most members of the dominant group, such as relatively generous unemployment compensation and seniority rights, enable them to wait out periodic unemployment. Hence, there is a need for another supply of workers, typically drawn from minorities and immigrants, who have no alternative but to accept employment in the secondary sector. Immigrants, in fact, are often willing to take these jobs because, as sojourners, they find the social stigma attached to the work to be less meaningful than do the

native-born. In contrast to the theory of the split labor market, which takes the existence of an ethnic difference among workers as a given, segmented-labor-market theory can explain why ethnic differences, especially between natives and immigrants, are so prevalent and persistent in the industrial societies of the West.

An economic explanation of ethnic differences is sometimes placed in a context of worldwide colonialism and capitalist exploitation (Rex 1981). Indeed, ethnic inequalities within a society are sometimes seen as the consequence of international relations between colonizers and the colonized. The notion that subordinate groups form economically exploited *internal colonies* in Western societies is an expression of this view (Blauner 1972). This notion is compatible with a hypothesis of a *cultural division of labor*, according to which positions in the socioeconomic order are assigned on the basis of cultural markers and hence ethnic origin (Hechter 1975).

The stratification approach need not focus exclusively on socioeconomic differences. Some scholars, in fact, prefer to see inequalities of power as more fundamental (Horowitz 1985; Stone 1985). This is a very general perspective on ethnic stratification, which is quite compatible with such fundamental notions as dominant and subordinate groups. According to it, social-class relations are but one instance, no matter how important, of the institutionalized inequalities between ethnic groups. Equally important, ethnic dominance cannot be reduced to, or explained solely in terms of, social-class mechanisms. (An implication is that class analysis of ethnic relations can be reductionist, an attempt to explain away ethnicity's causal independence.) Thus, the antagonism and sectarian violence between Catholics and Protestants in Northern Ireland is not comprehensible solely in terms of a social-class analysis, even though aggregate class differences between the groups exist as a result of centuries-long Protestant domination. This domination, the legacy of the colonial treatment of Ireland by the British, is manifest in a number of areas—in separate residential neighborhoods and schools, in social relations between members of the two groups, and in the political system. In short, domination encompasses much more than social-class privilege and gives even

working-class members of the Protestant group a sense of status and superiority.

Distinguishing empirically between ethnic stratification based on power and that rooted in economic structure has proven difficult. In one attempt, Hubert Blalock (1967) formulated a *power threat hypothesis*, to be contrasted with one derived from economic competition between groups. These two hypotheses can be tested in the relationship between discrimination and the size of a minority group. In particular, threats to the power of the dominant group are expected to result in discrimination that rises sharply with increases in the size of a minority; the same is not true for economic competition. So far, this test has been applied mainly to the American South (Tolnay and Beck 1995).

Theories concerning power differentials among ethnic groups border on the third major approach to the study of ethnicity, with its focus on ethnic-group resources. This approach, like the preceding one, takes its point of departure from the inequalities among groups. However, its vision is less one of the domination of some groups over others than it is of a more balanced competition that is affected by characteristics of the groups, such as their numbers, their solidarity, and their ability to form separate ethnic subeconomies. Such characteristics can give the group and its members relative advantages, or disadvantages, in this competition. Insofar as advantages are conferred, there may incentives for individuals to maintain their attachments to a group rather than assimilate. In a sense, theories of ethnic-group resources can be seen as counterarguments to assimilation theories.

This is certainly clear in Nathan Glazer and Daniel Patrick Moynihan's ([1963] 1970) politically based explanation for the continuing importance of ethnicity in the United States. These authors acknowledge that immigrant cultures fade quickly under the impact of the assimilation process; assimilation is accomplished to this degree. However, ethnicity comes to coincide with differences in American circumstances, such as residential and occupational concentrations, which are similarly affected by government policies and actions. Hence, ethnicity takes on importance in the political sphere: Ethnic groups become "interest groups," reflecting the interests of many similarly

situated individuals. This role breathes new life into what might otherwise languish as an Old World social form. Glazer and Moynihan give many examples of the working of such interest groups in New York City.

Others have argued that ethnicity has become "politicized" in many contemporary societies, including many industrialized ones, and this leads to an unanticipated ethnic "resurgence." Daniel Bell (1975) states one basis for this point of view, claiming that politics is increasingly replacing the market as the chief instrument of distribution and that politics recognizes only group claims, thus enhancing ethnicity's political import. (The direction of change seems to have shifted since then, however.) In a more general fashion, Francois Nielsen (1985) contends that ethnicity offers a wider basis for political recruitment than the chief alternative, social class, and therefore ethnic-based movements have a greater chance for success. Addressing the situation in Third World societies, Donald Horowitz (1985) sees the ethnic political conflict that troubles many of them as originating in part in colonial policies and then being intensified by the anxieties of groups over their status in the postcolonial order.

Students of ethnic politicization have focused especially on the phenomenon of ethnic mobilization, which is epitomized in separatist movements in modern states, as in the Congo, Quebec, and Tibet (Olzak 1983). Mobilization can be regarded as one manifestation of the state of ethnic solidarity, a core concept in the literature on ethnicity. Ethnic groups marked by *solidarity* can be defined as self-conscious communities whose members interact with each other to achieve common purposes, and *mobilization* occurs when members take some collective action to advance these purposes. Recent research on ethnic movements appears to demonstrate that they are not generally interpretable in modern polities as the vestiges of traditional loyalties that have yet to be submerged by the modernization processes attendant upon development; rather, such movements can be outcomes of these processes and thus increase as economic development proceeds. The specific causes of this linkage are disputed, however (Olzak 1983).

Culture is another domain in which the search for group resources has been carried out. The

group-resources approach is compatible with the cultural-pluralist description of society, described earlier. More commonly in the past than today, the relative success of ethnic groups has been explained in terms of cultural traits. Quite often, the advantages these give have been analyzed in social-psychological terms. A well-known attempt along these lines was that of Bernard Rosen (1959), who matched American ethnic groups against the profile of the "achievement syndrome," a configuration of values that was presumed to predispose individuals to success. Included was an orientation to the future rather than the past and a downplaying of fatalism. In Rosen's analysis, the presence or absence of these traits in the culture of a group was explained according to the group's history and experience, and frequently in terms of the culture of the society from which it came. This sort of analysis, presuming stable cultural traits and rooting socioeconomic success in social-psychological prerequisites, has fallen into disfavor of late. In fact, it is often seen more as popular myth than as social science (Steinberg 1989). Cultural explanations, however, are not limited to the social-psychological realm. As one example, Ivan Light (1972) has devised an intriguing partial explanation for the entrepreneurial proclivities of different groups—in terms of the extent to which their cultures sponsor mechanisms that generate capital for the start-up of small businesses. Light argues that the business success of some Asian groups can be understood in part as an outcome of the rotating-credit association, a traditional social form imported from their home societies. Nevertheless, sociologists recently have stressed the malleability of culture and have tended to view it more as an adaptation to, and hence outcome of, socioeconomic position than as a cause of it. Consequently, cultural interpretations currently play only a minor role in the study of ethnicity. This may be a neglect engendered by cyclical intellectual fashion—in the future, they may loom larger, especially in the analysis of the immigrant groups proliferating in many societies (see, e.g., Zhou and Bankston 1998).

A focus of intense interest in recent years has been on the economic resources some groups are able to attain and thus on the advantages and opportunities adhering to ethnicity for their members. This interest is expressed in somewhat divergent research streams, running along distinctive

conceptual channels. One has been carved out around the linkage that appears in many societies between minority-group status and entrepreneurial activity. This linkage makes sense in terms of the disadvantages borne by many minority groups in mainstream economies, where they may suffer from various forms of discrimination and be channeled into low-status positions. Entrepreneurial activity, then, represents an attempt to evade these economic disadvantages. But, as many observers have pointed out, this hypothesis alone cannot account for the wide variation in entrepreneurial levels and forms among groups (Light 1984). An early attempt at a general theory is that of middleman minorities, which begins from the observation that a few groups, such as the Chinese and Jews, have occupied entrepreneurial niches in numerous societies (Bonacich 1973). The theory views entrepreneurialism, especially in commercial forms, as consistent with the sojourner status and interstitial position of these groups, between elites and masses. Yet this theory is too specific to account for contemporary immigrant entrepreneurialism, which frequently, for instance, involves nonsojourner groups. Therefore, Ivan Light (1984) has turned toward broader conceptual accounting schemes, seeing a range of ethnic and class resources as behind entrepreneurialism. Very intriguing here is the notion of ethnic resources, which include the established ethnic networks that train newly arrived immigrants and set them up in business. This notion helps to account for the clustering that is so obvious in ethnic small business, such as the concentration of New York's Koreans in greengroceries and dry cleaning.

A second stream of research builds partly on the immigrant proclivity toward entrepreneurialism. The theory of the ethnic enclave, developed by Alejandro Portes and various collaborators, holds that some groups are able to form ethnic subeconomies, which shelter not only entrepreneurs but also workers from the disadvantages they would face in the secondary sectors of the mainstream economy (Portes and Bach 1985). Enclave theory is particularly interesting because it provides a material motive for resisting assimilation. As exemplified in the case of the Cubans of Miami, enclave-forming groups typically contain a high-status stratum composed of individuals with professional occupations, capital, or both, along

with lower-status strata of workers seeking employment. A key to a full-fledged enclave is the establishment of networks of firms in interrelated economic sectors. The success of these firms is predicated on ethnic loyalties to an important degree. Workers and bosses may find mutual advantage where they share the same ethnicity. Workers may be willing to work longer hours or for lower wages, thus enhancing the profitability of a business, because they are able to work in a culturally familiar environment (usually speaking their mother tongue, for example). Workers may also have the opportunity to learn about running a business, and some eventually graduate to become entrepreneurs themselves. Enclave economies may be sustained in part by servicing the needs of their own ethnic communities, but if they are to be truly robust, they must also plug into the mainstream economy. This is the case, for instance, with the many ethnic firms in the American garment industry.

Despite its attractiveness on theoretical grounds, the implications of the enclave economy are disputed. One criticism is that such an economy offers few benefits for workers; the economic gains accrue to ethnic entrepreneurs (Sanders and Nee 1987). In addition, there is growing recognition that fully formed enclave economies are uncommon (Logan et al. 1994). These problems have led investigators to reinvigorate a broader notion, that of the *ethnic niche*, which refers to any economic position where a group is sufficiently concentrated to draw advantage from it, typically by being able to steer its own members into openings (Model 1997; Waldinger 1996). Thus, one can speak of an entrepreneurial niche, such as the Koreans have established in various lines of small business, or of an occupational niche, exemplified by the former dominance of the Irish in municipal employment in numerous cities. The ethnic-niche idea implicates other notions, such as the operation of ethnic networks that assist group members in finding positions in a niche. The niche idea is also frequently linked to that of an ethnic queue, an hierarchical ordering among minority groups, and to demographic and socioeconomic shifts. The latter open up niches, as exemplified by the withdrawal of white ethnics from some lines of small business in American cities, and the former determine which other groups are best positioned to take advantage of the openings (Waldinger 1996).

Oddly, a relatively neglected dimension of the ethnic-resources perspective concerns ethnic communities themselves, despite an almost universal recognition among scholars that some ethnics prefer to live in communities where their fellow ethnics are a numerous, if not the predominant, element of the population. Ethnic neighborhoods continue to be a salient aspect of metropolitan life in the United States and connected to inequalities that affect the well-being and life chances of their residents; and now they are emerging on a substantial scale in suburban settings (Horton 1995). A longstanding idea is that the residents of "institutionally complete" communities are less likely to assimilate (Breton 1964). Given the burgeoning of immigrant communities in the United States and elsewhere, it seems certain that this scholarly neglect will soon be repaired.

The final orientation, the social constructionist one, is so new that it cannot yet be said to have accumulated a substantial corpus of findings (for general reviews, see Nagel 1994; Omi and Winant 1996). This is not to deny its roots in the classical conception of ethnicity, as exemplified by the Weberian definition cited earlier, with its emphasis on the subjective view and, implicitly, on the relation of ethnic boundaries to social closure. As its name implies, this perspective stresses that ethnic boundaries and meanings are not preordained but malleable and thus that an understanding of ethnic distinctions must generally be sought in contemporary, rather than historical, circumstances. This perspective is especially attuned to the possible emergence of new forms of ethnicity, as some see, for instance, in the cultural hybridity associated with the rising frequency of mixed racial ancestry in the United States. There is also an emphasis on heightened ethnic fluidity, even the potential for revolutionary shifts, in the present because of the rise of the global economy and associated phenomena, such as large-scale migrations across borders, cultural diffusions, and transnational networks (Sassen 1988).

The most striking findings to emerge from this perspective concern historical shifts in racial boundaries, confounding the lay view that racial distinctions are determined by impossible-to-overlook physical differences among humans. Yet, historically, such boundaries have shifted in the United States within relatively brief intervals. During their immigrations, Irish Catholics, Italians, and

Eastern European Jews were all perceived as racially different from native-born whites, as nineteenth-century cartoon depictions of the Irish demonstrate. Today, the racial element in the perception of ethnic differences among whites has disappeared. The limited historical studies have not yet fully explicated the decades-long process by which this happened but make clear that it was not benign, as immigrants used violence and stereotyping, among other means, to create social distance between themselves and African Americans and thereby make plausible their candidacy for “whiteness” (see Ignatiev 1995; Roediger 1991). Then, their acceptability to other white Americans grew as they climbed the social ladder and mixed occupationally and residentially with other whites.

In conclusion, one must acknowledge that the literature on ethnicity remains unsettled in its theoretical core. The persistence—perhaps even the resurgence—of ethnic difference and conflict in societies throughout the world has attracted much attention from sociologists and other social scientists. But the paradoxes associated with ethnicity, evidenced in the United States by the assimilation of some groups and the continued separateness and even subordination of others, have yet to be resolved. They remain fruitful for sociology, nevertheless: The study of ethnicity has produced some of the discipline’s most striking findings and, no doubt, will continue to do so.

ETHNOCENTRISM

See Ethnicity; Nationalism.

ETHNOGRAPHY

Ethnographic research (also referred to as *field research* or *participant observation*) is a qualitative social science method that involves the observation of the interactions of everyday life, whether in public parks, business organizations, or mental health clinics. It is social constructionist, exploring intersubjective cultural meanings rather than positivist “social facts,” or laws. The theoretical intent of ethnography is inductive, generating concepts and theories from the data. However, in sociology, ethnography is also associated with micro-level theories such as symbolic interactionism, ethnomethodology, labeling theory, and dramaturgy. In particular, the theories of everyday life developed by Georg Simmel (1950) and Erving Goffman (1959) form part of the disciplinary repertoire from which workers in the field draw their concepts. Some field researchers also link their ethnography to critical, macro-theoretical frameworks emphasizing power relations within hierarchies of gender, class, race, age, nationality, or sexual orientation (Diamond, 1993).

The goal of field research is on the development of analytic descriptions or grounded theories (Glaser and Strauss, 1967) of the social world, usually written but sometimes audio- or videotaped. As Clifford Geertz (1988) notes, “thick description” is the foundation of ethnography.

But equally important is analysis: the generation of concepts, patterns, or typologies from thick description, and their linkage to concepts, theories, and literatures already established in the discipline. Although some academic fieldworkers may have other goals (such as helping the people in the setting), most seek to publish their ethnographic work as books or articles. There are also some field researchers who have turned to alternative forms of inscription, such as poems or plays, to try to bring to life the social worlds they study or (as in autoethnography) inhabit.

HISTORIES OF ETHNOGRAPHY

The contemporary origins of sociological ethnography are traced to the “Chicago School” of 1915–1940 (Bulmer 1984), and to nineteenth century sociological theory, reformist endeavors, and anthropological exploration. “Origin myths” seek the roots of ethnography in the writings of ancient and medieval travelers who sought first-hand knowledge of other cultures. Herodotus, for example, has been called the father of both history and sociology. In the fifth century B.C.E., Herodotus traveled to distant lands and recorded comments about the peoples and customs he found there; throughout the centuries into modern times, European, Persian, and Chinese explorers, traders, and missionaries followed suit. But it was in the nineteenth century, with the development of sociology as a discipline, that first-hand observation became part of the modern methodological repertoire.

Although the canonical work of the nineteenth century European theorists such as Karl Marx, Max Weber, and Émile Durkheim was macro-level and comparative-historical, the works are read for their ethnographic warrant. In particular, Weber’s concept of *verstehen*, read as an interpretive immersion into the subjective worlds of respondents, is cited as an epistemological foundation of contemporary ethnography. Feminist ethnographers of the late twentieth century have added the names of prominent nineteenth and early twentieth century women to the histories of field research, citing Harriett Martineau’s interest in the everyday lives of women and children, and Charlotte Perkins Gilman’s “autoethnographic” account of her moral treatment for neurasthenia (Bailey 1996).

Anglo-American reform movements also played a part in the development of nineteenth and early twentieth century observational methods. With an Enlightenment focus on reason and the scientific method, reform efforts came to be accompanied by observational studies of the problems seen as needing remediation, from conditions in mental hospitals to poverty in the streets of London or New York. The work of reformist scholars such as Beatrice Webb and Charles Booth in Victorian London among the poor involved the use of survey and field research methods. During the same era, Beatrix Potter took a position in a London sweatshop in order to document working conditions and attempt to change them (Bailey 1996).

British and American anthropology, following Bronislaw Malinowski's lead, instituted several of the key elements of field research: the time commitment, immersion in the geographical space of the respondents, the use of cultural insiders as key informants, and the inscription of observations and thoughts. Other aspects of ethnographic research are traced to the Chicago School, with its eclectic mix of pragmatist philosophy, symbolic interaction, journalistic interests, and reformist tendencies (Bulmer 1984; Becker 1999). Robert Park's injunction to his Chicago students has been taught to subsequent generations of ethnographers:

go and sit in the lounges of the luxury hotels and on the doorsteps of the flophouses; sit on the Gold Coast settees and on the slum shakedowns; sit in the Orchestra Hall and in the Star and Garter Burlesk. In short, gentlemen, go get the seat of your pants dirty in real research (Bulmer 1984; 97).

The Chicago School sociologists pioneered the case study method, which included oral histories, documents, statistical surveys, and some fieldwork. And it was from Chicago that the themes of 1950s to 1970s fieldwork emerged: the focus on studies of everyday life exemplified by the work of Goffman (1959), and on labeling and deviance by Howard Becker (1963) and others. The methods learned by contemporary sociological ethnographers are grounded in the Chicago, neo-Chicago (Fine 1995) and "California" schools (Adler and Adler 1987), while there has also been convergence with other disciplines practicing ethnography, such as anthropology, education, and business.

DOING ETHNOGRAPHIC RESEARCH

Introductory texts on ethnographic research (for example, Bailey 1996; Lofland and Lofland 1995) emphasize the nonlinear aspect of the method: the reflexive interplay of data collection, writing, and analysis. However, two distinct sets of activities are involved in doing ethnography: interacting within the "field" and inscription. Inscription occurs in the form of field notes (and perhaps diaries, memos, analytic notes, and other writings) and drafts of the ethnographic paper or monograph. Interaction within the field poses the usual everyday life issues of roles and relationships, together with more particular concerns such as human subjects regulations, research ethics, and entrée. Thus, the methodology of field research poses intertwined issues of representation and interaction.

Before initiating research in the field, the ethnographer selects a setting, and makes her preparations for attempting entrée. These preparations may be as simple as walking across the road to the local park, or as complex as negotiating with the governments of Cuba and the United States for permission to travel and stay in Havana. For many studies, especially funded team ethnography, it is necessary for the ethnographer to obtain permission to do the study from Institutional Review Boards (IRBs) at her University, and perhaps at the organization she wishes to study, for example, a prison or mental hospital. These Institutional Review Boards ensure that the fieldworker's plans are in compliance with the basic tenets of human subjects protections: informed consent (which is often not possible in non-interview based field research) and protection of confidentiality (in practice, not naming respondents, nor providing identifying details in published work).

All fieldwork in public places, and some fieldwork in other places, is exempt from IRB scrutiny, but no fieldwork is exempt from ethical considerations. Ethical issues that have preoccupied ethnographers for several decades are those associated with the deception of respondents. In covert fieldwork, where the ethnographer pretends to be a member of the setting (for example, Alcoholics Anonymous), the respondents are deceived about the researcher's identity and purposes. This level of deception is probably less common than it was up until the early 1980s. More common, however, is fieldwork in settings where the researcher

is already a member or participant, such as a bar where he is employed, or a bisexual or gay organization of which he is a member. In this type of “nonstranger” research, the fieldworker’s identity is known, but she may or may not share her new research purposes with the other members.

Entrée and Incorporation. In a setting where she is initially a stranger, the ethnographer must negotiate entrée into the setting. If this is a public park, she simply goes and sits on a park bench. If this is an organization, she will have already negotiated initial entrée with an administrative “gatekeeper,” and now must thread her way through the geographical and relational space of the setting, from the first to the last time she does fieldwork there. It is a truism of field research that entrée is not a one-time event: both physical and relational entrée must continually be negotiated and renegotiated throughout the field study. Initial setting gatekeepers may be followed by new gatekeepers of other parts of the setting, while “freeze outs” bar the door to some occasions or locales.

Once in the door, hoping to be allowed to stay and move about (and perhaps conduct formal or informal interviews), the researcher is incorporated into the setting: assigned a physical and conceptual space within the field by each individual respondent, and by groups of people within the setting. The language of incorporation, as against that of role playing, highlights the reciprocal nature of the interaction between the respondents and the ethnographer, in which the researcher cannot just “decide” what kind of role to play, but, rather, is assigned a place by the people in the setting. The ethnographer’s personal and status characteristics—gender, age, nationality, appearance—are an important aspect of incorporation, and determine the place that will be afforded him within the setting. These characteristics may, indeed, preclude or smooth access to particular persons, events, or parts of the field. Much has been written about gender and ethnography (Warren and Hackney 2000, since gender and sexuality are focal elements of hierarchy, interactions, and relationships within many settings).

Incorporation is a powerful emotional force field for many ethnographers, drawing them into the web of relationships in the field. Old hands at fieldwork warn of the necessity—if an analytic

description is to be written—of balancing immersion with distance, touching cognitive and emotional base with both disciplinary concepts and out-of-setting roles in order to avoid engulfment in the field (Pollner and Emerson 1988). Researchers who begin as members of the setting they are studying sometimes report the opposite, becoming more detached as they move from immersed membership to analytic observer: the field, once warmly familiar, can become a place of distance and even alienation.

In the classic language of the “research bargain,” ethnographers may find that they are approached and sometimes used as economic, medical, status, labor, or even sexual resources in the organizations or communities where they conduct their fieldwork. Fieldwork “warnings and advice,” although they avoid the positivist language of bias, note that such research bargains may take a toll on researchers in the form of time, emotions or funds. And at times, the incorporation of the ethnographer into the setting makes leaving the field emotionally difficult, although practically necessary. Some ethnographers, anthropologists in particular, revisit “their” fields at intervals of years or months in order to document change over time. But, once out of the field, the researcher is faced with the disciplinary requisite of starting or finishing the ethnographic writing of the inscription already begun in the field.

Ethnographic Representation. The endpoint of fieldwork is ethnographic representation: an article or book about the field, published in a scholarly journal, or as a monograph or trade book. Two major publication outlets for sociological ethnographies are the *Journal of Contemporary Ethnography* and *Qualitative Sociology*; fieldworkers may also publish in general, specialty (for example, gerontology or education), or anthropology journals. Many published ethnographies are “realist tales” (Van Maanen 1988), written in the traditional style of the analytic description: “I am here and this is what is going on here.” Some are “confessional tales” which focus on the writer rather than on the respondents, while others experiment with alternative representational forms such as poetry or plays. There is also a well-established tradition of visual sociology which includes photography, film, video, and the internet together with more contemporary genres such as performance ethnography.

Written ethnographic representations begin with fieldnotes: the inscription of the field (Emerson et al. 1995). Fieldworkers are taught and exhorted to write down everything they can, including verbatim conversations, in the service of thick description. This exhortation approaches feasibility in bounded settings such as a self-help group meeting that occurs once a week for fifty minutes. It becomes more problematic when the ethnographer is faced with an entire village, or even perhaps a large urban area. In practice, fieldworkers often take note of, and inscribe, aspects of events and persons to which they habitually attend; for example, one person studying a restaurant takes note of spatial patterns, while another inscribes social types by appearance and clothing, and still another notes the interaction between servers and cooks.

The inscription of fieldnotes is vital to the traditional ethnographic enterprise, since the identification of analytic patterns is difficult without an adequate amount of field notes (what is “adequate” varying with the size and complexity of the field). Alongside fieldnotes (separated by parentheses, or on separate pieces of paper), fieldworkers write memos, diaries, and analytic notes which record their own feelings and thoughts, analytic ideas and possibilities, and sometimes events which they do not want recorded in their formal fieldnotes. Although most fieldnotes have no audience but the self, fieldnotes written for graduate seminars or funded team research may be read by instructors, supervisors, or co-workers. In inscribing the Other, fieldnotes also inscribe the self (Warren 2000).

POSTMODERN ETHNOGRAPHY AND BEYOND

Ethnography, like most corners of the social sciences, has been affected by postmodernism. As representations, both fieldnotes and published ethnographies are open to the postmodern critiques of social scientific representation, critiques which began in sociology with the work of Joseph Gusfield (1976) on the literary rhetoric of sociological writing. One result of this postmodern critique is the deconstruction of realist or traditional ethnography, which, in turn, has resulted in a withdrawal from the field (the Other) into the text or the self. This movement away from traditional fieldwork has given rise to an ironic reversal

of earlier exhortations to “get out of the armchairs and into the streets.” There is a joke in ethnographic circles today that goes something like this: Respondent to Ethnographer: “Well, enough about you. Why don’t we talk a bit about me?”

While the postmodern ethnography of the 1990s sometimes takes place in the armchair and away from the streets, dwelling upon the self rather than upon the Other, it is likely that the new century and millenium will see a renewed concern with the activities, as well as the representations, of ethnography. Those sociologists concerned with relations of power and hierarchy—of gender, race, class, and nation—are particularly concerned that a focus on textual discourse and polyvocality (attending equally to the voices of the ethnographer and those of all the respondents) does not erase the critical function of ethnographic research. Jaber Gubrium and James Holstein (1997) suggest that contemporary ethnographers attend to both the “what” (the field), and the “how” (the representations of fieldwork), becoming “self-consciously attentive to both the world researched and the researcher” (1997: 212). This is the reflexivity toward which our ethnographic practice strives at the beginning of the twenty-first century.

ETHNOMETHODOLOGY

Ethnomethodology is a field of sociology that studies the commonsense resources, procedures, and practices through which the members of a culture produce and recognize mutually intelligible objects, events, and courses of action. The field emerged in the late 1960s in reaction to a range of sociological perspectives, most prominently structural functionalism, which treated conduct as causally determined by social structural factors. In contrast, ethnomethodology stressed that social actions and social organization are produced by knowledgeable agents who guide their actions by the use of situated commonsense reasoning. Rather than treating the achievement of social organization as a given from which the analysis of social structure could proceed, ethnomethodological research was directed at the hidden social processes

underlying that achievement. The resulting research focus on the properties of commonsense knowledge and reasoning represents one strand of what has been termed the "cognitive revolution" in the social sciences. As a sociological perspective however, ethnomethodology deals with the socially shared and publicly accountable nature of commonsense reasoning rather than with psychological aspects of cognitive processes. Its primary research stance has been descriptive and naturalistic rather than explanatory or experimental.

BACKGROUND AND DEVELOPMENT

The basic outlook of ethnomethodology was developed by Harold Garfinkel (1967a) during a twenty-year period spanning graduate research at Harvard under the supervision of Talcott Parsons through an extensive number of empirical investigations at UCLA. Garfinkel's starting point was the vestigial treatment in the sociological analyses of the 1950s of how actors employ knowledge to understand and act in ordinary social contexts (Heritage 1984). With respect to the prevailing treatment of internalized norms as motivational "drivers" of behavior, Garfinkel noted that the achievement of goals requires actions based on knowledge of real circumstances and that where coordinated action is necessary, that knowledge must be socially shared. What is the character of this knowledge? How is it implemented and updated? By what means are shared and dynamically changing knowledge and understanding concerning actions and events sustained? Merely to raise these questions was to point to fundamental deficiencies in the theory of action.

In developing answers to these questions, Garfinkel drew on the theoretical writings of the phenomenological sociologist Alfred Schutz (Schutz 1962–1966). Schutz observed that each actor approaches the social world with a "stock of knowledge at hand" made up of commonsense constructs and categories that are primarily social in origin. The actor's grasp of the real world is achieved through the use of these constructs, which, Schutz stressed, are employed presuppositionally, dynamically, and in a taken-for-granted fashion. Schutz also observed that these constructs are held in typified form, that they are approximate and revisable, that actions are guided by a patchwork of "recipe knowledge," and that

intersubjective understanding between actors who employ these constructs is a constructive achievement that is sustained on a moment-to-moment basis. Ethnomethodology took shape from Garfinkel's efforts to develop these theoretical observations into a program of empirical research.

A major component of these efforts took the form of the famous "breaching experiments," which were inspired by the earlier "incongruity experiments" pioneered by Solomon Asch and Jerome Bruner. The breaching experiments employed a variety of techniques to engineer drastic departures from ordinary expectations and understandings about social behavior. By "making trouble" in ordinary social situations, Garfinkel was able to demonstrate the centrality of taken-for-granted background understandings and contextual knowledge in persons' shared recognition of social events and in their management of coordinated social action. He concluded that understanding actions and events involves a circular process of reasoning in which part and whole, foreground and background, are dynamically adjusted to one another. Following Karl Mannheim, he termed this process "the documentary method of interpretation." In this process, basic presuppositions and inferential procedures are employed to assemble linkages between an action or an event and aspects of its real worldly and normative context. The character of the action is thus grasped as a "gestalt contexture" (Gurwitsch 1966) that is inferentially and procedurally created through the interlacing of action and context. Here temporal aspects of actions and events assume a central significance (Garfinkel 1967a), not least because background and context have to be construed as dynamic in character. Within this analysis, presuppositions, tacit background knowledge, and contextual detail are the inescapable resources through which a grasp of events is achieved.

Garfinkel (1967a) also showed that the recognition, description, or coding of actions and events is an inherently approximate affair. The particulars of objects and events do not have a "one-to-one" fit with their less specific representations in descriptions or codings. The fitting process thus inevitably involves a range of approximating activities that Garfinkel terms "*ad hoc* practices" (Garfinkel 1967a). This finding is, of course, the inverse of his well-known observation that descriptions, actions, and so forth have *indexical* properties: Their sense

is elaborated and particularized by their contextual location. An important consequence of these observations is that shared understandings cannot be engendered by a "common culture" through a simple matching of shared words or concepts but rather can only be achieved constructively in a dynamic social process (Garfinkel 1967a). Similar conclusions apply to the social functioning of rules and norms.

In summary: Garfinkel's researches indicate that every aspect of shared understandings of the social world depends on a multiplicity of tacit *methods of reasoning*. These methods are procedural in character, they are socially shared, and they are ceaselessly used during every waking moment to recognize ordinary social objects and events. A shared social world, with its immense variegation of social objects and events, is jointly constructed and recognized through, and thus ultimately rests on, a shared base of procedures of practical reasoning that operationalize and particularize a body of inexact knowledge.

In addition to functioning as a base for understanding actions, these procedures also function as a resource for the production of actions. Actors tacitly draw on them so as to produce actions that will be *accountable*—that is, recognizable and describable—in context. Thus, shared methods of reasoning are publicly available on the surface of social life because the results of their application are inscribed in social action and interaction. As Garfinkel (1967a) put it: "The activities whereby members produce and manage the settings of organized everyday affairs are identical with members' procedures for making these settings *accountable*" (p. 1).

While the results of Garfinkel's experiments showed that the application of joint methods of reasoning is central to the production and understanding of social action, they also showed that the application of these methods is strongly "trusted" (Garfinkel 1963, 1967a). This "trust" has a normative background and is insisted upon through a powerful moral rhetoric. Those whose actions could not be interpreted by means of this reasoning were met with anger and demands that they explain themselves. Garfinkel's experiments thus showed the underlying *morality* of practical reasoning and that the procedural basis of action and understanding is a part—perhaps the deepest part—of

the moral order. Such a finding is consistent with the view that this procedural base is foundational to organized social life and that departures from it represent a primordial threat to the possibility of sociality itself.

CONTEMPORARY RESEARCH INITIATIVES

Garfinkel's writings have stimulated a wide range of commentary, theoretical reaction, and empirical initiatives. In what follows, only the latter will be described. Empirical research in ethnomethodology will be discussed under three headings: (1) social structures as normal environments, (2) the creation and maintenance of social worlds, and (3) studies of work. A fourth, and possibly the most conspicuous, initiative—conversation analysis—is discussed elsewhere in this Encyclopedia.

Social Structures as Normal Environments.

In his theoretical writings, Schutz (1962) argued that human consciousness is inherently typifying and that language is the central medium for the transmission of socially standardized typifications. In a number of his empirical studies, Garfinkel developed this idea in relation to social process, noting the ways in which commonsense reasoning is used—often within a moral idiom—to typify and normalize persons and events. A number of influential ethnomethodological studies have taken up this theme and focused on the ways in which participants may be actively or tacitly engaged in creating or reproducing a texture of normality in their everyday affairs.

Much of this work was focused in the fields of deviance and bureaucratic record keeping. This focus was far from accidental. In both fields, the participants are concerned with the administration of socially consequential categories and in both—with their indigenous preoccupation with classification and definition—normalizing processes were close to the surface of organizational life and were somewhat easier to track. Pioneering studies in this area included Sudnow's (1965) analysis of "normal crimes," in which he showed that California lawyers employed models of "typical" offenders and offences in plea-bargaining procedures that departed substantially from the provisions of the California criminal code. Zimmerman's (1969) work on record keeping in a public welfare agency showed that bureaucratic records employed

typifications of clients that could only be interpreted by reference to detailed background knowledge of the organization's procedures (see also Garfinkel 1967a, pp. 186–207). Wieder's (1974) work on a halfway house for paroled narcotics offenders showed that a "convict code" profoundly shaped how staff and inmates perceived events inside the institution—with disastrous consequences for its success.

Related works on deviance—by Cicourel (1968) on the policing of juveniles and by Atkinson (1978) on suicide—crystallized points of friction between ethnomethodology and more traditional approaches to the study of deviant behavior. Both studies examined the social processes underlying the classification of deviants. Each of them detailed a complex of commonsense considerations that enter into the determination of the nature of a deviant act and (in the case of juvenile offenders) the treatment of its perpetrator.

Cicourel's study showed that police treatment of juveniles was informed by a lay theory that posited a connection between juvenile offenses and the home background of the offender. Offenses by juveniles from "broken homes" were treated more seriously than offenses by those from other social backgrounds. In consequence, offenses by juveniles from broken homes were more likely to be officially reported, were more commonly the object of court proceedings, and had a greater tendency to result in custodial sentences. Police records, Cicourel showed, embodied a related process of idealization and typification in which case records, as they were developed through the system, became increasingly concise, selective, and consistent with the assumptions, objectives, and dispositions of the legal agencies. At the core of Cicourel's argument was the claim that the processing of juvenile offenders exhibits a circular process. Basic assumptions about the causal factors associated with juvenile crime were being used to normalize offenders and were built into the differential treatment of juveniles. From this point, these assumptions became built into police records and statistics and, finally, into social scientific treatments of the statistics that "recovered" the initial assumptions as valid explanations of juvenile crime.

Similar conclusions were reached by Atkinson (1978) in relation to the treatment of suicide.

Drawing on the work of Garfinkel (1967G) and Douglas (1967), Atkinson argued that police conceptions of “typical suicides” profoundly influenced how particular cases of sudden death were investigated and treated. These conceptions not only influenced individual verdicts but, through the accumulation of verdicts, the official statistics on suicide. Atkinson concluded that sociological studies of suicide based on official statistics are unavoidably engaged in decoding the commonsense typifications of suicide that were constitutive in the recognition of, and verdicts on, individual cases and that accumulate in the statistical record.

In sum, ethnomethodological studies of typification in relation to deviance and organizational records have had both “constructive” and “deconstructive” moments. New and important social processes that inform the categorial activities of public agencies of various kinds have been uncovered. At the same time, these discoveries have challenged traditional sociological treatments of official statistics. The “deconstructive” conclusion that official statistics of social phenomena may be largely artifactual and, in many cases, can tell us only about the kinds of assumptions and practices that animate the relevant officials has provoked debates in the discipline that are unresolved to the present date.

The Creation and Maintenance of Social Institutions and Social Worlds. An important aspect of ethnomethodological theorizing is the notion that social institutions are sustained as real entities through vocabularies of accounts (or accounting frameworks) through which the events of the social world are recognized and acted upon. Although this idea can be traced back to C. Wright Mills (1940), it found vivid expression in Garfinkel’s (1967a) analysis of a transsexual individual, which he used as an occasion to investigate the nature of gender as (1) the achievement of a particular individual that (2) was made possible by the person’s grasp of, and subscription to, appropriately “gendered” practices and accounting frameworks that are generally hidden or taken for granted by normally sexed persons.

A number of subsequent studies have developed this preoccupation with the role of accounting frameworks that are employed in the taken-for-granted production and reproduction of social

institutions and social realities. An early and influential work was Wieder’s (1974) study of the role of the “convict code” in a halfway house for paroled narcotics offenders. Wieder showed the ways in which the code—which prescribed a range of activities hostile to staff members—functioned both as a fundamental way of seeing “what was going on” in the halfway house and as a resource that could be invoked in accounting for noncompliant conduct in interaction with staff members. Of particular interest is Wieder’s finding that the “code” functioned in these ways among both offenders and staff despite their distinctive and conflicting perspectives on the activities of the halfway house. In transcending the formal power structure of the institution, the code was the predominant medium through which events were defined and acted upon by all participants and, for this reason, served as a source of power and control for the offenders.

At a still more general level, Pollner (1974; 1987) has explored the ways in which a version of reality is socially sustained within a collectivity. Our sense of reality, he argues, is a social institution that is sustained by particular socially organized practices, which he labels “mundane reason.” Within this framework of practices, we start from the presumption that real-world objects and events are intersubjectively available as determinate, definite, noncontradictory, and self-identical. That this presumption is actively sustained, he shows, emerges in environments—ranging from everyday events to more specialized contexts such as the law courts, mental hospitals, and research science—where witnesses disagree in their depiction of objects and events. In such contexts, Pollner observes, a range of procedures are invoked that discount one version of events and privilege the other. The invocation of such procedures sustains (by restoring or repairing) persons’ belief in a single noncontradictory reality. “Explaining away” a witness’s testimony—by, for example, arguing that he couldn’t have seen what he saw, was not competent to do so, or was lying or even insane—functions in the way described by Evans-Pritchard (1937) as the “secondary elaboration of belief.” Such secondary elaborations, Pollner observes, are inevitably used in defense of the factual status of all versions of the world. They are the universal repair kit of the real. Pollner’s work has stimulated a range of empirical

studies in a variety of settings, ranging from mental hospitals (Coulter, 1975) to a research community of biochemists (Gilbert and Mulkay 1984), and has strongly influenced the recent “discourse analysis” movement in social psychology.

Workplace Studies. In recent years, ethnomethodological research has been most prominently visible in social studies of science (Lynch 1995) and in studies of knowledge and action in the workplace (Button 1993). These studies are continuous with earlier investigations in that they examine the practical context and practical achievement of scientific and workplace activities. However they also radicalize earlier studies in their demonstrations of the practical contingencies that underly the production and use of “hard” scientific and technological findings just as much as they do more ephemeral cultural objects such as sketch maps (Garfinkel 1996, in press).

The workplace studies began with a focus on embodied courses of practical reasoning and action that are involved in the technically competent performance of work tasks that range from playing jazz (Sudnow 1978) to proving a mathematical theorem (Livingston 1986), laboratory work in brain science (Lynch 1985), or astronomical discovery (Lynch et al. 1983). Work in these fields was studied for the detailed texture of the shop-talk and workbench practices that comprise the recognizably competent performance of work tasks. A further focus on workplace studies has emerged from Lucy Suchman’s (1987) pioneering study of human-machine communication. A very large body of ethnomethodological work has focused on a variety of aspects of machine-mediated observation and communication (for representative studies from a large corpus, see Button 1993, Luff et al. in press), as well as fundamental aspects of the relationship among computers, human action, and communication (Agre 1997; Button et al. 1995). Another set of studies addresses disciplinarily specific processes of representation in science (Lynch and Woolgar 1990), police work in courtroom testimony (Goodwin 1994), and historical events in the political context of congressional hearings (Lynch and Bogen 1996). Finally, a new body of work by Lynch and his collaborators (see Jordan and Lynch 1998) examines the nature and application of scientific techniques concerned with DNA sequencing in a variety of contexts, ranging from research and industrial to forensic contexts. This

research explores the contingencies that support the stability and objectivity of these techniques in some contexts, while subverting them in others.

CONCLUSION

Since its emergence in the 1960s, ethnomethodology has developed as a complex set of research initiatives that have raised topic areas, problems, and issues for analysis where none were previously seen to exist or perceived to be relevant. A number of these initiatives have had a pronounced “deconstructive” dimension that has sometimes appeared iconoclastic or even nihilistic (Pollner 1991). Yet in its oscillation between constructive and deconstructive tendencies, ethnomethodology has been a significant site of theoretical and empirical innovation within sociology. It is exerting a continuing impact on the sensibility of the discipline. Finally, it has also had a wide ranging influence on a range of adjacent disciplines that are concerned with knowledge systems, communication, action, and practical reasoning

EVALUATION RESEARCH

BRIEF HISTORY

There is no uniformly accepted definition of what constitutes evaluation research. At perhaps its narrowest point, the field of *evaluation research* can be defined as “the use of scientific methods to measure the implementation and outcomes of programs for decision-making purposes” (Rutman 1984, p. 10). A broader, and more widely accepted, definition is “the systematic application of social research procedures for assessing the conceptualization, design, implementation, and utility of social intervention programs” (Rossi and Freeman 1993, p. 5). A much broader definition is offered by Scriven (1991), who suggests that evaluation is “the process of determining the merit, worth and value of things” (p. 1). In the latter definition, the notion of what can be evaluated is

not limited to a social program or specific type of intervention but encompasses, quite literally, everything.

Any description of the history of evaluation research depends on how the term is defined. Certainly, individuals have been making pronouncements about the relative worth of things since time immemorial. In the case of social programs, proficiency requirements to guide the selection of public officials using formal tests were recorded as early as 2200 B.C. in China (Guba and Lincoln 1981). Most observers, however, date the rise of evaluation research to the twentieth century. For example, programs in the 1930s established by the New Deal were viewed as great opportunities to implement social science methods to aid social planning by providing an accounting of program effects (Stephan, 1935). Modern evaluation research, however, underwent explosive growth in the 1960s as a result of several factors (Shadish et al. 1991). First, the total amount of social programming increased tremendously under the administrations of Presidents Kennedy, Johnson, and Nixon. New programs were directed toward social issues such as education, housing, health, crime, and income maintenance. Second, along with these huge financial investments came the concern by Congress about whether these programs were achieving their intended effect. As a result, Congress began mandating evaluations. Third, program managers were concerned whether programs were being implemented in the manner intended, and consequently data were required to monitor program operations. In addition, there were intellectual issues about how best to implement programs and the relative effectiveness of various approaches to offsetting various social ills. Outcome data were needed to compare competing approaches. The result was a burgeoning demand for trained evaluators; and the large number of scientists involved in the common enterprise of evaluation became sufficient to support the development of evaluation research as a scientific specialty area.

The field of evaluation research is no longer expanding at the rate it was in the 1960s and 1970s (Freeman 1992). By the 1980s, there was a substantial decline in the funding for evaluation activities that was motivated, in part, by the budget cuts of the Reagan administration. By then, however, the field of evaluation research had been established.

It continues to thrive for several reasons (Desautels 1997). First, difficult decisions are always required by public administrators and, in the face of continuing budget constraints, these decisions are often based on accountability for results. Second, an increasingly important aspect of service provision by both public and private program managers is service quality. Monitoring quality requires information about program practices and outcomes. Third, there is growing public demand for accountability in government, a view increasingly echoed by government representatives. Meeting these demands requires measurement of results and a management system that uses evaluation for strategic planning and tactical decision making.

Early in its history, evaluation was seen primarily as a tool of the political left (Freeman 1992). Clearly, that is no longer the case. Evaluation activities have demonstrated their utility to both conservatives and liberals. Although the programs of today may be different from those launched in the 1960s, evaluation studies are more pervasive than ever. As long as difficult decisions need to be made by administrators serving a public that is demanding ever-increasing levels of quality and accountability, there will be a growing market for evaluation research.

PURPOSES OF EVALUATION RESEARCH

A wide variety of activities are subsumed under the broad rubric of "evaluation research." This diversity proceeds from the multiplicity of purposes underlying evaluation activities. Chelimsky (1997) identifies three different purposes of evaluation: evaluation for accountability, evaluation for development, and evaluation for knowledge.

Accountability. From the perspective of auditors and funding agencies, evaluations are necessary to establish accountability. Evaluations of this type frequently attempt to answer the question of whether the program or policy "worked" or whether anything changed as a result. The conceptual distinction between program and policy evaluations is a subtle but important one (Sonnad and Borgatta 1992). Programs are usually characterized by specific descriptions of what is to be done, how it is to be done, and what is to be accomplished. Policies are broader statements of objectives than programs, with greater latitude in how they are implemented and with potentially more

diverse outcomes. Questions addressed by either program or policy evaluations from an accountability standpoint are usually cause-and-effect questions requiring research methodology appropriate to such questions (e.g., experiments or quasi-experiments). Studies of this type are often referred to as summative evaluations (Scriven 1991) or impact assessments (Rossi and Freeman 1993). Although the term “outcome” evaluation is frequently used when the focus of the evaluation is on accountability, this term is less precise, since all evaluations, whether conducted for reasons of accountability, development, or knowledge, yield outcomes of some kind (Scriven 1991).

Development. Evaluation for development is usually conducted to improve institutional performance. Developmental evaluations received heightened importance as a result of public pressure during the 1980s and early 1990s for public management reforms based on notions such as “total quality management” and “reinventing government” (e.g., see Gore 1993). Developmental evaluations often address questions such as: How can management performance or organizational performance be improved? What data systems are necessary to monitor program accomplishment? What are appropriate indicators of program success and what are appropriate organizational goals? Studies designed primarily to improve programs or the delivery of a product or service are sometimes referred to as formative or process evaluations (Scriven 1991). In such studies, the focus is on the treatment rather than its outcomes. Depending on the specific question being addressed, methodology may include experiments, quasi-experiments, or case studies. Data may be quantitative or qualitative. Formative or process evaluations may be sufficient by themselves if a strong relationship is known to exist between the treatment and its outcomes. In other cases, they may be accompanied by summative evaluations as well.

Knowledge. In evaluation for knowledge, the focus of the research is on improving our understanding of the etiology of social problems and on detailing the logic of how specific programs or policies can ameliorate them. Just as evaluation for accountability is of greatest interest to funding or oversight agencies, and evaluation for performance is most useful to program administrators, evaluation for knowledge is frequently of greatest interest to researchers, program designers, and

evaluators themselves. Questions might include such things as the causes of crime, homelessness, or voter apathy. Since these are largely cause-and-effect questions, rigorous research designs appropriate to such questions are generally required.

CONTEMPORARY ISSUES IN EVALUATION

Utilization of Findings. Implicit in the enterprise of evaluation research is the belief that the findings from evaluation studies will be utilized by policy makers to shape their decisions. Indeed, such a view was espoused explicitly by Campbell (1969), who argued that social reforms should be regarded as social experiments and that the findings concerning program effectiveness should determine which programs to retain and which to discard. This process of rational decision making, however, has not been consistently embraced by policy makers and has been a source of concern and disillusionment for many evaluators. Rossi (1994) sums up the situation by noting:

Although some of us may have entertained hopes that in the “experimenting society” the experimenter was going to be king, that delusion, however grand, did not last for long. It often seemed that programs had robust lives of their own, appearing, continuing, and disappearing following some unknown processes that did not appear responsive to evaluations and their outcomes. (p. 26)

One source of the utilization problem, as Weiss (1975, 1987) has noted, is the fact that evaluations take place in a political context. Although accomplishing its stated objectives is important to program success, it may not be the only—or even the most important—measure of program success. From this perspective, it is not that administrators and policy makers are irrational—they simply use a different model of rationality than do evaluators. Indeed, the view of policy makers and program administrators may be more “rational” than that of evaluators because it has been shown repeatedly that programs can and do survive negative evaluations. Programs are less likely, however, to survive a hostile congressional committee, negative press, or lack of public support. There are generally multiple stakeholders, often with competing interests, associated with any large program. Negative findings are of very little use to individuals whose reputations and jobs are dependent on program

success. Thus, rather than bemoaning a lack of utilization of findings, evaluators need to recognize that evaluation findings represent only one piece of a complex political process.

Evaluators concerned with utilization frequently make a distinction between the immediate or instrumental use of findings to make direct policy decisions versus the conceptual use of findings, which serves primarily to enlighten decision makers and perhaps influence later decision making (Leviton and Hughes 1981). In a related vein, Scriven (1993) makes an important distinction between “lack of implementation” and “lack of utilization.” Lack of implementation merely refers to a failure to implement recommendations. In contrast, utilization is more ambiguous. It is often not clear what outcomes or actions actually constitute a utilization of findings. Evaluation findings can have great utility but may not necessarily lead to a particular behavior. For example, a consumer can read an evaluation of a product in a publication such as *Consumer Reports* and then decide not to buy the product. Although the evaluation did not lead to a particular behavior (i.e., purchasing the product), it was nonetheless extremely useful to the consumer, and the information can be said to have been utilized. Some observers have noted that the concern about underutilization of evaluation findings belies what is actually happening in the field of evaluation research. Chelimsky and Shadish (1997) provide numerous examples of how evaluation findings have had substantial impacts on policy and decision making, not only in government but also in the private sector, and not only in the United States but internationally as well.

Quantitative Versus Qualitative Research. The rise of evaluation research in the 1960s began with a decidedly quantitative stance. In an early, influential book, Suchman (1967) unambiguously defined *evaluation research* as “the utilization of scientific research methods and techniques” (p. 7) and cited a recent book by Campbell and Stanley (1963) on experimental and quasi-experimental designs as providing instruction on the appropriate methodology. It was not long, however, before the dominance of quantitative methods in evaluation research came under attack. Cook (1997) identifies two reasons. First, there has been a longstanding debate, especially in sociology, over the merits of qualitative research and the limits of quantitative methods. Sociologists brought the debate with

them when they entered the field of evaluation. Second, evaluation researchers, even those trained primarily in quantitative methods, began to recognize the epistemological limitations of the quantitative approach (e.g., Guba and Lincoln 1981). There were also practical reasons to turn toward qualitative methods. For example, Weiss (1987) noted that quantitative outcome measures are frequently too insensitive to detect program effects. Also, the expected time lag between treatment implementation and any observed outcomes is frequently unknown, with program effects often taking years to emerge. Moreover, due to limited budgets, time constraints, program attrition, multiple outcomes, multiple program sites, and other difficulties associated with applied research, quantitative field studies rarely achieved the potential they exuded on the drawing board. As a result, Weiss recommended supplementing quantitative with qualitative methods.

Focus on the quantitative–qualitative debate in evaluation research was sharpened when successive presidents of the American Evaluation Association expressed differing views on the matter. On the qualitative side, it was suggested that the focus on rigor associated with quantitative evaluations may have blinded evaluators to “artistic aspects” of the evaluation process that have traditionally been unrecognized or simply ignored. The time had come “to move beyond cost benefit analyses and objective achievement measures to interpretive realms” in the conduct of evaluation studies (Lincoln 1991, p. 6). From the quantitative perspective, it was acknowledged that while it is true that evaluations have frequently failed to produce strong empirical support for many attractive programs, to blame that failure on quantitative evaluations is akin to shooting the messenger. Moreover, at a time when research and statistical methods (e.g., regression discontinuity designs, structural equations with latent variables, etc.) were finally catching up to the complexities of contemporary research questions, it would be a shame to abandon the quantitative approach (Sechrest 1992). The ensuing controversy only served to polarize the two camps further.

The debate over which approach is best, quantitative or qualitative, is presently unresolved and, most likely, will remain so. Each paradigm has different strengths and weaknesses. As Cook (1997) points out, quantitative methods are good for

generalizing and describing causal relationships. In contrast, qualitative methods are well suited for exploring program processes. Ironically, it is the very differences between the two approaches that may ultimately resolve the issue because, to the extent that their limitations differ, the two methods used jointly will generally be better than either used singly (Reichardt and Rallis 1994).

Research Synthesis. Evaluation research, as it was practiced in the 1960s and 1970s, drew heavily on the experimental model. The work of Donald Campbell was very influential in this regard. Although he is very well known for his explication of quasi-experimental research designs (Campbell and Stanley 1963; Cook and Campbell 1979), much of his work actually de-emphasized quasi-experimentation in favor of experiments (Shadish et al. 1991). Campbell pointed out that quasi-experiments frequently lead to ambiguous causal inferences, sometimes with dire consequences (Campbell and Erlebacher 1970). In addition, he noted that experiments have wide applicability, even in applied settings where random assignment may not initially seem feasible (Campbell and Boruch 1975). Campbell also advocated implementing such rigorous methods in the evaluation of social programs (Campbell 1969). As a result, Campbell is frequently credited with proposing a rational model of social reform in which a program is first evaluated using rigorous social science methods, such as experiments, when possible, and then a report is issued to a decision maker who acts on the findings.

Whatever its source, it was not long before the rational model was criticized as being too narrow to serve as a template for evaluation research. In particular, Cronbach and colleagues (Cronbach et al. 1980) argued that evaluation is as much a political process as a scientific one, that decisions are rarely made but more likely emerge, that there is rarely a single decision maker, and that programs are often amorphous undertakings with no single outcome. From Cronbach's perspective, the notion that the outcome of a single study could influence the existence of a program is inconsistent with the political realities of most programs.

Understanding the ensuing controversy requires an understanding of the notion of validity. Campbell distinguished between two types of validity: internal and external (Campbell 1957; Campbell and Stanley 1963). Internal validity refers to

whether the innovation or treatment has an effect. In contrast, external validity addresses the issue of generalizability of effects; specifically, "To what populations, settings, treatment variables, and measurement variables can this effect be generalized" (Campbell and Stanley 1963, p. 5). Campbell clearly assigned greater importance to internal validity than to external validity. Of what use is it, he asked, to generalize experimental outcomes to some population if one has doubts about the very existence of the relationship that one seeks to generalize (Shadish et al. 1991)? Campbell's emphasis on internal validity was clearly consistent with his focus on experiments, since the latter are particularly useful in examining causal relationships.

In contrast, Cronbach (1982) opposed the emphasis on internal validity that had so profoundly shaped the approach to evaluation research throughout the 1960s and 1970s. Although experiments have high internal validity, they tend to be weak in external validity; and, according to Cronbach, it is external validity that is of greatest utility in evaluation studies. That is, decision makers are rarely interested in the impact of a particular treatment on a unique set of subjects in a highly specific experimental setting. Instead, they want to know whether a program or treatment, which may not always be administered in exactly the same way from agency to agency, will have an effect if it is administered on other individuals, and in other settings, from those studied in the experimental situation. From Cronbach's perspective, the rational model of evaluation research based on rigorous social research procedures is a flawed model because there are no reliable methods for generalizing beyond the factors that have been studied in the first place and it is the generalized rather than the specific findings in which evaluators are interested. As a result, Cronbach viewed evaluation as more of an art than a scientific enterprise.

The debate over which has priority in evaluation research, internal or external validity, seems to have been resolved in the increasing popularity of research syntheses. Evaluation syntheses represent a meta-analytic technique in which research results from numerous independent evaluation studies are first converted to a common metric and then aggregated using a variety of statistical techniques. The product is a meaningful summary of the collective results of many individual studies. Research synthesis based on meta-analysis has

helped to resolve the debate over the priority of internal versus external validity in that, if studies with rigorous designs are used, results will be internally valid. Moreover, by drawing on findings from many different samples, in many different settings, using many different outcome measures, the robustness of findings and generalizability can be evaluated as well.

Although meta-analysis has many strengths, including increased power relative to individual studies to detect treatment effects, the results are obviously limited by the quality of the original studies. The major drawback to meta-analysis, then, deals with repeating or failing to compensate for the limitations inherent in the original research on which the syntheses are based (Figueredo 1993). Since many evaluations use nonexperimental designs, these methodological limitations can be considerable, although they potentially exist in experiments as well (e.g., a large proportion of experiments suffer from low external validity).

An emerging theory underlying research syntheses of experimental and nonexperimental studies, referred to as critical multiplism (Shadish 1993) and based on Campbell and Fiske's (1959) notion of multiple operationalism, addresses these issues directly. "Multiplism" refers to the fact that there are multiple ways of proceeding in any research endeavor, with no single way being uniformly superior to all others. That is, every study will involve specific operationalizations of causes and effects that necessarily underrepresent the potential range of relevant components in the presumed causal process while introducing irrelevancies unique to the particular study (Cook 1993). For example, a persuasive communication may be intended to change attitudes about an issue. In a study to evaluate this resumed cause-and-effect relationship, the communication may be presented via television and attitudes may be assessed using paper-and-pencil inventory. Clearly, the medium used underrepresents the range of potential persuasive techniques (e.g., radio or newspapers might have been used) and the paper-and-pencil task introduces irrelevancies that, from a measurement perspective, constitute sources of error. The term "critical" refers to the attempt to identify biases in the research approach chosen. The logic, then, of critical multiplism is to synthesize the results of studies that are heterogeneous with

respect to sources of bias and to avoid any constant biases. In this manner, meta-analytic techniques can be used to implement critical multiplism ideas, thereby increasing our confidence in the generalizability of evaluation findings.

The increasing use of research syntheses represents one of the most important changes in the field of evaluation during the past twenty-five years (Cook 1997). Research synthesis functions in the service of increasing both internal and external validity. Although it may seem that the use of research syntheses is a far cry from Campbell's notion of an experimenting society, in reality Campbell never really suggested that a single study might resolve an important social issue. In "Reforms as Experiments" (1969) Campbell states:

Too many social scientists expect single experiments to settle issues once and for all. . . . Because we social scientists have less ability to achieve "experimental isolation," because we have good reason to expect our treatment effects to interact significantly with a wide variety of social factors many of which we have not yet mapped, we have much greater needs for replication experiments than do the physical sciences. (pp. 427-428)

Ironically, perhaps, the increasing use of research syntheses in evaluation research is perfectly consistent with Campbell's original vision of an experimenting society.

DIRECTIONS FOR THE FUTURE

The field of evaluation research has undergone a professionalization since the early 1970s. Today, the field of evaluation research is characterized by its own national organization (the American Evaluation Association), journals, and professional standards. The field continues to evolve as practitioners continue the debate over exactly what constitutes evaluation research, how it should be conducted, and who should do it. In this regard, Shadish and colleagues (1991) make a compelling argument that the integration of the field will ultimately depend on the continued development of comprehensive theories that are capable of integrating the diverse activities and procedures traditionally subsumed under the broad rubric of evaluation research. In particular, they identify a number of basic issues that any theory of evaluation must

address in order to integrate the practice of evaluation research. These remaining issues include knowledge construction, the nature of social programming and knowledge use, the role of values, and the practice of evaluation.

Knowledge Construction. A persisting issue in the field of evaluation concerns the nature of the knowledge that should emerge as a product from program evaluations. Issues of epistemology and research methods are particularly germane in this regard. For example, the controversy over whether quantitative approaches to the generation of knowledge are superior to qualitative methods, or whether any method can be consistently superior to another regardless of the purpose of the evaluation, is really an issue of knowledge construction. Other examples include whether knowledge about program outcomes is more important than knowledge concerning program processes, or whether knowledge about how programs effects occur is more important than describing and documenting those effects. Future theories of evaluation must address questions such as which types of knowledge have priority in evaluation research, under what conditions various knowledge-generation strategies (e.g., experiments, quasi-experiments, case studies, or participatory evaluation) might be used, and who should decide (e.g., evaluators or stakeholders). By so doing, the field will become more unified, characterized by common purpose rather than by competing methodologies and philosophies.

Social Programming and Knowledge Use. The ostensible purpose of evaluation lies in the belief that problems can be ameliorated by improving the programs or strategies designed to address those problems. Thus, a social problem might be remediated by improving an existing program or by getting rid of an ineffective program and replacing it with a different one. The history of evaluation research, however, has demonstrated repeatedly how difficult it is to impact social programming. Early evaluators from academia were, perhaps, naive in this regard. Social programs are highly resist to change processes because there are generally multiple stakeholders, each with a vested interest in the program and with their own constituencies to support. Complicating the matter is the fact that knowledge is used in different ways in different circumstances. Several important distinctions concerning knowledge use

can be made: (1) use in the short term versus use in the long term, (2) information for instrumental use in making direct decisions versus information intended for enlightenment or persuasion, and (3) lack of implementation of findings versus lack of utilization of findings. These different types of use progress at different rates and in different ways. Consequently, any resulting program changes are likely to appear slow and sporadic. But the extent to which such change processes should represent a source of disappointment and frustration for evaluators requires further clarification. Specifically, theories of evaluation are needed that take into account the complexities of social programming in modern societies, that delineate appropriate strategies for change in differing contexts, and that elucidate the relevance of evaluation findings for decision makers and change agents.

Values. Some evaluators, especially in the early history of the field, believed that evaluation should be conducted as a value-free process. The value-free doctrine was imported from the social sciences by early evaluators who brought it along as a by-product of their methodological training. This view proved to be problematic because evaluation is an intrinsically value-laden process in which the ultimate goal is to make a pronouncement about the value of something. As Scriven (1993) has cogently argued, the values-free model of evaluation is also wrong. As proof, he notes that statements such as "evaluative conclusions cannot be established by any legitimate scientific process" are clearly self-refuting because they are themselves evaluative statements. If evaluators cling to a values-free philosophy, then the inevitable and necessary application of values in evaluation research can only be done indirectly, by incorporating the values of other persons who might be connected with the programs, such as program administrators, program users, or other stakeholders (Scriven 1991). Obviously, evaluators will do a better job if they are able to consider explicitly values-laden questions such as: On what social values is this intervention based? What values does it foster? What values does it harm? How should merit be judged? Who decides? As Shadish and colleagues (1991) point out, evaluations are often controversial and explosive enterprises in the first place and debates about values only make them more so. Perhaps that is why values theory has gotten short shrift in the past. Clearly, however,

future theory needs to address the issue of values, acknowledging and clarifying their central role in evaluation research.

The Practice of Evaluation. Evaluation research is an extremely applied activity. In the end, evaluation theory has relevance only to the extent that it influences the actual practice of evaluation research. Any theory of evaluation practice must necessarily draw on all the aforementioned issues (i.e., knowledge construction, social programming and information use, and values), since they all have direct implications for practice. In addition, there are pragmatic issues that directly affect the conduct of evaluation research. One important contemporary issue examines the relationship between the evaluator and individuals associated with the program. For example, participatory evaluation is a controversial approach to evaluation research that favors collaboration between evaluation researchers and individuals who have some stake in the program under evaluation. The core assumption of participatory evaluation is that, by involving stakeholders, ownership of the evaluation will be shared, the findings will be more relevant to interested parties, and the outcomes are then more likely to be utilized (Cousins and Whitmore 1998). From an opposing perspective, participatory evaluation is inconsistent with the notion that the investigator should remain detached from the object of investigation in order to remain objective and impartial. Not surprisingly, the appropriateness of participatory evaluation is still being debated.

Other aspects of practice are equally controversial and require clarification as well. For example: Who is qualified to conduct an evaluation? How should professional evaluators be trained and by whom? Should evaluators be licensed? Without doubt, the field of evaluation research has reached a level of maturity where such questions warrant serious consideration and their answers will ultimately determine the future course of the field.

KARL KOSLOSKI

EVENT HISTORY ANALYSIS

Event history analysis is a collection of statistical methods for the analysis of longitudinal data on the occurrence and timing of events. As used in sociology, event history analysis is very similar to linear or logistic regression analysis, except that the dependent variable is a measure of the likelihood or speed of event occurrence. As with other regression methods, event history analysis is often used to develop causal or predictive models for the occurrence of events. Event history analysis has become quite popular in sociology since the mid 1980s, with applications to such diverse events as divorces (Bennett et al. 1988), births (Kallan and Udry 1986), deaths (Moore and Hayward 1990), job changes (Carroll and Mayer 1986), organizational foundings (Halliday et al. 1987), migrations (Baydar et al. 1990), and friendship choices (Hallinan and Williams 1987).

Although event history methods have been developed and utilized by statistical practitioners in a variety of disciplines, the term *event history analysis* is primarily used in sociology and closely allied disciplines. Elsewhere the methodology is known as survival analysis (biology and medicine), failure-time analysis (engineering), or duration analysis (economics). Introductory treatments for social scientists can be found in Teachman (1983), Allison (1984, 1995), Tuma and Hannan (1984), Kiefer (1988), and Blossfeld and Rohwer (1995).

For a biostatistical point of view, see Collett (1994), Kleinbaum (1996), or Klein and Moeschberger (1997).

EVENT HISTORY DATA

The first requirement for an event history analysis is event history data. An event history is simply a longitudinal record of when events occurred for an individual or a sample of individuals. For example, an event history might be constructed by asking a sample of people to report the dates of any past changes in marital status. If the goal is a causal analysis, the event history should also include information on explanatory variables. Some of these, such as race and gender, will be constant over time while others, such as income, will vary. If the timing of each event is known with considerable precision (as with exact dates of marriages), the data are called continuous-time data. Frequently, however, events are only known to have occurred within some relatively large interval of time, for example, the year of a marriage. Such data are referred to as discrete-time data or grouped data.

Event history data are often contrasted with panel data, in which the individual's status is known only at a set of regular, fixed points in time. For example, employment status and other variables may be measured in annual interviews. Panel data collected at frequent intervals can often be treated as discrete-time event history data. But if the intervals between data collections are long, one of the major attractions of event history analysis can be lost—the ability to disentangle causal ordering. While this capability is by no means unequivocal, the combination of event history data and event history analysis is perhaps the best available nonexperimental methodology for studying causal relationships.

PROBLEMS WITH CONVENTIONAL METHODS

Despite the attractiveness of event history data, they typically possess two characteristics that make conventional statistical methods highly unsuitable. Censoring is the most common problem. Suppose, for example, that the aim is to study the causes of divorce. The sample might consist of a

number of couples who married in 1990 and who are followed for the next five years. For the couples who get divorced, the length of the marriage is the principal variable of interest. But a large fraction of the couples will not divorce during the five-year interval. Marriages that are still in progress when the study ends are said to be *censored*. The problem is to combine the data on timing with the data on occurrence in a statistically consistent fashion. Ad hoc methods, such as excluding the censored cases or assigning the maximum length of time observed, can lead to substantial biases or loss of precision.

The second problem is time-varying explanatory variables (also known as time-dependent covariates). Suppose, in our divorce example, that the researcher wants to include number of children as a predictor of divorce. But number of children may change over the marriage, and it is not obvious how such a variable should be included in a regression model. If there were no censored cases, one might be tempted to regress the length of the marriage on the number of children at the end of the marriage. But longer marriages are likely to have produced more children simply because more time is available to have them. This would produce a spurious positive relationship between number of children and the length of the marriage.

One method for dealing with the censoring problem has been around since the seventeenth century and is still widely used—the *life table*. The life table is one example of a variety of methods that are primarily concerned with estimating the *distribution* of event times without regard for the effects of explanatory variables. For a comprehensive survey of such methods, see Elandt-Johnson and Johnson (1980). The remainder of this article focuses on regression methods that estimate the effects of explanatory variables on the occurrence and timing of events.

ACCELERATED FAILURE-TIME MODELS

Suppose the goal is to estimate a model predicting the timing of first marriages, and the sample consists of women who are interviewed at age twenty-five. For each woman ($i=1, \dots, n$), we learn her age in days at the time of the marriage, denoted by T_i .

For women who still were not married at age twenty-five (the censored cases), T_i^* is their age in days at the time of the interview. We also have data on a set of explanatory variables x_{i1}, \dots, x_{i11} . For the moment, let us suppose that these are variables that do not change over time, such as race, parents' education, and eighth-grade test scores.

One class of models that is appropriate for data such as these is the accelerated failure-time (AFT) model. The general formulation is

$$\log T_i = \beta_0 + \beta_1 x_{i1} + \dots + \beta_2 x_{i2} + \varepsilon_i \quad (1)$$

By taking the logarithm on the left-hand side, we ensure that T_i is always greater than 0, regardless of the values of the x variables. Specific cases of this general model are obtained by choosing particular distributions for the random disturbance ε_i . The most common distributions are normal, extreme-value, logistic, and log-gamma. These imply that T_i has distributions that are, respectively, lognormal, Weibull, log-logistic, and gamma, which are the names usually given to these models. The disturbance term ε_i is assumed to be independent of the x 's and to have constant variance.

If there are no censored data, these models can be easily estimated by ordinary least-squares regression of $\log T$ on the x 's. The resulting coefficients are best linear unbiased estimators. But the presence of censored data requires a different method. The standard approach is maximum likelihood, which combines the censored and uncensored data in an optimal fashion. Maximum likelihood estimation for these models is now widely available in several statistical packages (e.g., BMDP, LIMDEP, SAS, SYSTAT, Stata).

Here's an example from criminology. In the early 1970s, 432 inmates from Maryland state prisons were followed for one year after their release (Rossi et al. 1980). The event of interest is the first arrest that occurred to each person during the one-year observation period. Only 26 percent of the released inmates were arrested. We'll use the following variables:

ARREST 1 if arrested, otherwise 0

WEEK Week of first arrest for those who were arrested (ranges 1 to 52); for those not arrested, week 52

FIN 1 if they received financial aid after release, otherwise 0

AGE Age in years at the time of release

RACE 1 if black, otherwise 0

MAR 1 if married at the time of release, otherwise 0

PRIO Number of prior convictions

Using these data, I estimated a Weibull version of the accelerated failure time model by maximum likelihood with the SAS® statistical package. Results are shown in Table 1. Looking first at the p -values, we see that race and marital status do not have a significant impact on the timing of arrests. On the other hand, we see highly significant effects of age and number of prior convictions, and a just barely significant effect of financial aid.

The negative coefficient for PRIO tells us that having more prior convictions is associated with *shorter* times to arrest. The positive coefficient for AGE tells us that inmates who were older when they released have *longer* times to arrest. Similarly, those who got financial aid have longer times to arrest. We can interpret the magnitudes of the coefficients by applying the transformation $100[\exp(\beta)-1]$, which gives the percentage change in time to event for a 1-unit increase in a particular independent variable. For PRIO we get $100[\exp(-.071)-1]=-6.8$, which tells us that each additional conviction lowers the time to arrest by 6.8 percent, controlling for other variables in the model. For FIN we get $100[\exp(.268)-1]=31$. Those who got financial aid have times to arrest that are 31 percent longer than those who did not get financial aid.

In addition to the Weibull model, I also estimated gamma, lognormal, and log-logistic models. Results were very similar across the different models.

PROPORTIONAL HAZARDS MODELS

A second class of regression models for continuous-time data is the proportional hazards model. To explain this model, it is first necessary to define the hazard function, denoted by $h(t)$, which is the fundamental dependent variable. Let $P(t+\Delta t)$ be the conditional probability that an event occurs in the time interval $(t+\Delta t)$, given that it has not already

Results from Weibull Regression Model Predicting the Time of First Arrest

Variable	Coefficient	Standard Error	Chi-Square	p-value
FIN	.268	.137	3.79	.05
AGE	.043	.015	8.00	.004
RACE	-.226	.220	1.06	.30
MAR	.353	.269	1.73	.19
PRIO	-.071	.020	12.85	.0003
Intercept	4.037	.402		

Table 1

occurred prior to t . To get the hazard function, we divide this probability by the length of the interval Δt , and take the limit as Δt goes to 0:

$$h(t) = \lim_{\Delta t \rightarrow 0} \frac{P(t, t + \Delta t)}{\Delta t} \tag{2}$$
