Other common symbols for the hazard function are $r(t)$ and $\lambda(t)$. The hazard may be regarded as the instantaneous likelihood that an event will occur at exactly time t . It is not a probability, however, since it may be greater than 1.0 (although never less than 0).

If $h(t)$ has a constant value c , it can be interpreted as the expected number of events in a 1-unit interval of time. Alternatively, $1/c$ is the expected length of time until the next event. Suppose, for example, that the events are residence changes, time is measured in years, and the estimated hazard of a residence change is .20. That would imply that, for a given individual, the expected number of changes in a year is .20 and the expected length of time between changes is $1/.20 = 5$ years.

Like a probability (from which it is derived), the hazard is never directly observed. Nevertheless, it governs both the occurrence and timing of events, and models formulated in terms of the hazard may be estimated from observed data.

The general proportional hazards (PH) model is given by

$$\log h_i(t) = \alpha(t) + \beta_1 x_{i1} + \dots + \beta_k x_{ik} \tag{3}$$

where $\alpha(t)$ may be any function of time. It is called the proportional hazards model because the ratio of the hazards for any two individuals is a constant over time. Notice that, unlike the AFT model,

there is no disturbance term in this equation. That does not mean that the model is deterministic, however, because there is random variation in the relationship between $h(t)$ and the observed occurrence and timing of events.

Different versions of the PH model are obtained by choosing specific forms for $\alpha(t)$. For example, the Gompertz model sets $\alpha(t) = \alpha_1 + \alpha_2 t$, which says that the hazard is an increasing (or decreasing) function of time. Similarly, the Weibull model has $\alpha(t) = \alpha_1 + \alpha_2 \log t$. (The Weibull model is the only model that is a member of both the AFT class and the PH class.) The exponential model—a special case of both the Weibull and the Gompertz models—sets $\alpha(t) = \alpha$, a constant over time. For any specific member of the PH class, maximum likelihood is the standard approach to estimation.

In a path-breaking paper, the British statistician David Cox (1972) showed how the PH model could be estimated without choosing a specific functional form for $\alpha(t)$, using a method called partial likelihood. This method is very much like maximum likelihood, except that only a part of the likelihood function is maximized. Specifically, partial likelihood takes account only of the ordering of events, not their exact timing. The combination of partial likelihood and the proportional hazards model has come to be known as Cox regression. The method has become extremely popular because, although some precision is sacrificed, the resulting estimates are much more robust. Computer programs that implement this method are now available in most full-featured statistical packages (SPSS, SAS, LIMDEP, BMDP, S-Plus, Stata, SYSTAT).

As an example, we'll estimate a proportional hazards model for the recidivism data discussed

Results from Cox Regression Model Predicting the Hazard of First Arrest

Variable	Coefficient	Standard Error	Chi-Square	p-value
FIN	-.373	.191	3.82	.05
AGE	-.061	.021	8.47	.004
RACE	.317	.308	1.06	.30
MAR	-.493	.375	1.73	.19
PRIO	.099	.027	13.39	.0003
Intercept	4.037	.402		

Table 2

earlier. The chi-squares and *p*-values shown in Table 2 for the five variables are remarkably similar to those in Table 1 that were obtained with maximum likelihood estimation of a Weibull model. On the other hand, the coefficients are noticeably different in magnitude and even have signs that are reversed from those in Table 1. The sign reversal is a quite general phenomenon that stems from the fact that the dependent variable is the time of the event in the AFT model and the hazard of the event in the PH model. People with high hazards are very likely to have events at any point in time, so their times to events tend to be short. By contrast, people with low hazards tend to have long times until event occurrence.

To interpret the magnitudes of the coefficients, we can use the same transformation used for the AFT models. Specifically, $100[\exp(\beta)-1]$ gives the percentage change in the hazard of an event for a 1-unit increase in a particular independent variable. Thus, for FIN we have $100[\exp(-.373)-1] = -31$, which says that those who got financial aid have hazards of arrest that are 31 percent lower than those who did not get aid. For AGE we have $100[\exp(-.061)-1] = -6$. Each additional year of age at release yields a 6 percent reduction in the hazard of arrest. Finally, each additional conviction is associated with $100[\exp(.099)-1] = 10.4$ percent increase in the hazard of an arrest.

The partial likelihood method also allows one to easily introduce time-varying explanatory variables. For example, suppose that the hazard for arrest is thought to depend on both financial aid (x_1) and employment status (x_2 , coded 1 for employed, 0 for unemployed). A suitable PH model might be

$$\log h(t) = \alpha(t) + \beta_1 x_1 + \beta_2 x_2(t) \quad (4)$$

which says that the hazard at time *t* depends on financial aid, on employment status at time *t*, and on time itself. If longitudinal data on income are available, models such as this can be estimated in a straightforward fashion with the partial likelihood method. How to do this is shown in Chapter 5 of Allison (1995).

MULTIPLE KINDS OF EVENTS

To this point, it has been assumed that all events can be treated alike. In many applications, however, there is a compelling need to distinguish among two or more types of events. For example, if the events of interest are job terminations, one might expect that explanatory variables would have vastly different effects on voluntary and involuntary terminations. For recidivism studies, it might be desirable to distinguish arrests for crimes against persons and crimes against property. The statistical analysis should take these distinctions into account.

All of the methods already discussed can be easily applied to multiple kinds of events. In essence, a separate model is estimated for each kind of event. In doing an analysis for one kind of event, one simply treats other kinds of events as though the individual were censored at the time when the event occurred, a method known as “competing risks.” Thus, no new methodology is required to handle this situation.

An alternative approach is to estimate a single event history model for the timing of events, without distinguishing different event types. Then,

after eliminating all the individuals who did not have events (the censored cases), one estimates a logistic regression model for the determinants of the type of event. This method of analysis is most appropriate when the different kinds of events are functionally alternative ways of achieving a single objective. For example, the event might be purchase of a computer and the two different types might be a Windows-based computer versus a Macintosh computer.

REPEATED EVENTS

The discussion so far has presumed that each individual experiences no more than one event. Obviously, however, such events as childbirths, job changes, arrests, and car purchases can occur many times over the life of an individual. The methods already described have been routinely applied to cases of repeated events, taking one of two alternative approaches. One approach is to do a separate analysis for each successive event. For example, one event history model is estimated for the birth of the first child, a second model is estimated for the birth of the second child, and so on. The alternative approach is to break each individual's event history into a set of intervals between events, treat each of these intervals as a distinct observation, and then pool all the intervals into a single analysis.

Neither of these alternatives is entirely satisfactory. The sequential analysis is rather tedious, wastes information if the process is invariant across the sequence, and is prone to selection biases for later events in the sequence. The pooled analysis, on the other hand, makes the rather questionable assumption that the multiple intervals for a single individual are independent. This can lead to standard errors that are biased downward and test statistics that are biased upward.

Several methods are available for dealing with the lack of independence. One is to estimate standard errors and test statistics using the robust method developed by White (1982). These robust standard errors have been incorporated into some Cox regression programs (e.g., Stata, S-Plus). Another is to do a "fixed-effects" Cox regression that stratifies on the individual (Allison 1996; Yamaguchi 1986). These models can be estimated with most Cox regression software, and they have the advantage of automatically controlling for all stable

characteristics of the individual. On the other hand, fixed-effects models cannot produce coefficient estimates for stable characteristics such as sex or race. Finally, there are "random-effects" or "frailty" models that explicitly build the dependence into the model as an additional random disturbance. Unfortunately, there is little commercial software available to estimate random-effects event history models.

DISCRETE-TIME METHODS

When event times are measured coarsely, the continuous-time methods already discussed may yield somewhat biased estimates. In such cases, methods specifically designed for discrete-time data are more appropriate (Allison 1982). Moreover, such methods are easily employed and are particularly attractive for handling large numbers of time-varying explanatory variables.

Suppose that the time scale is divided into a set of equal intervals, indexed by $t = 1, 2, 3, \dots$. The discrete-time analog of the hazard function, denoted by P_t , is the conditional probability that an event occurs in interval t , given that it has not occurred prior to t . A popular model for expressing the dependence of P_t on explanatory variables is the logit model

$$\log\left(\frac{P_{it}}{1-P_{it}}\right) = \alpha_t + \beta_1 x_{i1} + \dots + \beta_2 x_{i2} \quad (5)$$

where the subscript on α_t indicates that the intercept may differ for each interval of time. Similarly the explanatory variables may take on different values at each interval of time. This model can be estimated by the method of maximum likelihood, using the following computational strategy:

1. Break each individual's event history into a set of discrete time units, for example, person-years.
2. Create a dependent variable that has a value of 1 for time units in which events occurred; otherwise use 0. Explanatory variables are assigned whatever values they had at the beginning of the time unit.
3. Pool all these time units, and estimate a logistic regression model using a standard maximum likelihood logit program.

Other models and computational methods are also available for the discrete-time case. These methods can be easily extended to allow for multiple kinds of events and repeated events.

PAUL D. ALLISON

EVOLUTION: BIOLOGICAL, SOCIAL, CULTURAL

The diverse forms of life on earth have emerged probably from a common source, through a process of evolution that has the following characteristics:

1. The course of evolution does not always proceed along a straight path (for example, from simple to complex forms). Instead, it can meander like a stream, directed largely by environmental circumstances, although also affected by limitations on the capacities of organisms to respond to environmental challenges, and by unpredictable "chance" factors. Occasionally it reverses direction in certain respects, as when our own distant monkey-like ancestors became adapted to life in

the trees, and our more recent ancestors readapted to living on the ground. When the course of evolution does reverse direction, it generally does so with respect to comparatively few features only, not all features. Thus, we humans retain various characteristics evolved earlier in connection with life in the trees: stereoscopic vision, visual acuity, reduced sense of smell, and hands adapted for grasping.

2. Different groups of organisms sometimes evolve in similar directions in certain respects when exposed to similar environmental conditions. Thus whales—descendants of mammals that lived on land—acquired fishlike shapes when they adapted to life in the water. However, parallelism in evolutionary development generally remains limited: different evolutionary lines do not come close to “merging.” Whales, even though living in the ocean and acquiring fishlike shapes, retain basic anatomical and physiological features of mammals, quite different from those of fish.

The life cycle of a human being involves fixed stages (infancy, childhood, adolescence, adulthood, old age) that represent an unfolding of innate potentialities and that culminate in inevitable death. The evolution of a new biological species, by contrast, is a unique historical development involving movement in directions shaped primarily by environmental pressures, without any inevitable “death” or other pre-determined end state.

A “Lamarckian” evolutionary process (named after Jean Baptiste Lamarck, 1744–1829), would involve inheritance of acquired characteristics. Thus, if evolution followed the Lamarckian pattern, giraffes might have acquired their long necks because in each generation necks were stretched (perhaps to obtain food high up in trees, or to detect approaching enemies), and because the effect of each generation’s stretching tended to be inherited by the generation that followed. However, Lamarckian ideas were found to be invalid long ago.

A different approach developed by Charles Darwin (1859) and others does not assume that

acquired characteristics (such as effects of neck-stretching) are inherited. Rather, it assumes (1) random or randomlike variation among the offspring in each generation (with some giraffes happening by chance to have longer necks than others); (2) natural selection, involving tendencies for certain variants (longer-necked giraffes) to survive and reproduce more than others; and (3) preservation through inheritance of the effects of natural selection (longer-necked giraffes tending to have similarly long-necked offspring, although—as suggested above—there would still be some random variation among these offspring with respect to neck length).

Darwinian ideas challenged traditional Christian religious beliefs by suggesting (1) that we are descended from ape-like creatures and, ultimately, from elementary life forms; (2) that our evolution was basically an unplanned outcome of diverse environmental pressures rather than something planned in advance; and (3) that the earth is old enough for evolutionary processes to have had time to produce the variety and complexity of life forms that we actually find. Although today still resisted by many on religious grounds, Darwinian theory ultimately came to be generally accepted by biologists, with important modifications and certain disagreements about details, and in combination with new knowledge in other areas of biology and other scientific disciplines that was not available to Darwin (see Gould 1982; Stebbins and Ayala 1985; Mayr and Provine 1998).

An inherited trait that has evolved over a long period of time (like the giraffe’s long neck) has very likely evolved because it makes some contribution to the survival and reproduction of the organisms possessing it, and because it has consequently emerged and persisted through the Darwinian mechanisms outlined above. However, some traits may appear and persist that are neutral in their implications for survival and reproduction, and even traits that have negative implications may appear and persist if they happen to be linked with traits whose implications are positive.

Bioevolutionary explanations of human social phenomena, sometimes under the label of “sociobiology” (see Wilson 1975), pose a challenge to sociology, as the following example suggests. Stepparents tend to abuse their stepchildren

more than biological parents tend to abuse their own children. Sociologists would ordinarily seek to explain this in a way that utilizes sociological and social-psychological concepts only, avoiding assumptions about inherited and biologically evolved traits. A sociobiologist, by contrast, would be more likely to view it as a human manifestation or extension of a biologically evolved tendency prevailing widely among nonhuman mammals: a tendency for individual mammals in stepparent-like positions to kill their “stepchildren,” thus increasing their own prospects for producing survivable offspring and perpetuating their own genes (see Beckstrom 1993, pp. 23–29).

An evolutionary explanation of an aspect of human life or society may present that aspect as having emerged (1) as a part of, or a continuation of, biological evolution (as illustrated in the discussion of stepparental child abuse above), or (2) through a process analogous to biological evolution but nevertheless distinct from it, that is, a process of social or cultural evolution. Concepts analogous to those of biological evolution are especially applicable to aspects of culture such as science (Hull 1988) and technology (Basalla 1988) in which the cumulative character of culture is most strongly manifested. Competing scientific hypotheses are the “randomlike variations” in science as an evolutionary process. Research results that evaluate such hypotheses select some of them for survival and others for extinction, and the knowledge that constitutes the outcome of this process in any given generation of scientists is “inherited” by subsequent generations through textbooks, teaching, and research publications. In technological evolution, positive selection (i.e., acceptance) of variations (innovations) depends not only on research results (i.e., on how well they “work”) but also on costs, competitive pressures, compatibility with prevailing culture, and other factors.

The evolutionary model is not appropriately applied to social or cultural changes that are cyclical, easily reversed, primarily planned, or repetitive. It may be usefully applied when a complex social or cultural transformation that would be hard to repeat or to reverse occurs gradually without being planned, through environmentally determined selections from among divergent alternative directions of change, and with enough

stability to preserve the results of past environmental influence (see Campbell 1965; Richter 1982, pp. 19–34).

Not every process that is called “evolutionary” seems to deserve that label. Some theories pertaining to major transformations of society illustrate this point.

The idea that human society evolves from simple beginnings through comparatively fixed stages came to be commonly accepted in the nineteenth century, although different theorists had different conceptions of what these stages were. Thus we find analyses of transitions from theological to metaphysical to “positivistic” thought-styles (Comte 1875); from savagery to barbarism to civilization (Morgan 1877); from tribalism to slavery, feudalism, capitalism, and then communism (Marx and Engels [1846] 1947); and from simple to compounded, doubly compounded and then triply compounded societies (Spencer [1885–1886] 1967).

When societies, cultures, or civilizations are said to pass from childhood to adulthood, and then to old age, or are said to grow and then decline, we have an analogy not with the evolution of a species but rather with the human life cycle, as illustrated in the works of Oswald Spengler and Arnold J. Toynbee. Nineteenth century “social-evolutionary” theories departed from the life-cycle model in that they did not involve the idea of decline or old age followed by death as the end point of a cycle. Quite the opposite: the trends they described tended to culminate in triumphant achievements—“positivism” (Comte), “civilization” (Morgan), “communism” (Marx and Engels), and societies “compounded” many times (Spencer). In this one respect, but only in this respect, these theories resembled the bioevolutionary model: biological species do not have to become extinct—even though many of them actually do—in the same sense that individuals have to die. However, these theories nevertheless reflect a life-cycle model, insofar as they involve one society after another following essentially the same pattern of development, just as one infant after another follows the same general route to adulthood. And they do not appear to involve, in any major way, the evolutionary mechanisms of random variation and selection. In fact, they are primarily theories of progress, not of evolution in any sense that biologists

would recognize, regardless of the “evolutionary” label commonly attached to them (Nisbet 1969).

The social-evolutionary idea fell into disfavor among sociologists around the turn of the twentieth century, but was revived several decades later with, for example, Talcott Parsons’ analysis of primitive, intermediate, and modern societies (1977), and Lenski and Lenski’s (1982) analysis of transitions from hunting-and-gathering to horticultural, agrarian, and industrial societies. Although based on more accurate and more extensive facts than were available in the nineteenth century, these newer schemes pertaining to the evolution of whole societies are nevertheless basically similar to their nineteenth century predecessors in that they present various societies as passing through specific stages in a predominantly unidirectional pattern, which, as noted above, represents a divergence from the bioevolutionary model. This is not necessarily a defect: the development of societies of new types may simply not be a process to which concepts of a bioevolutionary sort are fully applicable.

Evolutionary concepts have been used not only in attempts to understand some social and cultural phenomena, as discussed above, but also in attempts to formulate and justify certain social policies. In the late nineteenth and early twentieth centuries, evolutionary concepts and associated slogans such as “survival of the fittest” appeared to provide rationales for what have been labelled “Social Darwinist” policies. Focusing on the selective (rather than on the random-variation) phase of the evolutionary process, various business, political, ideological, and military leaders in several countries, along with some scholars in several disciplines (including the sociologists Herbert Spencer and William Graham Sumner), emphasized the importance of the struggle for survival in maintaining a hardy population and a vigorous society, and opposed social welfare measures that they thought would mitigate that struggle. Supporters of this approach differed in several ways: some emphasized individual struggle, others, group (e.g., racial or national) struggle; some emphasized nonviolent means (e.g., economic competition), and others, armed conflict (see Hofstadter 1955).

A statement by Darwin himself illustrates the basic idea underlying “Social Darwinism.” Although Darwin did not oppose smallpox vaccination, he

worried about its effects: “There is reason to believe that vaccination has preserved thousands, who from a weak constitution would formerly have succumbed to smallpox. Thus the weak members of civilized societies propagate their kind. No one who has attended to the breeding of domestic animals will doubt that this must be highly injurious to the race of man” (Darwin [1871] 1897, p. 134).

Darwin did not believe that war led to the selective survival of the fittest people, as he thought smallpox tended to do. Quite the opposite: he saw war as destroying “the finest” young men while those with “poor constitutions” would avoid fighting and thus survive and reproduce.

But evolutionary concepts can be applied at diverse levels. Nineteenth-century war might have led to the selective survival of societies or governments that were “fittest” in some sense, even if not to the survival of the “fittest” young men within particular societies. Some Social Darwinists adopted that perspective. Thus: “Storm purifies the air and destroys the frail trees, leaving the sturdy oaks standing. War is the test of a nation’s political, physical and intellectual worth. The State in which there is much that is rotten may vegetate for a while in peace, but in war its weakness is revealed. . . . It is better to spend money on armaments and battleships than luxury, motormanias and other sensual living” (Baron Karl von Stengel, cited by Angell 1911, p. 168).

There is a problem here: what an exceedingly powerful storm is most likely to leave standing are not sturdy oaks but blades of grass. And this leads to a question: what does “survival of the fittest” actually mean? Defining the fittest as “those who survive” would make the phrase tautological, but any other definition would very likely make it untrue except under a limited range of conditions. In any case, “fitness” is not necessarily equivalent to “desirability” as we might define that, or to what the people of a society actually desire.

The problem of defining “fitness” may be illustrated by examining what Darwin said about smallpox. Suppose people who would have succumbed to smallpox if not vaccinated, but who were actually saved by vaccination, have descendants who inherit their potential vulnerability to that disease. In this respect, such descendants might be considered relatively “unfit.” But if these descendants are all protected from smallpox by

vaccination, or if smallpox itself is permanently eliminated, then “potential vulnerability to smallpox” might have no practical implications and might not entail “unfitness” in any practically relevant sense.

If the term “Social Darwinism” is to be applied to attempts to improve society through competition and struggle that eliminate some variants while perpetuating others, then attempts to improve society by improving people within society (through education, health care, and so on) might reasonably be labelled “Social Lamarckism.” The fact that Lamarckian ideas have been empirically disconfirmed and rejected in explanations of biological evolution has no bearing on the question of the reasonableness of analogous ideas in the socio-cultural realm. And, in both biological and socio-cultural contexts, Lamarckian and Darwinian ideas can logically coexist and have done so. Darwin himself accepted the validity of Lamarckian ideas in explaining biological evolution, even while he was developing different ideas of his own; the decisive rejection of Lamarckism by evolutionary biologists came after Darwin had died. And Herbert Spencer, who coined the Darwinian phrase “survival of the fittest” and has traditionally been considered a major Social Darwinist, has also been called a Social Lamarckist (Bowler 1995, p. 113) on the ground that he was more committed to struggle as a (Lamarckian) means for invigorating and improving the individuals who participate in it, than to struggle as a (Darwinian) means for eliminating the “unfit.”

Partial artificial control over reproduction and hence over the evolutionary process is illustrated by methods used to develop new variants of farm animals, work animals, laboratory animals, and pets. Improvements in these methods have ultimately led to “cloning,” which involves total and exact replication of individuals’ inherited characteristics without mating. Control over human reproduction was sought on a limited basis by a “eugenics” movement that emerged in the late nineteenth century, founded by Darwin’s cousin Francis Galton. This movement achieved some successes, including arrangements for sterilization of some criminals and mentally ill people in various jurisdictions. However, it also faced problems, including: lack of consensus about the traits to be targeted; complexities in the process of hereditary transmission (for example, the fact that parents

may transmit to their offspring a defect that they do not manifest themselves); political and legal obstacles to compulsory eugenic measures in societies with well-established traditions of democracy and personal freedom; and, the difficulty of distinguishing between traits transmitted through heredity and traits transmitted through socialization. Supporters of eugenics did not always care about this last point: they sometimes assumed that preventing people with undesirable traits from having children would reduce the prevalence of people bearing these traits regardless of how the traits themselves were transmitted from one generation to the next.

The eugenics movement developed in a tragically racist direction. Some major leaders of the movement in the United States thought that white people of northern European ancestry constituted a superior race and regarded as genetically inferior the southern and eastern Europeans who were immigrating to the country in large numbers. The movement came to be discredited after its ideas came to be used in Hitler’s Germany to support genocidal killings of Jews and members of various other groups.

EXCHANGE THEORY

See Social Exchange Theory.

EXPECTATION STATES THEORY

Expectation states theory is a well-established, ongoing research program investigating various aspects of group interaction. The focus is on small, task-oriented groups; the central interest is in both the processes through which group members assign levels of task competence to each other and the consequences this assignment has for their interaction. Originating as a single theory developed by Joseph Berger (1958), expectation states

theory has grown to include various branches sharing a core of basic concepts, definitions, and propositions about group interaction processes, as well as methodological and metatheoretical assumptions. Thus, the program in fact contains not just one theory but several. (Unless otherwise specified, the expression “expectation states theory” refers here to the entire program rather than to any particular theory within it.) Expectation states theory has received strong support from extensive empirical research.

Two key concepts in the program are “status characteristics” and “performance expectations.” A status characteristic is any valued attribute implying task competence. Such characteristics are viewed as having at least two levels (e.g., being either high or low in mechanical ability, being either male or female), one carrying a more positive evaluation than the other. They are also defined as varying from specific to diffuse, depending on the range of their perceived applicability. For instance, mechanical ability is usually considered to be relatively specific, or associated with well-defined performance expectations. Gender, on the other hand, is frequently treated as diffuse, or carrying both limited and general performance expectations. The “diffuseness” refers to the fact that since there is no explicitly set limit to the expectations, the characteristic is viewed as relevant to a large, indeterminate number of different tasks. Other attributes commonly treated as diffuse status characteristics are ethnicity, skin color, socio-economic class, level of education, organizational rank, age, and physical attractiveness.

Performance expectations link status characteristics to observable behavior. Thus, levels of these characteristics are associated with levels of competence and corresponding expectations that, in turn, determine what is known as “the power and prestige order of the group.” This concept refers to a set of interrelated behaviors, namely, the unequal distribution in the offer and acceptance of opportunities to perform, the type of evaluations received for each unit of performance, and the rates of influence exerted among group members. Note, then, that performance expectations are distinguished from evaluations of units of performance: while the latter are evaluations of a single act, the former refer to the level of competence that a person is predicted to exhibit over a

number of such performances. Once formed, expectations tend to be stable, since the behaviors that make up the power and prestige order of a group operate in a way that reinforces the status quo.

Research in expectation states theory follows a situational approach. Propositions are formulated from the point of view of an individual (also referred to as “self” or “focal actor”) who performs a given task with a partner (“other”). Performance expectations are therefore relative to a specific pair of actors, and an individual is not seen as holding high (or low, or medium) expectations for self but, rather, an “expectation state” that is defined in terms of self *and* other. In other words, the focal actor is said to hold expectations for self that are either higher than, lower than, or equal to, the expectations he or she holds for the partner. Such expectations are also conceptualized as relative to a particular situation. Thus, for example, with a different partner or in the context of a different task, a person’s expectation state could vary. It should also be noted that an expectation state is a theoretical construct, not an observable phenomenon. In particular, although expectations are seen as reflecting a person’s beliefs about the distribution of task competence in the group, they are *not* assumed to be self’s conscious calculations of advantage (or disadvantage, or equality) in this respect. Rather, what is proposed are models to be used to predict the focal actor’s behavior, and this person is to be seen only *as if* he or she performed the operations specified in the models.

Propositions in expectation states theory also have been formulated within well defined scope conditions, or clauses specifying the limits within which the propositions apply. Since scope conditions are part of the theory, they are expressed in abstract terms (as are the key concepts of “status characteristic,” “performance expectations,” and “power and prestige order”). Three important scope conditions are that the focal actor is assumed to: (1) value the task in question (he or she views it as having two or more possible outcomes, none due exclusively to chance, and considers one of these to be success and the other failure); (2) be task-oriented (motivated to do the task well); and (3) be collectively oriented (prepared to accept the partner’s ideas if they are thought to contribute to the task solution). In other words, the third scope condition specifies that solving the task must be

more important to the focal actor than any other considerations (such as having his or her individual contributions accepted, or being liked by the partner).

The situational approach and the use of scope conditions are part of an overall theory-construction strategy whereby the initial focus is on the simplest contexts, which are studied with the aid of minimum assumptions. Complexities are then added gradually as knowledge accumulates. More recent expectation states research has, for example, extended the investigation from dyads to larger groups. Similarly, the scope condition of collective orientation has been relaxed in some of these studies, with results showing that status still affects expectations under such circumstances.

The core of the theory investigates the performance expectations an individual forms about self and other in settings where the two are engaged in the joint solution of a task. As indicated previously, the focal actor is assumed to value the task and to be both task-oriented and collectively oriented. A valued task implies that competence at the task is more desirable than incompetence, and therefore that levels of task ability constitute a status characteristic for that actor. Basically, the assignment of levels of this characteristic and corresponding performance expectations may occur in one of two ways: directly, from actual evaluations of task performance, or indirectly, on the basis of other status characteristics of the performers that self perceives to be relevant to the task. For simplicity, I first consider situations where expectations are formed exclusively in one fashion or the other. These two ways comprise the major branches of expectation states theory, the former focusing on the effects of performance evaluations and the latter on the effects of other status information. These branches and their development are described below. (Because of space limitations, the emphasis in this article is on the basic ideas, and specific references can only be given for a sample of the theoretical and empirical work done in the program. This sample consists of key earlier pieces and a selection of the more recent research. It should be noted, however, that expectation states theory has been a collaborative effort from its beginnings and that a considerable number of researchers have worked in it. For references to their individual contributions at the various stages of the program, see the reviews and edited

collections, as well as the examples of research, mentioned at the end of this article.)

Initial work in the first branch of the theory investigated the formation of performance expectations in situations where two persons begin their interaction as status equals (i.e., they have no information from either inside or outside the group that would enable them to assign different levels of task competence to each other). In this case, the assignment of levels of competence that eventually occurs is the result of a generalization from evaluations of units of performance. These evaluations may be made by the performers themselves as they resolve disagreements between them regarding the correct solution to the task (Berger and Conner 1969; Berger and Snell 1961) or by a "source" or third party with the right to evaluate the performers (Crundall and Foddy 1981; Webster 1969; Webster and Sobieszek 1974). Moreover, the evaluations may or may not be made through the use of objective criteria. Various other topics were later investigated within this branch. These include the effects on expectations of the type of evaluations received (e.g., either positive or negative; either highly or moderately positive), the consistency of these evaluations (e.g., across performances or across sources), and the types of attributes that confer evaluative competence on a source (such as level of task competence or vicarious exposure to the task). Other recent work has dealt with the effects of applying either strict or lenient standards for competence (as well as for lack of competence) to the processing of evaluations. The study of second-order expectations (those based on self's perceptions of the expectations held by the partner) also has received attention in this program, and is of direct relevance to this branch.

The second branch of the theory is primarily concerned with situations where the actors differ in status. It is in this branch, which has come to be known as "status characteristics theory," that a large proportion of expectation states research has been conducted. This work started with the investigation of situations in which two persons are differentiated with respect to a single diffuse status characteristic (Berger et al. [1966] 1972; Moore 1968). Furthermore, this difference constitutes the only information that the focal actor has about self and other, and he or she treats the attribute as a diffuse status characteristic (i.e., attaches different evaluations to its various levels

and holds different performance expectations, specific as well as general, for each level).

The basic proposition in this branch states that unless the focal actor believes the characteristic to be irrelevant to the task at hand, he or she will use the status difference between self and other to organize their interaction. In other words, performance expectations for the task will be the result of importing status information from outside the group. This process is known as "status generalization." Let us consider gender as an example (with "man" carrying a more positive valuation than "woman") and assume that the focal actor is a man and that his partner is a woman. The theory predicts different expectations, depending on what the individual believes the sex linkage of the task to be. If the task is perceived as masculine (one at which, in general, men do better than women), self will use this information to infer that he is the better of the two. If he has no information about its sex linkage (perceives the task as neither associated with nor dissociated from sex differences), the "burden-of-proof principle" will apply: those of lower status will be considered to have inferior task competence, unless they demonstrate the opposite. Accordingly, also in this situation, the man will expect to be more competent at the task than his female partner. On the other hand, the theory predicts that he will *not* form expectations of his own superiority if the task has been explicitly dissociated from gender. Finally, if the valued task is perceived to be one at which women generally excel, the prediction is that the male actor will consider himself inferior to his female partner.

It is important to emphasize that the above predictions assume that gender is a diffuse status characteristic for the focal actor (and that, in this example, "man" carries a higher value than "woman"). If gender is not such a characteristic, the propositions do not apply. Because of the inclusion of this scope condition, the theory is able to incorporate cultural, historical, and individual differences. Thus, through this condition, it incorporates the fact that although gender is a diffuse status characteristic in most societies, it is more so in some than in others. The extent to which this is the case also may vary within a given society and from one historical period to another. Furthermore, the theory reflects the fact that even in

strongly sexist societies there are likely to be individuals who are less sexist than the majority, and perhaps some who are not sexist at all. (This may be due, for example, to variations in socialization practices within a given culture, and/or to the different degrees of success of these practices). Note that the theory assumes that women, *as well as* men, may treat gender as a diffuse status characteristic and devalue women's performances. (For a theoretical account of the social construction of status beliefs, see Ridgeway 1991).

Let us then reanalyze the earlier example from the point of view of the female actor, and assume that she considers gender to be a diffuse status characteristic to the same degree as her male partner does. The theory predicts that she will then form expectations that are exactly complementary to those of her partner. Thus, if she either views the task as masculine or relates it to sex differences through a burden-of-proof process, she will consider herself the less competent of the two performers. (She will not form such expectations if she sees the task as dissociated from gender, and will believe herself to be the better performer if she views the task as feminine.) However, as with most status systems, those persons who benefit from the existing order can be expected to be more supportive of it than those who do not, socialization practices notwithstanding. Thus it could be that men tend to meet this scope condition more than women do. This is not an issue about the theory itself but an empirical matter regarding the particular instances to which it applies. Note, also, that while the preceding discussion has been limited to gender for the sake of providing an example, the comments are meant to apply to any diffuse status characteristic. In general, the strength of the link between status and expectations is a function of the extent to which the attribute is a status characteristic for the focal actor.

Performance expectations formed through status generalization may, of course, be affected by other factors. Accordingly, the basic ideas of the initial formulation of status characteristics theory have been expanded and elaborated in several directions. In particular, these include the study of situations where actors possess more than one status characteristic. These may be either specific or diffuse, or either consistent or inconsistent with each other in terms of the levels of competence

they imply. Furthermore, as a set, they may either equate or differentiate the performers to various degrees (Berger et al. 1977). This extended formulation specifies the conditions under which the available status items will become salient (or "activated"), as well as the rules by which they will be processed. It is proposed that all (and only) activated items will be used and that they will be combined according to the following principles: inconsistent information will have more impact than consistent information, and each additional item of consistent information will have less weight than it would by itself. Furthermore, this version includes referent actors (nonparticipating actors who serve as objects of comparison for the performers) and their role in the formation of expectations.

The two main branches of the program have not developed independently of each other. In fact, the branches touch and intertwine at various points, as expectations are formed on the basis of *both* performance evaluation and status information. For example, the extent to which the focal actor accepts the evaluations from a source is often affected by the diffuse status characteristics (and their levels) of everyone involved in the situation. Of particular interest is the resilience of status-based expectations when these are contradicted by actual performance evaluations. This resistance shows itself in, for example, the higher level of performance that lower-status actors have to achieve in order to escape the effects of status generalization. The inconsistency between performance evaluation and status information is of course a special case of the extension of status characteristics theory to more than one attribute. A recent theoretical proposal in this area links the resilience to the use of double (or even multiple) standards for both competence and incompetence that protect higher-status actors and penalize lower-status ones.

Other expectation states research, also of relevance to both branches, has included a rich variety of topics. For example, theoretical and empirical work has investigated the relationship between performance expectations and reward expectations, the status-value view of distributive justice, the transfer of expectations across actors and situations, and the legitimation of status positions. The latter work examines how and why individuals come to view the status hierarchies in which they

are involved as right and proper. Also of special interest is the analysis of the way in which task settings generate emotional reactions and how these, in turn, affect performance expectations. Other important areas have been: The extension of status characteristics theory to include self-fulfilling effects of status on performance; the study of the role that status cues (such as accent, dress, demeanor) have in the assignment of task competence; and the work on how the attribution of personality characteristics (such as friendly, rigid, outgoing) and moral characteristics (such as honest, fair, selfish) affects this assignment and is, in turn, affected by it.

No review of expectation states theory would be complete without a discussion of three features that, together with those mentioned earlier, serve to characterize this program. *First*, a sizable portion of the research has used a standardized experimental situation involving two subjects (Webster and Sobieszek 1974, Appendices 1 and 2). The utilization of an experimental approach clearly is well suited to the program's analytical strategy of investigating the effects of a few variables at a time, and the standardized setting has contributed to cumulativeness in the research findings by allowing comparability across studies. In this setting, the task consists of a series of trials, each involving a binary choice regarding visual stimuli, with subjects allowed to interact only indirectly (as opposed to face-to-face) with each other. The situation consists of two phases. In the first phase, performance expectations are formed on the basis of information controlled by the experimenter. This may include evaluations of each person's task performance, cues regarding the participants' other status characteristics, or a combination of the two. In the second phase, each trial consists of an individual initial choice, the experimentally controlled communication of the partner's choice, and a final individual choice. In most trials, the communication indicates that the partner disagrees with the subject. The dependent variable of central interest is the amount of influence (one of the components of the power and prestige order of the group) that a partner exerts on the subject in the resolution of those disagreements. Several versions of this setting, including computerized ones, have now been developed. (Additional bases of empirical support for the theory include direct evidence from research conducted in discussion

groups, classrooms, and various other settings—such as those mentioned below—as well as indirect evidence from work originating in several other theoretical traditions. These studies corroborate and extend the knowledge gained through the use of the standardized setting. For a review of the different types of support for the theory, see Berger et al. 1989).

Second, the program has been characterized by a strategy of stating propositions as part of deductive systems. These systems have been formalized to various extents, and different techniques (such as stochastic models, a Bayesian approach, graph theory, fuzzy set theory) have been used. The most comprehensive of these formulations is the graph theoretic model of the extended version of status characteristic theory (Berger, Fisek, Norman, and Zelditch 1977). This model has also been used to formalize other areas of the program, such as the formation of expectations in groups where members initially are status equals, and the legitimation and delegitimation of status hierarchies.

Third, from its beginnings, researchers in the program have shown a definite interest in applications and interventions designed to understand and alleviate specific social problems. A large portion of this work has included the development of techniques to reduce the effects of status generalization, particularly those based on skin color and ethnic background, in classroom settings (Cohen 1972, 1982; Cohen and Lotan 1997; Entwisle and Webster 1972). It is important to note that this research has progressed in close association with theoretical work; thus applications and interventions have both stimulated and benefited from the development of abstract formulations.

Expectation states theory continues to generate strong interest among researchers in group processes and related areas, and to develop in several directions. For example, the refinement, expansion, and integration of various aspects of the program are currently under way. There are also some exciting new areas of research, such as the study of the relationship between status and various other factors in the assignment of task competence, namely affect (emotions and sentiments), formal authority, power, dominance, and social identity. Furthermore, the notion of an "expectation state" has been generalized from its

original reference to status-based processes, to incorporate those concerning affect and control. Finally, the research methodology has been extended to comprise a wide range of settings and tasks, including face-to-face contexts, larger groups, interactions where selected aspects of formal organizations have been re-created, vignette studies, computerized tasks, and settings where actors are not required to be collectively oriented.

For reviews and assessments of the expectation states program at various stages, see Berger (1988); Berger, Rosenholtz, and Zelditch (1980); Berger, Wagner, and Zelditch (1985, 1989); Meeker (1981); Ridgeway and Walker (1995); Wagner and Berger (1993); Webster and Foschi (1988a). For edited collections of work on various topics, see Berger, Conner, and Fisek (1974); Berger and Zelditch (1985; 1998b); Szmataka, Skvoretz, and Berger (1997); Webster and Foschi (1988b). For examples of the more recent research, see Balkwell, Berger, Webster, Nelson-Kilger, and Cashen (1992); Cohen and Zhou (1991); Foschi (1996); Foschi, Lai, and Sigerson (1994); Gerber (1996); Lovaglia and Houser (1996); Lovaglia, Lucas, Houser, Thye, and Markovsky (1998); Riches and Foddy (1989); Ridgeway (1989); Ridgeway, Boyle, Kuipers, and Robinson (1998); Ridgeway and Johnson (1990); Shelly and Webster (1997) Stewart and Moore (1992); Troyer and Younts (1997); Wagner, Ford, and Ford (1986); Webster and Whitmeyer (1999). For discussions of the program's methodological and metatheoretical assumptions, see Berger and Zelditch (1998a); Berger, Zelditch, and Anderson (1972); Cohen (1989, esp. chap. 6); Zelditch (1969).

EXPERIMENTS

Sociologists usually reserve the term *experiment* for studies in which the researcher manipulates one or more key independent variables; that is, for studies in which the experimenter controls the decision as to which subjects are exposed to what level of the independent variable. Although experiments comprise a minority of sociological research studies, they are still quite common. Laboratory versions are traditional in much of sociological social psychology (examples are Bonacich 1990; Molm 1990). Field experiments are prominent in program evaluations, particularly in applied areas such as education (e.g., Slavin and Karweit, 1985), criminal justice (e.g. Rossi et al. 1980; see also Zeisel, 1982), and even large-scale social policy efforts such as studies of a proposed guaranteed minimum income (Hannon et al. 1977). Questionnaire experiments (such as Schuman and Presser 1981) test various methodological questions, while "vignette" experiments (such as Rossi and Nock 1982) have become popular approaches to the study of attitudes.

The primary attraction of the experimental method is undoubtedly that it is more persuasive than other methods in its fit with causal arguments (Kish 1987). Campbell and Stanley, whose 1963 book is the most influential discussion of experiments for contemporary sociologists, call this "internal validity" (for other historically important discussions of experiments, see especially Cochran and Cox 1957; Fisher 1935). To them, "true" experiments are studies in which subjects are randomly allocated into "experimental" and "control" groups. The former receive a "treatment," such as an educational program, while the latter do not. Randomization allows the researcher to assume the similarity of groups at the beginning of the treatment, with known statistical chances of error, and to avoid a variety of "threats" to the validity of the conclusion that the treatment "caused" any found differences between the groups in post-treatment behavior or other outcome. In

contrast, "quasi-experiments" (most other forms of research), which do not use randomization, require a variety of additional, often heroic, assumptions in order to make causal inferences (see Lieberman 1985 for an argument that these assumptions may be generally unacceptable).

A MODEL

Consider an experiment to test the proposition that increasing the sensitivity to Hispanic cultures of non-Hispanic second-grade teachers will improve the performance of Hispanic children in their classes, particularly students with poor English-language skills. Teachers are randomly assigned to attend one of three seminars on Hispanic cultures that vary in intensity (experimental treatments) or a seminar on Asian culture (control). Following the approach of Alwin and Tessler (1974), Figure 1 presents a model of this experiment. Our proposition is tested by estimating the relationship between two "unobservable" variables—student performance in second grade (Y) and the sensitivity of their teachers (X). The variables are "unobservable" in the sense that we cannot unambiguously and directly measure the rather complex concepts we have. For example, true "student performance" probably includes facility with mathematics, language acquisition, and many other components, each of which we can measure only imperfectly. The model also contains two other variables that may be unobservable—the "Hispanic intensity" of the course (T), and the English-language skill of the student (L)—and might include a fifth unobservable variable (as indicated by the broken line), which is the student's performance in first grade (P). Including P would allow us to test for the effect of taking the seminar on *change* in student performance.

As is conventional in such models, each unobservable variable is measured by indicators (x_1, x_2, t_1 , etc.) and is affected by a stochastic term (e_x, e_T , etc.) representing our inability to measure the concept perfectly with our indicators as well. It is obvious that student performance (Y and P) would be best measured by a series of indicators such as teacher's ratings, grades in various topics, and performances on standardized tests. Since similar or identical measures of Y and P might be used, errors could be correlated, as shown by the curved line between e_{y2} and e_{p2} , thereby biasing

Figure 1

NOTE: Model based on Alwin and Tessler

results. This is why Campbell and Stanley (1963) argue in favor of generally using “post-test only” designs.

Alwin and Tessler call x_1 and x_2 “manipulation checks.” Hispanic culture seminars (T) may or may not change a given teacher’s sensitivity toward Hispanic students (X). It is even possible that Asian culture seminars make teachers more sensitive to all minorities, including Hispanics. Heckman and Smith (1995) also point out that subjects who do not get the “treatment” in field experiments can sometimes find “substitutes.” For example, the teachers assigned to Asian culture seminars might feel they also need sensitivity to Hispanic

culture and take courses in the subject voluntarily. All these possibilities point out that if we simply assume that T successfully manipulated X , we might be making a grave error. There may actually be little difference in Hispanic sensitivity (X) between experimentals and controls. We will have to check, which means that we will have to measure X .

VARIATIONS IN TREATMENT

Experimenters rarely realize that they often need to measure T as well as Y , even if T is “under their control.” If the treatment is complicated, assigning a subject to be treated does not guarantee that

he or she receives the treatment that is intended. The instructor in one of the culture seminars might do a poor job of presenting the materials. A teacher might be ill and miss one of the sessions. Most experimenters assume that the relationship between T and X is 1.0, but that is frequently, perhaps mostly, not the case. To estimate the actual effect of T on X , various “treatment checks” (t_1, t_2) would be required.

Note that a sophisticated experimental design may often require many levels of the “treatment” and even of the “control.” Or there may be no “control” at all, just comparison among different treatments. If X is conceptualized as a continuous variable, such as the intensity of the seminar (where T may be number of sessions), there is no reason to have only three levels of T . Instead, we might randomly assign each member of the treatment group to a different number of sessions from one to a whole semester (if the seminar was being offered at the university anyway). This is particularly important in something like a guaranteed income experiment, where a wide range of levels of guaranteed income are possible. We might even wish to have every family receive a different level of income support, so as to well represent the possible range and thus help us choose the best level of support for an actual program.

Furthermore, note that in our example the control group is not comprised of teachers who get no seminars at all. This is to avoid what has been commonly termed the “Hawthorne effect,” in which experimental subjects respond to the attention they get by being sent to a seminar rather than to the content (Hispanic culture) of the seminar itself. Designs that do not attend to the effects of just being treated are always subject to errors of interpretation. Of course, an even more sophisticated design might include a second control group of teachers who were not even informed that others were attending seminars (and perhaps other control groups at various levels of “intensity” of the Asian culture seminar, as well). The “no seminar” group would provide data that allow us to estimate the size of the difference in class performance between students whose teachers had attended sensitivity seminars and students in a school system with no sensitivity program at all.

The Hawthorne effect is actually only one example of a general class of problems that might

arise in interpreting found relationships (or nonrelationships) between T and Y . Smith (1990) argues that even if T does manipulate X as designed, it might also affect some additional unmeasured and perhaps untheorized variable (A) that in turn has an important effect on Y . This is particularly a problem for “real-world” experiments. For example, teachers who take the Hispanic culture seminars might be treated with more respect by their Hispanic principal, who feels closer to them. These teachers may have no greater sensitivity, but may work harder and teach better in response to the principal’s behavior. If A is not in the causal model, the effects of A on Y will be misattributed to X . Thus, some of the difficulties with nonexperimental research designs can affect complex experimental research as well.

BLOCKING

In most studies, a number of variables other than X may seem to the researcher to be probable causes of Y . Unlike A , above, these variables are both theorized and measurable. However, these variables cannot be manipulated, either because such manipulation is impossible or because it is otherwise undesirable. For example, English-language facility (L) would probably affect the performance of most second-grade students in the United States. The experimenter cannot manipulate this characteristic of the subjects. Because of randomization we expect T , and hence X , to be uncorrelated with L (see Figure 1) and with all other variables. However, sampling variation means that we might be unlucky, so that T and L are empirically correlated among the students we are actually studying. Under these conditions our estimate of the relationship between X and Y may be unbiased, but it is also less efficient than when L is controlled, because we add sampling error to other sources of error.

We can increase the efficiency of the estimate by using L as a “blocking variable,” perhaps by using their ranks on L to create matched pairs of students. We then randomly assign one of the two highest-rated students to the experimental group and the other to the controls, one of the two second-highest-rated students to the experimental group and the other to the controls, and so forth, until the lowest L pair is assigned. We thus guarantee a correlation of 0 between T and L . In our

analysis, we can statistically estimate the effects of blocked variables, such as L on Y , and reduce the variance that we attribute to “error.”

COST

Efficiency is particularly important because experiments are often very expensive. When “real life” manipulates the independent variables—for example making one person male and the other female, one born to rich parents another to poor—the researcher does not have to pay for the “treatment.” But experiments usually require the researcher to get the subject to do something, which can often be done only through pay, and then to do something to the subject, which also usually costs money. In our example, the teachers will have to be paid for their time spent going to the seminars, and so will the instructors of those seminars. These costs generally mean that experimenters very much need to keep the number of subjects they study small, which threatens the internal (and external, see below) validity of the research.

GENERALIZATION

The most frequent criticism of experiments is that their results are often difficult to generalize, a problem Campbell and Stanley (1963) call “external invalidity.” Because treatments tend to require special arrangements, the sample studied is usually restricted to some relatively “special” group, which is therefore unrepresentative (Kish 1987) of the population to whom we might like the results to apply. For example, getting students from more than one or two school systems to participate in our study is hard to imagine. Certainly a random sample from all the Hispanic students in the whole country is impossible. Yet the school system to which we have access, and within which we do the study, might be very atypical. For example, it may be a suburb whose Hispanic community is comparatively well-off. A strong relationship between X and Y might exist in a poorer community, but our study might estimate the relationship as 0. It is possible to do representative samples in experiments (see Marwell and Ames 1979), particularly those involving such things as question wording (e.g., Schuman and Presser 1981). However, such opportunities are rare.

Experiments also usually prescribe strong “control” over various extraneous conditions. To assure that they all get the identical treatment, the teachers might be brought to a tightly run seminar at the university. However, if the program were actually implemented as a regular policy by a number of school systems, many of the seminars would be taught at the schools, at various times, by various leaders, and so forth. Can one generalize from the experiment to everyday practice? As Kish (1987) points out, experiments are often necessarily weak on the *reality* of the conditions they impose on subjects.

Campbell and Stanley spend much of their time discussing the possibility that the very process of measuring the variables of interest may make the experiment unrepresentative of other situations. For example, if we measure performance in both the second (Y) and first (P) grades with the same standardized test, some students might have had their learning during the second grade affected by taking the test in the first grade. They might have become sensitized to the material asked in the early test and “learned” it more than would students in the “real world” who had not been tested. Again, the issue is whether what appear to be the effects of X on Y might not be the effects of some interaction between X and P —and therefore not be generalizable to the usual situation in the school. This is one reason Campbell and Stanley recommend using “post-test only” designs (i.e., without P) where feasible, relying on randomization to make groups equivalent.

In fact, interactions with nonmanipulated independent variables are a particular problem for experiments. For example, the sensitivity program may work only with Hispanic students who are at least second-generation Americans. First-generation Hispanics have such language problems that “sensitivity” matters much less than other skills. If our community contains only first-generation students, we may falsely assume that sensitivity training was generally worthless (Smith 1990).

CONCLUSIONS

Although recognizing the advantages of experimental studies for making causal inferences, sociologists have tended to associate experiments with

laboratory-based studies and to denigrate the possibility of generalizing from their results. A broader view of experiments sees them as serving a variety of purposes in a variety of settings, while retaining the association with causal models that makes them attractive.

One of the less recognized of these advantages is that experiments tend to force the researcher to clarify the causal model underlying his or her argument, since such theoretical clarity is necessary for the development of an effective design.

The future of experiments in sociology seems particularly uncertain at this time. On the one hand, the growth of observational and historical studies, along with the continuing influence of econometric methods and large data sets, all appear to be reserving for experiments a smaller and smaller part of the research agenda. The study of group structure and group behavior, perhaps the sociological area most suffused with experimental research, appears to be shifting out of sociological centers and journals and into business schools and publications. Technically skilled economists and sociologists such as Heckman and Smith have been rethinking the problems of experiments and have been making clearer their shortcomings, even for causal assertions.

On the other hand, work on sociological topics done in business schools, sometimes by trained sociologists, need not be interpreted as a decline in interest or activity by the field. Within sociology there has been a growth of attention to social networks, and some of the work in this area has used experiments to good effect.

The reconsideration of experiments by economists has followed a surge of interest in experimental methods by a growing number of economists, with the institutionalization of a journal called *Experimental Economics*, a book with same title (Davis and Holt 1993), and even a *Handbook of Experimental Economics* (Kagel and Roth 1991). The growth of interest by economists is largely (although not entirely) driven by the increasing willingness of government and other large funders to undertake experimental evaluations of social programs in areas such as welfare reform, education, and criminal justice. Sociologists have played a continuing and central role in these efforts, and the end of such investments does not seem in sight.

GERALD MARWELL

EXTREME INFLUENCE – THOUGHT REFORM, HIGH CONTROL GROUPS, INTERROGATION AND RECOVERED MEMORY PSYCHOTHERAPY

That social influence is ever present and pervasive is one of the most fundamental observations that may be made about social life. While we are both guided and constrained by the influence factors present at every moment in our lives, we typically fail to fully appreciate how much of an effect cultural, community, and interpersonal influences have on our values, beliefs, and choices. This is in part due to the fact that we rarely find ourselves in situations in which essentially all of the influence forces to which we are exposed are strongly organized and directed in support of a particular ideology, perception, and/or set of actions—rather we usually find ourselves in social situations in which the factors pressuring us to act in one way are offset somewhat by opposing pressures directing us toward different value positions, understandings of the world, and/or different actions. The variability and diversity of the influences to which we are exposed allow us to maintain a sense that we are the source of our choices and actions and contribute to our sense of personal autonomy, freedom of choice, and individuality.

The substantial power of community and interpersonal influence to shape perceptions and actions can most clearly be appreciated through the study of social environments in which influence factors are hyper-organized rather than relatively loosely knit together. It is through the study

of influence environments that have been consciously designed to elicit conformity, promote radical change in a person's values and beliefs, and influence an individual's choices that it is possible to gauge the extent to which our sense of personal autonomy and individuality is rooted in social organization. Four examples of environments constructed for the purpose of inducing radical and dramatic shifts in major components of persons' values or perceptions, or both, or environments designed to induce a shift on a single, but nevertheless important decision will be briefly reviewed herein—programs of thought reform or coercive persuasion (such as programs of political reeducation attempted in China under Mao); programs of indoctrination carried out by ideologically focused high control groups (groups labeled as cults and organizations that market experiences that are alleged to psychologically transform an individual); modern police interrogation tactics that, through psychological means, elicit false confessions from innocent suspects; and quack psychotherapy treatments in which patients are led to mislabel hypnotic fantasies, dreams, and hunches as "recovered memories" of lengthy histories of sexual abuse that were entirely unknown to them prior to entering treatment.

REEDUCATION PROGRAMS

Coercive persuasion and *thought reform* are alternate names for programs of social influence capable of producing substantial behavior and attitude change through the use of coercive tactics, persuasion, and/or interpersonal and group-based influence manipulations (Schein 1961; Lifton 1961). Such programs have also been labeled "brainwashing" (Hunter 1951), a term more often used in the media than in scientific literature. However identified, these programs are distinguishable from other elaborate attempts to influence behavior and attitudes, to socialize, and to accomplish social control. Their distinguishing features are their totalistic qualities (Lifton 1961), the types of influence procedures they employ, and the organization of these procedures into three distinctive subphases of the overall process (Schein 1961; Ofshe and Singer 1986). The key factors that distinguish coercive persuasion from other training and socialization schemes are (1) the reliance on intense interpersonal and psychological attack

to destabilize an individual's sense of self to promote compliance, (2) the use of an organized peer group, (3) applying interpersonal pressure to promote conformity, and (4) the manipulation of the totality of the person's social environment to stabilize behavior once modified.

Thought-reform programs can vary considerably in their construction. The first systems studied ranged from those in which confinement and physical assault were employed (Schein 1956; Lifton 1954; Lifton 1961, pp. 19–85) to applications that were carried out under nonconfined conditions, in which nonphysical coercion substituted for assault (Lifton 1961, pp. 242–273; Schein 1961, pp. 290–298). The individuals to whom these influence programs were applied were in some cases unwilling subjects (prisoner populations) and in other cases volunteers who sought to participate in what they believed might be a career-beneficial, educational experience (Lifton 1961, p. 248).

Significant differences existed between the social environments and the control mechanisms employed in the two types of programs initially studied. Their similarities, however, are of more importance in understanding their ability to influence behavior and beliefs than are their differences. They shared the utilization of coercive persuasion's key effective-influence mechanisms: a focused attack on the stability of a person's sense of self; reliance on peer group interaction; the development of interpersonal bonds between targets and their controllers and peers; and an ability to control communication among participants. Edgar Schein captured the essential similarity between the types of programs in his definition of the coercive-persuasion phenomenon. Schein noted that even for prisoners, what happened was a subjection to "unusually intense and prolonged persuasion" that they could not avoid; thus, "they were coerced into allowing themselves to be persuaded" (Schein 1961, p. 18).

Programs of both types (confined/assaultive and nonconfined/nonassaultive) cause a range of cognitive and behavioral responses. The reported cognitive responses vary from apparently rare instances, classifiable as internalized belief change (enduring change), to a frequently observed transient alteration in beliefs that appears to be *situationally adaptive* and, finally, to reactions of nothing less than firm intellectual resistance and

hostility (Lifton 1961, pp. 117–151, 399–415; Schein 1961, pp. 157–166).

The phrase *situationally adaptive belief change* refers to attitude change that is *not* stable and *is environment dependent*. This type of response to the influence pressures of coercive-persuasion programs is perhaps the most surprising of the responses that have been observed. The combination of psychological assault on the self, interpersonal pressure, and the social organization of the environment creates a situation that can only be coped with by adapting and acting so as to present oneself to others in terms of the ideology supported in the environment (see below for discussion). Eliciting the desired verbal and interactive behavior sets up conditions likely to stimulate the development of attitudes consistent with and that function to rationalize new behavior in which the individual is engaging. Models of attitude change, such as the theory of Cognitive Dissonance (Festinger 1957) or Self-Perception Theory (Bem 1972), explain the tendency for consistent attitudes to develop as a consequence of behavior.

The surprising aspect of the situationally adaptive response is that the attitudes that develop are unstable. They tend to change dramatically once the person is removed from an environment that has totalistic properties and is organized to support the adaptive attitudes. Once removed from such an environment, the person is able to interact with others who permit and encourage the expression of criticisms and doubts, which were previously stifled because of the normative rules of the reform environment (Schein 1961, p. 163; Lifton 1961, pp. 87–116, 399–415; Ofshe and Singer 1986). This pattern of change, first in one direction and then the other, dramatically highlights the profound importance of social support in the explanation of attitude change and stability. This relationship has for decades been one of the principal interests in the field of social psychology.

Statements supportive of the proffered ideology that indicate adaptive attitude change during the period of the target's involvement in the reform environment and immediately following separation should not be taken as mere playacting in reaction to necessity. Targets tend to become genuinely involved in the interaction. The reform experience focuses on genuine vulnerabilities as

the method for undermining self-concept: manipulating genuine feelings of guilt about past conduct; inducing the target to make public denunciations of his or her prior life as being unworthy; and carrying this forward through interaction with peers for whom the target develops strong bonds. Involvement developed in these ways prevents the target from maintaining both psychological distance or emotional independence from the experience.

The reaction pattern of persons who display adaptive attitude-change responses is not one of an immediate and easy rejection of the proffered ideology. This response would be expected if they had been faking their reactions as a conscious strategy to defend against the pressures to which they were exposed. Rather, they appear to be conflicted about the sentiments they developed and their reevaluation of these sentiments. This response has been observed in persons reformed under both confined/assaultive and nonconfined/nonassaultive conditions (Schein 1962, pp. 163–165; Lifton 1961, pp. 86–116, 400–401).

Self-concept and belief-related attitude change in response to closely controlled social environments have been observed in other organizational settings that, like reform programs, can be classified as total institutions (Goffman 1957). Thought-reform reactions also appear to be related to, but are far more extreme than, responses to the typically less-identity-assaultive and less-totalistic socialization programs carried out by organizations with central commitments to specifiable ideologies, and which undertake the training of social roles (e.g., in military academies and religious-indoctrination settings (Dornbush 1955; Hulme 1956).

The relatively rare instances in which belief changes are internalized and endure have been analyzed as attributable to the degree to which the acquired belief system and imposed peer relations function to fully resolve the identity crisis that is routinely precipitated during the first phase of the reform process (Schein 1961, p. 164; Lifton 1961, pp. 131–132, 400). Whatever the explanation for why some persons internalize the proffered ideology in response to the reform procedures, this extreme reaction should be recognized as both atypical and probably attributable to an interaction between long-standing personality traits and

the mechanisms of influence utilized during the reform process.

Much of the attention to reform programs was stimulated because it was suspected that a predictable and highly effective method for profoundly changing beliefs had been designed, implemented, and was in operation. These suspicions are not supported by fact. Programs identified as thought reforming are not very effective at actually changing people's beliefs in any fashion that endures apart from an elaborate supporting social context. Evaluated only on the criterion of their ability to genuinely change beliefs, the programs have to be judged abject failures and massive wastes of effort.

The programs are, however, impressive in their ability to prepare targets for integration into and long-term participation in the organizations that operate them. Rather than assuming that individual belief change is the major goal of these programs, it is perhaps more productive to view the programs as elaborate role-training regimes. That is, as resocialization programs in which targets are being prepared to conduct themselves in a fashion appropriate for the social roles they are expected to occupy following conclusion of the training process.

If identified as training programs, it is clear that the goals of such programs are to reshape behavior and that they are organized around issues of social control important to the organizations that operate the programs. Their objectives then appear to be behavioral training of the target, which result in an ability to present self, values, aspirations, and past history in a style appropriate to the ideology of the controlling organization; to train an ability to reason in terms of the ideology; and to train a willingness to accept direction from those in authority with minimum apparent resistance. Belief changes that follow from successfully coercing or inducing the person to behave in the prescribed manner can be thought of as by-products of the training experience. As attitude-change models would predict, they arise "naturally" as a result of efforts to reshape behavior (Festinger 1957; Bem 1972).

The tactical dimension most clearly distinguishing reform processes from other sorts of training programs is the reliance on psychological coercion: procedures that generate pressure to

comply as a means of escaping a punishing experience (e.g., public humiliation, sleep deprivation, guilt manipulation, etc.). Coercion differs from other influencing factors also present in thought reform, such as content-based persuasive attempts (e.g., presentation of new information, reference to authorities, etc.) or reliance on influence variables operative in all interaction (status relations, demeanor, normal assertiveness differentials, etc.). Coercion is principally utilized to gain behavioral compliance at key points and to ensure participation in activities likely to have influencing effects; that is, to engage the person in the role-training activities and in procedures likely to lead to strong emotional responses, to cognitive confusion, or to attributions to self as the source of beliefs promoted during the process.

Robert Lifton labeled the extraordinarily high degree of social control characteristic of organizations that operate reform programs as their totalistic quality (Lifton 1961). This concept refers to the mobilization of the entirety of the person's social, and often physical, environment in support of the manipulative effort. Lifton identified eight themes or properties of reform environments that contribute to their totalistic quality: (1) control of communication, (2) emotional and behavioral manipulation, (3) demands for absolute conformity to behavior prescriptions derived from the ideology, (4) obsessive demands for confession, (5) agreement that the ideology is faultless, (6) manipulation of language in which clichés substitute for analytic thought, (7) reinterpretation of human experience and emotion in terms of doctrine, and (8) classification of those not sharing the ideology as inferior and not worthy of respect (Lifton 1961, pp. 419–437, 1987).

Schein's analysis of the behavioral sequence underlying coercive persuasion separated the process into three subphases: *unfreezing*, *change*, and *refreezing* (Schein 1961, pp. 111–139). Phases differ in their principal goals and their admixtures of persuasive, influencing, and coercive tactics. Although others have described the process differently, their analyses are not inconsistent with Schein's three-phase breakdown (Lifton 1961; Farber, Harlow, and West 1956; Meerloo 1956; Sargent 1957; Ofshe and Singer 1986). Although Schein's terminology is adopted here, the descriptions of phase activities have been broadened to reflect later research.

Unfreezing is the first step in eliciting behavior and developing a belief system that facilitates the long-term management of a person. It consists of attempting to undercut a person's psychological basis for resisting demands for behavioral compliance to the routines and rituals of the reform program. The goals of unfreezing are to destabilize a person's sense of identity (i.e., to precipitate an identity crisis), to diminish confidence in prior social judgments, and to foster a sense of powerlessness, if not hopelessness. Successful destabilization induces a negative shift in global self-evaluations and increases uncertainty about one's values and position in society. It thereby reduces resistance to the new demands for compliance while increasing suggestibility.

Destabilization of identity is accomplished by bringing into play varying sets of manipulative techniques. The first programs to be studied utilized techniques such as repeatedly demonstrating the person's inability to control his or her own fate, the use of degradation ceremonies, attempts to induce reevaluation of the adequacy and/or propriety of prior conduct, and techniques designed to encourage the reemergence of latent feelings of guilt and emotional turmoil (Hinkle and Wolfe 1956; Lifton 1954, 1961; Schein 1956, 1961; Schein, Cooley, and Singer 1960). Contemporary programs have been observed to utilize far more psychologically sophisticated procedures to accomplish destabilization. These techniques are often adapted from the traditions of psychiatry, psychotherapy, hypnotherapy, and the human-potential movement, as well as from religious practice (Ofshe and Singer 1986; Lifton 1987; Singer and Lalich 1995).

The *change* phase allows the individual an opportunity to escape punishing destabilization procedures by demonstrating that he or she has learned the proffered ideology, can demonstrate an ability to interpret reality in its terms, and is willing to participate in competition with peers to demonstrate zeal through displays of commitment. In addition to study and/or formal instruction, the techniques used to facilitate learning and the skill basis that can lead to opinion change include scheduling events that have predictable influencing consequences, rewarding certain conduct, and manipulating emotions to create punishing experiences. Some of the practices designed to promote influence might include requiring the target

to assume responsibility for the progress of less-advanced “students,” to become the responsibility of those further along in the program, to assume the role of a teacher of the ideology, or to develop ever more refined and detailed confession statements that recast the person’s former life in terms of the required ideological position. Group structure is often manipulated by making rewards or punishments for an entire peer group contingent on the performance of the weakest person, requiring the group to utilize a vocabulary appropriate to the ideology, making status and privilege changes commensurate with behavioral compliance, subjecting the target to strong criticism and humiliation from peers for lack of progress, and peer monitoring for expressions of reservations or dissent. If progress is unsatisfactory, the individual can again be subjected to the punishing destabilization procedures used during unfreezing to undermine identity, to humiliate, and to provoke feelings of shame and guilt.

Refreezing denotes an attempt to promote and reinforce behavior acceptable to the controlling organization. Satisfactory performance is rewarded with social approval, status gains, and small privileges. Part of the social structure of the environment is the norm of interpreting the target’s display of the desired conduct as demonstrating the person’s progress in understanding the errors of his or her former life. The combination of reinforcing approved behavior and interpreting its symbolic meaning as demonstrating the emergence of a new individual fosters the development of an environment-specific, supposedly reborn social identity. The person is encouraged to claim this identity and is rewarded for doing so.

Lengthy participation in an appropriately constructed and managed environment fosters peer relations, an interaction history, and other behavior consistent with a public identity that incorporates approved values and opinions. Promoting the development of an interaction history in which persons engage in cooperative activity with peers that is not blatantly coerced and in which they are encouraged but not forced to make verbal claims to “truly understanding the ideology and having been transformed,” will tend to lead them to conclude that they hold beliefs consistent with their actions (i.e., to make attributions to self as the source of their behaviors). These reinforcement procedures can result in a significant degree

of cognitive confusion and an alteration in what the person takes to be his or her beliefs and attitudes while involved in the controlled environment (Bem 1972; Ofshe et al. 1974).

Continuous use of *refreezing* procedures can sustain the expression of what appears to be significant attitude change for long periods of time. Maintaining compliance with a requirement that the person display behavior signifying unreserved acceptance of an imposed ideology and gaining other forms of long-term behavioral control requires continuous effort. The person must be carefully managed, monitored, and manipulated through peer pressure, the threat or use of punishment (material, social, and emotional) and through the normative rules of the community (e.g., expectations prohibiting careers independent of the organization, prohibiting formation of independent nuclear families, prohibiting accumulation of significant personal economic resources, etc.) (Whyte 1976; Ofshe 1980; Ofshe and Singer 1986).

The rate at which a once-attained level of attitude change deteriorates depends on the type of social support the person receives over time (Schein 1961 pp. 158–166; Lifton pp. 399–415). In keeping with the *refreezing* metaphor, even when the reform process is to some degree successful at shaping behavior and attitudes, the new shape tends to be maintained only as long as temperature is appropriately controlled.

One of the essential components of the reform process in general and of long-term *refreezing* in particular is monitoring and controlling the contents of communication among persons in the managed group (Lifton 1961; Schein 1960; Ofshe et al. 1974). If successfully accomplished, communication control eliminates a person’s ability to safely express criticisms or to share private doubts and reservations. The result is to confer on the community the quality of being a spy system of the whole, upon the whole.

The typically observed complex of communication-controlling rules requires people to self-report critical thoughts to authorities or to make doubts known only in approved and readily managed settings (e.g., small groups or private counseling sessions). Admitting “negativity” leads to punishment or reindoctrination through procedures

sometimes euphemistically termed “education” or “therapy.” Individual social isolation is furthered by rules requiring peers to “help” colleagues to progress, by reporting their expressions of doubt. If it is discovered, failure to make a report is punishable, because it reflects on the low level of commitment of the person who did not “help” a colleague to make progress.

Controlling communication effectively blocks individuals from testing the appropriateness of privately held critical perceptions against the views of even their families and most-valued associates. Community norms encourage doubters to interpret lingering reservations as signs of a personal failure to comprehend the truth of the ideology; if involved with religious organizations, to interpret doubt as evidence of sinfulness or the result of demonic influences; if involved with an organization delivering a supposed psychological or medical therapy, as evidence of continuing illness and/or failure to progress in treatment.

The significance of communication control is illustrated by the collapse of a large psychotherapy organization in immediate reaction to the leadership’s loss of effective control over interpersonal communication. At a meeting of several hundred of the members of this “therapeutic community” clients were allowed to openly voice privately held reservations about their treatment and exploitation. They had been subjected to abusive practices which included assault, sexual and economic exploitation, extremes of public humiliation, and others. When members discovered the extent to which their sentiments about these practices were shared by their peers they rebelled (Ayalla 1998).

Two widespread myths have developed from misreading the early studies of thought-reforming influence systems (Zablocki 1991). These studies dealt in part with their use to elicit false confessions in the Soviet Union after the 1917 revolution; from American and United Nations forces held as POWs during the Korean War; and from their application to Western missionaries held in China following Mao’s revolution.

The first myth concerns the necessity and effectiveness of physical abuse in the reform process. The myth is that physical abuse is not only necessary but is the prime cause of apparent belief

change. Reports about the treatment of POWs and foreign prisoners in China documented that physical abuse was present. Studies of the role of assault in the promotion of attitude change and in eliciting false confessions even from U.S. servicemen revealed, however, that it was ineffective. Belief change and compliance was more likely when physical abuse was minimal or absent (Biderman 1960). Both Schein (1961) and Lifton (1961) reported that physical abuse was a minor element in the understanding of even prison reform programs in China.

In the main, efforts at resocializing China’s nationals were conducted under nonconfined/nonassaultive conditions. Millions of China’s citizens underwent reform in schools, special-training centers, factories, and neighborhood groups in which physical assault was not used as a coercive technique. One such setting for which many participants actively sought admission, the “Revolutionary University,” was classified by Lifton as the “hard core of the entire Chinese thought reform movement” (Lifton 1961, p. 248).

Attribution theories would predict that if there were differences between the power of reform programs to promote belief change in settings that were relatively more or less blatantly coercive and physically threatening, the effect would be greatest in less-coercive programs. Consistent with this expectation, Lifton concluded that reform efforts directed against Chinese citizens were “much more successful” than efforts directed against Westerners (Lifton 1961, p. 400).

A second myth concerns the purported effects of brainwashing. Media reports about thought reform’s effects far exceed the findings of scientific studies—which show coercive persuasion’s upper limit of impact to be that of inducing personal confusion and significant, but typically transitory, attitude change. Brainwashing was promoted as capable of stripping victims of their *capacity* to assert their wills, thereby rendering them unable to resist the orders of their controllers. People subjected to “brainwashing” were not merely influenced to adopt new attitudes but, according to the myth, suffered essentially an alteration in their psychiatric status from *normal* to *pathological*, while losing their capacity to decide to comply with or resist orders.

This lurid promotion of the power of thought-reforming influence techniques to change a person's capacity to resist direction is entirely without basis in fact: No evidence, scientific or otherwise, supports this proposition. No known mental disorder produces the loss of will that is alleged to be the result of brainwashing. Whatever behavior and attitude changes result from exposure to the process, they are most reasonably classified as the responses of normal individuals to a complex program of influence.

The U.S. Central Intelligence Agency seems to have taken seriously the myth about brainwashing's power to destroy the will. Due, perhaps, to concern that an enemy had perfected a method for dependably overcoming will—or perhaps in hope of being the first to develop such a method—the Agency embarked on a research program, code-named MKULTRA. It was a pathetic and tragic failure. On the one hand, it funded some innocuous and uncontroversial research projects; on the other, it funded or supervised the execution of several far-fetched, unethical, and dangerous experiments that failed completely (Marks 1979; Thomas 1989).

Although no evidence suggests that thought reform is a process capable of stripping a person of their will to resist, a relationship does exist between thought reform and changes in psychiatric status. The stress and pressure of the reform process cause some percentage of *psychological casualties*. To reduce resistance and to motivate behavior change, thought-reform procedures rely on psychological stressors, induction of high degrees of emotional distress, and on other intrinsically dangerous influence techniques (Heide and Borkovec 1983). The process has a potential to cause psychiatric injury, which is sometimes realized. The major early studies (Hinkle and Wolfe 1961; Lifton 1961; Schein 1961) reported that during the *unfreezing* phase individuals were intentionally stressed to a point at which some persons displayed symptoms of being on the brink of psychosis. Managers attempted to reduce psychological pressure when this happened, to avoid serious psychological injury to those obviously near the breaking point.

Contemporary programs speed up the reform process through the use of more psychologically

sophisticated and dangerous procedures to accomplish destabilization. In contemporary programs the process is sometimes carried forward on a large group basis, which reduces the ability of managers to detect symptoms of impending psychiatric emergencies. In addition, in some of the “therapeutic” ideologies espoused by thought-reforming organizations, extreme emotional distress is valued positively, as a sign of progress. Studies of contemporary programs have reported on a variety of psychological injuries related to the reform process. Injuries include psychosis, major depressions, manic episodes, and debilitating anxiety (Glass, Kirsch, and Parris 1977, Haaken and Adams 1983, Heide and Borkovec 1983; Higget and Murray 1983; Kirsch and Glass 1977; Yalom and Lieberman 1971; Lieberman 1987; Singer and Ofshe 1990; Singer and Lalich 1995, 1996).

HIGH CONTROL GROUPS AND LARGE GROUP AWARENESS TRAINING

Political reeducation in China was backed by the power of the state to request, if not to compel participation. Contemporary examples of the use of extreme influence that rise to the level of attempting to induce a major shift in belief typically lack the power to coerce someone into remaining involved long enough for the persuasive procedures of the program to unfreeze, change, and refreeze a person's values, perceptions, and preferences. Rather, participants must be attracted to the group and participate long enough for the tactics utilized during the unfreezing phase to destabilize the person's sense of identity so that he or she will be motivated to adopt the new world view or the new perceptions promoted by the program's managers, will desire to maintain association with committed believers in the new perspective, and will thereby obtain the long-term social support necessary to restabilize his or her identity.

Contemporary thought-reform programs are generally far more sophisticated in their selection of both destabilization and influence techniques than were the programs studied during the 1950s (Ofshe and Singer 1986; Singer and Lalich 1995, 1996). For example, hypnosis was entirely absent from the first programs studied but is often observed in modern programs. In most modern

examples in which hypnosis is present, it functions as a remarkably powerful technique for manipulating subjective experience and for intensifying emotional response. It provides a method for influencing people to imagine impossible events such as those that supposedly occurred in their "past lives," the future, or during visits to other planets. If persons so manipulated misidentify the hypnotically induced fantasies, and classify them as previously unavailable memories, their confidence in the content of a particular ideology can be increased (Bainbridge and Stark 1980).

Hypnosis can also be used to lead people to allow themselves to relive actual traumatic life events (e.g., rape, childhood sexual abuse, near-death experiences, etc.) or to fantasize the existence of such events and, thereby, stimulate the experience of extreme emotional distress. When imbedded in a reform program, repeatedly leading the person to experience such events can function simply as punishment, useful for coercing compliance.

Accounts of contemporary programs also describe the use of sophisticated techniques intended to strip away psychological defenses, to induce regression to primitive levels of coping, and to flood targets with powerful emotion (Ayalla 1998; Haaken and Adams 1983; Hockman 1984; Temerlin and Temerlin 1982; Singer and Lalich 1996). In some instances stress and fatigue have been used to promote hallucinatory experiences that are defined as therapeutic (Gerstel 1982). Drugs have been used to facilitate disinhibition and heightened suggestibility (Watkins 1980). Thought-reform subjects have been punished for disobedience by being ordered to self-inflict severe pain, justified by the claim that the result will be therapeutic (Bellack et al. *v.* Murietta Foundation et al.).

Programs attempting thought reform appear in various forms in contemporary society. They depend on the voluntary initial participation of targets. This is usually accomplished because the target assumes that there is a common goal that unites him or her with the organization or that involvement will confer some benefit (e.g., relief of symptoms, personal growth, spiritual development, etc.). Apparently some programs were developed based on the assumption that they could be used to facilitate desirable changes (e.g., certain

rehabilitation or psychotherapy programs). Some religious organizations and social movements utilize them for recruitment purposes. Some commercial organizations utilize them as methods for promoting sales. In some instances, reform programs appear to have been operated for the sole purpose of gaining a high degree of control over individuals to facilitate their exploitation (Ofshe 1986; McGuire and Norton 1988; Watkins 1980).

Virtually any acknowledged expertise or authority can serve as a power base to develop the social structure necessary to carry out thought reform. In the course of developing a new form of rehabilitation, psychotherapy, religious organization, utopian community, school, or sales organization, it is not difficult to justify the introduction of thought-reform procedures.

Perhaps the most famous example of a thought-reforming program developed for the ostensible purpose of rehabilitation was Synanon, a drug-treatment program (Sarbin and Adler 1970, Yablonsky 1965; Ofshe et al. 1974). The Synanon environment possessed all of Lifton's eight themes. It used as its principle coercive procedure a highly aggressive encounter/therapy group interaction. In form it resembled "struggle groups" observed in China (Whyte 1976), but it differed in content. Individuals were vilified and humiliated not for past political behavior but for current conduct as well as far more psychologically intimate subjects, such as early childhood experiences, sexual experiences, degrading experiences as adults, etc. The coercive power of the group experience to affect behavior was substantial as was its ability to induce psychological injury (Lieberman, Yalom, and Miles 1973; Ofshe et al. 1974).

Allegedly started as a drug-rehabilitation program, Synanon failed to accomplish significant long-term rehabilitation. Eventually, Synanon's leader, Charles Diederich, promoted the idea that any degree of drug abuse was incurable and that persons so afflicted needed to spend their lives in the Synanon community. Synanon's influence program was successful in convincing many that this was so. Under Diederich's direction, Synanon evolved from an organization that espoused non-violence into one that was violent. Its soldiers were dispatched to assault and attempt to murder persons identified by Diederich as Synanon's enemies (Mitchell, Mitchell, and Ofshe 1981).

The manipulative techniques of self-styled messiahs, such as People's Temple leader Jim Jones (Reiterman 1982), and influence programs operated by religious organizations, such as the Unification Church (Taylor 1978) and Scientology (Wallis 1977; Bainbridge and Stark 1980), can be analyzed as thought-reform programs. The most controversial recruitment system operated by a religious organization in recent American history was that of the Northern California branch of the Unification Church (Reverend Moon's organization). The influence program was built directly from procedures of psychological manipulation that were commonplace in the human-potential movement (Bromley and Shupe 1981). The procedures involved various group-based exercises as well as events designed to elicit from participants information about their emotional needs and vulnerabilities. Blended into this program was content intended to slowly introduce the newcomer to the group's ideology. Typically, the program's connection with the Unification Church or any religious mission was denied during the early stages of the reform process. The target was monitored around the clock and prevented from communicating with peers who might reinforce doubt and support a desire to leave. The physical setting was an isolated rural facility far from public transportation.

Initial focus on personal failures, guilt-laden memories, and unfulfilled aspirations shifted to the opportunity to realize infantile desires and idealistic goals, by affiliating with the group and its mission to save the world. The person was encouraged to develop strong affective bonds with current members. They showed unflinching interest, affection, and concern, sometimes to the point of spoon-feeding the person's meals and accompanying the individual everywhere, including to the toilet. If the *unfreezing* and *change* phases of the program succeeded, the individual was told of the group's affiliation with the Unification Church and assigned to another unit of the organization within which *refreezing* procedures could be carried forward.

POLICE INTERROGATION AND FALSE CONFESSIONS

Police interrogation in America was transformed in the twentieth century from a method of gaining

compliance relying largely on physical coercion into one that relies almost exclusively on psychological means (Leo 1992). Psychological methods of interrogation were developed to influence persons who know they are guilty of a crime to change their decision to deny guilt, to admit responsibility for the crime, and to confess fully to their role in the crime (see Hilgendorf and Irving 1981; Ofshe and Leo 1997a,b). Compared to the other extreme influence environments described in this entry, a police interrogation is of relatively short duration and is entirely focused on the single issue of eliciting a confession. It is nevertheless an environment in which a person can be influenced to make a dramatic shift in position—from denial of guilt to confession.

The techniques and tactics that lead a guilty suspect to admit guilt constitute an impressive display of the power of influence to change a person's decision even when the consequence of the shift is obviously disadvantageous. If the procedures of interrogation are misused, modern interrogation methods can have an even more impressive result. If the influence procedures and techniques of modern interrogation methods are directed at innocent persons, some false confessions will result (Bedau and Radelet 1987; Leo and Ofshe 1998). In most instances when an innocent person is led to give a false confession the cause is coercion—the use of a threat of severe punishment if the person maintains that he is innocent and an offer of leniency if he complies with the interrogator's demand to confess. Most persons who decide to comply and offer a false confession in response to coercion remain certain of their innocence and know that they are falsely confessing in order to avoid the most severe possible punishment.

Under some circumstances, however, interrogation tactics can cause an innocent person to give what is called a persuaded false confession—a false confession that is believed to be true when it is given. Influence procedures now commonly used during modern police interrogation can sometimes inadvertently manipulate innocent persons' beliefs about their own innocence and, thereby, cause them to falsely confess. Confessions resulting from accomplishing the *unfreezing* and *change* phases of thought reform are classified as persuaded false confessions (Kassin and Wrightsman 1985;

Gudjonsson and MacKeith 1988; Ofshe and Leo 1997a). Although they rarely come together simultaneously, the ingredients necessary to elicit a temporarily believed false confession are: erroneous police suspicion, the use of *certain* commonly employed interrogation procedures, and some degree of psychological vulnerability in the suspect. Philip Zimbardo (1971) has reviewed the coercive factors generally present in modern interrogation settings. Richard Ofshe and Richard Leo (1989, 1997a) have identified those influence procedures that if present in a suspect's interrogation contribute to causing *unfreezing* and *change*.

Techniques that contribute to *unfreezing* include falsely telling a suspect that the police have evidence proving the person's guilt (e.g., fingerprints, eyewitness testimony, etc.). Suspects may be given a polygraph examination and then falsely told (due either to error or design) that they failed and the test reveals their unconscious knowledge of guilt. Suspects may be told that their lack of memory of the crime was caused by an alcohol- or drug-induced blackout, was repressed, or is explained because the individual is a multiple personality.

The techniques listed above regularly appear in modern American police interrogations. They are used to lead persons who know that they have committed the crime at issue to decide that the police have sufficient evidence to convict them or to counter typical objections to admitting guilt (e.g., "I can't remember having done that."). In conjunction with the other disorienting and distressing elements of a modern accusatory interrogation, these tactics can sometimes lead innocent suspects to doubt themselves and question their lack of knowledge of the crime. If innocent persons subjected to these sorts of influence techniques do not reject the false evidence and realize that the interrogators are lying to them, they have no choice but to doubt their memories. If the interrogator supplies an explanation for why the suspect's memory is untrustworthy, the person may reason that "I must have committed this crime."

Tactics used to *change* the suspect's position and elicit a confession include maneuvers designed to intensify feelings of guilt and emotional distress following from the suspect's assumption of guilt.

Suspects may be offered an escape from the emotional distress through confession. It may also be suggested that confession will provide evidence of remorse that will benefit the suspect in court.

RECOVERED MEMORY PSYCHOTHERAPY

The shifts in belief and conduct promoted during political reeducation concern an intellectual analysis of society and one's role in it; in the context of high control groups the beliefs are about theology and one's role in a community; and in police interrogation the newly created beliefs concern a crime the suspect has no knowledge of having committed. The progression in these illustrations is from influence efforts directed at an intellectual or philosophical assumption to that of an influence effort directed at changing beliefs about a single fact—Did the suspect commit a crime and not know of it due to a memory defect? The final example of extreme influence and belief change is arguably the most dramatic example of the power of interpersonal influence and particular influence techniques to change a person's beliefs about the historical truth relating to a major dimension of his or her life history, such as whether or not he or she had been viciously raped and horribly brutalized by a parent (or parents, or siblings, or teachers, or neighbors, etc.) for periods of as long as two decades.

Psychotherapy directed at causing a patient to retrieve allegedly repressed and therefore supposedly unavailable memories (e.g., of sexual abuse, and/or having spent one's life suffering from an unrecognized multiple personality disorder, and/or having spent one's childhood and teenage years as a member of a murderous satanic cult) is one of the most stunning examples of psychological/psychiatric quackery of the twentieth century. It is also perhaps the most potent example of the power of social influence to predictably create beliefs (in this case beliefs that are utterly false) and thereby alter a person's choices and conduct (Loftus 1994; Perdergrast 1995; Ofshe and Watters 1994; Spanos 1996).

The elements of a thought-reforming process are visible in the steps through which a patient undergoing recovered memory therapy is manipulated. The patient's identity is destabilized by the therapist's insistence that the reason for the patient's distress or mental illness is that she or he

suffered a series of sexual traumas in childhood that he or she don't know about because he or she has *repressed* them. Recovered memory therapists organize their treatment programs on the presumption that repression exists despite the fact that the notion of repression was never more than a fanciful, unsubstantiated speculation that was long ago rejected as useless by the scientific community that studies human memory (Loftus 1994; Crews 1998; Watters and Ofshe 1999). Recovered memory therapists rely on assertions of authority, claims of expertise, and outright trickery (e.g., inducing the patient to experience hypnotic fantasies of sexual abuse that they lead patients to misclassify as memories and interpreting the patient's dreams as proof that they suffer from repressed memories) to convince the patient of the existence of repression. Recovered memory therapists rely on the alleged "repression mechanism" to undermine patients' confidence in their normal memories of their lives. If patients can be successfully convinced that repression exists and that the hypnotic fantasies that the therapist suggests to them are memories of events that happened during their lives, they can no longer trust that they know even the broad outlines of their life histories.

Once the patient's identity has been destabilized, the therapist guides the patients to build a new identity centered on his or her status as victim of sexual abuse. This victim role may include requiring the patient to learn to act as if she or he suffers from multiple personality disorder, or suggesting that the patient publicly denounce, sue, or file criminal charges against the persons who supposedly abused them.

CONCLUSION

Extreme influence environments are not easy to study. The history of research on extreme influence has been one in which most of the basic descriptive work has been conducted through post-hoc interviewing of persons exposed to the influence procedures. The second-most frequently employed method has been that of participant observation. In connection with work being done on police interrogation methods, it has been possible to analyze contemporaneous recordings of interrogation sessions in which targets' beliefs are actually made to undergo radical change. All this work

has contributed to the development of an understanding in several ways.

Studying these environments demonstrates that the extremes of influence are no more or less difficult to understand than any other complex social event. The characteristics that distinguish extreme influence environments from other examples of social settings are influence in the order in which the influence procedures are assembled and the degree to which the target's environment is manipulated in the service of social control. These are at most unusual arrangements of commonplace bits and pieces.

As it is with all complex, real-world social phenomena that cannot be studied experimentally, understanding information about the thought-reform process proceeds through the application of theories that have been independently developed. Explaining data that describe the type and organization of the influence procedures that constitute an extreme influence environment depends on applying established social-psychological theories about the manipulation of behavior and attitude change. Assessing reports about the impact of the experiences on the persons subjected to intense influence procedures depends on the application of current theories of personality formation and change. Understanding instances in which the thought-reform experience appears related to psychiatric injury requires proceeding as one would ordinarily in evaluating any case history of a stress-related or other type of psychological injury.

FACTOR ANALYSIS

Factor analysis is a mathematical and statistical technique for analyzing differences among units of analysis and the structure of relationships among variables assessing those units. The units of analysis may be persons, groups, organizations, ecological units, or any other justifiable basis of aggregation although persons are most often the focus of analysis. The chief purpose of the method is the attainment of scientific parsimony, which is achieved by positing a set of latent common factors that underlie the data. The factor model was developed by Charles Spearman (1904a, 1927) to be used to describe economically the correlations among mental test scores observed for persons. Spearman's famous bi-factor model of intelligence held that measures of mental abilities had two major sources: a factor common to all measures of ability, which he called the *g*-factor (factor of general ability), and a specific component of variation (an *s*-factor) unique to the test. For example, a test of numerical ability may be affected in part by a general factor of intelligence as well as a factor specific to numerical aptitude. This model, although never the predominant psychological theory of mental tests, has persisted in the culture in the sense that people often believe there is a general factor of intelligence underlying performance across different domains (see Gould 1981 for a critique of this view).

Although Spearman's work did not go very far beyond such a simple model, his approach to model construction and theory testing using tetrad

differences has provided the basis for much further work (see, e.g., Glymour et al. 1987). Many contemporaries of Spearman—Cyril Burt, Karl Pearson, Godfrey Thomson, J. C. Maxwell Garnett, and others—working in the fields of human abilities and statistics also contributed to the development of factor analysis. Several worked to modify Spearman's bi-factor model to include multiple factors of intelligence. But the most radical departure from the *g*-factor view of human intelligence came with Thurstone's (1938) publication of *Primary Mental Abilities*, in which he demonstrated empirically through the application of *multiple factor analysis* that several common factors were necessary to explain correlations among measures of human abilities. While Thurstone (1947) is usually credited with the popularization of this more general technique, the concept of multiple factor analysis first arose in the work of Garnett (1919–1920; see Harmon 1976).

Multiple factor analysis proved to be a major advance over the Spearman model, which was later to be seen as a special case (the one-factor case). Multiple factor analysis permitted a general solution to the possibility of positing multiple factors (*k*) in a set of variables (*p*). Within this framework, two competing research strategies emerged, each resting on distinct principles. One was based on Pearson's principle of *principal axes*, which was later developed by Hotelling (1933) as the method of *principal components*. This approach emphasized the objective of “extracting” a maximum of variance from the set of *p* variables so that the *k* factors explained as much of the variance in

the variables as they could. This tradition still exists in approaches to factor analysis that rely on principal components analysis, and, although many researchers use the technique, they are likely to be unaware of the objectives underlying the approach (see Harman 1976).

In contrast to the strategy of maximizing the variance explained in the variables, the other basic strategy—more squarely in the tradition of Spearman—emphasized the objective of reproducing the observed correlations among the variables. These two objectives—one emphasizing the extraction of maximum variance in the variables and the other emphasizing the fit to the correlations among the variables—eventually became the object of serious debate. However, with time there has emerged a consensus that the “debate” between these approaches rested on a misconception. The method of principal axes, which is the basis of principal components analysis—involving the analysis of a correlation matrix with unities in the diagonal—is now better understood as a computational method and not a model, as the factor analysis approach is now considered (see Maxwell 1977).

The early developments in the field of factor analysis and related techniques were carried out primarily by psychometricians. These early developments were followed by many important contributions to estimation, computation, and model construction during the post-World War II period. Some of the most important contributions to the method during the 1950s were made by a sociologist, Louis Guttman. Guttman made important contributions to the resolution of the issue of deciding upon the best number of latent factors (Guttman 1954), the problem of “factor indeterminacy” (Guttman 1955), and the problem of estimating communalities (Guttman 1956), among many others. Guttman (1960) also invented yet a third model, called *image analysis*, which has a certain elegance but is rarely used (see Harris 1964; Kaiser 1963).

Research workers in many fields made contributions to the problem of deciding how best to represent a particular factor model in a theoretical/geometrical space, via the transformation or rotation of factors. Methods of rotation included the quartimax (Neuhaus and Wrigley 1954), varimax (Kaiser 1958), and oblimax (Harman 1976), among

others. Several contributions were made during the early development of factor analysis with respect to the most useful strategies for estimating factor scores (see reviews by Harris 1967 and McDonald and Burr 1967) and for dealing with the problem of assessing factorial invariance (e.g., Meredith 1964a, 1964b; Mulaik 1972). Beginning in the mid-1960s the advances in the field of factor analysis have focused on the development of maximum-likelihood estimation techniques (Lawley and Maxwell 1971; Jöreskog 1967; Jöreskog and Lawley 1968); alternative distribution-free techniques (Bentler 1983, 1989; Bentler and Weeks 1980; Browne 1974, 1984; Browne and Shapiro 1988); the development of confirmatory factor analysis, which permits the setting of specific model constraints on the data to be analyzed (Bentler 1989; Jöreskog 1966, 1967, 1970, 1971a, 1973; Jöreskog and Sörbom 1986); and the development of factor analysis strategies for categorical variables (Christofferson 1975; Jöreskog and Sörbom 1988; Muthén 1983, 1988).

Factor analysis is used extensively by sociologists as a research tool. It is used in at least four related ways. *First*, it is frequently used as a data reduction or item analysis technique in index construction. *Second*, it is used as an exploratory device for examining the dimensional structure of content within a well-specified domain. *Third*, it is used as a confirmatory, hypothesis-testing tool aimed at testing prior hypotheses about the dimensional structure of a set of variables. And *fourth*, it is used to conceptualize the relationships of multiple indicators of latent variables in a causal modeling framework in which a factor model is assumed for the relationships between latent variables and their indicators. After a brief introduction to each of these four ways in which factor analytic tools are used in sociological research, this discussion covers the basic factor model and issues that arise in its application, either in the *exploratory* or *confirmatory* frameworks of analysis.

DATA REDUCTION APPROACHES

When a researcher wishes to build a composite score from a set of empirical variables, factor analysis and related techniques are often useful. Indeed, it is perhaps in this area of “index construction” that factor analysis is most often used by sociologists. There are various related data

reduction approaches that fall under the heading of “dimensional analysis” or “cluster analysis,” but the basic goal of all these techniques is to perform some decomposition of the data into sets of variables, each of which is relatively independent and homogeneous in content. When factor analysis is used in this way the researcher is essentially interested in determining the sets of linear dependence among a set of variables that are intended to measure the same general domain of content. The factor analysis of such variables may proceed in a number of different ways, but the basic goal is to determine the number of clusters of homogeneous content and the extent of relationship among various clusters or factors. Relationships among factors may be conceptualized either in terms of uncorrelated (or orthogonal) sets of factors or in terms of correlated (or oblique) factors. Such analyses are often supplemented with information on how to build “factor scores,” with item-analysis information, such as item-to-total score correlations, and with information estimating the “internal consistency” or “reliability” of such composite scores (see Greene and Carmines 1979; Maxwell 1971).

When using factor analysis and related techniques as a basis for index construction, one of two situations is typically the case. Either the investigator has some a priori basis for expecting that items in a set have a common factor (or common factors) underlying them, and therefore the investigator has certain well-founded expectations that the items can be combined into a scale, *or* the investigator has no a priori set of hypotheses for what clusters will be found and is willing to let the inherent properties of the data themselves determine the set of clusters. In the first case confirmatory factor models are appropriate, whereas in the second case exploratory methods are mandated. In either case the use of factor analysis as a data reduction tool is aimed at the development and construction of a set of “scores,” based on factor analysis, that can then be introduced as variables in research.

Exploratory Factor Analysis. As noted above, in situations where the researcher has no a priori expectations of the number of factors or the nature of the pattern of loadings of variables on factors, we normally refer to applications of factor analysis as exploratory. In the case of exploratory factor analysis the goal is to find a set of k latent

dimensions that will best reproduce the correlations among the set of p observed variables. It is usually desirable that k be considerably less than p and as small as possible. In exploratory factor analysis one typically does not have a clear idea of the number of factors but instead begins with uncertainty about what the data will reveal. The most common practice is to find k orthogonal (uncorrelated) dimensions that will best reproduce the correlations among the variables, but there is nothing intrinsic to the factor analytic model that restricts the conceptual domain to several orthogonal dimensions.

Confirmatory Factor Analysis. Confirmatory factor analysis, in contrast, refers to situations in which the investigator wishes to test some hypotheses regarding the structure of relationships in the presence of a strong set of assumptions about the number of factors, the values of the factor pattern coefficients, the presence or absence of correlations of factors, or other aspects of the model. In confirmatory factor analysis it is essential that one begin with a theory that contains enough detailed specification regarding constraints that should be imposed on the data in order to provide such a test, whereas in exploratory factor analysis there is no requirement that one specify the number of factors and expected relationships to be predicted in the data. Confirmatory approaches are thus more theory-driven, whereas exploratory approaches are more data-driven (see Alwin 1990). However, much of the so-called confirmatory factor analysis that is carried out in modern social and behavioral science is in fact exploratory, and much current research would be more realistically appraised if such confusion did not exist. Often, there is considerable tinkering with “confirmatory” models in order to improve their fit to the data, either by removing variables or by loosening up (or “freeing”) certain parameters. It is also often the case that the “confirmatory” factor analyses are actually preceded by an exploratory analysis, and then a confirmatory model based on these results is fit to the same data. Although very common, this approach “capitalizes” on chance and gives an illusory sense that one has confirmed (or verified) a particular model. Placed in the proper perspective, there is nothing in principal wrong with the approach, as long as the “test” of the model is cross-validated in other data.

FACTOR ANALYSIS AND MULTIPLE INDICATOR CAUSAL MODELS

In the 1960s and 1970s, with the introduction of causal modeling strategies in social science (see Blalock 1964; Duncan 1966, 1975; Heise 1968), a fundamental shift occurred in the nature and uses of the common factor models by sociologists. Methods and the logic of causal modeling with nonexperimental statistical designs had been around for a long time. Due largely to the influence of Lazarsfeld (1968), causal inference strategies had been prevalent especially among analysts of sample survey data since the 1940s, but the research strategies were based on tabular presentation of data and the calculation of percentage differences. In the early 1960s there was a general infusion of techniques of causal modeling in sociology and other social science disciplines. Path analysis, principal of these newly adopted techniques, of course, was invented before 1920 by the great geneticist Sewall Wright, but his contributions were not appreciated by social and behavioral scientists, including the psychometricians responsible for the development of factor analysis. Wright (1921) developed path models as *deductive* systems for deriving correlations of genetic traits among relatives of stated degree. He also used the method inductively to model complex economic and social processes using correlational data (Wright 1925).

Psychometricians, like Spearman, had been dealing with models that could be thought of as “causal models,” which could be understood in Wright’s path analysis framework—common factors were viewed as the causes underlying the observed variables—but Spearman and others who developed common factor models were unfamiliar with Wright’s work. None of the early psychometricians apparently recognized the possibility of causal relationships among the latent variables of their models, or for that matter among their indicators. However, with the publication of work by Jöreskog (1970) and others working in the “new” field of *structural equation models* (see Goldberger 1971, 1972; Goldberger and Duncan 1973; Hauser and Goldberger 1971); the convergence and integration of linear models in the path analysis tradition and those in the factor analysis tradition provided a basic “breakthrough” in one of the major analytic paradigms most prevalent in social science. These developments were assisted by the interest in conceptualizing measurement

errors within a causal analysis framework. A number of researchers began to incorporate conceptions of measurement error into their causal analyses (Alwin 1973a, 1974; Blalock 1965, 1969, 1970; Costner 1969; Duncan 1972; Heise 1969; Siegel and Hodge 1968), ushering in a new approach that essentially combined factor models and path models.

At about this same time, Karl Jöreskog and his colleagues were developing efficient procedures for estimating the parameters of such models—called LISREL models, named after Jöreskog and his colleagues’ computer program, LISREL—and this provided a major impetus for the widespread use of confirmatory approaches to the estimation of structural equation models. Jöreskog’s (1967) early contributions to maximum-likelihood factor analysis became readily applied by even the most novice of analysts. Unfortunately, the widespread availability of these techniques to researchers who do not understand them has led to serious risks of abuse. This can be true of any technique, including the techniques of exploratory factor analysis. In any event, the proper use and interpretation of the results of LISREL-type model estimation is a significant challenge to the present generation of data analysts.

THE COMMON FACTOR MODEL

The formal mathematical properties of the common factor model are well known and can be found in many of the accompanying references. It is useful for purposes of exposition briefly to review its salient features. Although the model can be most compactly represented using vector and matrix notation, it is normally best to begin with a scalar representation for the data, such as in equation 1.

$$\begin{aligned}
 z_1 &= a_{11}f_1 + a_{12}f_2 + \dots + a_{1k}f_k + u_1 \\
 z_2 &= a_{21}f_1 + a_{22}f_2 + \dots + a_{2k}f_k + u_2 \\
 &\dots \\
 z_p &= a_{p1}f_1 + a_{p2}f_2 + \dots + a_{pk}f_k + u_p
 \end{aligned}
 \tag{1}$$

Here the z variables are empirical quantities observed in a sample of units of observation (e.g., persons, groups, ecological units), and for present purposes the variables are standardized to have a mean of zero and standard deviation of unity. This

scaling is not a requirement of the model. In fact, in confirmatory factor models, it is often desirable to leave the variables in their original metric, especially when comparing the properties of these models across populations or subpopulations (see Alwin 1988b).

According to the common factor model, each observed z variable is, then, a linear function of a set of k latent or unobserved variables and a residual variable, ui , (also unobserved), which contains variation specific to that particular variable and random measurement error. The a coefficients in equation 1 are “factor loadings.” They reflect the linkage between the “observed” variables and the “unobserved” factors. In the case of uncorrelated factor these loadings equal the correlations of the variables with the factors. The loadings thus provide a basis for interpreting the factors in the model; factors obtain their meaning from the variables to which they are linked and vice versa. Thus, in many investigations the primary objective is to estimate the magnitudes of these factor loadings in order to obtain a meaningful understanding of the nature of the data.

The k latent variables are called *common* factors because they represent common sources of variation in the observed variables. As such, these common factors are thought to be responsible for covariation among the variables. The unique parts of the variables, by contrast, contribute to lack of covariation among the variables. Covariation among the variables is greater when they measure the same factors, whereas covariation is less when the unique parts of the variables dominate. Indeed, this is the essence of the model–variables correlate because they measure the same things. This was the basis of Spearman’s original reasoning about the correlations among tests of mental ability. Those tests correlated *because* they measured the same general factor. In the general case those variables that correlate do so because of their multiple sources of common variation.

Common variation in the aggregate is referred to as *communality*. More precisely, a variable’s communality is the proportion of its total variation that is due to its common sources of variation. The communality of variable i is denoted h^2_i . A variable’s *uniqueness*, denoted u^2_i , is the complement of the communality; that is, $u^2_i = 1.0 - h^2_i$. The

uniqueness is thought of as being composed of two independent parts, one representing *specific* variation and one representing *random measurement error* variation; that is, $u^2_i = s^2_i + e^2_i$. (This notation follows traditional psychometric factor analysis notation. Each of these quantities is a variance, and, thus, in the covariance modeling or structural equation modeling tradition these quantities would be represented as variances, such that $\sigma^2_{ui} = \sigma^2_{ii} + \sigma^2_{ei}$ [see below].) Specific variance is *reliable* variance, and thus the reliability of variable i can be expressed as $r^2_i = h^2_i + s^2_i$. Unfortunately, because of the presence of specific variance in most variables, it is virtually impossible to use the traditional form of the common factor model as a basis for reliability estimation (see Alwin 1989; Alwin and Jackson 1979). The problem is that the common factor model typically does not permit the partitioning of u^2_i into its components, s^2_i and e^2_i . In the absence of specific variance, classical reliability models may be viewed as a special case of the common factor model, but in general it is risky to assume that $e^2_i = u^2_i$. Alwin and Jackson (1979) discuss this issue in detail. Some attempts have been made to augment the traditional latent “trait” model inherent in the common factor model by adding “method” factors based on the *multitrait–multimethod* design of measurement within the framework of confirmatory factor models (see Alwin 1974; Alwin and Jackson 1979; Werts and Linn 1970). This provides a partitioning of the specific variance due to method, but it does not provide a general solution to the problem of handling specific variance.

Returning to the above example (in equation 1), in Spearman’s case (the one-factor case) each variable contains a common factor and a specific factor, as shown in equation 2.

$$\begin{aligned} z_1 &= a_{11}f_1 + s_1 \\ z_2 &= a_{21}f_1 + s_2 \\ &\dots \\ z_p &= a_{p1}f_1 + s_p \end{aligned} \tag{2}$$

In this case $h^2_i = a^2_i$ and $u^2_i = s^2_i$. Spearman’s (1927) theory in essence assumes perfect measurement, not unlike most common factor models. However, unlike researchers of today, Spearman was very

concerned about measurement errors, and he went to great lengths to correct his observed correlations for imperfections due to random errors of measurement (Spearman 1904b). Thus, when applied to such corrected correlational data, these assumptions may be appropriate.

As can be seen from the equations for Spearman's model (equation 2), the correlations among variables z_i , and z_j , $r_{ij} = E[z_i z_j]$ (the expected value of the cross-products of the z scores for the two variables) may be written as $r_{ij} = a_i a_j$. For example, if $p = 3$, the correlations among the variables can be written as $r_{12} = a_1 a_2$, $r_{13} = a_1 a_3$, and $r_{23} = a_2 a_3$. In vector notation (introduced in greater detail below), the common parts of the correlations among the variables of the model are composed of the matrix product AA' . In the case where $p = 3$, the matrix A is written as in equation 3,

$$\begin{bmatrix} a_1 \\ a_2 \\ a_3 \end{bmatrix} \tag{3}$$

and the product AA' is written as in equation 4.

$$\begin{bmatrix} a_1 a_1 & a_1 a_2 & a_1 a_3 \\ a_2 a_1 & a_2 a_2 & a_2 a_3 \\ a_3 a_1 & a_3 a_2 & a_3 a_3 \end{bmatrix} \tag{4}$$

The variances of the variables are also affected by the common factors, but, as indicated in the foregoing, there is a residual portion of variance containing specific and unreliable variance. In Spearman's model the variance of variables i is as shown in equation 5.

$$\begin{aligned} \sigma_{z_i}^2 &= 1.0 = a_i^2 + \sigma_{u_i}^2 \\ &= a_i^2 + \sigma_{s_i}^2 + \sigma_{e_i}^2 \end{aligned} \tag{5}$$

Then it can be seen that the correlation matrix is equal to $R = AA' + U^2$, where the matrix U^2 for the $p = 3$ case is written in matrix form as in equation 6.

$$\begin{bmatrix} \sigma_{u_1}^2 & 0 & 0 \\ 0 & \sigma_{u_2}^2 & 0 \\ 0 & 0 & \sigma_{u_3}^2 \end{bmatrix} \tag{6}$$

These results have general applicability, as will be seen below.

ESTIMATION AND TESTING OF THE FACTOR MODEL

Before proceeding to the more general uses of the model, it is important to review the logic behind Spearman's approach. In the general Spearman case, the correlation of two variables is equal to the product of their loadings on the general factor; that is, $r_{ij} = a_i a_j$. Recall that under this model the a coefficients represent the correlations of the variables with the factor. Spearman reasoned therefore that if the model were true (that is, if a single unobserved common factor could account for the correlations among the observed variables), then certain things had to hold in the empirical data.

Spearman reasoned that, if the single factor model holds, the partial correlation between any two variables, holding constant the underlying common factor, $r_{ij \cdot f}$ should be zero. This stems from the fact that the numerator of this partial correlation, $r_{ij} - r_{if} r_{jf}$, is zero, because *under the model* $r_{ij} - a_i a_j = a_i a_j - a_i a_j = 0$. Of course, it is not possible to calculate such a partial correlation from the data because the factor score, f , does not exist except in the theory. Spearman, however, recognized a specific pattern to the components of the correlations *under the model*. He noted that, if the single factor model held for $p = 4$, the intercorrelations of the variables had to satisfy two independent conditions, referred to by Spearman (1927) as *vanishing tetrads*, shown in equation 7.

$$\begin{aligned} r_{12} r_{34} - r_{14} r_{23} &= 0 \\ r_{13} r_{24} - r_{14} r_{23} &= 0 \end{aligned} \tag{7}$$

Note that the case of $p = 3$ is a trivial case, since a one-factor model can always be used to describe the intercorrelations among three variables. For $p = 5$ there are $[p(p - 1)(p - 2)(p - 3)]/8$ different tetrads (see Harman 1976), which equals fifteen. Not all of the possible tetrad differences formed from these fifteen are independent, and for one factor to explain the correlations, there are $p(p - 3)/2$ independent tetrad differences. Thus, in the case of five variables there are five tetrad differences that must vanish, and for six there are nine, and so forth.

Although in recent years there has been a revival of interest in Spearman's vanishing tetrads for sets of four variables (Glymour et al. 1987), at

the time he developed this logic there was little that could be done computationally with very large problems. Thurstone (1947) developed the *centroid* method as an approximation to the principal axes approach involved in Spearman's early work, which was in common use during the 1940s and 1950s, but with the development of the high-speed computer, principal axes methods became (and remain) quite common in many applications of the model.

In exploratory factor analysis, where the number of factors of the model is not known beforehand, estimation is carried out by way of an eigenvalue/eigen-vector decomposition of some matrix, either R or some estimate of $R - U^2$. There is a wide variety of types of factor analyses that can be done—principal component factor analysis (which analyzes the p first nonzero components of R), communality-based factor analysis (which analyzes R with a communality estimate in the diagonal), alpha factor analysis, canonical factor analysis, or image analysis (see Harris 1963, 1964). Few developments have been made in these approaches since the 1960s, although there continues to be considerable debate about the desirable properties of these various approaches (e.g., see Widaman 1991).

Perhaps the most important development affecting exploratory factor analysis since the 1960s has been the development of maximum-likelihood factor analysis. Maximum-likelihood estimation, however, requires the prior estimate of the number of factors. These methods are most often discussed in connection with confirmatory factor analysis, although the approach to exploratory factor analysis discussed by Lawley and Maxwell (1971) illustrates how a form of traditional exploratory factor analysis can be done by setting minimal constraints on the model and testing successive hypotheses about the number of factors. A discussion of these models occurs in a subsequent section on confirmatory factor analysis. Before this, a more formal presentation of the factor model in matrix form is given, along with a discussion of several of the longstanding problems that dominate the literature on factor analysis, specifically the problem of estimating communalities, the problem of estimating factor scores, and the problem of determining factorial invariance.

THE FACTOR MODEL IN MATRIX NOTATION

We can generalize the model given above for the case of multiple factors, k , in matrix notation. And again, the factor model can be easily represented in terms of the data matrix at hand. (The model can also be written compactly in vector notation for populations of interest. This is the approach taken in the subsequent discussion of confirmatory factor analysis.) The data matrix in this case can be represented as a p by n array of variable scores. Let Z' symbolize this p by n data matrix. Using this notation, write the common factor model for a set of p variables as $Z' = AF' + UW'$ where Z' is as defined above, A is a p by k *factor pattern matrix* (in the case of uncorrelated factors A is called the *factor structure matrix*), F' is a k by n matrix of hypothetical factor scores, U is a p by p diagonal matrix of unique-score standard deviations (defined such that the element u_i is the square root of the unique variances, $\sigma^2 u_i$), and W' is a p by n matrix of hypothetical unique scores. Note that the factors (both common and unique) are never observed—they exist purely at the hypothetical level. Note also that because we have standardized the variables (the z 's) to be centered about the mean and to have standard deviations of unity, the factor scores in this model are theoretically standardized in the same fashion. In other words, $E(F'F) = I_k$, and the variances of the unique scores are equal to $E(W'W) = U^2$, assumed to be a diagonal matrix.

Traditionally, the factor model assumed that the factors of this model were uncorrelated, that the unique parts of the data (the W) are uncorrelated with the common parts (the F), and that the unique variation in variable i is uncorrelated with the unique variation in variable j , for all i and j . In matrix notation, the factor model assumes that $E(F'F) = I_k$, $E(W'W) = U^2$, and $E(F'W) = E(W'F) = 0$. In other words, the factors of the model are uncorrelated with one another and have variances of unity. Also, the common factors and unique factors are uncorrelated, and the unique factors are uncorrelated among themselves.

This type of notation helps clarify the fact that factor analysis is in effect interested in the "reduced" data matrix, $Z' - UW'$, rather than Z' . Consequently, the factor model is concerned with

the decomposition of the matrix $R - U^2$ (the correlation matrix with communalities in the diagonal) rather than R (the correlation matrix with unities in the diagonal), since in equation 8 we demonstrate the following:

$$\begin{aligned} R &= E(Z'Z) = E(AF' + UW')(AF' + UW')' \\ &= AA' + U^2 \end{aligned} \tag{8}$$

and $R - U^2 = AA'$.

This demonstrates an often misunderstood fact—namely, that factor analysis focuses on the reduced-correlation matrix, $R - U^2$, rather than on the correlation matrix (with 1s in the diagonal). As will be clarified below, this is the fact that differentiates factor analysis from principal components analysis—the latter operates on the correlation matrix. In factor analysis, then, one must begin with some estimate of $I - U^2$ or H^2 , the matrix of communalities, and then work on the decomposition of $R - U^2$. This poses a dilemma, since neither the common nor unique factors are observed, and it is therefore not possible to know U^2 and H^2 beforehand. The objective is to come up with an estimate of H^2 that retains a positive semidefinite property to $R - U^2$. At the same time, H^2 is one aspect of what one wants to discover from the analysis, and yet in order to estimate the model one must know this matrix beforehand. The solution to this problem is to begin with an “estimate” of the communalities of the variables, and then through an iterative procedure new estimates are obtained and the solution is reached through convergence to some criterion of fit.

COMMUNALITY ESTIMATION AND THE NUMBER OF FACTORS

Determining the number of factors in exploratory factor analysis is one of the fundamental problems involved in arriving at a solution to the parameters of the factor model. The problem essentially involves determining the rank, k , of the matrix $R - U^2$, where these matrices are as defined above. Technically, we want to find a matrix U^2 that will retain the property of positive semidefiniteness in $R - U^2$ with the smallest possible rank (Guttman 1954). The rank of this matrix in this case is the minimum number of factors necessary to reproduce the off-diagonal elements of R . Thus, the problem of

determining k is closely related to the communality estimation problem, that is, determining an estimate for the diagonal of $R - U^2$, that is, H^2 .

Guttman (1954) outlined the problem of deciding on the number of factors and compared three principles for estimating k via solutions to the communality estimation problem. He described a “weak lower bound” on the number of factors, k_1 , as the nonnegative roots (eigen values) of the matrix $R - I$. This is equivalent to the number of roots of R greater or equal to unity, since R and $R - I$ differ only by I , and their roots differ therefore only by unity. Guttman shows that k_1 is a lower bound to k , that is, $k \geq k_1$. A second principle, one that also implies another approach to estimating communality, is based on the matrix $R - D$, where D is a diagonal matrix whose elements, $1 - r_j^2$ ($j = 1, p$), are the result of unity minus the square of the largest correlation of variable j with any of the $p - 1$ other variables. Guttman shows that k_2 is also a lower bound to k , such that $k \geq k_2$. A third and perhaps the most common approach to estimating communalities is based on the idea that the squared multiple correlation for each variable predicted on the basis of all the other variables in the model is the upper limit on what the factors of the model might reasonably explain. If we define the matrix $R - C^2$, where C^2 is a diagonal matrix whose elements C_j^2 ($1, p$) are equal to $1 - r_j^2$, where r_j^2 is the squared multiple correlation of variable j with the remaining $p - 1$ variables. Guttman shows that k_3 is also a lower bound to k . This third lower bound is often referred to as Guttman’s *strong* lower bound since he showed the following relationships among the lower bounds: $k \geq k_3 \geq k_2 \geq k_1$. In practice, k_1 may be adequate but it could be wrong, and, if wrong, it is likely to be too small. The use of k_1 is probably questionable in the general case. The use of k_2 is obsolete and not practicable. It estimates communality in the way of the Thurstone centroid method, which is only a rough approximation to a least-squares approach. Perhaps the best solution is the choice of k_3 . It is less likely to overlook common factors, as k_1 might, since $1 - s_j^2$ is a lower bound to h_j^2 . It should be pointed out that the lower bounds k_1 and k_3 are what distinguish the two main approaches to factor analysis, namely an incomplete principal components decomposition (referred to as principal components factor analysis) and the principal factor method of analysis.

FACTOR ANALYSIS VERSUS PRINCIPAL COMPONENTS ANALYSIS

It was mentioned above that it is not understood well enough that factor analysis is concerned mainly with the matrix $R - U^2$ rather than with R . This is in fact one of the things that distinguishes factor analysis from principal components analysis. However, the differences between the two are more fundamental. Factor analysis is based on a *model*, a particular theoretical view (hypothesis, if you like) about the covariance (or correlational) structure of the variables. This model states (as given above) that the correlation matrix for a set of variables can be partitioned into two parts—one representing the common parts of the data and one representing uniqueness—that is, $R = A'A + U^2$. The factor model states, first, that the off-diagonal elements of $A'A$ equal the off-diagonal elements of R and, second, that the elements of U^2 (a diagonal matrix) when added to the diagonal elements of $A'A$ give the diagonal elements of R . Thus, the factor model posits a set of k hypothetical variables ($k < p$) that can account for the interrelationships (or correlations) of the variables but not for their total variances.

In contrast to this, principal components is not a model in the same sense—it is best viewed as a method. It is one method for obtaining an initial approximation to the common factor model (see Guttman's weak lower bound, discussed above), but it is extremely important to distinguish such an "incomplete" principal components solution (one associated with the roots of R that are equal to or greater than unity) from the full-rank principal components decomposition of R (see Maxwell 1977).

Any square symmetric nonsingular matrix, for example, $R = R'$, can be written in the form $R = QD^2Q'$, where D^2 is a diagonal matrix of order p containing eigen values ordered according to decreasing magnitude, and Q is a matrix of unit-length eigen vectors (as columns) associated with the eigen values. Q is an orthonormal matrix, $Q'Q = I = QQ'$. This model is referred to as the principal components decomposition of R . Typically, one either analyzes a correlation matrix with 1s in the diagonal, or a covariance matrix with variances in the diagonal, in the application of this decomposition. In this model the correlation matrix, R , is formed by a centered or deviation-score data matrix scaled so that the variables have variances of

unity. Let Z' be the $p \times n$ data matrix, as above. Note that the expected value of $Z'Z = QD^2Q'$, since $Z' = QDY'$.

If the correlation matrix is of full rank, then there will be p columns in Q . This means that in this case the principal components model involves a transformation of p variables into a set of p orthogonal components. When the correlation matrix is singular, meaning that the rank of the matrix is less than p , the principal components decomposition is said to be incomplete, but from the point of view of factor analysis this is often irrelevant since it is the matrix $R - U^2$ that is of interest to the factor analyst.

If P is an $r \times p$ components matrix ($P = QD$), and $r = p$, then it is well known that $Y' = (P'P)^{-1}P'Z' = P^1Z'$, where Y' is a set of r component scores, P is as defined above, and Z' is a $p \times n$ data matrix involving p variables and n units of observation (e.g., persons, cities, social organizations). In other words, component scores (in contrast to factor scores) are directly calculable.

THE ROTATION PROBLEM—CORRELATED VERSUS UNCORRELATED FACTORS

Principal components are by definition *uncorrelated* with one another. The basic objective of the method is to obtain a set of p orthogonal (uncorrelated) new variables via a linear transformation of the p original variables. Factors are different. Factors may be uncorrelated, and in classical exploratory factor analysis one always begins with a set of uncorrelated factors, but in general this is not a requirement. Indeed, in exploratory factor analysis the factors one obtains are uncorrelated because of the nature of the methods used, but normally one performs a transformation or rotation of these factors to achieve a more pleasing representation for interpretation purposes.

Two types of rotations are available—those that preserve the uncorrelated nature of the factors, such as the varimax and quartimax rotations (see Kaiser 1958; Neuhaus and Wrigley 1954), and those that allow the factors to be correlated. The latter are called "oblique" rotations because they move the factors out of the orthogonal reference into a vector space that reduces the geometric

angles between them. Using either of these approaches, the basic goal of rotation is to achieve what Thurstone called *simple structure*, the principle that variables should simultaneously load highly on one factor and low on all other factors. These rotational approaches are relatively straightforward and discussed in all of the textbook descriptions of factor analysis.

FACTORIAL INVARIANCE

Following Thurstone's (1938, 1947) discussions of factor analysis, students of the method have frequently been concerned with the problem of the correspondence between factors identified in separate studies or in subgroups of the same study. Using Thurstone's terminology, a concern with the correspondence of factors refers to the *invariance* of factors. The concern with factorial invariance has generated an array of methods for comparing factors (see Mulaik 1972). The most common approach to the problem involves the computation of an index of *factor similarity* for corresponding factors given estimates of a factor model using the same variables in two or more samples. The details of various strategies for estimating factor similarity will not be covered here, as descriptions can be found in a variety of factor analysis textbooks.

These approaches were developed primarily for results obtained from exploratory factor analysis, and it can be argued that the issues of factorial invariance can be more fruitfully addressed using the methods of confirmatory factor analysis (see Jöreskog 1971b; Lawley and Maxwell 1971). The technical aspects of these methods will not be reviewed here, as they have been expounded elsewhere (see Alwin and Jackson 1979, 1981). Suffice it to say that issues of factorial invariance can be phrased, not only with respect to the correspondence of the factor pattern coefficients (the *A* matrix) across populations, but also with respect to other parameters of the model as well, particularly the matrix of factor interrelationships (correlations and covariances) and the matrix of disturbance covariances.

It is perhaps useful in this context to raise a more general question regarding the nature of factorial invariance that is sought in the analysis of the factorial content of measures. In general there

is no consensus regarding whether stronger or weaker forms of invariance are necessary for comparisons across populations or subpopulations. Horn and associates (1983), for example, suggest that rather than the "equivalence" of factor structures across populations, weaker "configurational" forms of invariance are "more interesting" and "more accurate representations of the true complexity of nature." By contrast, Schaie and Hertzog (1985, pp. 83-85) argue that the condition of factorial invariance, that is, "the equivalence of unstandardized factor loadings across multiple groups," is critical to the analysis of differences among groups and developmental changes within groups.

Clearly, these represent extremes along a continuum of what is meant by the question of factorial invariance. On the one hand, for strict comparison of content across groups, it is necessary to have the same units of measurement, that is, invariance of metric. This requires the same variables measured across populations, and some would also argue that such invariance of metric requires that the relationships of the variables and the factors be equivalent across populations (see Jöreskog 1971a). On the other hand, if the same pattern of loadings seems to exist, it may be an example of misplaced precision to require equivalence in the strictest sense. Of course, the resolution of these issues has implications for other uses to which factor analysis is typically put, especially the construction of factor scores and the use of causal modeling strategies to compare substantive processes across groups.

THE PROBLEM OF FACTOR SCORE ESTIMATION

Researchers using the common factor model as a data reduction tool typically engage in the estimation of such models in order to obtain scores based on the factors of the model, which can then be used to represent those factors in further research. As will be shown here, *factor scores* can never be computed directly (as in the case of *component scores*). Factor scores are always estimated, and, due to the nature of the factor model, "estimated factor scores" never correlate perfectly with the underlying factors of the model. An important

alternative to factor scores is what have come to be called “factor-based” scores, which are scores derived from the results of the factor analysis, using unit versus zero weightings for the variables instead of the factor score weights derived from one or another method of estimating factor scores. Factor-based scores, which are frequently more easy to justify and much more practical, typically correlate so highly with factor score estimates as to make one skeptical of the need for factor score estimates at all (see, e.g., Alwin 1973b).

However, it is important that factor analysts understand the nature of the factor score estimation problem, regardless of whether factor score estimates become any more appealing than the simpler and more stable factor-based scores. The factor score estimation problem can best be seen in terms of an interest in solving for the matrix F' in the above matrix representation of the common factor model, $Z' = AF' + UW'$. This can be done analytically, but, as will be seen, it is not possible to do so empirically because of the nature of the model. To solve for F' in this model we arrive at the following representation (without going through all of the necessary steps): $F' = (A'A)^{-1} A' [Z' - UW']$. The calculations implied by this expression cannot actually be carried out because one never knows W' . This is known as the “factor measurement problem,” which results in the fact that factor scores cannot be computed directly and must therefore be estimated.

The question, then, becomes whether it is possible to estimate factor scores in a manner that is useful, given what is known— Z , A , and U^2 . Several approaches have been set forth for estimating the factors, all of which involve some transformation of the data matrix Z' into a set of k scores that vary in their properties (see Harris 1967; McDonald and Burr 1967). Most of these methods bear some resemblance to the analytic solution for F' above, but there are some technical differences. One of the most commonly misunderstood facts involved in the estimation of factor scores is that the factor pattern coefficient matrix, A , cannot be applied directly to the estimation of factors; that is, F' cannot be estimated by $A'Z'$. This, of course, should be clear from the above representation, but it is often used, probably due to ignorance of the more “correct” factor score estimation strategies.

There are four recognized strategies for estimating scores representing the common factors of the model, given Z , A , and U^2 (Alwin 1973b). All of these approaches are typically discussed for a model such as that discussed above, namely a set of uncorrelated factors scaled to have 0 means and standard deviations of 1. It is not the purpose of the present discussion to evaluate the properties of these various approaches to factor score estimation, but a brief summary can perhaps provide a guide to the technical literature on this topic. It is important to emphasize that *none* of these approaches produces factor score “estimates” that are perfectly correlated with the underlying factors of the model. Some of these approaches produce *univocal* score estimates, meaning that each factor score correlates *only* with the factors they are intended to measure and not with factors they are not intended to measure. Only one of the approaches produces a set of factor score estimates that reflect the property of uncorrelated factors with unit standard deviations. But it is difficult in practice to evaluate the desirability of any of the properties of factor score estimates.

METHODS OF CONFIRMATORY FACTOR ANALYSIS

Confirmatory factor analysis, unlike the methods of exploratory factor analysis, begins with prior knowledge regarding the number of factors and something about the nature of their relationships to the observed variables. In the absence of such knowledge, confirmatory factor analysis is not appropriate. In the typical situation of confirmatory factor analysis, then, the investigator begins with some specific theoretical hypotheses involving a model that can be tested against the data. Naturally, there is an extremely large number of such possible models, so it should be obvious that the techniques cannot easily be used to “search” for the best possible set of restrictions involving k factors (but see Glymour et al. 1987).

The bulk of this review has been devoted to the use of exploratory techniques of factor analysis. This imbalance is perhaps justified, given what is known within sociology about the common factors in our data. Exploratory factor analysis techniques are likely to be much more useful,

especially at a stage where less knowledge has been developed. And within a field like sociology, where there is a broad variety of competing concepts and paradigms, exploration of data may often be the most salutary strategy. There are, however, clear-cut instances where the use of confirmatory factor analysis techniques is in order, and the remainder of this discussion focuses on these situations.

Consider the following model for a set of p variables: $y = v + \lambda \eta + \varepsilon$, where v is a vector of location parameters or constants representing the origins of measurement of the p observed variables, η is a vector of k latent variables or factors, and ε is a vector of random disturbances for the p observed variables. The covariance properties associated with η and ε are basically the same as those discussed in the section on exploratory factor analysis for F and W , except that in general these are not required to be uncorrelated within the common factor set. And, of course, there is no restriction on the metric of the variables; that is, the p variables and k factors are not necessarily standardized to have 0 means and standard deviations of unity. The coefficient matrix, λ , is a matrix of regression coefficients relating the p observed variables to the k latent factors. In the case of a single population, one can easily consider the p variables centered (which would remove the vector of location constants) and scaled to have unit variance, but in the situation where one wants to compare populations neither of these constraints is probably desirable.

The use of these models requires the distinction between constrained and unconstrained parameters. Typically, one refers to parameters of the model as *fixed* if they are constrained to have a particular value, such as a factor loading of 0 or, in the case of the variance of a latent factor, a variance of unity. By contrast, the unknown parameters of the model, for example the λ s, are referred to as *free* parameters, which means that they are estimated in the model under the constraints specified for *fixed* parameters. Thus, one speaks of fixed or constrained parameters on the one hand and free or estimable parameters on the other. The major breakthrough in the use of this type of model was the development of computer programs that allow one to fix certain parameters of the model to known quantities while estimating

the free parameters under these constraints. The general approach also allows one to specify causal connections among the latent factors of the model, and it allows one to specify correlations among the errors in the variables and the errors in the equations connecting the latent factors.

Consider the factor model for the situation where there are $p = 4$ variables and $k = 2$ factors, with the pattern of factor pattern coefficients shown in equation 9, where the first two variables are believed to measure η_1 and the third and fourth variables are said to measure η_2 . This is the kind of situation described by Costner (1969), who developed an approach to confirmatory factor analysis using Spearman's tetrad differences. Of course, there are more efficient estimation strategies than those proposed by Costner. In any event, the point of this example is that the investigator begins not only with a specific number of factors in mind but also with a specific set of assumptions about the pattern of loadings.

$$\Lambda = \begin{bmatrix} \lambda_{11} & 0.0 \\ \lambda_{21} & 0.0 \\ 0.0 & \lambda_{32} \\ 0.0 & \lambda_{42} \end{bmatrix} \tag{9}$$

In the general case the covariances and correlations of the common factors of the model, $E(\eta'\eta)$, can be symbolized by Ψ (sometimes this matrix is denoted as Φ , but there are many ways in which to symbolize these quantities), and the covariances of the disturbances (or errors) on the variables can be symbolized by θ_c . Neither of these two matrices, Ψ and θ_c , is required by the model to be diagonal, although in the simplest form of the confirmatory model, θ_c is often assumed to represent a set of uncorrelated disturbances. In more complicated forms of the model, within constraints placed by the identification problem, both of these matrices can be nondiagonal. In either case, the model here is written with the assumption that the investigator has prior theoretical knowledge regarding the number of sources of common variation and that the η vector exhausts those sources.

Any application of this model requires that it be *identified*, which essentially means that there must be enough independent information within the covariance and correlation structure being

analyzed sufficient to solve for the unknown parameters of the model. In general, there need to be k^2 constraints on a particular common factor model, that is, in the parameters in λ and ψ . Other constraints, of course, are possible. Space does not permit the discussion of these matters, but a detailed treatment of these issues can be found elsewhere (see Alwin 1988a; Alwin and Jackson 1979).

The True-Score Models. It can be shown that a well-known class of measurement models that form the basis for *classical test theory* (Lord and Novick 1968) can be specified as a special case of confirmatory factor analysis (see Alwin and Jackson 1979; Jöreskog 1971a). In brief, by placing particular constraints on the λ and θ , matrices of the model, one can estimate the parameters of models that assume the measures are *parallel*, *tau-equivalent*, or *congeneric*. Of course, as indicated earlier, in order to use the common factor model in such a fashion, one must be reasonably sure that there is little or no specific variance in the measures. Otherwise, one runs the risk of confusing reliable specific variance with measurement error variance.

Multitrait–Multimethod Models. In addition to the application of confirmatory factor analysis to the estimation of classical true-score models, several attempts have been made to augment the traditional latent “trait” model, inherent in the classical model, by the addition of “method” factors based on the *multitrait–multimethod* design of measurement within the framework of confirmatory factor models (see Alwin 1974; Alwin and Jackson 1979; Werts and Linn 1970). This provides a partitioning of the specific variance due to method, but it does not provide a general solution to the problem of handling specific variance. While these models can be very useful for partitioning item-level variance into components due to trait, method, and error, they place relatively high demands on the measurement design. And while the required designs are relatively rare in practice, these models help sensitize the researcher to problems of correlated method error (see e.g., Costner 1969). Recent work in this area has shown that the multitrait-multimethod model can be fruitfully applied to questions of survey measurement quality, assessing the extent to which correlated measurement errors account for covariation among survey measures (see Alwin, 1997; Scherpenzeel, 1995).

Multiple-Indicator, Multiple-Cause Models.

One of the simplest forms of causal models involving latent common factor models is one in which a single latent endogenous variable having several indicators is determined by several perfectly having measured exogenous variables. Jöreskog (1974) and Jöreskog and Goldberger (1975) refer to this as a *multiple-indicator, multiple-cause* (MIMC) model. This kind of model has certain similarities to the canonical correlation problem (see Hauser and Goldberger 1971).

Analysis of Change–Simplex Models. One type of model that can be viewed as a confirmatory factor model, and is useful in analyzing change with respect to the latent common factors over time, falls under the rubric of *simplex* models (Jöreskog 1974). Such models are characterized by a series of measures of the same variables separated in time, positing a Markovian (lag-1) process to describe change and stability in the underlying latent variable. This model can be used in situations where there is a single variable measured over time (see Heise 1969) or in situations where there are multiple measures of the latent variable at each time (see Wheaton et al. 1977).

These models have proven to be valuable in the study of human development and change, especially applied to panel studies of individual lives over time (Alwin 1994, 1995a; Alwin and Krosnick 1991; Alwin et al. 1991; Asendorf 1992.); A related set of models in this area are latent growth curves, in which levels and trajectories of the growth in latent factors can be conceptualized and estimated (e.g., Karney and Bradbury 1995; McArdle 1991; McArdle and Anderson 1990; Willett and Sayer 1994). In such applications the focus is on the nature of growth processes and the correlates/predictors of individual change in latent factors over time. This is a natural extension of traditional methods of confirmatory factor analysis and causal modeling strategies within the context of longitudinal data.

Causal Modeling of Factors. If one obtains multiple measures of factors, for which common factor models are believed to hold, and the factors can be specified to be causally related, then it is possible to use confirmatory techniques to estimate the causal influences of factors on one another. Of course, one must be able to justify these

models strongly in terms of theoretical considerations, and there must be considerable prior knowledge (as in the use of confirmatory factor analysis) that justifies the specification of such measurement models. The logic involved in dealing with the linkage between observed and unobserved variables is essentially that involved in confirmatory factor analysis, while the logic applied in dealing with the causal linkages among factors is that involved in path analysis and structural equation modeling. The main point is that the parameters of models that essentially contain two parts—a measurement part specifying a model linking observed and latent variables and a structural model linking the latent variables—can be estimated within the framework of LISREL-type models. The measurement part can typically be viewed within the framework of confirmatory factor analysis, although in some cases an “induced variable” model is more appropriate (Alwin, 1988b).

CONCLUSION

This review is designed to provide an overview of the major issues involved in the use of factor analysis as a research tool, including both exploratory and confirmatory techniques. There are several useful textbook discussions of factor analysis that will aid those who desire further study. Among these, the texts by Gorsuch (1984), Harman (1976), Mulaik (1972), McDonald (1985), and Lawley and Maxwell (1971) are some of the best sources on exploratory factor analysis. There are some recent texts offering instruction on the conceptual understanding and practical guidance in the use of these confirmatory factor analysis and causal modeling strategies (e.g., Bollen 1989; Loehlin 1992). The newest developments in the area involve advances in the analysis of categorical and ordinal data, statistical estimation in the presence of incomplete data, the provision of graphic interfaces for ease of specification of causal models. There are now several major competitors in the area of software packages that can be used to estimate many of the confirmatory factor models discussed here. Although these several packages offer largely comparable material, each offers a somewhat special approach. The LISREL approach to the analysis of covariance structures was first made available in the early 1970s. It is now in its

eighth version and offers many improvements to its use (Jöreskog and Sörbom 1996a). The LISREL8 program is now supplemented by PRELIS (Jöreskog and Sörbom 1996b), which provides data transformation capabilities, and by SIMPLIS (Jöreskog and Sörbom 1993), which provides a simple command language for formulating LISREL-type models. There are several alternatives to the LISREL approach, including EQS (Bentler 1992), AMOS (Arbuckle 1997), and Mplus (Muthén and Muthén 1998), among others, which provide many attractive features (see West, 1997).

FAMILISM

See Filial Responsibility; Family and Household Structure; Intergenerational Relations; Intergenerational Resource Transfers.

FAMILY AND HOUSEHOLD STRUCTURE

The family system of the United States is often characterized as consisting of nuclear-family households—that is, households consisting of no more than the parent(s) and dependent children, if any (Lee 1999). This is certainly true of the great majority of family households. In fact, there has never been a point in American history in which extended-family households predominated statistically (Ruggles 1994a; Seward 1978). In 1997 only about 4.1 percent of all families in the United States were "related subfamilies"—a married couple or single parent with children living with a related householder (U.S. Bureau of the Census 1998, Table 69). However, an analysis of census data from 1970 through 1990 by Glick and colleagues (1997) showed that the percentage of all households containing nonnuclear kin increased from 9.9 percent in 1980 to 12.2 percent in 1990, reversing a nearly century-long pattern of decline. In 1910 about 20 percent of the households of white families and 24 percent of those of black families contained nonnuclear kin (Ruggles 1994b). Apparently we have seen a long-term decline in the prevalence of extended-family households, very slightly counterbalanced by an increase in the 1980s; what happened in the 1990s is not yet known.

Not all of the of the households that do not contain extended families consist of the stereotypical

nuclear family of two parents and their dependent children, however. There is great diversity among American families and households, and this diversity is increasing. Table 1 presents data on the composition of American households and families from 1960 to 1998. Even over this relatively brief period, substantial changes are apparent. The average size of both households and families decreased dramatically from 1960 to 1990, although they have both been stable in the 1990s. Many fewer households contain families and married couples in the late 1990s than in 1960, while the proportion of nonfamily households has more than doubled and the proportion of single-person households has nearly doubled. Female householders have increased substantially as a proportion of both all households and all families.

There are many factors responsible for these changes. To understand them, changes in marriage rates and age at marriage, divorce and remarriage rates, rates of nonmarital cohabitation, the departure of children from their parents' homes, and the predilection of unmarried persons to live alone will be briefly examined. Each of these factors has affected family and household structure.

Marriage rates have declined considerably since 1960 (see Table 2). This is not readily apparent from the "crude" marriage rate (the number of marriages per 1,000 population) because this rate does not take the marital status or age distributions of the population into account. The crude marriage rate was artificially low in 1960 because, as a result of the postwar baby boom, a large proportion of the population consisted of children too young to marry. The rates per 1,000 unmarried women (for both ages 15 and over and ages 15 to 44) show the frequency of occurrence of marriage for persons exposed to the risk of marriage, and here there is clear evidence of decline. Some of this, however, is attributable to increases in the median age at first marriage, which declined throughout the twentieth century until about 1960, but has been increasing rapidly since 1970. As age at marriage increases, more and more people temporarily remain unmarried each year, thus driving the marriage rate down. The best evidence (Oppenheimer et al. 1997) indicates that a major cause of delayed marriage is the deteriorating economic circumstances of young men since the

FAMILY AND HOUSEHOLD STRUCTURE

Changes in U.S. Households and Families Since 1960

	1960	1970	1980	1990	1998
Number of households (in 1,000s)	52,799	63,401	80,776	93,347	102,528
Average size	3.35	3.14	2.76	2.63	2.62
Family households (%)	85.04	81.15	73.72	70.80	69.13

SOURCE: U.S. Bureau of the Census (1998; Table 69), and Current Population Reports, P20-509 and earlier reports.

1970s. Perhaps the improving economy of the later 1990s will eventually produce some change in this trend.

The rising divorce rate has also contributed greatly to the declining proportion of married-couple households and the increases in female householders and single-person households. The crude divorce rate rose from 2.2 per 1,000 in 1960 to 5.2 in 1980 (reaching peaks of 5.3 in both 1979 and 1981) but has declined modestly since then to 4.3 in 1996. The rate of divorce per 1,000 married women 15 and older followed a similar pattern, reaching a high of 22.6 in 1980 and declining to 19.5 in 1996. Some of this decline is illusory, because the large baby boom cohorts are aging out of the most divorce-prone years (Martin and Bumpass 1989). However, although the divorce rate remains high, it has not been increasing since 1980.

Sweeney (1997) notes that, for recent cohorts, about half of all marriages have involved at least one previously married partner. However, rates of remarriage after divorce have been declining steadily. Annual remarriage rates were 204.5 per 1,000 divorced men and 123.3 per 1,000 divorced women in 1970; by 1990 they had decreased to 105.9 for men and 76.2 for women (U.S. Bureau of the Census 1998).

Decreasing marriage and remarriage rates and increasing divorce rates have combined to produce increases in single-person and single-parent households. This trend is mitigated, however, by

the increasing prevalence of nonmarital heterosexual cohabitation. Most such unions (those without children) appear as nonfamily households in Table 1. Evidence from the National Survey of Families and Households (Bumpass 1994; Waite 1995) shows that, in the early 1990s, nearly one-quarter of all unmarried adults aged 25 to 29 were cohabiting. This percentage declines with age, but still exceeded 20 percent for those in their late thirties. The National Survey of Family Growth found that, in 1995, more than 41 percent of all women aged 15 to 44 had cohabited or were currently cohabiting (National Center for Health Statistics 1997). Of course many of the women who had not cohabited at the time of the survey will do so in the future. The best estimates suggest that more than half of all couples who marry now cohabit prior to marriage; further, about 60 percent of all cohabiting unions eventuate in marriage (Bumpass 1994; Bumpass et al. 1991).

To a considerable extent the increase in cohabitation has offset the decline in marriage. This is particularly the case among blacks, for whom the decrease in marriage rates over the past several decades has been much more precipitous than it has been for whites (Raley 1996; Waite 1995). Although cohabiting unions are less stable than marriages, ignoring cohabitation results in substantial underestimates of the prevalence of heterosexual unions in the United States.

In spite of the increase in cohabitation, changes in marriage and divorce behavior have had substantial effects on household and family structure

FAMILY AND HOUSEHOLD STRUCTURE

Changes in U.S. Marriage and Divorce Since 1960

	1960	1970	1980	1990	1996
Number of marriages (in 1,000s) ¹	1,523	2,159	2,390	2,443	2,344

NOTE: 1. Monthly Vital Statistics Report, Vol. 43, No. 12 (S), July 14, 1995 for 1960–90; and U.S. Bureau of the Census (1988): Table 156 for 1996.

2. U.S. Bureau of the Census, Current Population Reports, P20–514 (March 1998) and earlier reports for 1960–90; and U.S. Bureau of the Census web site for 1996.

3. Monthly Vital Statistics Report, Vol. 43, No. 9 (S), March 22, 1995 for 1960–90; and U.S. Bureau of the Census (1998): Table 156 for 1996.

in the United States over the past four decades. Fewer people are marrying, those who marry are doing so at later ages, more married people are divorcing, and fewer divorced people are remarrying. This means that Americans are living in smaller households than they did in 1960, but there are more of them. The rate of growth in the number of households has substantially exceeded the rate of growth in the number of families. Referring back to Table 1, from 1960 to 1998 the number of households increased by more than 94 percent, while the increase in the number of families was only about 57 percent. Over the same time period, the total population of the United States increased by just under 50 percent (U.S. Bureau of the Census 1998, Table 2). Our population, therefore, is distributed in a larger number of smaller households than was the case in 1960.

One cause of the decline in household size shown in Table 1 is decreased fertility. The fertility rate (number of births per 1,000 women aged 15 to 44) was 118.0 in 1960; by 1997 it had decreased to 65.0, although most of the decrease occurred prior to 1980 (National Center for Health Statistics 1999). The trend toward smaller households and families is reflective to some extent of decreases in the number of children per family.

A larger cause of the decrease in household size, however, is the proliferation of single-person

households, as shown in Table 1. Single-person households consist of three types of persons: the never-married, who are primarily young adults; the divorced and separated without coresident children, who are primarily young and middle-aged; and the widowed who live alone, who are primarily elderly. Each of these types has increased, but for somewhat different reasons. Each must therefore be examined separately.

As shown in Table 2, average ages at marriage have risen markedly since 1960, and the percentage of young adults who have never married has increased proportionately (Waite 1995). This has been accompanied by a long-term decline (since prior to World War II) in the average age of leaving the parental home (Goldscheider 1997). Prior to 1970 most of this decline was driven by decreasing ages at marriage, but since then it has reflected an increasing gap between leaving the family of orientation and beginning the family of procreation. More young adults are living independently of both parents and spouses. Some of them are cohabiting, of course, but increasing numbers are residing in either single-person or other nonfamily households (Goldscheider 1997; White 1994).

Since about 1970 there has been some increase in the proportion of young adults who live with their parents. This marks the reversal of a

long-term decline in age at leaving home (White 1994). This is, in part, a by-product of increasing age at marriage. However, decreases in exits from parental homes to marriage have been largely offset by increases in exits to independent living, so this recent increase in young adults living with parents is actually very small (Goldscheider 1997). On the other hand, there is increasing evidence that the process of launching children has become much more complex than in previous years. Goldscheider (1997) also shows that the proportion of young adults who return to their parents' homes after an initial exit has more than doubled from the 1930s to the 1990s; increases have been particularly striking since the early 1960s. This is a response, in part, to the rising divorce rate, but also an indication that it has gotten increasingly difficult for young adults, particularly young men, to make a living (Oppenheimer et al. 1997). Nonetheless, the proportion of young adults living independently of both parents and spouses continues to increase, contributing to the prevalence of nonfamily households.

The increase in divorce and decrease in remarriage have contributed to the rise in single-person households, as formerly married persons establish their own residences and, increasingly, maintain them for longer periods of time. They have also contributed to the rise in family households that do not contain married couples. As shown in Table 1, families headed by females (without husband present) increased from 10 percent of all families in 1960 to nearly 18 percent in 1998. Families headed by males (without wife present) also increased, from 2.8 percent of all families in 1960 to 5.5 percent in 1998. Among families with children under 18 in 1998, 20 percent were headed by women without spouses and 5 percent by men without spouses (U.S. Bureau of the Census 1998, Table 70).

As a consequence of these changes plus the rise in nonmarital childbearing, the proportion of children under 18 living with both parents decreased from 88 percent in 1960 to 68 percent in 1997 (U.S. Bureau of the Census 1998, Table 84). In addition, there is a large race difference in the living arrangements of children. Only 35 percent of black children lived with both parents in 1997, compared to 75 percent of white children. More than half (52 percent) of all black children lived

with their mothers only, as did 18 percent of white children. Further, 8 percent of black children and 3 percent of white children lived with neither parent. Some of these children are living with, and being cared for by, their grandparents (Pebbley and Rudkin 1999). This raises the issue of the living arrangements of older persons.

A somewhat longer perspective is necessary to observe changes in the living arrangements of older persons. Ruggles (1994a) has shown that, in 1880, nearly 65 percent of all elderly whites and more than 57 percent of all elderly nonwhites lived with a child. Since about 18 percent of all older persons had no living children, Ruggles estimates that about 78 percent of whites and 70 percent of nonwhites who had children lived with a child. By 1980 the percentages living with children had decreased to 16 for whites and 29 for nonwhites. There is little evidence of major changes in the proportion living with children since 1980. Further, Ruggles (1996) found that only 6 percent of all elderly women and 3 percent of elderly men lived alone in 1880. By 1997 the percentages living alone had increased to 41 for women and 17 for men (U.S. Bureau of the Census 1998, Table 50). The growth of single-person households among older people has been particularly rapid since about 1940.

Two sets of factors appear to be primarily responsible for the "migration" of older people from typically sharing households with their children in the late nineteenth century to living alone (or with their spouses only) in the late twentieth century. First, the family life cycle was quite different in 1900 than today. People married a bit later (and markedly later than in the 1960s and early 1970s), had more children, and had children later in life. Consequently, a significant proportion of people in their sixties had unmarried children who simply had not yet left the parental home. Ruggles (1994a) shows that, in 1880, about 32 percent of all unmarried elders and 57 percent of the married resided with a never-married child. Of course many of these children may have remained home precisely in order to care for their aging parents. Unmarried elders were more likely to live with married children.

Second, economic factors played a major role. Social Security did not exist until 1940. In 1900, 85

percent of all men between the ages of 65 and 69 were in the labor force, as were 49 percent of all men 85 and over (Smith 1979). However, this option was much less available to women; the comparable proportions in the labor force were 12 and 6 percent. Many older persons, particularly women, had no means of support other than their children. Rates of coresidence of aging parents with their adult children have decreased as the prosperity of the elderly has increased; more can now afford to live independently.

However, Ruggles (1994a) found that wealthier older people were more likely to share a household with children than were poorer elders in the nineteenth century, and the majority of multigenerational families lived in households headed by the elderly parent(s). These facts suggest that adult children benefited economically from coresidence and that the possibility of inheriting a farm or business from aging parents may have motivated many adults to coreside with parents. Today coresidence is more common among poorer than wealthier people (Ruggles 1994a, 1996).

As of March 1998, 41 percent of all women aged 65 and older lived alone, as did 17 percent of all older men. These percentages increase to 53 percent and 22 percent for women and men, respectively, for those age 75 and over (U.S. Bureau of the Census Web site). The reason for this large gender difference, of course, is the difference in marital status between men and women. Among men 75 and over, nearly two-thirds are married and less than one-quarter are widowed; among women these figures are almost exactly reversed. According to 1980 census data, the proportion of all elderly persons living alone increases from 22 percent among those 65 to 69 to more than 41 percent in the 85–89 age category, then drops to 33 percent for those 90 and over (Coward et al. 1989), after which the modal category becomes living with children. Older persons who have lost their spouses through death are clearly exhibiting a tendency to live alone as long as possible, which for many of them extends into the latest years of life.

Older persons now constitute nearly 13 percent of the total population of the United States, compared to about 4 percent in 1900. With so many of them maintaining their own residences,

either with their spouses or alone following widowhood, their contribution to the proliferation of small and single-person households is substantial.

If so many older persons lived with their children in the late nineteenth century, why were there so few extended-family households? Ruggles (1994a) shows that just under 20 percent of the households of whites contained extended families in both 1880 and 1900; this compares to less than 7 percent in 1980, but it was still very much a minority statistical pattern. There were three primary reasons. First, because of more limited life expectancies and relatively high fertility rates, there were proportionally few older people in the population, so where they lived made less difference to the nation's household structure. Second, as noted above, many older persons lived with an unmarried child; unless other relatives are present, this arrangement constitutes a nuclear-family household regardless of the age of the parent. Third, while these cohorts of older persons typically had many children (an average of 5.4 per woman in 1880), these children did not live together as adults, so older persons could live with only one; their remaining children lived in nuclear families. Ruggles (1994a) estimates that more than 70 percent of all elders who could have lived with a child actually did so in 1880; the comparable percentage in 1980 was 16. In comparison to the last century, older persons today are much less likely to live with children and much more likely to live alone, contributing to the proliferation of small and single-person households.

To this point, factors that have contributed to long-term decreases in household and family size, and consequent increases in the numbers of households and families, have been elucidated. There is evidence of changes in these directions in all age segments of the population. These trends do not mean, however, that more complex family households are not part of the contemporary American experience.

As noted at the beginning of this entry, the United States has never been characterized by a statistical predominance of extended-family households, although it appears that the preference was for intergenerational coresidence in the form of stem families (families containing an older parent or parents and one of their married children) until

the early years of the twentieth century. But extended family households do occur today. At any single point in time, they constitute less than 10 percent of all households (Glick et al. 1997; Ruggles 1994a). However, a dynamic perspective presents a somewhat different picture.

Beck and Beck (1989) analyzed the household compositions of a large sample of middle-aged women who were followed from 1969 to 1984. The presence of nonnuclear kin in their households was noted for specific years and was also calculated for the entire fifteen-year period. In 1984, when these women were between the ages of 47 and 61, only 8 percent of white married women and 20 percent of white unmarried women lived in households containing their parents, grandchildren, or other nonnuclear kin. The proportions were higher for comparable black women: 27 percent of the married and 34 percent of the unmarried. However, over the fifteen years covered by the survey, about one-third of all white women and fully two-thirds of the black women lived in a household containing extended kin at some point.

These and other data (Ruggles 1994a, 1994b) show that today blacks are more likely than whites to live in extended-family households. This was not the case until about 1940. What has happened is that the decrease in intergenerational coresidence since the late nineteenth century has been much steeper for whites than for blacks. This is probably connected to much lower rates of marriage among blacks; living in multigenerational households is much more common for unmarried than for married persons. It may also reflect the shift in the distribution of extended families from the wealthier to the poorer segments of the economic structure. Rather than serving as a means of ensuring inheritance and keeping wealth in the family, extended family living today is more likely to be motivated by a need to share and conserve resources.

The family and household structure of the United States has changed dramatically over the past century, in spite of the fact that our family system has remained nuclear in at least the statistical sense. More and more Americans are living in single-person households before, between, and after marriages. More are living in single-parent households. Collectively Americans are spending smaller proportions of their lives in families of any description than they did in the past (Watkins et al.

1987). However, they are more likely than ever before to live in nonmarital heterosexual unions, and many of them live in households that contain nonnuclear kin at some point in their lives. In fact, there is evidence (Glick et al. 1997) that the proportion of extended-family households increased between 1980 and 1990.

The growth of small and single-person households is in many ways indicative of the fact that more Americans can now afford to remain unmarried, leave unhappy marriages, and maintain their own residences in later life. The proliferation of households represents the proliferation of choices. The consequences of these choices remain to be seen.

FAMILY AND POPULATION POLICY IN LESS DEVELOPED COUNTRIES

In 1798, Thomas Malthus penned his famous dictum that agricultural productivity increases arithmetically while populations increase geometrically. Ever since that time, scholars have concerned themselves with the relationship between population dynamics and economic development. With the rise of the modern nation-state, interest grew in how governmental family and population policies might affect the health of national economies. At the turn of twenty-first century comes, accelerating economic globalization, the decline of communism, and the growing influence of the United Nations and other international organizations provide an increasingly complex context within which to understand family and population policy in less developed countries.

The designation of countries as “less developed” or “more developed” (or “developing” versus “developed”, “newly industrializing” versus “industrialized”) relies on a multidimensional construct of development, ranging from the conditions of education and health to agricultural surplus generation, industrialization, and capital accumulation (Staudt 1997). Perhaps the best single measure of development is a country’s real gross domestic product (GDP) per capita (Crenshaw et al. 1997). However, while meager per capita productivity is characteristic of less developed countries, these nations fall along a productivity continuum of considerable range. Less developed countries also vary greatly in size, geographic location, and quality of natural resources. A study of population dynamics in seventy-five developing nations included countries as diverse as Mexico, Brazil, Sierra Leone, Rwanda, Egypt, Pakistan, Malaysia, and the Philippines (Crenshaw et al. 1997).

Like more developed nations, some of these countries have highly centralized governments; others are weak states with little coordination of productive or distributive activities. All, however, are perceived as promoting some form of family policy. In many of these countries, policies that attempt to regulate the family per se as a social institution are not explicitly articulated. Rather, policies regarding the family often operate indirectly through measures directed toward population control (e.g., family-planning programs and

GARY R. LEE
PADMA SRINIVASAN

restrictions on internal migration) or economic development (e.g., agrarian reform and import-substitution policies). In some parts of the developing world (e.g., China, India, the Islamic states), extensive legal and political measures attempt to govern the formation, functioning, and dissolution of families more directly through, for example, laws on inheritance, dowry, divorce, and filiation. These more explicit family policies often bear the traces of traditional religious interests, but they may also reflect attempts to “modernize” countries by weakening traditional patriarchal control over the disposition of property and the labor of family members. Thus, family policy in less developed countries, whether indirect or explicit, is inextricably bound to questions of economic development, including those concerning the relationship between population and resources.

As a result, few social scientists today treat comparative family policy as an arena of inquiry separate or distinct from comparative studies of population or economic development policy. In fact, attempts to define “family policy” as a distinct object of study have been conspicuously absent from the scholarly literature since the late 1970s (for an example of one such attempt, see Kamerman and Kahn 1978). In part, waning efforts to define and examine family policy per se reflect heated debates about whether a uniform definition of the “family” is useful or appropriate. Feminist critiques in particular have challenged uniform definitions of the family as overly monolithic, static, and undifferentiated, claiming that these definitions ignore the diversity of family patterns not only in less developed nations but also in “modern” countries such as the United States (Beneria and Roldan 1987; Collins 1991; Baca Zinn 1990).

These definitional disputes have given rise to different concepts of what the family is. For example, some scholars argue that variations in household and kinship relations exist worldwide; they tend to prefer the term “household” to “family,” defining the former as a residential unit wherein people live in close proximity and organize activities to meet daily needs (Chow and Berheide 1994). Others, however, argue that adopting the household as the unit of analysis, with an attendant focus on how households respond “strategically” to the external economic and political environment, obscures conflicts of interest that arise within households (Bourque and Warren 1987; Wolf

1992). These critics tend to conceptualize the family or household not as a unit or entity but as a site that offers a cultural and moral context for the interaction of personalities, for the production and consumption of goods, and for the reproduction of populations (Acker 1988). This view of the family tends to emphasize how different interests within families are shaped by gender and age—interests that are themselves related to competition and conflict between larger systems of authority and of control over labor (e.g., capitalism, socialism, patriarchy) within national settings.

Although the study of family policy in less developed nations has largely been overtaken by more fundamental debates about the “proper” unit of analysis, some of these arguments provoke new ways of thinking about *why* developing nations have an interest in the regulation of families. The question of what constitutes a “family” for the purposes of analyzing policy might be found in answers to the question: What is it that families do, in addition to their contributions to population dynamics and economic development, that captures the interest of governments? That is, why do states have a “compelling interest” in families?

Part of an answer may be found in Cherlin’s (1999) definition of the “public family,” a definition that attempts to locate the contribution of families to the public welfare in their caring for dependent members of the population, such as children, the sick, and the elderly. Adapting Cherlin’s definition to a global context, public families may be defined as one adult, or two or more adults who are related by marriage, kin ties, shared parenthood, or coresidence, who is/are taking care of dependents and the dependents themselves. In nearly every society, most caretaking of dependents is performed within a small web of relations like those defined above. Although this work is largely unpaid, it is of great social value, being necessary for the reproduction of a society from one generation to the next. Hence the state’s interest in how well families manage the care of dependents. But government interest extends beyond merely ensuring the replenishment of a population. As Folbre (1994) argues, the caretaking that goes on within families can result in the production of valuable public goods—most notably through the rearing of children who will grow up to be productive adult members of a society. Thus, governments have an interest in promoting

caretaking within families that gives rise to positive collective benefits (productive members of the next generation, including those who will continue to provide caretaking within families).

Policies that provide explicit incentives for family caretaking in the form of tax breaks or government subsidies for day care, parental leave, or child allowances tend to emerge in countries with a highly developed welfare-state apparatus, which presumes the existence of large, stable (if not expanding) public revenues. That is, these policies tend to presume an already-high level of economic development that ensures stable public revenues. The European social democracies—in particular, Sweden—are examples in this regard (Acker 1994). However, some developing countries, such as China, have instituted policies that support caretaking in the form of parenting education programs, child allowances, maternity leave, and planning for social security for the aged (Chow and Chen 1994). The difference in the Chinese case, as in that of other less developed nations, is that these policies are tethered to population policies and goals. The Chinese government, for example, makes eligibility for forms of caretaking support contingent on compliance with its one-child policy, levying penalties in the form of fines, wage deductions, possible job demotion, and forfeiture of other social benefits on parents who have a second child (Chow and Chen 1994). Thus, caretaking policies in the developing world are often put into place as a mechanism for achieving family planning or development goals that aim, over the long term, to ensure national prosperity; they less often derive from such prosperity to begin with, as in the West. The extent to which developing countries manage to implement such “conditional” caretaking policies depends on the strength of the state—in particular, on whether this strength relies on autocratic forms of rule (e.g., China). In developing countries with weaker governments or less autocratic systems of power, support for caretaking more often arises from the adoption of programs or initiatives that are funded by international organizations committed to population control and/or globally organized economic growth. These programs often take the form of children’s health initiatives, such as immunization and nutritional-support projects sponsored by the World Health Organization and the World Bank.

A second aspect of governmental interest in the family among less developed countries concerns the role of family and kin networks as the matrix for traditional authority relations. In many emerging nation-states, political power remains locally controlled by clans or confederations of kin that resist attempts by central governments to consolidate power. Loyalties to religious or ethnically based claims to authority also tend to be coupled closely with loyalties to family and larger kin groups. Thus, the emergence of explicit family policies in less developed countries may reflect attempts on the part of central governments to wrest political control from clans or lineages (such as in sub-Saharan Africa; see Migdal 1988). In some parts of the developing world, changes in family law and policy are a function of competition between bureaucratic state interests and traditional religious claims to authority. For example, in the mid-1950s the government of Tunisia outlawed “repudiation,” or the husband’s Quranic, unilateral prerogative to terminate a marriage at will without judicial involvement. Prior to this time, family matters had been regulated by traditional Islamic doctrine, with allegiance to Islamic law being regionally based and deeply rooted in kin loyalties (Charrad 1994). Changes in the Tunisian civil code to abolish repudiation and make judicial intervention mandatory for divorce had the effect of unifying and strengthening the judicial system by creating a national network of courts. In terms of actual implementation of the new code, judges found themselves shifting between the values of traditional Islamic doctrine and the principles of reform. Nonetheless, the new policy has had a transformative effect on the structure of Tunisian rule, strengthening and consolidating the power of civil law. The case of the Philippines offers another example of how government policy toward families reflects competition between religious and more secular authority claims; the 1986 Philippine constitutional statement about the family reflects an uneasy compromise between Roman Catholic groups and more liberal elements of Filipino society (“Proceedings of the Constitutional Commission” 1986).

In short, despite widespread disagreement in the literature over definitions of “family” and the scope of “family policy,” government policies in less developed nations reveal interests in the caretaking of dependents and in the consolidation

and centralization of authority that might be usefully thought of as targeting “the family.” In contrast to the field of family policy, the terrain of population policy is much more clearly defined, though no less marked by controversy. Population policies differ from family policies because the former are designed to meet specific demographic goals. The most common population policies found in less developed countries are those that attempt to ameliorate population growth by reducing birthrates, for example, through programs in family-planning education and in the distribution of contraceptives (International Institute for Sustainable Development 1994). Other population policies attempt to control migration flows from, for example, rural to urban economic sectors in an attempt to control the mobility of labor and patterns of economic development. These migration policies are especially prevalent in sub-Saharan African countries, where increasing urbanization and the influx of wartime refugees from neighboring areas have placed severe pressures on cities and depleted the supply of labor for rural agriculture. For example, in the 1980s Zambia took steps to curb rural-to-urban migration and promote the resettlement of rural areas through such measures as removing subsidies for commodities in urban areas, a “back to the land” policy, and youth training programs in agriculture and farm management, carpentry, and other rural community-building skills (Mijere and Chilivumbo 1994).

Several demographic problems are a source of shared concern among less developed nations. Concern over rapid population growth has motivated a variety of family-oriented laws and programs, including raising the minimum legal age for marriage in order to shorten the reproductive span during which women are exposed to regular sexual activity (Piepmeier and Hellyer 1977), providing free family-planning services, and, as in China, offering incentives and disincentives for childbearing that involve the provision or withholding of housing, paid maternity leave, and medical or educational services (Greenhalgh 1990; Quah 1990).

Another demographic problem faced by many less developed countries is the lengthening of childhood dependency through adolescence and the concomitant rise of an independent youth culture brought about by the earlier onset of puberty and rising ages at marriage (United Nations

1989). A number of governments in Asia have established sex education or “family life education” policies and programs that target burgeoning adolescent populations, partly as a way of maintaining government family-planning programs in the face of declining levels of marital fertility (Xenos 1990). Other governments have increasingly differentiated youth from adults in their constitutions (Boli-Bennett and Meyer 1978), and programs that explicitly target adolescents and youth are an increasingly important element of social policy in less developed nations (see Central Committee on Youth 1988; Paxman 1984).

Another emerging demographic problem affecting many less developed countries is the growth of the aged population, a situation that typically arises whenever birthrates fall. While less developed nations may have a clear and compelling interest in the production of children as “public goods,” the question of how to care for a growing population of the aged amid declining birthrates and the emergence of smaller families raises thorny issues. In some countries, policies are being considered to keep this burden within families rather than making it a government responsibility, reflecting the state’s reluctance to absorb the costs of dependency among those who are no longer members of the productive work force.

All three of the above concerns—about rapid population growth, an expanding youth culture, and care for the aged—mark the recent history of policy in China. The Chinese one-child policy was adopted in 1979 to ameliorate population pressure on China’s food supply and to reduce state expenditures. Later, it developed into a policy promoting modernization and economic development, with the Chinese government offering several rationales for planned fertility: It would foster better health care for children and mothers, establish better social conditions for the rearing of future generations, increase work efficiency and political awareness, and promote equality of the sexes (Huang 1982). The government created a number of assistance programs, such as fertility education, free birth control and abortion, and planning for social security for the aged; it also offered numerous economic incentives for compliance, such as extra maternity leave, housing or

farmland, free doctor visits, day care, and wage bonuses.

Overall, these provisions appear to have relieved China's population crisis: As of 1994, population growth rates were the lowest since 1949, and the percentages of women marrying at an early age and bearing more than one child have declined (Beijing Review 1995). But because enforcement of the one-child policy is left to local jurisdictions, implementation and outcomes vary by location. The policy appears to have gained greater acceptance in the wealthier, more urban provinces, where the incentives are more abundant. Even in these areas, however, the policy has had an important, unanticipated consequence: The preciousness of the single child has led parents, especially mothers, to spend more time on child care and housework than parents in multiple-child households. Instead of promoting women's greater participation in employment, the policy has led to a reassertion of women's traditional roles as homemakers and nurturers. The policy's weakening of the traditional Chinese system of old-age dependence on adult children (primarily sons) was more readily anticipated, but an alternative system of old-age support has yet to emerge.

As the aims (though not the consequences) of the Chinese policy illustrate, another area of concern involves global social movements, including those supporting equal rights for women and other oppressed groups (Bandarage 1997; Chow and Berheide 1994; Staudt 1997). A second global trend is that of environmentalism (McMichael 1996). A variety of "green" movements have emerged that question the assumptions behind unrestricted economic growth and have redefined the debate about development in Third World countries, focusing on the need for agricultural sustainability, the protection of ecologically vulnerable habitats (particularly in the tropical zones), and the maintenance of biodiversity. Concerns about the environmental degradation sometimes wrought by development projects are often coupled with concerns about the rights and well-being of oppressed groups—particularly in Africa, where mining and rural development policies have differentially affected female-headed households

and, as in the case of South Africa, magnified racial inequalities (Schonfield 1994).

Emerging global viewpoints and the sanction given to them by international organizations represent another trend that is likely to influence future policy concerning families in developing countries. In the 1990s alone, various arms of the United Nations offered explicit recommendations on a range of policies, including those on education, family health, women's labor-force participation, and the family (International Institute for Sustainable Development 1994, 1995). Often these recommendations arose from the participation of nongovernmental organizations (NGOs) in planning and development activities. Such recommendations have been closely tied to the system of international aid that includes donors such as the World Bank and the U.S. Agency for International Development. However, the growing visibility of NGOs at U.N. conferences such as the 1994 Cairo Conference on Population and Development and the 1995 Beijing Conference on Women in part reflects the NGOs' lack of efficacy at the national level: These conferences provide forums for NGOs that have encountered resistance from national governments or have failed to mobilize support from the local populace (Baden and Goetz 1997).

Local and national resistance to NGO or multilateral initiatives regarding families sometimes stems from the belief that these initiatives have been "co-opted" by large international aid agencies that neglect the needs of local populations and their families (Mukherjee 1993). For example, donor-influenced policies in Malawi have disadvantaged female-headed households, favoring households headed by men, even though the traditional culture recognizes the mother-child pair as the most important family unit (Rodgers 1980; Spring 1986). Donor-influenced structural adjustment policies (SAPs) have become another source of conflict about policy. In response to recent economic stagnation and the Third World debt crisis, these adjustments have involved reducing levels of government employment, "floating" national currencies, and cutting tariffs and subsidies, while encouraging export-driven economic growth through labor-intensive manufacturing. In

many countries, women have responded by increasing their participation in home-based industries, often to provide themselves with security should a spouse lose a formal-sector or government job as a result of structural adjustment (Osirim 1994).

The case of Zimbabwe provides an example of how these SAPs can come into conflict with the aims of government policies concerning families. In the early 1980s, Zimbabwe passed laws that ensured women's claims to property in the event of divorce and allowed married women to obtain loans and property in their own names to establish businesses. These laws, supplemented by government loan and training programs to assist women entrepreneurs, were designed to encourage the greater participation of women in national development and to advance their civil rights. However, the advent of Zimbabwe's SAP in 1990 signaled a shift in priorities toward "shrinking the state." The resulting increases in transportation, wholesale, and licensing costs for businesses were particularly hard on women entrepreneurs, some of whom had become the sole wage earners of their families after their husbands had lost a government job (Osirim 1994).

The increasing involvement of transnational social movements, international donor agencies, and nongovernmental organizations in policy development raises an important issue: the strain in many less developed countries between a Western vision of the family that may be supported by the government, NGOs, or international aid agencies, and the traditional family forms supported at the local, grassroots level. In many less developed countries, the government vision of the family may result from the colonial experience, the exposure of elites to Western society, or the perception that a more Westernized family system fits better with other governmental goals, such as economic development or undermining the traditional authority of kin, religious, or ethnic groups. Wherever political struggle focuses on family and population policies, however, the underlying issue often at stake—to which debates in the literature attest—is competition between alternative definitions of the family.

JULIE BRINES

FAMILY AND RELIGION

Social scientific notions of the disappearance or vestigialization of religion and family are deeply

rooted in our theoretical conceptions of the social processes that created the modern world and that now are transforming that modernity into postindustrial, postmodern society. Theories of modernization envision social change as entailing the rationalization of all spheres of existence. In a statement characterizing the classic modernization approach, Moore (1963, p. 79) says, "A major feature of the modern world . . . is that the rational orientation is pervasive and a major basis for deliberate change in virtually every aspect of man's concerns." There is little room for the seemingly irrational and unscientific impulses of religion, primary emotions, and familial concerns.

With this approach, the secularization of religion is a given. Moore (1963, p. 80) states, "Even with regard to the role of religion in human affairs, the 'rational spirit' takes the form of *secularization*, the substitution of nonreligious beliefs and practices for religious ones." Though religion survives, it addresses "personal misfortune and bereavement" above all else in modern society (Moore 1963, p. 104).

Furthermore, "economic modernization" tends to have "negative consequences for extended kinship systems" and leads to "extensive 'family disorganization'" accompanying the "breakdown of traditional patterns and the incomplete establishment of new institutions" (Moore 1963, p. 102). For modernization theorists, although families remain significant as consumption units, the "decline" of the family (Popenoe 1988) is, at minimum, a metaphor for its consignment to a peripheral societal role. The analogue of the notion of linear secularization of religion is the idea of the loss of family functions (Vago 1989, pp. 150-157). Shaped in the eighteenth and nineteenth centuries, modernization views have continued to dominate public opinion and much of social scientific discourse. In general, according to modernization theories, both family and religion are relegated to the "private" sphere, set apart from the broader social processes and, thus, less significant than those broader processes.

Despite this widespread orientation, a revolution in the social sciences has been gaining momentum over the last twenty years or so. The

message of this revolution is that the modernization perspective is no longer an adequate vision for understanding the dynamics of modernity or the potentials of postmodernity for religion and family. In the sociology of religion, the paradigm shift moves social science away from a focus on religion as a disconnected phenomenon to a much more complex view of the nature of religious inter-institutional relations. Reflecting this shift, numerous scholars have begun to examine religion as an influence on and as an effect of varied social, political, and economic variables (e.g., Carter 1996; Cousineau 1998; Hammond 1985; Misztal and Shupe 1992; Roberts 1995; Rubenstein 1987; Shupe and Misztal 1998; Swatos 1992; Witte 1993). A market model of religion, based in rational choice propositions, has become the most strongly debated version of the new way of looking at the religious institution (Hadden 1995; Warner 1993; Young 1997).

Similarly for the family, there are many who now argue that, in spite of its changing forms and functions, the family as an institution remains crucially central to social processes and to the patterns of change determining the future of human societies (cf. Cherlin 1996). If not taken into consideration, family processes themselves are liable to torpedo efforts at planned social change and to deflect the vectors of unplanned change in unexpected directions (Settles 1996).

Attuned to the inter-institutional perspective, this article examines the linkage between family and religion. Then, after discussing social change processes, we make the point that the religion and family linkage today is important not only in the burgeoning private sphere but in the public realm as well. In spite of its importance, sociologists have given relatively little attention to family and religion together (Thomas and Cornwall 1990). A few journal articles and four collected volumes have addressed this institutional linkage. D'Antonio and Aldous (1983) and Thomas (1988) edited general volumes, and a collection by Ammerman and Roof (1995) focused on family and religion in relation to work. As of 1999, only one book (Houseknecht and Pankhurst 2000) had taken an international comparative approach to the topic. (An expanded

discussion of some of the themes presented here can be found in the introduction of the latter volume.)

THE RELIGION AND FAMILY LINKAGE

In order to understand the significance of religion and family for both the private and public spheres, we must see clearly their unique characteristics and how they interrelate. The inter-institutional relations between family and religion are strong and qualitatively different from other institutional relationships. Berger (1967) noted that in premodern societies kinship was permeated with religious meaning, and in modern societies religion remains closely connected to the family. Hargrove (1979), in her systematization of the sociology of religion, argued that religion and family have had a close relationship throughout history in both Western and non-Western societies. D'Antonio and colleagues (1982) also stressed the significance of the connections between these two institutions.

Both the familial and religious institutions are characterized by what MacIver (1970, p. 45) called cultural rather than secondary interests. In other words, associations within the religious and familial spheres pursue interests for their own sake, because they bring direct satisfaction, not because they are means to other interests, as in the case of economy and polity. Both family and religion are devoted to organizing primary group relations. They stand out as the only two institutions that deal with the person as a whole rather than just segmented aspects of individual lives. These various similarities that religion and family share serve to strengthen the inter-institutional ties between them.

The interrelations between the institutions of religion and family are reciprocal (Thomas and Henry 1985; Thornton 1985). Religion provides the symbolic legitimation for family patterns (cf. Berger 1969), and the family is a requisite for a vigorous religious system because it produces members and instills them with religious values. In fact, numerous familial events are marked in religious contexts (e.g., weddings and funerals), and many religious observances take place within the familial setting (e.g., prayers at meals and bedtime).

The special affinity of religion and family as institutions takes varied forms. Almost everywhere, religion provides ritual support for family and kinship structures. This is the case even in a highly secularized society such as Sweden (Trost and Palm 2000). In some societies, this ritual support may be seen in ancestor rites or memorialization, for example, in Cameroonian Kedjom rites (Diduk and Maynard 2000), Japan's core religion (Smith 2000), Taiwan's folk religion (Yang et al. 2000), and French Mormonism (Jarvis 2000). Such practices support family life and, at the same time, fulfill a central function for religion itself (cf. Berger 1969, p. 62). In fact, Jarvis argues that the familism of Mormonism, expressed both ritually and in church values, is its greatest asset in the eroding environment for traditional families in France. Moreover, utopian experiments and new religious movements often take the family as their essential focus. According to Christiano (2000), in the Unification Church ("Moonies"), the family serves as more than the organizing metaphor for the group: It provides a basic model for the church's self-conception.

FAMILY, RELIGION, AND SOCIAL CHANGE

The institutions of family and religion, in their interactions with each other and with the rest of society, can be considered in terms of two broad social change patterns—institutional differentiation and institutional dominance. Secularization can be seen as a special instance of institutional differentiation, and we discuss the concept and its use below, indicating the value of religious economy models over the conventional secularization approach.

Institutional Differentiation. Underlying all the dimensions of social change is the notion of institutional differentiation. This phenomenon implies greater specialization. Although the paths and extent of institutional differentiation vary across societies, when differentiation does proceed, we see fundamental changes in inter-institutional relations (cf. Alexander and Colomy 1990; Beckford 1989). Institutional differentiation affects all institutions, and we argue more broadly that one cannot assume inter-institutional isolation of religion

and family in the private sphere, even in highly differentiated societies. The effects of these institutions are always felt across inter-institutional divisions in some measure. In this section, we examine the issue of differentiation of religion and family conceptually.

Our previous description of the religion and family linkage as involving special affinity and reciprocity was not to say that religion and family always and everywhere are, or must be, equally intimately entangled. We can see a continuum in the level of differentiation of these institutions. On the one end of the continuum, Islam in Egypt (Houseknecht 2000) displays a lack of differentiation, an elaborate interweaving of the two institutions that makes each strongly dependent on the other. And research on the Cameroonian Kedjom funerary rites (Diduk and Maynard 2000) provides an example of religious practices that are hardly differentiated from the kinship context; they are precisely an affirmation of the kinship patterns of Kedjom society.

On the opposite end of the spectrum, Sweden, a country in which the Lutheran Church is officially established and a large majority of the population are nominal members, is highly secular. Developments in the family there have widely diverged from the traditional model that Protestant Christianity had advocated. In Sweden, the two institutions are intertwined only in limited ways (Trost and Palm 2000). It is primarily in regard to life-cycle rites that the two intersect. The individualized faith of many Americans also accompanies a highly differentiated system of institutional relationships (Christiano 2000).

Secularization Theories. Secularization is a special process of differentiation in which that which was previously under the “sacred canopy” (Berger 1969) of religion is removed from that realm and placed in a nonreligious institutional context. Allegedly, education, the acceptance of science, urbanization, industrialized work-life, and the like take away the mystery of religion and strip it of its “plausibility” in many areas of concern. Thus, cure of disease, protection from misfortune, explanation of the universe, and so forth are made

rational and thus not subject to religious intervention. In this approach, religion remains relevant only for very personal spiritual quests and solace in the private sphere, and most of its social institutional ramifications become, first, empty shells, and eventually vanish.

The notion of a unilinear process of secularization has long troubled many sociologists (cf. Hadden and Shupe 1986; Hadden 1987; Hammond 1985). Some have developed variants that see secularization as a cyclical process with long historical waves. Nisbet (1970), for example, reminds us of the rationality of the eras of classical Greece and of the Renaissance and Age of Reason, with the period from first century Rome to the Renaissance having Christianity “virtually eliminating secular rationalism from the European continent for more than a thousand years” (p. 391). Though we are now in a rationalizing or secularizing age, “To argue permanence for this age would be, on the testimony of history, absurd” (p. 391). Recently, as we shall see, sociologists of religion have focused upon shorter waves of secularization and have viewed the process as self-limiting. The most prominent versions of this approach apply economic models to religious markets, putting aside the notion that religion must be irrational or otherwise antimodern. Some of these postsecularization theorists argue for a rational choice approach to religion (Young 1997), an approach that is largely alien to the mode of thought underlying secularization theory.

In the long debate about the validity of notions of secularization within the sociology of religion, it has become clear that secularization cannot be understood in a simplistic way, if one wants to keep the concept at all. While certain evidence of secularization seems apparent, there are counter-movements suggesting that religion is truly vital in the modern world (cf. Marty and Appleby 1995). The spread of Liberation Theology throughout Latin America in the 1970s and 1980s (Berryman 1987; Smith 1991), followed by the more recent explosion of evangelical, fundamentalist, and pentecostal Protestantism in the same world region (Martin 1990), suggest the power of the human concern regarding spiritual or nonempirical matters. Similarly, the tenacious attachment of Americans to belief in God (Greeley 1989, 1992; cf. Wald

1986), their high levels of religious activity, and the numerical growth and public voice of evangelical Protestantism indicate that religious sentiment of some sort is compatible even with a society that is highly developed socioeconomically. Going beyond the simple Marxist assertion that religion is illusion, even if religious claims are often masks for the interests of power or wealth, religion must be understood as a very real and consequential part of sociocultural life.

Casanova (1994) carried out one of the most extensive recent cross-cultural analyses of religion, a close examination of the conditions of evangelical Protestantism and Catholicism in the United States and of Catholicism in Brazil, Spain, and Poland. He argued that the social scientific literature depicts secularization as having three correlated dimensions, but his research challenges this idea by convincingly showing that the three dimensions are not always present together. First, Casanova accepts the validity of claims that secularization entails a structural differentiation of the religious institution from other institutions as societal modernization takes place. This differentiation means, in particular, the “emancipation of the secular spheres from religious institutions and norms” (Casanova 1994, p. 6). However, the second dynamic often subsumed under secularization—the decline in religious beliefs and practices—cannot be taken for granted, and it does not necessarily follow from the first. The third dynamic, which is the core of the privatization thesis, is that religion will sequester itself in the private sphere under modernity, and, according to some analysts, will be marginalized there. However, this process, too, cannot be assumed to be associated with secularizing institutional differentiation. The second and third dynamics are unwarranted correlates of the first. While Casanova would have us accept the first as the true essence of secularization, he argues that the second and third are not supported by empirical evidence and should not be seen as part of the secularization process.

While there is no question that institutional differentiation is a sort of master process of the modern era, we cannot assume that it has progressed equally far everywhere. As already noted,

cases like modern Egypt and Cameroon, though both experiencing significant pressures toward greater differentiation, evidence far less differentiation between family and religion, and between these two and other institutions, than does, for example, the United States or Sweden. Furthermore, even if there is great differentiation, one cannot presume that the influences of the religious and familial institutions end. As the debates on abortion policy illustrate, even in a highly differentiated society like the United States, there is plenty of room for religious assertions beyond the alleged parameters of secularized religion and into political life. This circumstance indicates that we cannot take for granted notions of the irrelevance of religion for social policy, as secularist analysts are prone to do.

In addition, it also is possible for there to be de-differentiation in a highly differentiated society. Some of this has happened in Belarus during the post-Soviet period (Vardomatskii and Pankhurst 2000). Better known to the U.S. public is the recent passage of laws in Russia favoring the Russian Orthodox Church (Pankhurst 1998) after many decades of antireligious, extremely secularist communist control under the Soviets and after a brief period of strict legal disestablishment of all religions between 1991 and 1997. Here are instances of seeming de-differentiation, where the gap between politics and religion is narrowed. Similarly, the debate in Indonesia over divorce law indicates efforts to reassert religious authority over a legal arena that had been under state control for several decades (Cammack et al. 2000).

Religious and Familial Markets. The notion of unilinear secularization seems untenable, but there are certainly processes of decline and growth in religious phenomena that must be explained. The general inter-institutional perspective focuses attention on relationships that are important for these variations in the strength and character of religion. In addition, sociologists of religion have found market model approaches useful, within the general inter-institutional perspective, for generating testable hypotheses about several aspects of religion and family in various societies.

Social differentiation approaches, including secularization theories, start from observations of

society from the top down. An alternative approach is to look from the bottom up, moving from the level of individual social action toward the institutional structures that the aggregation of such action creates. Such an approach is found in rational choice theories, which begin by analyzing patterns of individual behavior according to the economic logic of consumer choice. In rational choice approaches to religion, churches and other religious organizations are seen as firms offering a variety of goods and services to consumer-believers and consumer-parishioners. When patterns of individual consumer choice are aggregated, market structures become apparent. Such markets provide the context within which patterns of supply and demand are worked out. They distribute goods and services to consumers, as well as "market share" to religious firms. Seen from the market model viewpoint, the issue of the strength of religion boils down to the likelihood on the part of potential consumer-believers to buy into a given religious belief or practice, or to affiliate with a given religious firm such as a temple or a missionary organization. Just as the level of economic purchases rises and falls over time, so does the level of various religious "products," like church membership or belief in God, rise and fall. What governs variation in purchases or adoptions (or church membership or belief in God) is the logic of rational choice among the options in the marketplace that are available to the consumer-believers or the consumer-members. Religious organizational leaders, like business executives, proffer a variety of products to the consuming public and vary the price of such products in order to attract consumer-believers. The leaders seek market share in the religious market.

This emerging "new paradigm" for understanding religious change relies upon economic models of the religious market to understand differing levels of religious group affiliation and participation (Hadden 1995; Warner 1993; Young 1997). Stark and Bainbridge (1987) provide an elaborate deductive theory of religion based upon rational choice principles, and this theory provides the backdrop for a series of more recent studies by these authors and collaborators (Hadden

1996). Perhaps most prominent among the studies developed in connection with this theoretical approach is Finke and Stark's (1992) analysis of American religion, which shows that, over the last three centuries, it has grown, rather than declined, in number of participants and proportion of the U.S. population, contrary to what secularization theory would predict. The authors argue that the growth is the result of competition in a pluralistic market. The economist Laurence Iannaccone (1995, 1997, and works cited in these sources) has elaborated several propositions in line with the theory and expanded the application of economic modeling.

The approach seems to hold greater promise for explaining and predicting the dynamism of religious phenomena than do other approaches that are primarily based in traditional functionalist secularization theorizing. For present purposes, its primary wisdom is that secularization processes are self-limiting. That is, when "the processes that erode commitments to a particular set of supernatural assumptions" (Stark and Bainbridge 1987, p. 311) advance far enough, the religious market will be open to new options. These options, according to Stark and Bainbridge (1987), take the form of either schisms from established groups, sects, or cults.

One of the great assets of the cultural market approach is that it is inter-institutional while at the same time giving individuals agency. That is, market-based institutions are structured by the individual patterns of choice that are aggregated in any society. Simultaneously, institution building is regulated by relationships with other institutions in an interactive process. Clearly, there are many avenues for development of other theoretical approaches to these issues. In particular, conflict theory, social movement theory, and Weberian theory have valuable traditions of analysis that apply to family and religion. Theoretically and conceptually, there are similarities between the market approach and these other approaches. But the market approach, which has assimilated numerous insights from other approaches, establishes a greater balance between micro and macro elements.

The economic model in which the market approach is rooted certainly has its own limitations. Perhaps its biggest problem for many readers is the use of a language that has its own implications that do not and should not apply to religious and familial processes. From a strict theoretical perspective, perhaps the most daunting criticism of the theory argues that religious choice by its nature cannot be strictly rational (cf., Chaves 1995; Demerath 1995; Neitz and Mueser 1997). It is this point of view that has discredited the theory most strongly in the religious studies field, where its advocates are relatively few. In his review of Finke and Stark's (1992) revisionist study of American religious history, Martin Marty (1993, p. 88) writes that their "world contains no God or religion or spirituality, no issue of truth or beauty or goodness, no faith or hope or love, no justice or mercy; only winning and losing in the churching game matters." The work, Marty says, is reductionistic, oversimplifying complex issues. Further, James Spickard (1998, p. 110), though expressing considerable sympathy for the rational choice model, has argued that "a rational-choice [*sic*] model can duplicate the overall structure of a religious marketplace, but it cannot demonstrate that individual people think in market terms."

Some sociologists (Ammerman 1997; Ellison 1995; Sherkat 1997) have contended that the notion of rational choice does not adequately take into account the structuring of individual preferences by a host of contextual, cultural, or environmental variables. Several have argued that the value of the approach in analyzing the open, pluralistic market of the United States may not extend to other societies (cf. Warner 1997). The approach also has been charged with being androcentric (Carroll 1996) and with ignoring gender as a variable (Neitz and Mueser 1997). These criticisms are important, but they do not, in our eyes, undermine the approach so much as indicate an agenda for research and further conceptual development.

At this juncture, it should be noted that much of the logic that has just been applied in the discussion of religion could presumably be extended to families. Among many social scientists, there is an overgeneralization from patterns of

differentiation related to families that is similar to that which Casanova identified in secularization thinking about religion (cf. Hargrove 1985). There is a widespread notion that changing patterns in the family (related to institutional differentiation) mean that the family is not centrally important in the modern age. From this premise, we are led to focus on the "private" family to the neglect of the "public" functions that the family retains (Cherlin 1996). It is as if the many "problems" of families remove the family from useful consideration. While scholars often take families for granted, there is clearly no more powerful socializer of the young and no other viable means for the reproduction of society through the birthing of new members than the family, whatever form it takes. If we assume the phenomenon can be identified by its function, that is, by what it does, rather than by its form, then we cannot imagine a society without families and without the effects that families by definition have.

Family sociologists and economists have long examined the economic side of families in its own right, looking at the effects on families of work, the household division of labor, the patterns of money and time budgets, and the like. There also have been significant studies using the market analogy to understand strictly familial phenomena. The economist Gary Becker (1973, 1974, 1976, 1981; Becker et al. 1977) has been the most deliberate in applying analytical tools from economics to family matters. (His impact on the religious economy approach is acknowledged by Iannaccone, 1997.) Others using economic analytical tools in studies of aspects of families that are not formally economic include Grossbard (1978), Huber and Spitze (1980), and Johnson (1980).

In an open "family market"—a notion that deserves much more elaboration and evaluation than we can give it here—the adoption of one family form over another (say, single parenting over dual parenting, isolated nuclear households over interconnected extended kin networks, or formal marriage over nonmarital cohabitation) would relate to the evaluation by participants of the costs and rewards associated with the adoption of the given form. Costs and rewards would be assessed by the individual taking into account the

surrounding culture and relevant subcultures, which would presumably restrict options for “choice” in numerous ways. Trost and Palm (2000) have outlined the conditions for a fairly open familial market system in Sweden.

As some work in the economic approaches to religion shows, one can include consideration of contextual variables in developing criteria of “choice” in such matters (see, for example, Ellison 1995; Iannaccone 1997; Sherkat 1997). Among significant influences on choice would be individual religious beliefs or the values of the religious affiliation a person may have, both of which are the product, to some degree, of the family socialization and community experience of the person. We can extend this line of thought by including a range of cultural variables that allow the research to be fully comparative, potentially applicable to any society or subsocietal unit. In short, conceptually exploiting the analogy with economic markets has potential for the analysis not only of religion but of family matters as well. In the end, such an approach would identify the conditions under which particular choices in the realm of families can be seen as signs of the strength of adaptive families rather than compromises of weak and ineffectual families.

Finally, it is interesting and important to note that the economic approach to religion relies on an understanding of religious choices as based in the household as much as in the individual. Religious “goods” are “household commodities” that the household invests other goods, labor, and skills in producing, according to Iannaccone (1997). In this imagery of the *household* producing religion, then, we again emphasize the intimate connection between religion and family. From this point, we need to establish its place in the larger sociocultural context.

Institutional Dominance in Modern Societies. Modern structures of institutional dominance—a concept first articulated by Williams in ([1955] 1970)—do not negate the importance of the religious and familial institutions. In many societies today, family and religion do not rank high in the relative dominance of major societal

institutions. On the contrary, there usually is some other institution that dominates the entire social system, most often the economy (as in Sweden and the United States, for example). Although this means that the economy is much more likely to be the instigator of social change in the less powerful institutions than vice versa, it does not follow that family and religion cannot initiate change as well. They can and they do, although such occurrences are much less frequent than in the case of the dominant institution(s).

Sometimes the question is asked, Do family and religion facilitate or hinder social change? But this question is an inappropriate one to ask. It is one that never is asked about the economy or the polity. Perhaps it is raised in the case of religion and family because these two institutions are viewed as conservative—as part of the past that is slowing down forward motion. This view, however, is untenable. All societal institutions—including family, religion, polity, economy, education, health care, welfare, and so forth—both facilitate and hinder social change. The direction of their effects depends on what best meshes with their interests at a particular point in time. Research on Brazil and Mexico illustrate facilitating effects of religion for change in gender roles. In fact, according to Rosado Nunes (2000), Catholicism in Brazil did more than facilitate—it orchestrated dramatic changes in women’s roles, restricting women to a very limited range of options within the household by the nineteenth century. Fortuny Loret de Mola (2000) showed how the mobilization of Protestantism in Mexico has provided for certain aspects of authority and legitimacy for women that the dominant Catholic culture did not support, that is, religion has fostered change in gender roles in a direction opposite to that of Brazilian Catholicism. While these examples evidence the change-oriented qualities of religion and family, work on Egypt (Houseknecht 2000) provides a good contrasting example in that it describes the hindering influences that religion and family can have with regard to social change in other institutions. Finally, in Godsell’s (2000) study of South Africa, we see examples of both facilitation and hindrance of social change by the religious and familial institutions. While the East Asian Hindu and Muslim

networks promote entrepreneurship, the black African Christian ones tend to inhibit the development of entrepreneurial activities.

In the modern world, the intersection of institutions is largely in the realm of economic issues—because of the dominance of the economic institution. This is true even in the interactions of noneconomic institutions, since the values and norms of the dominant institution “permeate a great many areas of life and enter into the operation of other institutions” (Gouldner and Gouldner 1963, p. 496).

RELIGION AND FAMILY IN THE PRIVATE AND PUBLIC SPHERES

Although analysts have tended to see family and religion as institutions of the private sphere, there is no question but that they are both found in the public sphere as well. In the following sections, we elaborate on the dynamics that are found within and between these spheres.

The Private Sphere. Some theorists have argued that “privatization” (Luckmann 1967; Berger 1967) characterizes religion in modern societies and that the private sphere is shared by the family (Berger 1969). With modernization, these two institutions tend to become more specialized and to take on new forms as they structure and give substance to the private sphere. A high degree of differentiation, though, does not put an end to the family and religion connection, even though it weakens the relationships that they have with each other and with other societal institutions. The private sphere may seem to be, in a macro sense, peripheral in the modern world, but it nevertheless is where we find a bedrock of mutually reinforcing relations between family and religion. As noted earlier, both of these institutions focus on primary relations, and, in the past, primary relations were much more encompassing of all inter-institutional relations. This meant that the points of intersection that these two institutions had with each other and with other societal institutions were many. In modernized societies, though, the relevance of primary relations has come to be

limited more to the private sphere than in the past. And it is in the private sphere where we see what is really unique about the family and religion linkage. It is here that the connection is cut to the bare bones, and it is here that we see the affinity (although reduced) that persists despite differentiation.

With modernization and postmodernity, the private sphere has emerged as a unique social phenomenon. Although family and religion come to be dominated by other societal institutions in the modern setting, the private sphere that they constitute is of growing importance. It is a buffer zone in which individuals receive support that helps them absorb the stresses and strains brought on by their public activities in other institutional spheres. Because the public and private domains become less and less well integrated, the need for retreat to privacy grows. Not only is the private sphere an essential retreat, but it is also a place where people can devote more and more of the bounty of economic development—increased leisure time, less constant concern with mere survival, and greater financial and other material assets. In short, the private sphere is expanding in the modern world both because of the social psychological need for it and because of the availability of greater resources that can be devoted to it.

The growth of the private sphere signifies one way that the importance of family and religion is growing. Roof (1993) and Wuthnow (1994a) have argued that a primary form of contemporary American religion is found in the self-help or support group (which is frequently located within the context of the church, though it need not be). Aimed at solving problems of individual adaptation, interpersonal relationships, and local community issues, such groups would seem to represent a therapy technique for private troubles. As the private sphere grows, this function grows to match. However, both Roof and Wuthnow also claim that these groups are, in fact, linking mechanisms which bring the private sphere and the public sphere into connection. They are means of overcoming one-dimensional individualism and of connecting the individual with the broader community.

The Public Sphere. The recognition that the private functions of religion and family are vital

and even expanding in modern societies is not inconsistent with the fact that the public side of these two institutions retains significance (cf. Beyer 1994). Both family and religion provide important public functions that, in the end, demand our attention. They are public functions that are in crisis in many ways in modern and globalizing societies, and understanding them clearly should aid those who seek to overcome the crises. Following the work of Cherlin (1996) on families and of Casanova (1994), Cochran (1990), and Wuthnow (1994b) on religion, we note that both these institutions provide a range of significant public goods. Such goods are general benefits for the society; they cannot be denied to those who did not participate in producing them, and they often are in short supply due to the tendency for nonproducers to “free-ride” on the efforts of those voluntary actors who take part in the production.

Families provide the public good of children—they give birth to them and raise them to be contributing members of society. These children, then, by being productive, paying taxes, and paying into Social Security and other pension systems, help support all persons in the society, but particularly persons who have aged past the productive years. In addition to reproduction, Cherlin (1996) asserts that, in bearing the burden of dependence created mostly by care for children and care for the frail elderly, families are providing public goods. These public functions are fewer than the public functions of families in the past (Demos 1970), but they are nevertheless extremely important in the modern world.

In a similar vein, religion provides important public goods as well. The first of these is moral values. In modern societies, many citizens do not nurture moral values through church participation and support, and yet the Ten Commandments are nearly universally honored as moral values. Although derived from religious sources and cultivated and rehearsed in religious settings on a regular basis, they are not perceived as sectarian or limited in applicability. They are the concrete form of broad societal values that are not, for the most part, in dispute. Still, it is only the religious groups—aided and abetted by families, of

course—who spend the time reminding us of the importance of these fundamentals. Even atheists profit from the order and social stability that such an emphasis nurtures (cf. Cochran 1990). While Durkheim (1973) thought that adequate progress would lead to the usurpation of this moral production role of religion by education, with schools sustaining the essential values for the modern society, this situation has not yet arrived. The difficulty in designing a moral program that can be taught in the schools seems only more and more dependent upon the interpretation of relevant faith traditions. The schools, rather than displacing religious groups in this task, seem to be calling upon them for clarification and support (cf. Wuthnow 1994b).

Cochran (1990) stresses that religion is also important as a forum for public participation, that is, a place where people come together and discuss, evaluate, lobby, and generally keep informed about public issues and problems. In fact, while the private side of religion focuses upon individual salvation, there is also the supremely public side of “prophetic” religion, to use Weber’s ([1922] 1963) term for the kind of religion that challenges and calls for reform in society. As a forum for participation, the church, synagogue, mosque, or temple provides a venue in which individuals and families work out their positions vis-à-vis the politics and economics of their communities.

Casanova (1994) argues that religions today are more and more asserting their influence and enunciating their interest in secular affairs, mostly rising against the presumptions of the state and the market to prevent their incursion into religious matters. There is a new era, he asserts, of “public religion.” The core of Casanova’s argument is that, instead of a retreat by religion into a segregated and marginalized private sphere, there is today a “deprivatization” of religion in the world as one after another faith reasserts its claims to an active role in the broader society, especially in politics and economics. The mobilization of religious groups around the abortion debate in the United States is one such example, with the well-known engagement of American Catholic and conservative Protestant groups in unexpected political contestation with the government (cf. Pankhurst

and Houseknecht 1983). Another form of this deprivatization is the demand that the church not ally itself with the political and economic elites when the latter create and enforce policies or patterns of control that disenfranchise segments of the population, such as the poor or minorities. From within the faith, there has arisen the counterdemand that the poor be given a chance to improve and to escape the bonds of poverty. We can see these counterdemands dramatically stated in the Liberation Theology of the 1980s in Latin America. They also are advocated by a variety of Christian groups in the United States (Hart [1992] 1996).

In the end, such processes indicate the reinvigoration of public religion around the world. For Casanova (1994), even Islamic movements can be seen in this light and should not be consigned to a peripheralized "fundamentalist reaction" to modernization. Whether progressive or conservative, public religions' calls for a new vision of politics and economic life are an essential characteristic of the present era. We cannot, then, think of religion as circumscribed by the private sphere, Casanova argues, and must not neglect the public roles that religions play if we are to perceive the modern world clearly.

In sum, religion and family, both public and private, are essential components of modern life. If anything, their future roles seem to be growing rather than shrinking. Biomedical advances promise to play out most dramatically the questions of life and death, spirit and body in the public church and the public family, which will have to adapt to longer life and, perhaps, longer periods of dependency for the elderly. The need to prepare children for appropriate careers in the new fields being created by technological advances will have to be addressed in the personal councils around the kitchen table that always so strongly influence the occupational choices that young people make. Those occupational choices will rely, in some indirect but profound ways, on the economic ethic that is espoused in the religious community that the family adheres to. In the Third World, development hinges, to some degree, on the fertility decisions made in the family under the influence

of the faith that defines appropriate sexual and reproductive behavior. In the process of economic and political change that so many societies experience as disruption and disorganization, family and religion provide important sources of stability and order, even as they adapt to the changing circumstances they find themselves in. It is there that one should go to find the processes working out the morality for the new age and the lifestyles for the new era.

FAMILY LAW

Family law is that body of law having to do with creating, ordering, and dissolving marital and family groups. Although the exact scope of family law is given differently by different authors, at its core family law is concerned with such issues and events as marriage, separation, divorce, alimony, custody, child support, and adoption, as well as the more arcane topics of annulment, paternity, legitimacy, artificial insemination, and surrogate parenting.

This entry on family law in the United States should be read with two important caveats in

mind. First, it is somewhat misleading to write of “United States” family law. Because the power to regulate domestic life is not one of the powers delegated to the federal government by the Constitution, in the United States most family law has been “a virtually exclusive province of the states” (*Sosna v. Iowa*, 419 U.S. 393 [1975]). Despite considerable variation in state law, however, certain general trends can be identified. Moreover, researchers have identified similar trends in a number of European countries (Glendon 1989).

Second, many kinds of law that affect the family cannot be discussed here. These include laws that are not ordinarily listed under the rubric of “family law” but that have significant effects on family life in this country. These range from the laws of inheritance to zoning regulations and regulations about social welfare programs. While the impact on the family of a diversity of laws seems to become increasingly significant, this is not a uniquely modern phenomenon. For example, 200 years ago poor laws affected family life in ways that anticipated the impact of modern welfare laws (tenBroek 1964).

As was typical of much of early law in this country, most American family law was received from English law; but family law was atypical in that much of it was not derived from secular or “temporal” English law. In England, from the late twelfth century (Pollock and Maitland 1898, Vol. 2, p. 367) until the passage of the Matrimonial Causes Act of 1857, issues pertaining to marriage and divorce were governed by canon law, and most family matters were thus subject to the jurisdiction of ecclesiastical courts. While the American colonies had no ecclesiastical courts, English canonical rules concerning family relations were incorporated—either by statute or by common law tradition—into the laws of the colonies and, later, the states (Clark 1980).

Notwithstanding its religious heritage, family law in this country was completely secular. Although marriages were frequently performed by members of the clergy, the authority to solemnize marriages was vested in them by the state, not the church. In legal theory, at the basis of the family

was a marriage that was a civil contract and not a religious sacrament.

This contractual view of marriage had some interesting consequences. For example, it led to official recognition of informal as well as formal marriage. This informal union, the so-called common law marriage, was effected by the simple express agreement of a man and a woman to be married, followed by their cohabitation. (Contrary to popular myth, common law marriages did not require a specific number of years to go into effect.) While today they are recognized only in fourteen states, until the twentieth century common law marriages were as valid as formal marriages in nearly every state (Wardle et al. 1988, § 3:17). Recognition of common law marriage meant that settlers on the geographic fringes of society, without access to officials, could enjoy the same protection of their property rights and their children’s legitimacy as was afforded in formal marriages. In 1833, Chief Justice Gibson of Pennsylvania ruled that rigid marriage laws were “ill adapted to the habits and customs of society as it now exists.” Not recognizing common law marriage, or so Gibson suggested, would “bastardize the vast majority of children which have been born within the state for half a century” (*Rodenbaugh v. Sanks*, 2 Watts 9).

After the Civil War, there was a movement to strengthen state regulation of marriage. Most states already required marriage licenses, but in antebellum America, courts had treated these licenses as a means “to register, not to restrict marriage” (Grossberg 1985, p. 78). By the end of the nineteenth century, however, marriage licenses had clearly become a means of social control. Because the process of acquiring a marriage license brought the couple under scrutiny of some official, licensing requirements helped states prevent marriages of people who were too young or too closely related, either by blood (consanguinity) or marriage (affinity). Official scrutiny of those seeking to wed also helped to enforce laws against bigamy and polygamy.

But legislators, encouraged by eugenicists who believed that crime, mental illness, and other social ills could be traced to hereditary biological

factors, also enacted laws enumerating other kinds of forbidden marriages. For example, marriage was prohibited to those not mentally capable of contracting owing to conditions variously labeled as insanity, lunacy, idiocy, feeble-mindedness, imbecility, or unsound mind (Clark 1968, pp. 95–96). Marriage was also prohibited to those physically incapable of performing the “marriage essentials.” Generally, this latter criterion involved only the capacity to have “normal” or “successful” sexual intercourse, not necessarily the ability to procreate. As one author explained it, “Copula, not fruitfulness, is the test” (Tiffany 1921, p. 29).

Eugenics also justified, scientifically, laws that prohibited people with certain diseases (e.g., epilepsy, tuberculosis, and venereal disease) and statuses (e.g., habitual criminal, rapist) from marrying. In most cases, such obstacles could be overcome only if the person consented to sterilization. Many believed such statutes were necessary to “prevent the demise of civilized-society” (Linn and Bowers 1978, p. 629). Even some of the most respected legal thinkers joined the eugenicists. Justice Oliver Wendell Holmes of the United States Supreme Court, for example, wrote that it would be “better for all the world, if instead of waiting to execute degenerate offspring for crimes, or to let them starve for their imbecility, society can prevent those who are manifestly unfit from continuing their kind” (*Buck v. Bell*, 274 U.S. 200 [1927]).

The most notorious marriage impediment was race. By 1930, thirty states had enacted statutes prohibiting interracial marriages (Clark 1968, p. 91). For the most part, these antimiscegenation laws forbade marriages between whites and blacks, but in several cases the prohibition was extended to, for example, white and Malays, whites and Mongolians, whites and Native Americans, and blacks and Native Americans (Kennedy 1959, pp. 59–69).

Divorce was even more strictly regulated than marriage. However, the absence of ecclesiastical restrictions made divorces much easier to obtain in the United States than in England. This was especially true in the northern states. A few states even allowed divorce simply where the cause

seemed “just and reasonable.” Connecticut, for example, permitted divorce for conduct that “permanently destroys the happiness of the petitioner and defeats the purpose of the marriage relation” (Clark 1968, p. 283). During the latter part of the nineteenth century such generous statutes were repealed, and divorce was allowed only in response to specific types of fault—usually adultery, desertion, cruelty, or long-term imprisonment.

Despite stringent regulation of entrance to and exit from marriage, husbands and wives in intact marriages were generally protected from legal scrutiny. Indeed, traditionally, the principle of nonintervention was so strong that neither husbands nor wives could invoke the law to resolve marital disputes even when they wished to. In one case, for example, the wife of a well-to-do but stingy husband asked the Nebraska courts to require him to pay for indoor plumbing and to provide a reasonable allowance to her. The court agreed that, given his “wealth and circumstances,” the husband’s attitude “leaves little to be said in his behalf.” But, said the court, “the living standards of a family are a matter of concern to the household and not for the courts to determine” (*McGuire v. McGuire*, 157 Neb. 226, 59 N.W.2d 336 [1953]). Similarly, the courts preferred a hands-off approach to parent–child relationships. As the United States Supreme Court ruled in 1944, “the custody, care, and nurture of the child reside first in the parents, whose primary function and freedom include preparation for obligations the state can neither supply nor hinder. . . . It is in recognition of this that [earlier] decisions have respected the private realm of family life which the state cannot enter” (*Prince v. Massachusetts*, 321 U.S. 158 [1944]).

The extent of the courts’ reluctance to intervene in family matters or, as it was sometimes put, to “disrupt family harmony,” was shown in the rule that spouses could not sue one another for personal torts or injuries. If, for example, a husband assaulted or battered his wife, she was enjoined from taking legal action against him in civil court (Keeton et al. 1984, pp. 901–902). In theory, the husband could be prosecuted in criminal court, but police and criminal courts too were reluctant to interfere in domestic matters (Pleck 1987, p. 187).

The practice of nonintervention was carried a step further at the turn of the century when the courts invented the doctrine of “parental immunity.” Owing to reasons of “sound public policy, designed to subserve the repose of families and the best interests of society” (*Hewellette v. George*, 68 Miss. 703, 9 So. 885 [1891]), an unemancipated minor was barred from suing his or her parents for negligent or intentional wrongdoing.

Owing to the state’s reluctance to intervene, the family has had a great deal of autonomy in this country, even to the extent that some have referred to the family as a “minisovereignty” (O’Donnell and Jones 1982, p. 7). In recent times, this autonomy has been justified on the basis of privacy rights. Speaking of the married couple’s right to make decisions about the use of contraception, the United States Supreme Court said in 1965, for example, “we deal with a right of privacy older than the Bill of Rights” (*Griswold v. Connecticut*, 381 U.S. 479 [1965]).

But things began to change in the late twentieth century. First, beginning in the 1960s, strict regulation of entrance to and exit from marriage began to unravel. In the 1967 case of *Loving v. Virginia*, the United States Supreme Court ruled unconstitutional all antimiscegenation laws, saying that the states had no right to “prevent marriages between persons solely on the basis of racial classification.” “Marriage,” said the Court, “is one of the ‘basic civil rights of man,’ fundamental to our very existence and survival” (388 U.S. 1; quoting *Skinner v. Oklahoma*, 316 U.S. 535 [1942]). Since *Loving*, many other marriage restrictions have been repealed or eased. Age requirements in many states have been lowered; the mental ability needed to contract marriage has been ruled to be less than that required for other sorts of contracts; and the necessary mental competency is presumed to be present unless there is “clear and definite” proof to the contrary. Moreover, “there is a trend in modern times to abolish affinity restrictions” (Wardle et al. 1988, § 2:09); only one state (Missouri) still prohibits epileptics to marry (Wardle et al. 1988, § 2:47), and in many states, even prison inmates are deemed to have a right to marry (*In re Carrafa*, 77 Cal. App.3d 788 [1978]).

These changes reflect the courts’ willingness to protect the rights of individuals to make their own choices about marriage and related matters. The decision to marry, according to the Supreme Court, is among “the personal decisions protected by the right to privacy” (*Zablocki v. Redhail*, 434 U.S. 374 [1978]).

Presumably, much the same can be said about the decision to divorce; recent changes in divorce laws have, if anything, been even more dramatic than changes in marriage laws. Implicitly accepting the principle that there is a right to divorce, the Supreme Court ruled in 1971 that welfare recipients could not be denied access to divorce courts because they could not afford to pay court costs and fees (*Boddie v. Connecticut*, 101 U.S. 371 [1971]). By the mid-1980s, every state had either replaced fault-based divorce laws with no-fault laws or added no-fault grounds to existing laws (Freed and Walker 1986, p. 444). No longer, then, must there be a “guilty” and an “innocent” party in a divorce. Instead, one spouse simply needs to assert that the couple is no longer getting along or has been living apart for a certain amount of time.

While regulations governing entrance to and exit from marriage and family life have decreased, there has been a corresponding increase in regulations affecting relations in ongoing families. Spousal immunity has been abolished in most states. Moreover, in many states the law recognizes the crime of “marital rape.” Similarly, children now have more rights that can be asserted against their parents. For example, minors have the right to obtain information about and to use birth control without a parent’s consent (*Carey v. Population Services International*, 431 U.S. 678 [1977]); to receive psychiatric care (*In re Alyne E.*, 113 Misc. 2d 307, 448 N.Y.S.2d 984 [1982]); and perhaps even to separate from their parents should the parents and children prove “incompatible” (*In re Snyder*, 85 Wash. 2d 182, 532 P.2d 278 [1975]). At base, says the Supreme Court, children “are ‘persons’ under the Constitution” and have rights that should be protected by the state (*Tinker v. Des Moines Independent School District*, 393 U.S. 503 [1969]).

Both the easing of marriage and divorce restrictions and the loss of family autonomy can be

traced to the growth of individual rights that began in the 1960s. The idea of family autonomy and privacy and, hence, the policy of nonintervention were traditionally based on “paternal” authority; the authority of the family patriarch. This pattern can be traced back to the Roman idea of *patria potestas*—or the right of the father to exert absolute control over his family, including the power of life or death.

Family autonomy and privacy that is based on paternal power is viable only when other members of the family are unable to invoke the power of the state against the father. It was for this reason, then, that traditionally the woman’s power to invoke the law was suspended from the moment of her marriage (Blackstone [1769] 1979, Vol. 1, p. 430). Children, likewise, had no legal standing until they reached the age of majority.

Things are much different today: While children still have many “legal disabilities,” they can no longer be regarded as chattel. Women have achieved at least technical legal equality (though whether this has served to their advantage in divorce law is still subject to debate—compare Weitzman 1985 and Jacob 1988). Although the courts still speak of “family privacy,” it is becoming clear that such privacy is based on family members’ individual rights and exists only as long as family members are not in serious conflict about how they wish to assert those rights.

Some mourn the loss of near total family autonomy; the family, they say, has lost its integrity (Peirce 1988). There is no doubt that the notion of family autonomy or privacy served an important value: It has been “a convenient way for dealing with a problem . . . [that is] especially acute in the United States—that of devising family law that is suited to the needs and desires of persons with different ethnic and religious backgrounds, different social status, and different standards of living” (Glendon 1989, p. 95). In many instances, however, nonintervention created private Hobbesian jungles in which the strong ruled and the weak could not call upon the law for help.

As we move into the twenty-first century, families will continue to play an important role in

society, and there can be little doubt that family relations will continue to be regarded as legally different from other relations and worthy of special legal protection. The question is, To whom is the law’s protection to be extended in domestic matters as the United States embarks upon the twenty-first century? Traditionally, lawmakers have extended this protection to a limited variety of relations—the father–mother–children household. If present trends continue, however, the traditional ideal-typical nuclear family will be something that is achieved (and perhaps aspired to) by only a small fraction of Americans (Difonzo 1997; Estlund and Nussbaum 1998; McIntyre and Sussman 1995; Reagin 1999).

As we move through the first decades of this new century, new and more complex family legal issues will emerge as people construct new communal arrangements, call them family, and seek the protections accorded by the law to more traditional arrangements (Dolgin 1999; Edwards 1999; Minow 1993). The most pressing question facing lawmakers is this: Will the law continue to afford its protections only to those domestic arrangements that mirror traditional family *forms*, or will it embrace and protect domestic arrangements insofar as they fulfill traditional family *functions*?

FAMILY PLANNING

The ability of couples to plan the size of their family and the timing of births has important sociological implications for both individual families and society as a whole. Women's roles and labor-force participation, the socialization of children, social and economic development, and ultimately the ability of the earth to sustain human life are all affected in one way or another by the ability of couples to practice family planning and the success with which they do so. In the United States, women expect to complete their childbearing with an average of 2.2 children per woman (Abma et al. 1997), and, on average, women have 2.0 births over their lifetime (Ventura et al.). Throughout the world, the average number of children desired varies from about two in most industrialized nations to between six and eight in some African nations (Alan Guttmacher Institute 1995). In order to limit lifetime births to the number desired, couples must abstain from intercourse, have high levels of contraceptive use, or resort to abortion. Indeed, sexually active women would average eighteen births over their lifetime if they used no contraception and no induced abortion (Harlap et al. 1991). This article summarizes information regarding sexual activity; the risk and occurrence of unplanned pregnancy; contraceptive use and failure; and the provision of family planning-related information, education, and services in the United States. For comparison, worldwide variation in the planning status of pregnancies and births and the use and availability of contraception are also presented.

EXPOSURE TO THE RISK OF PREGNANCY

Most Americans begin to have intercourse during their late adolescence and continue to be sexually

active throughout their reproductive lives. In 1995, 55 percent of all men aged 15–19 in the United States had had intercourse (Sonenstein et al. 1998). Similarly, about half of all women aged 15–19 report ever having had sex (Table 1). These data, collected in 1995, indicate a leveling off in the trend toward earlier ages of sexual initiation. Whereas the percentage of adolescents who reported being sexually experienced rose steadily throughout most of the 1980s, the percentage of adolescent females who had ever had sex did not change significantly between 1988 and 1995 and the percentage of adolescent males who were sexually experienced actually fell during that period (Singh and Darroch 1999).

Once sexually active, most women become at risk for an unintended pregnancy. Table 1 shows information on the percentage of all U.S. women aged 15–44 who are at risk for becoming pregnant by age and union-status groups (currently married, cohabiting, formerly married or never married). The proportion who are not at risk of an unintended pregnancy because they have never had intercourse decreases quickly from 50 percent of teenagers 15–19 to only 1 percent of all women aged 35–44. Five to seven percent of women in all age groups have had intercourse but are not currently in a sexual relationship (i.e., they have not had sex within the last three months). Some 5 percent of women are infertile, or noncontraceptively sterile, because of illness, surgery (that was not for contraceptive purposes), menopause, or some other reason. The proportion that is infertile increases steadily with age, from 1 to 2 percent of women under 30 to about 13 percent of those aged 40–44. Some women, especially those in their twenties and early thirties, are not at risk of an *unintended pregnancy* because they are already pregnant, postpartum, or seeking pregnancy. Eleven to fifteen percent of women aged 20–34 are in this category.

Women who are at risk for an unintended pregnancy account for more than two-thirds of all women ages 15–44 at any point in time. Women at risk are those who are currently in a sexual relationship, are fertile, and wish to avoid becoming pregnant. The proportion of women at risk of

unintended pregnancy increases from less than 40 percent of teenagers to about three-quarters of all women ages 25–44. Women who are currently married or cohabiting are most likely to be at risk for unintended pregnancy—81 to 83 percent of them are at risk, compared with 72 percent of formerly married women and 49 percent of never-married women. The most common reason some married or cohabiting women are not at risk of unintended pregnancy is that they are pregnant, postpartum, or trying to become pregnant. Among women who have never been married, never having had intercourse or no recent intercourse are the most common reasons.

OCCURRENCE OF UNINTENDED PREGNANCY

Nearly one-half of all pregnancies (49 percent) in the United States are unintended (Henshaw 1998), that is, they occur to women who want to have a baby later but not now (generally called “mistimed”) or to women who did not want to have any (more) children at all (called “unwanted”) (Table 2). The proportion of pregnancies that are unintended is highest among adolescents—78 percent—and varies considerably by age. The percentage of pregnancies that are unintended is lowest among women aged 30–34 (33 percent) and rises again among older women to 51 percent among women aged 40 and older. Unintended pregnancies are also relatively more likely to occur among never-married women (78 percent), black women (72 percent), and low-income women (61 percent for women under 100 percent of the federal poverty level).

The percentage of pregnancies that are unintended has declined in recent years—from 57 percent in 1987 to 49 percent in 1994 (see Table 2). These declines have occurred across all age categories but have been more significant among older women. These declines have also been more significant among low-income women. In 1987, 75 percent of all pregnancies to women with family incomes under 100 percent of the poverty level were unintended. This dropped to 61 percent in 1994. In comparison, the percentage of unintended pregnancies to women with incomes 200 percent or more of the federal poverty level fell from 45 percent in 1987 to 41 percent in 1994.

Percentage Distribution of Women Aged 15–44 According to Exposure to the Risk of Unintended Pregnancy, by Age and Union Status, National Survey of Family Growth, 1995

	Total	AGE						UNION STATUS			
		15–19	20–24	25–29	30–34	35–39	40–44	Currently Married	Cohabiting	Formerly Married	Never Married

Table 1

SOURCE: Alan Guttmacher Institute tabulations of the 1995 National Survey of Family Growth (Cycle V).

NOTE: *Have not had intercourse in the past three months.

Among all unintended pregnancies, more than half (54 percent) end in an abortion while 46 percent result in an unintended birth. This relationship differs for adolescents, who, in recent years, have been more likely to resolve unintended pregnancies with a birth. More than one-half of all unintended pregnancies to adolescents result in an unintended birth (55 percent), while 45 percent are resolved with an abortion. These percentages represent a significant change in the resolution of unintended pregnancies among adolescents. Throughout the 1980s, adolescents who were pregnant unintentionally were more likely to obtain an abortion (55–53 percent) than to carry the pregnancy to term.

Nearly half (48 percent) of all women aged 15–44 have had at least one unintended pregnancy at some time in their lives; 28 percent have had one or more unplanned births, 30 percent have had one or more abortions, and 11 percent have had both. Given current rates of pregnancy and abortion, by the time they are 45 years old, the typical woman in the United States will have experienced 1.42 unintended pregnancies and 43 percent will have had an abortion.

Women who are using no contraceptive method account for about 8 percent of all women at risk

of unintended pregnancy, but, because they are more likely to become pregnant than are those using a method, they account for nearly one-half of all unplanned pregnancies, an estimated 47 percent. Significant reductions in unintended pregnancy and abortion could occur with increased contraceptive use, with more effective use of existing methods, and with the development and marketing of additional methods.

CONTRACEPTIVE USE

Women and men in the United States rely on a variety of contraceptive methods to plan the timing and number of children they bear and to avoid unintended pregnancies. Surgical contraceptive sterilization is available to both men and women. Oral contraceptives, Depo Provera injectibles, Norplant implants, the IUD, and female barrier methods such as the diaphragm and the cervical cap are available from physicians and clinic providers. Other methods—condoms and spermicidal foam, cream, jelly, and film—can be purchased over the counter in pharmacies or other stores. Instruction in periodic abstinence is available from physicians and other family planning providers as well as through classes where only that method is taught.

More than nine in ten women aged 15–44 in 1995 who were at risk of unintended pregnancy

Percentage of All Pregnancies (Excluding Miscarriages) That are Unintended by Women's Age, Marital Status, Race, Ethnicity and Poverty Status, 1987 and 1995

WOMEN'S CHARACTERISTICS	% OF ALL PREGNANCIES THAT ARE UNINTENDED	
	1987*	1994**
All women	57.3%	49.2%

NOTE: na=not available.

were using a contraceptive method, as shown in Table 3. Thirty-six percent relied on contraceptive sterilization of themselves or their partner, 52 percent used reversible medical methods, 5 percent used nonmedical methods such as withdrawal and periodic abstinence, and 7.5 percent were currently using no contraceptive, even though they were at risk of unintended pregnancy.

Patterns of contraceptive use differ by age. Younger women at risk of unintended pregnancy are more likely than older women to use no method of contraception. Nearly one in five teenage women at risk use no method, compared to 6 to 7 percent of women at risk aged 25 and older. The proportion using reversible medical methods declines steeply with age—from more than four out of five women aged 20-24 to less than one-quarter

of those ages 40-44. Oral contraceptives are the most commonly used method among women under 30, used by 35 to 48 percent of these women. Condoms are second in popularity among this age group, used by 23 to 30 percent of women. Although fewer than 3 percent of women at risk use Depo Provera injectible contraceptives, this method has grown in popularity since its introduction into the United States, particularly among young women. Eight percent of teenagers at risk used this method. As women become older and complete their families, male and female contraceptive sterilization become increasingly common, rising steeply from 5 percent of women at risk aged 20-24 to one in five women in their late twenties and to two out of three women aged 40-44. Among women in their twenties, female sterilization is about four times more common than vasectomy. The margin narrows among older women to between two and two and a half times more common.

The proportion of women at risk of unintended pregnancy who use no contraceptive method is highest among never-married women, 14 percent as compared to 5 percent of those who are currently married or cohabiting and 8 percent of formerly married women. Sterilization is the most frequently used method among women who are currently married (46 percent) as well as formerly married women (50 percent). The pill is the most commonly used method among never-married women (38 percent) and cohabiting women (34 percent). Condoms are most likely to be used by never-married women (28 percent).

Although poor women and minority women at risk of unintended pregnancy have, in the past, been more likely than higher-income and non-Hispanic white women to be using no contraceptive method, these differences have lessened. Compared to the 1980s, in 1995 there were no significant race/ethnicity or poverty differences in the percentages of women at risk of unintended pregnancy who used no method of contraception. However, there is some variation in the types of methods used among these subgroups. Low-income women are less likely to rely on reversible methods and more likely to rely on sterilization than higher income women. Forty percent of women at risk of unintended pregnancy who are under

Table 3

SOURCE: Alan Guttmacher Institute tabulations of the 1995 National Survey of Family Growth (Cycle V).

NOTE: *Female barrier methods include the diaphragm, cervical cap, sponge, and female condom.

150 percent of the poverty level use sterilization compared to 32 percent of women at 300 percent of the poverty level and above. Poor women relying on sterilization are much more likely than higher-income women to have been sterilized themselves rather than have a partner who has had a vasectomy. Female sterilization accounts for 92 percent of all contraceptive sterilization among poor women, compared with 58 percent among those with higher incomes.

CONTRACEPTIVE EFFECTIVENESS

Pregnancies occur to couples using contraceptive methods for two reasons—because of the inadequacy of the method itself or because it was not used correctly or consistently. Estimates have been made (either theoretically or empirically during clinical trials) regarding the efficacy of each contraceptive method given perfect use (Trussell 1998). In addition, estimates are made that measure the typical use effectiveness of each method, which relates to the experience of an actual group of users. The most recent estimates of typical use contraceptive effectiveness by method have been

made using the 1995 National Survey of Family Growth, corrected for abortion underreporting and standardized for variation in the proportions of women from different subgroups using certain methods (Fu et al. 1999). Failure rates differ by method, with some methods consistently showing higher effectiveness than other methods. Rates also differ by sociodemographic subgroup within study populations.

Table 4 provides estimates of method-specific failure rates given both perfect use and typical use for the most commonly used reversible contraceptive methods. For each contraceptive method, the typical failure rates observed among women are substantially higher than the estimated rates given perfect use, and the rates differ widely among marital status, age, and poverty of women subgroups. The lowest failure rates are achieved with long-acting hormonal contraceptives that require little user compliance. Among methods that women must use daily or per coital episode, oral contraceptives are most effective, while spermicides, withdrawal, and periodic abstinence have the highest failure rates. In general, women who are young,

Estimated Percentage of Women Who Would Experience a Contraceptive Failure During the First Twelve Months of Perfect Method Use* and the Corrected Use-failure Rates Given Typical Method Use for all Users and for Age, Poverty, and Marital Status Subgroups of Women Experiencing the Lowest or Highest Use-failure Rates**

METHOD	Perfect Use*	Typical Use**
Total		13.1
Norplant implants	0.05	2.0
Depo Provera injectible	0.3	3.5
Oral contraceptives	.1 to .5	8.5
Diaphragm/cervical cap	6/9 to 26	13.2
Male condom	3	14.9
Spermicides	6	28.2
Withdrawal	4	26.0
Periodic abstinence	1 to 9	21.8

Table 4

SOURCES: *Trussell (1998), Table 31-1, p. 800. The ranges presented correspond to different formulations of the method, except for the cervical cap, where the range is due to woman's parity status. **Fu et al., (1999), (From corrected Table 1, available on <http://www.agi-usa.org/pubs/journals/3105699.html>).

unmarried or cohabiting, and poor have higher failure rates. The differences in failure rates between methods and between subgroups of women are much greater than what any difference in method effectiveness or in the biology of women would cause and are assumed primarily to reflect differences in the correctness and consistency of method use (although reporting errors may also play a role).

FAMILY PLANNING INFORMATION AND EDUCATION

Rising public concern over the occurrence of unintended pregnancy and, particularly, of unintended, nonmarital adolescent pregnancy and childbearing in the United States has drawn attention to the manner in which young people are educated about sexuality, contraception, and how to avoid pregnancy and other negative consequences of

sexual activity. Parents and other adults have long played a key role in controlling the sexual behavior of adolescents and in providing basic information about sex and pregnancy avoidance. During the past twenty-five years, there has been a proliferation of organized efforts to augment the information, education, and support traditionally provided by families. Beginning with programs and services for young pregnant women, these efforts have expanded to include legislative mandates regarding the teaching of sexuality or family life education in schools, development and distribution of a variety of sexuality-education curricula, as well as integrated community interventions and media involvement. Organized efforts to implement sexuality education and related activities have also been influenced by growing public concern and awareness of HIV/AIDs and the need to provide young people with the information and means to avoid infection.

Increasingly, policies and programs to encourage abstinence among unmarried teenagers have become popular. Some of these programs attempt to accomplish this objective by giving young people encouragement, offering moral support and teaching interpersonal skills to resist pressures to become sexually active. Others, which seek to convince teenagers that sex before marriage is immoral, emphasize the negative consequences of sexual intercourse, occasionally withhold or distort information about the availability and effectiveness of contraception (Alan Guttmacher Institute 1994a). In fact, although most public schools provide some sort of sexuality education to middle or junior and senior high school students, the education provided is often too little, too late.

On a broader scale, community and service organizations have implemented interventions aimed at increasing the life options of disadvantaged young people through, for example, role models and mentoring, community service projects, job training, and activities aimed at reducing risky behaviors. Such interventions are expected indirectly to reduce levels of unintended teenage pregnancy, childbearing, and sexually transmitted infections, based on the belief that teenagers who are more positive about their futures are less likely

to participate in risk-taking behaviors, including risky sexual practices.

Other policies or programs implemented with the hope of reducing unprotected teenage sexual behavior include (1) comprehensive school-based sexuality-education curricula that include discussion of abstinence but also include information about contraceptive methods and services; (2) programs that address the social pressures faced by teenagers to have sex and that provide modeling and practice of communication, negotiation, and refusal skills; (3) condom availability programs in schools; and (4) multicomponent programs that include communitywide activities—such as media involvement, social marketing, and links between school-based activities and contraceptive service providers (Alan Guttmacher Institute 1994a).

Evaluations of a variety of programs and approaches aimed at affecting teenage sexual and reproductive behavior, although still somewhat inconclusive, have shown that some programs have had a positive effect on the behavior of youth. In addition, results of multiple studies indicate that the provision of contraceptive information and access does not encourage young people to become sexually active at younger ages. Reviews of the evaluation research point to the need for integrated approaches that both address the antecedents of sexual risk taking (e.g., poverty, violence, social disorganization) and provide young people (who will soon become adults) with the information, skills, and resources to make responsible decisions about sexual behavior and the avoidance of unintended outcomes (e.g., Kirby 1997).

CONTRACEPTIVE SERVICE PROVISION

In the United States, women can receive contraceptive services from private practice general and family practitioners and obstetrician-gynecologists, as well as from publicly supported clinics run by hospitals, health departments, community health centers, and Planned Parenthood affiliates or independent clinic providers. In addition, some teenage and young adult women receive contraceptive services from school-based clinics and college or university health centers.

Private practice physicians are the most numerous providers in the United States that are available to women seeking contraceptive information and services. More than 40,000 family practice doctors and nearly 30,000 obstetrician-gynecologists provide office-based outpatient services (Alan Guttmacher Institute 1997). About seven in ten women seeking family planning services report going to a private practitioner or health maintenance organization (HMO) for their care (Aloma et al. 1997).

Annually, some 6.5 million U.S. women receive contraceptive services, supplies, and information from more than 7,000 publicly supported family planning clinics, located in 85 percent of all U.S. counties (Frost 1996). Family planning clinics, using a combination of federal, state, and local funds, provide care to those who cannot afford services from private physicians or who cannot use private physicians for other reasons. In most clinics, fees are based on the client's ability to pay, confidential services to teenagers are assured, and a full range of contraceptive methods are offered. As a result, family planning clinic clients are primarily low-income (57 percent are below 100 percent of the federal poverty level, and 33 percent are between 100 percent and 249 percent of the federal poverty level) and young (20 percent are under age 20; 50 percent are aged 20–29). Although a majority of clinic clients are non-Hispanic whites, nearly 40 percent are minority women (19 percent are black, 14 percent are Hispanic, and 7 percent are Asian or other races) (Frost and Bolzan). Lower-income women go to clinics primarily because they cannot afford physicians' fees, because the clinic is more conveniently located, or because the clinic will accept Medicaid payment. Adolescents often go to clinics because of the free or low-cost services and because they are afraid a private physician will tell their parents about their contraceptive use. In addition, some women, especially teenagers who have never been to a physician on their own, go to clinics because they do not know a physician who would serve them. Clinic clients usually shift to private physicians when their incomes rise and as they become older.

Sixty percent of all publicly supported clinics receive federal Title X support and must therefore

follow federal standard of care guidelines. These guidelines provide medical protocols as well as mandates regarding confidentiality and key areas of outreach that clinics should seek to address. As a result, many publicly supported clinics provide outreach and information or education in local schools or in other community locations. These clinics often seek to reach out to women (and men) in need of contraceptive care who have special needs or risk factors for unintended pregnancy (e.g., because of homelessness, drug or alcohol abuse, domestic violence, or other reasons).

The provision of contraceptive services, like all areas of health care, has been affected by changes in the structure of health care financing and the rise of managed care. In the past, most privately insured women had employer-based indemnity health insurance plans that rarely covered either routine gynecological checkups or reversible contraceptive services and supplies. However, such plans often covered sterilization services. Today, most privately insured women are enrolled in managed care plans. These plans are more likely to cover preventative care, including routine gynecological checkups and some reversible contraceptive services and supplies. However, not all managed care plans cover all or even most methods, and often the process of obtaining contraceptive services within managed care plans places additional burdens on women seeking contraceptive care. These burdens include prior authorization requirements that may cause some women to delay care or forgo sensitive care that a woman may not want to disclose to her primary care physician (Alan Guttmacher Institute 1994b, 1996).

INTERNATIONAL COMPARISONS

Women in the United States have both similarities and differences with women throughout the world in their efforts to plan the number and timing of children. In adolescence, American women are somewhat less successful in their attempts to prevent unplanned pregnancies than are young women in most other industrialized countries. Table 5 presents recent birthrates among women aged 15–19 for selected European and North American

countries. Although there is no evidence that young women in the United States are more (or less) sexually active than young women in many other industrialized countries, the United States has adolescent birthrates that are nine to ten times higher than the rates for the Netherlands and Sweden and more than twice as high as the rates for Canada, England, and Wales. The factors responsible for these differences are not entirely clear; however, it is likely that they are due in part to differences in the levels of disadvantage among countries, to variation in the family planning education and services provided to youth and to greater or lesser openness regarding sexuality among countries.

In developing countries, young women marry earlier and have children at younger ages than in the United States. More than half of the young women in sub-Saharan Africa bear a child during the teenage years and about one-third of the young women in Asia, North Africa, the Middle East, and Latin America bear children as teens, compared to just one-fifth of teenage women in the United States. Although the situation is improving and the proportion of adolescents using contraception is increasing in many developing countries, few married adolescents use contraceptive methods and high percentages of sexually active unmarried adolescents rely on traditional nonmedical methods, such as withdrawal and periodic abstinence. Greater use of reliable contraceptive methods by adolescents worldwide is often hampered by inadequate or inaccurate information, poor access to services, and community expectations that value early childbearing within marriage and punish sexual activity outside of marriage. As a result, a substantial proportion of births to adolescents are unplanned—40 to 60 percent in several Latin American and sub-Saharan African countries, and 20 percent or more even in countries where almost all births are to married adolescents. By comparison, 66 percent of adolescent births in the United States are unplanned (Alan Guttmacher Institute 1998).

The patterns of pregnancy, childbearing, and contraceptive use among women of all ages vary from region to region throughout the world. Table 6 presents information on pregnancy rates

Adolescent Birthrates for Selected European and North American Countries, Mid-1990s

COUNTRY	BIRTHS PER 1,000 WOMEN AGED 15-19
Switzerland	5.7
Netherlands	5.8
Italy	6.9
Sweden	7.7
Spain	7.8
Denmark	8.3
Belgium	9.1
Slovenia	9.3
Finland	9.8
France	10.0
Greece	13.0
Germany	13.2
Norway	13.5
Austria	15.6
Czech Republic	20.1
Portugal	20.9

(per 1,000 women aged 15-44), planning status of pregnancy, abortion, and contraceptive use for women in different regions of the world. Women in Africa experience the highest rates of pregnancy, the lowest percentage of pregnancies aborted, and the highest percentage of married women

using no contraceptive method. Although women in the United States have somewhat higher pregnancy rates than women in most of Europe and other North American countries, they have significantly lower pregnancy rates than most of the women in the rest of the world. The percentage of pregnancies that are planned varies considerably among the different regions of the world, from only 25 percent of pregnancies in eastern Europe being planned to 54 percent of African pregnancies being planned. Similarly, there is variation in the percentage of pregnancies that are aborted and in the patterns of contraceptive use. Compared to other regions of the world, the percentage of U.S. pregnancies that are aborted is similar to that in most of Europe and Latin America but less than half the percentage in eastern Europe. In terms of contraceptive use, married women in the United States are more likely than women in most other regions of the world (except for East Asia) to choose sterilization as their method of contraception. Married women in Africa and in Europe (both eastern and western Europe) rarely choose sterilization, and high percentages of Europeans rely on nonmedical methods, such as withdrawal.

Worldwide, only 47 percent of all pregnancies (including miscarriages) are planned and, at the same time, 42 percent of married women are using no method of contraception. In most regions of the world, one-third or more of married women use no method. Ensuring greater information, education, and access to family planning services worldwide has the potential to greatly reduce the level of unplanned pregnancy and abortion.

FAMILY POLICY IN WESTERN SOCIETIES

The dramatic growth in the industrial capacities and economic power of the United States and the countries of Western Europe since World War II has demonstrably improved the per capita income and quality of life of the average citizen in these countries. Based on such indicators as available health services, declining death rates, unemployment protection, and retirement benefits, it is reasonable to infer that, more than at any other time in human history, the majority of the people in these countries are assured that they can obtain the basic elements necessary for their survival and the survival of their families. Moreover, their quality of life, as measured by education, availability and quality of housing, ownership of automobiles and other durable goods, and available leisure time, suggests a lifestyle heretofore reserved only for the rich.

It is ironic that this unparalleled affluence has been accompanied by fundamental changes in family structure and family relationships—changes that challenge our basic conceptions of how families are organized and function. Marital stability and the size of the birthrate are common indicators of family health (Kittrie 1997). Over the early 1970s, virtually all the highly industrialized countries have experienced accelerating increases in divorce, decreased family size, increases in pregnancies among unmarried women, and an increase in childless marriages. Unlike many Third World countries, where population is growing at a rapid rate, birthrates in Western countries are below the level of population replacement (see Van de Kaa 1987 for Western Europe; Sweet and Bumpass 1987 for the United States). According to Census Bureau data, the American family reached its smallest size in 1990.

There is general agreement among family scholars that these changes are due, at least in part, to the expanding number of married women in the labor force. In 1920, about 9 percent of the families in the United States included wives who were employed outside the home (Hayghe 1990, p. 14). By 1987 the number of dual-earner families outnumbered families in which the husband was the only breadwinner by two to one (Lerner 1994). This situation does not change appreciably when children enter the family. Labor-force participation for married women with children under the age of six increased from 18.6 percent of all married women in 1960 to 63.6 percent in 1997. For married women with children between the ages of six and thirteen, the rate peaked in 1997 at 76.5 percent. Similar data exist for countries in Western Europe. Haavio-Mannila and Kauppinen (1990) note that full-time homemaking has almost disappeared in the Nordic countries. These changes have had a direct impact on the division of labor in the family and an indirect effect on marital-role relationships. Closely linked to women's growing labor-market activity is the fact that they are making better use of the educational opportunities available to them. There is evidence that educational achievement is converging for males and females in most of the Western world (Haavio-Mannila 1988).

As both educational and occupational career opportunities increase for women, there is a tendency to delay marriage. In the United States, the median age for first marriage peaked in 1996 for men (27.1 years) and in 1997 for women (25.0 years). Moreover, with growing educational equality and an increased ability to compete effectively for jobs in markets that value the skills obtained through education, the time such women spend raising children becomes more costly, both economically and psychologically (Sweet and Bumpass 1987). The result is fewer children per family and less time spent in parent-child interaction in those families with offspring (Lerner 1994).

These changes have altered marital and parental roles in families. Sweet and Bumpass (1987), describing the situation for U.S. families, claim that although husbands have made only a modest contribution to sharing household duties, they can no longer claim the role of "breadwinner." The conception of the prototypical family as consisting

of a legally married husband and wife living together for a lifetime, raising children in a household managed by the wife and mother and financially supported by the husband and father, is anachronistic. Indeed, such family structures constitute less than 7 percent of families in the United States (Lerner 1994).

Many scholars regard this decline in traditional family structures with considerable alarm. The decline is associated with values that emphasize individualistic and self-oriented goals over family well-being and, by extension, concern for others in the community. It is argued that these values lead to social isolation, growing levels of interpersonal distrust, and the the involvement by individuals in an endless and empty search for gratification (Elshtain 1997).

Other scholars, though not sanguine about the human problems created by these changes, tend to consider them as inevitable consequences of increased individual opportunity and freedom. Such freedom can only occur when developed societies establish equality between the sexes and underwrite the financial and social risks of illness, job loss, and aging. To the extent that greater individual autonomy and freedom of opportunity are gained at the cost of stable family relations, that cost should be borne (Myrdal 1967). Most important, those who look positively upon these changes point with approval to the changing role of women. The increased participation of women in the labor force in all industrialized countries has increased women's freedom to choose their own lifestyles, both in the world of work and in the family (Lerner 1994). If changes in family structure contribute to greater equality and greater opportunities for women to achieve their full potential, then, it is argued, society as a whole benefits (Lanca 1997).

Interestingly, people on both sides of the debate tend to define themselves as pro-family. Virtually everyone seems to acknowledge the social importance of the family in caring for and socializing children. There is also a perception of the family as a sanctuary that provides its members with protection, affection, and succor in what is often a hostile and, generally, impersonal environment. For the most part, advocates of both perspectives accept as problematic the fact that, increasingly, families fail to carry out these functions.

The high divorce rate, single-parent households, teenage pregnancy, and domestic violence are disturbing components in modern family life, and there is general agreement that something should be done about these problems. There is a consensus in all the advanced industrialized countries that the family is a proper concern of public policy. There are, however, fundamental differences in the conceptions of what that policy should be, what institutions or groups should be responsible for implementing policy, and what types of families or individuals should be the targets of such policy.

A conservative movement seeks to reverse the trends discussed above by shoring up the traditional family. They advocate reinforcing the importance of legal marriages, making divorce more difficult, emphasizing parental responsibility for the care and protection of children, and, more generally, strengthening the family by protecting it from government intrusions. Governments, from this perspective, should be restrained from taking over responsibilities that "rightfully" belong to the family. In this view, only limited indirect support in the form of tax relief or tax credits to help families care for their dependent members and to make homeownership easier are considered appropriate forms of government involvement (Carlson 1988). Advocates of restricting government involvement maintain that families, if left alone, would function quite well. Some critics of government involvement in family life argue for the privatization of most social services geared toward helping families. The essential claim is that privately organized and funded services to families would be more efficient and would protect the right of the family to make choices for itself (Brodkin and Young 1989).

Related to this position is the argument that a weakening of the family can be attributed to constitutional neglect—a failure to define and protect the status of the family as a publicly recognized institution (Kittrie 1997). Additionally, it is argued that contemporary social policy emphasizes individualistic interests rather than family concerns, thus reducing the family to a contractual arrangement rather than a socially recognized institution.

At the other extreme there are those who believe that the appropriate role of government is to assist the family in maximizing individual potential for each family member. They maintain that, in

democratic societies, government should mediate among various interest groups, each seeking its own advantages. Only the government, responsible to the electorate, is in a position to protect the public interest. Far from weakening the family, the government, it is argued, is the only institution in a position to use its resources to support and strengthen families and their members. This is especially true for families with children living under current conditions of rapid social change. Thus, it is argued that “social and demographic changes have combined to diminish the likelihood that families can assure their children’s healthy growth and development without help from outside the family” (Schorr et al. 1986).

Some have maintained that the question of government intervention is a moot point, since governments (as political entities) serve the purposes of their most influential constituencies. For example, they point to government tax incentives to assist businesses, the building of highways in the 1950s to benefit the automobile industry, and the government’s readiness to come to the aid of large corporations, banks, and savings and loan associations during times of crisis. In brief, for many observers, the notion of “minimalist government”—the ideal advocated in the rhetoric of the Reagan administration in the 1980s—is not a reality in any modern country (Kahn and Kamerman 1975). The real question is not whether government should come to the aid of its citizens, but which citizens will be the beneficiaries of such aid.

William J. Wilson’s (1987) answer to the question is that government services should be as universal as possible. Rather than limiting services to crisis intervention and emergencies or providing aid just to the disadvantaged, public services should be expanded to cover all citizens. Wilson maintains that only when public programs serve all segments of a society will it be possible to prevent system breakdowns and integrate all elements as productive members of the society.

The disagreements about what is appropriate family policy are so basic that it is hard to identify “objective” investigations or investigators. Policy implies advocacy, and advocacy implies bias. As a consequence, debates circle around such fundamentals as what is meant by the phrase *family policy*; indeed, there is disagreement on what is meant by *family*. Consider the following three

definitions: (1) “The family is a society limited in members but nonetheless a true society, anterior to every state or nation, with rights and duties of its own, wholly independent of the commonwealth” (Pope Leo XIII, quoted in Strong and DeVault 1989, p. 6). (2) “The family consists of two or more persons living together and related by blood, marriage or adoption” (U.S. Bureau of the Census 1990). (3) “One or more adults related by blood, marriage, or affiliation who cooperate economically, share a common dwelling place, and may rear children” (Strong and DeVault 1996, p. 15). Note that definition (1) places the family as independent and free from the state. By implication, what goes on in the family is none of the government’s business. Definition (2) restricts the family to shared residence and formal kin ties determined by blood or legal marriage, whereas definition (3), by introducing the vague term *affiliation*, is intended to include under the family label such “family” forms as cohabiting families and gay and lesbian families.

Still other definitions point to the fact that families need not always reside in the same household to maintain familial bonds and obligations, suggesting that emotional ties may be more salient than biological ties when defining family. A recent public opinion poll found that only 22 percent of respondents defined the American family in terms of blood, marriage, or adoption (Footlick 1990).

Those who define the family as the Census Bureau does are more likely to advocate policies that support only households whose members are linked through legally defined ties of kinship. Those who adhere to definition (3), on the other hand, are more likely to advocate government recognition of and assistance to different kinds of heterosexual and same-sex unions formed only by the consent of the participants without any state recognition or sanction. Adherents of definitions (1) or (2) are more likely to maintain that governmental aid to some of the groups that fit definition (3) is not aid to families but a major contribution toward the declining significance of the family in modern life (Kittrie 1997).

Despite disagreements concerning an adequate definition, some shared understanding of what is meant by “family” is necessary to provide a referent for the discussion that follows. The working

definition provided below is designed to incorporate essential elements that make up most definitions. It is, however, not likely to satisfy staunch advocates of any particular policy orientation. The family is defined here as *any group of individuals who are bound together by publicly acknowledged and socially sanctioned kinship ties*. The key to this definition is in the concept of *kinship*. Kinship is a special type of social relationship determined by ancestry, marriage, and adoption. In every society certain kin have designated duties toward and responsibilities for other members of the kin group. These responsibilities are obligatory; the only way an individual can free him- or herself from such obligations is by ceasing to be kin, a difficult, if not impossible, task. These obligations tend to be lifelong. For key kin the obligations can pertain to virtually all physical and emotional needs of family members. For example, in modern industrial societies parents are expected not only to care for their children's physical needs but to provide them with love and affection and to prepare them to function effectively in the real world. Failure to do so can result in severe sanctions against the parent. Thus all Western industrialized countries have laws designed to require that parents provide financial support and care for their children, even if the husband and wife are separated. Each country also has laws designed to sanction parents for physically abusing or neglecting their minor children. Similar obligations accrue as a consequence of marriage. Formal marriages are legal entities sanctioned by the state (and often the church), and violations of the marital agreement are monitored and adjudicated by reference to secular laws, sacred laws, or both.

Whereas the care, nurturance, and socialization of children continue to be the responsibility of parents, the care of aging parents by adult children is becoming less common. Social Security and retirement pensions, national health programs, and public support for housing for the elderly have been introduced in all highly industrialized countries. As these programs increase, family obligations tend to decline.

The tendency toward declining family responsibility for its members extends beyond care for the elderly. Over the years, as modes of production have changed, the family has gradually relinquished responsibility for providing either employment or occupational training for its members.

The family is no longer directly responsible for formal and religious education, and, more recently, responsibility for child care has tended to be relegated to nonfamily institutions. As the family gives up these functions to the workplace, schools, and churches, its relative power and influence on the economic and political life of the society diminishes. The issue thus becomes whether public policy, established and administered by agents of the governmental or economic segments of society, should be used to assist this weakened institution. More specifically, the question arises whether public services in the form of health care, housing, unemployment insurance, support for education, maternity benefits, support for child care, and so forth help to strengthen the family in its remaining responsibility for the care, nurturance, and socialization of its members or further weaken it by making family members dependent on nonfamily sources for benefits and social support. This is the key question surrounding the debate over what is a proper family policy in the Western world.

The term *policy*, like *family*, is burdened with multiple meanings and definitions. It has been variously described as the means for focusing on fundamental problems of individuals in relation to societies (Lasswell 1968), a set of decisions designed to support an agreed-upon course of action (Zimmerman 1988), or as governmental goals (Dumon and Aldous 1979). Thus the different definitions have covered the gamut, from means to process to goals. Kahn's (1969) conception of policy incorporates these elements within a context that gives it specific meaning. He refers to policy as "the general guide to action, the cluster of overall decisions relevant to the achievement of the goal, the guiding principles, the standing plan" (p. 131). Thus, a definition that seems to have some consensual meaning would hold that policy is a commitment to action that utilizes a consciously designated strategy designed to attain specified goals.

Although some writers insist that the term *policy* is applicable only to governmental action, the more general view is that any actor, whether an individual or a large collectivity, can make and implement policy (Zimmerman 1988). What is important, and the source of considerable debate, is the fit between the policy goals and the actor's ability to implement those goals. For example, individual families of moderate means are not

likely, by themselves, to be able to implement a policy for attaining high-standard, low-cost day care for their children; conversely, neither national governments nor national corporations are likely to be able effectively to develop policies for resolving neighborhood conflicts between ethnic groups. The difficulty is not only in matching appropriate levels of scale (e.g., community problems are best solved by community organizations); it also lies in the actor's ability to bring the right resources to bear on a given problem. This requires access to relevant information, the ability to recruit appropriate personnel, and control over the appropriate resources. The debate about family policy generally focuses on three primary issues: goals, the strategies designed to attain those goals, and the appropriate agencies for implementing these strategies. The sharpest differences concerning these issues are apparent at the national level.

The differences among policy goals, strategies, and designated agents are most evident when we compare the approach to family policy in the United States with the industrialized nations of Western Europe. As noted earlier, the United States shares many of the same family problems with these countries. The solutions offered in the form of public policy, however, differ considerably. The United States, often referred to as the "reluctant welfare state," has tended to be less forthcoming than the European countries in providing funds or services for its families or individuals. Moreover, there has been a strong inclination to have agencies other than government administer and implement social programs. America's revolutionary history has left its citizens with a pervasive distrust of government; rather than viewing government as a source of aid and assistance to its people, they often consider it a threat capable of usurping individual freedom and autonomy (Schorr 1979). Where the family is considered, this fear of government is enhanced by the tradition in Anglo-Saxon jurisprudence of noninterference in family life (Glendon 1989).

Differences in approach to family policy in the United States and Western Europe are also affected by the different cultural, racial, and ethnic compositions of the various countries. For example, despite the recent immigration of foreign workers to European countries such as West Germany, Switzerland, and Sweden, no European country approximates the United States in its ethnic

and racial heterogeneity. Whereas minorities make up between 6 and 7 percent of the population of countries like West Germany and Sweden, the nonwhite and Hispanic minorities in the United States represent 20 percent of the population (*Statistical Abstract of Sweden 1990*; *Statistisches Jahrbuch für die Bundesrepublik Deutschland 1989*; U.S. Bureau of the Census 1990).

Also important are the differences between the countries in the extent to which governments are centralized and can make policy at the national level. With the exception of Switzerland, the Western European countries tend to be more centralized. This makes it possible to have a meaningful national debate about the pros and cons of a national family policy. Such a debate in the United States is less conclusive, principally because decision-making power on such an issue is distributed among federal, state, and local governments (Dumon and Aldous 1979).

These factors tend to contribute to one incontrovertible fact: The United States has less legislation directly concerned with assisting families and provides less financial support designated to aid families than any other advanced Western industrial society (Kahn and Kamerman 1983; Kittrie 1997).

Americans have been more reluctant than Europeans to pass legislation that might be interpreted as violating the sanctity and the privacy of the family. Legislators in most European countries seem willing to write laws designed to protect the child's safety, health, and psychological well-being without great concern that such legislation might interfere with family prerogatives (Glendon 1989). Although the reluctance of the U.S. courts to venture into the family domain is gradually changing, especially in the areas of child-support enforcement and prevention of domestic violence, they have moved much more slowly and reluctantly in this area than their counterparts in the Scandinavian countries, France, the Netherlands, and West Germany. It would be unheard of, for example, for courts or legislatures in the United States to follow the Swedish example and forbid parents to spank their children (Davis 1997).

Although divorce is a common condition in all the Western developed countries, the United States and England have been hesitant to interfere in the financial arrangements resulting from divorce on

behalf of the children involved. This is not the case in the Nordic countries or in continental Europe, where, according to Glendon (1989), there is "genuine judicial supervision of the spouses' financial arrangements for children: mechanisms to ensure that child support is fixed at realistic and fair levels; highly efficient collection systems; 'maintenance advance systems' in which the state not only collects unpaid child support, but partially absorbs the risk of non-payment of advancing support up to a fixed amount in cases of default" (pp. 236-237).

The available data indicate that, with the possible exception of Social Security benefits for the elderly, the United States is not as generous as most of the European countries with regard to funding programs designed to assist families (Kahn and Kamerman 1983). This is most apparent when we consider families with children. The United States has tended to limit its assistance to such programs as Aid to Families with Dependent Children, which was geared toward providing financial aid to single-parent families living below the poverty line. Some additional assistance is provided to poor families through food stamps (unique to the United States) and, in the short run, unemployment insurance. Financial assistance to all families with children generally takes the form of a standard income tax deduction of \$2,700 for each dependent child. For families whose income is below \$10,000 an earned income credit is provided.

Most of the countries of Western Europe, on the other hand, provide direct cash payments to families for each child. These payments are tax-free and serve as family income supplements. The per-child payments tend to increase with increased family size. Funds are also provided to assist families during the childbearing phase in the form of direct grants to cover income loss and pre- and postnatal medical care (Kamerman and Kahn 1981).

The Nordic states and Western continental Europe also provide direct housing assistance for both rental and homeownership payments. Housing allowances generally decrease as income rises, thus providing an income leveling mechanism in these countries (Herrstrom 1986). Unlike the U.S. policy of tax deductions for interest paid on mortgages, which benefit better-off families, the European housing allowances tend to favor lower-income families (Kahn and Kamerman 1983; Herrstrom 1986).

In addition to these direct income-transfer programs, many of the countries in Western Europe provide a variety of benefits designed to assist families with the child-rearing challenges associated with both parents' working outside the home. Sweden, for example, provides a guaranteed pregnancy leave as well as a nine-month parental leave at 90 percent of salary and an additional three months at a flat rate (Lerner 1994). Austria, Germany, Norway, and the Netherlands have policies of at least three months of paid leave at 100 percent salary. Denmark and France have policies of at least sixteen weeks at 90 percent of salary, and Finland has a policy of eleven months at 80 percent of salary (Lerner 1994). Efforts are underway in Finland to extend this type of parental leave to three years. In the Nordic countries parents during the first three years of a child's life can choose to obtain state support for one parent to remain home with the child or to use the funds for day-care services. By comparison, the Family Support Act, passed in 1988 in the United States, renewed the requirement that a proportion of mothers receiving public assistance find employment (Michel 1998). At the same time, efforts to pass universal child-care legislation failed. Until January 1993, the United States was the only industrialized nation without a national parental leave policy (Lerner 1994).

Regardless of the merits of the American and European approaches to family policy, one significant current fact differentiates family conditions in the United States from those in the developed countries of continental Europe: In 1993, 40.1 percent of children under age six living in the United States were poor (U.S. Bureau of the Census 1994). This high level of poverty in the midst of affluence has produced a growing sense of despair and hopelessness concerning the life chances of these children. Miller (1990) summarizes the available data as follows: "Many studies have documented the much poorer health status of poor and minority children, the greater rates of child abuse, the higher incidence of injuries and death attributable to violence and crime, high rates of illiteracy, teenage pregnancy, educational failure and school dropouts." He goes on to note that the communities in which these children live are more dangerous, the schools are less adequate, and the rates of drug abuse are higher than in the general population. A sizable proportion of these children, but by

no means all, are African American Hispanic, or Native American. The majority live in female-headed, single-parent families, a phenomenon increasingly referred to as the “feminization of poverty” in the United States.

Thus, the essential issue concerning family policy for Americans is inextricably linked with the questions of poverty and what to do about it. The fact that this situation does not exist in the advanced countries of Europe (with the possible exception of the United Kingdom) raises the inevitable question whether the family policies of these “welfare states” have anything to offer Americans in their search for solutions to the problem of family poverty.

It will come as no surprise that expert opinion on this issue is greatly divided. Differences exist even among those who usually share the same ideological perspective. Some who are concerned with providing greater equality in our society advocate programs such as those in Western Europe. Wilson (1987, p. 149) refers to such programs as “universal programs of reform,” that is, programs that provide services for all citizens rather than earmarking aid for just minorities or the poor. The advantages of such programs are that since all citizens benefit, there is no stigma attached to being a recipient and no resentment among nonrecipients that taxes are being spent to benefit others.

This position is not universally shared even among those committed to egalitarian solutions. Some feel strongly that massive resources must be put into play to assist only those families at the greatest risk of being trapped in an abyss of poverty and hopelessness (Schorr 1988).

Predictably, those more concerned with issues of freedom than equality have argued that the problem of poverty in the United States is not the result of inadequate public services but rather is a consequence of such services. According to Carlson (1988), the “matriarchal welfare state has produced family disruptive results” and the “poverty crisis, the ageism crisis, the teen pregnancy crisis, the overpopulation crisis, the juvenile delinquency crisis, the eugenics crisis, the child abuse crisis, the youth suicide crisis” have all contributed to expanding the power of the state at the expense of

the family (p. 273). Charles Murray (1984) compiled an impressive amount of data that purports to illustrate that public services designed to reduce poverty in the United States were ineffectual. Murray’s data have been challenged by a number of investigators, and the ensuing debate reaffirms the difficulty in interpreting data relevant to this issue in ways that are free of bias. The difficulty is that socioeconomic conditions change so rapidly that it is not likely that any single factor can or should be justified as constituting the cause for poverty.

Whatever the causes, poverty is a reality in the United States, and, increasingly, the discrepancies in the distribution of wealth in this country demand the attention of policy makers (Phillips 1990). It also seems apparent that, given the ubiquity of the family in social life, any policy regarding poverty must also be a policy pertaining to families. Whether that policy will be concerned with all families or just the poor remains to be seen; whether it will be a national policy or policies instigated and implemented at the state levels, and whether its funding will be in the form of direct grants or tax benefits and incentives, is also hard to predict. It is likely, however, given American traditions and the deep differences that exist within the country about family policy, that the eventual solutions and compromises reached will be different from those that have evolved in Europe. Nevertheless, in this world of instant communication and visibility, the state of the family in Europe and the resources available to European families must have an impact on the policy decisions made in the United States.

FAMILY ROLES

See *Alternative Life Styles; American Families; Parental Roles.*

FAMILY SIZE

Family size may be considered from two perspectives. At the individual (micro) level, it defines one aspect of an individual's family background or environment. As such, it represents a potential influence on the development and accomplishments of family members. At the societal (macro) level, family size is an indicator of societal structure that may vary over time, with concomitant implications for individual development and social relations in different cohorts. In this essay, consideration is given to both aspects of family size, as it is reflected in sociological theory and research.

While the term *family size* is sometimes used to represent the total number of individuals comprising a family unit, Treas (1981) argues convincingly for decomposing the concept into two components: numbers of children and numbers of adults in the household. This distinction is important, as observed patterns of change in overall family size may be attributable to one component or the other, as may effects of overall family size. In the present discussion, family size is defined in terms of the number of children in the household.

A further distinction is made between family size in the parental and filial households, sometimes referred to as the family of origin (or orientation) and the family of procreation. Some use the term *sibship size* to refer to the number of children in an individual's parental family (Blake 1989; Ryder 1986). However, the two are not directly comparable: Mean family size takes into account those families which have no children, while mean sibship size is necessarily restricted to families with children.

Family size can also be differentiated from fertility, which reflects the aggregate numbers of births relative to the numbers of women in the population, without regard for the distribution of those births across family units. Fertility and family size are both important characteristics of cohorts; however, for assessing relationships at the

individual level, family size or sibship size is the more meaningful construct (Ryder 1986).

The subsequent sections address the following aspects of family size: demographic trends in family size, antecedents and correlates of family size, and implications of sibship size and family size for child and adult members of the family.

DEMOGRAPHIC TRENDS

The twentieth century has witnessed substantial change in both fertility and family size (as indicated by the number of children in the household), with the overall trend being toward smaller families. Such trends can be examined through comparisons of fertility rates and mean family size, and also through investigation of parity distributions—that is, the numbers of families with zero, one, two (and so on) children.

Drawing on fertility tables compiled by the National Center for Health Statistics, Ryder (1986) presents time-series data for successive cohorts of women in the United States born between 1867 and 1955 (and who would thus be bearing children between approximately 1885 and 1975) that show the following general trends in fertility and family size:

1. Total fertility declined by 52 percent in the period being considered, from 4.00 for women born in 1867–1870 to 1.92 for women born in 1951–1955. A similar rate of decline occurred in marital fertility.
2. This decline was punctuated by a temporary upsurge in fertility for women born in 1916–1940, who were bearing children during the two decades following World War II (the “baby boom” years).
3. Variation in fertility rates increased for cohorts through 1910 and since then has consistently decreased, suggesting that in recent years there have been fewer women bearing no children or large numbers of children and an increasing concentration of families of moderate size.
4. Family size (the mean number of children in the family) decreased by 61 percent from a high of 7.3 for women born in 1867–1870 to 2.8 for women born in 1951–1955.

It thus appears that during the period under consideration, mean family size decreased at an even faster rate than fertility. Further, the increased fertility during the baby boom years appears to have been offset by reduced variation in fertility for those cohorts of women, with the result that mean family size held relatively constant during that period, then continued its pattern of decline.

Treas (1981) examined changes in family size between 1955 and 1978 for whites and for nonwhites, using data from the March Current Population Surveys. Throughout the period, nonwhites consistently had larger families than did whites: In 1955 the mean number of children was 1.26 in white families and 1.80 in nonwhite families; in 1978 the corresponding figures were 1.04 and 1.56. During this period Treas found similar patterns of increases in family size through the 1960s, followed by decreasing family size in the 1970s, for both groups. However, the shifts were considerably more pronounced among nonwhite families.

Data obtained from the U.S. Census on the distribution of family sizes (parity distributions) provide further insight on the trend toward smaller families. During the years between 1970 and 1988 the proportion of families with no children under eighteen increased substantially, from 44 percent to 51 percent, while the proportion of families with one child or two children increased only slightly (from 18 percent to 21 percent and from 17 percent to 18 percent, respectively). However, the proportion of families with three or more children decreased markedly, from 20 percent to 10 percent during this period. Among black and Hispanic families, the increase in families with no children was not as pronounced as among white families, but the increases in families with one or two children were greater, as were the decreases in families with three or more children (U.S. Bureau of the Census 1990, p. 51).

Further insight into the decline in family size is provided by investigations of parity progression, or the probability of having (or intending to have) an additional child at each parity level. Decomposing his time-series data into parity progressions, Ryder (1986) reports that the baby boom was the result of an increase in progression from parities one and two, but that progression from parities

three and higher have shown consistent declines. Similarly, data on intended parities show that the proportions intending progression from parity one have increased over time, while the intended progression ratios for parity three and higher have declined.

Other data on ideal, or normative, family sizes support this pattern of increasing concentration of smaller families. West and Morgan (1987) cite historical data showing that fertility norms have fluctuated in parallel with fertility rates and family sizes: During the 1930s and early 1940s two- and three-child families were preferred. During the post-World War II era three- and four-child families became the ideal, but in the late 1960s preferences reverted to the two- or three-child family. They further report that, among a sample of contemporary adults, a significant majority (64.8 percent) view the two-child family as ideal; that belief was surprisingly consistent across various subgroups defined by current family size, marital status, race, and religion.

At the same time that families have tended to become smaller on average, there has been increased variability in the timing of childbearing. One trend that has been widely noted has been the increase in childbearing among teenagers, particularly among those who are of lower socioeconomic statuses (SES), nonwhite, and less academically able youth (Card and Wise 1978). At the same time, there has been an increase in the proportion of women who delay childbearing until their early and mid-thirties or who remain childless (Bloom and Trussell 1984). As will be discussed below, the timing of the first birth has implications for the eventual family size and thus for the development and accomplishment of family members.

In sum, in the United States there appears to have been a strong shift toward smaller families, with the ideal being a two- or three-child family. A similar trend toward smaller families is found in other developed countries, while in developing countries families are more likely to be larger (Lopreato and Yu 1988). One exception to this generalization concerns countries, such as the People's Republic of China, that are trying to implement a policy of restricting families to one child. However, while the policy appears to have led to lower mean family sizes, numerous families have

continued to have two or more children, and a preferred family size of two continues to be the mode (Whyte and Gu 1987).

ANTECEDENTS AND CORRELATES OF FAMILY SIZE

Determinants of family size have been investigated at both the societal and the individual level. At the societal level, researchers have sought to account for differences in fertility and family size over time or between societies. Easterlin (1980) advanced the theory that changes in fertility and family size over time are a function of individuals' economic resources and aspirations. He attributes the baby boom surge in fertility and family size to the generation of young men following World War II who experienced high wages, as a result of the expanding economy, and had relatively low material aspirations, as a result of being raised during the Depression. Conversely, the baby boom generation confronted increased competition for jobs, which, combined with higher aspirations, led to the "baby bust" of the 1970s and 1980s. One implication of Easterlin's theory is that smaller birth cohorts are likely to experience more favorable labor markets, resulting in higher fertility.

A variation of this theory is espoused by Devaney (1983), who argues that the decline in fertility observed during the 1960s and 1970s can be attributed to increases in female wages and female employment, which in turn served to depress fertility, rather than to conscious decisions to limit fertility in the face of disadvantageous economic conditions. Her analyses, based on national fertility data and data on female labor-force participation rates and male and female earnings, suggest (1) that female labor-force participation and fertility are highly and negatively correlated and (2) that female wage rates are the dominant factor in explaining recent variations in fertility and female employment. While this model differs from Easterlin's in terms of the process by which economic factors are thought to influence fertility, they are similar in viewing fertility as a response to economic market conditions.

Studies of developing countries have focused on several sociocultural as well as socioeconomic factors associated with fertility and family size:

modernization (Levy 1985); contraceptive use and family-planning programs (Koenig et al. 1987); and cultural attitudes and values, such as the perceived old-age security value of children (Rani 1986) or the view of children as risk insurance (Robinson 1986).

At the individual level, researchers have examined the extent to which fertility and family size may vary depending on individuals' family backgrounds, social and psychological characteristics, or economic status. Inverse relationships between social class and family size have been documented in a number of data sets: Individuals from larger families tend to have less-well-educated fathers who have lower-status occupations. Also, farm background is associated with larger family sizes (Blake 1989).

Parents' sibship size (the number of siblings that each parent had) is a second major determinant of family size: Women and men from larger families are more likely to have larger families (Ben-Porath 1975; Thornton 1980). This gives rise to an apparent paradox: While there is an overall trend toward small families, a high proportion of children come from larger families (Blake 1989). This paradox arises from the distinction noted above between cohort fertility rates, which are based on all women or all families, and children's sibship sizes, which are necessarily limited to women or families who have had children.

Retherford and Sewell (1988) investigated the relationship between intelligence and family size in their analysis of data from the Wisconsin Longitudinal Study of the High School Class of 1957, finding that the overall relationship between IQ and family size was negative for both sexes. However, the relationship proved to be much stronger for females, who showed consistent declines in family size as IQ increased. Among men the relationship was less consistent. Retherford and Sewell also reviewed the results of other, earlier studies, noting that the negative relationship between IQ and family size appears to have become more pronounced in the post-baby boom cohorts.

Additional factors associated with family size pertain primarily to family and achievement-related characteristics of the mother: More education, later age at marriage, longer interval between marriage and the birth of the first child, and

employment status are all associated with smaller families—that is, fewer children (Wagner et al. 1985). Family configuration has also been found to be associated with increased family size, with the probability of having an additional child being higher in families with all children of the same sex (Gualtieri and Hicks 1986). Also, only children are disproportionately likely to come from broken families (Blake 1989).

The interaction between wives' employment and childbearing has been a topic of much study, as women have increasingly entered or remained in the work force, but the results obtained are inconsistent. Waite and Stolzenberg (1976) found a significant negative relationship between wife's work and family size. However, based on analyses of longitudinal data that allowed for the study of recursive processes as well as inclusion of several additional measures, Bagozzi and Van Loo (1988) found no causal relationships between wife's employment and family size; they suggested that both labor-force participation and family size are codetermined by the wife's achievement motivation, sex-role norms, and perceived value of children.

Oropesa (1985) used data from the National Opinion Research Center (NORC) General Social Surveys to test the hypotheses represented in Easterlin's model at the micro level, using relative affluence as the predictor and expected family size as the outcome of interest. He found that relative affluence is more likely to be associated with expected births for women than for men, and that the effects are stronger with regard to expected births in the short term than with total expected family size.

The research cited above focuses on static determinants of childbearing and family size. However, some investigators have examined fertility and childbearing decisions as a dynamic process, influenced by life situation and life events, that may change over time, as well as by relatively fixed individual characteristics. One line of investigation has focused on timing of first birth as a determinant of eventual family size. Card and Wise (1978) and Hofferth and Moore (1979) demonstrated that early first births are associated with larger families; Bloom and Trussell (1984) similarly demonstrated that delayed childbearing is associated with smaller average family sizes, as well as with childlessness.

A second line of research has investigated the relationships between parity level and fertility decisions. Udry (1983) examined the relative influence of initial fertility plans and intervening life events (such as births during the interval, change in household income, change in education, female work status, change in marital satisfaction) on couple's fertility decisions at different parity levels. He found that including intervening events in the analyses improved the prediction of both fertility plans and, especially, actual fertility behavior, providing support for a sequential model of fertility decision making. White and Kim (1987) investigated whether the determinants of fertility choices vary by parity; they found a nonlinear relationship between fertility determinants and childbearing, especially with regard to factors related to women's roles. Both sex-role traditionalism and achievement in nonfamily roles were associated with a higher probability of having a child at parity zero or one, but a lower probability of having a child among women at higher parities. These findings are somewhat contrary to those based on cross-sectional analyses of family size, suggesting the importance of taking parity level into account in such investigations.

IMPLICATIONS OF SIBSHIP AND FAMILY SIZE

The effects of sibship/family size and family composition on children and on adults has long been a topic of popular interest and in recent years has become the focus of a considerable body of sociological and psychological inquiry. In particular, attention has been directed to effects of sibship size on children's cognitive development, physical and social-psychological development, educational attainment, and socioeconomic attainment and mobility. Consideration is also given to effects of family size on parents and on family well-being.

Cognitive Development. Interest in the relationship between sibship size and intelligence dates back to Anne Anastasi's (1956) review, which found an inverse relationship between the two. Subsequent empirical studies, in the United States as well as in Europe, using various measures of ability and controlling for family background characteristics, have confirmed this finding (Belmont and Marolla 1973; Breland 1974; Claudy et al. 1974). Blake (1989) provides a comprehensive review of

this literature, including a discussion of limitations and weaknesses in the prior studies.

Only children present a special case. Numerous studies have reported that only children do not perform as well on intelligence measures as do children from two-child families. Indeed, in the Belmont and Marolla study (1973), only children were found to be lower in intelligence than first-borns in families up to size four, and lower than second-borns in families up to size three. Claudy and associates (1974) obtained similar results after controlling for differences in SES. However, when differences in family composition were taken into account by restricting the sample to only children in two-parent families, the differences between only children and first-born children in larger families became nonsignificant (Claudy et al. 1979).

In an effort to account for the observed relationships between sibship size and intellectual ability, Zajonc (1976) introduced the "confluence model," which postulates that the intellectual environment in the home, defined by the combined intellectual levels of the parents and children, accounts for the observed relationships. According to his theory, the intellectual level is at its peak in families with two adults and no children; as the number of children in the home increases, the intellectual environment afforded to any individual child is effectively diluted. There are two implications of the "confluence model": Children from smaller families should show higher intelligence, and children born earlier in families should show higher intelligence. While the former hypothesis has been supported by a number of empirical studies, the latter did not account for the findings pertaining to only children. In response, Zajonc expanded the confluence model, postulating that younger siblings provide an opportunity for teaching, thus enriching the intellectual experience of older children; the lower intellectual performance of only children is attributed to the fact that they cannot avail themselves of this opportunity. While the confluence model has generated considerable discussion and debate, particularly regarding possible interactions between family size and birth order, and with family SES (for example, see Steelman 1985; Zajonc 1986), a systematic test of the model remains to be conducted.

Blake (1989) identifies two limitations in the previous work: lack of differentiation of various

kinds of intellectual ability (such as verbal and nonverbal) and potential interactions with SES. She finds that the inverse relationship between sibship size and intelligence holds for measures of verbal skill, but not for measures of nonverbal ability, and that the verbal ability deficits observed among children in large families are not limited to those from more disadvantaged backgrounds.

Physical and Social-Psychological Development. Compared with other outcome measures, relatively little attention has been given to the study of sibship-size effects on children's physical and social-psychological development. Mednick and associates (1985) and Wagner and associates (1985) provide brief reviews of this literature. Family size has been found to be inversely related to children's height and weight; it is also positively correlated with morbidity and mortality. With regard to social-psychological development, children from larger families have been found to have poorer self-concepts, to value conformity and self-control rather than independence and self-expression, and to show a greater tendency toward anti-social behavior. They are also less likely to be interested in white-collar occupations.

Blake (1989) investigated the relationship between sibship size and educational expectations, using data from three different cohorts of youth, and found that young people from smaller families, as well as from higher-status families, tend to have higher educational goals. These effects, however, are mediated through ability and grades as well as through parents' expectations.

Educational Attainment. Blake's (1989) book *Family Size and Achievement* provides the most comprehensive assessment to date of this area. Two sets of questions are addressed: First, does sibship size affect educational expectations and attainment, and if so, where in the educational process? Second, what is the relative importance of sibship size, relative to other measures of family background?

With regard to the first question, sibship size does appear to have a substantial effect on educational attainment. Individuals from small families had approximately two additional years of schooling, relative to their peers from larger families—net of differences attributable to parental characteristics. The greatest impact on education occurred at the high school level, with individuals

from larger families more likely to drop out of high school.

With regard to the second question, relative to other background variables in the analysis, sibship size was consistently second in importance for years of schooling, behind father's education. However, the negative effects of large families were somewhat mitigated by high parental SES and by membership in certain religious or ethnic groups. Similarly, the effects of parental SES were somewhat mitigated for youth in small families.

Some have argued that sibship size is simply a proxy for otherwise unmeasured characteristics of parents' family background and does not exert any independent effect on education in its own right. To address this concern, Blake (1989) examined the extent to which children from different-sized families have different home environments that might, in turn, influence educational attainment. In particular, attention was given to characteristics of the home setting (such as time spent reading newspapers, reading books, watching television) and to parental behaviors directed toward the child (such as encouragement, correction, goal setting). Children from smaller families were more likely to spend time in intellectual and cultural pursuits, to spend time playing alone, to have been read to as children, and to have had music or dance lessons. However, no significant differences were found in parental values for their children or in parenting style after parents' education and SES were taken into account. Thus, while there appear to be differences in the home environments afforded to children in smaller versus larger families, these differences do not appear to be attributable to differences in parental values or parenting style.

Socioeconomic Attainment and Mobility. A long tradition of research has addressed the question of how family background conditions or constrains individuals' socioeconomic attainment and social mobility. While primary consideration has been given to the impact of family social resources (father's education and occupation) on children's attainment, sibship size also was found to be related to occupational attainment (Blau and Duncan 1967). Among both women and men, those from larger families were more likely to have lower-status jobs and lower earnings, even after adjusting for differences in fathers' SES and educational attainment, both of which are correlated

with family size. Among women, the effect of sibship size on earnings was stronger than the effect of father's occupation (Featherman and Hauser 1976). Using path analysis to model both indirect and direct relationships, however, Duncan and associates (1972) found that the negative effect of sibship size on men's occupational status could be accounted for primarily by the effect of sibship size on educational attainment. This finding lends some support to arguments that larger families result in a dilution of family economic resources, thus constraining the opportunities available to children.

Parents' Economic Well-Being. Duncan and associates (1972) examined the impact of family size (as contrasted with sibship size) as a contingency in men's socioeconomic attainment, finding a slight and negative effect on occupational status but a positive effect on earnings, net of other background variables. Studies that included women found evidence of reciprocal relationships between family size and labor-force participation, which in turn affected women's career attainment (Waite and Stolzenberg 1976). However, as noted previously, Bagozzi and Van Loo (1988) suggested that women's work and family size are not causally related but are mutually dependent on other, achievement-related characteristics of the wife.

Relationships have been reported between the timing of childbearing and subsequent economic well-being. Card and Wise (1978) found that teenage parents of both sexes tended to have less education, lower job prestige, and lower earnings, relative to later childbearers, net of differences in background characteristics. Investigating this relationship in greater depth, Hofferth and Moore (1979) found that the effects of early childbearing on women's subsequent earnings were primarily attributable to the larger family sizes of these women and to the consequent implications for (less) work experience. However, they also found that early childbearing was less of a handicap for black women, due to weaker relationships between early childbearing and subsequent education and employment. Hofferth (1984) found that among women aged 60 or over, the number of children per se was not related to measures of economic well-being, but that the timing of childbearing was: Those who delayed the first birth until after age thirty had higher family incomes and higher standards of living than did women

whose first child was born before age thirty. This relationship was most pronounced among delayed childbearers who had small families, suggesting an interaction between timing of childbearing and family size.

Massagli (1987) has argued for a life-cycle model of the process of stratification that incorporates information on family size in both the parental and the filial generations. He hypothesizes that sibship size does not affect socioeconomic attainment directly but, rather, is related to the timing of early life-cycle transitions and to marital fertility; the observed negative effects of sibship size on attainment are attributed to the product of the relationship with life-cycle transitions and marital fertility and the negative effect of marital fertility on attainment.

Parental Attitudes and Well-Being. Wagner and associates (1985) review a number of studies of effects of family size on parental attitudes and parental health. They find that parental attitudes and treatment of children vary with family size: Larger families are more family centered, with a greater role played by fathers; at the same time, parents in larger families tend to be more authoritarian and more inclined to treat all children alike. Parents in larger families have also been found to have poorer marital relations. Finally, men and women who have many children are at greater risk of hypertension and other physical ailments.

In sum, sibship size and family size both appear to exert significant influence on the children and on the parents. Sibship size is closely related to family socioeconomic background, however, which is also a major influence on children's development and attainment. As a result, care must be taken to differentiate between effects of sibship size per se and effects of socioeconomic background. Similarly, family size among adults (the number of children they have) is highly correlated with socioeconomic status, intelligence, and other characteristics; again, it is important to consider the effects of family size net of these other factors. In many instances, the effects of sibship size and family size appear to be indirect. For example, sibship size is highly correlated with educational attainment and thus with subsequent occupational attainment. Similarly, among adults, family size is correlated with employment and thus with socioeconomic attainment. Finally, family size is often

closely related to other characteristics of the family: Among children, it may be related to birth order, and among parents, it may be related to the timing of childbearing. Understanding these indirect as well as direct relationships yields a better understanding of the ways in which, and the extent to which, sibship size and family size may affect the lives of children and adults.

AT THE TURN OF THE CENTURY

The United States—as well as other developed and developing countries—has witnessed significant changes in fertility patterns and in family structure, which together combine to impact family size. This closing section reviews the more salient of these developments and examines how they have been reflected in recent sociological and demographic research.

Family Size and Fertility. Because family size is inextricably linked to fertility, it has been impacted by the fertility transition (i.e., the change from higher to lower rates of fertility) that has been well documented in the United States and is now being seen in both developed and developing societies elsewhere in the world. In the United States fertility has remained relatively constant since the early 1980s, ranging from 1.7 to 1.9 births per woman. However, this apparent stability masks a dramatic shift toward having children at later ages, especially among white women (Chen and Morgan 1991) and more highly educated women (Rindfuss et al. 1996).

The stability seen in the United States is in sharp contrast to Europe, where most countries have experienced significant declines in fertility during this period, and to many developing countries, which are also now evidencing fertility declines (Rutenberg and Diamond 1993; Thomas and Muvandi 1994). Global fertility projections for the twenty-first century (released by the United Nations in 1992) range from 1.7 to 2.5 births per woman (Cohen 1996). These declines have been linked to three factors:

1. Widespread changes in the *social and economic roles and opportunities* available to women, including the increased availability of child care (Hirschman and Guest 1990; Mason and Kuhlthau 1992; Rindfuss et al. 1996)

2. Increased availability of *contraception and family-planning services*, as well as in some developing countries policies supporting fertility limitation in some developing countries (Axinn 1992; DeGraff 1991; Lavelly and Freedman 1990; Njogu 1991)
3. Changes in the *social norms governing childbearing and child rearing*, including the emerging concept of “numeracy” about children—that is, the idea of having a particular family size as a goal—in developing countries (van de Walle 1992)

Corresponding decreases in actual and expected family size are also seen for this period. The average family size in 1993 was 3.16, down from 3.29 in 1980; similarly, the proportion of family households with three or more children had fallen by half since 1970 (Dortch 1993). On the 1994 General Social Survey 55 percent of Americans reported that they preferred two-child families—up from 41 percent in 1972—while the percentage of preferring substantially larger families declined commensurately. By 1988, the proportion of women expecting to remain childless had increased to 9 percent (National Center for Health Statistics 1996).

Family Size and Family Structure. Family size is also closely linked to family structure and to changes in patterns of family formation. Two somewhat related changes in particular have significantly impacted the size of family units: increased rates of marital dissolution and increased rates of out-of-wedlock births, both of which have contributed to a dramatic increase in single-parent family units.

Rates of *marital dissolution* have increased dramatically, both in the United States and elsewhere. In the United States more than half of all marriages are now expected to end in divorce; in less developed countries, approximately 25 percent of first marriages, on average, have dissolved as a result of death, divorce, or separation (Bruce et al. 1995). Not only does marital dissolution contribute directly to smaller family size (Lillard and Waite 1993); it also has an indirect effect—maternal divorce not followed by remarriage substantially reduces children’s preferred family size (Axinn and Thornton 1996).

Beginning in the 1980s, women were increasingly likely to have *children out of wedlock*, signaling

a significant change in the norms governing childbearing. By the early 1990s, 2 out of 3 black children and nearly 1 of 4 white children were born to unmarried mothers (Smith et al. 1996). One-fourth of these out-of-wedlock births were to cohabiting couples (Bumpass 1990). Thus, while fewer women were marrying and staying married, alternative family structures involving children were emerging.

The number of *single-parent families* in the United States grew dramatically from 1960 (10.5 percent) to 1990 (23.3 percent) (Garasky and Meyer, 1996). As a result, it is estimated that half of today’s young children will spend some time in single-parent family (Bumpass 1990). While the majority of single-parent family units are headed by the mother, the number of father-only families has grown at nearly twice the rate as the number of mother-only families. Nor is this phenomenon limited to the United States: In the former Soviet Union, the proportion of households headed by a single parent doubled in the fifteen-year period from 1980 to 1995 to 20 percent; in developing countries, the incidence of female-headed households as of 1995 ranged from 11 percent in the Philippines, to 13 percent in Mexico, to 19 percent in Cameroon, to more than 25 percent in Hong Kong (Bruce et al. 1995).

Implications for the Study of Family Size.

Returning to the framework initially presented in this essay, what are the implications of these trends and developments for the conceptualization of the “family” and “family size,” and for research on the correlates and implications of family size?

Conceptualization of the “family” and “family size.” The decreasing variance in family size is being offset by increasing complexity in family structure. In addition to the growing interest in single-parent families—and within that category, differentiation of mother-only and father-only families—researchers also identify nonmarital cohabitation (Bumpass 1990), parent-stepparent and blended families (Astone and McLanahan 1991; Dortch 1993; Wojtkiewicz 1993), and intergenerational households (Macunovich and Easterlin 1990). This evolving conceptualization of the family and—in particular—family structure is of interest not only in its own right but also for its implications for models of intergenerational transmission of status, resources, and values (Smith et al. 1996).

Correlates of changes in family size and structure. Increasingly research is directed toward linking social change at a macro level to individual-level fertility behavior. Structural factors, including increased labor-force participation of women (Rindfuss et al 1996), availability of contraceptive technology (Lavelly and Freedman 1990), and availability of child care (Mason and Kuhlthau 1992; Rindfuss et al. 1996), continue to be a subject of study in both developed and developing countries. Of equal interest is the social context surrounding child-bearing decisions, including the husband's and wife's own values regarding desired family size (Thomson 1997; Thomson et al. 1990), their parents' preferences and behavior (Axinn et al. 1994; Axinn and Thornton 1996), and societal norms (van de Walle 1992). As increasing attention is given to fertility transitions occurring in other countries, attention is also being given to identifying cultural factors that can potentially bias data and findings, such as nonresponse or qualitative responses to questions about expected or desired family size (Hermalin and Liu 1990; Riley et al. 1993).

Implications of changes in family size and structure. Considerable attention continues to be devoted to studying the impact of family size and structure on children's achievement. The inverse relationship between family size and children's attainment that has been widely documented in the United States is also observed in a number of developing countries, including Thailand (Knodel and Wonsith 1991), Vietnam (Anh et al. 1998), Ghana (Lloyd and Gage-Brandon 1995), and Israel (Shavit and Pierce 1991). Research is increasingly focusing on delineating the processes underlying these relationships, including the greater availability of parental economic and interpersonal resources in smaller families (Downey 1995; Macunovich and Easterlin 1990; Powell and Steelman 1993). Similarly, studies of the negative impact of marital disruption on children's achievement also explore how social factors such as reductions in parental expectations and involvement mediate this relationship (Astone and McLanahan 1991; Wojtkiewicz 1993).

These changes in family size and structure have significant implications for policy as well as for research. Domestically, Dortch (1993) raises the question of how the trend toward smaller

families will impact caring and support relationships for older family members, especially as the number of older American increases over the next few decades. In developing countries, where many governments are proactively working to foster economic development and social well-being, policies supporting lower fertility and smaller families may have both direct and indirect benefits: As the number of children coming from smaller families increases, so too should their prospects for educational and economic attainment (Knodel and Wonsith 1991).

FAMILY VIOLENCE

Physical violence of all types, from slaps to murder, probably occurs more frequently in the family than in any other setting or group except the armed services or police in time of war or riot. This article summarizes the prevalence rates and examines reasons for the high rates, with emphasis on the characteristics of the family as a social institution and on social inequality.

Physical violence is defined as an act carried out with the intention or perceived intention of causing physical pain or injury to another person (Gelles and Straus 1979). For certain purposes, the term "assault" is preferable because much intrafamily violence is a statutory crime. However, not all violence is criminal. Hitting a misbehaving child is legal and expected in all but a few countries. Corporal punishment of an "errant wife" was legal under common law in the United States until the 1870s (Calvert 1974).

Child abuse was not regarded as a widespread social problem by sociologists, family therapists, or the public until the 1960s (Nelson 1984; Pfohl 1977), and wife beating not until the women's movement made it a national issue in the mid-1970s. The subsequent emergence of public concern about and research on these and other aspects of family violence reflects major social changes, including the following:

1. The social activism of the 1960s, which sought to aid oppressed groups of all types, was extended to this aspect of the oppression of children and women.
2. The rising homicide and assault rates, violent political and social protest and assassinations, terrorist activity, and the Vietnam War sensitized people to violence.
3. Disenchantment with the family in the 1960s and early 1970s facilitated the

perception of negative features of family life, including violence.

4. The growth of paid employment by married women provided the economic means for them no longer to tolerate the abuse that had long been the lot of women.
5. The reemerged women's movement made battering a central issue in the mid-1970s and gave it wide publicity.
6. The creation by the women's movement of a new social institution—shelters for battered women—did more than provide material assistance. Shelters were ideologically important because they concretized and publicized a phenomenon that had previously been ignored.
7. Changes in theoretical perspectives in sociology put the consensus model of society under attack by conflict theory. The inevitability of conflict in all human groups, including the family, was recognized, along with the possibility of violent conflict.

PREVALENCE OF FAMILY VIOLENCE

Homicide. In the United States, about one-quarter of all murders involve family members (Straus 1986). In other industrialized countries the percentage is much higher, for example, 40 percent in Canada and 67 percent in Denmark (Straus 1987). These high percentages occur because Canada has a low homicide rate and Denmark an even lower one: The few family homicides that occur are a large proportion of the low overall rate. This suggests that when homicide has been almost eliminated in a society, such as in Denmark, the family is the setting in which it is most likely to persist. Homicides of domestic partners have been decreasing in the United States since the mid 1970s (Greenfeld et al. 1998) and in Canada (Fedorowycz 1999).

OFFICIAL STATISTICS ON CHILD ABUSE AND SPOUSE ABUSE

National statistics on child abuse in the United States have been published since 1976. These statistics vastly underestimate the actual extent of

child abuse. Many times more children are severely beaten each year but do not come to public attention. Officially reported cases grew from about 600,000 in 1976 to about 3 million annually in the mid-1990s. However, rather than being a 400 percent increase, the growth in cases reported to child protective services reflects social changes such as mandatory child abuse reporting laws, hot lines, child abuse education campaigns, an increasingly educated population, and a growth in professionals concerned with aiding and protecting children. These changes led the public and professionals to report cases that previously would have been ignored. This is consistent with historical and survey evidence suggesting that the true incidence of physical child abuse has been slowly decreasing since the late seventeenth century (Radbill 1987; Straus and Gelles 1986).

There are no official statistics for the United States on violence between spouses because the Uniform Crime Reporting System used by almost all police departments does not record the relationship between victim and offender. A new "incident-based reporting system" includes that information and is now being used in twelve states. However, because only about 7 percent of domestic assaults come to the attention of the police (Kaufman Kantor and Straus 1990), the new system will uncover only a small fraction of the cases. A similar problem makes the U.S. National Crime Survey (Gaquin 1977-1978; U.S. Department of Justice 1980) vastly underestimate the incidence of wife beating (Straus 1999). The public tends to consider assault by a spouse as a "family problem" rather than a "crime" and rarely informs the survey interviewer of such events.

The National Family Violence Surveys. National surveys of U.S. families were conducted in 1975 (Straus et al. 1980) and 1985 (Gelles and Straus 1988), and national surveys focused on specific aspects of family violence were conducted in 1992 (Kaufman Kantor et al. 1994) and 1995 (Straus et al. 1998). These studies provide a better estimate of the prevalence of family violence than is possible from police statistics or crime studies. They were made possible by the development of the "Conflict Tactics Scales" to measure family violence (Straus 1990; Straus et al. 1996). The resulting rates, which are based on the 6,002 households surveyed in 1985, are many times greater

than rates based on cases known to child welfare professionals, the police, shelters, or the National Crime Survey, but they are still believed to be lower-bound estimates.

Sixteen percent of the couples surveyed reported one or more incidents involving physical violence during the previous twelve months. Attacks by husbands on wives that were serious enough to warrant the term "wife beating" (because they involved punching, biting, kicking, choking, etc.) were reported for 3.2 percent of wives, resulting in a lower-bound estimate of 1.7 million beaten women. The National Family Violence Surveys, and all other studies of marital violence that do not use samples selected from the clientele of shelters and similar agencies, find that women assault their husbands at about the same rate as men assault their wives (Straus 1999); however, women are injured at seven times the rate of injury to men (Stets and Straus 1990; Straus 1990).

The most violent role within the family is that of parent, because almost all parents use corporal punishment (Straus and Stewart 1999). More than a third of the parents of infants in the 1995 survey reported hitting their child that year. Ninety-four percent of parents of three- to five-year-old children used corporal punishment. The percentage decreased steadily from age five on, but one-third of parents of children in their early teens reported hitting the child that year.

Child abuse is more difficult to operationalize than *corporal punishment* because the line differentiating *abuse* from *physical punishment* is to a considerable extent a matter of social norms. If one includes hitting a child with an object such as a belt, paddle, or hairbrush, the 1995 national survey data found a rate of 4.9 percent (Straus et al. 1998), which is twelve times higher than the rate of cases reported to protective service agencies in 1995.

Intrafamily relationships between children are also extremely violent. But, like the violence of parents, it is not perceived as such because there is an implicit normative tolerance. Almost all young children hit a sibling, and more than a third hit a parent. Even in their late teens (age fifteen to seventeen), the rate of violence between siblings is enormous: More than two-thirds of that age group hit a sibling during the year of the survey.

EXPLANATIONS OF FAMILY VIOLENCE

Numerous family characteristics affect the level of family violence, several of which are discussed below.

High Level of Family Conflict. One characteristic of the family that helps account for the high rate of violence is its inherently high level of conflict. One reason for high conflict is that, as in other primary groups, family members are concerned with “the whole person.” Consequently, there are more issues over which conflict can occur than in nonprimary relationships. Moreover, when conflict does occur, the deep commitment makes arguments emotionally charged. A disagreement about music with colleagues at work is unlikely to have the same emotional intensity as when children favor rock and parents favor Bach. The likelihood of conflicts is further multiplied because families usually consist of both males and females and parents and children, thus juxtaposing differences in the orientations and interests of different genders and generations. The family is the prime locus of the “battle of the sexes” and the “generation gap.”

Norms Tolerating or Requiring Violence. Although conflict is endemic in families, it is not the only group or institution with a high level of conflict. Conflict is also high in academic departments and congressional committees, yet physical violence is practically nonexistent in those groups. Additional factors are needed to explain why violence is so much more frequent in the family than in other groups. One of these is the existence of cultural norms that tolerate or require violence. The clearest example is the right of parents to use corporal punishment to correct and control a child. At least two-thirds of Americans believe that “it is sometimes necessary to discipline a child with a good hard spanking” (Straus and Mathur 1996). These norms contrast with those prevailing within other institutions. Even prison authorities are no longer permitted to use corporal punishment.

Similar norms apply to husband–wife relations. However, they are implicit and taken for granted, and therefore largely unrecognized. Just as parenthood gives the right to hit, so the marriage license is also an implicit hitting license (Gelles and Straus 1988; Greenblat 1983). As with other licenses, rules limit its use. Slapping a spouse,

for example, is tolerable if the spouse is perceived to be persisting in a serious wrong and “won’t listen to reason.” Many of the men and women interviewed by Gelles (1974) expressed this normative principle with such phrases as “I asked for it” or “She needed to be brought to her senses” (p. 58).

The common law right of a husband to use corporal punishment on an “errant wife” was recognized by U.S. courts until the late nineteenth century (Calvert 1974). Informally, it lived on in the behavior of the public, the police, and the courts, and it continues to do so. Under pressure from the women’s movement, this is changing, but slowly. There have been major reforms of police and legal procedures, but the general public and many police officers continue to believe that “it’s their own business” if spouses are violent to each other, provided the blow is not severe enough to cause an injury that requires medical treatment, whereas they would not tolerate a similar pattern of assault in an office, factory, or church. Only a very small percent of men believe that a legal sanction would be likely if they assaulted their wife (Carmody and Williams 1987). In one study, of the more than 600 women who were assaulted by their husbands, the police were involved in only 6.7 percent of the incidents and an arrest was made in only five cases (Kaufman Kantor and Straus 1990). The probability of legal sanction for assaulting a wife is even less than the .008 indicated by those five cases, because two-thirds of the 600 women were assaulted more than once during the year of the survey.

Family Socialization in Violence. In a certain sense it begs the question to attribute the high rate of family violence to norms that tolerate, permit, or require violence because it does not explain why the norms for families are different from those for other social groups or institutions. There are a number of reasons, but one of the most fundamental is that the family is the setting in which physical violence is first experienced and in which the normative legitimacy of violence is learned. As noted above, corporal punishment is experienced by at least 94 percent of American children (Straus and Stewart 1999). Corporal punishment is used to teach that certain types of behavior are not condoned, but simultaneously,

social learning processes teach the legitimacy of and behavioral script for violence.

The example of corporal punishment also links love with violence. Since corporal punishment begins in infancy, parents are the first, and usually the only, ones to hit an infant. From the earliest level of psychosocial development, children learn that those to whom they are most closely bonded are also those who hit. Second, since corporal punishment is used to train the child in morally correct behavior or to teach about danger to be avoided, it establishes the normative legitimacy of hitting other family members. Third, corporal punishment teaches the cultural script for use of violence. For example, parents often refrain from hitting until their anger or frustration reaches a certain point. The child therefore learns that anger and frustration justify the use of physical force.

As a result of these social learning processes, use of violence becomes internalized and generalized to other social relationships, especially such intimate relationships as husband and wife and parent and child. The National Family Violence Surveys found that the more corporal punishment experienced as a child, the higher the probability of hitting a spouse (Straus et al. 1980; Straus and Yodanis 1996). Many children do not even need to extrapolate from corporal punishment of children to other relationships because they directly observe role models of physical violence between their parents.

Gender Inequality. Despite egalitarian rhetoric and the trend toward a more egalitarian family structure, male dominance in the family and in other spheres remains an important cause of family violence (Straus 1976). Most Americans continue to think of the husband as the “head of the family,” and many believe that status gives him the right to have the final say. This sets the stage for violence, because force is ultimately necessary to back up the right to have the final say (Goode 1974).

Numerous structural patterns sustain the system of male dominance: The income of women employed full time is about a third lower than the income of men, and money is a source of power. Men tend to marry women who are younger, shorter, and less well educated; and age, physical

size, and education form a basis for exercising power. Thus, the typical marriage begins with an advantage to the man. If the initial advantage changes or is challenged, many men feel morally justified in using their greater size and strength to maintain the right to have the final say, which they perceive to have been agreed on at the time of the marriage (LaRossa 1980). As a result, male-dominant marriages have been found to have the highest rate of wife beating (Coleman and Straus 1986; Straus et al. 1980), and societies in which male-dominant marriages prevail have higher rates of marital violence than more egalitarian societies (Levinson 1989; Straus 1994).

The privileged economic position of men also helps to explain why beaten wives so often stay with an assaulting husband (Kalmuss and Straus 1983). Women with full-time jobs earn only about 65 percent of what men earn (U.S. Bureau of the Census 1992). When marriages end, children stay with the mother in about 90 percent of the cases. Child support payments are typically inadequate and often defaulted on after a year or two. No-fault divorce has worked to the economic disadvantage of women (Weitzmen 1986). Consequently, many women stay in violent marriages because the alternative is bringing up their children in poverty.

Other Factors. Many other factors contribute to the high rate of intrafamily violence in the United States, even though they do not explain why the family is, on the average, more violent than other groups. Space permits only some of these to be identified briefly.

The empirical evidence shows that the greater the number of stressful events experienced by a family, the higher the rate of marital violence and child abuse (Makepeace 1983; Straus 1980; Straus and Kaufman Kantor 1987). In addition to specific stressful events that impinge on families, chronic stresses, such as marital conflict and poverty, are also strongly associated with child abuse and spouse abuse.

Almost all studies find a strong association between drinking and family violence (Coleman and Straus 1983; Kaufman Kantor and Straus 1987). However, even though heavy drinkers have two to three times the violence rate of abstainers, most heavy drinkers do *not* engage in spouse abuse or child abuse (Kaufman Kantor and Straus 1987).

The higher the level of nonfamily violence in a society, the higher the rate of child abuse and spouse abuse (Levinson 1989; Straus 1977). The nonfamily violence can be in the form of violent crime or socially legitimate violence such as warfare. The carryover of violent behavior from one sphere of life to another may be strongest when the societal violence is "legitimate violence" rather than "criminal violence," because most individual acts of violence are carried out to correct some perceived wrong. Archer and Gartner (1984) and Huggins and Straus (1980) (1980) found that war is associated with an increase in interpersonal violence. Straus constructed an index to measure differences between the states of the United States in the extent to which violence was used or supported for socially legitimate purposes, such as corporal punishment in the schools or expenditure per capita on the National Guard (Baron and Straus 1989). The higher the score of a state on this Legitimate Violence Index, the higher the rate of *criminal* violence such as homicide (Baron and Straus 1988) and rape (Baron and Straus 1989).

Family violence occurs at all social levels, but it is more prevalent at the lowest socioeconomic level and among disadvantaged minorities. Socioeconomic group differences in corporal punishment of children or slapping of spouses are relatively small, but the more severe the violence, the greater the socioeconomic difference. Thus, punching, biting, choking, attacking with weapons, and killing of family members occur much more often among the most disadvantaged sectors of society (Linsky et al. 1995; Straus et al. 1980).

The Overall Pattern. No single factor, such as male dominance or growing up in a violent family, has been shown to account for more than a small percentage of the incidence of child abuse or spouse abuse. However, a study of the potential effect of twenty-five such "risk factors" found that in families where only one or two of the factors existed, there were no incidents of wife beating during the year studied. On the other hand, wife beating occurred in 70 percent of the families with twelve or more of the twenty-five factors (Straus et al. 1980). Similar results were found for child abuse. Thus, the key to unraveling the paradox of family violence appears to lie in understanding the interplay of numerous causal factors.

THE FUTURE

During the period 1965 to 1985, the age-old phenomena of child abuse and wife beating underwent an evolution from "private trouble" to "social problem" and, in the case of wife beating, to a statutory crime. Every state in the United States now employs large numbers of "child protective service" workers, and there are national and local voluntary groups devoted to prevention and treatment of child abuse. There are more than 1,000 shelters for battered women, whereas none existed in 1973. There are growing numbers of treatment programs for batterers and of family dispute mediation programs. Criminal prosecution of violent husbands, although still the exception, has become frequent, often with mandated participation in a treatment program as an alternative to fines or incarceration (Sherman et al. 1992). After lagging behind the states for more than a decade, in 1994 Congress passed the Violence Against Women act, which provides funds for services, education, and research. In the 1990s there was also an exponential growth of family therapy by psychologists and social workers, and psychology replaced sociology as the discipline most active in research on family violence.

Comparison of the 1975, 1985, and 1992 National Family Violence Surveys found a substantial reduction in the rates of child abuse and wife beating (Straus 1995; Straus and Gelles 1986; Straus et al. 1997). However, domestic assaults *by* women remained about the same, perhaps because there has been no national effort to confront this aspect of family violence and perhaps because it is a perverse aspect of the movement toward gender equality. These decreases in family violence are an acceleration of a centuries-long trend. The acceleration probably results from a combination of the educational programs, services, and legal changes discussed in this article; as well as from changes in characteristics of the family and the society that lie at the root of family violence. These include increases in the educational level of the population, later marriages, and fewer children, all of which reduce family stress; parent education programs and media, which help parents manage children without corporal punishment or more severe violence; greater equality between men and women, which reduces some of the power struggles that lead to violence; and wives in paid jobs and a greater acceptability of divorce, which (along with

shelters for battered women) enables more women to escape from violent marriages. Although child abuse and spouse abuse rates have declined, they are still extremely high. American society still has a long way to go before a typical citizen is as safe in his or her own home as on the streets or in the workplace.

MURRAY A. STRAUS

FEMINIST THEORY

The term *feminist theory* is an invention of the academic branch of the mid- and late twentieth-century feminist movement. It refers to generating systematic ideas that define women's place in society and culture, including the depiction of women—large questions, indeed. The task of feminist theorists is necessarily monumental. It requires the wisdom, courage, and perseverance that Penelope displayed as she wove and unwove her tapestry to trick the suitors who sought to appropriate her kingdom and so steal her child's birthright.

For many reasons the task of feminist theorists is difficult. First, it is interdisciplinary. Literary critics, art historians, musicologists, historians, and philosophers—to name some specialists associated with the humanities—have all offered powerful and sometimes conflicting ideas about women in society and culture. So have sociologists, anthropologists, economists, psychologists, and psychoanalysts. Although the biological and physical sciences do not usually make fruitful contributions to contemporary debates about social and cultural issues, feminist scientists have posed questions that challenge the presuppositions of their own fields. They, too, have augmented the scope of feminist theory. Indeed, specialists in so many disciplines have offered apt ideas that no one essay or writer can even pretend to outline the scope of contemporary feminist theory. This presentation will concentrate on ideas developed in the social sciences.

Second, because feminist theory has its basis in the current women's movement, it is necessarily infused with the political concerns of the contemporary era. (Any system of arranging facts, including the writing of history, is necessarily influenced by the dominant concerns and ideologies of its times.) The most important of these is the relationship among race (ethnicity), gender, and class, both cross-culturally and historically. For even as Americans and Europeans have sought to confront institutionalized racism and sexism, as well as the unequal distribution of income and wealth in their own nations, women in developing nations have posed issues regarding the application of generalizations based on those experiences to their own situations. So, too, historical research has

raised the challenge of process—namely, the problem that any particular historical outcome is not predetermined, so that the development of relationships among gender, class, and race (or ethnicity) may vary greatly. Such variations make the act of generalizing hazardous, if not foolhardy.

Third, feminist theory has not merely existed in a sociopolitical context but has been informed by it. This means that many theorists realize that their ideas have been influenced by their own material conditions and cultures. Thus, they have had to confront epistemological issues, including the meaning of objectivity and the way male dominance has shaped notions important to all branches of human inquiry. Put somewhat differently, theorists have broached two issues: (1) the inextricable association between ideas and methods of inquiry, and (2) how both dominant ideas and methods have been influenced by the male hegemony over academic and scientific discourse. As is true in most contemporary fields of study, each of these issues is controversial.

Given these challenges, one might well wonder why anyone would try to generate feminist theory. But feminist academics felt that they could make a significant contribution by using their training first to document and later to analyze women's place in society. When the feminists of academe began to debate their understandings of women's place in society and culture, no sure path seemed available. With the exception of Simone de Beauvoir's *The Second Sex* (1952), men had penned the two canonized (nineteenth-century) texts most familiar to these academics, namely John Stuart Mill's *The Subjection of Women* and Frederick Engels's *The Origins of Private Property, the Family, and the State*. Although Western women had debated their own situation since at least 1400, when, as Joan Kelly (1982) notes, Christine de Pisan “sparked . . . the four-century-long debate . . . known as the *querelle des femmes*,” twentieth-century academics were largely ignorant of that polemical tradition. Instead, they had been schooled in the thought of great men—whose writings were included in the first anthologies of feminist thought, such as Miriam Schneir's *Feminism: The Essential Historical Writings* (1972) and Alice Rossi's *The Feminist Papers* (1973). Such anthologies also introduced American academics to great women outside their own fields.

Nonhistorians learned of the generative ideas of participants in the Seneca Falls convention of 1848, as well as about Susan B. Anthony, Emma Goldman, and the British activist Emily Pankhurst; noneconomists met Charlotte Perkins Gilman; non-literary critics met Virginia Woolf. Although feminist intellectuals might find strength in the knowledge that other women had provided trail markers to guide their way, antifeminists were not convinced that gender inequality still existed.

Thus, the first task confronting feminist theory was to document both past and present inequalities. Many of the early writings addressing this project discussed women as either “other” or “victim.” These characterizations ran through writings that might be classed as either liberal (the belief that women have the same capabilities as men and should receive equal treatment); socialist Marxist (variations of the notion that capitalism created or augmented gender inequality); or radical feminist (versions of the idea that women are inextricably different from men and at least equal, and possibly superior, to them).

WOMAN AS OTHER AND AS VICTIM

To some extent the notions of “other” and “victim” are implicit in any mid-twentieth-century demonstration of inequality. Those who are maltreated for unacceptable reasons appear to be victims, as implicit in the late 1960s’ and early 1970s’ political slogan “Don’t blame the victim.” They seem to be “others” because of the historical and cross-cultural tendency of dominant groups to justify discriminatory actions by arguing that members of subdominant groups are “alien,” not fully human, or simply “not like us.” (In the American case, blacks were deemed “not fully human” when procedures for counting the male population were defined in the early years of the Republic.) This dichotomy between “subject” and “object,” “self” and “other,” has also been crucial to modern European thought, including the philosophic basis for de Beauvoir’s *The Second Sex*, which was Jean-Paul Sartre’s concept of existentialism. Such notions seemed to provide a conceptual framework with which to document *sexism*, a term introduced by those members of the American women’s movement who had participated in the civil rights movement and who wished for a term that

reverberated with connotations of despicable conduct implicit in the more familiar term *racism*. That is, academic feminists could view themselves as demonstrating how specific practices or institutions viewed women as “others,” maltreated them, and so transformed them into “victims” not responsible for their “despised” status. Once those processes were identified, feminist activists could seek to reform or to revolutionize the relevant institutions.

Social scientists provided confirmation of victimization by gathering data comparing women and men. Men were more likely to dominate professions (even such “female work” as grade school teaching and librarianship, in which men were likely to be principals and department heads), earn more money, receive higher education, be awarded scholarships and fellowships, earn advanced degrees, hold positions of political leadership, be granted credit cards, be treated as legally responsible for their actions, and be permitted to make decisions about their own bodies. (Both theorists and activists hotly discussed the “body issues” such as abortion, incest, rape, and sexual harassment and wife battering.) Psychologists and psychiatrists pointed out that their colleagues had equated mental health with supposedly male characteristics. Humanists demonstrated that in art, music, and literature, men had inscribed themselves in the “cultural canon.” Not only did the canon identify men’s accomplishments as the “most important” Western works, but the so-called Western cultural tradition also represented history, literature, art, and philosophy from a male point of view. Sometimes these great works dwelled on the dichotomy between the concepts of madonna and whore; sometimes on the secular objectification of women’s sexuality (as seen in renditions of the female nude). Whether religious or secular, both the cultural canon and academic knowledge were discovered to ignore or belittle women in various ways, as well as to devalue their contributions to civic and cultural life throughout the centuries.

Feminists confronted the dilemma of what to do about this devaluation. Liberal feminists seemed to echo one theme implicit in de Beauvoir’s *The Second Sex* and Mill’s *The Subjection of Women*: Become more like men—that is, remove the barriers preventing women from having the same opportunities as men, and, in the future, women will accomplish as much as men. Because, as some

psychologists argued, there is no innate difference between women and men, equal treatment and equal opportunity will result in equal accomplishment.

The solution offered by Marxist and socialist feminists was not all that different from the ideas of liberals. They, too, believed that the eradication of obstacles would liberate women. But Marxist and socialist feminists were haunted by the “problem of the hyphen.” That is, for them, the barriers confronting women were not simply posed by what all feminists termed “patriarchy” (shorthand for “male dominance”). Rather, as they saw it, patriarchy was itself inextricably related to capitalism. So, disentangling that relationship was a complex task. If capitalism had been a primary cause of women’s inferior position, then women should have found greater equality in noncapitalist nations. In actuality, women had *not* prospered under the brands of communism found in the Soviet Union, Eastern Europe, or China. In those nations, too, women were clustered in jobs that paid less than those filled by men of equivalent education.

As feminists learned, communist lands had treated women favorably while still in their revolutionary stages. For example, in the Soviet Union of the 1920s, “changes in property relationships and inheritance laws weakened the family as an economic unit and reduced the dominance of the male household head, while new family codes undermined the legal and religious basis of marriage and removed restriction on divorce” (Lapidus 1978, p. 60). By undercutting the power of both the church and the traditional family, these measures strengthened the state. Once the Communist party had institutionalized its power and declining birthrates challenged economic growth, however, it redefined the family as “the bulwark of the social system, a microcosm of the new socialist society . . . [supposed] to serve above all as a model of social order” (Lapidus 1978, p. 112). Divorce became difficult; motherhood was defined as a contradiction, simultaneously a joy and the “supreme obligation of Soviet women.” As in capitalist countries, the Soviet Union then began to glorify women’s role in the family (what feminist theory identified as the private sphere).

The discrepancy that arose between communist practice and socialist theory created a theoretical dilemma. One might insist that the so-called communist countries had radically departed from

the theoretical ideal, and so the impact of socialism on women’s lives had yet to receive a valid test. One might point to the relatively enlightened laws of the Scandinavian societies, where social policies assisted women who tried to combine work and family life. But even in these nations, women assumed more of the responsibility for children than did men. Although Scandinavian laws enabled father or mother to take parental leave after the birth or adoption of a child, few men exercised that legal right. Thus, another option seemed necessary: One might seek to reconceptualize the link between private property and patriarchy.

Anthropologists and historians were among the first feminists to attempt that (re)vision. Three of their solutions were particularly influential. First, drawing on de Beauvoir, some anthropologists (and at least one sociologist) returned to the idea of woman as other (see Rosaldo and Lamphere 1974). They suggested that extant societies embodied an analogy: Woman is to nature as man is to culture. That is, traditional and industrialized societies assumed that woman is closer to nature than man is. Men had supposedly thrust themselves upon nature and transformed it.

Second, some theorists incorporated Marxist notions by pointing out that men had defined women as private property. Rubin (1975) offered the most influential argument about what she termed “the sex/gender system.” Assuming that women and men are more like than unlike one another, she asked how societies create “difference” or transform sex into gender. Answering her question, she retained her anthropologist’s conviction that kinship relations are at the basis of society while she drew on her own “freely interpretive” readings of Claude Levi-Strauss and Sigmund Freud. In essence, Rubin argued, men exchange women to create and to cement their own social relationships. This exchange “does imply a distinction between gift and giver. If women are the gifts, then men are the exchange partners. And it is the partners, not the presents, upon whom reciprocal exchange confers its quasi-mystical powers of social linkage. The relations of such a system are such that women are in no position to realize the benefits of their own circulation. As long as the relations specify that men exchange women, it is the men who are the beneficiaries of the product of such exchanges—social organization” (Rubin 1975, p. 174).

Prohibitions on incest keep this exchange system going because they intend to ensure the availability of women to be exchanged. Yet the women must be willing to be “gifts”; that is, they must have internalized the appropriate societal norms. Supposedly, what Freud describes as the Oedipal complex provides that internalization. According to Rubin, the Oedipal complex is a record of “how [contemporary] phallic culture domesticates women” (1975, p. 198). Furthermore, psychoanalytic findings about women’s inferiority to men is a palimpsest “of the effects in women of their domestication” (p. 198). Thus, any society based on the exchange of women has molded the inequalities of the sex/gender system into its very essence. According to Rubin, this generalization is as applicable to today’s industrialized societies as to nonindustrial societies. What feminists term *patriarchy* is actually the operation of the sex/gender system. By implication, to achieve equality, feminists had to challenge the sex/gender system.

Third, some historians and anthropologists responded to the conflation of capitalism and patriarchy by seeking nonindustrial models where women held power. Mainly they sought examples of women as a force in the public sphere. Eleanor Leacock wrote about one classic case, the Iroquois. In the Iroquois Confederation, women elected the (male) chiefs and were also empowered to remove them from office. In medieval society, Joan Kelly maintained, (aristocratic) women had power over the education of their daughters. During the Renaissance, men absconded with that power, devalued the knowledge women had shared, deprived women of the right to educate one another, and also denied women equal access to the then newly discovered “classics.” Kelly concluded her article by suggesting that the Renaissance had a different meaning for women and men; and so, by challenging historians’ periodization, another conclusion was also possible. One might infer that during the Renaissance, men transformed women into victims.

By viewing women as either other or victim, all these theorists were implicitly accepting the male assumption that the public sphere is more important than the private. Even the search for examples of women who had once collectively held significant political power can be viewed as an affirmation of the dominant (male) view that the public sphere is more important than the private (home).

However, the third approach—the search for examples of institutionalized female power—also foreshadowed a new phase of feminist theory: “the (re)vision of public and private spheres.” As introduced by the poet Adrienne Rich, the term *(re)vision* is a deliberate pun referring to both a reconsideration of past ideas and a new vision of women’s role in society.

THE (RE)VISION OF PUBLIC AND PRIVATE SPHERES

In the late 1970s, the feminist movement was maturing; many middle- and upper-class women (including nonfeminists) began to flock to the male-dominated professional schools from which they had once been excluded. Feminists in several fields began to reassess the value of activity in the private sphere—the world of the home in which most women were ensconced. Could the private sphere serve as a launchpad for social change? Had it ever done so? Are these spheres indeed separate, or does the persistence of this dichotomy conflate the errors of nineteenth-century thought? (A reconsideration of the relationship between the public and private spheres is implicit in the titles of such books as *Beyond Separate Spheres* and *Private Woman, Public Stage*. In sociology, Marxist and socialist feminists use different language to discuss women’s and men’s spheres.)

Nineteenth-century social theories had implied that the private sphere was of equal importance to the public world of work. Although the early nineteenth-century “cult of domesticity” banished women to the home, where they were to serve as models of religiosity and virtue, they were also enshrined as “mothers of civilization”—a role that might imply power. But from the vantage of the late twentieth century, the role of “mother of civilization” did not seem so vital. If the private sphere was so important, why was the role of “parent of civilization” not available to men, who historically seemed almost to have monopolized positions of power? If the roles of women and men (wives and husbands) were of equal importance, as Talcott Parsons had implied, why were American women more likely than men to complain of the sorts of physical and mental ailments associated with an inferior social position?

Yet, in the late 1970s, historians, anthropologists, and some sociologists began to find positive

aspects of women's role in the private sphere. According to historians, women had used their roles to initiate social reforms. They had been especially active in trying to ameliorate some of the social problems resulting from the transformation of an agricultural society into an industrial one. For example, through voluntary associations, middle- and upper-class women in New York tried to decrease the destructive impact of poverty on the poor, especially on poor women. In Oneida County, they sought to reform the behaviors of the many single men who had moved to the city from the farms, lived in boarding houses, and sometimes disrupted the civil order. That the activities of the volunteers resulted in the enshrinement of women in the home once their activities had been successful is a historical irony (Ryan 1981). But that outcome is irrelevant to the main theoretical point offered by feminist theorists: Activity that nineteenth-century women had viewed as an extension of their roles in the private sphere had indeed influenced the public sphere. Put somewhat differently, the domestic and public spheres are not necessarily dichotomous.

Yet problems remain. First, variations suggest that generalization is premature. Second, rejection of the dichotomy between domestic and public spheres challenges the residues of nineteenth-century thought remaining in twentieth-century theories but does not necessarily lead to new theoretical formulation. Indeed, neither historical nor anthropological discoveries of variations on the common pattern—male dominance—*necessarily* facilitate theorizing. Rather, they might and did lead some feminists to search for the origins of male dominance (as in the article by Gayle Rubin) and to champion causal explanations.

Yet the (re)vision of public and private spheres did enable some feminist theorists to ask new questions. The anthropologist M. Z. Rosaldo (1980) explains:

Sexual asymmetry can be discovered in all human social groups, just as can kinship systems, marriages, and mothers. But asking "Why?" or "How did it begin?" appears inevitably to turn our thoughts from an account of the significance of gender for the organization of all human institutional forms (and reciprocally, of the significance of all social facts to gender) toward dichotomous

assumptions that link the roles of men and women to the different things that they, as individuals, are apt to do.

Rosaldo (1980) continues:

What traditional social scientists have failed to grasp is not that sexual asymmetries exist but that they are as fully social as the hunter's or the capitalist's role, and that they figure in the very facts, like racism or social class, that social science claims to understand. A crucial task for feminist scholars emerges, then, not as the relatively limited one of documenting pervasive sexism as a social fact—or showing how we can now hope to change or have in the past been able to survive it. Instead, it seems that we are challenged to provide new ways of linking the particulars of women's lives, activities, and goals to inequalities wherever they exist.

To advance beyond naivete, feminist theories must grasp *how* meanings of gender are constructed, not why they exist.

Sociologist Nancy Chodorow provided one such demonstration in her now-classic but still controversial *The Reproduction of Mothering*. Using psychoanalytic object-relations theory and some elements of Marxist thought, she argued that in contemporary capitalist societies the roles of women and men within the family (re)produce the roles women and men are expected to fill in Western societies. Because women are responsible for the care of small children, young girls and boys initially identify with their mothers. Girls are encouraged to continue this relational identification with their mothers; boys are not. For girls, the omnipresence of women in early childhood leads to a problem of boundaries—of knowing where their mothers end and they begin. As adults, this lack of boundaries may be advantageous: Out of their ability to see the world as others do, they may have a richer emotional life than men and also be more emphatic than they are. For boys, the omnipresence of women means that men learn the meaning of masculinity through the eventual demand that they separate from their mothers and identify with a role (male gender). Theirs is a positional identification. Ultimately, Chodorow argues, these scenarios play themselves out so that women and men try to reproduce the sorts of

modern families in which they were reared. Additionally, Chodorow (1978) claims,

An increasingly father-absent, mother-involved family produces in men a personality that both corresponds to masculinity and male dominance as these are currently constituted in the sex-gender system, and fits appropriately with participation in capitalist relations of production. Men continue to enforce the sexual division of spheres as a defense against powerlessness in the [capitalist] labor market. Male denial of dependence and of attachment to women helps to guarantee both masculinity and performance in the world of work.

She continues,

The relative unavailability of the father and the overavailability of the mother create negative definitions of masculinity and men's fear and resentment of women, as well as the lack of inner autonomy in men that enables, depending on the particular family constellation and class origin, either rule-following or the easy internalization of the values of the organization.

Chodorow's theory is controversial. Some liberals object to the inference that women are more empathetic than men. They claim that psychological studies show that women and men have the same innate emotional capabilities. Nevertheless, radical feminists—people who believe that male dominance is the primary cause of women's subjugation—sometimes celebrate women's alleged superiority to men.

Others challenge Chodorow's theory by questioning whether any theory about the modern American family can possibly be applied to other historical epochs or cultures. Yet this objection misses the point in two ways. First, Chodorow discusses a specific time and place—contemporary America. Her contrast between how women and men learn their (relational or positional) roles should be even more important today than it was in 1978 when *The Reproduction of Mothering* was first published. Since 1978 the percentage of female-headed households has increased. Concomitantly, more young boys have even less contact with men; they must form the positional identifications that, Chodorow claims, prepare them to uphold the orientations to work and

family required to maintain postindustrial capitalism. Second, Chodorow anticipated Rosaldo's call to understand how gender is socially constructed to articulate with other roles. She did not ask the origin of all sex/gender systems.

Chodorow's argument is important in a third way: She transforms "normal" understandings of men's and women's roles. She turns one current interpretation of Freud's thought, object-relations theory, on its head. Woman-centered (written from the perspective of a feminist) yet comparative (examining both women and men), Chodorow's book anticipated the challenge that feminist scholarship currently offers other theoretical projects.

CHALLENGING CONVENTIONAL INTERPRETATIONS

The theme of difference is key to Carol Gilligan's *In a Different Voice* (1981). Extending and (re)vising Lawrence Kohlberg's work on the development of moral judgments among men, Gilligan argues that Kohlberg's scale of moral maturity slights women. Kohlberg argues that the highest stages of maturity involve the application of "rules to universal principles of justice" (Gilligan 1981, p. 18). In Kohlberg's model, women seem stuck at an intermediate stage because of their lack of opportunity to enter the public sphere and so to master and to apply those universal principles. Gilligan contends that Kohlberg has erred in his assessment of women (and other subordinated groups). In the case of women, he has not understood how their concepts of morality are based on their socialization. On the basis of her empirical studies and Chodorow's argument, Gilligan concludes that women do not make inferior moral judgments but different ones. They employ a relational ethic that stresses interpersonal caring, including a responsibility for self and others.

Gilligan's theory is as controversial as Chodorow's—perhaps even more so. Radical feminists cite this theory to argue again that women are morally superior to men. Some liberal feminists, who are interested in pushing for women's entry to upper levels of corporate management, use Gilligan's theory to claim that women are better equipped than men to develop innovative management styles that bind teams to the corporation. Other liberals (e.g., Epstein 1989) insist that there

are no *innate* psychological distinctions between women and men.

However, both Chodorow and Gilligan raise an additional issue, potentially more controversial than the debates about “innate” gender differences. They try at one and the same time to follow the practices of their respective disciplines and to view social life from a woman’s perspective. Since science, social science, and the literary canon are based on male perspectives (as is true of Kohlberg’s studies), how are we to forge an epistemology (and hence a methodology) that can simultaneously claim veracity and be true to women’s experience of the social world? Can any theory that is either androcentric (man-centered) or gynocentric (woman-centered) be valid?

FEMINIST THEORY AND THE PROBLEM OF KNOWLEDGE

Some scientists or social scientists might believe that the question of validity applies only to explicitly interpretive work. After all, many decades have passed since Heisenberg enunciated his famous principle that the technologies (and by extension the theories and methods) used to view a phenomenon necessarily influence what is viewed. Supposedly, scientists and social scientists have been taking this principle into account as they explain how their generalizations apply “all other things being equal.” But feminist theorists, like postmodern theorists, have challenged the very basis of the deductive methods at the heart of contemporary science and social science. They “question the very foundation of post-Enlightenment science and social science: the ‘objectivist illusion’ (Keller 1982) that observation can be separated from explanation, the knower from the known, theory from practice, the public from the private, culture from nature, and other dualisms that undergird systems of social stratification” (Hess 1990, p. 77). The feminist challenge differs from other deliberations about epistemology because, as Hess observes, it is “more political.”

The work of scientist Evelyn Fox Keller is exemplary of this controversy. Keller has written rather abstract philosophic essays on such issues as Plato’s epistemology and Bacon’s notions of mastery and obedience to argue that modern science is infused with “male” notions. Rather than attempt to present these complex arguments briefly,

let us concentrate on a more concrete work, Keller’s biography of biologist Barbara McClintock, *A Feeling for the Organism* (1982).

In this biography, Keller claims that McClintock accomplished her Nobel Prize-winning research on the transposition of genes in part because McClintock’s research style radically departed from the dominant male model, molecular genetics. According to Keller, the dominant model presumed a hierarchical structure of genetic organization that resembles organizational charts of corporate structure and assumes a unidirectional flow of information. That assumption permitted the quick payoffs in research on the structure of specific bacteria that facilitates significant scientific findings (and so careers). The hierarchical model, though, is also supposedly a “male” model.

McClintock, however, believed in a more complex and less hierarchical “old-fashioned” model: “To McClintock, as to many other biologists, mechanism and structure have never been adequate answers to the question ‘How do genes work?’ To her an adequate understanding would, by definition, have to include an account about how they function in relation to the rest of the cell, and, of course, to the organism as a whole” (Keller 1985, p. 168). In this view, even a genome is an organism, and it, too, must be considered in relation to its environment.

Keller does not claim that McClintock’s model was female: McClintock was trained by men. Keller does argue that many biologists have missed the essence of McClintock’s vision. Keller includes among them biologists who are trying to incorporate McClintock’s work on transposition into the hierarchical model. And, Keller believes,

The matter of gender never does drop away. . . . The radical core of McClintock’s stance can be located right here. Because she is not a man, in a world of men, her commitment to a gender-free science has been binding; because concepts of gender have deeply influenced the basic categories of science, that commitment has been transformative. In short, the relevance of McClintock’s gender in this story is to be found not in its role in her personal socialization but precisely in the role of gender in the construction of science. (Keller 1982, p. 174)

For, Keller explains, contemporary science names the object of its inquiry (nature) “as female and the parallel naming of subject (mind) as male” (1982 pp. 174). Thus, women scientists are faced with a necessary contradiction between their roles in the world and their role as scientist. Even as the social structure of science tends to place women on the periphery of the invisible colleges that constitute the scientific world, that contradiction may limit the creative scientific imagination of both women and men.

However, as Keller readily admits, not all men believe in the hierarchical model. Nor, to paraphrase Keller, have they all “embraced” the notion of science as a female to be put on the rack and tortured to reveal her secrets. But, Keller insists, both the naming of subject and object and the hierarchical model are androcentric and limit the possibilities of scientific inquiry.

Keller’s work has been challenged on a number of grounds. Stephen Jay Gould has launched the most telling attack. His field, paleontology, is also dominated by men but rejects the hierarchical “male” model. Unlike nineteenth-century evolutionary thought, contemporary theories do not view human beings as the proud culmination of the past. Other lifeforms have been more successful. Furthermore, to reconstruct the past, paleontologists must grasp “wholes.” Cynthia Fuchs Epstein adds that one cannot even argue that, as social scientists, women have been more empathic or observant than men. Epstein’s counterexample is Erving Goffman, whose ability to “see” is almost legendary among sociologists.

For the purposes of this article, it is irrelevant whether Keller, Gould, or Epstein is correct. What matters is that developments in feminist theory have led feminists to participate in the postmodern debate about the nature of knowledge. During the late 1980s, this debate was at the center of controversies in the social sciences and the humanities. It will probably remain important for some years to come. The debate infuses interpretations of literary works, reconstructions of the past, and understandings of social scientific models. It seems to transcend schools of thought. Marxists are divided about postmodernism, as are liberals and, within the feminist community, radicals. Feminist theory has followed the course of all contemporary theories because feminists, too, are members of the

societies about which they write and which they are trying to change.

Throughout this essay, terms such as *liberal*, *Marxist* or *socialist*, and *radical* feminists have been intended to distinguish different political orientations and experiences that shaped each group of feminists, as so well documented in histories and sociologies of the mid-twentieth-century feminist movement. By 1990, these very different groups of feminists had become self-consciously aware; that is, many understood that even as feminism had sought social change, it, too, had shaped and been shaped by its environment. For instance, Stacey (1990) argued that in the late 1960s and early 1970s, as feminism stressed female participation in the public sphere and denigrated motherhood, it contributed to rising divorce rates and the devaluation of feminine tasks.

In the 1990s, feminist theory has maintained its own questions and has continued to be divided into camps that emphasize either the similarities between women and men or the differences between them. However, as is axiomatic, all enterprises are embedded in and shaped by their structural contexts. Feminist theory has not been an exception to this well-known rule.

In the 1990s, feminist theories have been influenced by general tendencies in other academic specialties. Although it is still rare (and perhaps because it is still rare) for someone to receive a Ph. D. from an academic department called “women’s studies,” “gender studies,” or “feminism,” feminist theory has become increasingly influenced by movements toward specialization within the social sciences. These movements have included the ever more narrow delineation of topics of inquiry, such that a business school course on women in non-profit organizations may share few if any readings with a sociology course on women and the professions and a course on men and masculinity taught in a school of family studies may not overlap an anthropology course on cross-cultural notions of masculinity. Additionally, within the social sciences, academic disciplines are so beset by specialized theories that researchers may encourage a thousand flowers to bloom by ignoring one another’s ideas rather than by addressing the basic and competing philosophic premises on which their theoretical systems are built. Within sociology, for instance, the articles of feminist theorists who

pledge allegiance to rational choice theory rarely cite the works of feminist theorists who use key ideas of the symbolic interactionists—and vice versa. Indeed, they may not even agree to call themselves feminist theorists, but rather speak of themselves as rational choice theorists interested in the problems of gender or as symbolic interactionists exploring theories about how women experience their bodies under the parameters set by a national medical system.

Nonetheless, there have been some general ideas about which feminist theorists have come to agree. Perhaps the most important of these is a problem central to all social science: to wit, the theoretical tension between approaches that emphasize individuals as the agents of social stability and social change and approaches that stress how either macro- or microstructures influence and shape both individuals and their decisions. Indeed, as more social scientists have come to agree that nature and nurture interact, the theoretical problems posed by agency and structure have become more salient.

One basic way that feminist theorists have dealt with these problems is to redefine gender itself. In the past, gender has been thought of as a cultural phenomenon—either normative patterns of behaviors, roles, or scripts. Today gender itself is being viewed as a structural phenomenon. This means that many feminist theorists now define gender as an institution, as basic to social structure as the economy, religion, education, and the state—and perhaps more basic than the family (Connell 1995; Lorber 1994). Such theorists emphasize that in some societies there are more than two (dichotomous) genders and that socially and historically embedded notions of gender influence the operation of all institutions, even as they are influenced by other sociohistoric institutions. Further, these theorists continue, identification of gender as an institution enables one to recognize that gender is stratified and that it is also processual (part of unfolding social processes). Thus, this redefinition of gender enables theorists to link structure and agency by discussing how individuals' gendered behavior (re)produces gendered social structures, much as Giddens's (1984) structuration theory seeks to marry structural and agentic approaches. Furthermore, the recognition of gender as an institution entails such a broad paradigmatic shift that, at one and the same time, it refocuses

how theorists view gender and facilitates work within different theoretical traditions. Adherents of symbolic interactionism, neofunctionalism, or rational choice theory could all absorb this notion into their work and test its implications with their method of choice (Ferree et al. 1999).

FEMININITY/MASCULINITY

Femininity and masculinity, or one's *gender identity* (Burke et al. 1988; Spence 1985), refer to the degree to which persons see themselves as masculine or feminine given what it means to be a man or woman in society. Femininity and masculinity are rooted in the social (one's gender) rather than the biological (one's sex). Societal members decide what being male or female means (e.g., dominant or passive, brave or emotional), and males will generally respond by defining themselves as masculine while females will generally define themselves as feminine. Because these are social definitions, however, it is possible for a person to be female and see herself as masculine or male and see himself as feminine.

It is important to distinguish *gender identity*, as presented above, from other gender-related concepts such as *gender roles*, which are shared expectations of behavior given one's gender. For example, gender roles might include women investing in the domestic role and men investing in the worker role (Eagly 1987). The concept of gender identity is also different from *gender stereotypes*, which are shared views of personality traits often tied to one's gender, such as instrumentality in men and expressiveness in women (Spence and Helmreich 1978). And gender identity is different from *gender attitudes*, which are the views of others or situations commonly associated with one's gender, such as men thinking in terms of justice and women thinking in terms of care (Gilligan 1982). Although gender roles, gender stereotypes, and gender attitudes influence one's gender identity, they are not the same as gender identity (Katz 1986; Spence and Sawin 1985).

From a sociological perspective, gender identity involves all the meanings that are applied to oneself on the basis of one's gender identification. In turn, these self-meanings are a source of motivation for gender-related behavior (Burke 1980). A person with a more masculine identity should act

more masculine, that is, engage in behaviors whose meanings are more masculine such as behaving in a more dominant, competitive, and autonomous manner (Ashmore et al. 1986). It is not the behaviors themselves that are important, but the meanings implied by those behaviors.

Beginning at birth, self-meanings regarding one's gender are formed in social situations, stemming from ongoing interaction with significant others such as parents, peers, and educators (Katz 1986). Although individuals draw upon the shared cultural conceptions of what it means to be male or female that are transmitted through institutions such as religion or the educational system, they may come to see themselves as departing from the masculine or feminine cultural model. A person may label herself female, but instead of seeing herself in a stereotypical female manner, such as being expressive, warm, and submissive (Ashmore et al. 1986), she may view herself in a somewhat stereotypically masculine manner, such as being somewhat instrumental, rational, and dominant. The point is that people view themselves along a feminine-masculine continuum, some seeing themselves more feminine, some as more masculine, and some as a mixture of the two. It is this self-perception along the feminine-masculine continuum that is their gender identity, and it is this that guides their behavior.

THE ROOTS OF FEMININITY/ MASCULINITY

In Western culture, men are stereotypically seen as being aggressive, competitive, and instrumentally oriented while women are seen as being passive, cooperative, and expressive. Early thinking often assumed that this division was based on underlying innate differences in traits, characteristics, and temperaments of males and females. In this older context, measures of femininity/masculinity were often used to diagnose what were understood as problems of basic gender identification, for example, feminine males or masculine females (cf. Terman and Miles 1936).

We now understand that femininity and masculinity are not innate but are based upon social and cultural conditions. Anthropologist Margaret Mead addressed the issue of differences in temperament of males and females in *Sex and Temperament in Three Primitive Societies* (1935). This early

study concluded that there are no necessary differences in traits or temperaments between the sexes. Observed differences in temperament between men and women are not a function of their biological differences. Rather, they result from differences in socialization and the cultural expectations held for each sex.

Mead came to this conclusion because the three societies showed patterns of temperament that varied greatly with our own. Among the Arapesh, both males and females displayed what we would consider a “feminine” temperament (passive, cooperative, and expressive). Among the Mundugamor, both males and females displayed what we would consider a “masculine” temperament (active, competitive, and instrumental). Finally, among the Tchambuli, men and women displayed temperaments that were different from each other, but opposite to our own pattern. In that society, men were emotional and expressive while women were active and instrumental.

Mead’s study caused people to rethink the nature of femininity/masculinity. Different gender-related traits, temperaments, roles, and identities could no longer be inextricably tied to biological sex. Since Mead’s study, the nature–nurture issue has been examined extensively, and with much controversy, but no firm conclusions are yet clear (Maccoby and Jacklin 1974). While there may be small sex differences in temperament at birth (and the evidence on this is not consistent), there is far more variability within each sex group (Spence and Helmreich 1978). Further, the pressures of socialization and learning far outweigh the impact of possible innate sex differences in temperament. We examine this next.

THE DEVELOPMENT OF FEMININITY AND MASCULINITY

There are at least three major theories that explain the development of femininity and masculinity: psychoanalytic theory (Freud 1927), cognitive-developmental theory (Kohlberg 1966), and learning theories that emphasize direct reinforcement (Weitzman 1979) and modeling (Mischel 1966). In all of these theories, a two-part process is involved. In the first part, the child comes to know that she or he is female or male. In the second part, the child comes to know what being female or male means in terms of femininity or masculinity.

According to psychoanalytic theory, one’s gender identity develops through identification with the same-sex parent. This identification emerges out of the conflict inherent in the oedipal stage of psychosexual development. By about age 3, a child develops a strong sexual attachment to the opposite-sex parent. Simultaneously, negative feelings emerge for the same-sex parent that are rooted in resentment and jealousy. By age 6, the child resolves the psychic conflict by relinquishing desires for the opposite-sex parent and identifying with the same-sex parent. Thus, boys come to learn masculinity from their fathers and girls to learn femininity from their mothers.

A later formulation of psychoanalytic theory suggests that mothers play an important role in gender-identity development. According to Chodorow (1978), mothers are more likely to relate to their sons as different and separate because they are not of the same sex. At the same time, they experience a sense of oneness and continuity with their daughters because they are of the same sex. As a consequence, mothers will bond with their daughters, thereby fostering femininity in girls. Simultaneously, mothers distance themselves from their sons, who respond by shifting their attention away from their mother and toward their father. Through identification with their father, boys learn masculinity.

Cognitive-developmental theory is another psychological theory of gender-identity development (Kohlberg 1966). Like psychoanalytic theory, it suggests that certain critical events have a lasting effect on gender-identity development, but these events are seen as cognitive rather than psychosexual in origin. Unlike psychoanalytic theory and learning theory (which is discussed next), cognitive-developmental theory sees the development of a gender identity as preceding rather than following from identification with the same-sex parent. Once a child’s gender identity becomes established, the self is then motivated to display gender-congruent attitudes and behaviors, well before same-sex modeling takes hold. Same-sex modeling simply moves the process along.

Kohlberg identifies two crucial stages of gender identity development: (1) acquiring a fixed gender identity and (2) establishing gender-identity constancy. The first stage begins with the child’s identification as male or female when hearing the

labels “boy” or “girl” applied to the self. By about age 3, the child can apply the appropriate gender label to the self. This is when gender identity becomes fixed. By about age 4, these gender labels are appropriately applied to others. Within another year or two, the child reaches the second critical phase, that of gender constancy. This is the child’s recognition that his or her gender will not change despite changes in age or outward appearance.

The most social of the theories of gender-identity development are the learning theories. In these theories, it is the social environment of the child, such as parents and teachers, that shapes the child’s gender identity. Here, parents and teachers instruct the child on femininity and masculinity, either directly through rewards and punishments or indirectly through acting as models to be imitated. Direct rewards or punishments are often given for outward appearance, such as what to wear (girls in dresses and boys in pants); object choice, such as toy preferences (dolls for girl and trucks for boys); and behavior (passivity and dependence in girls and aggressiveness and independence in boys). Through rewards and punishments, children learn appropriate appearance and behavior. Indirect learning of one’s gender identity emerges from modeling same-sex parents, teachers, peers, or models in the media. Children imitate rewarded models’ thoughts, feelings, or behavior because they anticipate that they will receive the same rewards that the models received.

MEASURING MASCULINITY AND FEMININITY: A PSYCHOLOGICAL VIEW

Conceptualizing masculinity and femininity and measuring these orientations in men and women originated in the work of Lewis Terman and Catherine Cox Miles (1936), who created a 455-item test to detect masculinity and femininity. They called it the Attitude Interest Analysis Test (AIAT) to conceal its purpose from subjects. The test included such things as word associations, inkblot associations, interest items, and introversion–extroversion items. For example, on the interest items, persons got femininity points for liking (and masculinity points for disliking) “nursing,” “babies,” and “charades.” Individuals received masculinity points for liking (and femininity points for disliking) “people with loud voices” and “hunting.” On the introversion–extroversion items, persons got

femininity points for agreeing (and masculinity points for disagreeing) that they “always prefer someone else to take the lead” and that they are “often afraid of the dark.” And they got masculinity points for agreeing (and femininity points for denying) that “as children [they were] extremely disobedient” and that they can “stand as much pain as others.” The responses did discriminate between the sexes, with men displaying higher masculinity and women displaying higher femininity.

Terman and Miles’s masculinity–femininity (M–F) scale became a model for M–F scales for more than three decades (see Morawski 1985 for a review). The M–F scales that followed shared four assumptions with the scale created by Terman and Miles. These included the assumptions that masculinity and femininity were: (1) deep-seated, enduring characteristics of people, (2) not readily apparent in overt behavior, (3) linked to mental health (an incongruence in sex and masculinity and femininity signaled problems in psychological adjustment), and (4) opposite ends of a continuum (Morawski 1987).

By the 1970s, researchers had become disenchanted with M–F scales, a timing that coincided with the reemergence of the women’s movement. Three criticisms had developed: (1) The early M–F scales fostered research that exaggerated the differences between men and women, (2) the feminine characteristics in M–F scales often carried negative connotations, and (3) the bipolar conception of masculinity–femininity was seen as problematic, that is, one could be masculine or feminine but not both (Morawski 1987). From the third criticism arose the concept of *androgyny* and scales to assess it (see Morawski 1987 for a review of the problems surrounding the concept of androgyny).

Androgyny is a combination or balance of masculinity and femininity, allowing for the possibility that individuals can express both. Instead of conceptualizing masculinity and femininity as opposite ends of a continuum, where masculinity on one end precludes one from being feminine on the other end, in androgyny, masculinity and femininity are separate dimensions that can be combined. People can be masculine, feminine, or both (androgynous). Two of the more famous inventories that emerged from the impetus to measure masculinity and femininity on separate, independent dimensions were in psychology: the Bem Sex

Role Inventory (BSRI) (Bem 1974) and the Personal Attributes Questionnaire (PAQ) (Spence and Helmreich 1978).

Both the BSRI and PAQ listed attributes that are positively valued for both sexes but are more normative for either males or females to endorse. These are known as the masculine scale and feminine scale, respectively. In the BSRI, respondents indicate the degree to which a series of descriptions are true about them. Examples of descriptions for the masculine scale include “acts as a leader,” “makes decisions easily,” and “willing to take risks.” Examples of descriptions for the feminine scale include being “affectionate,” “gentle,” and “sensitive to the needs of others.”

In the PAQ, respondents rate themselves on a series of bipolar items. For the masculine scale, the items range from masculine to not masculine, while the items for the feminine scale range from feminine to not feminine. Examples of items from the masculine scale include “very independent” (vs. “not at all independent”) and “can make decisions easily” (vs. “has difficulty making decisions”). The feminine scale includes bipolar items such as “very emotional” (vs. “not at all emotional”) and “very helpful to others” (vs. “not at all helpful to others”). In addition to the masculinity and femininity scales, the PAQ has a third scale, labeled masculinity–femininity, that is in keeping with the bipolar M–F measurement tradition. The bipolar items for this scale are culturally appropriate for males on one end, and culturally appropriate for females on the other. Typical items include “very dominant” (vs. “very submissive”) and “feelings not easily hurt” (vs. “feelings easily hurt”).

With separate measures of masculinity and femininity, it is possible to ask about the relationship between the measure of masculinity and the measure of femininity. When this relationship was examined, it was found that the two scales were not strongly negatively related, as would be expected if masculinity were the opposite of femininity. Instead, using either the BSRI or the PAQ, the two ratings were relatively unrelated; a person’s score on one scale did not predict that person’s score on the other scale (Bem 1974; Spence and Helmreich 1978). People had all combinations of scores. Initially, people who combined high scores on masculinity with high scores on femininity were labeled

as androgynous (Bem 1977; Spence and Helmreich 1978). Later, androgyny was indicated by a small difference between masculinity and femininity scores, representing balanced levels of these two characteristics. The other classifications were masculine (high M and low F scores), feminine (high F and low M scores), and undifferentiated (low F and low M scores).

The BSRI and the PAQ are embedded in very different theories about how gender-related characteristics are organized. For Bem (1981, 1993), scores on the BSRI measure not only the different dimensions of masculinity and femininity; more importantly, the scores measure an underlying unidimensional construct known as *gender schematization*. Gender schematization is an internalized tendency to see the world in gendered terms. One who is gender-schematic classifies stimuli as male or female rather than other according to other dimensions that could equally be used. Those who score high on masculinity or high on femininity are gender-schematic because they tend to organize information along gender lines. Androgynous people are gender-aschematic.

Spence (1984, 1993), on the other hand, suggests that gender phenomena are multifactorial. In this view, there are numerous attributes, attitudes, and behaviors that culturally distinguish between men and women, but these are not bound together as a single underlying property such as gender schematization. For Spence (1985; Spence and Sawin 1985) the important underlying construct is *gender identity*, or one’s sense of being masculine or feminine. Culturally defined personality traits, physical attributes, abilities, and occupational preferences, among other things, all contribute to one’s gender identity in unique and individualized combinations. Individuals draw upon these gender characteristics and choose those qualities that are compatible for them as they define themselves as masculine or feminine and ignore other gender qualities. Thus, while societal members may agree on the representation of masculinity and femininity, one’s own masculinity and femininity tends to be more variable and idiosyncratic in nature.

Rather than conceptualizing the items on the PAQ and the BSRI as referring to the broad categories of masculinity and femininity, Spence

maintains that these items tap into socially desirable instrumental and expressive traits in men and women, respectively (Spence and Helmreich 1978, 1980). While these traits are related to masculinity and femininity, they do not define one's overall gender identity. They are simply one of the set of contributors to one's gender-based self-image. This is supported by the fact that scores on the PAQ and BSRI are not strongly related to scores on other measures of gender attitudes, attributes, and behaviors (Spence 1993; Spence and Sawin 1985).

MEASURING MASCULINITY AND FEMININITY: A SOCIOLOGICAL VIEW

In sociology, the symbolic interactionist view of masculinity-femininity (Burke 1989; Burke et al. 1988; Burke and Tully 1977) shares much in common with the view held by the psychologist Spence and her colleagues. For symbolic interactionists, gender identity is understood in the context of a body of research known as identity theory (Stryker 1980). According to identity theory, the self is an organized collection of hierarchically arranged identities (self-meanings) that serve as a source of motivation for our behavior (Burke 1980). Identities are organized as control systems that act to maintain congruency between the internalized self-meanings (one's identity standard) and perceptions of the meaning of the self in ongoing social situations (Burke 1991). The key in this is one's self-meanings (Osgood et al. 1957).

Individuals' gender identity as masculine or feminine is based on the meanings they have internalized from their association with the role of male or female, respectively, in society. Since these are self-meanings, they cannot be directly observed; they must be inferred from behaviors and expressions in which people engage. Gender identity is one of many role identities people hold. In sociology, we assume that roles do not stand in isolation but presuppose and are related to counterroles (Lindesmith and Strauss 1956). For example, the role of teacher takes on meaning in connection with the role of student, the role of mother takes on meaning in relation to the role of child, and so on. The same is true of identities.

Just as the meaning of student (the student identity) is understood in relation to that of teacher (the teacher identity), so too is the meaning of

male (masculinity) relative to that of female (femininity). The meanings of masculine and feminine are necessarily contrastive. To be male (masculine) is to be not female (feminine) and vice versa (Storms 1979). Gender meanings thus relate to one another as opposite ends of a single continuum, returning to the bipolar conceptualization of masculinity and femininity. Indeed, masculinity and femininity are negatively related when individuals are asked to judge themselves based on the self-descriptors "masculine" and "feminine" (Spence 1993). Interestingly, young children initially do not see masculine and feminine characteristics as opposites, but as they get older, their views of the genders become increasingly bipolar (Biernat 1991). This contrasting of masculinity and femininity in self-meanings does not necessarily hold for behaviors, since one can engage in both masculine and feminine behaviors.

The procedure that symbolic interactionists use to measure gender identity is based on the method devised by Burke and Tully to measure self-meanings (1977). In an analysis of middle school children's gender identities, Burke and Tully first collected sets of adjectives from children that the children themselves used to describe the images of boys and girls. These adjectives, together with their opposites, were used as adjective pairs to form a semantic differential scale to measure the meanings of the male and female roles (Osgood et al. 1957). The stem for the semantic differential was "Usually [boys, girls] are . . . "Then, through a statistical procedure known as discriminant function analysis, the researchers selected those items that best discriminated between the meanings of boys and girls. Examples of items that best distinguished "girl" meanings from "boy" meanings for these children included "soft" (vs. "hard"), "weak" (vs. "strong"), and "emotional" (vs. "not emotional"). After selecting the most discriminating items, children's self-descriptions ("As a [boy, girl] I usually am . . .") were then summed to form a scale of gender identity.

A gender identity scale constructed along the lines described above has certain properties. First, the scale evolves out of the meanings of maleness in relation to femaleness that actually are held in the population from which the sample is drawn. This procedure contrasts with much research that

uses attributes that are assumed to carry meanings of masculinity and femininity with no attempt to check whether they have these meanings for respondents. Second, the measure outlined above incorporates the assumption that meaning is contrastive. The meaning of female is in contrast to the meaning of male and vice versa. Third, by focusing upon self-meanings, we separate issues of who one is (gender identity) from what one does (gender roles) or what one believes (gender attitudes and stereotypes). From this perspective, androgyny may be thought of not as combining masculine and feminine meanings, but as being flexible in the kinds of behaviors in which one engages (sometimes more masculine in meaning, sometimes more feminine in meaning). We now review some of the important research on gender identity that has emerged out of the Burke-Tully method, for which the symbolic interactionist perspective has served as the backdrop.

RESEARCH ON FEMININITY AND MASCULINITY

The symbolic interactionist perspective suggests that the self is defined through interactions with others. Burke and Tully's (1977) work found that children with cross-sex identities (boys who thought of themselves in ways similar to the way most girls thought of themselves and vice versa) were more likely than children with gender-appropriate identities: (1) to have engaged in gender-inappropriate behavior, (2) to have been warned about engaging in gender-inappropriate behavior, and (3) to have been called names like "tomboy," "sissy," or "homo." Not surprisingly, boys and girls with cross-sex gender identities were more likely to have low self-esteem.

Another symbolic interactionist tenet is that people will choose behaviors that are similar in meaning to the meanings of their identities (Burke and Reitzes 1981). Burke (1989) found that among middle school children, boys and girls with a more feminine gender identity earned higher grades than those with a more masculine gender identity. This was true independent of the child's sex, race, or grade, the subject area, or the sex of the teacher. Since the early years of schooling are more likely to be "feminized" because there are more female

than male teachers (Lipman-Blumen 1984), children with a more feminine identity will likely perform better in a "feminine" institution. Among college students, research has shown that males and females with a more feminine gender identity are more likely to inflict and sustain both physical and sexual abuse in dating relationships (Burke et al. 1988). People with more feminine gender identities are likely to be more emotionally expressive and relationship-oriented. Aggression may be used as a last resort to attain a closer relationship.

Within the symbolic interactionist tradition, research demonstrates that the meanings that people attribute to themselves as masculine or feminine (their gender identity) are sometimes more important in predicting how they will behave than is their gender (male or female). For example, early research on conversational behavior reported that males were more likely than females to use more dominant and assertive speech patterns in interaction, such as interrupting (West and Zimmerman 1983) and talking more (Aries 1976). However, a later review of the many empirical studies on interruptions and time spent talking showed that gender had inconsistent effects (James and Clarke 1993; James and Drakich 1993). This inconsistency might be explained through an analysis of gender identity rather than gender. For example, research shows that persons with a more masculine gender identity, irrespective of their gender as male or female, are more likely to use overlaps, interruptions, and challenging statements in a conversation (Drass 1986; Spencer and Drass 1989).

While gender identity may sometimes be more important than gender in determining outcomes, it is also possible for one's gender (male or female) and one's gender identity (masculine or feminine) to each result in different displays of behavior. For example, in an analysis of problem-solving discussions between newly married spouses, females and those with a more masculine gender identity were more likely to express negative, oppositional, and dominating behavior, such as complaining, criticizing, or putting down their spouse (Stets and Burke 1996). While masculinity more than femininity should increase dominating behavior (as discussed above), it was surprising that females engaged in more dominating behavior than males.

It was discovered that this dominating behavior emerged especially from females who were viewed by their spouses as being in a weak, subordinate position in our society. These women were apparently using coercive communication to counteract the (subordinate) view of them and gain some control. The problem is that in compensating for their weaker status by behaving in a dominant fashion, women may unwittingly be reminding men of their weak position.

While one's gender identity is generally stable over time, it sometimes changes in response to different experiences. To examine stability and change in gender identity, Burke and Cast (1997) examined the gender identities of newly married couples over the first three years of marriage, finding that the year-to-year stability in gender identity was moderately high. This means that while the gender identities of the respondents did change over this period of time, they did not change markedly. Looking from month to month or week to week, there was almost no observable change.

Identity theory suggests that identities are most likely to change in the face of persistent changes in the environment. The birth of a first child represents a dramatic and persistent change in the environment that confers femininity on women and masculinity on men. Burke and Cast showed that when a couple had their first child, women's gender identities became more feminine and men's gender identities become more masculine. Social psychological processes may also modify one's gender identity. Burke and Cast also found that the more a spouse took the perspective of the other in the marriage, the more the spouse shifted his or her gender identity in the direction of the other's gender identity. The other's gender identity was thus verified and supported by the spouse, which may act to minimize marital conflict.

THE FUTURE

We mention below several avenues of possible future work in femininity/masculinity. Many more avenues could be identified, for this is an area rich for continuing investigation, but our space is limited. First, we are only beginning to understand issues of stability and change in one's gender

identity. How might gender identities be modified through participation in societal institutions such as the economy, religion, and politics? For example, to what extent and in what ways might employers socialize employees into particular views of being masculine or feminine in order to maintain a smooth flow of work and profit? Are some people more resistant to this socialization than others? Is this issue tied to how relevant gender identity is to individuals?

Related to the above is a second avenue of research, that is, the salience of gender identity across individuals, groups, even cultures. Salience refers to the probability that a particular identity will be invoked in a situation (Stryker 1980). This will vary by situation, but it also varies across individuals. For some, gender is not very relevant, and for others gender is almost always relevant. This returns us to Bem's notion of gender schematization, or the tendency to see the world in gendered terms. What makes gender identity more or less salient for people, and what are the consequences of that?

Third, we know very little about subcultural, cultural, and cross-cultural differences in the meanings that are attached to femininity and masculinity. Most of what we know concerns Western cultures, yet as Margaret Mead discovered long ago, these patterns are not universal. We need to investigate the variation in the meanings of being masculine and feminine. Such studies may help us understand a society's division of labor, its differential power and status structure, and how its privileges and responsibilities are allocated. To modify the social system may mean first modifying individual beliefs about masculinity and femininity.

FERTILITY DETERMINANTS

There have been two periods of intense interest in the determinants of fertility by demographers.

The first period, which encompasses the late nineteenth and early twentieth centuries, was dominated by a concern about differential fertility within Western countries; in this period, leaders of the eugenics movement enlisted the services of demographers to learn how these differentials could be reduced, either by increasing the fertility of some groups or lowering the fertility of others. The second period, encompassing the 1940s to the late 1980s, was dominated by concern about differences in fertility (and thus in population growth rates) between Western countries and those countries known variously as, “less developed,” “developing,” “Third World,” and, most recently, “Southern.” In this period, there was little effort to raise fertility in low-fertility societies but a great deal of effort by an international population movement composed of neo-Malthusians and family planners to lower fertility in high-fertility societies by promoting the use of modern contraception. Again, policy makers turned to demographers to learn about the determinants of fertility. At the end of the twentieth century, fertility appears to have a lower place on the agenda of demographers. In some Western countries where national population growth rates are below replacement, there is increasing concern about fertility that is considered to be too low; groups that have fertility considered to be too high are largely adolescents and, in some countries, immigrants. Many Southern countries and some Western policy makers, however, remain concerned about levels of fertility, particularly in poor countries where fertility declines are just beginning. I begin by describing fertility determinants in pretransition societies (those characterized by an absence of deliberate attempts to limit family size) and then describe fertility transitions in Europe and the Third World.

DEFINITIONS

Fertility refers to the actual childbearing performance of individuals, couples, groups, or populations. Fertility transitions are best defined not in terms of a change in level (from high to low) but rather in terms of reproductive practices. Pretransition societies are those in which *married* couples do not effectively stop childbearing once

they reach the number of children they desire; correspondingly, the onset of a fertility transition is marked by the adoption of practices to stop childbearing before the woman's physiological capacity to reproduce is exhausted. More precisely, in pretransition societies behavior is not parity-specific; that is, it does not depend on the number of children the couple has already borne (Henry 1961). At some point in time, presumably all societies were pretransition; currently, there are few societies where fertility remains high (most are in sub-Saharan Africa) and even fewer where there are no signs that a fertility transition may have begun (Bongaarts and Watkins 1996).

FERTILITY DETERMINANTS IN PRETRANSITION SOCIETIES

Despite the absence of parity-specific control in pretransition societies, fertility varies across individuals, couples, and groups: Observed total fertility rates for a population are as high as twelve (married Hutterites in the 1920s) and as low as four to five (the Kung hunters and gatherers in the 1970s and rural Chinese farmers around 1930). Important advances in understanding the sources of this variation followed a distinction between the "proximate" determinants of fertility and the "true" determinants of fertility, a distinction that owed much to an earlier systematic classification of influences on fertility made by Kingsley Davis and Judith Blake (1956). The proximate determinants are *direct* determinants of fertility, the combination of biological and behavioral channels through which the "true" determinants—the social, economic, psychological, and environmental factors—affect fertility (Bongaarts 1978).

In pretransition societies, the two most important of the proximate determinants of the overall level of fertility are marriage patterns and breast-feeding patterns. The other proximate determinants—fecundability (the monthly probability of conceiving among women who menstruate regularly but do not practice contraception), the use of contraception, the risk of spontaneous intrauterine mortality, and induced abortion—play a lesser role in accounting for variations in fertility (Bongaarts

and Menken 1983). Marriage patterns are important, since in most societies childbearing occurs within marriage. Thus, the proportion of women who are currently married at the ages at which reproduction is physiologically possible has a major influence on fertility. There is a striking difference between the marriage patterns of Western Europe and countries of European settlement, such as the United States, Australia, and New Zealand, and societies in other parts of the world, particularly Asia and Africa. In the former, marriage has been relatively late at least since the fourteenth century, and substantial proportions of women remain lifelong spinsters. In Africa and Asia, the typical pattern has been that marriage for women is early (usually as soon as a woman is able to bear a child she marries), and virtually all women marry. Obviously, the reproductive span in Western countries has been on average shorter than that in Asian and African societies. The peculiar Western European marriage pattern is associated with a nuclear family household ideal. In Western countries, couples typically set up their own households after marriage; in Asia and Africa, in contrast, the ideal has usually been that sons bring wives into their parents' household, while daughters go to live in the parental households of their husbands (Laslett 1972). Since the ability to support one's own household is associated with age, it is not surprising that the age of marriage has been later in Western countries than elsewhere.

Within marriage, the major determinants of variations in fertility across groups in populations in which little or no contraception is practiced is breast-feeding, since nursing inhibits the return of ovulation. In addition, in some societies a period of abstinence from sexual intercourse is prescribed by local custom, often because it is believed that intercourse during this period will harm the mother or the child. Post-partum abstinence taboos have been found to vary from a few weeks to as much as a year; if these are followed, they can account for substantial variations in marital fertility. Little research has been done on the determinants of post-partum abstinence. They are clearly cultural, in the sense that they characterize societies of interacting individuals, but they may also be linked to other factors.

Although differences in marriage patterns and breast-feeding patterns account for much of the observed differences in fertility across groups in pretransition societies, it is unlikely that their variation reflects variation in desired family size, for either the individual or the couple. Whether marriage was early or late, or whether breast-feeding was short or long, seems largely the outcome of other social concerns (Kreager 1982). It is probable that these patterns were determined by community norms or social structures, rather than individual preferences: Communities seem to have differed more in these respects than did individuals within these communities (Watkins 1991).

FERTILITY TRANSITIONS

It is conventional to distinguish between fertility transitions in Western societies and those in other parts of the world. There are evident differences not only in geography but also in timing, with Western fertility transitions occurring earlier. In addition, fertility transitions in non-Western countries were promoted by an international population movement that played a major role in making modern contraception accessible in the Third World, whereas fertility declines in the West occurred without such efforts by governments or social movements. There have recently been a number of reviews of the determinants of fertility change; taken together, they show little consensus on similarities or differences in other determinants of fertility change (Hirschman 1994; Kirk 1996; Mason 1997), although most include mortality decline, the perception that large numbers of children are increasingly unaffordable, the attitudes and moralities concerning family life, and the costs of birth control (Casterline in press).

The earliest sustained fertility transitions at the national level occurred in France, where fertility decline began around the time of the French Revolution, and in the United States, where fertility control was evident in a number of New England communities by the end of the first quarter of the nineteenth century and widespread among women who married on the eve of the Civil War (David and Sanderson 1987). Other fertility transitions spread throughout Europe between 1870

and 1930 (Coale and Watkins 1986), with similar timing in Australia. These changes began in the core countries of northwest Europe and occurred later in the periphery of Central Europe and the Mediterranean countries. In contrast, most analysts agree that there was little evidence of efforts to deliberately stop childbearing or a decline in marital fertility anywhere in the developing world before 1960, except for Argentina, Uruguay, and Chile (largely populated by settlers from Western Europe).

The observation was nearly universal that industrialization was causing this decline, with those who were in more industrial settings (i.e., cities) having lower fertility than rural populations. Industrialization was thought to produce a rising standard of living, an increasingly complex division of labor, an open class system, a competitive social milieu, and individualism. These changes, most thought, induced a desire for smaller families (Hodgson and Watkins 1997). What most concerned observers of fertility changes was the differential fertility by class and ethnicity; the latter was particularly important in late nineteenth- and early twentieth-century America, a period of massive immigration from Eastern, Central, and Southern Europe (Watkins 1994). Although some early observers saw the declining fertility of the wealthy and the urban as fostering prosperity, by the last quarter of the nineteenth century most emphasized the consequences of differential fertility for the composition of the population. For example, U.S. President Theodore Roosevelt decried the "race suicide" of upper-class women who were avoiding marriage or having small families: "The greatest problem of civilization is to be found in the fact that the well-to-do families tend to die out; there results, in consequence, a tendency to the elimination instead of the survival of the fittest" (1907, p. 550). At the time, eugenicists worried that the "prudent and thoughtful" would be the ones to practice birth control, while knowledge of birth control was unlikely to affect the fertility of the "reckless" lower classes (Hodgson and Watkins 1997, pp. 473–474). Women, according to most commentators, were the instigators of fertility decline, and many linked their turn to

abortion and contraception to their reassessment of the value of motherhood. The problem was seen to be particularly acute among elite women. When initial attempts to persuade elite women to bear more children failed, attention was turned to persuading others to have fewer, and access to contraception was gradually liberalized. In Western countries the concerns of demographers and policy makers with domestic population composition faded with the widespread low fertility of the 1930s, and the eugenics movement was dealt a serious blow by its association with Nazi Germany in the 1930s and 1940s.

In the 1950s, Western attention turned to population growth rates in developing countries, many of which had until recently been colonies of Western countries. Mortality was declining, but until the 1960s, fertility in most developing countries was relatively high and apparently stable, aside from brief fluctuations associated with wars, famines, and other upheavals. This stimulated the formation of an international population movement, an alliance of neo-Malthusians, who emphasized the problems consequent on rapid population growth, and birth-controllers, who emphasized the importance of providing women with the means to control their reproduction. Subsequently, the previous pattern of stable reproduction came to an abrupt halt with the onset of rapid fertility transitions in a majority of countries. Between the early 1960s (1960–1965) and the late 1980s (1985–1990), the total fertility rate of the developing world as a whole declined by an estimated 36 percent—from 6.0 to 3.8 births per woman (United Nations 1995). Declines have been most rapid in Asia and Latin America (–42 and –43 percent respectively), less rapid but still substantial in the Middle East and North Africa (–25 percent), and almost nonexistent in sub-Saharan Africa. These averages conceal wide variations among countries in the timing of the onset of transitions and their subsequent pace. At one end of the spectrum of experience are a few countries (e.g., Hong Kong and Singapore) where a fertility transition started around 1960, followed by swift further reductions to the replacement level. At the other extreme are other countries, mostly in sub-Saharan Africa, that have not yet entered the transition.

These remarkable trends in reproductive behavior have been extensively documented in censuses and surveys, and the empirical record is not in dispute (Bongaarts and Watkins 1996). The causes of these trends, however, are the subject of often-contentious debate. Conventional theories of fertility decline, from the modernization versions dominant in the 1950s and 1960s to neoclassical economic and rational actor versions of recent decades, assume the fundamental importance of socioeconomic change, much as did nineteenth-century theories about industrialization and fertility decline. Socioeconomic development results in shifts in the costs and benefits of children and hence in the demand for them. As desired family size declines, fertility reduction soon follows with the widespread adoption of birth control, especially when governments make contraceptive services available through family-planning programs. While this broad explanation is widely accepted, analysts vigorously debate the precise variables and processes involved in this chain of causation. These disagreements have been stimulating and fruitful, producing a wide variety of increasingly refined and detailed views that have guided empirical investigations.

Although rises in female marriage age have contributed to the decline in fertility, this decline is largely due to the adoption of new behavior in marriage: More precisely, it is due to the adoption of parity-specific control using modern contraceptives. In Europe, fertility declines were accomplished initially by the use of abortion, withdrawal, and/or abstinence by married couples to stop childbearing, and only later by the use of modern contraceptives to space children as well as to limit their number. In the Third World, fertility decline was closely associated with the use of modern contraceptives.

Why did fertility decline? Why did couples start to deliberately limit the number of children they bore? What are the “true” determinants of fertility? While a comprehensive theory of fertility would account for both the shift from high to low fertility and variations in fertility at each stage of the fertility transition, most of the attempts to understand the social, economic, and cultural influences on fertility have focused on attempts to

understand the onset of the fertility transition. Almost anything that distinguishes traditional from modern societies has been considered relevant to the explanation of the fertility decline (Cleland 1985; see also reviews of fertility determinants by Hirschman 1994; Kirk 1996; Mason 1997).

The most influential theories that have guided demographic research into the determinants of fertility over the last four decades have been those that assume the fundamental importance of economic factor. Predominant in the 1960s and 1970s was the theory of the demographic transition (classic statements are Davis 1963; Freedman 1961–1962; Notestein 1953; Thompson 1929). Demographic transition theory is based on the assumption that the means of fertility control used in the early stages of the Western fertility transition were always known. Hence, fertility declines can be attributed to changes in the motivations of individuals or couples, changes thought to be related to “modernization,” especially increasing literacy, urbanization, the shift to paid, nonagricultural labor, and declines in infant and child mortality. Neoclassical economic theory, and in particular the New Home Economics associated with Gary Becker (1991), provides a translation from macro-level structural changes to the micro-level calculus of parents (for a more thorough review, see Pollak and Watkins 1993).

Empirical examinations driven by these theories gave them some support. It is now generally acknowledged that economic factors—often described in terms of the “costs” and “benefits” of children—are important determinants of fertility decline. It is, however, also acknowledged that economic factors do not provide a complete explanation. Currently, interesting research focuses on several additions to classical demographic transition theory and to neoclassical economic approaches.

Much attention has been devoted to evaluating the role of family-planning programs in the fertility decline in the Third World, where it seems that the methods used initially in the West were either not known or considered too costly in personal terms (Knodel et al. 1984). In the 1950s, it became evident that population growth rates in

Third World countries were high because of declining mortality but stable fertility. This was believed to have substantial consequences, ranging from changes in the composition of the world's population (an increasing proportion of which was projected to come from Third World countries) to effects on Third World countries themselves, including famine, political instability, and the constraints that population growth was expected to place on the ability of these countries to develop economically and to modernize more generally. This led to concerted efforts by international agencies, Western governments, and Third World countries themselves to reduce fertility by making modern contraception desirable and accessible in the Third World (Hodgson and Watkins 1997). There has been considerable debate about the effectiveness of these efforts, with some according them little importance (e.g., Pritchett 1994) and others giving them more weight (e.g., Bongaarts 1997). There was a significant impact on fertility levels in the late 1980s, but whether this program effect operates primarily by affecting the timing of the onset of the transition or by the pace of fertility decline cannot be determined with available data (Bongaarts and Watkins 1996).

There has also been considerable interest in institutional determinants of fertility change. These are typically social institutions (e.g., systems of landholding) but occasionally are emergent properties of the collective behavior of individuals (Smith 1989). Therefore, in understanding the frequent association between education and fertility decline, for example, it may be more relevant to ask what proportion of the community has attended school than to ask whether a particular individual has. Similarly, both class relations and gender relations are aspects of the community rather than the individual, and both are likely to be associated with fertility change.

Another perspective emphasizes ideational change. Ideational changes are sometimes broadly, sometimes more narrowly, defined. Among the former is a shift in ideational systems toward individualism, which offered justification for challenging traditional authorities and practices, including those that concerned reproduction

(Lesthaeghe 1983). In a similar vein, John Caldwell argues that much of the fertility decline in developing countries can be explained in terms of the introduction of images of the egalitarian Western family into the more patriarchal family systems of the developing world. It was not so much that the relative balance of costs and benefits of children changed, but that the moral economy shifted: It came to be seen as inappropriate to derive economic benefit from one's children (Caldwell 1982). Among the narrower ideational changes are re-evaluations of the acceptability of controlling births within marriage (Watkins in press) and changes in the acceptability of modern family planning (Cleland and Wilson 1987). Explanations for fertility declines in terms of ideational change are often linked to a focus on diffusion as an important mechanism of change, where diffusion can be postulated as stemming from a central source such as the media (e.g., Westoff and Rodríguez 1995) and/or from person to person in global, national, and/or local networks of social interaction (Bongaarts and Watkins 1996). It is likely that personal networks influence fertility through social learning and the exercise of social influence (Montgomery and Casterline 1996). Intensive efforts to examine local networks of social interaction and their relation to fertility are currently underway in several countries (Agyeman et al 1995; Behrman et al. 1999; Entwistle et al. 1997).

What will happen to fertility in the future? In Western countries, fertility is close to replacement level, although in some (e.g., Italy, Spain) it is well below. There is less variation in fertility than there was either in pretransition societies or during the transition (Watkins 1991). Most couples desire only a few children (rarely more than two), and most use effective means to achieve their desires. Accordingly, analysts have concentrated on the determinants of fertility in specific subgroups of the population, such as teenagers or ethnic or racial minorities. In doing so, they have drawn on much the same combination of socioeconomic characteristics, institutional factors, and ideational change. For example, the higher fertility of teenagers is usually explained in terms both of their differing socioeconomic characteristics and

of their lesser access to effective contraception, as well as to an unwillingness to use it.

Few expect fertility to rise, and there seems to be a consensus that fertility will either remain around replacement level or decline further (see, e.g., Lesthaeghe and Willems 1999). The predictions of even lower fertility in the West are based on a combination of proximate and true determinants. Since the 1960s, marriage age has risen sharply in most developed countries, as have divorce rates; if these trends continue—and as long as most children continue to be born within marriage—lower fertility will follow. There has also been some increase in the proportion who are unable to bear children, in part because some couples postpone marriage and childbearing so long that they are unable to have the children they want, and in part because it is likely that involuntary sterility associated with sexually transmitted diseases may have increased at least slightly (Menken 1985). But the major predictions of lower fertility in the future emphasize the characteristics of modern societies that make childbearing less rewarding compared to the other opportunities available to women and the continued inroads into the family that individualism is making (Keyfitz 1986; Preston 1986; Schoen et al. 1997).

Similarly, fertility is likely to begin to decline in Third World countries that have not yet begun a fertility transition and to continue to decline in those where this process has begun. The course of fertility decline in countries where fertility is now low suggests that once the process of the fertility transition has started, fertility levels decline monotonically until very low levels are reached. Moreover, there is no turning back: The new reproductive behavior is not abandoned. Thus, it is likely that past differences in fertility both within and across countries will diminish.

FIELD THEORY

It was perhaps only the youthful optimism of a new science that allowed Kurt Lewin and his colleagues to believe that they had within their grasp the key elements of a "field theory of the social sciences." Social psychology made great strides in 1930s and 1940s. Lewin and Lippitt (1938) seemed to have demonstrated in the laboratory the inherent superiority of democracy over autocracy. Lewin (1948) provided a theoretical framework for resolving social conflicts, and after his death his colleagues quickly shaped his legacy into a social scientific theory (Lewin, 1951). How could they resist? The physicists had just announced developments that shook the foundations of Newtonian physics. It was expected that Einstein, safely ensconced in the Institute for Advanced Studies, would any day announce the "unified field theory" that would once again make the physical world an orderly place. Could they ask less of the social sciences?

By 1968 one of Lewin's former students, Morton Deutsch, would declare field theory—and all other grand theories of social psychology—moribund. A few years later, Nicholas Mullins (1973) would eulogize the entire field of small group research as "the light that failed," a victim of the untimely death of its only real intellectual leader, Kurt Lewin. Mullins's borrowing of the Kipling title is compelling not only because it suggests that small group research promised much and failed to deliver but also because it suggests that field theory extended its reach beyond its grasp. In recent years there has been a revival of interest in field theory, though, for better or worse, much of the youthful optimism has faded.

LEWIN AND THE ORIGINS OF FIELD THEORY

Lewin's (1935) *A Dynamic Theory of Personality* called for a shift in psychology from the Aristotelian to the Galilean mode of thought. Epitomized by the now-classic formulation "behavior is a function of personality and environment," or $B=f(PE)$, the new perspective placed social psychology squarely at the intersection of psychology and sociology.

It required abandoning the hope that social behavior could be explained by reference to personality variables and seeking explanations in the dynamic relationships among actors and situations. In this book, Lewin defined the building blocks of the field theory that was to come: force (a vector directed at a point of application), valence (the push or pull of the force), and conflict (the opposition of roughly equivalent forces). At this point, he clearly had in mind a metric space of social life, the concepts of vector and direction having limited meaning in topological (or nonmetric) space.

The young field of topological mathematics soon freed Lewin from the necessity of defining a metric space of social life. In *Principles of Topological Psychology*, he defined the new nonmetric space: "By this term is meant that we are dealing with mathematical relationships which can be characterized without measurement. No distances are defined in topological space" (Lewin 1936, p. 53). The concept was a failure; his presentation to the mathematicians at MIT made it clear that he had overreached. He had ventured into the murky realm of topology when, in fact, he always intended to return to metric space. Two additional difficulties also appear in this volume. First, Lewin insisted that the new topological psychology deal with the entire life-space of the individual. Much as Simmel (1917) conceived of the individual as lying at the intersection of various "social circles," Lewin saw the individual life-space as made up of the totality of available social relations. For practical purposes, this made the specification of a single life-space almost impossibly complex. If one then tried to understand even a small group of actors by merging life-spaces, the problem became overwhelming. Second, Lewin often seemed to think of life-space in terms of physical space. Thus, locomotion almost literally meant moving from one physical location to another. This confusion of metaphor with reality prevented Lewin from proposing a consistent conceptual space of the sort suggested by Borgatta (1963), Bales (1985), and others.

A collection of Lewin's (1948) more applied American papers, *Resolving Social Conflicts*, appeared the year he died. Lewin translated concrete conflicts into abstract life-space "capsules." They were

designed to illustrate the concept of "range of free movement" as "a topological region encircled by other regions that are inaccessible" (Lewin 1948, p. 5). The researchers who followed him have since used his graphic depiction of life-space as capsules only rarely. In the same volume, Lewin defined two useful characteristics of the boundaries between sectors of the life-space: sharpness (the clarity of boundaries) and rigidity (the ease with which boundaries may shift). *Field Theory in the Social Sciences*, a collection of Lewin's more theoretical writings, appeared in 1951. In these papers, Lewin introduced the most crucial concepts. Conflict is defined as "the overlapping of two force fields," force as "the tendency toward locomotion," and position as "a spatial relation of regions" (1951, pp. 39-40). The example of a conflict between husband and wife illustrates Lewin's concept of "subjective" and "objective" social fields. The subjectively defined life-spaces of two people differ, and so a single interpersonal act may have very different meanings for the two actors. Repeated reality testing is necessary to bring the individuals to a consensually defined "objective" social life-space.

Lewin never really succeeded in developing a predictive theory of group dynamics: "The clarification of the problems of past and future has been much delayed by the fact that the psychological field which exists at a given time contains the views of that individual about his future and past" (Lewin 1951, p. 53). The field is still struggling with this problem, lacking an adequate theory of even state-to-state transition.

In the years following Lewin's death, the focus shifted from the theoretical to the applied. Much of the work done at the University of Michigan's Research Center for Group Dynamics and at the National Training Laboratory's facilities in Bethel, Maine, was only very loosely tied to the concepts of field theory. While Lewin is often credited with founding the field of organizational development (Weisbord 1987), his careful work on the nature of the social field is often ignored in favor of deceptively simple quotes such as "There's nothing so practical as a good theory." While Lewin believed that he could not be sure that he had fully understood a social situation unless he

could change it, he never assumed that the ability to bring about change implied understanding. Only in the past several years has attention returned to the difficult legacy of an incomplete field theory.

THE CURRENT STATE OF FIELD THEORY

The Society for the Advancement of Field Theory was founded at a Temple University conference in 1984. Stivers and Wheelan (1986) have since published the proceedings of the conference as *The Lewin Legacy*. Later, papers from the two subsequent biennial conferences have been published as *Advances in Field Theory* (Wheelan et al. 1990).

The Lewin Legacy includes historical essays and applications of field theory to therapy, education, organizational development, and community psychology. A brief set of papers at the end calls for a revitalization of Lewinian thought, particularly within the tradition of action research. It is clear, however, that the authors are responding more to Lewin's research philosophy than to the theoretical constructs of his field theory.

Advances in Field Theory continues to focus on application, but with more explicit reference to theory. Gold's (1990) paper titled "Two Field Theories" addresses the issue of whether field theory is a "real theory" or simply an "approach." It distinguishes between the theory as described above and the approach—or "metatheory"—that has served as the guide for the generations of scholars that followed Lewin. Pointing out that much of social psychology has drifted away from the consideration of social life-space toward the understanding of internal cognitive processes, the author calls for a revitalization of the Galilean mode of thought. The remainder of the volume is once again directed toward the solution of practical problems. The authors deal with families, psychiatry, human development, education, conflict, organizations, and cross-cultural concerns. Virtually all of this work seems to draw on Lewin's "approach," or "metatheory," rather than his "specific field theory."

All of this is not to deny the tremendous impact that Lewin and his students have had on

both academia and the resolution of social problems. What impressed his students most was Lewin's commitment to democracy and fairness. This commitment started in the research community, where he unselfishly gave of his time and intellect to help his students and colleagues expand their understanding of society. It extended to society at large. He and his students worked on behalf of the war effort during World War II and actively combated prejudice at home. As Weisbord (1987) has pointed out, the field of organizational development (OD) probably owes its existence and current shape to Lewin and his students. Organizational development is as much an ideology as a theory of change; its democratic value orientation owes much to the ideas of Kurt Lewin. Citing Marrow's (1969) excellent biography of Lewin, Weisbord draws parallels between the lives of Frederick Taylor and Kurt Lewin. Lewin's "humanization of the Taylor system" can be thought of as a blueprint for achieving the central goal of organizational development: increasing organizational effectiveness through the application of social science knowledge. In the seminal work in the field, *The Human Side of Enterprise*, Douglas McGregor (1960) blends the social science of Kurt Lewin with the humanistic psychology of Abraham Maslow (1954). The origins of participatory management, teambuilding, feedback, process consultation, and third-party intervention lie in both the theoretical and empirical work of Lewin and his colleagues: Ronald and Gordon Lippett, Ralph White, Kurt Back, Kenneth Beene, Dorwin Carwright, Alvin Zander, and others.

REKINDLING THE LIGHT: ATTEMPTS AT SYNTHESIS

The group process school, with its origins in Parsonian functionalism, has recently moved toward integration with the group dynamics school. Bales (1985), tracing the origins of field theory to Dewey's (1896) "reflex arc," suggested that his three-dimensional conceptual space of social interaction made possible a new field theory. He argued for the universality of the dimensions but stopped short of offering the integration: "The new field theory of social psychology is the needed

framework, I believe, for the long-desired integration of social psychology. But to explore that thesis is a major undertaking, and here we must be content with a tentative case for the major dimensions of the framework" (Bales 1985, p. 17). Bales's colleagues (Hare et al. 1996) have since announced the existence of this "new field theory," but it has yet to be published in full and the academic community seems not to be eager to accept it as a major theoretical advance. Whether or not opinion changes as a result of the forthcoming publication of Bales's *Social Interaction Systems: Theory and Measurement* (1999) remains to be seen, but Bales's past efforts have been seen as much stronger in measurement than in theory. To the extent that Bales's new field theory has succeeded, it has been an operationalization of Lewin's concept of subjective life-space. His current theories of polarization are organized around positive and negative images in the minds of individual participants, not around consensual social reality.

Polley (1989) validated an updated set of dimensions and offered a series of explicit operational definitions for the basic concepts of Lewinian field theory. Figure 1 presents a "field diagram" that illustrates some of the basic principles. Two dimensions of interpersonal behavior (friendly-unfriendly and conventional-unconventional) define the plane of the diagram, and the third (dominant-submissive) is represented by circle size. Larger circles represent more dominant members, while smaller circles represent less dominant members. Members close together in the plane of the field diagram are drawn closer by vectors of positive valence, while distinct subgroups repel one another by vectors of negative valence. Members positioned at right angles to the central conflict between two subgroups tend to serve as mediators if they lie toward the "friendly" side of the space and as scapegoats if they lie toward the "unfriendly" side of the space. Both have the potential to draw opposing subgroups together, reducing the severity of the conflict. These analyses are based on "group average" perceptions and so are an attempt to operationalize Lewin's "objective" or consensual life-space. In 1994, Polley and Eid attempted an integration of the three major fields of

small group theory: Lewin's group dynamics, Bales's group process, and Moreno's sociometry. But again, while the methodology and theory are in use at a number of research centers, there has been no consensus among the academic community that either the synthesis or the operationalization of field theory have succeeded.

Two additional lines of research have drawn heavily on field theory concepts. Both developed observation systems based for the measurement of temporal patterns in groups. McGrath's (1991) research group developed a theory known as time, interaction, and performance (TIP) and an observation system known as TEMPO. Wheelan's (1999) research group is seeking to develop a model of group development based on a synthesis of Lewinian group dynamics and Bion's psychodynamic theory of groups. (For more information on these two lines of research, see Observation Systems.)

THE FUTURE OF FIELD THEORY

It now appears that Deutsch's announcement of the death of field theory was essentially correct, though there are a few signs of life, as indicated above. However, neither *Psychological Abstracts* nor *Sociological Abstracts* have listed "field theory" as a research topic in recent years. A search of the years 1985–1999 using *PsyINFO* revealed 177 books and articles under the key phrase "field theory." Of those, 65 dealt not with social field theory but with unrelated concepts that simply happened to share the same name. Of the remaining 112 citations, 31 were historical in nature and 63 used field theory as what Gold (1990) refers to as a "general approach" rather than as a specific theory capable of generating testable hypotheses. The remaining 18 articles use field theory as a specific theory. The applications of specific field theory are varied; the articles summarized below are not inclusive but should serve to give the flavor of the impact of Lewinian field theory.

Houston and associates (1988) and Dube and associates (1991) have applied field theoretic concepts to the study of customer evaluation of quality of service. Their model integrates concepts from marketing with those from Lewinian field theory

Figure 1. A Three-Dimensional Field Diagram, Showing Two Subgroups, a Mediator, and a Scapegoat.

to develop a deeper understanding of customer satisfaction. Granberg and Holberg (1986) compared behavioristic theory with field theory in attempting to explain voting behavior in Sweden and the United States. They conclude that field theory provides greater explanatory power than behavioristic psychology. In a related series of studies, Dillbeck (1990) and Assimakis and Dillbeck (1995) have employed field theory concepts to explain the effect of a Transcendental Meditation program on social change and perceptions of

quality of life. Viser (1994) pitted field theory against Lazarsfeld's sociological model of voting behavior and contends that field theory provides a better explanation of voter choice. Greenberg (1988) employed field theory concepts of competing force fields to develop a model of employee theft behavior. Diederich (1997) used field theory as the basis for her multiattribute dynamic decision model (MADD), which she uses to predict decision making under time constraints. In the field of communications, Hample (1997) and

Greene (1997) have based theories of “message production” on the Lewinian concepts of life-space and planes of reality and unreality. In the realm of therapy, Barber (1996) has employed field theory to the understanding of the educational community as an agent of change. Dube and Schmitt (1996) tested field theory-based predictions of perceived time judgments. They demonstrated that “unfilled intervals” were perceived to be longer if they occurred during a social process rather than before or after the process. Smith and Smith (1996) identified the concept of the social field as necessary and sufficient for the explanation of social behavior. Finally, Diamond (1992) contrasted field theory and rational choice as explanations for social policy choices and concluded that field theory explains many effects that are dismissed as “irrational” by the rational choice model. This brief tour of empirical research is not intended as comprehensive, but it does suggest that field theory as a specific theory continues to be taken seriously in a variety of disciplines.

There may never be a widely accepted “grand theory” of social psychology. Certainly, the attempts that we have seen so far have not received widespread support from sociologists and psychologists. Still, Kurt Lewin’s legacy is alive and well—as a philosophical orientation in a number of applied fields, such as organizational development, social work, conflict management, and therapy; as a general orientation for researchers in sociology and psychology; and even as a specific theory that continues to generate testable hypotheses. His all-too-brief career has served, and will likely continue to serve, as a guiding light to generations of researchers, practitioners, and social activists.

RICHARD B. KETTNER-POLLEY

FILIAL RESPONSIBILITY

The term *filial responsibility* denotes the "responsibility for parents exercised by children. The term emphasizes duty rather than satisfaction and is usually connected with protection, care, or financial support" (Schorr, 1980, p. 1). Although it is popularly believed that the obligation of children to care for their parents has ancient origins based on widely held moral beliefs, both historical and sociological evidence suggests that neither element of this belief is true (Finch 1989; Schorr 1980).

LEGAL MANDATES FOR FINANCIAL SUPPORT

One source of the persistent belief in both the historical existence of filial responsibility and its moral derivation stems from an equally persistent belief that there was a time in the past when "the family" had a stronger sense of responsibility for looking after its aging members (Finch 1989). However, a literature on the history of families and demographic trends has emerged that consistently refutes this belief (Laslett 1972). Central to this literature is an understanding of the effects of the demographic transitions, medical advancements, and changes in social and health practices that have resulted in a significant increase in the numbers of persons living into old age. Together these factors have resulted in dramatic changes in the population structure of modern societies wherein the aging segments account for a significantly higher proportion of the population than ever before (Himes 1994). Put simply, until recently only an extremely small segment of the population survived into an extended and dependent old age (Anderson 1980).

Furthermore, due to the nature of the preindustrial economy, those persons who did

survive into old age were not dependent upon the goodwill of or a sense of obligation on the part of their children to assure their financial support. In preindustrial economies both land and businesses, which served as the family's source of sustenance, were owned by the oldest generation and passed down to the younger generation only at death. Hence, it was not the oldest generation that was dependent upon the younger generation, but rather the younger generation that was dependent on the older generation for housing and income. What care may have been provided to parents was, therefore, not necessarily based on a sense of moral obligation but instead stemmed from economic necessity (Haber and Gratton 1994; Schorr 1980).

As long as this economic basis for support existed, there was no need for filial responsibility laws (Schorr 1980). Only with the introduction of an industrial economy that provided a means for children to leave the parental home and obtain an income was there a need for the community to regulate filial responsibility. As Finch (1989, p. 84) notes:

Much of the historical evidence. . . suggests that under the harsh conditions of poverty which prevailed for most people in the early industrial period, family relationships necessarily were highly instrumental, with support being offered only if there was. . . hope of mutual benefit precisely because anything else would have been an unaffordable luxury (p. 84).

The shift to an industrial economy changed the financial base of the family and introduced the possibility of independent access to financial resources by children. This shift effectively emphasized the possibility of elders becoming destitute (Bulcroft et al. 1989).

LEGAL MANDATES FOR FINANCIAL SUPPORT

From their first inception in Roman and English codes, filial responsibility laws were enacted as a means to protect the public purse (and minimize the financial responsibility of the wealthy class) (Jacobson 1995). The aim of such laws was to enable public authorities to recover the costs of

maintaining paupers by making claims on those relatives assumed to be naturally bound by normal obligations of kinship to offer support. The poor laws established for the first time in history that the community would help an indigent parent only after the means of his child had been exhausted (Schorr 1980). These laws were not simply about poverty; they were laws intended to govern the lower class in order to keep down public expenditure. This motivation continues to underlie current laws and practices concerning the care of the elderly in both England and the United States. Despite the moral rhetoric in which filial responsibility laws are often couched, these laws emerged not as a result of moral values but in response to the threat of the growing financial burden that dependent elders posed to an industrial society (Jacobson 1995; Montgomery 1999).

Perhaps this absence of a moral basis for filial responsibility laws accounts for the inconsistency among states in the statement of filial responsibility. Filial responsibility laws, which in 1999 existed in some form in twenty-two states, are variously located in domestic statutes, poor laws, penal codes, and human resource laws. The nature of the fiscal responsibility incorporated into these statutes varies widely and tends to be quite vague. There are variations in the specificity as to which members of the family are responsible and the conditions under which they are responsible. Moreover, these laws are inconsistently enforced (Narayanan 1996), and many questions have been raised about their constitutionality and practicality (Jacobson 1995). For the most part, filial responsibility as incorporated in laws is limited to financial support; and these laws have generally gone unenforced. In fact, several court challenges to Medicaid laws have affirmed the illegality of states' requiring adult children to pay for care provided under Medicaid regulations (Jacobson 1995; Kline 1992).

ATTITUDES TOWARD FILIAL RESPONSIBILITY

Just as the discrepancy between the existence of filial responsibility laws and the lack of enforcement suggests an equivocal attitude toward children's responsibilities, results of attitude surveys about filial responsibility have been inconsistent.

While there is evidence that both parents and children acknowledge the existence of filial responsibility as a social expectation, individuals' reports of filial responsibility have been found to differ as a function of the type of support (Ganong et al. 1998), geographic distance from parents (Finley et al. 1988), income (Lee, Netzer and Coward 1994), and ethnicity (Lee et al. 1998; Stein et al. 1998). Findings regarding gender differences in attitudes toward responsibility have been mixed (Ganong et al. 1998).

Surveys generally yield respectable percentages of responses favoring filial responsibility as long as the question is limited to ethical and general terms (Schorr 1980). However, a majority of aged persons oppose filial responsibility when the question is reframed to introduce an individual's personal responsibility or to force a choice between the child and governmental/ community sources as the primary source of support (Schorr 1980). Recent studies have revealed a general trend in both Western and Asian cultures toward acceptance of the government or insurance programs as the source most appropriately responsible for financial support of the elderly (Sung 1990). The introduction of Social Security and Supplemental Security Income (SSI) in the United States and the introduction of national health care programs for the elderly in most other developed countries exemplify this trend. In a similar trend, adult children and their parents express a preference for independent living arrangements for the two generations even in Asian countries, where filial piety has long been a central value (Bleiszner and Hamon 1992).

Current practices of filial responsibility in the form of financial support correspond to these expressed preferences. For most families, the flow of financial support between generations is primarily from the oldest generation to the younger generation; and in most developed countries the two generations most commonly reside in separate housing units (Goldscheider and Lawton 1998). When parents and adult children do live together, it is usually due to the needs of the younger generation or the mutual benefits for both generations. The situation of a parent moving into the home of an adult child is relatively rare and is usually associated with a need for personal care rather than a need for housing.

FILIAL RESPONSIBILITY AS DIRECT PARENT CARE

The assumption by large numbers of adult children of responsibilities for the welfare and direct care of their parents has been the most significant change in family roles and filial responsibility practices in recent history. Although the motives that prompt adult children to care for their frail parents are not well understood, the predominance of adult children among informal caregivers is undisputed when all types and levels of assistance are considered. The prevalence of children as sources of emotional support, assistance with transportation and banking matters, and help with household chores and activities of daily living has been widely documented over the past two decades (e.g., Brody 1985; Merrill 1997).

Gender Differences. There is, however, a significant difference between sons and daughters in their caregiving activities and experience. Almost uniformly, studies have shown that greater numbers of daughters than sons assist their parents with a wider range of tasks. Daughters' predominance is especially strong with respect to direct personal assistance to their impaired parents (Merrill 1997). As a rule, daughters are more likely than sons to help elders with household chores, especially food preparation and laundry chores, as well as with personal care tasks that require hands-on care and daily assistance (Montgomery 1992). In contrast, sons tend to concentrate their efforts on tasks that are more circumscribed and sporadic, such as occasional shopping trips and annual yard and house maintenance activities.

The difference in the types of tasks that sons and daughters assume is related to the types of caregiving roles that each group tends to assume. Daughters are not only more likely to engage in caregiving tasks; they are also more likely to assume the role of primary caregiver (Merrill 1997). As such, they are more likely to provide "routine" care over longer periods of time (Matthews and Rosner 1988; Stoller 1990). Sons, in contrast, assume supportive roles that require commitments over shorter periods of time; they tend to be peripheral helpers within a caregiving network rather than the central actors (Matthews 1995).

There is evidence that gender differences in patterns of care persist across cultures and classes. However, these patterns are mediated by the level

of dependency of the elder and the size and gender composition of the family network (Coward and Dwyer 1990; Matthews 1995). Fewer gender differences are observed in patterns of care for parents with low levels of disability. Also, sons from family networks that do not include daughters tend to provide care in a style that is more similar to that of daughters.

Numerous explanations have been advanced to account for the observed divergence of caregiving behaviors between sons and daughters. Most of these explanations center on differences between male and female *roles* and gender differences in power within the family and within society in general (see Finley 1989). However, there is little evidence to support any of the hypothesized explanations, and none of them account for the persistence of divergent parent care activities.

Class Variations. Patterns of parent care have also been found to differ within the United States by class and income. Lower-class and working-class caregivers are more likely to live with the elder and to provide direct care. In contrast, higher economic status has been found to be associated with larger financial gifts and help with procuring services (Merrill 1997). This tendency for wealthy families to purchase care for the elderly has also been noted in a wide range of countries at different stages of development throughout the world (Kosberg 1992).

Cultural Variations. Cultural differences in informal care have been the focus of a number of studies. However, evidence of cultural differences in parent care within the United States remains equivocal. Greater levels of kin support among African Americans and Hispanics than among whites have been documented in a few studies (Lee et al. 1998; Tennstedt and Chang 1998); but other researchers have reported no differences in informal support (Belgrave and Bradsher 1994) or have documented greater use of informal supports by whites (Silverstein and Waite 1993). These inconsistencies in findings are likely due to differences in sampling designs and the confounding of ethnicity with socioeconomic status.

AFFECTION AND OBLIGATION

The persistence of parent care activities, despite the absence of legal or economic imperatives,

has often led researchers and policy makers to focus on affection as the primary motivation for these filial responsibility practices (Jarrett 1985). Numerous studies have noted the relationship between affection and the felt obligation to provide for parent care (Blieszner and Hamon 1992) as well as the importance of attitudes of obligation as correlates of contact with and assistance to parents (Walker et al. 1990). However, there is a growing literature that questions the importance of "affection" as the primary force underlying filial responsibility and/or the performance of caregiving tasks. Repeatedly, it has been shown that there can be emotional closeness between parent and child without contact or aid being given (Walker et al. 1989). At the same time, it has been shown that children who do not feel a great amount of affection for their parents are still able and willing to provide needed assistance (Lee and Sung 1997; Walker et al. 1990). Furthermore, there is growing evidence that caregiving is governed by a cluster of motives that encompass both affection and obligation (Belgrave and Bradsher 1994). For many children, affection may influence the way in which responsibilities are experienced, but these children frequently provide care simply because parents need care (Litwin 1994) or because they perceive few alternatives (Guberman et al. 1992).

PARENT CARE AS A CONSEQUENCE SOCIAL POLICY

It has been suggested that the lack of alternatives for parent care is due to existing social policy, which incorporates assumptions about filial responsibility although it does not necessarily explicitly legislate this responsibility (Finch 1989; Montgomery 1999). Specifically, as implemented and practiced, policies and programs concerned with services for the elderly in both developed and developing countries reflect the belief that there is a latent willingness, presumably based upon a residual sense of responsibility that can be activated. The decline in economic liability of children for their parents, which has resulted from the introduction of old-age pensions and health care programs for the elderly, has not been accompanied by a decline in expectations that children will care for and support their parents. In fact, the general trend in long-term care policy, which has emphasized the benefits of community-based care,

has been accompanied by a greater expectation of family care (Finch 1989; Hendricks and Hatch 1993). This expectation for relatives to provide direct care, however, remains more implicit in current long term-care policies than the fiscal liability of relatives, which was explicitly written into the original English poor laws and later adopted by many states (Doty 1995; Kapp 1995). For example, changes in Medicare coverage that are related to the prospective payment system have resulted in shorter hospital stays for elders, who are now being discharged with greater needs for assistance (Estes et al. 1993). The assumption appears to be that family members are, or should be, available to provide such care. Another example of the way in which current policy delegates the direct care responsibilities to family members is found in eligibility guidelines for (SSI), which reduce benefits for beneficiaries who live with other persons or who receive in-kind contributions from them (Hendricks and Hatch 1993). Built into this provision is the expectation that family members will provide the beneficiary with needed care at no cost. Although these regulations assure minimal financial commitment for states that otherwise would be responsible for nursing home care, they differ from fiscal responsibility laws in that the assignment of such responsibility is more diffuse (Doty 1995).

Most often, the delegation of responsibility for direct care to family is implicit rather than explicit. Expectations for direct care are often conveyed directly and indirectly to adult children by case-workers and physicians who serve as gatekeepers for community services (Doty 1995). Even when elders are eligible for assistance through formal providers, there is often pressure placed on family members to perform care (Guberman et al. 1992). When resources are scarce and must be rationed, the living arrangement of the elder as well as the gender and location of relatives become criteria for the distribution of services. The effect of these family characteristics on distribution of home- and community-based services is contingent upon the elder's level of functioning. For elders with low- to mid-level disability, priority for in home care services is given to those who live alone, with the expectation that family members will provide the necessary care for elders who live with them (Greene and Coleman 1995). In contrast, elders with high levels of disability who live with family members

are more likely to receive home care services than those who live alone because discharge planners and case managers view such supports as supplemental but not sufficient for an elder living alone to remain in the community (Doty 1995).

Regardless of the elder's level of functioning, when practitioners convey expectations for care to family members, they are often influenced by cultural and gender norms regarding the division of labor within households (Walker 1983). Cumulative results overwhelmingly show that long-term care, like housework and child care, has been institutionalized as women's work (Keith 1995). Practitioners, who serve as gatekeepers for community resources, tend to offer greater supports to male caregivers and convey lower expectations for sons to provide direct care services (Doty 1995). The impact of these practices has been observed by researchers, who report care-sharing patterns that are associated with gender and note that sons tend to receive more assistance from formal service providers than do daughters (Merrill 1997).

The clear line between long-term care policies and family care patterns provides evidence that care patterns are not simply a result of choices made by family members to adhere to some "inherent" moral order. Rather, these patterns of care emerge as a consequence of laws and practices that limit the alternatives available to family members (Neysmith 1993). Taken together, the evidence regarding filial responsibility suggests trends in laws and practice that reflect a decline in expectations for financial support of the elderly but a simultaneous growth in expectations for children, especially daughters, to support parents in more direct ways. There is also an indication that filial responsibility, as practiced in terms of both financial and direct care, stems largely from necessity and is created by social policies and practices that tend to invoke a questionable or mythical moral basis for such responsibility.

RHONDA J. V. MONTGOMERY

THE FRENCH SCHOOL OF SOCIOLOGY

The French School of Sociology was formed during the last decade of the nineteenth century and the first quarter of the twentieth century. The nucleus of the school was created by Emile Durkheim (1858–1917), to whose work was joined the crystalizing efforts in the new science that were performed by the team of *L'Année sociologique*, which was founded in 1898. In recent times, scholars have undertaken the examination of the effects of this major contribution to the field by studying the vicissitudes of Durkheim's legacy from the period between the two world wars and onward. We have also concentrated on clarifying the methods that permitted the exploitation and application of this legacy. In this regard, from 1979 to 1982, P. Besnard has fully informed us on the establishment and functioning of assistance strategies in the university and publishing fields. As important as the stakes of power may be, they are much less so than the thematic orientations that Durkheim and his disciples assigned to the science that, in 1838, Comte publicly baptized "sociology." Thus, in this entry, we will first apply ourselves to the task of recalling the path that was forged by the French School of Sociology; we will then examine schematically how it was charted and, finally, discuss the new directions in which sociological research is currently headed.

PRINCIPAL BRANCHES OF THE FRENCH SCHOOL OF SOCIOLOGY

Problems of periodization are particularly acute in the field of the history of ideas. They are associated with problems related to affiliations, to influences, to rupture and continuity in thought, and to collaboration. Of what, precisely, does "a group," "a school," or "a generation" in a given discipline consist? In his amply documented and unjustly maligned *Manuel de sociologie* (first published in 1950), A. Cuvillier resolved the question a priori: In the history of sociology there exists a "before" and "after" Comte, a series of national schools as well as an ensemble of disciplinary cross-currents. Today, one would more likely delineate a "before" and "after" Durkheim and to regard differently those who are situated upstream of him. At present, it is more precisely posited that "sociological

tradition,” formed in the nineteenth century, begins to have meaning with and after the appearance of four Durkheim masterpieces—*De la division du travail social* (1993), *Les règles de la méthode sociologique* (1995), *Le Suicide* (1997), *Les Formes élémentaires de la vie religieuse* (1912)—and that this tradition finds its origins in the works of Montesquieu and Rousseau, who are considered to be “the precursors of sociology.” As a rule, innovators tend to undervalue the works of those who preceded them. As the founder of scientific sociology, Durkheim does not escape this rule. He is even considered an obstacle according to a whole current of opinion, the perpetual ignorance of which has even given rise to the belief in a “blank” between Comte and Durkheim in the development of the discipline (cf. Yamashita 1995).

The concept of a scientifically based sociology was thus imposed. This concept affirms the specificity of social context; it pays close attention to the morphological substratum. While accenting collective tendencies, “forces which are just as real as cosmic forces,” it shows that “social life is essentially made up of representations.” From the introduction of the concept of anomie in the dissertation of 1893 to the analysis of the sacred and of beliefs that was developed in the 1912 work, the principal themes of a general sociology and those of specialized sociologies are freed from prejudices and preconceptions by a rigorously codified approach. Almost entirely, the domains in which they were implemented were “covered” with Durkheimians: judicial sociology by, notably, H. Lévy-Bruhl, economic sociology by F. Simiand (1873–1935), moral and political sociology by P. Fauçonnet and especially C. Bouglé (1870–1940), and religious sociology being particularly well by H. Hubert and M. Mauss (1872–1950). Again, the latter does not limit himself to this one sector, any more than M. Halbwachs (1877–1945) does to social morphology, or L. Lévy-Bruhl (1857–1939) to the writing of a masterpiece, *La morale et la science des mœurs*, published in 1903. Many other specialists—G. Bourgin, L. Gernet, M. Granet, C. Lalo, and so forth—produced works that, combined with those of their master, had a profound influence abroad. It was thus understood that every new development in the discipline had to rest upon the base that Durkheimism had furnished.

The fact that this vigorously formulated concept of sociology provoked the marginalization of

other trends is not at all surprising. Such was the case with the School of Social Reform, founded by F. Le Play (1806–1888), with the dissident school of E. Emolins, and with all the more or less obedient followers of Le Play whose allegiance inspired the family of monographs gathered together in *Les Ouvriers européens* (1855–1879) and *Les Ouvriers des deux mondes* (1857–1885): P. Bureau, E. Cheysson, P. Descamps, P. du Maroussem, P. de Rousiers, and the abbot of Tourville, all of whom were forgotten innovators, but all of whom were recently discovered by Kalaora and Savoya (1989). One will simply note that the collections of *La Réforme sociale* (from 1881 onward), those of *La Science sociale*, directed by Demolins after 1886, and those of *Le Musée social* (which became *Cahiers du Musée social* after 1945) comprise a documentary corpus parallel to that of *L'Année sociologique*. The same may be said for the *Revue internationale de sociologie*, published from 1893 onward by René Worms (1867–1926), who was the director of the International Sociological Library from 1896, the author of an important work, *Philosophie des sciences sociales* (3 vol., 1903–1907), and, most notably, the founder in 1894 of the International Institute of Sociology and in 1895 of the Society of Sociology of Paris.

One may, however, extend to sociology the relation that R. Aron extended for the field of history expanded into historiography: Every society produces the social science that it needs. Durkheim’s brand of sociology, strongly tinged with morality, was necessary to the Third Republic, which had been badly shaken by successive crises (Panama, boulangisme, the Dreyfus affair). Scholars have often stressed the concerns that are raised in Durkheim’s work about political thought, which is itself centered on social integration and cohesion; these concerns are evidenced by the course he taught in 1902–1903 entitled *L’Éducation Morale*. With regard to these concerns, what could be worth provoking objections raised in the name of old-fashioned individualism, and what interest could this “intermental” psychology present—that is, a collective conceptualized by G. Tarde (1843–1904), author of *Lois de l’imitation* (1890) and of *Logique sociale* (1894)—against which Durkheim polemicizes so effectively and so unjustly? A number of ruptures were deliberately intentional on Durkheim’s part; it was against psychology that he intended to build sociology, while

refusing moreover to consider history to be a science and simultaneously reducing economics to nothing more than an incarnation of metaphysics. He was so effective that, whereas in Germany sociology could be developed at the crossroads of history, economics, and psychology, in France all the conditions were right for it to be defined in opposition to these disciplines.

Perhaps this sociological tradition was ordered at a later date. One has only to refer to the *Eléments de sociologie* by C. Bougle and J. Raffault (first edition, 1926; second edition, 1930) to measure the reshaping that occurred between the two world wars. The range of this anthology is wide open, from Bonald to Jaurès, and passing by way of Constant, Tocqueville, and Guizot. Texts by Le Play and Tarde figure alongside those of Durkheim and some of the Durkheimians who, of course, carve out the lion's share. Spencer, Frazer, Jhering, and Mommsen are among the others who are cited, while excerpts of *Principes historiques du droit* by the Russian, P. Vinogradoff, are presented. Yet, more than because of the authors they assemble, these selected pieces interest us because of whom they exclude: Tönnies, Weber, Simmel, Michels, Mosca, Pareto, and Comte, who is only cited a single time! Shortly thereafter, Aron introduced *Sociologie allemande contemporaine* (1935) to French researchers, but for a long while he remained closed to the sociology of Pareto. Other perspectives finally emerged on the eve of World War II: a major contribution to this process was made by Stoetzel, who was the founder of the IFOP in 1938 and of the review *Sondages* in 1939 upon his return from the United States, where he became acquainted with Gallup's works; he would later devote his doctoral thesis to a *Esquisse d'une théorie des opinions* (1943). With Stoetzel was born in France an electoral psychosociology during the electoral ecology inaugurated in 1913 by A. Siegfried's *Tableau politique de la France de l'Quest*. Other important contributors to the broadening of perspectives were G. Bataille, R. Caillois, and M. Leiris, who were reunited within the College of Sociology between 1938 and 1939; as brief as the existence of this institution was, it was the framework for interdisciplinary contributions on myth, the sacred, the imaginary, and the problems of the age (democracy and totalitarianism) that are still striking today for their modernity.

FRENCH SOCIOLOGIES OF TODAY

Rupture or continuity? For M. Verret, co-author with H. Mendras of a collection of studies entitled *Les Champs de la sociologie française* Mendras and Verret (1988), there is no doubt about the answer: "French contemporary sociology cannot be understood without taking into consideration the great rupture between the two world wars; 1940 was a terrible critical test for French society. . . . There is nothing surprising about the fact that during this disaster, French sociology was also on the rocks. This includes not only Durkheimian sociology which constituted the latest face of it, but all the tradition from which it proceeded." The rereading of the fundamental chapters of *Traité de sociologie générale* (2 vols., 1958–1960), begun by G. Gurvitch (1897–1965) a dozen years after the end of World War II, leads one to nuance this assessment, which links devastation and reconstruction. A number of their authors began their careers before the rupture of 1940: This is the case of the taskmaster himself, whose *L'Idée de droit social* was published in 1932; of G. Friedman, who, beginning in 1936, inaugurated in France research in industrial sociology; and of J. Stoetzel. Others began during the Occupation: for example, A. Girard, working within the framework of the Alexis Carrel Foundation, which was transformed upon the Liberation into the National Institute of Demographic Studies. The documentation upon which they rely owes a great deal to Durkheim and his disciples.

May one say that these authors, senior and junior—F. Bourricaud, J. Cazeneuve, H. Mendras, and others—approach the study of social phenomena in a radically new spirit by breaking the connections established in the twentieth century between knowledge and power over society, by abandoning the research of the great consonance targeted by Durkheimism, and by stripping the discipline of its conquering aspects? It would seem not. A degree of optimism characterized the works of sociologists during the two and a half decades that followed the end of World War II. This is indicated by a flourishing of publications, all marked by a certain voluntarism, like the essays gathered together through the initiative of the French Society of Sociology under the title *Tendances et volontés de la société française* (1966). In a number of areas, people trusted this young science: One expected from its application a decisive improvement in the

government of mankind and in the management of things: various adjustments in the highly industrialized societies and in the developing countries such that they might contribute to the realization of the chosen model of growth.

However, many changes took place behind this permanence that had found its incarnation in a Durkheimian orthodoxy. G. Davy (1883–1973), whose *Eléments de sociologie* (1932) was republished in 1950, beginning in 1931, gathered together “sociologists of yesterday and sociologists of today” who were in the pursuit of the same goals. Those which are easiest to identify are of an institutional nature: the creation, under the auspices of the National Center of Scientific Research, of the Center for Sociological Studies, organizer of important “sociological weeks” that treated various issues such as *Industrialisme et technocratie* (1948), *Villes et campagnes* (1951), and *La Famille contemporaine* (1954); the constitution of numerous research groups (such as the Social Ethnology group run by P.-H. Chombart de Lauwe) and of associations like the one for the Development of the Sociology of Work; and the launching of new reviews, for example, the *Cahiers Internationaux de Sociologie*, founded in 1946 by G. Gurvitch, then, ten years later, the *Archives de Sociologie des Religions*, an organ of the sociology of religions group over which G. Le Bras presided, and two more in 1960. *La Revue Française de Sociologie* by J. Stoetzel, and *Sociologie du travail* by G. Friedman. On the academic front, sociology integrated with the study of philosophy became an entirely separate discipline with the creation of a B.A. in Sociology in 1958; this was the beginning of full academic recognition, which would lead to the institution of an *agrégation* in Social Science in 1976.

To these organizational transformations are added conflicts of paradigms. They are linked to the affirmation of, to use the expression of D. Lerner (1959), the “American concept,” that is, to the diffusion of a concept and a practice of sociology that had come from the far side of the Atlantic. Without oversimplifying, one can, in fact, say that during the period under consideration, the study of social facts was pursued on the one hand within the framework of functionalism, and on the other, on the bases of historical and dialectical materialism. It occurred on a basis of debate, called upon in the 1960s to take a polemical and ideological turn, when one wrongly and sterilely opposed the

descriptive and the explicative, the qualitative and the quantitative, empirical research and theoretical speculation, the exploitation of investigation and of social criticism.

Against the sociological scientism with which one assimilated the new American referent (whether it concern the sociometry of J.-L. Moreno or the functionalism of T. Parsons, the works of R. K. Merton or those of P. Lazarsfeld), the tenets of the dialectic hark back to C. W. Mills, who denounced the invasion of bureaucratic techniques into the social sciences (in *The Sociological Imagination*, 1957), and to P. Sorokin, vigorous critic of the compulsion to enumerate which then reigned, notably in electoral sociology. Imported into France, the German quarrel in the social sciences which, in the beginning of the 1960s, pitted T. Adorno, one of the principal representatives of the Frankfurt School, against K. Popper, the great epistemologist of Vienna, underlined the rift between the protagonists of both camps. Caught up in the turbulence of the late 1960s, sociology then entered a period of crisis (cf. R. Boudon 1971). The gulf widened between the functionalist sociologists, who adhered to systemic analysis, which could be denounced (and not without reason) for its schematism, its optimism, and its conservatism, and their adversaries who countered with a critical rhetoric that often sounded hollow, unsubstantiated as it was by precise data concerning controversial problems such as social change.

The major event of this period would remain, for French sociology, the coming of structuralism, with, in the background, the antagonistic conceptual orientations of G. Gurvitch, who was a proponent of the study of global societies, and of R. Aron, who shared the open perspective of Tocqueville. With the replacement of the Marxist explicative schema by the theorized structural analysis of C. Lévi-Strauss, a mutation of knowledge occurred: A paradigm centered on the idea of conflict was replaced by another that was formed of the stable elements of structure; new modes of conceptualization appeared and with them, new intellectual modes. The history of ideas shows how, in the succession of such modes, a model that has been dominant is shaken, and how it loses or even exhausts the merit that has been attributed to it. The reemergence of structuralism, which one must take care not to confuse with structural analysis, and whose range and limits have been

stressed, permitted the subsistence of four theoretical orientations that P. Ansart (1990) has clearly identified. These have certain affinities with the four schools distinguished by A. Touraine (1988): genetic structuralism, dynamic sociology, the functionalist and strategic approach, and, finally, methodological individualism.

These theoretical models reflect different visions of the world. Thus, P. Bourdieu's analyses lead to a highlighting of the division of society into classes; studies of the frequenting of museums or of the *grandes écoles* reveal practices that differ widely according to origin and to class. Associated with the study of determining structures, which is the goal of genetic structuralism, are the analyses of the author of *La Distinction* (1979) and those of the research team he conducts, who publish their works in *Actes de la recherche en sciences sociales*. The epistemology they display can be qualified as "poststructuralist" because of the introduction of the concept of *habitus* and because of the importance of the developments that support this conceptual proposition. Associated with the study of social dynamism are the names G. Balandier and A. Touraine. The former, beginning with African societies, conceptualized economic and social change; the latter, working from a base of the sociology of work, theorized collective action and social movement. Individual behavior and the problems posed by their aggregation occupies a central place in the work of R. Boudon, notably in *Effets pervers et ordre social* (1977), in *La Logique du social* (1979), and in *La Place du désordre* (1984).

One will note the cleavage that separates the latter two theoretical constructions (M. Crozier, R. Boudon) from the preceding ones. These latter constructions reveal the same structural social model of social determinations: The former prioritize the strategy of the participant and value the individual; nevertheless, their openness to social psychology remains distinct. Thus, M. Crozier reapproaches several interactionist models for treating interaction as a generalizable element, as though interaction revealed the totality of the regulations of a system of action. One is aware, on the other hand, of the close relationship between individualism and social interactionism.

It is not only the radical position that exists between the principles applied by genetic structuralism and those which prevail in methodological

individualism that must here be noted, the "epistemological distance" being perfectly measured by the debate on the inequality of chance. A nodal point of divergence appears, constituted by the conception of this *subject*. What is, in fact, the subject in generic structuralism and in a strategic conception of individual actions? Whether it be a question of the analysis of conflicts and of the representation of social relationships that it implies, a question of symbolic systems which contemporary sociologists are working to rethink, or finally a question of the place, the role and the function of the sociologist in the city, it clearly appears, as P. Ansart (1990) notes, that "the works of R. Boudin mark a critical position with regard to other sociological paradigms . . . , and, like every explicitly critical position, this position clearly marks the divergences, the points of disagreement which can be taken to be, on the epistemological level, insurmountable" (p. 285).

To conclude, these four theoretical orientations prolong and renew tendencies that were charted in the nineteenth century. In a certain manner, P. Bourdieu carries on the ambition of the first sociologists of the nineteenth century, which was picked up by Durkheim: that of constituting a science of social phenomena, with the certitude that social reality is indeed a reality and that it is ponderable by means of strictly codified rules. One can also say that dynamic sociology retains a vision of the world that has its origins in the works of Saint-Simon, Comte, Marx, and Spencer, insofar as these thinkers posed the problem of social change and proposed explicative models for it. One also recognizes without difficulty that in the background of methodological individualism may be distinguished the influence of Tocqueville, Weber, the Austrian marginalist school, and the debates of the Vienna Circle. As for the functionalist and strategic approach, one may consider it to be the inheritor of an administrative science that, with M. Vivien and M. Block, was put into place in the second half of the nineteenth century.

CONCLUSION

What, all in all, is sociology in France at the end of the twentieth century? The statement made at the beginning of the 1990s by J.-M. Berthelot in *La*

Construction de la sociologie (1991) is still valid. The programmatic crossovers that have been identified and the new uncertainties that have been discerned have been both confirmed and emphasized. To these, one adds a transformation of the very objective of sociology by reason of a notable subjectivization of social material. Often denounced as a fetishistic idea, society tends to be thought of as an ensemble of forms and networks of *sociability*, in the same way that *individual*, a simple statistical element passively submitted to diverse sorting operations, tends to be substituted by a complex *individuality*, more or less free of contradictions, the subject of a statement that claims to be “personal” and, in all cases rebellious to classification, recalcitrant toward enumeration and cut off from the “masses”. To weigh the new relationships maintained by the individual and society, one has recourse to sociologies that, unlike those of Durkheim and his followers, remained engaged in the psychological givens: Such is indeed the direction of interest aroused by the recent translations of G. Simmel’s works, in which, in the analysis of phenomena under study, the content is less important than the form and the part more significant than the whole.

One sees to what degree, in this perspective, the rereading of “sociological tradition” is imposed, as well as the reintegration into the discipline’s history of contributions that had more or less been excluded from it, and of reflections on the epistemology of the social sciences. Concurrently being pursued is a *conceptual clarification*, including the admirable *Dictionnaire critique de la sociologie*, continually reedited since its appearance in 1982 by R. Boudon and F. Bourricaud, which is its point of departure and canonical example. At the same time, also being pursued is the analysis of *social problems* related to the evolution of mores (the family, the young, the relations between generations, etc.) and to economic transformations (unemployment, exclusion, social justice, etc.). Finally, parallel to these pursuits is the research being conducted on the improvement of descriptive and explicative models of the changes that society is witnessing today. One points out in this regard the exemplary character of the investigation being conducted by Louis Dirn (anagram for *lundi soir*), that is, the group of sociologists who meet at the beginning of each week in the company of H. Mendras and M. Forsé. Thus, for the most

part freed from past dogmatism, French sociology today asserts its vitality by better adjusting its procedures for examining social objects and phenomena to which it is working to give a sense.

BERNARD VALADE

FUNCTIONALISM AND STRUCTURALISM

Sociology’s first theoretical orientation was functionalism. In trying to legitimate the new discipline of sociology, Auguste Comte (1830–1842,

1851–1854) revived analogies made by the Greeks and, closer to his time, by Hobbes and Rousseau that society is a kind of organism. In so doing, Comte effectively linked sociology with the prestige of biological science. For functional theory, then, society is like a biological organism that grows, and as a consequence, its parts can be examined with respect to how they operate (or function) to maintain the viability of the body social as it grows and develops. As Comte emphasized (1851–1854, p. 239), there is a “true correspondence between Statical Analysis of the Social Organism in Sociology, and that of the Individual Organism in Biology” (1851–1854, p. 239). Moreover, Comte went so far as to “decompose structure anatomically into *elements, tissues, and organs*” (1851–1854, p. 240) and to “treat the Social Organism as definitely composed of the Families which are the true elements or cells, next the Classes or Castes which are its proper tissues, and lastly, of the cities and Communes which are its real organs” (pp. 211–212). Yet, since these analogies were not systematically pursued by Comte, his main contribution was to give sociology its name and to reintroduce organismic reasoning into the new science of society.

It was Herbert Spencer who used the organismic analogy to create an explicit form of functional analysis. Drawing upon materials from his monumental *The Principles of Biology* (1864–1867), Spencer’s *The Principles of Sociology* (1874–1896) is filled with analogies between organisms and society as well as between ecological processes (variation, competition, and selection) and societal evolution (which he saw as driven by war). Spencer did not see society as an actual organism; rather, he conceptualized “superorganic systems” (organization of organisms) as revealing certain similarities in their “principles of arrangement” to biological organisms (1874–1896, part 2, pp. 451–462). In so doing, he introduced the notion of “functional requisites” or “needs,” thereby creating functionalism. For Spencer, there were three basic requisites of superorganic systems: (1) the need to secure and circulate resources, (2) the need to produce usable substances, and (3) the need to regulate, control, and administer system activities (1874–1896, part 2, p. 477). Thus, any pattern of social organization reveals these three classes of functional requisites, and the goal of sociological analysis is to see how these needs are met in empirical social systems.

Later functionalists produced somewhat different lists of requisites. Émile Durkheim argued that sociological explanations “must seek separately the efficient cause [of a phenomenon]—and the function it fulfills” (1895, p. 96), but, in contrast to Spencer, he posited only one functional requisite: the need for social integration. For Durkheim, then, sociological analysis would involve assessment of the causes of phenomena and their consequences or functions for meeting the needs of social structures for integration.

Were it not for the activities of theoretically oriented anthropologists, functionalism probably would have died with Durkheim, especially since Spencer’s star had faded by World War I (Turner and Turner 1990). As the traditional societies studied by early anthropologists were generally without a written history, anthropologists were confronted with the problem of explaining the existence of activities and structures in these societies. The explanatory problem became particularly acute in the post-World War I period with the demise of evolutionism and diffusionism as deciphering tools (Turner and Maryanski 1979). Functional analysis provided a novel alternative: Analyze structures such as kinship or activities such as rituals in terms of their functions for maintaining the society. It was A. R. Radcliffe-Brown ([1914] 1922, 1924, 1935, 1952) who sustained the Durkheimian tradition by emphasizing the importance of integrative needs and then analyzing how structures—most notably kinship systems—operate to meet such integrative requisites. In contrast, Bronislaw Malinowski (1913, 1944) extended functional analysis in a more Spencerian direction, emphasizing that there are distinct system levels (biological, social, and cultural), each of which reveals its own distinctive requisites. Extending Spencer and anticipating Talcott Parsons, Malinowski (1944) posited four basic requisites at the social system level: (1) production and distribution, (2) social control and regulation, (3) education and socialization, and (4) organization and integration.

Thus functionalism was carried to the midpoint of the twentieth century by anthropological work. Then during the 1930s, a group of Harvard sociologists—led by a graduate student, Robert Merton (1949)—began thinking about functional analysis, especially as it had been carried forth by

Radcliffe-Brown and Malinowski (Turner and Maryanski 1979). As a result, many of Merton's fellow students became the leading figures in the revival of functionalism in sociology. This revival began with Kingsley Davis and Wilbert Moore's classic article on "Some Principles of Stratification" (1945), followed by Davis's basic text, *Human Societies* (1948), and a variety of articles and books by others listing the "functional requisites" of societies (e.g., Levy 1952). But it was Talcott Parsons, a young Harvard instructor during Merton's tenure as a graduate student, who was to become the archfunctionalist of modern times (Parsons 1951; Parsons et al. 1953). For Parsons, the social universe was conceptualized in terms of four distinct types and levels of "action systems" (culture, social, personality, and organismic/behavioral), with each system having to meet the same four functional needs: (1) adaptation (securing and distributing environmental resources), (2) goal attainment (mobilizing resources to goals or ends), (3) integration (coordinating system parts), and (4) latency (managing tensions within parts and generating new parts). The operation and interchanges of structures and processes within and between system levels were then analyzed with respect to these basic requisites.

As functional theorizing became dominant in American theory in the 1950s and 1960s, criticism escalated. Opposition came from several different quarters and took a number of distinctive lines of attack. From interactionist theorizing came criticism about functionalism's failure to conceptualize adequately the nature of actors and the process of interaction (Blumer 1969); from Marxist-inspired theory, which was just emerging from the academic closets in the post-McCarthy era, came attacks on the conservative and static nature of analysis that emphasized the functions of phenomena for maintaining the status quo (e.g., Coser 1956; Dahrendorf 1958; Mills 1959); from theory construction advocates came questions about the utility of excessively classificatory or typological theories that pigeonholed phenomena in terms of their functions (e.g., Merton 1957, pp. 44-61); and from philosophers and logicians came questions about tautology and illegitimate teleology in explanations that saw phenomena as meeting needs and needs as generating phenomena (e.g., Dore 1961). The result was the decline of functional theorizing in the early 1970s.

Functionalism has never fully recovered from these criticisms, although there persist vibrant modes of functional analysis in many disciplines, both within and outside of the social sciences. Within sociology, functionalism adapted to a hostile intellectual environment in several ways. One was to downplay functional requisites in a "neofunctionalism" (Alexander 1985; Alexander and Colomy 1985) and, instead, emphasize the dynamics that had always been at the center of functional analysis: differentiation and social change. As with Parsons, neofunctionalism maintains the analytical distinctions among culture, social system, and personality; and as with Durkheim and Radcliffe-Browne, integration among (1) cultural symbols, (2) differentiating social systems, and (3) persons is given emphasis without, however, the baggage of functional requisites. Another strategy was to maintain Parsons's functional requisites, expanding and elaborating his scheme, but at the same time generating testable propositions (Münch, 1982). In this way, the criticism that Parsons's theory was, in reality, a category system could be mitigated because a system of categories could be used to generate propositions and hypotheses. Still another approach was to downplay the notion of functional requisites, as was done by neofunctionalists, and analyze specific institutional systems in terms of their consequences for overcoming the problem of system complexity generated by differentiation (Luhmann 1982). Yet another effort emphasized cultural processes and the functions of rituals, ideology, and values for integrating social structures (Wuthnow 1987). A final strategy has been to translate the notion of functional requisites into a more ecological perspective, with the notion of requisites being translated into selection pressures in a way that corresponds to the notion of functions in the biological sciences (Turner 1995). That is, function becomes a shorthand way to summarize selection processes as they operated in the past to create a new structure. When this logic is applied to sociocultural processes, function is simply a name given to selection forces; and the analysis shifts from listing requisites to assessing how selection pressures increases or decreases for certain types of sociocultural formations.

Aside from changing under the impact of critiques leveled against it, functionalism has also

spawned a number of other theoretical traditions. The most obvious is structuralism, which will be examined in more detail shortly, but there is another that is equally important in sociology, namely, human ecology. Human ecology is a perspective that comes from Spencer's and Durkheim's sociology. Both Spencer and Durkheim recognized that any social structure or system of symbols exists in a resource environment and that there is often competition for resources among alternative structures and symbols when social density increases. Thus, religious or political ideologies must compete for adherents, or businesses or governmental agencies must compete in their respective resource niche. Ecological reasoning came initially via the Chicago School's interest in how areas of cities were utilized, and like Durkheim and Spencer before them, members of the Chicago School visualized the competition for space created by dynamic real estate markets in Darwinian terms (e.g., Park 1936; Park et al. 1925; Hoyt 1939). Later others (Hannan and Freeman 1977) applied the idea of niche, niche density, competition, and selection to populations of organizations to examine their rates of success and failure. Thus, one of the more visible theoretical perspectives in sociology comes from early functionalists, who not only borrowed an image of society as being like an organism but also developed ideas that paralleled those of Darwin in examining the mechanisms behind sociocultural differentiation (or "social speciation"). For them, differentiation is both the context of niche specialization and the result of previous competitions, as sociocultural forms compete with each other, with those unable to compete in one niche dying, moving to a new niche, or creating a new niche (and, thereby, increasing the level of differentiation).

The other major offspring of functionalism were various lines of structuralism that were inspired primarily by Durkheim's and various collaborators' work. Durkheim (1893, 1895) implicitly borrowed Comte's distinction between statics and dynamics, although Durkheim conceptualized social statics in Montesquieu's terms as social "morphology." Static or morphological analysis was seen to involve an assessment of the "nature," "number," "interrelations," and "arrangement" of parts in a systemic whole (Durkheim 1895, p. 85). For Durkheim, sociological explanation still

sought to discover "cause" and "function," but the basic structural units of sociological analysis—that is, the "things" that are caused and functioning—are to be classified by "the nature and number of the component elements and their mode of combination" (Durkheim 1895, p. 81).

FRENCH STRUCTURALISM

French structuralism stood Durkheim on his head through Claude Lévi-Strauss's (1945a, [1949] 1969, 1963) adoption of ideas in less sociologically prominent works by Durkheim and his nephew, Marcel Mauss. In Durkheim's "Incest: The Nature and Origin of the Taboo" (1898) as well as his and Mauss's *Primitive Classification* ([1903] 1963), emphasis shifts to the origins and functions of rules of exogamy and to human classification systems and modes of symbolic thought. For Durkheim and Mauss, the way that humans cognitively perceive and classify the world reflects the morphological or material structure of society (nature, number, arrangement, and combination of parts). In developing this argument, which Durkheim repeats in less extreme form in *Elementary Forms of the Religious Life* (1912), Durkheim and Mauss posit all the basic elements of Lévi-Strauss's (1963) structuralism. First, although societies differ in their evolutionary development, they are all fundamentally similar because they are based upon the same "underlying principles" (Durkheim and Mauss [1903] 1963, p. 74), and these principles provide individuals with a basis for classifying and constructing their universe. Second, "mythology" is a universal method of classification. Third, such classification systems represent "relations of things" to each other and "are thus intended, above all, to connect ideas, to unify knowledge" (p. 81). Fourth, classification systems are, in essence, created by oppositions in the material social world—sacred—profane, pure—impure, friends—enemies, favorable—unfavorable.

This last idea, which Lévi-Strauss was to conceptualize as "binary oppositions," is carried further by Mauss (in collaboration with Henri Beuchat) in *Seasonal Variations of the Eskimo: A Study in Social Morphology* ([1904–05] 1979), where the sharp dualisms of Eskimo life are outlined as they are created by the seasonal nature of Eskimo activities. Later, in *The Gift* ([1925] 1941), Mauss reasserts Durkheim's earlier conclusion that activity, such as

the famous Kwakiutl potlatch, is a surface exchange reflecting a “deeper” and “more complex” underlying structure in which gifts symbolize and assure the continuation of social relations among diverse groups.

Lévi-Strauss regarded *The Gift* as the inauguration of a new era in the social sciences and saw Mauss as a new Moses “conducting his people all the way to a promised land whose splendour he would never behold” (Lévi-Strauss [1950] 1987, pp. 41–45). Following directly in Mauss’s footsteps, Lévi-Strauss ennobled the concept of exchange as a “total social phenomena” by arguing in his first major work, *The Elementary Structures of Kinship*, that a “principle of reciprocity” is the most general and universal property of society, with the exchange of women as the most fundamental expression of this principle (Lévi Strauss [1949] 1969, pp. 60–62).

Yet it is doubtful that these ideas alone would have produced structuralism. Two other scholars are critical to Lévi-Strauss’s transmutation of Durkheim and Mauss. One is Robert Hertz, a young member of Durkheim’s “Année School.” Before his death in World War I, Hertz produced a number of essays, the two best-known ones being published in *Death and the Right Hand* ([1909] 1960). In this work, Hertz continues the Durkheim–Mauss theme of the duality in the structure of society and documents how this is reflected in ideas about society (myths, classifications, and other “representations”), but the imagery is much more like modern structuralism in that the goal of inquiry is (1) to show the meaning of observed facts in their interrelations and (2) to uncover the underlying structural principles beneath the surface of such observed phenomena.

The final and perhaps most critical influence on Lévi-Strauss’s reversal of Durkheim is the Swiss linguist Ferdinand de Saussure ([1915] 1966), whose lectures, posthumously published under the title *Course in General Linguistics*, serve as the pioneering and authoritative work for modern-day structural linguistics. Saussure appears to have influenced Lévi-Strauss indirectly through Nikolai Trubetzkoi ([1949] 1964, 1968) and Roman Jakobson (1962, 1971), but they simply extend Saussure’s key insight that language is a system whose units—whether sounds or morphemes—are only points in an overall structure. Moreover, while speech

(*parole*) can be directly observed, it reflects an underlying system or language structure (*langue*), and, thus, it is critical to use *parole* to discover the *langue*.

In Lévi-Strauss’s hands, this combined legacy was to produce French structuralism. At times, Lévi-Strauss is critical of Durkheim, but he concludes in the end that Durkheim’s work “is an inspiration” (Lévi-Strauss 1945b, p. 522) and that “the entire purpose of the French school lies in an attempt to break up the categories of the layman, and to group the data into a deeper, sounder classification” (Lévi-Strauss 1945b, pp. 524–525). In early work such as *The Elementary Structures of Kinship* (Lévi-Strauss [1949] 1969), there is a clear debt to Durkheim and Mauss as Lévi-Strauss seeks to uncover the underlying principles (such as “reciprocity”) of bridal exchanges, but he soon turns to the methods of structural linguistics and sees surface social structures (Durkheim’s “morphology”) as reflecting a more fundamental reality, lodged in the human unconscious and the biochemistry of the human brain and involving “rules and principles” to organize “binary oppositions” that are used to create empirically observable patterns of social reality (Lévi-Strauss 1953). But these empirical patterns (e.g., myths, beliefs, kinship structures) are not the “really real” structure; they are like *parole* is to *langue*, a reflection of a deeper structural reality of which existing phenomena are only the surface realizations.

Thus, by the middle of the twentieth century, Lévi-Strauss (1953) had created a structuralism concerned with understanding cultural and social patterns as reflections of universal mental processes rooted in the biochemistry of the human brain. His basic argument can be summarized as follows: (1) The empirically observable must be viewed as a system of relations, whether these be a kinship system, elements of myth or folk tales, or any sociocultural pattern. (2) Statistical models of these observable systems need to be developed in order to summarize the empirically observable relations among components. (3) These models are, however, only surface manifestations of more fundamental reality and must, therefore, be used to construct mechanical models in which the organization of binary oppositions is organized by basic rules lodged presumably in the human brain. (4) These mechanical models are the more “real” since they

get at the underlying processes by which sociocultural systems are generated by the biology and neurology of the brain.

Marshall Sahlins (1966) once sarcastically remarked of Lévi-Strauss's scheme that "what is apparent is false and what is hidden from perception and contradicts it is true." But Levi-Strauss was not alone in this kind of neurological reasoning. Within linguistics, Noam Chomsky (1980) was making a similar argument, asserting that the brain is wired to produce generative grammars that are less the result of the sociocultural environment of humans than of the structure of their brains. We might term these kinds of structuralisms "biostructuralism" because they all argue that the social world as it is perceived and structured is being systematically generated by rules of organization that are part of the neurobiology of the human brain.

Not all structuralists went this far. Most were content to argue that symbol systems and social structures are organized by rules that need to be discovered. Since the rules are not obvious when examining symbols and text, the task of structural analysis is to uncover the underlying rules, programs, principles, and other generative forces that have produced a particular system of symbols or social structure. The presumption that these rules are built into the neurology of the brain was rarely invoked in most structuralist analysis, whether in the social sciences or the humanities.

Within sociology proper, structuralism exerted a rather vague influence. For a time in the 1970s and 1980s, it was quite faddish to search for the underlying structure of texts, social structures, cultural systems, and virtually any phenomena studied by sociologists. Jargon from structuralism appeared in the works of prominent theorists, such as Anthony Giddens's (1984) use of the notion of "structural principles" as part of the explanation for how the "rules and resources" are implicated in "structuration." Others such as Richard Harvey Brown (1987) proclaimed that we should conceptualize "society as text" in which methods of structural linguistics can get at the underlying forms that organize societies. A variety of texts and edited books on structuralism began to appear (e.g., Rossi 1982), but in the end this kind of analysis did not take a firm hold in American

sociology. It had a much greater influence in continental Europe, but here, too, structuralist sociology did not last very long (Giddens 1987).

But arising out of structuralism came "poststructuralism," which was even more vague than structuralism. Still, poststructuralism did take hold and evolved into or merged with what is now called "postmodernism." Ironically, postmodernism is generally anti-science and highly relativistic, emphasizing that there are no grand narratives. All is text, and none should enjoy a privileged voice. By the time poststructuralism had become part of a broad postmodern movement, then, it bore little resemblance to the scientific stance of structuralists, who were not only decidedly pro-science but also were committed to discovering the universal principles by which texts and all other human systems are generated, giving such a discovery a highly privileged voice.

Despite its origins in structural linguistics, French structuralism became ever more vague. In contrast, structuralism took a very different turn in England and the United States, evolving into one of the most precise ways of conceptualizing structures. While French-inspired structuralism got much of the press, British and American versions of network analysis have endured. These approaches also come out of Durkheim, particularly the British line but also the American line, although today the two approaches are the same.

BRITISH STRUCTURALISM

Radcliffe-Brown's early works were decidedly functional in the Durkheimian tradition of analyzing sociocultural patterns in terms of their functions for the larger social whole. Radcliffe-Brown also began to develop a conception of structure that was very close to Durkheim's emphasis on the number, nature, and relations among parts. And increasingly, Radcliffe-Brown emphasized structural analysis over functional analysis, stressing the importance of examining relations among entities. Radcliffe-Brown's disagreement with Lévi-Strauss is clear in a letter: "I use the term 'social structure' in a sense so different from yours as to make discussion so different as to be unlikely to be profitable. While for you, social structure has nothing to do with reality but with models that are built

up, I regard social structure as a reality” (quoted in Murdock 1953). A key British figure in the transition from Durkheim’s emphasis on relations among entities was S. F. Nadel (1957), a social anthropologist who separated structural from functional analysis and emphasized that structural analysis must concentrate on the properties of relations that are invariant and always occur rather than the nature of the actors in these relations. For Nadel, structure is to be viewed as clusters of networks of relations among positions or actors. This point of view was developed into network analysis by J. Clyde Mitchell (1974) and John A. Barnes (1972), who took Nadel’s imagery and converted it into a more pure form of network analysis.

AMERICAN STRUCTURALISM

At the same time that French-inspired structuralism was making inroads into American intellectual life, social psychologists in the United States were developing an alternative way to examine structure. Jacob Moreno (1953) was critical here, as he developed the methodology of sociograms in which a matrix of relations among a set of actors was plotted and then converted into a line drawing of relations. Studies by Alex Bavelas (1948) and Harold Leavitt (1951) on communication in groups were the first to assess how the network structure of groups influenced patterns of communication. At about the same time, gestalt and balance theory approaches by Fritz Heider (1946), Theodore Newcomb (1953), and Dorwin Cartwright and Frank Harray (1956) used network graphs to examine patterns of balance in groups. Concurrently within mathematics, a more formal system of notation for networks was being developed (Luce and Perry, 1949), and it is from this system that modern-day network analysis emerged.

THE MERGER OF BRITISH AND AMERICAN STRUCTURALISM INTO NETWORK ANALYSIS.

The British and American lines of what became network analysis are now merged in a view of structure that emphasizes (1) nodes or positions in a system, (2) mapping the relations among these nodes, and (3) examining generic patterns and forms of ties along such dimensions as the nature,

number, direction, reciprocity, transitivity, centrality, equivalence, density, and strength of ties. A fairly standard vocabulary and set of analytic techniques have emerged from network analysis, and the approach is now used in many other areas of sociological analysis. Thus, Durkheim’s original vision of structure has been more fully realized in contemporary network analysis.

FUNCTIONALISM AND STRUCTURALISM TODAY

Functionalism and structuralism share common roots, especially the works of Durkheim and Mauss, and hence it should not be surprising that these two theoretical traditions reveal certain affinities. First, both emphasize that the subject matter of sociology is to be relations among parts. Second, both stress part-whole analysis—the functions of parts for sustaining the whole in functionalism, and the view that parts are understood only as elements of a more inclusive whole, revealing underlying properties, in structuralism. Beyond these affinities, however, functionalism and structuralism diverge. French structuralism moves toward a highly vague view of underlying structures below visible phenomena whose generative processes constitute reality, whereas the merger of British and American network approaches moves toward analysis of the form of relations among interrelated units. In contrast, functionalism sustains an emphasis on how units meet the needs of larger social wholes, or it moves toward models of system differentiation during historical change and, alternatively, toward ecological models of population differentiation. It is safe to say that, today, all forms of functionalism and structuralism, even the network branch of structuralism, have little in common besides part-whole analysis. But even here, this kind of part-whole approach is conducted in very different ways by functionalists and structuralists.

Moreover, neither functionalism nor structuralism represented coherent approaches as we enter the twenty-first century. Functionalism was plagued by its emphasis on functional requisites, whereas French structuralism was always handicapped by a vagueness about what structure is. And so, few sociologists today would proclaim themselves to be either functionalists or structuralists;

these labels have negative connotations, and most seek to avoid such stigmatizing labels. If they perform elements of functional or structuralist analysis, they do so by another name.

FUTURES STUDIES AS HUMAN AND SOCIAL ACTIVITY

Future thinking has always been part of human history, for humans become human when they think about the future, as John McHale (1969) wrote. Some form of future thinking exists in almost all known societies; it is a universal phenomenon, as Wendell Bell (1997) writes, that ranges from divination, which involves the unveiling of the unknown, to the recent development of futures studies. Divination may be related to decisions taken by whole tribes and nations, just as the aim of scientifically rigorous futures studies is to support decision making.

In this particular context, it is important to trace the development of future thinking and the formalization of futures studies after World War II.

TERMINOLOGY

As in most disciplines, issues of terminology in futures studies are related as much to the word itself as to the underlying concept expressed by it.

From the 1940s to the 1970s, *forecasting* was the most important concept of futures studies. In 1967, Eric Jantsch defined *forecasting* “as a probabilistic statement, on a relatively high level of confidence about the future” (p. 15). In this rigorous definition, the use of the adverb “relatively” indicates the element of uncertainty that is always present in futures studies in general.

In France and in Spanish-speaking countries, however, they tend to prefer the term *prospective*. The term and the concept were actually born in France in the 1950s when Gaston Berger (1958) described *prospective* as “a way of focusing and concentrating on the future by imagining it full-blown rather than by drawing deductions from the present” (p. 3). In *prospective*, the main element is a project for the future. The idea is that by understanding the past (which cannot be changed but only interpreted), one can, in the present, choose from among the many possible and probable futures the one that is more desirable. According to Bertrand de Jouvenel (1967), the present cannot be changed either, as it is but a fleeting moment. Hence, the future is the only space we have to influence. Clearly, the prospective approach is completely different from the forecasting approach, as Michel Godet (1979) has correctly underlined.

The term *prevision*, as indicated by Barbieri Masini (1993) is not used in English or in French. In English it is thought to have the specific meaning of *pre-vision*, or seeing ahead (something not possible, as the future does not exist); in French it is not used because of its theological associations. In Italian the term *previsione* is used because a term equivalent to prospective does not exist. *Prospettiva* has a different meaning and projection is closer to forecast, which, as already mentioned here and discussed by Godet (1979), does not have the implications of prospective. Consequently when the term *previsione* is used in Italian it is necessary to qualify it. For example, *previsione umana* and *previsione sociale*, which has in itself the capacity to build a set of futures that are different from the past and the present (as with prospective) but with the addition of some other qualifications, as indicated by Barbieri Masini and Medina (1993). In

this meaning, to build the future is seen simultaneously as a need, a choice, and a way of life that are related to the human being and to a given society. The need is due in part to the rapidity of change in modern times but also to an ethical requirement to create a future that is humane, as Josef Fuchs (1977) says, and at the same time social, as related to social choices. According to Barbieri Masini (1993), embedded in *previsione umana e sociale* is the need to build the future, but with a choice in terms of deciding to propose one or many alternative futures. It is a way of life, as it goes beyond a discipline and becomes a distinguishing feature of a group of people. Hence, *previsione umana e sociale* has the following basic functions: It is geared to a project of the future; it clarifies the goals of a given person or social group; and it is educational, in terms of helping to create responsibility for the future.

Prognosis is a term that is very much used in German-speaking countries and in Central and Eastern Europe. It is very close to forecast and forecasting.

Among the many other terms, it is important to mention *futuribles*, which was used by Bertrand de Jouvenel (1967) to indicate the many possible, probable and desirable futures that exist. In the debate about *futuribles*, Jouvenel’s thinking is reminiscent of the thinking of many in the Middle Ages, especially the emphasis put on freedom by the Jesuit Molina (in 1588), whose writings were published in 1876 in France. Jouvenel, in the conceptual discussion of terms, especially “*futuribles*,” refers to the discussion of the symmetry between the past and the future that took place in the eighteenth century and goes back to 1588 to the Jesuit Molina who had favored the position of human freedom of choice in relation to the interpretation of the past and the choice of the future.

An interesting more recent term is *foresight*. Actually it was first used by D.H. Wells in 1932 in a speech for the BBC advocating the need for experts in foresight. As described by Irvin and Martin (1984), nowadays the term is mostly used in the sense of outlook, meaning a cluster of systematic attempts to look ahead and to choose more effectively. Foresight takes into account the fact that there is not one future but many—only one of which, however, will occur. Foresight is also used at the national level as a support for national

planning, to identify the possible technological futures and their environmental and social impact.

As regards the actual discipline, in addition to *futures studies*—a very broad term that contains all the different ways of looking at the future, from projection to utopia—there is the term *futurology*, which was defined by Ossip Flechtheim (1966) as the search for the logic of the future in parallel to the search for the logic of the past in history. Unfortunately, this concept has lost its correct meaning and is now used casually to refer to any fantasy about the future.

Futuristics is another term that is often used, especially in North America. Its meaning is similar to that of futures studies.

A BRIEF HISTORY OF FUTURES STUDIES

It is hard to establish a definite date for the beginning of futures studies. Many indicate the period immediately after World War II with the development in the United States of what was called *technological forecasting* at RAND (Research and Development) Corporation. According to Wendell Bell (1997), this can be linked to the *operational research* conducted in the United Kingdom to predict and project the moves of the German bombers.

More or less in the same period, the Europeans also contributed to what may be considered the “beginnings” of futures studies—in France, Bertrand de Jouvenel with *futuribles* and Gaston Berger with *prospective*, followed by Pierre Massé and many others; Pater in the Netherlands, Fred Polak with his important books *The Image of the Future* and *Prognosis: A Science in the Making*.

The three major organizations dealing with futures studies were established at the end of the 1960s: the World Futures Studies Federation, which started in embryo in Oslo in 1967 and was formally founded in Paris at UNESCO in 1973; the World Future Society, essentially a North American organization founded by Edward Cornish in 1967; and the Club of Rome, founded in Rome by Aurelio Peccei and Alexander King in 1968. The latter in particular had a major impact on decision making with the project “The Limits to Growth,” which is still relevant both in relation to the limits

of the earth and of the need to look at the future in the long term, and in relation to a cluster of human and social issues (the global problematic).

The 1970s posed a serious challenge to futures studies. The severe economic crisis of that period showed that in looking at the future it is necessary to address many aspects and paces of change, given that economic and technological changes are much more rapid than social and cultural changes, for example. The 1970s also challenged the concept of the future as being linear development of the present and the past. There was a re-appraisal of futures studies in the 1980s, especially in Europe. In countries such as the Netherlands, Sweden, and Finland, futures studies acquired political importance. In the 1990s developing countries also started to make use of futures studies; with the exception of India, China, and certain Latin American countries, most developing countries had had little interest in futures studies up until then. In the same period, futures studies reemerged very strongly in the United States with the launching of such major projects as the Millennium Project, supported by the United Nations University and the Smithsonian Institute. The Millennium Project, directed by Jerome C. Glenn and Theodore J. Gordon, studies the major threats and challenges of the future and produces the “state of the future” report. The debate on methodologies was also revived, sparking the publication of many basic texts that became prominent in the world debate. Schools of futures studies emerged in Finland and Hungary, and there was increased interest in Australia.

Numerous sociologists have made important contributions to futures studies: William F. Ogburn was appointed by President Herbert Hoover to chair the Research Committee on Social Trends as early as 1929. Harold Lasswell, who laid the foundations for the science of political choices also wrote many less well-known articles on futures perspectives. Daniel Bell wrote the famous report of the Commission Toward the Year 2000 for the American Academy of Arts and Sciences in 1967. John McHale wrote many books and contributed to the founding of the World Futures Studies Federation in the 1960s and 1970s. Elise Boulding greatly contributed with her work on peace in the future and the role of women in the future. One

could mention many more names. The main point to stress is that futures studies and sociology have not always been considered two separate and distinct disciplines.

CHARACTERISTICS OF FUTURES STUDIES

Many characteristics of futures studies relate to the linking of present action with future results. Barbieri Masini (1993) identifies seven characteristics in particular:

1. *Transdisciplinary*. Futures studies go beyond the interdisciplinary nature of social science. Futures studies needs the parallel approaches of different disciplines as well as the combined effort of many approaches in addressing the complexity of present problems in a rapidly changing society. It needs disciplinary approaches that identify common assumptions and use common methodologies. In terms of methodologies, examples of such approaches are the Delphi and the scenario-building methods, which function with the support of mathematics, statistics, economics, sociology, history, and psychology. To quote Fred Polak: "all kinds of separate, fragmented portions of the jigsaw puzzle are of little avail, unless they are fitted together in the best possible way, to form an image of the future depicting a number of main areas of development" (1971, p. 261).

2. *Complex*. This represents the other side of the transdisciplinary nature of futures studies. As a concept, complexity was much debated in futures studies, even before it became a clear issue in social sciences, because it is related to uncertainty: The greater the complexity of a given situation, the greater the level of uncertainty; the greater the number of variables needed to describe a social situation, the greater the uncertainty. Because the future is so uncertain, futures studies has to devise methods for lowering the level of uncertainty: One such method is alternative scenario building.

3. *Global*. Its global nature is probably the best-known characteristic of futures studies. It is now generally accepted that the future is determined by a continuous interplay between local issues and global issues. Some issues emerge as local and then become global, such as an economic crisis in a given country or part of the world. Some issues are

born global and subsequently affect the local level such as the greenhouse effect.

4. *Normative*. The impact of the normative is much greater in futures studies than is usually the case in social sciences. Frameworks of values and systems of values can never be completely eliminated in futures studies. Many methods try to lower the level of impact of the normative, but it is always present: Thinking about the future, making decisions about the future, is always related to some hope or fear.

5. *Scientific*. This is the most debated characteristic of futures studies, precisely because the normative is always present. Great effort has been made to invent devices and methods for increasing the scientific level of futures studies. If it is not possible to define futures studies as scientific, then it must be absolutely rigorous in terms of application and methods. It must be used according to strict scientific rules. Yehezkel Dror (1974) stresses the importance of combining a clinical and a human approach.

6. *Dynamic*. Futures studies is very dynamic: It is constantly in search of stronger foundations, of better approaches, and of more effective methods for facing the rapidity of change.

7. *Participatory*. There is less consensus on this characteristic of futures studies than on the previous ones. It is obvious that futures studies methods should be developed with the participation of those who are responsible for choosing the future, that is, decision makers at every level. This may not be possible at every step in the application of methods, but it is certainly something to strive for. Participation is definitely an essential characteristic of scenario-building and Delphi applications.

LIMITS OF FUTURES STUDIES

Like all disciplines futures studies has limits. Barbieri Masini (1993) has singled out six such limits.

1. *Self-altering*. The moment a forecast, or the result of a futures study, becomes public, it produces consequences that alter the reality in which it operates. In other words, a self-realizing or a self-defeating effect may invalidate the value of the forecast. This danger was underlined long ago by Robert Merton ([1938] 1973) and is still valid today.

2. *Psychological aspects.* These are crucial in futures studies, as inevitably in looking ahead one is influenced by hopes and fears. Fear of the unknown is ever present and can have a negative impact on the need to think in alternative terms as the future requires. It is also easy to underestimate the changes that will occur in the future.

3. *Irrational aspects.* In future processes and events there is always an irrational element that cannot be quantified or evaluated; for example, the whims of a given head of state or the religious reaction of a given population.

4. *Implicit hypotheses.* These are present in any futures exercise. This aspect is of course related to the normative characteristic mentioned earlier, however, in using futures studies, it is essential to detect the implicit hypotheses.

5. *A posteriori verification.* A definite limit of futures studies is that it is only possible to verify the validity of a given study after the events forecast have occurred. This is often done and is an extremely useful way of learning more about the application of methods.

6. *Availability of reliable data.* This clearly is a crucial aspect: Any future-oriented study must be able to rely on good quantitative and qualitative data. There may, for example, be a lack of historical data on which to base a forecast or a lack of relevant ad hoc surveys. This is one of the most important limits of futures studies, for if forecasts are to be reliable, data must be rigorously evaluated.

METHODS

Before entering the debate on methods, it is important to underline the accepted typology of futures studies methods. Futures studies can be *extrapolative* (opportunity-oriented) or *normative* (mission-oriented). The definitions in parenthesis are those of Eric Jantsch (1967). In other words, to extrapolate from the past to the present and into the future constitutes one group of methods, of which projections are one. Another is to start from what is needed in the future—an image, a goal, an objective—and work backward, searching in the present for possible and probable ways of realizing it. Nowadays futures studies are never wholly

extrapolative or normative; they usually emphasize one or the other aspect, given the normative characteristic of futures studies.

SCENARIOS

The term and method were introduced by Herman Kahn during the 1960s. Nowadays *scenario* is a general term that is used to refer to different approaches: those of the Stanford Research Institute (SRI), of the Battelle Institute, of the studies by Michel Godet and others. A scenario can be defined as an ensemble created to describe a future situation and the sequence of events leading from the present situation to a future one.

Theoretically speaking, scenarios are a synthesis of several different hypothetical routes (events, actors, strategies) that lead to different possible futures. Practically speaking, scenarios often describe specific sets of events and variables that have been put together with the aim of focusing on causal processes and related decision-making. According to Herman Kahn (1967), scenarios answer the following basic questions: How does a situation evolve step by step from the present to the future? What are the possible alternatives that different actors in the different moments of decision making can use in order to anticipate, change, or facilitate the process?

From an epistemological point of view, scenarios are analytical and empirical constructions. They are hypotheses that do not “predict” the future but rather indicate a series of options and probable situations. No scenario will ever precisely anticipate the occurrence of a given event; rather it will suggest alternatives with the aim of sensitizing decision makers to what might happen. Hypotheses are never invented but are founded on a rational, consistent diagnosis of the forces that may model events. According to Michel Godet (1995), the scenario hypothesis should respond to the following five conditions. They must be: pertinent, coherent, realistic, important, and transparent.

Scenarios are instruments for better decision making. Their aim is to lower the level of uncertainty and increase the level of understanding of the consequences of actions in the present.

In looking at scenarios, one presumes an awareness on the part of the author of the rapidity and

interrelatedness of change, which will affect both decisions and the understanding of consequences, which can change a preexistent situation, either completely or in part. Scenarios are both synoptic and simultaneous: They can be used to analyze many variables at once and identify the respective turning points in terms of decision-making in steps of five, ten, or twenty years. Timing depends on the area of interest. For example, in the economic area the time span considered will be much shorter than in the educational area.

In recent years, use of the scenario technique has increased greatly, as have its applications. The scenario method seems to be particularly useful in the following situations: (1) to detect long-term trends that can help to formulate alternative within a given context; (2) to identify potential discontinuities and situations and alert organizations, countries, or regions to foresee them and thus prepare contingency plans; (3) to alert organizations, regions, or countries of possible interrelated changes as a reference for planning; (4) to provide a basis for analyzing risks as interactions between socio-economic areas that may lead to risks and are not understandable if seen only in a specific and isolated area; (5) to evaluate the results of different strategies in different areas that may not have been developed in the awareness of interrelations.

In the public sector the best-known applications include the following. In the 1960s, Herman Kahn used scenarios connected to military and strategic studies that were developed at the RAND corporation. In the 1960s and 1970s, territorial planning by DATAR was used in France. Scenarios derived from systems analysis and global models, such as *The Limits to Growth* by Meadows and Meadows (1972), analyzed the global consequences of the interrelated growth of population, agricultural production, industrial development, environmental pollution, and use of natural resources. Finally, Jacques Lesourne directed an important exercise of Interfutures for the Organization for Economic Cooperation and development (OECD), which identified the alternatives of the relationships between the North and the South regions of the world.

In scenario building the private sector intervened, perhaps late, but in a sophisticated manner. Shell International Petroleum Company (Royal

Dutch/Shell Group) used scenarios before the energy crises of 1973 and before the debacle of the Soviet Union, its major competitor in the petroleum area. Other large oil companies followed Shell's example and made extensive use of scenarios—ARGO in the late 1970s and, more recently, Pacific Gas and Electric.

In the private sector scenarios are used by enterprises in many sectors. Financial services have used scenarios to understand competitors and regulate uncertainty. Insurance companies, such as the Allied Irish Bank, have used scenarios to support strategic planning within a constantly changing context.

G

GAME THEORY AND STRATEGIC INTERACTION

A *game* is a situation that involves two or more decision makers (called *players*), where (1) each player faces a choice between at least two behavioral options, (2) each player strives to maximize utility (i.e., to achieve the greatest payoff possible), and (3) the payoff obtained by a given player depends not only on the option that he or she chooses but also on the option(s) chosen by the other player(s). In virtually all games, some or all of the players have fully or partially opposing interests; this causes the behavior of players to be proactive and strategic.

The *theory of games* is a branch of applied mathematics that rigorously treats the topic of optimal behavior in two-person and n -person games. Its origins go back at least to 1710, when the German mathematician-philosopher Leibniz foresaw the need for a theory of games of strategy. Soon afterward, James Waldegrave (in Montmort 1713; 1980) formulated the concept of maximin, a decision criterion important to game theory. In his book *Mathematical Psychics*, Edgeworth (1881; 1995) made explicit the similarity between economic processes and games of strategy. Later, theorists such as Zermelo (1913) stated specialized propositions for certain games (e.g., chess). Not until the work of Borel ([1921–1927] 1953) and von Neumann (1928), however, did the foundations of a true theory of games appear. A landmark of the modern era, von Neumann and Morgenstern's *Theory of Games and Economic Behavior* (1944), extended game theory to problems involving more

than two players. Luce and Raiffa (1957) published the first widely used textbook in game theory. For more details regarding the early history of game theory, see Dimand and Dimand (1996) and Weintraub (1992).

Game theory has continued to develop substantially in recent years. Many introductory presentations of the modern mathematical theory are available. Among these are Friedman (1990), Jones (1980), Myerson (1991), Owen (1982), Romp (1997), and Szep and Forgo (1985).

Beyond its status as a branch of applied mathematics, game theory serves social scientists as a tool for studying situations and institutions with multiple decision makers. Some of these investigations are empirical, while others are primarily analytic in character. The dependent variables of central concern in games include allocation of payoffs (i.e., who receives what rewards or bears what costs) and formation of coalitions (i.e., which of various possible alliances among players occur in a game.) Other concerns include whether outcomes of a game are stable or not, whether outcomes are collectively efficient or not, and whether outcomes are fair or not in some specific sense.

GAME-THEORETIC CONCEPTS

Mathematical game theory provides three main tools that assist in the analysis of multiperson decision problems. These include a descriptive framework, a typology of games, and a variety of solution concepts.

Descriptive Framework. At base, a description of any game requires a list of all players, the strategies available to each player, the logically possible outcomes in the game, and the payoff of each outcome to each player. In some instances, a game's description also includes a specification of the dynamic sequence of play and of the (possibly limited or incomplete) information sets available to players. Payoffs in a game are expressed in terms of *utility*; this provides a standard means of comparing otherwise diverse outcomes.

An analyst can model or represent a game in various forms. *Extensive form* depicts all possible strategies of players in a tree format. It is especially useful for modeling games in which play occurs in stages or over time. *Strategic form* (also called normal form or a "payoff matrix") shows payoffs to players as a function of all strategy combinations. *Characteristic function form* lists the minimum payoffs assured for each of the coalitions in a game. Whereas extensive and normal forms pertain to virtually all types of games, characteristic function form pertains only to cooperative games (i.e., games that permit coalitions).

Typology of Games. The second tool from game theory is a general typology of games. This provides a means of codifying or classifying games vis-à-vis one another. At base, there are four major types of games. Games can be either *static* (i.e., single time period) or *dynamic* (multiple time periods), and they can involve either *complete information* (all relevant information is shared and held in common) or *incomplete information* (some information is private and held only by some players). Much of classic game theory was formulated with reference to static games involving complete information; more recent developments have extended the theory to dynamic games and also to games involving incomplete information.

Games can be *two-person* or *n-person* (more than two players), and they can be further classified as *cooperative* or *noncooperative*. Cooperative games permit players to communicate before reaching decisions and include some mechanism that enables players to make binding agreements regarding coordination of strategies. Noncooperative games do not permit players to communicate or to form binding agreements prior to play. In other words, cooperative games enable players to form coalitions whereas noncooperative games do not.

Among cooperative games, some are *sidepayment games* while others are *nonsidepayment games*. Sidepayment games permit players to transfer payoffs (utility) within coalitions; nonsidepayment games do not. A further distinction applicable to cooperative sidepayment games is that between *simple games* and *nonsimple games*. Simple games are those in which the characteristic function assumes only two values, whereas nonsimple games are those in which the characteristic function has more than two values. Analysts use simple games primarily to model social processes with binary outcomes (e.g., win-lose, succeed-fail, etc.)

Solution Concepts. The third set of tools provided by game theory is a variety of solution concepts. A *solution concept* is theory of equilibrium that predicts (behaviorally) or prescribes (normatively) the allocation of payoffs to players in games. In other words, a solution concept specifies how a game will turn out when played. For this reason, solution concepts are among the most important contributions of game theory.

Game theorists have developed numerous solution concepts. These differ not only in the underlying assumptions but also in the predictions they make. For static noncooperative games, the most prominent solution is the Nash equilibrium (Nash 1951); there are many extensions of this concept (summarized in van Damme 1987). Other approaches to the solution of noncooperative games are those of Harsanyi and Selten (1988) and Fraser and Hipel (1984).

For static cooperative games, there are several classes of solution concepts. One prominent class consists of solutions that predict outcomes which are collectively rational (i.e., imputations). Included in this class are the core (Aumann 1961; Gillies 1959), the Shapley value (Shapley 1953), and the nucleolus (Schmeidler 1969). Other solutions in this class are the disruption nucleolus (Gately 1974; Littlechild and Vaidya 1976), the disruption value (Charnes et al. 1978), the p-center solution (Spinetto 1974), and the aspiration solution (Bennett 1983). Another class of solutions for cooperative games includes concepts that make payoff predictions contingent upon the coalition structures that form during play; these payoff allocations are usually coalitionally rational. Included are the $M_1(i)$ bargaining set (Aumann and Dreze 1974; Aumann and Maschler 1964), the competitive bargaining

set (Horowitz 1973), the kernel (Davis and Maschler 1965), the Myerson–Shapley solution (Aumann and Myerson 1988; Myerson 1977), the equal division kernel (Crott and Albers 1981), and the alpha-power solution (Rapoport and Kahan 1982). Recently, a third class of solutions has emerged for cooperative games. Solutions in this class attempt not only to determine endogenously which coalition structure(s) will emerge but also to specify the associated payoffs to players. One solution in this class is the central-union theory (Michener and Au 1994; Michener and Myers 1998), which predicts coalition formation probabilistically. Another solution in this class is the viable proposals theory (Sengupta and Sengupta 1994).

EXPERIMENTAL STUDIES OF GAMES

Laboratory experimentation on two-person and n -person games commenced in the early 1950s (e.g., Flood 1952) and it continues to the present. Some gaming studies are primarily descriptive in nature, whereas others investigate the predictive accuracy of various solution concepts.

Experiments of Two-Person Games. Investigators have conducted literally thousands of experiments on two-person games. Most of these treat noncooperative games, although some do treat cooperative games in various forms. Some studies investigate constant-sum games, whereas others treat non-constant-sum games (primarily such archetypal games as the prisoner’s dilemma, chicken, battle of the sexes, etc.).

The major dependent variables in the two-person studies are the strategies used by players (particularly the frequency of cooperative choices) and the payoffs received by players. Independent variables include the type of game, strategy of the confederate, information set, interpersonal attitudes of players, sex of players, motivational orientation of players, and magnitude and form of payoffs.

Some of this research seeks to understand how differences in game matrices affect play (Harris 1972; Rapoport et al. 1976). Another portion describes how players’ strategies vary as a function of the confederate’s strategy (i.e., partner’s history of play over time); this is reviewed in Oskamp (1971). Another portion of this work investigates

the extent to which predictions from the minimax theorem approximate observed payoffs in constant-sum games; Colman (1982, ch. 5) reviewed these findings. Still other work covers cooperative bargaining models; Roth (1995) reviewed research on bargaining experiments. Some experimentation on two-person games has addressed the impact of players’ value orientation on cooperation (McClintock and Liebrand 1988; Van Lange and Liebrand 1991). General reviews of experimental research on two-person games appear in Colman (1982), Komorita and Parks (1995), and Pruitt and Kimmel (1977).

Experiments of n -Person Noncooperative Games. There are several lines of experimentation on n -person noncooperative games. One line investigates multiperson compound games derived from 2×2 matrices (e.g., n -person chicken, n -person battle of the sexes, etc.). Important among these is the n -person dilemma (NPD) game, wherein individually rational strategies produce outcomes that are not collectively rational. The NPD serves as an abstract model of many phenomena, including conservation of scarce natural resources, voluntary wage restraint, and situations involving the tragedy of the commons (Hardin 1968; Hartwick and Yeung 1997; Moulin and Watts 1997). The literature contains many experimental studies of the NPD and other social dilemmas (e.g., Liebrand et al. 1992; Rapoport 1988). In addition to varying the payoff matrix itself, studies of this type investigate the effects of such factors as group identity, self-efficacy, perceptions of other players, value orientation, uncertainty, and players’ expectations of cooperation. Reviews of research on NPDs and similar games appear in Dawes (1980), Kollock (1998), Komorita and Parks (1999), Liebrand and colleagues (1992), Liebrand and Messick (1996), and Messick and Brewer (1983).

A related line of research is that by experimental economists on markets and auctions (Smith 1982). This work investigates market structures (such as competitive exchange, oligopoly, and auction bidding) in laboratory settings (Friedman and Hoggatt 1980; Plott and Sunder 1982). Many of these structures can be viewed as noncooperative games. Plott (1982) provides a review of studies investigating equilibrium solutions of markets—the competitive equilibrium, the Cournot model, and the monopoly (joint maximization) model.

There is an increasingly large experimental literature on auctions, some of which is game-theoretic in character. Since auctions usually entail incomplete information (buyers have private information about their willingness to pay and ability to pay), these studies investigate the effects on bidding behavior of such variables as differential information, asymmetric beliefs, and risk aversion. They also investigate different institutional forms, such as English auctions, Dutch auctions, double auctions, and sealed bid-offer auctions (e.g., Cox et al. 1984; Smith et al. 1982). Reviews of the theoretical literature on auctions appear in Engelbrecht-Wiggans (1980), Laffont (1997), and McAfee and McMillan (1987). Kagel (1995) provides a survey of experimental research on auctions.

Experiments of n -Person Weighted Majority Games. Weighted majority games are an important subclass of cooperative, sidepayment, simple games. They serve as models of legislative or voting systems. Theorists have developed many special solution concepts for these games. Early theories applicable to weighted majority games are the minimum power theory and minimum resource theory (Ganson 1961). Riker's size principle predicts the formation of minimal winning coalitions in these games. Other theories for weighted majority games include the bargaining theory (Komorita and Chertkoff 1973; Kravitz 1986) and the equal excess model (Komorita 1979). The bargaining theory posits that players in a coalition will divide payoffs in a manner midway between equality and proportionality to resources (votes) contributed. The equal excess model is similar but uses the equal excess norm instead of proportionality.

Numerous experiments on coalition bargaining in weighted majority games have tested these and related theories (e.g., Cole et al. 1995; Komorita et al. 1989; Miller and Komorita 1986). Results of these studies generally support the bargaining theory and the equal excess model over the others, although all have deficiencies. Reviews of some experiments in this line appear in Komorita (1984) and Komorita and Kravitz (1983).

Experiments of Other n -Person Cooperative Games. Beyond NPD and weighted majority games, investigators have studied a wide variety of n -person cooperative games in other forms. The primary objective of the work is to discover which

game-theoretic solution concepts predict most accurately the outcomes of these games.

Numerous studies have investigated cooperative sidepayment games in characteristic function form (e.g., Michener et al. 1986; Murnighan and Roth 1980; Rappaport 1990). Other studies have investigated similar games in strategic form. This work shows that in games with empty core, solution concepts such as the nucleolus and the kernel predict fairly well; in games with a nonempty core, however, the Shapley value is often more accurate. Reviews of parts of this research appear in Kahan and Rapoport (1984), Michener and Potter (1981), and Murnighan (1978).

Other studies have investigated cooperative nonsidepayment games. Some of this research pertains to bargaining models in sequential games of status (Friend et al. 1977). Other research tests various solution concepts (such as the core and the lambda transfer value) in nonsidepayment games in strategic form (McKelvey and Ordeshook 1982; Michener et al. 1985; Michener and Salzer 1989).

Another line of experimentation on cooperative nonsidepayment games is that conducted by political scientists interested in committee games or spatial voting games. These are n -person voting games in which policies are represented as positions in multidimensional space. For the most part, this research attempts to test predictions from alternative solution concepts (Ferejohn et al. 1980; Ordeshook and Winer 1980). Some of this work has led to new theories, such as the competitive solution (McKelvey and Ordeshook 1983; McKelvey et al. 1978), and to further developments regarding established ones, such as methods for computing the Copeland winner (Grofman et al. 1987). Experimental research on spatial games is reviewed in McKelvey and Ordeshook (1990).

DYNAMIC GAMES

Although early developments in game theory centered primarily on static games (i.e., games in which interaction among players is single-period or single-play in nature), many subsequent developments have addressed *dynamic games* occurring over time. In a dynamic game, time (or stage) is an important consideration in strategy, and the choices and actions of players at any stage are conditional on the history of prior choices in the game. There

is a growing theoretical literature on various classes of dynamic games, including repeated games, differential games, and evolutionary games. Introductions to the topic of dynamic games appear in Friedman (1990), Fudenberg and Tirole (1991), Owen (1982), and Thomas (1984). The empirical literature on dynamic games is still small relative to that on static games, although experimental studies of repeated games appear increasingly often.

The term *supergame* refers to a sequence of (ordinary) games played by a fixed set of players. One important type of supergame is the *repeated game*, wherein the same constituent game is played at each stage in the sequence. For instance, if some players play a prisoner's dilemma game again and again, they are engaging in a repeated game. At this point in historical time, the dominant paradigm for the study of dynamic strategic behavior is that of repeated games. Certain repeated games are of interest because they allow collectively rational outcomes to result from noncooperative equilibrium strategies. Axelrod (1984) has analyzed the development of cooperation in repeated games. Selten and Stoecker (1983) have used a learning theory approach to model end-game behavior of players in repeated prisoner's dilemma games. Aumann and Maschler (1995) have studied repeated games with incomplete information. A survey of literature on repeated games appears in Mertens and colleagues (1994a,b,c).

Theorists have developed various solution concepts applicable to repeated games and multistage games. Among these are the backward induction process, the subgame perfect equilibrium (Selten 1975), and the Pareto perfect equilibrium (Bernheim et al. 1987). Cronshaw (1997) describes computational techniques for finding all equilibria in infinitely repeated games with discounting and perfect monitoring.

Another class of dynamic games is the *differential game*, played in continuous time. Much of the literature on differential games focuses on the two-person zero-sum case. Some applications of differential games are military, such as pursuit games, where the goal of, say, a pursuing aircraft is to minimize time or distance required to catch an evading aircraft (Hajek 1975). The classic works on differential games include Friedman (1971) and Isaacs (1965). Models of differential games with more than two players are discussed in Leitman

(1974). Other useful works on differential games include Basar and Bernard (1989) and Lewin (1994). The vector-valued maximin for these games is discussed in Zhukovskiy and Salukvadze (1994).

Biologists and economists have used game theoretic concepts to study *evolutionary games*, which are dynamic models of social evolution that explain why certain inherited traits (i.e., behavioral patterns) arise in a human or animal population and remain stable over time. In some evolutionary games (especially those with animal populations), the individuals are modeled as having neither rationality, nor conscience, nor expectations, so strategy selection and equilibrium derive from behavioral phenotypes rather than from rational thought processes. Models of this type often incorporate such phenomena as mutation, acquisition (learning), and the consequences of random perturbations. Theorists have advanced various concepts of evolutionary stability and evolutionarily stable strategies (Amir and Berninghaus 1998; Bomze and Potscher 1989; Gardner et al. 1987; Maynard Smith 1982). Summaries and extensions of work on evolutionary games appear in Bomze (1996), Friedman (1991, 1998), Samuelson (1997), and Weibull (1995).

INSTITUTIONAL ANALYSIS VIA GAME THEORY

Economists and political scientists have long used game theory in the analysis of social institutions. In work of this type, an analyst specifies an institution (such as a Cournot oligopoly or an approval voting system) in hypothetical or ideal-typical terms and then applies game-theoretic solution concepts to see which payoff allocation(s) may result at equilibrium. Through this approach, an analyst can compare the outcomes of alternative institutional forms with respect to stability, efficiency, and fairness. Broad discussions and reviews of this literature appear in Schotter (1981, 1994), Schotter and Schwodiauer (1980), and Shubik (1982, 1984).

Economic Institutions. Von Neumann and Morgenstern (1944) were among the first to explore the role of n -person game theory in economic analysis. Since that time, economists have analyzed a variety of institutions in game-theoretic terms, including *oligopoly and other imperfect markets*. Markets in which there are only a few sellers

(oligopoly), two sellers (duopoly, a type of oligopoly), one buyer and one seller (bilateral monopoly), and so on, lend themselves to game-theoretic analysis because the payoffs to each player depend on the strategies of the other players.

Economists have modeled oligopolies both as noncooperative games and as cooperative games. Several analyses of oligopolies as noncooperative games show that the standard Chamberlin price-setting strategy is equivalent to a Nash equilibrium in pure strategies (Telser 1972). Beyond that, various analyses have treated oligopoly as a noncooperative multistage game. These analyses have produced generalizations concerning the effects of adjustment speed, demand and cost functions, and incomplete information regarding demand on the dynamic stability of the traditional Cournot solution and other equilibria (Friedman 1977; Radner 1980).

Analyses of collusion among oligopolists usually view this as a cooperative game. These treatments analyze outcomes via such solution concepts as the core or the bargaining set (Kaneko 1978). Reviews and discussions of game-theoretic models of oligopoly appear in deFraja and Delbono (1990), Friedman (1983), Kurz (1985), and Shubik (1984). Game theoretic literature on collusive equilibria is surveyed in Rees (1993).

A second topic of interest to game-theoretic economists is general equilibrium in a *multilateral exchange economy*. An early paper (Arrow and Debreu 1954) modeled a general competitive exchange economy (involving production, exchange, and consumption) as a noncooperative game, and then showed that a generalized Nash equilibrium existed for the model. Other theorists have modeled a multilateral exchange economy as a cooperative n -person game. Shubik (1959) showed that the core of such a game is identical to Edgeworth's traditional contract curve. More generally, Debreu and Scarf (1963) showed that the core converges to the Walrasian competitive equilibrium. Telser (1996) discussed the core as a tool for finding market-clearing prices in economies with many inputs and outputs. Roth and Sotomayor (1990) discussed the matching problem in labor and marriage markets.

By representing an economy as an n -person cooperative game, analysts can investigate general equilibrium even in markets that do not fulfill the

neoclassical regularity assumptions (e.g., convexity of preferences, divisibility of commodities, absence of externalities) (Rosenthal 1971; Telser 1972). Beyond that, some economists model general equilibrium in game-theoretic terms because they can introduce and analyze a variety of alternative institutional arrangements. This includes, for instance, models with or without trade, with or without production, with various types of money (commodity money, fiat money, bank money, accounting money), and with various types of financial institutions (shares, central banks, bankruptcy rules, and the like) (Dagan et al. 1997; Dubey and Shubik 1977; Karatzas et al. 1997). Depending on the models used, such cooperative solutions as the core, Shapley value, and nucleolus play an important role in these analyses, as does the Nash noncooperative solution.

A third concern of game-theoretically oriented economists is the analysis of *public goods and services* (e.g., bridges, roads, dams, harbors, libraries, police services, public health services, and the like). Of special relevance is the pricing and cross-subsidization of public utilities; a central issue is how different classes of customers should divide the costs of providing public utilities.

Theorists can model such problems by letting the cost function of a public utility determine the characteristic function of a (cooperative) cost-sharing game. Games of this type are amenable to analysis via such solution concepts as the Shapley value (Loehman and Whinston 1974), the nucleolus (Littlechild and Vaidya 1976; Nakayama and Suzuki 1977), and the core (Littlechild and Thompson 1977), each of which represents alternative cost-sharing criteria. Moulin (1996) compared alternative cost-sharing mechanisms under increasing returns. Other work has used game-theoretic concepts to model negotiation with respect to provision of public goods (Dearden 1998; Schofield 1984a). A survey of experimental research on public goods appears in Ledyard (1995).

Political Institutions. Like economists, political scientists have analyzed a variety of institutions in game-theoretic terms. One broad line of work—termed the study of *social choice*—investigates various methods for aggregating individual preferences into collective decisions (Moulin 1994). Of special concern is the stability of outcomes produced by alternative *voting systems* (Hinich and Munger

1997; Nurmi 1987; Ordeshook 1986). Analysts have studied many different voting systems (e.g., majority voting, plurality voting, weighted voting, approval voting, and so on.) Strikingly, this work has demonstrated that in majority voting systems where voters choose among more than two alternatives, the conditions for equilibria (i.e., the conditions that assure a decisive winner) are so restrictive as to render equilibria virtually nonexistent (Fishburn 1973; Riker 1982).

Topics in voting include the detailed analysis of cyclic majority phenomena (generalized Condorcet paradox situations), the analysis of equilibria in novel voting systems such as weighted voting (Banzhaf 1965) and approval voting (i.e., a method of voting wherein voters may endorse as many candidates as they like in multicandidate elections) (Brams and Fishburn 1983), and the development of predictive solution concepts for voting systems that possess no stable equilibrium (Ferejohn and Grether 1982).

A second line of work by game theorists concerns the strategic manipulation of political institutions to gain favorable outcomes. One topic here is the consequences of manipulative *agenda control* in committees (Banks 1990; Plott and Levine 1978). Another topic is the effects of *strategic voting*—that is, voting in which players strive to manipulate the decision by voting for candidates or motions other than their real preferences (Cox and Shugart 1996; Feddersen and Pesendorfer 1998; Niemi and Frank 1982). Analyses by Gibbard (1973) and Satterthwaite (1975) showed that no voting procedure can be completely strategy-proof (in the sense of offering voters no incentive to vote strategically) without violating some more fundamental condition of democratic acceptability. In particular, any voting mechanism that is strategy-proof is also necessarily dictatorial. An important issue here is how to design voting systems with at least some desirable properties that encourage sincere revelation of preferences.

A third broad line of work concerns the *indexing of players' power* in political systems (Owen 1982, ch. 10). Frequently this entails assessing differences in a priori voting strength of members of committees or legislatures. For example, a classic study applied the Shapley–Shubik index of power to the U.S. legislative system and assessed the relative power of the president, senators, and

representatives (Shapley and Shubik 1954). Other measures of power include the Banzhaf–Coleman index (Banzhaf 1965; Dubey and Shapley 1979) and Straffin's probabilistic indices (Straffin 1978).

A fourth game-theoretic topic is *cabinet coalition formation*, especially in the context of European governments. This topic is of interest because political fragmentation can produce instability of cabinet coalitions, which in turn can lead to collapse of entire governments. Work on this problem ties in with that on spatial voting games and weighted majority games, discussed above. Some cabinet coalition models stress policy (or ideological) alignment among members, while other models stress the transfer of value (payoffs) among members. Important theoretical models include DeSwaan (1973), Grofman (1982), Laver and Shepsle (1996), and Schofield (1984b).

GENDER

Gender, race, ethnicity, and social class are the most commonly used categories in sociology. They represent the major social statuses that determine the life chances of individuals in heterogeneous societies, and together they form a hierarchy of access to property, power, and prestige.

Gender is the division of people into two categories, “men” and “women.” Through interaction with caretakers, socialization in childhood, peer pressure in adolescence, and gendered work and family roles, women and men are socially constructed to be different in behavior, attitudes, and emotions. The gendered social order is based on and maintains these differences.

In sociology, the main ordering principles of social life are called *institutions*. Gender is a social institution as encompassing as the four main institutions of traditional sociology—family, economy, religion, and symbolic language. Like these institutions, gender structures social life, patterns social roles, and provides individuals with identities and values. And just as the institutions of family, economy, religion, and language are intertwined and affect each other reciprocally, as a social institution, gender pervades kinship and family life, work roles and organizations, the rules of most religions, and the symbolism and meanings of language and other cultural representations of human life. The outcome is a gendered social order.

The source of gendered social orders lies in the evolution of human societies and their diversity in history. The gendered division of work has shifted with changing means of producing food and other goods, which in turn modifies patterns of child care and family structures. Gendered power imbalances, which are usually based on the ability to amass and distribute material resources, change with rules about property ownership and inheritance. Men’s domination of women has not been the same throughout time and place; rather, it varies with political, economic, and family structures, and is differently justified by religions and laws. As an underlying principle of how people are categorized and valued, gender is differently constructed throughout the world and has been throughout history. In societies with other major social divisions, such as race, ethnicity, religion,

and social class, gender is intricately intertwined with these other statuses.

As pervasive as gender is, it is important to remember that it is constructed and maintained through daily interaction and therefore can be resisted, reformed, and even rebelled against. The social construction perspective argues that people create their social realities and identities, including their gender, through their actions with others—their families, friends, colleagues. It also argues that their actions are hemmed in by the general rules of social life, by their culture’s expectations, their workplace’s and occupation’s norms, and their government’s laws. These social restraints are amenable to change—but not easily.

Gender is deeply rooted in every aspect of social life and social organization in Western-influenced societies. The Western world is a very gendered world, consisting of only two legal categories—“men” and “women.” Despite the variety of playful and serious attempts at blurring gender boundaries with androgynous dress and desegregating gender-typed jobs, third genders and gender neutrality are rare in Western societies. Those who cross gender boundaries by passing as a member of the opposite gender, or by sex-change surgery, want to be taken as a “normal” man or woman.

Although it is almost impossible to be anything but a “woman” or a “man,” a “girl” or a “boy” in Western societies, this does not mean that one cannot have three, four, five, or more socially recognized genders—there are societies that have at least three. Not all societies base gender categories on male and female bodies—Native Americans, for example, have biological males whose gender status is that of women. Some African societies have females with the gender status of sons or husbands. Others use age categories as organizing principles, not gender statuses. Even in Western societies, where there are only two genders, we can think about restructuring families and workplaces so they are not as rigidly gendered as they are today.

WHY GENDER AND NOT SEX

Gender was first conceptualized as distinct from sex in order to highlight the social and cultural processes that constructed different social roles

for females and males and that prescribed sex-appropriate behavior, demeanor, personality characteristics, and dress. However, *sex* and *gender* were often conflated and interchanged, to the extent that this early usage was called “sex roles” theory. More recently, gender has been conceptually separated from sex and also from sexuality.

Understanding gender practices and structures is easier if what is usually conflated as sex/gender or sex/sexuality/gender is split into three conceptually distinct categories—sex (or biology, physiology), sexuality (desire, sexual preference, sexual orientation, sexual behavior), and gender (social status, position in the social order, personal identity). Each is socially constructed but in different ways. Gender is an overarching category—a major social status that organizes almost all areas of social life. Therefore bodies and sexuality are gendered—biology and sexuality, in contrast, do not add up to gender.

Conceptually separating sex and gender makes it easier to explain how female and male bodies are socially constructed to be feminine and masculine through sports and in popular culture. In medicine, separating sex from gender helps to pinpoint how much of the differences in longevity and propensity to different illnesses is due to biology and how much to socially induced behavior, such as alcohol and drug abuse, which is higher among men than women. The outcome is a greater number of recorded illnesses but longer life expectancy for women of all races, ethnicities, and social classes when compared to men with the same social characteristics. This phenomenon is known in social epidemiology as “women get sicker, but men die quicker.”

SOCIAL CONSTRUCTION OF GENDER

As with any other aspect of social life, gender is shaped by an individual’s genetic heritage, physical body, and physiological development. Socially, however, gendering begins as soon as the sex of the fetus is identified. At birth, infants are placed in one of two sex categories, based on the appearance of the genitalia. In cases of ambiguity, since Western societies do not have a third gender for hermaphrodites as some cultures do, the genitalia are now “clarified” surgically, so that the child can be categorized as a boy or a girl. Gendering then

takes place through interaction with parents and other family members, teachers, and peers (“significant others”). Through socialization and gendered personality development, the child develops a gendered identity that, in most cases, reproduces the values, attitudes, and behavior that the child’s social milieu deems appropriate for a girl or a boy.

Borrowing from Freudian psychoanalytic theory, Nancy Chodorow developed an influential argument for the gendering of personalities in the two-parent, heterogendered nuclear family. Because women are the primary parents, infants bond with them. Boys have to separate from their mothers and identify with their fathers in order to establish their masculinity. They thus develop strong ego boundaries and a capacity for the independent action, objectivity, and rational thinking so valued in Western culture. Women are a threat to their independence and masculine sexuality because they remind men of their dependence on their mothers. However, men need women for the emotional sustenance and intimacy they rarely give each other. Their ambivalence toward women comes out in heterosexual love–hate relationships and in misogynistic depictions of women in popular culture and in novels, plays, and operas.

Girls continue to identify with their mothers, and so they grow up with fluid ego boundaries that make them sensitive, empathic, and emotional. It is these qualities that make them potentially good mothers and keep them open to men’s emotional needs. But because the men in their lives have developed personalities that make them emotionally guarded, women want to have children to bond with. Thus, psychological gendering of children is continually reproduced.

To develop nurturing capabilities in men and to break the cycle of the reproduction of gendered personality structures would, according to this theory, take fully shared parenting. There is little data on whether the same psychic processes produce similarly gendered personalities in single-parent families, in households where both parents are the same gender, or in differently structured families in non-Western cultures.

Children are also gendered at school, in the classroom, where boys and girls are often treated differently by teachers. Boys are encouraged to develop their math abilities and science interests; girls are steered toward the humanities and social

sciences. The result is that women students in the United States outnumber men students in college, but only in the liberal arts; in science programs, men still outnumber women. Men also predominate in enrollment in the elite colleges, which prepare for high-level careers in finance, the professions, and government.

This data on gender imbalance, however, when broken down by race, ethnicity, and social class, is more complex. In the United States, upper- and middle-class boys are pushed ahead of girls in school and do better on standardized tests, although girls of all social statuses get better grades than boys. African-American, Hispanic, and white working-class and poor boys do particularly badly, partly because of a peer culture that denigrates “book learning” and rewards defiance and risk taking. In the context of an unresponsive educational structure, discouraged teachers, and crowded, poorly maintained school buildings, the pedagogical needs of marginal students do not get enough attention; they are also much more likely to be treated as discipline problems.

Children’s peer culture is another site of gender construction. On playgrounds, girls and boys divide up into separate groups whose borders are defended against opposite-gender intruders. Within the group, girls tend to be more cooperative and play people-based games. Boys tend to play rule-based games that are competitive. These tendencies have been observed in Western societies; anthropological data about children’s socialization shows different patterns of gendering. Everywhere, children’s gender socialization is closely attuned to expected adult behavior.

GENDER AND WORK

Whether they have fully internalized Western society’s gender binarism and social construction of gender differences or rebelled against gender typing, adults encounter a gendered work world. The workplaces in industrialized societies are either gender-segregated or composed of all one gender. During the 1970s and 1980s, decades in which women were thought to have made inroads into many occupations previously dominated by men in the United States, about 6 percent of occupations saw an increase of women workers that was significantly greater than the increase of women

overall in the paid labor force during that period. Rather than desegregating occupations, most of the new women workers went into occupations where most of the employees were women, and those who went into occupations where the employees were predominantly men soon found that their coworkers became predominantly women. Some U.S. occupations that went from having a predominance of workers who were men to mostly women workers were personnel, training, and labor relations specialists; computer operators; and insurance adjusters, examiners, and investigators. These occupations had *resegregated*. When women and men work in nontraditional occupations, gender typing is often maintained symbolically, as when policewomen view their work as social work and men nurses emphasize the technical and physical strength aspects of what they do.

The processes that sort women and men of different racial and ethnic groups into different types of work include a matching of ranked workers and jobs, or *queues* of workers and jobs. Workers are ranked by employers from their first picks to their last. Jobs are ranked by workers similarly. Lower-ranked workers get the chance to move into better jobs than they have held in the past when these jobs are abandoned by favored workers or there are too few of these workers to go around, such as in wartime. The process works the other way, too; when there are too few of the best jobs for the preferred workers, as in a recession, only the best qualified or experienced among them will be hired; those with fewer credentials and less seniority move down the queue, bumping out lower-ranked workers. When workers are moving up, the most preferred on the basis of race, ethnicity, and gender usually get the better jobs. If gender segregation is so rigid that men will not apply or be hired for “women’s work,” when manufacturing jobs decline or are taken elsewhere, women in service, sales, and clerical work may continue to work as men’s unemployment rates rise.

Workers rank jobs on the basis of payoff for education and experience in salaries and also in fringe benefits, prestige, autonomy, security, and chances of promotion. For some workers, having any job may be an improvement over economic dependency. Employers’ preferences for workers, however, are not so uniform. Some will rank gender and race above qualifications; others will choose the most highly qualified of the preferred race and

gender and then go down the line, looking for the most qualified each time. Another variable employers factor in is the going pay scale for the workers they want; they may have to settle for less preferred workers to see more of a profit or sacrifice some profits to avoid protests from highly paid entrenched workers.

Although worker demographics, industry growth, and employer preferences produce changes in occupational gender composition, the main factor that redistributes workers of different races and genders is change in the structure of the work process and in the quality of particular jobs within occupations, which can be manipulated by employers. That is, jobs can be automated and deskilled or made part time or home based to justify reducing labor costs, with a few better-paid workers retained in supervisory positions.

During shifts of labor queues up and down the job ladder, the potential for conflict between women and men as well as between members of dominant and subordinated racial and ethnic groups is high. Dominant men want to perpetuate the work conditions that justify their high pay; employers who want to reduce their labor costs degrade the work process so they can hire cheaper labor, and then these new workers are accused of depressing the job's qualifications and skills. Gender segregation of jobs is historically the way employers have kept their men workers satisfied, while expanding the number of cheaper women workers. Such job divisions undercut unions that want to organize women and demand the same pay for them as similarly situated men workers. In a growing or stable job market, dominant men are much less resistant to incoming new types of workers, since they do not see them as competition. In those cases, the job may come closer to being integrated along lines of gender and race.

Occupational gender segregation does not result in separate but equal jobs. Rather, women's work tends to be lower in pay, prestige, and fringe benefits, such as health insurance. Workers themselves rate jobs where most of the employees are women as inferior to jobs where most of the employees are men. The criteria are number and flexibility of hours, earnings, educational requirements, on-the-job training, having a union contract, extent of supervision and place in the hierarchy, repetitiveness, risk of job loss, and being a

government employee. Workers rate women's jobs as better in vacation days and not getting dirty at work, even though changing bedpans is as "dirty" as changing oil pans. If wages were used to compensate for unattractive nonmonetary job characteristics, women's jobs would have to pay four times as much as men's jobs for workers to rate them equally. Nor is there a trade-off of pay for compatibility with child care—most full-time jobs held by mothers are incompatible with parenting demands; flexibility of schedules and control and timing of work-related tasks are the prerogatives of men managers, not their women secretaries.

The best-paid jobs are shaped on an ideal, dominant man's career—long-term, continuous work in the same occupation, with steady pay raises and a pension at retirement. Men's gender status is an advantage to them as workers; they are expected to earn more money when they marry and when they have children, so employers tend to view them as better workers than women. Women workers are felt to be entitled only to supplementary wages, whether they are married or single, because they are not considered legitimate workers but primarily wives and mothers. In actuality, research has shown that married women with children work harder and are more productive than married men with children.

The structured patterns of opportunities and access far override most individual employers' tastes or individual workers' motivations, ambitions, personal desires, and material needs. By the 1970s in the United States, adolescent girls were considerably less likely than in previous years to plan on entering an occupation in which most of the workers were women, especially if they lived in a woman-headed household. But they continued to value working with people, helping others, using their abilities, and being creative; boys wanted jobs with status, high earnings, freedom from supervision, and leadership potential. The jobs women are likely to end up in are more gender typed and less fulfilling than their occupational aspirations, but ambitious and hard-working men can often reach their early goals.

Women of all educational levels and men disadvantaged because of race, immigrant status, lack of education, or outmoded job skills are profitable workers because they tend to receive low wages; they also get promoted less frequently and

therefore receive fewer raises. Many work part time and get no benefits. They can be paid little because the pool of such workers is larger than that of privileged men workers. The size and social characteristics of the pool of low-waged workers are affected by state policies encouraging or discouraging the employment of women, the influx of immigrants, and the flight of capital from one area of a country to another or offshore.

Other processes that segregate and stratify occupations are *segmentation* and *ghettoization*. Segmented occupations are horizontally or vertically divided into sectors with different educational or credential requirements for hiring, different promotion ladders, different work assignments, and different pay scales. Typically, these segments are gendered and frequently also exhibit racial and ethnic clustering. However, occupations in which almost all the workers are of one gender can also be segmented. For instance, in the United States, doctors and nurses are gender-segregated segments in hospitals. Physicians are segmented between those in primary care and those who are hospital-based specialists, who have more prestige and power and higher incomes. Women physicians are often found in primary care. Nursing is also segmented into registered nurses, licensed practical nurses, nurses' aides, and home health workers. Nurses are virtually all women, but the segments are racially differentiated: The majority of registered nurses tend to be white or Asian-American; most of the lower-paid health workers tend to be black or Hispanic. Men who go into nursing tend to specialize in the more lucrative specializations and become administrators.

Segmentation is legitimized by bureaucratic rules or legal requirements for qualifying credentials, but ghettoization separates the lower-paid "women's" jobs from the better-paid "men's" jobs within an occupation through informal gender typing. What is dubbed "women's work" or "men's work" has a sense of normality and naturalness, an almost moral quality, even though the justification for such typing is usually an after-the-fact rationalization. The assumption is that the skills, competence, strength, and other qualities needed to do a job are tied up with masculinity and femininity, but gendered identities as workers are constructed in the gendered organization of the workplace and reinforced in training and organizational sociability, such as company golf games and sports teams.

Within gender-typed occupations, jobs or specialties may be gender typed in the opposite direction. For example, the majority of physicians are men in the United States and women in Russia, but the same specialties are seen as appropriate for one gender—pediatrics for women and neurosurgery for men. In both countries, neurosurgery pays better and has more prestige than pediatrics.

Both structural segmentation and gender typing that puts some jobs into a low-wage ghetto have the same results. They limit the extent of competition for the better positions, make it easier for privileged workers to justify their advantageous salary scales, and create a group of workers whose lack of credentials or requisite skills legitimate their lower pay. Credentials and skills, however, as well as experience, are manipulated or circumvented to favor workers with certain social characteristics, as when men with less lower-rank experience in women's jobs are hired as supervisors. In addition, femaleness and maleness are stereotypically linked to certain capabilities, such as finger dexterity and physical strength; gender then becomes the discriminant criterion for hiring, not what potential employees can actually do with their hands, backs, and heads.

Promotion ladders are also gender segregated. Women and men who are not of the dominant racial or ethnic group tend not to rise to the top in their work organization, unless practically all the workers are women or men of the same racial or ethnic group. White men tend to dominate positions of authority whether or not they are numerically predominant. This pattern is known as the *glass ceiling*—the lid on women's rise to the top of their work organizations. In occupations where the majority of the workers are women, positions of authority tend to be held by men—elementary school teachers are predominantly women in the United States, but principals and superintendents are predominantly men. That is, token men in a woman's occupation tend to be promoted faster than the women workers. This parallel phenomenon has been dubbed the *glass escalator*.

These pervasive patterns of occupational segregation and stratification are the result of deliberate actions and also inaction on the part of governments, owners and managers, and organized groups of workers—and change has to come from the same sources. Since gender segregation involves

occupations and professions, job titles, and specific work sites, integration has to involve more than simply increasing the numbers of women. True occupational gender equality would mean that women and men would have the same opportunities to obtain professional credentials and occupational training, and would be distributed in the same proportions as they are in the paid work force across workplaces, job titles, occupations, and hierarchical positions. Instead, in most industrialized countries, women are overrepresented in clerical and service jobs, low-prestige professional and technical work, and sales. In developing countries, and in areas of industrialized countries where there are concentrations of poor people and recent immigrants, women tend to be concentrated in labor-intensive factory work, agriculture, and the informal (off-the-books) economy.

This gendered organization of paid labor dovetails with the gendered organization of domestic labor. Low pay, uninteresting jobs, and the glass ceiling encourage single women to marry and married women to devote energy and attention to child rearing and domestic work. The job market encourages women to be a reserve army of labor—available for full-time work in times of scarce labor, but fired or put on part-time schedules when there is less work. Better job opportunities are offered to men of the dominant racial and ethnic groups to encourage them to give their all to the job. Employers (mostly men) benefit from women's cheap labor and men's need to earn more to support a family; men who live with women benefit from women's unpaid labor at home. Highly educated and professional women are caught in the structural conflicts of these two forms of labor; in order to compete with the men of their status, they have to hire "wives"—other women to do their domestic work. This pool of paid domestic labor historically is made up of the least advantaged women—native poor and recent immigrants of a variety of racial and ethnic groups.

GENDER INEQUALITY

Gender inequality takes many different forms, depending on the economic structure and social organization of a particular society and on the culture of any particular group within that society. Although we speak of *gender* inequality, it is usually women who are disadvantaged when compared to

similarly situated men. In the job market, women often receive lower pay for the same or comparable work and are frequently blocked in their chances for advancement, especially to top positions. There is usually an imbalance in the amount of housework and child care a wife does compared to her husband, even when both spend the same amount of time in waged work outside the home. When women professionals are matched with men of comparable productiveness, men get greater recognition for their work and move up career ladders faster. On an overall basis, work most often done by women, such as teaching small children and nursing, is paid less than work most often done by men, such as computer programming and engineering. Gender inequality also takes the form of girls getting less education than boys of the same social class. It often means an unequal distribution of health care services between women and men, and research priorities that focus on diseases men are more likely to get than women.

Gender inequality takes even more oppressive and exploitative forms. Throughout the world, women are vulnerable to beatings, rape, and murder—often by their husbands or boyfriends, and especially when they try to leave an abusive relationship. The bodies of girls and women are used in sex work—pornography and prostitution. They undergo cosmetic surgery and are on display in movies, television, and advertising in Western cultures. In other cultures, their genitals are mutilated and their bodies are covered from head to toe in the name of chastity. They may be forced to bear children they do not want or have abortions or be sterilized against their will. In countries with overpopulation, infant girls are much more often abandoned in orphanages than infant boys. In cultural groups that value boys over girls, if the sex of the fetus can be determined, it is girls who are aborted.

Gender inequality can also disadvantage men. In many countries, only men serve in the armed forces, and in most countries, only men are sent into direct combat. It is mostly men who do the more dangerous work, such as firefighting and policing. Although women have fought in wars and are entering police forces and fire departments, the gender arrangements of most societies assume that women will do the work of bearing and caring for children, while men do the work of protecting them and supporting them economically.

Most women in industrial and postindustrial societies do not spend their lives having and caring for babies, and most women throughout the world do paid and unpaid work to supply their families with food, clothing, and shelter, even while they are taking care of children. The modern forms of gender inequality are not a complementary exchange of responsibilities, but a social system within which women are exploitable. In a succinct summary of gender inequality, it was estimated by a United Nations report in 1980 that women do two-thirds of the world's work, receive 10 percent of the world's income, and own 1 percent of the world's property.

The major social and cultural institutions support this system of gender inequality. Religions legitimate the social arrangements that produce it, justifying them as right and proper. Laws support the status quo and also often make it impossible to redress the outcomes—to prosecute husbands for beating their wives, or boyfriends for raping their girlfriends. In the arts, women's productions are so often ignored that they are virtually invisible, which led Virginia Woolf to conclude that *Anon* must have been a woman. Much scientific research assumes that differences between women and men are genetic or hormonal and looks for data to support these beliefs, ignoring findings that show gender overlaps or input from the social environment. In the social sciences, gender is entered into research designs only as a binary, erasing the effects of racial, social class, and ethnic variations.

Except for the Scandinavian countries, which have the greatest participation of women in government and the most gender-equal laws and state policies, most governments are run by socially dominant men, and their policies reflect their interests. In every period of change, including those of revolutionary upheaval, men's interests, not women's, have prevailed, and many men, but few women, have benefited from progressive social policies. Equality and justice for all usually means for men only. Women have never had their revolution because the structure of gender as a social institution has never been seriously challenged. Therefore, all men benefit from the "patriarchal dividend"—women's unpaid work maintaining homes and bringing up children; women's low-paid work servicing hospitals, schools, and myriad other workplaces.

Gender inequality is deeply ingrained in the structure of Western, industrialized societies. It is built into the organization of marriage and families, work and the economy, politics, religion, sports, the arts and other cultural productions, and the very language we speak. Making women and men equal, therefore, necessitates social, not individual, solutions.

CHANGING GENDER

Changing a gendered society entails structural and institutional change. Attitudes and values must change, too, but these are often altered when social policies and practices shift. Which changes have occurred since the beginning of the feminist movement of the early 1970s and which have not? What kind of programs target institutions and social structures? What is still needed for gender equality?

Affirmative action and comparable worth pay scales were two efforts to effect structural change—one to desegregate occupations and the other to distribute economic rewards for work on a gender-neutral basis. Affirmative action (hiring women in occupations dominated by men and men for work usually done by women) was widely implemented in the United States and did desegregate some occupations, but without continuous effort, gender segregation reestablishes itself as jobs and work organizations change. Another effort to establish gender-neutral work policies was comparable worth pay scales—assessing the characteristics of the job and paying on the basis of type of work done, not on who does the work. These programs were not widely implemented; women's work continues to be paid less than men's even when a man does the work. Women have entered the professions, especially medicine and the law, in large numbers and have moved up career ladders, but in most large-scale corporations and professional organizations, the top positions of authority are still held by men.

Sexual harassment guidelines have been another effective effort at changing thinking about acceptable behavior, and again, while the results are imperfect (and the guidelines are being used in ways that do not empower women), thinking about what was "normal" behavior in the workplace did change drastically.

In Europe, but not in the United States, subsidized parental leave for either parent and child care for every mother has changed mothering from a full-time occupation to something that can be combined with paid work out of the home without a constant struggle. The Scandinavian countries provide “daddy days”—leave time in the first year of a newborn’s life that the father must take or it is forfeited.

A radical effort at restructuring government has taken place in France—a proposed program for mandating equal numbers of women and men representatives at the national level of government. Parity is not likely to become a widespread policy, but even redressing gender imbalance would give women and men a more equal opportunity to make laws and influence social policy. Gender differences in voting patterns in the United States indicate that women do have a different perspective on many issues. For women to be elected in greater numbers, powerful men now in politics would have to encourage young women to consider a career in politics, foster their advancement through mentoring, nominate them for national offices, and campaign with them and raise money for them when they run for office. Paradoxically, it has seemed easier for women to become heads of state than for these same states to vote in an equal number of women and men in their governing bodies. It has also been easier for women to become heads of parliamentary governments, where a party chooses the prime minister. The appointment of women to high positions, such as Madeleine Albright as U.S. Secretary of State, has also been welcomed. Yet when it comes to directly putting women into leadership positions of great authority, whether in government or in major corporations, there is still a public reluctance to grant women as much power as men.

On a more personal level, some people have structured their families to be gender-equal on every level—domestic work, child care, and financial contribution to the household economy. However, as long as work is structured for a married-man-with-wife career pattern, and men’s work is paid better than women’s work, gender-equal families will be very hard to attain by the majority of people. Other heterosexual couples have reversed roles—the woman is the breadwinner and the man cares for the children and keeps house. Here, the problem is that the domestic world is so gendered

that male househusbands suffer from ostracism and isolation, as well as from a suspicion of homosexuality. Oddly, lesbian and gay couples who have reared children in a variety of family arrangements have blended more easily into hetero-coupled social worlds, at least in some communities. Corporate and government policies that offer health insurance and other benefits to any couple in a long-term household arrangement have also helped to restructure family life in ways that do not assume heterosexuality and marriage. Note, however, that communal domestic households have waned in popularity in Western countries, although they are the norm in polygamous cultures.

Least amenable to change have been the gendered divisions of work in the global economy. Financed by capital from developed countries, work organizations around the world exploit the labor of young, unmarried women under sweatshop-like conditions, while reserving better-paid jobs and support for entrepreneurship to men. The policies of the International Monetary Fund and other financial restructuring agencies do not include among their goals gender desegregation or encouraging women’s education and access to health resources. In many developing countries, violence and sexual exploitation, as well as the heterosexual spread of AIDS, seriously undermine efforts to upgrade the lives of women and girls.

In sum, to change gendered social orders to be more equal (or, alternatively, less gendered) will take individual effort and modification of gender-stereotyped attitudes and values, but most of all, a restructuring of work and family through the policies and practices of large-scale corporations and the governments of dominant nations.

JUDITH LORBER

GENERAL LINEAR MODEL

See Analysis of Variance and Covariance; Causal and Inference Models; Correlation and Regression Analysis.

GENOCIDE

When, in 1881, the German anti-Semite Dühring urged a "final settling of accounts" with the Jews, he spoke, rather obliquely, of the need for a "Carthaginian" solution (p. 113f.). This was not merely a euphemism, however, as it might now seem. On the contrary, it was well known that Rome had utterly destroyed Carthage in the last Punic War. Hence Dühring's meaning was clear. But his phrasing remained cryptic because the vocabulary of mass death had not yet attained technical precision. Not until World War II, in fact, were the terms "genocide" and "crimes against humanity" introduced. Thus, in December 1948, when the United Nations declared the willful destruction of an entire people to be a breach of international law—a principle enshrined in the U.N. Convention for the Prevention and Punishment of the Crime of Genocide—the very word for mass murder was still novel.

CONCEPTUAL ROOTS

The word "genocide" was coined by the jurist Raphaël Lemkin in his book *Axis Rule in Occupied Europe*. "New conceptions require new terms," Lemkin wrote. "By 'genocide,' we mean the destruction of a nation or . . . ethnic group"—that is, "murder, though on a vastly greater scale" (1944, pp. 79, 91).

Mass murder, of course, is hardly new. But only since the French Revolution has there been widespread concern with what the philosopher Hegel called "the fanaticism of destruction," which

aims, Hegel said, to eliminate all enemies, real or imagined ([1821] 1991, p. 38). An early expression of this concern came from Gracchus Babeuf, the leading socialist in the French Revolution, who decried the "exterminating wheel" of Robespierre's Terror. Robespierre's "general system of government," Babeuf contended, is also a "general system of extermination" ([1794] 1987, pp. 96–98). In a similar spirit, the liberal poet August von Platen deplored the Russian repression of the Polish revolution of 1831 as an instance of "*Volksmorder*" (Jonassohn 1998, p. 140). Others later made similar charges. But it was not until the Nazi Holocaust that the international community felt the need to adopt a special term for the attempted murder of a people.

In 1945, soon after Lemkin's book appeared, the defeated Nazi rulers were charged with "deliberate and systematic genocide." A year later the United Nations ratified a working definition of genocide as the "denial of the right of existence of entire human groups" (Kuper 1981, pp. 22–23). Lemkin's new coinage had won swift acceptance. Since then, it has become universally popular—and equally controversial.

GLOBAL VIOLENCE

The popularity of the idea of genocide reflects its continuing relevance in today's world. Globally, there were at least forty-four state-organized mass slaughters in the period from 1945 to 1989, many of which were quasi-genocidal by almost any definition. These massacres resulted in an average of 1.6 million to 3.9 million deaths per annum—significantly more, that is, than the total number of fatalities caused by all wars and natural disasters in this period. And in every decade since 1945 another 1.85 million people have died in wars and civil wars (Gurr and Harff 1989). Nor has the picture improved since 1989. In 1993, for example, there were twenty-three wars, 25 million refugees, and a record number of armed U.N. interventions in conflicts around the world (Gurr and Harff 1994). In 1994, a genocidal massacre in Rwanda caused roughly 850,000 deaths (Smith 1998). Elsewhere—in Burundi, east Timor, and myriad other places—similar if smaller tragedies have unfolded.

Many groups, in other words, have been victims of systematic violence in the recent past, and

allegations of genocide abound. Yet the concept itself remains elusive—partly, indeed, thanks to its own success. So many people now equate genocide with evil that nearly every conflict is marked by charges and countercharges of genocide. Abortion, birth control, forced sterilization, intermarriage, and desegregation are just a few of the countless practices that have been labeled genocidal. Almost anything controversial, it seems, can be called genocide.

For social scientists, plainly, the matter is more complex. This was clear from the outset in Lemkin's work, which remains paradigmatic in many ways.

TOTAL WAR

Sociologically, Lemkin believed that the Holocaust was not a contingent feature of German Nazism but rather an expression of intrinsic Nazi tendencies. As an absolutist form of nationalism, Nazism claimed absolute sovereignty over non-Germans on the ground of purported German racial-national superiority. This, in turn, led to a Nazi conception of war as Total War—the conviction, that is, that wars are not merely struggles between states but rather inevitable racial contests between peoples, with total victory or defeat as the ultimate outcomes. And the Nazi repudiation of universalist ethics inspired the belief that, in Total War, enemy peoples may be totally destroyed without ethical qualms.

Genocide was not, however, the entire Nazi agenda. On the contrary, in Lemkin's view, genocide was a single part of a many-sided strategy. The ultimate Nazi goal was to build a German empire, and in pursuing this goal only certain types of enemies were slated for annihilation: Jews, who were seen as the poisonous racial antithesis of everything German; so-called Gypsies, who were regarded as racially inferior pests; and a variety of others (including democratic intellectuals, Marxists, and resistance fighters) whom the Nazis saw as irreconcilable political foes. Enemies of other kinds, however, were to be ruled rather than massacred. Some, indeed, were to be incorporated into the Nazi empire as lesser "Germanic" peoples (including the Dutch, Flemings, and Scandinavians). Others, including Russians, Serbs, and Poles, were to be enslaved and reduced in numbers (by limits on

birthrates, food rationing, etc.) but were not to be liquidated *per se*.

AN AGE OF ABSOLUTES

For Lemkin, that is, genocide was a strand in the fabric of Nazi war aims. And though the genocidal aspect of Nazi policy had historical precedents, it was also uniquely modern in many ways. Neither of the two pillars of the Holocaust ("master-race mythology and aggressive technology") could be grasped apart from specifically modern forces, including science and industry, nationalism, racism, and statism. Nor could modern German militarism be equated with the warrior ethics of times past. Other peoples had periodically committed mass murder, but German militarism had risen to new heights of virulence, driven, Lemkin concluded, by an acute "national and racial emotionalism" that was given a uniquely destructive force by modern technology (1944, p. xiv).

The consequence, as the sociologist Jessie Bernard noted shortly after the war ended (1949, p. 652), is that "ethnic conflict in our day has taken an unexpectedly brutal turn," even reaching the level of "exterminating whole peoples—genocide." Previous conflicts, however brutal, now seemed relatively small and unsystematic by comparison.

VARIETIES OF GENOCIDE

This is not to say, however, that genocide is entirely unique to modernity. In recent decades, sociologists have tended to agree that the willful destruction of entire peoples is, in fact, an ancient practice, common to many cultures. But it is also widely accepted that mass murder has assumed new forms in the twentieth century (as Lemkin said). This change is not merely quantitative but qualitative, and it is often framed in terms of a contrast between two ideal-types: (1) *instrumental genocide*, or mass murder to achieve pragmatic goals; and (2) *ideological genocide*, or mass murder as an end in itself.

Save for a relatively small proportion of cases that prefigure contemporary trends (e.g., wars of religion like the Crusades), most premodern genocides were essentially instrumental in nature. Modern genocides, in contrast, are often said to be largely if not primarily ideological—though instrumental motives remain powerful as well.

THE ORIGIN OF MASS MURDER

Many scholars, like Kurt Jonassohn, believe that genocides have occurred “throughout history in all parts of the world” (Jonassohn 1988, in Chalk and Jonassohn 1990, p. 415). Leo Kuper, in a classic study, called genocide “an odious scourge which has inflicted great losses on humanity in all periods of history” (1981, p. 11). Sociobiologists, meanwhile, have been even bolder, claiming that genocide is not only universal for humanity but for our closest evolutionary relatives as well (including chimpanzees and our evolutionary ancestors; cf. Diamond 1991, p. 264). E. O. Wilson, the founder of sociobiology, has speculated that genocide may be a “primitive cultural capacity,” rooted in “the possession of certain genes,” that confers a selective advantage on predatory groups that wish to spread their genes at the expense of their neighbors (1980, p. 298).

In reality, however, there is very little evidence of anything like genocidal violence in the evolutionary or historical record until comparatively recently. Sociobiologists who defend the idea that people and chimps share “a continuous, 5-million-year habit of lethal aggression” have offered, as their best evidence, the testimony of witnesses who report that, in more than 100 years of observation at four sites, seven chimps were assaulted by groups from neighboring chimp communities; and though none of the victims were killed on the spot, several later died or disappeared (Wrangham and Peterson 1996, pp. 16–21, 63).

This, it seems plain, is slight evidence for the large claim that people and their relatives and ancestors are genocidal by nature. Little else in the ethological or evolutionary record seems to lend credibility to this claim. Nor does history before the discovery of agriculture show significant evidence of mass murder.

To date, the earliest known evidence of collective violence is a gravesite in the Nile Valley containing fifty-nine men, women, and children, most of whom were killed by weapons with projectile points. This massacre, dating back 12,000–14,000 years, was “almost certainly” a consequence of disruptions produced by a crisis in the proto-agricultural system that was evolving in the region (Reader 1998, p. 146). The only other authenticated evidence of mass violence in remote antiquity is

a similar but smaller burial ground in Bavaria dating back 7,700 years (Frayser 1997).

PLOUGHSHARES INTO SWORDS

In general, archaeological evidence makes it clear that wars, massacres, and even murders were comparatively rare in pre-agricultural days (Ferguson 1997). And the ethnographic evidence shows that, while hunter-gatherers are seldom entirely non-violent, they have significantly fewer wars, internal conflicts, and interpersonal violence than agrarian peoples (Ember and Ember 1997; Ross 1993). Even the famously “fierce” Yamomami of northern Brazil and Venezuela seem to have been driven to violence as much by the influence of outside forces as by internal pressures (Ferguson 1992). “It seems unlikely,” as the genocide scholars Chalk and Jonassohn conclude, “that early man engaged in genocide during the hunting and gathering stage” (1990, p. 32).

For some peoples, this stage lasted until the recent past. For humanity as a whole, hunting and foraging remained universal until roughly 11,000 years ago. Shortly afterwards, agriculture arose in the Middle East; and then, in succession, in China 11,000 years ago in Papua, Mexico, and the Andes 10,000 years ago in West Africa 6,000 years ago and elsewhere.

Once agriculture had appeared, mass violence assumed new dimensions.

EMPIRE AND TERROR

The first weapons of war, and the earliest signs of mass warfare, appeared at the dawn of the agrarian era. In the ensuing millenia the first true wars were fought (Ferrill 1997, pp. 18–19). The intent of these wars was usually instrumental—to win land and labor, to keep enemies at bay, to build states and empires. This was the context in which mass violence became familiar. Genocide in particular was almost always linked to empire building in this period.

Historically, empire builders generally seek tribute or servile labor from the peoples they conquer, which leads them to spare the lives of noncombatants, especially peasants. This was the

spirit in which Sumerian, Hittite, and Babylonian epics of remote antiquity warned of the folly of genocide (Cohn 1996). But as fortified cities emerged as obstacles in the path of empire, conquest sometimes took more brutal forms. And peasant resistance often provoked vengeful repression. Hence, by the third millennium B.C.E., genocidal conquests had become comparatively common in the early Egyptian empire (Jonassohn 1998). Elsewhere, genocidal massacres seem to have become common by the first millennium B.C.E.

The Assyrians in particular became legendary for their merciless assaults on fortified cities, including Babylon, which Sennacherib decimated in 689 B.C.E. The goal of such assaults was usually to destroy an imperial or commercial rival. The preferred method was to lay siege to a city and starve its citizens into submission by burning crops and destroying livestock. Once a campaign of this kind triumphed, the conquerors would often raze the defeated city, salt the earth, and slaughter the citizens. The legalistic Romans dubbed this practice "devastation."

Early "devastations" included the destruction of Melos by Athens in 416 B.C.E. (for refusing to take sides in the Peloponnesian Wars); the destruction of two Sicilian cities by Carthage in 409 B.C.E.; and the annihilation of Carthage by Rome in 146 B.C.E. In the latter case, as many as 150,000 people are said to have died.

THE CONTINUATION OF WAR BY OTHER MEANS

Sociologists have identified a range of motives for instrumental genocide. Chalk and Jonassohn, for example, say that most genocides of this type (which they call "utilitarian") have been prompted by the wish to acquire wealth, to terrorize real or potential enemies, or to avert threats (1990, pp. 34-36). Until comparatively recently, motives of this kind have been the main effective spurs to genocide both in the circum-Mediterranean world and elsewhere. In brief, it seems that whenever empires fight, great opportunities and equally great dangers are at stake. In such cases, genocidal massacres can become the extraordinary means of attaining goals that, in other contexts, would be pursued by ordinary statecraft.

Examples abound. Canton was gutted in 879 C.E. and its population was decimated. In the twelfth century C.E., Afghan conquerors from Ghur destroyed the city of Ghazni and all its men. In the next century the Mongols laid waste to Transoxania and Khurasan, evidently killing hundreds of thousands of people. Not long afterwards, all 12,000 of the Meos people (south of Delhi) were killed in the wake of a failed uprising. Many events in the sixteenth-century Spanish conquest of the Americas were plainly genocidal. And many other examples of this kind can be cited as well (Chalk and Jonassohn 1990; Jonassohn, 1998).

A related form of genocide accompanied the rise of modern colonialism. In the Americas, for example, the English Puritans liquidated the Pequot in 1637, the French destroyed the Natchez in 1731, and Argentine settlers virtually eliminated the Araucanians in 1878-1885. In Africa, many peoples have been devastated by colonial conquests; some (including the Herero of Namibia and the Matumbi of Tanzania) have suffered mass destruction. Many indigenous peoples in Australia have been destroyed, and in Tasmania the entire aboriginal population was extinguished by 1876.

These are just a few of the many cases in which genocide has accompanied instrumental conquest.

IDEOLOGICAL GENOCIDE

In some cases, however, genocide is not an instrumental means to an end, but rather an end in itself. Genocides of this type, in which the destruction of entire peoples is sought for intrinsic reasons, are generally classified as "ideological" (Fein 1993; Smith 1987). These massacres, which are typically fueled by religious or ethnoracial fanaticism, are often among the deadliest of genocides, since they seek to destroy targeted peoples for reasons of "principle," not simply expediency. And they are often instrumentally irrational in an almost chemically pure sense. In 1994, for example, the rulers of Rwanda were so preoccupied by the wish to annihilate an unarmed ethnic minority that they left themselves virtually defenseless against an army of invading rebels from Uganda (Des Forges 1999). Between 1975 and 1979, the Pol Pot regime wrought havoc across the length and breadth of Cambodia in a vain effort to purge Cambodia of every trace of foreign, urban, and intellectual influence (Kiernan

1996). In the Nazi Holocaust, the German leaders diverted vital resources from the Russian front to fuel the militarily useless operations of the death camps (Postone 1980). Earlier, during World War I, Turkey failed to finish the strategically crucial Berlin–Bagdad railway largely because the Turkish rulers were so intent on destroying the Armenians that they liquidated large numbers of Armenian construction workers (Jonassohn 1998).

Genocides of this type are thus doubly destructive—first, because they are prosecuted with systematic ruthlessness; and second, because they often hurt the perpetrators as well as the victims.

BEFORE IDEOLOGY?

Only a few instances of premodern mass violence are clearly ideological in inspiration—including, for example, the Crusades and the persecution of Cathar heretics in thirteenth-century Languedoc. But many other early cases also reveal a noninstrumental side.

Beginning in 1634, for example, the Iroquois fought a series of “mourning wars” against the Hurons, which resulted in large-scale massacres of Huron men and women. The main object, in this case, was to “requicken,” in the bodies of Huron children, the spirits of Iroquois who had died in epidemics. This was perhaps not an “ideological” motive in the modern sense, but it was clearly inspired by religious belief (Richter 1992). Similarly, the genocidal massacres that accompanied the Mongol conquests were fueled, in part, by apocalyptic faith in Mongol destiny (Jagchid and Hyer 1979). And several Indian cases recorded by Jonassohn (1998) were largely religious in character—for example, the massacre of Jains by the Hindu king of Pandya in the eleventh century C.E., the destruction of the Buddhist majority of Bihar by Muslim conquerors in the twelfth century C.E., and the persistent efforts of Bahmani sultans to exterminate or convert Hindus in the Deccan region in the period 1347–1482 C.E.

Broadly defined, in other words, ideological genocide may have been more common in the past than scholars have tended to say. But it is nonetheless plain that the twentieth century marked a new departure. Only in this century did mass murder routinely followed paths defined by doctrine.

A NEW SELF-CONSCIOUSNESS

Raphaël Lemkin had been well aware that genocidal practices predated the twentieth century (Fein 1993). But he believed that the absolutist racism and nationalism of the modern era gave contemporary mass murder decisive new features. Above all, genocide was now pursued with heightened self-consciousness. In the characteristic genocides of the twentieth century—most notably the liquidation of Armenians by Turkey in World War I, the Nazi Holocaust during World War II, and the postwar massacres of minority groups by governments in Indonesia, Pakistan, Cambodia, Burundi, and Rwanda—the intent was genocidal from the start. Entire groups were sentenced to death for ideological as well as geopolitical reasons. And these sentences were pronounced with full awareness of their antihumanistic implications, since they defied the humanitarian trend, rooted in Puritanism and bourgeois constitutionalism (Tergel 1998; Troeltsch [1912] 1958), which had swept the Euro-Atlantic world in the nineteenth century.

What explains this genocidal intent? What gives “ideological” genocide its compelling force? For Lemkin the answer lies, in part, in social psychology. He sees evidence, in particular, of such psychological tendencies as cynicism, denial, “contempt for the victim,” and “exaggerated pride,” among others (1992, pp. 189–235). This line of reasoning is richly developed in the research literature on the personality traits most relevant to genocide: aggressiveness, submissiveness, and punitiveness. It was first shown, in a flawed but classic study (Adorno et al. 1950), that these three traits systematically covary in structured and intelligible ways. Later research has significantly refined this original discovery.

It is now well understood that certain kinds of harsh personal experience tend to make people (1) *submissive* to leaders and (2) *aggressive* toward—outsiders. And people imbued with this dually obedient and violent tendency are often exceptionally willing to persecute or fight those who are authoritatively defined as their “enemies” (Altemeyer 1996; Hopf 1993; Lederer and Schmidt 1995). The significance of this fact for the study of genocide was revealed by Ross, who showed that conflict intensity is strongly related to personality variables of just this type. While objective social divisions tend to determine *who fights whom*—class versus

class, nation versus nation, and so forth—personality-forming experiences play an exceptionally large role in determining the destructiveness of any given conflict. Ross found, after systematically studying the interplay of forty-one variables in ninety nonindustrial societies, that “the more affectionate and warm and the less harsh the socialization in a society, the lower the level of political conflict and violence” (1993, p. 99); and indeed, no other single factor has a greater impact.

DIVIDED SOCIETIES

Patterns of socialization are thus highly relevant to the study of genocide. No less relevant are structural determinants—few of which, however, have yet received systematic attention. This is largely due to the fact that the sociology of genocide is still just a few decades old. While studies of anti-Semitism, ethnocentrism, and the Holocaust have been common throughout the postwar era, the study of genocide as a phenomenon *sui generis* was first pursued in the 1970s by a small cohort of sociologists—Dadrian, Kuper, Fein—who have remained central to the enterprise ever since.

Leo Kuper, the “doyen of genocide scholars” (Charny 1994, p. 64), set the stage for much of the research that was to follow. Focusing entirely on the twentieth century, Kuper noted that genocide in this century has been distinctive in several ways. In addition to the rising influence of ideological motives, Kuper observed that contemporary genocides are also exceptionally likely to occur within divided societies, as autocratic states seek to defend their monopoly of power against the challenges of domestic rivals. Genocidal massacres are still common in the conflicts between societies as well—especially, Kuper says, when imperialist motives are at work—but internal conflicts are now especially acute. This is particularly true in postcolonial societies, many of which were profoundly destabilized by the experience of colonial rule. Such societies are often pure artifacts of the colonial imagination, rigidly stratified and ethnically divided in new and untenable ways. When dissent arises in these “new nations,” the rulers—*sans* consent—resort to coercion, often on a grand scale. Hence the state-sponsored massacres in such postcolonial realms as Indonesia, the former “East Pakistan” (now Bangladesh), Rwanda, and Burundi. And communal divisions in these nations run so

deep that genocidal massacres often unfold entirely within civil society, unbidden by the state (Kuper 1981).

Many of Kuper’s themes were adapted from classical texts by Sartre (1968) and Cohn (1967), and many later scholars have pursued variations on these themes (see Andreopolous 1994; Totten et al. 1995). Except for Jonassohn, who delves into remoter history, most social scientists continue to focus mainly on twentieth-century cases (Dadrian 1995; Mazian 1990; Melson 1992; Wallimann and Dobkowski 1987). Much has been learned about these cases. Yet in many ways genocide remains as elusive as ever. Part of the problem is definitional.

DUELLING DEFINITIONS

As the study of genocide proves, definitions are deeply political. This was apparent from the beginning of the United Nations debate over genocide in 1948. For the Russian delegates, “genocide” was a logical effect and extension of fascist doctrine, revolving around the victimization of racial and ethnic groups. Others argued that social classes and political groups can also be the victims of genocide. When the final vote was taken, religious as well as national and ethnic groups were identified as possible targets of genocide, but political groups were excluded. And the United Nations further limited the applicability of its definition by specifying that genocide entails an “intent to destroy” some group, “in whole or in part.” Since proving intent is notoriously difficult, some delegates questioned whether the Genocide Convention, so restricted, could ever be enforced. Similar doubts were voiced about the idea of “destroying” a group. Lemkin, in his original formulation, had said that genocide can take cultural as well as physical forms. But does this mean that efforts to sabotage the culture, language, or religion of a group are just as much “acts of genocide” as attempts to physically destroy the group?

Questions of this kind quickly proved to have direct political relevance. In 1951, W. E. B. Du Bois, Paul Robeson, and others addressed a book-length petition to the United Nations accusing the U.S. government of systematically genocidal actions against African Americans (Patterson et al. 1951). Reluctance to entertain charges of this kind

led many U. S. senators to oppose the Genocide Convention; and, indeed, the United States did not endorse the Convention until 1986 (LeBlanc 1991). Nor did the United Nations prove eager to enforce the Convention. Not until the Rwandan massacres of 1994, in fact, did the United Nations classify a postwar event as “genocide”—and even this came after the fact. It has remained extremely difficult, in short, for policy makers to operationally define or apply the notion of genocide.

Scholars, meanwhile, have spent considerable time on definitional issues. Kuper offered an influential distinction between genocide and “genocidal massacre” as a means of distinguishing the attempted murder of entire peoples from large-scale massacres that are not prompted by the wish to destroy groups *in toto*. He did not, however, establish clear criteria for this distinction, which limits its utility. Nor has any other approach won consensus. Thus, debate rages over the classification of many events: “the rape of Nanking,” Stalin’s purges, the nuclear bombing of Hiroshima, the carpet bombing of Vietnam, “human-made” famine in Mao’s China, and similar events. Other debates pivot on questions of principle. Are there unintended genocides? Is genocide distinct from the destruction of a culture? Does genocide belong on a continuum with other forms of destructiveness, or is it qualitatively unique?

THE LIMITS OF CLASSIFICATION

Many answers have been given to these questions, but it remains far from clear that “genocide” is, indeed, a unitary phenomenon or amenable to general explanation. Most scholars have tended to focus on relatively clear cases of mass murder inspired by modern racial-national ideologies, but even these vary in significant respects. Another approach, proposed by the psychologist Charny (1994), is to subsume the full range of mass-destructive practices into a wider matrix; but it seems unlikely that the criterion of mass destructiveness alone is sufficient to justify treating ecological catastrophe, ethnic slaughter, and cultural repression as elements in a unified field of events.

For fuller, more nuanced understanding, comparative research is needed on a widening scale. Whether the general notion of “genocide” will continue to prove compelling remains to be seen.

GERMAN SOCIOLOGY

NOTE: *Although the following article has not been revised for this edition of the Encyclopedia, the substantive coverage is currently appropriate. The editors have provided a list of recent works at the end of the article to facilitate research and exploration of the topic.*

“German Sociology” has two specific traits: It is part of the general humanities tradition of German culture—that is, it has a philosophical orientation—and it emphasizes epistemological reflection, favoring the understanding of human action through *verstehen* (intuitive oneness with the explanandum). This is the way in which Raymond Aron (1935) characterized sociology in Germany,

studying it at the time of the Nazi regime, when it was mainly a memory and not a living field of knowledge or profession.

Since then a large number of books and essays in the United States have treated sociology as practiced in Germany, at least some of which broaden the image (Nisbet 1966; Fletcher 1971; Oberschall 1965, 1972; Schad 1972; Freund 1978). The dominant meaning of the intellectual commodity called German sociology—as continued in the works of Salomon (1945), Barnes (1938), Coser (1977), Zeitlin (1981), and especially Meja, Misgeld, and Stehr (1987)—is that of grand theory with a teleological meaning. This “German Sociology” is only a small part of sociology in Germany, but it is the aspect to which the intellectual community at large reacts; and it is reinforced by selectivity in translation and citation. For the social sciences in the United States, those parts of sociology in other countries which are least like American sociology are searched out as welcome completions.

THE CLASSICAL PERIOD

By the turn of the twentieth century, sociology had become an exciting intellectual concern in the United States, France, England, and Germany. Since an educated person at that time was expected to know English, German, and French, there was intensive direct interaction. Of special importance were the exchanges among Albert Schäffle (1884), Ferdinand Tönnies (1887), Emile Durkheim (e.g., 1887), and Georg Simmel (1890). Durkheim first made a name for himself in France by reviewing German social science literature by authors such as Wilhelm Wundt and, especially, Ferdinand Tönnies, and was therefore attacked as a Germanophile. Tönnies’s distinction *Gemeinschaft* (community) and *Gesellschaft* (society) influenced Durkheim’s dichotomy mechanical and organic solidarity, and Tönnies in turn commented on Durkheim’s notion of the division of labor as the central element in social evolution (Gephardt 1982). Initially the builders of large “systems,” such as Ludwig Gumplowitz (1883), Gustav Ratzenhofer (1893), and Theodore Abel (1929), dominated German sociological literature.

In a review of the period up to 1914, Leopold von Wiese (1959) lists Ferdinand Tönnies, Max Weber, and Werner Sombart as the most important sociologists; the list should also include Alfred

Vierkandt, Franz Oppenheimer, Alfred Weber, Roberto Michels, and Hermann Kantorowicz (Käsler 1984). This inner circle of sociologists of the “classical period” is still influential today.

In the closing days of the German empire, sociology was established in an elitist academy with Tönnies as president, Sombart as vice president, and von Wiese as the eminence gris. Simmel and Weber were considered to be the leading scholars within this academy, even though both had become merely observers. In 1912, after numerous editions, Tönnies’s *Gemeinschaft und Gesellschaft*, first published in 1887, at last achieved wide recognition among the educated public, paralleling the impact of Edward A. Ross’s *Social Control* in the United States.

THE WEIMAR PERIOD

Upon the reestablishment of sociology in 1919, von Wiese was able to retain bureaucratic control over the policy of the academy and largely over its conventions. Not until the end of the 1920s was the first chair of sociology instituted in Frankfurt. However, during the fourteen years of the Weimar Republic, forty professorships were created that combined sociology with another discipline, such as economics, philosophy, or law. Eight periodicals had *Sociology* in their titles, and another eight regularly published sociological contributions. Von Wiese was instrumental in founding the first permanent research institute at the University of Cologne, *Forschungsinstitut für Sozial- und Verwaltungswissenschaften*, in 1919 (Alemann 1978), followed in 1923 by the *Institut für Sozialforschung* in Frankfurt (Jay 1973). In the early 1930s nearly all universities in Germany regularly offered courses in sociology, and by the mid-1920s the *Deutsche Gesellschaft für Soziologie* had begun to question the wisdom of opposing a degree curriculum in the universities.

The 1920s were a time of abrasive partisanship in German intellectual life. René König groups the various positions along a dividing line between left and right Hegelians, the Kantian tradition having paled in the humanities (König 1987). Left Hegelian translates into Marxism, but that itself was very heterogeneous. When Eisenstadt and Curelaru (1976, p. 122) and Zeitlin (1981, p. v) maintain that “a critical reexamination of Marxism” is a main

focus of German sociology, this is an error; Marxists and non-Marxists mostly tended to ignore each other, although not in the 1920s.

“In the 1920s there was no dominant figure in sociology, which evolved in a number of milieus with little common direction. Even within its local centers in the Weimar Republic there was practically no paradigmatic unity” (Lepsius 1987, p. 40). These local centers were Frankfurt, Cologne, Berlin, and (later) Leipzig. In this characterization of the Weimar turmoil, there are two omissions: Max Weber’s influence is not mentioned, and the Frankfurt School is bypassed. In both cases it is done for the same reason: at that time they were not very important for sociology. Shortly after accepting a professorship in Munich, Weber died in 1920. Some of his most important works on religion had appeared during the war, and his magnum opus, *Wirtschaft und Gesellschaft* (Economy and Society) was published posthumously by his wife Marianne Weber. Other works by Weber were not readily available until after about 1925.

The Institut für Sozialforschung in Frankfurt did not see itself as an institute for sociologists. Felix J. Weill, who obtained the funds for the institute from his grain merchant father, would have preferred to call it Institute for Marxism, but it was then judged prudent to choose the neutral title Social Research. All of the members shared an aesthetic disgust with bourgeois society, though they themselves were from well-off-to-very-rich families, and they wanted to convert fellow intellectuals to this view. The most important effect of the institute until the 1940s, however, was to give younger social scientists a chance to develop their talents: Max Horkheimer, Karl August Wittfogel, Franz Borkenau, Leo Löwenthal, Herbert Marcuse, and Theodor Adorno. “Although without much impact in Weimar, and with even less during the period of exile that followed, the Frankfurt School was to become a major force in the revitalization of Western European Marxism in the postwar years” (Jay 1973, p. 4).

AN END TO SOCIOLOGY

It is easier to name sociologists who did not emigrate as the Nazi regime came to power than to list the émigrés. Of all the sociologists with a reputation, only the social philosopher Hans Freyer welcomed the new regime. Werner Sombart, who

during his lifetime took just about every political stance available, was in an anticapitalist anti-Semitic phase around 1933. It must have protected him when, in 1938, he ridiculed racism and the glorification of the people. Franz Oppenheimer and Eric Vögelin were eventually forced to emigrate, even though they tried to remain. Othmar Spann lost his professorship in 1938 and was imprisoned. Ferdinand Tönnies, whose show of opposition bordered on the suicidal, was ostracized. Alfred Weber was dismissed. Alfred Vierkandt had to cease lecturing. Alfred von Martin resigned. The Deutsche Gesellschaft für Soziologie was suspended in 1934 by von Wiese in order to avoid a takeover. Von Wiese stopped publishing the *Kölner Zeitschrift* in the same year, and from then on, lectured only on the history of economic thought. René König, a young candidate for a professorial career who had to emigrate in 1935, attributes to the Nazis a complete stoppage of sociology worthy of its name (König 1978, p. 14).

A SECOND BEGINNING

Sociology after 1945 could not have been a continuation of a tradition; and even if it had been possible, it would not have been a discipline in which basic issues had been settled. This is especially true for the issue of professionalization, which translates into the question “What public are the sociologists addressing?”

Emigrants returning to Germany (René König, Max Horkheimer, Theodor W. Adorno, Siegfried Landshut, Helmut Plessner, Arnold Bergsträsser, Emmerich K. Francis, and, much later, Norbert Elias) often had been influenced by developments in America. American sociology was most influential, since books from the United States often were the only ones available. The “Young Turks” of sociology born between 1926 and 1930—Karl Martin Bolte, Rainer M. Lepsius, Burkhard Lutz, Renate Mayntz, Erwin K. Scheuch, and Friedrich Tenbruck—studied the subject in American universities.

Three of the five research centers of the period of reconstruction were financed by foreign sources: the Sozialforschungsstelle Dortmund with funds from the Rockefeller Foundation; the UNESCO Institute for Social Research in Cologne, through the initiative of Alva Myrdal; and the Institut für Sozialwissenschaftliche Forschung in Darmstadt,

with American government money. The trade unions established sociology as a “democratic discipline” in Hamburg at the Akademie für Gemeinschaft. Von Wiese reopened the institute in Cologne that later was integrated into the university. With generous financing from American sources, such as the government-sponsored Voice of America, the Institut für Sozialforschung in Frankfurt resumed operations. And in Göttingen, Hans Paul Bahrdt took up the tradition of industrial sociology of the late Weimar times and founded the Soziologisches Forschungsinstitut, Göttingen—the SOFI Institut. Thus, from the resumption of sociology in Germany, there was an infrastructure for empirical social research well connected to the international community. With the exception of von Wiese’s institute, however, it later proved to be impossible to integrate these institutes for empirical research into the universities, and therefore the UNESCO Institute, the Sozialforschungsstelle Dortmund, and the Darmstadt group ceased to exist.

Empirical social research at that time was largely understood to be an import from the United States. At the UNESCO Institute in Cologne and in Darmstadt, important community studies inspired by American studies of the 1930s and 1940s were carried out. The reports by Renate Mayntz and Erich Reigrotzki are still very much worth reading. Parallel to this, survey research was developed as a commercial service; here, too, the American standards of the time were immediately imported. Of great influence were the survey units that the American and British governments had begun as their troops moved into Germany. It was in these survey units that the core personnel of the later German institutes learned their techniques (Scheuch 1990b).

The 1950s were characterized by a coexistence of professors who had learned sociology largely on their own before 1945 and a larger number of sociologists born between 1926 and 1930 who were virtually identical in skill and outlook with their American contemporaries. For this generation Weimar sociology was forgotten, and the classics were read with an American selectivity and perspective.

By the end of the 1950s sociology—in terms of chairs, curricula, students, and volume of empirical research—had surpassed the level of 1933. Much against the wishes of von Wiese and

Horkheimer, the German Sociological Association had been transformed from an elitist academy into a professional association with increasingly important sections or research committees in which the Young Turks were able to attract followers. The sections for industrial sociology (for the more theoretically minded) and for methodology (for the mainly empirically oriented) offered an alternative to the plenary meetings that were still dominated by professors who were the last academic mandarins of German tradition. In research nearly everyone who later influenced the discipline worked on social stratification, which as a central topic succeeded the community studies of the first half of the 1950s. Among the Young Turks and their following a structural functional approach was the common paradigm, and Talcott Parsons was held to be the great theorist of the time.

Sociology was a deeply divided discipline. One dividing line pitted those who had emigrated against sociologists who had supported the Nazi regime. Hans Freyer, Arnold Gehlen, and Helmut Schelsky were accused of collaborating with the regime; Gunter Ipsen did more than that; and Karl-Heinz Pfeffer and Karl Valentin Müller were justly denounced as racists. In 1960 the German Sociological Association nearly split along the dividing line between collaborators with the Nazi regime and the majority led by former immigrants.

However, it was not possible simply to dismiss Gehlen and Schelsky as former Nazi sympathizers. While they had been exactly that, they now did important scholarly work. Gehlen developed an anthropology that included perhaps the best approach to the analysis of social institutions, and Schelsky had initiated many important studies on youth, the family, and social stratification. The two men published a textbook in sociology that saw four editions within three years (Gehlen and Schelsky 1955).

The second dividing line ran between the Frankfurt Institute and all others. Horkheimer, Adorno, and Pollack had been successful in the United States, the home of modern sociology. By now their Marxism had toned down to a variant of left Hegelianism that they christened “critical theory.” Initially a political camouflage, it now characterized the retained commitment to cultural criticism of bourgeois society. The combination of

Marxism with cultural criticism proved to be a winning message with the cultural establishment.

The opposition to Schelsky/Gehlen and Adorno/Horkheimer crystallized around René König, whom von Wiese had invited to Cologne. Originally a pure humanist—he wrote what is considered the standard monograph on Niccolò Machiavelli (1941)—in exile he had identified with the post-Durkheim school in France. Upon returning to Germany in 1950, he recognized the need to familiarize the young generation of sociologists and sociology students with mainstream American sociology. Although himself not a quantitatively minded scholar, he encouraged quantitative social research as an antidote to the temptations of speculative grand theory. Knowing his personal preference for cultural anthropology and French culture, it is ironic that he was the key figure in thoroughly Americanizing the larger part of an academic generation in sociology.

König's *Soziologie heute* (Sociology Today, 1949), a sociological rendering of existentialist philosophy, was the first postwar best-seller in sociology. The dictionary of sociology that he edited (1958) brought together most of the Young Turks and became the largest selling sociology book ever in Germany, with more than twenty editions and almost half a million copies. Most important for the profession, however, was the two-volume handbook of empirical social research (1962) that he edited, conceived along the lines of Gardner-Lindzey's *Handbook of Social Psychology* (König 1962). The handbook is still a standard for empirical sociology and has gone through several editions. All of these works were translated into English, French, Spanish, and Italian, and some into Japanese as well.

The different positions in the first phase of sociology after 1945 were sorted into three "schools" that were to constitute sociology in Germany: the Frankfurt School, the Cologne School, and the Schelsky school. Within the discipline the Cologne school set standards for curricula and research, the *Kölner Zeitschrift* being stronger than the Dortmund-based *Soziale Welt*. The readers of these two largest social science journals do not overlap much. *Kölner Zeitschrift* is the journal for the discipline, while *Soziale Welt* is for practitioners of social science in bureaucracies and the helping professions. Thus, the publics of the three "schools"

were different and have remained so: the Frankfurt school for the cultural intelligentsia; the Cologne school for social scientists; the Schelsky school for practical applications in welfare and bureaucracy. It was largely the pressure from the respective audiences more than the preferences of the professors that for a long time caused sociology in Germany to be divided into these three camps.

THE TIME OF EXPANSION

The second most formative decade was the 1960s. It marked a return to important subjects of the classics and to some authors of that time. The Americanization of the discipline had peaked.

After the vituperous quarrels in the Deutsche Gesellschaft in the 1950s it was agreed to meet in closed session at Tübingen in 1961, to discuss basis issues in a purely scholarly atmosphere. Unexpectedly this led to a controversy between two radically different views of social science, the chief protagonists of which were Theodor W. Adorno and Karl Popper (Adorno 1962), between science as a vehicle for emancipation and a scientific view of science. Popper's work is in the philosophy of science rather conventional sociology. For Adorno empiricism means supremacy of instrumental reasoning, which subjugates reason to the rule of facts; empiricism is tantamount to "treating facts as fetishes" (Adorno 1969, p. 14). This dispute was continued by two nonsociologists—the economist Hans Albert and the philosopher Jürgen Habermas—as the "positivism controversy," Habermas representing the Frankfurt school of critical theory and Albert the Cologne school of neopositivism (Adorno 1975). This was a revival of the methodological controversies in the Verein für Socialpolitik in the decade prior to 1914.

The controversy between Habermas und Albert occurred during the 1964 sociology convention that was dedicated to the rediscovery of Max Weber. The topic that sent shock waves throughout the cultural establishment (Stammer 1965) was the revival of the debate on value judgments as part of science. The "radical" sociologists who began to appear at this time took as their central argument the charge that positivism was blind to the forces its research served.

The repercussions were much larger: the arguments of critical theory against positivism became

a credo among the cultural intelligentsia. It is important for an understanding of sociology in Germany that this old controversy did not spring from developments within the discipline; rather, it became an unavoidable topic because the intellectual environment forced it onto sociology.

Meanwhile, a seeming alternative to the Cologne and Frankfurt Schools, though closely related to the latter in its concerns, became the major intellectual success: Ralf Dahrendorf with his *Gesellschaft und Demokratie in Deutschland* (1965). How was the Nazi regime possible? Could it reappear in a different guise? This topic keeps emerging in Germany as a central focus in intellectual attempts at self-analysis. In the 1980s the intellectual public expected answers from a controversy among historians; in the 1960s the expectations were focused on sociology and Dahrendorf.

Dahrendorf, trained as a philosopher, is a self-taught sociologist. By temperament he is a moralist, as is evident in his dissertation exploring the idea of justice in Marx's thought (1954). He was subsequently among the Young Turks who concentrated on industrial sociology, and published an immensely successful book on the subject (Dahrendorf 1956) that overshadowed a more original monograph by Heinrich Popitz, Hans Paul Bahrdt, Ernst-August Jüres and Hanno Kesting (1957) that is yet to be recognized internationally as a classic. Among younger sociologists Dahrendorf became a central focus of controversy as a result of his long essay on role theory, in which he characterizes modern society as a cage of obligations that prevent individuality from asserting itself (Dahrendorf 1959b). While the profession largely rejected this notion as a misperception of role theory and economics, the book *Homo Sociologicus* remained for decades the most popular sociological treatise among students (Dahrendorf, 1959b). An essay on chances for complete social equality was Dahrendorf's contribution to the topic of social stratification (Dahrendorf 1961), then dominant among the Young Turks. A much more important publication for an understanding of his concerns is his treatment of the United States as the one case where presumably there was an attempt to construct a society in the spirit of the French Enlightenment (Dahrendorf 1963). Characteristically, Dahrendorf takes as his point of departure a source of general intellectual importance, in this case Alexis de Tocqueville's report on the United States in the 1830s.

As Adorno had introduced the concerns of the cultural public into the profession, so Dahrendorf did the same for the intelligentsia concerned with public affairs. In the English-speaking world he is often included in sociological curricula as a conflict theoretician, but there is no conflict theory in his writings, except for an attempt at a taxonomy of conflicts. The label *conflict theoretician* was affixed because of his criticism of Talcott Parsons, whose structural functionalism he accused of glorifying social harmony. Dahrendorf's central theme is to explore the chances for the values of British liberalism to become the guiding principle in society. In practical life this orientation met with mixed success.

In the 1970s Dahrendorf returned to England to become the first foreign president of the London School of Economics. He later became a professor at Oxford and remains a respected commentator on public affairs with a continuing interest in sociology as an intellectual endeavor. Although frequently in error in his statements that have empirical content, he is invariably sensitive in choosing topics that relate the discipline to an intellectual public.

The mood of the times was moving away from the liberal creed of Dahrendorf. The controversies in the United States, stimulated by the Vietnam intervention, were taken up by politicized students in Germany. Marxism was believed to provide answers that the liberal promise of the postwar Western world apparently could not. The varieties of Marxism were studied with religious fervor.

At the 1968 convention of the German Sociological Association demands for an alternative to mainstream sociology, especially the "Cologne Americanism," exploded. Adorno had chosen as the congress's theme, "Late Capitalism or Industrial Society"—alternative ways of conceptualizing the same reality. The term "late capitalism" was favored by Neo-marxists as implying that the demise of bourgeois society was imminent. It also implied that the notion of a basic sameness of all industrial societies—that the United States and the Soviet Union were structurally related as industrial societies—was wrong. The Neo-Marxist conceptualization "late capitalism" and, by contrast, critical theory implied that the social orders of the Soviet Union and the United States were

dedicated to a different telos, and that this difference was what mattered most (Adorno 1969).

With the May 1968 uprising in Paris, the student movement in Germany turned into a crusade for leftism as the mandatory creed on campus, and specifically for sociologists. For a moment the adherents of the Frankfurt school could see the student movement as the realization of their hopes. Max Horkheimer had always rejected any methodological constraints on philosophizing, and on any scholarship. Methodology would restrict science to the factual, while for Horkheimer, Adorno, and Bloch the prime goal of scholarship was creative utopianism. According to Horkheimer, it was now up to science to provide the answers given earlier by religion (Horkheimer 1968). The student movement, however, accused the Frankfurt school of running away from reality, and critical theory of having only negative messages and no direction for positive action. Adorno had always maintained this view (Adorno 1969). Deposing a ruling class would not change the basic character of relations that were permeated with instrumental reasoning; there was no longer a revolutionary subject to realize the cause of emancipation. After some very ugly clashes, Adorno died in 1969. Dahrendorf turned against the student movement, as did such well-known sociologists as Helmut Schelsky and Helmut Schoeck. Erwin Scheuch's *Anabaptists of the "Affluent Society"* (1968) became a best-seller. Even Habermas, irritated by the uncompromising nature of the New Left, severed his connection by diagnosing its "left fascism" (Habermas 1969).

In the turbulent years that followed 1968, sociologists were more concerned with reacting to the New Left than with developments of their own. Sociology had been utterly surprised by a student movement that it neither predicted nor understood. Rainer Lepsius contrasts this situation with the immediate success of empirical sociology in analyzing the right-wing protest NPD party (National-Demokratische Partei Deutschlands) of the late 1960s (Lepsius 1976, p. 7).

The public, however, identified sociology with the New Left. An explosion of leftist literature, using sociological terminology, buried the output of sociologists. The public image of sociology became one of a haven for radicals opposed to bourgeois society. For about ten years after 1968,

sociology became the quarry for cultural discourse. Academic fields that were based on shared beliefs in civil society and cultural values—such as pedagogy, art appreciation, literary criticism, and political education—had their criteria damaged, even destroyed. Sociology was used to provide an alternative rationale: service to the cause of emancipation from bourgeois society. Tenbruck (1984) has charged that sociology had "colonized" the humanities, and even life in general. It actually was the other way around: as the humanities lost their belief in civil society, they raided sociology for arguments in the name of society. Professional sociology completely lost control over the use of its vocabulary—with disastrous results for the self-selection of students of sociology and the standing of the field in the world of scholarship.

The student protest movement, and various alternative cultures loosely associated with it, became a regular part of public life in Germany, as it had in the United States. It became fashionable to call a great number of protest forms *sociology* while denouncing the profession carrying out "normal science" (Kuhn 1970) as "bourgeois" sociology. Sociologists were asked to react to fashionable topics of the day, such as permissive education, Third World dependency, mind-expanding drugs, feminism, gay power, autonomous living. Many of the newly appointed professors went along, contributing to the erroneous public impression that sociology was spearheading the cultural revolution in the name of anticapitalism. The opposite was true: sociologists often caved in to demands from the protest movements.

Even in a less turbulent intellectual environment, the period between 1968 and 1973 would have been most unsettling, because it was a period of unique expansion. By the mid-1960s social democratic state governments had been convinced by proponents of the Frankfurt school that sociology should be included in the curricula of secondary education. The profession was divided on this, and as late as 1959 Dahrendorf counseled against the inclusion of sociology in degree curricula even at universities. With the youth, however, sociology was a huge success; many teachers were needed, and that meant many more professors. In 1968 there were fifty-five tenured positions as professor of sociology in the Federal Republic of Germany; in 1973 there were 190 (Lamnek 1991). From that

year, the rate of expansion levelled, and by 1980 there were 252 “chairs” (Sahner 1982, p. 79).

Lepsius modified this feeling of an avalanche of sociology overwhelming academe (Lepsius 1976, p. 12). At the beginning of the 1970s, sociology had 1.3 percent of all the positions in university budgets, no larger a share than ten years earlier; 1.2 percent of the students took a major in sociology, also the percentage before the expansion; public money for sociological research had always hovered around 1 to 2 percent of all grants. The universities had expanded with explosive rapidity, and in this general explosion sociology merely kept its former share.

As a discipline, sociology, however, was among those least prepared to keep its place during an expansion that within a few years quadrupled the number of students in the Federal Republic. Consequently a great many sociologists were appointed to tenured positions who in other times would not have been. In this process the discipline lost cohesion and common scholarly standards.

THE CONSOLIDATION

After 1968 the Deutsche Gesellschaft für Soziologie was taken over by the Young Turks; from their ranks Dahrendorf, Scheuch, and Lepsius were successively president. The leadership of the association was tired of conventions serving as forums for all kinds of protests, thus further damaging the reputation of the field. Consequently, biannual sociological conventions were suspended until 1974, when a meeting was held in Kassel. While the field had a Babel of views, there was now agreement to coexist.

At the Kassel convention of 1974, a custom was started called *Theorievergleich* (comparison of theory). This is in reality a juxtaposition of sociological “denominations,” not a weighing of alternative theoretical propositions (Lepsius 1976, sec. II). At that time four such denominations were defined: (a) behaviorism, the chief proponent of which in Germany was Karl-Dieter Opp; (b) action theory as represented by Hans-Joachim Hummel; (c) functionalism and systems theory, with Niklas Luhman as its prominent representative; and (d) historical materialism, which translates into Marxism. Somewhat later, parts of behaviorism and action theory amalgamated to

become rational choice; two German-speaking Dutch sociologists, Reinhard Wippler and Siegwart Lindenberg, are its best-known proponents. Phenomenological sociology has been successful especially among young sociologists, with Jürgen Helle as the chief representative.

The lines between these denominations keep shifting as new variants emerge. In general, though, this approach to theory—to choose a topic such as evolution and then listen to what each denomination has to say about it—appears to have spent itself.

Concern with theory in Germany again means reacting to theory builders, a most dissimilar pair of whom dominated the scene in the 1970s and early 1980s: Jürgen Habermas and Niklas Luhmann. Luhmann is a self-taught sociologist who studied law and became a career administrator. His first specialty was the sociology of organization, which showed a strong influence of Chester I. Barnard. Subsequently Luhmann analyzed phenomena of the *Lebenswelt* (the key term of phenomenology for the world of immediate, unreflected experience—in contrast to the world that science portrayed) at that time influenced by the phenomenologist Edmund Husserl, as in Luhmann’s monograph on trust as the basis for social cohesion. Luhmann later met Talcott Parsons, whose work he understood from the perspective of a systems theorist. From then on, he focused on pure theory, going so far as to reject the application of theoretical statements to the empirical world, declaring empirical evidence to be irrelevant for his theoretizing (Luhmann 1987). Since Luhmann writes prolifically in English, his views should be well known outside Germany.

It will be helpful to note his shift in emphasis over the years. The central notion was first functional differentiation as the guiding principle in evolution. This results in an increasing competence of the system if the functionally differentiated areas are allowed to develop their area-specific rationality (*Eigenlogik*). The economy is seen as a prime example of an *Eigendynamik*, provided it is not shackled by attempts at political or ethical guidance. Differentiated systems, according to Luhman, need constant feedback to permit a creative reaction. Luhman conceptualizes these feedbacks as *selbstreferenzielle Prozesse* (self-referential processes). More recently he has become interested in

chaos theory and has given self-organization—which he calls *Autopoiesis*—a central place in explaining system functioning. It appears that the interest in Luhman has increased as his writings have become more abstract and his terms more outlandish—something he does self-consciously, since he can be a lucid writer.

This is less true for Jürgen Habermas, a philosopher who is self-taught in sociology. He calls his approach *critical sociology*, a choice that expresses his initial indebtedness to left Hegelianism of the Frankfurt school. While he has included Marxist terminology in his writings, he is probably best understood as a sociological disciple of the idealistic philosopher Fichte. In this perspective society is a problem for man's true calling: emancipation. He understands emancipation in the spirit of the French Enlightenment. The characteristic element of Habermas's "critical sociology" is *doppelte Reflexivität* (double feedback): the sociologist reflects on the context of discovery, and again on the context of utilization of his findings. With this attitude Habermas approaches the problematic relationship between theory and praxis (a Hegelian variant of practice) at a time when human existence is determined by a technological *Eigendynamik*. Habermas's writings, available in translation, are internationally known. Viewed over a period of around thirty years, it seems that he is sliding into a position of Great Cultural Theory, of the kind like Pitirim Sorokin's. And in becoming a synthesizer, he becomes more empirically minded, as Luhman ascends into the more abstract.

SOCIOLOGY AS "NORMAL SCIENCE"

While practically all German universities offer degrees in sociology up to the doctoral level, there are some centers in terms of number of students, research facilities, and number of teaching personnel. In terms of faculty size, these centers are Bielefeld, Berlin, and Frankfurt, Munich, Cologne, and Mannheim. If one includes among the criteria the number of degrees granted, then Bochum, Hamburg, and Göttingen must be added as centers.

There is now a very developed infrastructure for empirical research. In addition to many public service research institutes both inside and outside universities, there are some 165 commercial institutes for market and social research, the largest employing 600 academics and having a business

volume of 90 million dollars. There is an academic network of three service institutions with a yearly volume of ten million dollars from the budgets of state and federal governments: the Informationszentrum, in Bonn, providing on-line information on research projects and literature abstracts; ZUMA, Zentrum für Umfragen, Methoden und Analysen, in Mannheim, doing some of the work of NORC, National Opinion Research Center, Chicago, and helping anyone in need of methodological support; and the Zentralarchiv in Cologne, which provides data for secondary analysis, as the Roper Center in the United States does. All three together form GESIS, Gesellschaft sozialwissenschaftliche Infrastruktureinrichtungen, Bonn, a package that can be used by the mostly small research institutes of German universities. There are also larger institutes, the biggest in terms of number of academics employed being the Deutsche Jugendinstitut (German Youth Institute) and the largest in terms of finance (eleven million dollars) being the Wissenschaftszentrum Berlin (Social Science Center in Berlin). All have regular budgets from tax money.

There is a yearly survey on work in progress, and between 1978 and 1988, 29,000 research projects were reported. The Zentralarchiv keeps a count on quantitative research, and limiting its attention only to such work where data are in machine readable format, the yearly academic production in quantitative research is around 900 projects. The preferred method is the personal interview, which during the years had a share of 50 percent for all projects where quantitative data were collected. The doorstep interview is being replaced by the telephone interview, although to a lesser extent than in the United States.

Among the more than 1,000 members of the German Sociological Association the attention given to applied fields is dominant. A content analysis of journal articles shows that only 15.4 percent of all published manuscripts—the rejection rate is around 80 percent of all articles submitted—deal with theory. The most important applied fields are (in order of frequency) industrial sociology, social psychology, methods of quantitative research, sociology of politics, and sociology of the family. All these have shares in publications above five percent. Twenty other fields of sociology contribute altogether 50 percent to journal publications (Sahner 1982).

Heinz Sahner's (1991) content analysis of the theoretical paradigms used in journal articles between 1970 and 1987 found the expected correlation with the intellectual climate. Marxism declined rapidly from the late 1970s, and it never dominated in German professional journals. Structural functional sociology is still the single most important theoretical paradigm, with phenomenological approaches gaining steadily. Even more so than earlier, sociology in Germany is now a multiparadigm field, including as a prominent part, "German Sociology."

GLOBAL SYSTEMS ANALYSIS

See Globalization and Global Systems Analysis.

GLOBALIZATION AND GLOBAL SYSTEMS ANALYSIS

Since the early 1960s, mounting empirical pressure has forced sociology to abandon the assumption that national societies could be understood without looking beyond their borders. The nation-state remains a crucial unit of analysis, but it must be analyzed as intertwined with the operations of a larger global social system. Global flows of culture, technology, people, goods, and capital determines to an ever larger degree how societies change at the national level. The dynamics of transnational social, economic and political structures have become a focus of study in their own right.

The value of international trade has grown more rapidly than the value of goods and services produced and sold within national boundaries.

Manufacturing means assembly of components from around the globe. Electronic youth culture in the United States revolves around Japanese cartoon characters, while a generation of Third World television viewers take their cultural cues from North American TV serials. Capital markets operate around the globe and around the clock as trading moves from Tokyo to London to New York over the course of each day. Sociologists cannot yet claim to understand the working of this global system, but a number of fruitful avenues of analysis have emerged since about 1960.

The approaches favored by sociologists have differed from the study of "international relations" as it has been traditionally defined. International relations approaches have seen the global system as structured primarily by interactions in which nations are unitary actors (see Waltz 1979). The global system is presumed to be structured largely by the distribution of national power among the advanced nations. Sociologists, on the other hand, have been very interested in how the global system is structured by flows of resources, people, ideas, and attitudes across geographic boundaries, flows that often occur without, or even in spite of, national actors.

Within sociology itself, "globalization" has been transformed from a relatively narrow field of study, largely within the political economy of development, to a central theme across a wide range of subfields within the discipline. The topic of globalization has also often drawn sociologists into interdisciplinary debates with political scientists, anthropologists, geographers, and even occasionally economists, among others. As recently as the late 1980s, a number of central approaches to global systems analysis could be identified—Marxism, modernization theory, dependency theory, and world-system theory. However, although these research traditions continue to be elaborated, studies of globalization have proliferated and research perspectives have become fragmented. This article reviews the early and continuing contributions of these perspectives and outlines the main themes that current global systems analyses are exploring.

MARXISM AND MODERNIZATION THEORY

In the years after World War II, Marxism and modernization theory debated vigorously the problems and consequences of capitalist development.

However, despite their ideological opposition, they shared some basic assumptions regarding the character of this development. In particular, they shared the assumption that the global system is dominated by processes of diffusion. In the words of the *Communist Manifesto*, the expansive character of capitalist production “draws all, even the most barbarian, nations into civilization.” Warren (1980) argues from a Marxist perspective that it is only by the expansion of economic ties to core countries, principally in the form of importing more foreign capital, that poor nations are likely to be able to reduce the gap that separates them from rich nations. Sklair (1991) argues that a world-system organized through nation states is being superseded by a “global system” dominated by transnational economic, political, and social structures. He points to the emergence of a transnational capitalist class that organizes the world economy to its own benefit, in contrast to the world systems view of contending national capitalist classes (for an empirical study, see Bottomore and Brym 1989). Robinson (1998) argues that sociology must move beyond nation-state based analytical approaches to make “transnational social structure” its proper object of study, since individuals are predominantly defined by their position in such transnational economic, political, and cultural structures rather than by national or local characteristics—transnational structures dominated by capital. Other Marxist-oriented theorists emphasize the irrationality of capitalist competition on a global scale, since competition between national capitalisms creates a crisis of profitability for capital due to global overcapacity, which in turn leads to declining conditions for labor (R. Brenner 1998; Walker 1999). Nonetheless, the emphasis remains the dilemmas of the diffusion of capitalism—the fact of that diffusion is presumed.

Investigating the prevalence of that complex of ideas and attitudes associated with “modernity” provided an important impetus for modernization theorists to take a global look at the diffusion of culture and social structures. In a classic study, Inkeles and Smith (1974) analyzed the attitudes of citizens in six Third World countries spread around the globe. Modern attitudes were found in social contexts more characteristic of advanced industrial countries. The more time respondents had spent living in cities or working in factories, the more

their attitudes resembled those associated with the culture of advanced industrial countries. The findings suggested a global system structured largely by processes of diffusion. The implicit model was one of gradual convergence around a similar set of “modern” values and attitudes. The spread of modern social institutions helps inculcate the values and attitudes, and the values and attitudes reinforce the institutions.

The work of Meyer and associates (Meyer 1980; Meyer et al. 1997a) shows how ideas and institutions originating in the advanced industrial countries become embodied in a global culture, which in turn shapes local institutions in all countries. Beginning from the surprising homogeneity of national political and economic institutional forms around the world, Meyer and associates (1997a) argue that contemporary actors, including nation-states, organize and legitimate themselves in terms of highly rationalistic, universalistic, world-cultural models. These models largely conform to the prescriptions of modernization theory, with core values such as citizenship, rationality, socioeconomic development, and so on. These models are diffused through the world system largely through the organizations and associations of “world society”—intergovernmental and nongovernmental transnational organizations which act to promote a “shared modernity” rooted in scientific rationalism and in which scientists and professionals are particularly dominant (Boli and Thomas 1999; Meyer et al. 1997a). Nation-states are not destroyed by globalization but, in contrast, the nation-state cultural form is diffused around the world through the institutions of world society.

An extensive body of empirical work has been developed in support of these theoretical insights. Boli-Bennett (1979), for example, examines the way in which national constitutions reflect global legal norms rather than local conditions. Ramirez and Boli (1982) look at the ways in which schools take on similar shapes around the globe as conceptions of what constitutes an effective educational institution come to be shared with surprising speed across geographical boundaries. Meyer and associates (1992) argue that world-society connections diffused mass education to former colonies, rather than education systems developing simply as a function of level of economic development. Meyer

and associates (1997b) examine how a world environmental regime emerged in recent decades through world-society associational processes, facilitated by the statelessness of this world society.

The interaction of these world-cultural forms with local contexts is unclear, however, as Meyer and associates (1997a) argue that there may be significant “decoupling” of these symbolic forms from the social practices in each context. Escobar (1995) argues that development discourses have relied exclusively on Western knowledge systems to the extent that non-Western knowledge systems are inherently marginalized by these “modernization” discourses. Ferguson (1990) shows that in Lesotho, the effect of modernization-inspired development policies was not to produce development but to depoliticize poverty and the further entrenchment of the state and Western modernizing influences. Other empirical work suggests that there are in fact a number of contesting models of the global economy, implying a more conflictual process than that depicted by Meyer and associates (Wade 1998).

Other social theorists take a more critical view of modernization while still placing the condition of modernity at the center of their analyses. Beck and associates (1994) have argued that advanced industrial societies are undergoing a new “reflexive modernization” that is closely tied to globalization. These authors see modernization bringing increased control over nature and society, as orthodox modernization theory predicts, but further rounds of modernization generating problems based precisely on its own success. The advance of rationalism and scientism remains central to their theories, but they are more skeptical about the ability of the experts to anticipate or control the side effects of their innovations. Pollution and other ecological disasters are critical political issues but also examples of how technical and social change can result in unanticipated system-level crises.

Giddens (1991) argues that modernity is inherently globalizing. Both are linked by the process of “disembedding”—the lifting out of social relations from local contexts of interaction. There are two main mechanisms of disembedding: symbolic tokens (universal media such as money) and expert systems (bodies of technical knowledge

that can be applied across a range of different contexts). Each produces a homogenization of social life across different contexts and relies on trust in absent repositories of expertise. With this trust, therefore, comes a strong element of risk, a risk that is an inherent element of the globalization process.

Beck (1992) places risk squarely at the center of his approach. For Beck, the populations of the advanced capitalist countries are living in a post-scarcity age where the major dilemmas are the side effects of success. Risks such as pollution are also inherently global in that they are not limited to the local contexts in which they are produced and also in that they have a tendency to affect all members of society relatively equally. We are also becoming increasingly conscious of these risks and therefore of our global interdependence with other societies. There is a new politics of risk—a politics that is concerned with the distribution not of “goods” but of “bads,” a politics that is not limited by territory and in which multiple groups of experts struggle to legitimate their expertise as the potential solution to risk management.

The globalization of modernist worldviews and their primary agents—scientists and professionals—is once again placed at the center of the analysis. However, Giddens and Beck add an understanding of the dilemmas associated with such globalized rationalist institutions. Lash and Urry (1994) point up the postmodernist emphasis on aesthetic symbols and signs, in contrast to the modernist emphasis on rationalism and the power of scientists and professionals. They direct our attention toward cultural consumption on a global scale rather than toward the diffusion of rationalist worldviews and their effects.

Sociologists concerned with modernity and modernization emphasize the diffusion of rationalistic organizational principles (such as the nation-state form) on a global scale rather than the spread of global capitalism. Individuals are culturally constituted by the global system as rationalized, individualized actors rather than as workers or members of classes, while capitalists take second place to experts as the prime movers of the historical process of globalization. Nonetheless, theorists of modernization and modernity share with Marxists the view of an increasingly rationalized world, for better or worse.

DEPENDENCY THEORY

In contrast, sociologists who analyzed the global system from a dependency perspective emphasized the extent to which Third World political economies evolve differently from those of First World countries because they confront a world dominated by already industrialized countries. Deriving their initial inspiration from economists such as Prebisch (1950) and Baran (1957), the dependency approach saw the global system as consisting of a “core” of advanced industrial countries connected both economically and politically to a larger “periphery” of poor nations, rather than as consisting simply of a set of nations that can be ranked along various continua according to individual characteristics such as size and wealth. The structure of the global system was conceptualized primarily in terms of trade and capital flows reinforced by political domination. The principal concern was with the consequences of these ties for social, political, and economic change in the countries of the periphery.

Cardoso and Faletto’s *Dependency and Development in Latin America* (1979 [1969]) is still the classic exemplar of this tradition. Their analysis shows that the way in which economic elites are connected to the global economy shapes not only their strategies of investment but also their willingness to make political alliances with other groups and classes. For example, Latin American countries whose primary ties to the core were formed by mineral exports under the control of foreign capital experienced a different political history from countries who relied on agricultural exports controlled by local elites.

The expectations of the dependency approach with regard to changes in the structure of the global system over time stand in sharp contrast to those of both traditional Marxist and modernization approaches. The dependency perspective emphasizes the ways in which economic elites and their allies in the periphery have an interest in preventing the full diffusion of economic capacities from core to periphery. For example, those who have an interest in the system of trading agrarian exports for core-country manufactures may consider nascent local industrialists to be competitors for both labor and political power.

Empirical work generated by the dependency perspective suggested that the consequences of

core–periphery capital flows, rather than being the most important stimulus to the growth of the periphery as Marxists like Warren suggested, might in fact create obstacles to growth. Korzeniewicz and Moran (1997) show that overall world income inequality increased between 1965 and 1992, particularly in the 1980s—the most significant component of that inequality being between-country inequality. Initial cross-national quantitative analyses discovered that the buildup of stocks of foreign capital had negative, rather than the expected positive, consequences for growth (Bornschiefer et al. 1978; Chase-Dunn 1975). Firebaugh (1992, 1996), however, shows that the negative effects of foreign investment are in part a result of methodological problems with the analyses and that, while foreign investment is less beneficial than domestic investment, it has a generally positive short-term effect on growth. Dixon and Boswell (1996a, 1996b) reformulate the dependency argument to emphasize the negative externalities associated with foreign investment that dampen the productivity of domestic investment. Kentor (1998) finds that dependency on foreign capital has particularly harmful effects on growth over the long term (thirty years) through the distortion and disarticulation of the domestic political economy. Crowley and associates (1998), in a review of cross-national quantitative studies in economics and sociology, find that foreign investment has a short-term positive effect on growth but plays a more negative role over the long term. However, the dynamics through which foreign investment generates negative externalities within a political economy are not well understood (Dixon and Boswell 1996b). While the findings of these studies are still contested, they clearly demonstrate that the results of transnational capital flows are not those predicted by a simple diffusionist model.

The impact of trade liberalization has been just as controversial as that of foreign investment. O’Hearn’s (1990) longitudinal analysis of the Republic of Ireland shows that while foreign investment did not have a direct negative effect, free trade (which was inextricably tied to the foreign-investment policy) had substantial negative effects on growth and inequality. Crowley and associates (1998) review studies of the impact of trade on growth and find that while export reliance is generally positively related to growth, this positive effect is reduced or reversed under conditions that

approximate to those theorized as “unequal exchange” (Emmanuel 1972). Rodrik (1997), reviewing the economics literature, finds that unskilled workers are likely to experience increased labor-market insecurity in the face of free trade, that nations may have legitimate reasons to limit trade, and that national systems of social security are indeed threatened by trade liberalization.

Again, quantitative cross-national studies played a valuable role in specifying the consequences of industrializing in an already industrialized world. Chase Dunn (1975) found that a greater role for foreign capital was associated with high levels of inequality, and his findings were confirmed by a variety of subsequent studies (e.g., Evans and Timberlake 1980; Rubinson 1976). These studies also confirm the political consequences of global economic ties. Delacroix and Ragin (1981) show that peripheral status in terms of trade relations is associated with weak state apparatuses. Bornschieer and Ballmer-Cao (1979) argue on the basis of cross-national data that core-peripheral capital flows strengthen the political position of traditional power holders at the expense of labor and middle-class groups.

One of the criticisms that can be leveled against the dependency approach is that it has focused too much on capital and not enough on labor. Whereas dependency theorists have been concerned with the consequences of transnational capital flows for labor in both periphery and core (e.g., Frobel et al. 1981), the tradition contains no series of cross-national quantitative analyses of either wage levels or the structure of international labor flows studies comparable to the literature on international capital flows. With some notable exceptions (e.g., Portes and Walton 1981) the global structure of labor flows and their consequences is understudied. The 1990s saw a series of valuable case studies of work under globalization, although the consequences of work organization patterns in shaping patterns of dependency has not been explored in detail (Bonacich et al. 1994; Hodson 1998; Salzinger 1997).

Even within a global economy that is becoming more polarized, there have been significant cases of upward mobility. Spain and Portugal, which once formed the core, later moved to the semiperiphery, where they are joined by Taiwan

and Korea, which have moved up from the periphery (Korzeniewicz and Moran 1997). Although dependency theory has concentrated on the obstacles to mobility facing peripheral economies, it has also stimulated a wide range of research on the causes of mobility within the world-system. Analysts of “dependent development” (Cardoso 1974; Evans 1979) argue that intensification of ties with core countries is a dynamic element in reshaping the political economies of Third World countries. Dependent development shares with classic Marxist approaches the assumption that capital flows between core and periphery can play a significant role in generating industrialization in the Third World. It emphasizes, however, that both the economic character of this industrialization and its social and political concomitants are likely to be different from the experience of core countries.

The question of domestic dynamics is particularly important in relation to explanations of the mobility of individual nations from one position to another. While such mobility depends in part on changes in the system as a whole, it also depends on the outcome of domestic political struggles. In his work on Chile, for example, Zeitlin (1984) argues that the outcome of political struggles among economic elites in the nineteenth century was determinative of Chile’s retaining its role as an exporter of raw materials rather than moving in the direction of trying to transform its mineral resources into more processed exports. Zeitlin’s analysis of Chile shows how the outcome of domestic political contests can perpetuate peripheral status.

Brenner’s (1976, 1977) interpretation of England’s rise to the core provides another example of the domestic roots of systemic mobility. In Brenner’s view, the differences between the agrarian strategies of England on the one hand and Spain and Portugal on the other were not simply the result of trade possibilities generated by changes at the level of the world-system. They depended crucially on interactions between peasant communities and agrarian elites at the local level, which in turn were rooted in longstanding historical characteristics of the peasant communities themselves.

Likewise, Taiwan and Korea are used as examples of the way in which internal dynamics may allow construction of more effective state apparatuses, which in turn enable a country to improve its

position in the global system (Evans 1987). In the East Asian developmental states, and especially in Japan and Korea, the state sat at the center of an alliance between the large business groups, domestic banks, and certain key state agencies—prodding and poking firms and banks in more developmental directions, organizing political alliances, and mobilizing social resources (Amsden 1989; Evans 1995; Wade 1990). Research stimulated by the dependency perspective has been both a powerful corrective to views of globalization as an inevitable, relatively even process of diffusion from the core to the periphery. Recognizing the obstacles to diffusion has also problematized the cases where mobility has occurred and has focused analysts' attention on the forces shaping a nation's ability to overcome these obstacles.

WORLD-SYSTEM THEORY

The dependency approach's contribution to our understanding of the international system has, however, been limited by the fact that it does not focus directly on the structure of the global system itself. The "world-system" approach, launched by Immanuel Wallerstein (1974) and others (see Chase-Dunn 1989) at the beginning of the 1970s, took the overall structure of the system as its starting point. Wallerstein's contribution lay not only in directing attention to analysis of the global system itself, but also in setting the contemporary capitalist world-system in the context of previous systems spanning more than one society.

In Wallerstein's world-system, the hierarchical structure is postulated as essential for its survival. The geographic expansion of northwestern Europe's economic and political influence beginning at the end of the "long" fourteenth century was, in Wallerstein's view, essential to the transformation of productive organization in that region. Subsequent interchange among regions with different modes of extraction has been central to sustaining the process of accumulation in the system as a whole. Wallerstein envisions at least three structural positions within the system. Defined in terms of the nature of their exchange relations with other regions, they are (1) the "core," which exports goods produced by processes more intensive in their use of capital and new technology; (2) the

periphery, which relies on the production of labor and resource-intensive goods; and (3) the semiperiphery, which "trades both ways". Arrighi (1994) emphasizes the role of finance in the world-system as a complement to the Wallersteinian focus on trade and the division of labor. He traces the process of capital accumulation across four systemic cycles of accumulation in the world-system. Each one is associated with a different hegemonic (state) power that coordinates the securing of the conditions for capital accumulation on a world scale.

Quantitative cross-national analysis provides support for the idea that countries can be categorized according to their interactions with other nations and that countries in the same position experience shared benefits (or costs). Snyder and Kick (1979), using "block modeling" techniques, found a block of nations whose characteristics corresponded roughly to those of the core, several blocks that corresponded to the periphery, and a set of nations with the intermediary properties attributed to the semiperiphery. Smith and White (1992) used a similar methodology but improved on Snyder and Kick by examining longitudinal changes in the structure of the system. They were able to demonstrate changes in the structure of relations within and between blocks of nations and chart the mobility of individual nations within the system. Van Rossem (1996), however, using an analysis of the role structure of the world economy, argues that world-system position has little direct effect on growth but is better seen as a framework within which nations can act rather than as a determining force in national economic development.

Some of the most interesting work stimulated by world-system thinking has involved analysis of systems that antedated the emergence of the contemporary one (e.g., Abu-Lughod 1989). Wallerstein argues that systems prior to the current one were primarily of two types. "Minisystems" extended across boundaries defined by unified political control and ethnic solidarity but did not come close to being global in scope. These minisystems have been the subject of a number of recent studies, with interesting comparisons across different world-systems (Chase-Dunn and Hall 1997; Chase-Dunn and Mann 1998). "World empires" joined various ethnic and social groups in a single division of

labor by extending political control over a broader geographic area. Only the contemporary capitalist world-system, however, unites such a broad geographic region (essentially the entire globe) in a single division of labor without unified political control of corresponding scope. Frank (1998) has challenged the Eurocentrism of world-systems theory, arguing that the Western European capitalist heyday is but an interlude in the dominance of Asia in the world economy. Arrighi and Silver (1999) compare the contemporary period to the two major hegemonic transitions—from Dutch to British power in the 1700s and from British to U.S. power in the early twentieth century. They argue that the financial expansion of the last two decades of the twentieth century, is not so much a sign of deepening globalization as of systemic crisis, with an uncertain outcome which depending largely on the response of the declining hegemonic power, the United States. The comparative perspective across geographic scales and historical time periods that world-systems theory can provide gives valuable insight into the novelty or otherwise of contemporary globalization processes.

Another interesting trend in current sociological work on the global system is the increasing concern of sociologists with the politics of international relations among states. The third volume of Wallerstein's (1989) epic analysis of the modern world-system makes it clear that the world-system perspective, often accused in the past of being excessively "economistic," is now focusing much more on the logic of interstate politics, an emphasis that is also central to Arrighi's work. At the same time, other major sociological figures have turned their attention to the political and military aspects of the international system (e.g., Giddens 1985; Mann 1988; Tilly 1992). There has also been some attempt within world-systems theory to incorporate the dynamics of households (Smith and Wallerstein 1992) and of social movements. The emphasis within the tradition remains firmly on structural, macro-level processes, despite an increasing attention to cultural constructions (Wallerstein 1990). World-systems theory does analyze how the core countries are affected by the development of the world-system—unlike in the previous perspectives. However, this analysis is concentrated on the struggle among core nations for hegemonic power within the world system.

There is very little analysis of the impact of peripheral development, or even of globalization processes more generally, on the core within any of the perspectives discussed so far.

A quite different systems perspective on globalization has been advanced by Robertson (1992). Building on a concern to link a Parsonian concept of social systems to an analysis of international relations, Robertson posits that globalization involves the structuration of a social system at the global level. He argues that this process of globalization has been underway since the early fifteenth century and has resulted in ever-increasing global complexity within the social system. He shares with world-systems theory a "long view" of the development of globalization tendencies. However, he rejects the "reductionism" and "economism" of world-systems theory in favor of an analysis of the cultural and social conditions of social order within a global system. Robertson argues that there is an intensification of global consciousness in the sense that individuals increasingly orient toward the world as a whole. This rise in global consciousness is sustained both by the greater material interdependence of people around the world and by the interplay of four components of the global social system: the individual self, the national society, the world-system of societies, and humankind (1992, p. 27). The self-definition of each element can no longer be sustained in isolation from the other elements—under conditions of globalization each component is constituted relative to the others, providing the defining feature of globalization.

CURRENT GLOBAL SYSTEMS ANALYSIS

Each of the "classical" perspectives on globalization has therefore generated insights into the process and continues to sustain a research tradition of its own. However, the theme of globalization has spread beyond the confines of these traditions to become a central organizing concept across a wide range of sociological perspectives and research. Since approximately the early 1980s, globalization has had an increasingly visible impact on the core countries themselves, shaping the concerns of sociologists located in those countries. Sociology itself has been at least partially globalized—both by the emergence of "indigenous" sociological

communities around the world and by the growing international communication between these communities (Albrow 1996). Previous eras of sociological research into the global system had been shaped by a concern for the impact of the core on the periphery. However, these new patterns of globalization and new locations and perspectives of sociologists have generated an interest in how specific components of that system are being rearticulated and in particular how the global, the local, and the national are being reconstituted (Waters 1995). This diverse body of research typically examines globalization by generating “theories of the middle range,” often as a reaction against what was seen as overly abstract or deterministic systems-level theories (Portes and Walton 1981). The diffusion of the concept of globalization through sociology and this concern for revealing the mechanisms of globalization were reflected in a fragmentation of perspectives in the 1990s. In the rest of this article, we will review some of this recent research, focusing on the issues of the globalization of production, the constitution of a “global culture” and the future of the state in a global economy.

Over the course of the 1970s and 1980s, a growing body of work emerged that took the influence of the global system seriously in its analysis of change at the domestic level while at the same time using analysis of domestic political struggles and their economic consequences to explain changing ties with the global system (see Evans and Stephens 1988). These attempts to integrate international and comparative analysis are not unique to sociology. A parallel trend can be observed in political science as well (see Gourevitch 1986; Putnam 1988).

In the 1990s, work on global and local production systems, while often informed by dependency theory, also took a somewhat different approach. Reich (1991) argues that “national champion” corporations are rapidly being transformed into “global webs,” or “virtual corporations,” that coordinate knowledge inputs from around the globe. Castells (1997) argues that the structural logic of society is increasingly expressed through a “space of flows” that stretches across the globe. Flows of capital, information technology, organizational interaction, images, sounds, and symbols are the expression of the dominant processes of global society. They are based on an electronic infrastructure,

supported through key nodes or locations, and directed by a dominant, managerial elite. Most people continue to live in the “space of places” where local context dominates their experience. However, the space of flows tends to dominate the space of places as function and power are increasingly organized in flows while experience remains rooted for the most part in places (Castells 1997, p. 428).

Organizational theory suggests, however, that the model of the virtual corporation is likely to be problematic as home and host country effects, corporate cultures, and sectoral characteristics still shape corporate strategies in significant ways. Gereffi advances the concept of “global commodity chains” (GCCs) as the organizational structure that ties together these various social and institutional contexts in a global production network (Gereffi 1994; Gereffi and Korzeniewicz 1994; Harrison 1994). These GCCs are dominated either by key producers or by dominant brand name marketing firms, creating “producer-driven” and “buyer-driven” GCCs. The overall organization of the GCCs and location within the GCC shape workers’ wages, conditions, and power in the workplace (Bonacich et al. 1994).

This perspective therefore goes well beyond perspectives that simply warn about capital mobility and virtual corporations. It also allows us to provide more nuanced accounts of the dynamics involved in territories’ dependency on foreign capital, although the analysis of the political contexts of GCCs has not yet been fully developed. This more nuanced analysis of global production structures also holds the potential for improved integration of the role of domestic dynamics in determining the position of individual nations within the system and, by extension, shaping the structure of the system itself.

Increased attention is also being paid to how, even in an era of globalization, long-established patterns of interaction and cultural forms can profoundly shape a nation’s ability to compete globally. The success of Japan, Korea, and Taiwan can, for example, be argued to be due in part to the contribution of communitarian, patrimonial, and patrilineal cultural logics to creating the organizational networks that are at the heart of these countries’ economic success (Orrú et al. 1997). A

country's historically shaped 'logic of social organization' can make it better suited to competition in particular industries—for example, a more decentralized, less hierarchical culture such as that of the United States may be more suitable for industries, such as software, that are based on knowledge sharing (Biggart and Guillen 1999; Guillen 1994).

Theorists of "industrial districts" have made a somewhat different point regarding the importance of local social and cultural practices in shaping global competitiveness. They argue that in an era of post-Fordist production, where information processing is critical and the need for "flexible specialization" central to competitiveness, local face-to-face relationships are necessary to build up the trust that supports such competitiveness (Piore and Sabel 1984). Initial versions of this approach pointed to long-established civic traditions, craft traditions, and kin relations as underpinning such organizational forms, in Italy in particular (Piore and Sabel 1984; Putnam 1993). Later research has explored the emergence of such cooperation and trust in "new" regions, such as Silicon Valley (Saxenian 1994), Hollywood (Storper 1997), Southern California (Scott 1993), and numerous other regions identified in a huge range of studies (Castells and Hall 1994). Sabel has explored at a theoretical level how such "constitutional orders" can develop or even be promoted by policy (Sabel 1996a).

Sassen explicitly attempts to integrate these local and global perspectives through an analysis of how labor flows are shaped by capital flows (Sassen 1988, 1998), how "global cities" arise as centralized nodes of control over decentralized production systems (Sassen 1990), how domestic structures of inequality are created by the demand for high-wage professionals and low-wage service workers (Sassen 1988, 1990), and how the state comes to play a critical role in globalization, even as it is transformed by the process (Sassen 1996, 1998). She extends this analysis to begin to analyze the incorporation of women into the global economy and the opportunities and threats posed for them by this process (Sassen 1998). Sassen demonstrates the interaction between transnational corporate networks and labor flows and territorial entities such as global cities and local and national states in shaping global capitalism.

This creative tension between local and global is also visible in research on "global culture." For many authors, the global reach of markets has brought with it the cultural construction of actors around the world as individualized consumers, often in association with the more general spread of U.S. cultural norms internationally (Barber 1995; Featherstone 1990; Ritzer 1993; Sklair 1991). Others see a reaction against this process in a return to "tribalism," in the increase in ethnic and nationalist conflicts and atrocities, and in the general struggle between "locals" caught in the space of places and "cosmopolitans" operating in the space of flows (Barber 1995; Castells 1997).

Each of these implies a vision of global culture as a homogenizing force, with local identities surfacing as a reaction against this domination or, in certain cases, exclusion. However, other authors emphasize how global cultural forms become transformed in the local culture and how local cultures form part of a more varied and heterogeneous global culture. Appadurai (1996) argues that global cultural flows are shaped by the multiplicity of perspectives generated by flows of people, money, technologies, ideologies, and media technologies and symbols. Working through these varied cultural landscapes, local cultures work to incorporate global symbols but in ways specific to the local context. There is no pure local culture that is untainted by global culture but rather a variety of local cultures that are increasingly interpenetrated and constantly remade out of elements of global cultural flows (Appadurai 1996; Hall 1991).

Research on migration and transnational communities provides an opportunity to examine the interaction of local and global forces in shaping "global culture." Hodagneu-Sotelo (1994) shows how migration can present opportunities for women to play a more central role in their communities and in mediating relations between the community and the state. Transnational communities of migrants emerge that may have huge economic and social impacts on the home and host countries by creating new identities and structuring flows of social and financial resources (Massey and Parrata 1998; Portes 1996). Another social group that has received much research attention, but rarely under the rubric of globalization, is professionals, who, as we have seen, are central to the process of globalization and are most likely to be integrated into global networks in the workplace (Reich 1991)

or in their migration patterns (Castells 1997). Finally, research into virtual communities promises to provide insights into the nature of community and shared culture in an ostensibly placeless cyberspace (Turkle 1995; Wellman et al. 1996).

Finally, we turn to the state, which is often claimed to be a doomed social actor in the face of globalization as mobile corporations, finance, migrants, and symbols undermine its economic, political, and cultural authority (Esping-Andersen 1996). Furthermore, globalization is one factor shifting the focus of politics away from the state and established interests and toward “new social movements” organized around new identities forged from “codes” from around the world (Melucci 1996). A variety of research, mainly in political economy, has aimed to show the continuing national diversity in socioeconomic organization and the persistent power of the state to shape economic outcomes (Boyer and Drache 1996; Hirst and Thompson 1996; Wade 1996). Indeed, globalization has in many ways been produced by states. Sassen (1998) argues that the state has played a key role in creating the international and local conditions for global production and capital accumulation. States have negotiated new legal regimes that secure the rights of capital on a global scale and have supported the strategic sites through which the global economy is organized. Economic sociology’s improved understanding of the social and political construction of markets can be applied very usefully to the continuing national diversity in state–market relations (Berger and Dore 1996). Fligstein (1990), for example, shows the domestic conditions for the increased U.S. corporate emphasis on finance, an emphasis that, at the end of the 1990s, threatened the East Asian economies (Wade 1998). The particular property rights and exchange rules underpinning the construction of a single market within the European Union have also been profoundly shaped by interstate negotiations (Fligstein and Mara-Drita 1996).

Neil Brenner (1998, 1999) argues that state structures and strategies are being reconstituted in order to mediate the global and local processes discussed above. The “glocal state” attempts to promote the global competitiveness of its major urban regions through increased ties to both local and international actors. Sassen (1999) points out that this remaking of certain parts of the state

apparatus to promote global competitiveness begins to shape the character of the state as a whole, as even those sections of the state still predominantly concerned with national social policy become accountable to the new priorities and as the national legal and institutional structure is changed to accommodate international capital. These processes are not inevitable, however, as the international hegemony of Anglo-American economic ideology contributes to the creation of a “leaner, meaner” state that retains the institutional capability to support capital even as its capacity to provide social services or to support civil society weakens (Evans 1997). This excessive global liberalization and integration of financial markets is likely to have a corrosive effect on domestic state capacities and social welfare (Block 1996).

The state is therefore remade by globalization, even as it plays a critical role in constituting the global economy. Sociologists are beginning to explore the implications of this reconstitution of the state for economic sovereignty and citizenship. Castells (1997) argues that a “network state” is emerging, a state in which sovereignty is pooled between increasingly intertwined local, national, and international levels of governance, such as in the European Union. Debates persist as to whether this network state means the eclipse of local or national institutions as European Union institutions increasingly come to predominate (Streeck and Schmitter 1991) or even as a “postnational society” is created in Europe (Habermas 1998). There are persistent examples within Europe, however, that local and national institutions continue to play a central role in generating economic and social progress. Recent examples include national corporatist institutions in the Netherlands (Visser and Hemerijck 1996), local “micro-corporatism” in Italy (Locke 1995; Regini 1995), and a combination of the two in the Republic of Ireland (Sabel 1996b).

States are clearly being transformed by both the localization and globalization of economic life. Boyer and Hollingsworth (1996) argue that economic action is best conceived of as “nested” within a combination of local, national, and international institutions, rather than as “embedded” within national regimes. Indeed, formal sovereignty is shifting away from the state in many cases—toward both privatized transnational legal

regimes (such as international commercial arbitration) and increasingly legitimate international human rights codes and instruments. These developments are also transforming the character of citizenship—on the one hand weakening certain provisions around economic and social citizenship (Sassen 1996) while on the other universalizing certain human rights (Soysal 1994). In short, then, the state remains a vital actor within the global system but one whose role, purpose, and structure are being transformed in new and unexpected ways.

Sociology itself is being transformed and globalized, if only partially up to this point. In the process, global systems analysis has moved from the specialization of a number of key theories to perhaps becoming a defining element of sociology in the twenty-first century. New methodologies are being developed to counter the abstraction of systems analysis and to provide insights into the process of globalization as revealed in local contexts and as practiced by social actors (Burawoy et al. forthcoming). What new theoretical and methodological traditions will emerge from this period of change remains unclear. Overall, our understanding of the global system must still be considered a project “under construction” rather than a finished set of tools easily applied to specific problems.

This is all the more true given the rapid changes in the global system itself. Some things are clear nonetheless. We know that trajectories of change in national societies cannot be analyzed without reference to the global system in which they are embedded any more than the analysis of change in individual communities can be attempted without awareness of the national society in which they are embedded; but we also know that the character of relations between an individual state and the larger system is shaped not just only by the evolution of the global system but also by the outcome of political struggles at the local level. We know that the nations located at the bottom of this structure are disadvantaged economically as well as politically, but we also know that mobility is possible. We know that diffusion of ideas and norms throughout the global system has a powerful influence on how social institutions are structured in individual nations, but we also know that this diffusion takes place within a system that has a very hierarchical structure. Increasingly, we understand that local

societies incorporate global cultural forms in complex and contested ways.

We know that the contemporary global system is an invention of the last half-dozen centuries; predicting how long it will endure is another question. For some, the future seems gloomy as the market threatens to undermine both state and society and lead to barbarism, as Polanyi (1944) suggested. For others, the future holds the possibility of the re-creation of civilizing institutions on a more comprehensive global scale. Still others seek to identify spaces for action within globalization processes, hoping to shape alternatives to the pessimistic Polanyian vision of creeping barbarism.

GOVERNMENT REGULATION

Government regulation is part of two larger areas of study, one encompassing all *state* policy making and administration, whether regulatory or not, the other encompassing all *regulatory* and *deregulatory*

activity, whether by the state or by some other institution. Viewed either way, the subject remains an interdisciplinary growth industry, with contributions made by political scientists, economists, legal scholars, historians, and sociologists. Scholarly emphasis in the 1990s on economic globalization and its consequences has added to an already rich literature on government regulation, deregulation, and re-regulation. Now attention is focused on the supranational as well as the national level. Cross-national, comparative studies of government regulation complement a large literature focused on the United States.

WHAT IS GOVERNMENT REGULATION?

There is no uniformly agreed-upon concept of regulation that separates it from other kinds of government activity. Mitnick (1980, pp. 3–19) offers a good overview of concepts of regulation. On the one hand, narrow definitions typically focus on government action affecting private business by policing market entry and exit, rate or price, and profit structures and competitive environment. Some narrow definitions confine regulatory activity to that undertaken by administrative agencies (see also Majone 1994). If courts are the exclusive site for state rule making and enforcement, it is not considered government regulation. On the other hand, the broadest definitions conceive of regulation as government action affecting private businesses or citizens. Government regulation then becomes virtually coterminous with all government policy making and administration, whether by legislatures, administrative agencies, courts, or some combination.

Mitnick (1980) shows that American scholarship has provided for much variation in the conceptualizing of government regulatory activity. However, Majone (1994) suggests that in the past, American concepts typically were narrower than those adopted explicitly or implicitly by European scholars. For example, self-labeled *regulation theory* is a "quasi-Marxist theory [in which] the notion of regulation . . . refers to institutions and norms that permit the reproduction of conflictual or contradictory social relations" (see Steinmetz 1996, p. 346). In this predominantly European tradition, modes of regulation are broad political-economic and cultural governance forms. They revolve

around capital accumulation and involve state action, including macroeconomic, social, and labor-market policies, but also involve systems of interest intermediation in the workplace, economic rule making by banks and other nongovernmental institutions, and cultural schemata followed and taught in families and schools. Lange and Regini (1989) and Regini (1995) reject such an all-encompassing definition of regulation in favor of a somewhat narrower one. But they also call attention to how regulatory action structures and reconciles conflicts and allocates resources, as well as coordinates interaction and relationships in production and distribution.

Lange and Regini (1989) argue that regulatory principles and regulatory institutions must be separated analytically. Both economic and political institutions regulate or engage in governance. We tend to equate market exchange principles with economic institutions and legal rulings and administrative decrees with the state. However, as Lange and Regini (1989) demonstrate, economic institutions also employ command and control logic, while the state may employ the logic of exchange. Most recently, European scholars have moved away from equating regulation with the realm of *all* institutional governance or of *all* government legislation and social control. Many now distinguish “the regulation issue” both from other modes of institutional governance and from other modes of state action, including nationalization and government planning (Majone 1994, p. 77).

Sabatier (1975) has offered a useful definition of *government* regulation in between the broad and narrow extremes. His definition is based on the goals and content of government policy, not on the means of enforcement. It highlights the distinction between government policing of behavior and government allocation of goods and services. Distributive (e.g., defense contracts) and redistributive policies (e.g., the income tax, social welfare policies) allocate goods and services. Government policing is self-regulatory if it polices behavior to the benefit of the group whose behavior is policed. It is regulatory if it “seek(s) to change the behavior of some actors in order to benefit others” (Sabatier 1975, p. 307). Pollution control, antidiscrimination, consumer protection, occupational safety and health, employment relations, and antitrust are examples of regulatory policies.

Sociologists often distinguish between economic and social regulation. Where economic regulation controls market activities, such as entry and exit or price controls, social regulation controls aspects of production, such as occupational safety and health standards and pollution control (e.g., Szasz 1986). The term *social regulation* is also used to signal regulation that directly affects people rather, or more than, markets (Mitnick 1980, p. 15). In the 1990s literature on European economic integration, a distinction has been made between regulation (governance oriented to making markets) and reregulation (governance oriented to constraining markets) (e.g., Streeck 1998). But the term *reregulation* is also used more broadly, to signal regulatory reform that both liberalizes markets and institutes new rules to police them (Vogel 1996).

Regulation is dynamic. It is “an ongoing process or relation” between regulator and regulated parties (Mitnick 1980, p. 6). Because of the nature of the legal system in the United States, regulation U.S.-style tends to involve issuing and applying legal rules (Sabatier 1975, p. 307). For example, Congress has legislated federal statutes to promote competitive markets, to prevent race and gender discrimination in employment, and to increase workplace safety. These laws have been interpreted and enforced by the appropriate federal administrative agencies and by the federal courts. Federal regulatory agencies include the Interstate Commerce Commission (ICC), Federal Trade Commission (FTC), Federal Communications Commission (FCC), Securities and Exchange Commission (SEC), Equal Employment Opportunity Commission (EEOC), National Labor Relations Board (NLRB), Environmental Protection Agency (EPA), Food and Drug Administration (FDA), and Occupational Safety and Health Administration (OSHA). (For case studies of many of these agencies, see Derthick and Quirk 1985; Wilson 1980b.)

Consistent with the U.S. emphasis on legal rules as implementing mechanisms, the institutional forms used to reach regulatory goals are varied. Breyer (1982) provides an overview of the ideal-typical workings of various government regulatory forms, including cost-of-service rate making (e.g., public utility regulation), standard setting (e.g., administrative rule making and enforcement

by the EPA and OSHA), and individualized screening (e.g., the FDA regulations pursuant to which food additives can be marketed). Mitnick (1980) also provides an overview of government regulatory forms and contrasts regulation by directive (e.g., administrative and adjudicative rule making) with regulation by incentive (e.g., tax incentives, effluent charges, and subsidies).

It is no accident that European scholars in the 1990s are devoting heightened attention to government regulation and are also beginning to conceive of it more similarly to their U.S. counterparts (see, e.g., Majone 1994; Scharpf 1997a; Vogel 1996). European economic integration has been accompanied by concern that national governments would compete to lessen business costs in part by lowering standards for environmental, health and safety, financial, and other regulations. European integration has also involved a cumulative process of European Court of Justice rule making geared to constructing and policing the integrated market (see e.g., Leibfried and Pierson 1995; Scharpf 1997a). Thus, European integration has created a situation in which courts and judicial review are more important than they were in the past.

According to Majone (1994, p. 77), “regulation has become the new border between the state and the economy [in Europe] and the battleground for ideas on how the economy should be run.” In addition, since national courts in ordinary administrative and civil proceedings apply the market-making and market-policing rules formulated by the supranational European Court, regulatory *law* is beginning to become visible to ordinary citizens of European countries as it has been for some time to citizens of the United States. These developments do *not* mean that we can assume a future convergence of either the concept or the reality of the “regulatory state” in Europe and the United States. They *do* mean that there is increasing potential for the cross-fertilization of scholarly concepts, theories, and empirical work from both sides of the Atlantic. These developments also provide new opportunities for informative comparative studies of government regulation.

THEORIES OF REGULATION

There are various general theoretical approaches to government regulation. Most are concerned

with regulatory origins or processes, but often they also address questions of impact, at least implicitly. Because regulation is not just an object of scholarly inquiry but also an ongoing political process, it is easy to confuse normative perspectives on regulation with explanations for the empirical phenomenon. Here, I focus on the latter, that is, on positive as opposed to normative theories. Mitnick (1980) and Moe (1987) provide detailed exposition and evaluation of a large range of these positive theories. All are theories of “interest.” Majone (1994) reviews the predominant normative perspective. The latter holds that corrective government action to improve economic efficiency is justified by such diverse types of market failure as natural monopoly, imperfect information and negative externalities (see also Breyer 1982).

Bernstein’s classic life-cycle theory argues that regulatory agencies designed in the public interest become captured by the powerful private interests they are designed to regulate (see Mitnick 1980, pp. 45–50). The diffuse majority favoring government regulation loses interest once the initial statute is legislated. This leaves the regulatory agency with few political resources to confront strong, well-organized regulatory parties with a large stake in agency outcomes.

Arguing that regulatory agencies are not simply captured by private interests but are designed from the beginning to do their bidding, Stigler (1971) and others have developed the economic theory of regulation. This theory assumes that all actors behave rationally in their own self-interest and so try to use government to achieve their own ends. But economic interest does not necessarily result in effective mobilization of resources. Because “there is a mobilization bias in favor of small groups, particularly those having one or more members with sizable individual stakes in political outcomes,” concentrated business interests have great advantages over diffuse groups in mobilizing for regulatory legislation (Moe 1987, pp. 274–275). Regulatory capture results when the costs of regulation fall upon a concentrated group (e.g., a particular industry such as railroads or airlines) and the benefits of regulation fall upon a diffuse group (e.g., consumers). Similarly, when benefits fall upon a concentrated group and costs on a diffuse one, regulation will be designed to benefit regulated parties.

The economic theory of regulation does not always predict capture. Generally, regulatory policies result from a chain of control running from economic groups to politicians to bureaucrats. These policies reflect the underlying balance of power among economic groups, whatever that balance may be. Considering different distributions of regulatory costs relative to regulatory benefits, Wilson (1980a, pp. 364–374) sketches four different scenarios for the origins of regulation. Exemplified by the origin and operation of the Civil Aeronautics Board, “client politics” is consistent with Stigler’s prediction that regulation reflects the regulated industry’s desires. Client politics result when costs are widely distributed and benefits are concentrated. When both costs and benefits are narrowly concentrated, both sides have strong incentives to organize and exert influence, so “interest group politics” results. Wilson views passage of the Commerce Act in 1886 as a product of conflict over rate regulation, in which interest group participants included railroads, farmers, and shippers.

According to Wilson, when both costs and benefits are widely distributed, interest groups have little incentive to form around regulatory issues because none can expect to capture most of the benefits or to avoid most of the costs. “Majoritarian politics,” in which the mobilization of popular opinion is likely to play an important role, governs passage of such legislation. Finally, “entrepreneurial politics” characterizes the dynamics of mobilization around policies that offer widely distributed benefits but narrowly concentrated costs. Here, although policy opponents benefit from the mobilization bias of small numbers and have strong incentives to organize, a “policy entrepreneur” can “mobilize latent public sentiment . . . [and] put opponents” on the defensive (Wilson 1980a, p. 370). For Wilson, pollution-control laws enforced by the EPA exemplify entrepreneurial politics. Although the traditional economic theory of regulation predicts ultimate capture of agencies created by entrepreneurial politics, Sabatier (1975) argues that such agencies can avoid capture by concentrated business interests if they actively develop a supportive constituency able to monitor regulatory policy effectively.

Economic theories of government regulation have much to say about the political dynamics of social groups seeking and resisting regulation, but

they do not attend to political and administrative institutions. In contrast, the positive theory of institutions “traces the congressional and bureaucratic linkages by which interests are translated into public policy” (Moe 1987, p. 279). This theory is one of a large group of more specific theories falling under the burgeoning “new institutionalism” in the social sciences (Eisner 1991; Powell and DiMaggio 1991). Like all variants of institutionalism, the positive theory of institutions argues that political institutions and rules of the game matter. Although actors try to create rules that lead to outcomes they favor, institutionalized rules may well be out of sync with underlying economic interests. Whether the regulatory policies of the U.S. Congress reflect any given economic interest depends on the distribution of that interest across congressional districts, the location of members of Congress who support that interest on particular committees with particular prerogatives and jurisdictions, and the rules of the congressional game.

The positive theory of institutions ordinarily begins with and focuses on the self-interest of actors in Congress and the regulatory agencies rather than that of actors outside these legislative and administrative institutions. It argues that legislative choice of regulatory forms as well as of regulatory content can be modeled as a function of the costs and benefits to legislators of selecting particular regulatory strategies (see, e.g., Fiorina 1982). These costs and benefits are a function of the distribution of economic interests across districts and the political-institutional rules of the game. In general, electoral incentives prevent members of Congress from placing high priority on controlling administrative agencies. The principal-agent models of control employed by the positive theory of institutions “suggest . . . that even when legislators do have incentives to control agencies toward specific ends” they probably will fail “owing to . . . conflicts of interest, information asymmetries, and opportunities for bureaucratic ‘shirking’” (Moe 1987, p. 281). Game-theoretic models of regulatory enforcement developed in this theory indicate ample opportunity for the capture of the regulators by regulated parties (Ayres and Braithwaite 1989). However, where some forms of capture are economically undesirable, others are economically (Pareto) efficient.

Other theoretical perspectives used by sociologists to study regulation include various forms

of neo-marxist political economy or class theory (see Levine 1988; Steinmetz 1997; Yeager 1990) and the political-institutionalist view developed by Theda Skocpol and others (Skocpol 1992; Weir et al. 1988). Where the former parallels the economic theory of regulation in focusing on the organization and mobilization of nongovernmental actors—specifically classes and segments of classes—in support of their interests, the latter parallels the positive theory of institutions in stressing the import of political structures and rules of the game. But in contrast to economic and positive theories, which largely model comparative statics (Moe 1987), class and political-institutional theories ordinarily focus on historical dynamics.

Political institutionalists stress, for example, the importance of feedback from prior to current regulatory policies and of political learning by government actors (see Pedriana and Stryker 1997). Feedback and political learning can help account for deregulation as well as for regulation (see Majone 1994). Class theorists stress how regulatory enforcement and cycles of regulation and deregulation evolve over time in response both to the structural constraints of a capitalist economy and to active struggles over regulation by classes and class segments. For example, Yeager (1990) argues that because government in a capitalist society depends on tax revenues from the private accumulation of capital, it tends to resolve conflict conservatively over such negative consequences of production as air or water pollution, so as not to threaten economic growth. Many aspects of U.S. regulatory processes make it likely that laws passed against powerful economic actors will be limited in impact or will have unintended effects that exacerbate the problems that initially caused regulation.

The effectiveness of regulatory statutes may be limited by implementation decisions relying on cost-benefit considerations because ordinarily costs are more easily determined than benefits and because cost-benefit analyses assert the primacy of private production. Moreover, government relies upon signals from private business to gauge when regulation is preventing adequate economic growth. Limited effectiveness of regulation also results from enforcement procedures tilted in favor of regulated parties that have the technical and financial resources needed to negotiate with agency officials. Corporate organizational forms encourage leniency and negotiations about compliance.

Corporate officials seldom are prosecuted for criminal violations because the corporate form makes it hard to locate individual culpability. Because courts emphasize proper legal reasoning when reviewing agency decisions, regulatory agencies may focus on procedure rather than substance. Ambiguous statutes are likely to heighten a procedural approach to regulatory enforcement (see Edelman 1992). In turn, focus on procedures over substance will tilt enforcement toward the interests of regulated parties. Finally, because no unit of government has complete control over any given policy from legislation through funding and implementation, parties bearing the cost of regulation need thwart regulation at only one point in the process, while supporters of regulation must promote it effectively at all points. In implementation, advocates of tough enforcement are likely to lose to more resource-rich segments of business seeking to limit regulation (Yeager 1990).

Notwithstanding forces that load regulatory processes in favor of the regulated business community and particularly the larger, more powerful corporations at the expense of smaller firms, consumers, environmentalists, and labor, class theorists also see limits on regulatory leniency. For example, Yeager (1990) argues that pollution-control enforcement biased toward large corporations dominating the U.S. economy will reproduce both the dominance of this business segment and of large-scale pollution. Regulatory ineffectiveness may lead to a loss of legitimacy for government as the public responds to higher risk and to perceived governmental failure by pressuring for additional pollution-control efforts.

Finally, although the concept of interest is central to theories of regulation, sociologists studying regulation are sensitive to the causal role of cultural schemata, norms, ideas, values, and beliefs as well as of economic and political interests and political institutions. For example, elaborating on Swidler's (1986) notion of culture as a tool kit, Pedriana and Stryker (1997) examine the diverse cultural strategies involved in the symbolic framing of regulatory enforcement efforts in U.S. equal employment law. They show that these frames are cultural resources developed by social and institutional actors in variable ways as a function of their variable political-economic, political-cultural, and legal circumstances. They also show how

actors' mobilization of cultural resources affects the subsequent path of regulatory policy making. Construction of cultural resources, then, is one key mechanism through which policy feedbacks occur and political learning is given effect. Meidinger (1987), too, highlights the role of culture, focusing on the way understandings—including understandings about costs, benefits, and appropriate trade-offs—are negotiated and enacted by actors in regulatory arenas. Because statutes are indeterminate, regulators always possess some discretion. In addition, the mutual interdependence among regulated parties and regulators calls attention to the formation of regulatory communities in which shared cognitive and normative orientations develop, forming the basis for ongoing regulatory cultures.

Ayres and Braithwaite (1989) harness the notion of regulatory culture to their search for economically efficient regulatory schemes. They approach the problem of regulatory capture through a synthesis of economic interest and socialization mechanisms. Seeking a social framework to facilitate economically efficient forms of capture while deterring inefficient capture, they point to benefits obtainable if all participants in regulatory processes that empower public interest groups adhere to a culture of regulatory reasonableness. For example, social and self-disapproval sanctions in a regulatory ethic that is firm but reasonable will inhibit regulators from capitulating to law evasion by industry and from punitive enforcement when industry is complying with regulatory law. Yeager (1990) has a somewhat different view of regulatory reasonableness. He views limits on regulatory laws controlling pollution as a function of prevailing cultural belief systems as well as of class and group relations. Notions of regulatory responsiveness and reasonableness are negotiated in enforcement interactions between regulators and regulated parties within an overall cultural framework attributing moral ambivalence rather than unqualified harm to regulated conduct. This facilitates adoption of a technical orientation to solving "noncompliance" problems rather than of a more punitive approach. Because the regulation of business has to be justified constantly within highly market-oriented cultures like the United States, administering market-constraining regulation itself becomes morally ambivalent and contributes to less aggressive enforcement.

FROM REGULATION TO DEREGULATION AND REREGULATION

Discussions of dynamism and change, whether through structural contradiction and class conflict as stressed by neo-Marxist perspectives, or through policy feedback and political learning as stressed by political-institutionalists, lead naturally toward explicit theorization and empirical research on periods or cycles of regulation and deregulation or reregulation. As Majone (1994) points out, deregulatory ideologies and politics in the United States were preceded by decades of scholarship on the economics, politics, and law of government regulatory processes. In Europe, by contrast, the term "deregulation" gained much more "sudden currency" (Majone 1994, p. 98). Unsurprisingly, on both sides of the Atlantic, the concepts and perspectives used to study deregulation parallel the alternative economic interest and political interest/political-institutional foci of theories of regulation themselves.

On the one hand, for example, Szasz (1986) analyzes deregulatory social movements in the United States through the lens of presumed accumulation and legitimation functions of the capitalist state. He suggests that changing economic circumstances provided political opportunity for the deregulatory movement in occupational safety and health. In the 1970s, a substantially worsening economy altered the balance of class forces and changed the political situation confronting the state. Deteriorating economic conditions weakened the economic and political power of organized labor, a major supporter of occupational safety and health legislation. These same conditions encouraged big business to join the already existing but to this point unsuccessful small business attacks on the Occupational Safety and Health Administration. Where small business argued for the complete elimination of OSHA, big business relied on cost-benefit analyses to argue that sound economics required reforming the implementation process. Though economic conditions made deregulation possible, the success it achieved and the form it took required business interests to mount a conscious, ideological campaign to mold favorable public opinion.

On the other hand, Derthick and Quirk (1985), examining deregulatory processes in the realm of *economic*, as opposed to *social* regulation, criticize

non-state-centered analyses of deregulation. They argue that, at least in the United States, regulated industries with a putative stake in deregulation did not ask to be deregulated. Nor were consumers' movements a major force. Instead, the deregulatory push emanated predominantly from within state regulatory agencies and courts, with commissioners and judges acting as policy entrepreneurs. Deregulatory politics and deregulation itself were only later and often quite reluctantly accepted by regulated industries such as airlines, trucking, and communications.

The foci of Derthick and Quirk (1985) and Szasz (1986) converge to highlight the role played by academic and policy think-tank experts in paving the way for and promoting pro-competitive regulatory reform. Szasz shows how U.S. economists and political scientists built a rationale for deregulation in the 1970s (see Breyer 1982 for a sophisticated but very readable overview of economic justifications and analyses of regulation and of economic justifications for deregulation). Derthick and Quirk (1985) push the role played by these experts further back in time, albeit noting that the earliest promoters of regulatory reform would never have anticipated the successful political movement for which they helped paved the way. Nonetheless, U.S. administrative law and public administration experts long had found fault with government regulatory structures and procedures. By the 1960s, economists had joined the chorus, attacking economic regulation for fostering costly inefficiencies and for shielding industries from competition. Economists also attacked economic and social regulation for producing costs in excess of benefits.

As Majone (1994) points out, where the United States tended to create regulated industries, allowing critics to catalogue subsequent *regulatory* failures, Europe traditionally tended toward public ownership, with its own set of corresponding failures to interpret and experience. When deregulatory ideologies were produced in Europe or diffused from the United States, privatization became the rallying point. But neither privatization nor the search for "less restrictive" or "less rigid" government intervention necessarily means the retreat of the state (Majone 1994, p. 80).

Deregulation is most precisely conceptualized as *reduction in the level of government regulation*. It

involves eliminating or reducing government rules or lessening their strictness (Vogel 1996). Strictly speaking, deregulation moves institutional governance toward *self*-governed markets. But according to Vogel (1996), much scholarship is remiss in equating deregulation with *any* kind of liberalization or pro-competitive regulatory reform (see, e.g., Derthick and Quirk 1985). Equating deregulation with market liberalization is undesirable because it forecloses by definitional fiat the question of whether and how liberalization may involve *more* government rule making rather than less. Liberalization may involve *changing* government rules rather than eliminating them (Vogel 1996).

Indeed, Vogel (1996) argues that across capitalist democracies the trends are toward what he terms reregulation rather than deregulation. Rather than reduce their levels of regulation of the private sector, governments have reorganized their control over it. When governments privatize previously nationalized industries and when they liberalize regulated markets to introduce more competition, ordinarily this involves both the reformulation of old rules and the creation of new ones. As the title of Vogel's book suggests, then, the price of "freer markets" is "more rules" (Vogel 1996; see also, e.g., Majone 1994; Streeck 1998). Increased conceptual precision helps Vogel solve what otherwise appears as a puzzle and paradox: that, as noted by Derthick and Quirk (1985), state actors themselves promote a great deal of deregulatory activity. To the question of why governments would take action apparently against their own interests, Vogel answers "they don't." Instead, as political-institutional perspectives on regulation would suggest, governments initiate regulatory *reform* and shape *reregulation* in their own interests. Pro-competitive regulatory reform represents neither "the triumph of markets over government" nor "the triumph of [economic] interests over government" (Vogel 1996, pp. 10, 13).

Vogel rejects exclusively economic theories of deregulation that argue either that increasingly integrated global markets force governments to deregulate or that interest groups, especially regulated industries, orchestrate reform. Instead, he provides a synthesis of sorts between economic and political-institutional views. He hypothesizes that, on the one hand, governments of advanced capitalist democracies *do* face a common set of economic and cultural pressures. Technologically

induced global market changes in particularly dynamic sectors like telecommunications and financial services compel governments to respond in *some* way, but without setting the terms of the response. Diffusion of market and deregulatory ideologies from the United States also exerts pressures—albeit somewhat less strong—for a response. In addition, this ideological diffusion helps explain why governments across the advanced capitalist world adopt similar reform *rhetorics*. It does *not* explain when and why they undertake reform action or the form their reregulation takes. Finally, governments do face a common politics of economic slowdown, in which they find that “the growth in demand for government services outpaces the growth of government resources for meeting this demand (Vogel 1996, p. 40). This creates political opportunity. But it does not explain why conservative and even left political parties take that opportunity in some countries, while neither left nor even conservative parties do so in others.

In short, according to Vogel’s theory of deregulation, there are a set of common forces for change—some stronger, some weaker, some broader, some narrower—that set the stage for specific national responses. However, “states themselves, even more than private interest groups, have driven the reform process” (Vogel 1996, p. 4). Governments in the advanced industrial world cannot ignore private groups’ interests and demands, but they take the initiative in shaping reform and constructing politically acceptable compromises. In this, governments do *not* converge in a common deregulatory trend. Instead, they adopt particular types and distinctive styles of reregulation as they achieve liberalized markets to different degrees. At its core, so-called deregulation is about “finding new ways to raise government revenue and designing new mechanisms of policy implementation” (Vogel 1996, p. 19). These goals typically concern states more than private interests, so it becomes no surprise that state actors actively mobilize to shape regulatory reform.

Vogel categorizes diverse reregulatory styles and processes in terms of two dimensions: whether the emphasis is more on liberalization or more on reregulation, and whether the reregulation undermines or enhances government control over industry. In turn, the diverse reregulatory styles and processes emerge as a function of variation

across countries in political-institutional regulatory regimes, developed over time as a function of each country’s own unique history, especially its history of industrialization. Regulatory regimes are “comprised of specific constellations of ideas and institutions” (Vogel 1996, p. 20). The ideas, or *regime orientation*, involve “state actors’ beliefs about the proper scope, goals and methods of government intervention in the economy and about how this intervention affects economic performance” (Vogel 1996, p. 20). Diverse regime orientations cause government officials to define the public interest in varied ways, to interpret common economic and ideological pressures and trends differently, and to conceive of different kinds of responses to such pressures and trends as appropriate. *Regime organization* involves how state regulators concerned with a given industry are structured internally and how they are linked to the private sector. In contemplating reform, government actors will assess how diverse alternatives are likely to affect existing institutions and arrangements. Differences in regime organization affect especially *who*—whether political parties, bureaucrats, and so forth—will control reform processes, *whether* government officials will try to refrain state capabilities, and *what* capabilities government officials will try to retain or develop for themselves in the reform process.

Vogel’s (1996) framework fundamentally reorients scholars to distinguish concepts of deregulation and reregulation and to approach both in terms of an overarching perspective that considers regulation, deregulation, and reregulation as part of the broader study of regulatory change. (Parallel efforts to integrate explanations of welfare development and retrenchment into a broader theory of change in social policy are equally underway [see, e.g., discussions in Steinmetz 1997; Stryker 1998]). Vogel’s framework is conducive to investigating the interaction of international pressures and domestic politics, as well as the interaction of governments and private actors. It is likewise conducive to investigating how institutional and cultural boundaries between public and private have been variably articulated across countries and over time, and to investigating how globalization shapes opportunities for and constraints on national-level government regulation and on the development of supranational regulatory institutions.

EMPIRICAL STUDIES

Empirical research on regulation includes studies of regulatory origins (e.g., Majone 1994; Sanders 1981, 1986; Steinberg 1982), processes (e.g., Edelman 1992; Eisner 1991; Moe 1987; Yeager 1990), and impact (e.g., Beller 1982; Donahue and Heckman 1991; Mendelhoff 1979). It also includes studies of deregulation and reregulation (e.g., Derthick and Quirk 1985; Streeck 1998; Szasz 1986; Vogel 1996). Studies of processes look at the evolution of regulatory forms (e.g., Majone 1994; Stryker 1989, 1990) as well as at the substance of regulatory rules (e.g., McCammon 1990; Melnick 1983; Vogel 1996). Researchers employ a variety of methodologies. These include quantitative assessment of causes and consequences of regulation (e.g., Donahue and Heckman 1991; Mendeloff 1979; Steinberg 1982) and quantitative models of regulatory processes (e.g., Edelman 1992; Edelman et al. 1999; Yeager 1990). They also include qualitative, case-oriented legal, historical, or comparative accounts of regulatory, deregulatory, and reregulatory evolution (e.g., Majone 1994; Melnick 1983; Sanders 1981; Stryker 1990; Szasz 1986; Vogel 1996). It is hard to generalize about findings from empirical studies of regulation. A few things, however, are reasonably clear.

First, no general theory or perspective on regulation enjoys unqualified support when stacked up against the variety and complexity of regulatory experiences. Second, all extant theories have something to offer the empirical analyst. Third, in response to the first and second points, the field seems to be moving away from accounts that focus on either economic interests or political-institutional rules to more integrative or synthetic accounts that encompass a role for both. Fourth, European Union integration has increased interest in empirical research on supranational regulatory bodies, as a key part of the broader study of multitiered governance structures. Fifth, empirical building blocks are being constructed for overarching concepts and theories that account for variation in regulatory regimes and for regulatory change, whether toward increased or decreased regulation or from one institutional principle (e.g., command and control) to another (e.g., market incentives). The rest of this article elaborates on these points.

Empirical studies suggest that economic interests and resources are a major factor but not the sole one, in the dynamics of political struggles over regulatory origins and administration (Moe, 1987; Sanders 1986; Stryker 1989, 1990; Szasz 1986; Yeager 1990). Political structures and rules of the game matter because they are the mechanisms through which economic and social actors must translate their interests into regulatory policy (Moe 1987). But for legislative, administrative, and judicial participants in policy processes, these institutional mechanisms also create independent interests in, and resources for, regulatory policy making. Sanders (1981) shows that the regulation of natural gas in the United States has been a function of four sets of regionally based economic interests, including gas producer regions of the United States and gas consumer regions, as well as of electoral rules and structures. Regulatory outcomes have resulted from a dynamic relationship among political actors who reflect the changing market positions of their constituents. "The potential for sectional conflict is exacerbated by the territorial basis of elections, the weakness of the party system, and a federal structure that not only encloses different political cultures and legal systems, but also supports fifty sets of elected officials sensitive to encroachments on their respective turfs" (Sanders 1981, p. 196).

Current regulatory structures and policies *do* have feedback effects constraining and providing opportunities for subsequent regulatory policies as well as for subsequent action by parties with interests at stake in regulation (Sanders 1981; Steinberg 1982; Stryker 1990). Feedbacks occur through cultural as well as political-institutional mechanisms and political learning (e.g., Pedriana and Stryker 1997; Vogel 1996). In this regard, Vogel's (1996) comparative study of deregulation and regulation of telecommunications and financial services in the United States, the United Kingdom, France, Germany, and Japan highlights the mediating role of nationally specific regime orientations. State actors interpret situations and conceive of responses through the lens of regime orientation. Their cognitive and normative interpretive work then shapes the form and content of regulatory reform. Pedriana and Stryker (1997) demonstrate that both general equal opportunity values and the specific language in which

they are expressed provide raw materials for construction of symbolic resources by actors struggling over the enforcement of equal employment and affirmative action law in the United States. The work of Majone (1994) and Boyer (1996), among others, suggests that political learning occurs through the experience and interpretation of regulatory failures as well as of market failures.

In addition, the legal structures and culture through which most regulation is administered in the United States significantly shape regulatory processes and outcomes. For example, Melnick (1983) shows how the narrow, highly structured, reactive, and adversarial legal processes through which pollution control takes place in the United States have led to court decisions that simultaneously extend the scope of EPA programs and lessen agency resources for achieving pollution control goals. Appellate judges tend to promote stringent antipollution standards because they are removed from local concerns and are likely to be inspired by broad public goals. In a different institutional location, trial judges observe the impact on local businesses and citizens of imposing strict regulation. Their flexibility in response to the perceived harm of strict regulation generates an equity-balancing enforcement that counteracts what is accomplished in standard setting.

Likewise, because legal mandates are not self-executing and many are ambiguous, the response of regulated parties is an important mediator of regulatory impact. This response includes actions taken by organizations to demonstrate their compliance with law. For example, Edelman (1992) and Edelman and colleagues (1999) show that organizations respond to federal equal employment law in the United States by creating equal employment opportunity policies, organizational units, and grievance procedures. These both promote symbolism over substance and shape later court constructions of what constitutes compliance and what will insulate organizations from liability. More obviously, the response of regulated parties also includes whether and how public and private institutions and individuals invoke regulatory law on behalf of aggrieved parties (e.g., Burstein 1991). Additionally, it includes how public and private actors mobilize the values and language encapsulated in the law as political-cultural and legal resources to *change* the law (e.g., Pedriana and Stryker 1997).

Yet another insight from empirical studies is that regulatory implementation is influenced by internal agency politics as well as by the agency's external environment. Likewise, technical experts play an important role in shaping regulatory evolution. Stryker (1989, 1990) has shown how, in conjunction with class and political institutional factors, intra-NLRB conflict between agency economists and lawyers over the proper administrative use of social science caused Congress to abolish the NLRB's economic research unit. Katzmann (1980) and Eisner (1991) have shown how internal jockeying by economists within the FTC changed enforcement priorities and outcomes over time. Even more generally, empirical studies of regulation and deregulation point to the justificatory and mobilizing import of diverse kinds of scientific and technical expertise (e.g., Derthick and Quirk 1985; Eisner 1991; Szasz 1986). While heavily relied upon to promote deregulation and pro-competitive regulatory reform, economic analysis also can be mobilized to promote more stringent regulation and diverse types of reregulation (e.g., Rose-Ackerman 1992; Stryker 1989).

Empirical studies of regulation also show that regulation often has unintended effects. Yeager (1990) shows how EPA sanctioning decisions and processes, while rational in the face of economic, political, and legal constraints on the agency, reproduce private sector inequality by favoring large corporations that have financial and technical resources. Large companies have greater access to agency proceedings than do small companies. Agency proceedings often change pollution-control requirements in favor of regulated firms, so that ultimately large corporations have fewer pollution violations. In decisions to apply the harshest sanctions—criminal and civil prosecutions—the EPA may well avoid tangling with the most resource-rich firms for fear of losing in court. Melnick (1983, p. 354) indicates a similar dynamic. Ostensibly neutral procedures, then, create inequitable law enforcement and may also help reproduce the problems that led to the initial pollution-control legislation.

Yet another important message emphasized by empirical studies of regulation in the 1990s is the need to consider the growth of supranational mechanisms of governance and how these interrelate with national government regulation. Majone

(1994), for example, shows that with minimal explicit legal mandate and with very limited resources, there has nonetheless been continuous growth in the final three decades of the twentieth century in regulation by the European Community (EC, now the European Union, or EU). Economic and social regulation is “the core” of EU policy making (Majone 1994, p. 77). It is undertaken by the European Commission (Commission) in tandem with the European Court of Justice (ECJ), now supplemented with a court of first instance (see Leibfried and Pierson 1995). Between 1967–1987, for example, even *before* the Single European Act recognized EC authority to legislate to protect the environment, there were close to “200 environmental directives, regulations and decisions made by the European Commission” (Majone 1994, p. 85). Consumer product safety, banking and financial services, and medical drug testing also have been areas of high-volume Commission regulatory activity. Regulation has provided a way for the Commission to expand its role in spite of tight EC budgets and the serious political-institutional constraints embedded in the EC’s legal framework, at the same time as EC member states have been willing to delegate to a supranational authority because agreements among the EC national governments had low credibility (Majone 1994).

In the regulatory arena, the ECJ has been as important as, or even more important than, the Commission (see, e.g., Leibfried and Pierson 1995). Ostner and Lewis (1995), for example, stress the *inter-relationship* of the Commission and the ECJ. Even before the Single European Act in 1987, “gender policies . . . evolved through the intricate interplay between these two supranational bodies, within the range of outcomes tolerated by member states. By the late 1980s the Court’s interpretations of article 199 [of the Treaty of Rome], Commission-fostered directives that [gave] the article concrete form and extend[ed] it, and the Court’s subsequent rulings about the meaning of the directives yielded a body of gender-related policies of substantial scope” (Ostner and Lewis 1995, p. 159). No wonder scholars have characterized the EU as a “state of courts and technocrats” (Leibfried 1992, p. 249) and have highlighted “the rise of the regulatory state in Europe” (Majone 1994, p. 77). In turn, European scholars’ awareness of the import of Commission and ECJ regulatory activity

has fueled their growing research interest in American-style regulation (Majone 1994; see also Leibfried and Pierson 1995).

Finally, although capture of government regulators by regulated parties can and does occur (see Sabatier 1975; Sanders 1981), it need not. Enactment of regulatory legislation can also lead to cycles of aggressive enforcement alternating with periods of capture or, similarly, to enforcement that oscillates between or among the interests at stake in regulation or between periods of regulation and deregulation or reregulation. For example, over time, FTC enforcement has alternated between favoring big or small business and core or peripheral economic regions of the United States (Stryker 1990). Sanders’s (1981) study of natural gas regulation in the United States shows that the initial federal legislation mixed goals of consumer protection and of industry promotion. Federal Power Commission interaction with its environment did not result in stable capture by gas producers but rather in oscillation between capture by gas consumers and capture by gas producers. Clearly, consumers, labor, and other subordinate groups can be, and have been, benefited by regulation (see, e.g., Sanders 1981; Steinberg 1982; Stryker 1989). But the political economy of capitalism also sets structural and cultural limits to these benefits (McCammon 1990; Szasz 1986; Yeager 1990).

In this regard, economic globalization and European economic integration enhance the political and economic resources of business groups at the expense of labor, providing pressures and opportunities for governments to undertake market-liberalizing regulatory reforms (Streeck 1995, 1998; Stryker 1998; Vogel 1996). However, these same processes also may generate counterpressures and counteropportunities. As Streeck (1998) shows, European integration has been a process of economic liberalization by international means. In this process, national-level regulations are exposed to competitive market pressures, including the threat of “regulatory arbitrage”—business corporations moving capital or firms from countries with less favorable regulations to countries with a more favorable regulatory climate. Competitive market pressures then further advance liberalization. But liberalization likewise “calls forth demands” from individuals and communities for market-constraining reregulation, so that they can “cope with the uncertainties of free markets and stabilize

their social existence in dynamically changing economic conditions” (Streeck 1998, p. 432).

A major challenge to theories and empirical research on government regulation in the future is to model and explain the historical and comparative dynamics of both economic and social regulation at intersecting subnational, national, and supranational levels. Further work should continue to address diversity and change over time and place in regulatory scope, levels, institutional forms, and cultural justifications. Ideally, further juxtaposition of abstract theory and concrete historical and comparative research, both qualitative and quantitative, can lead to integrated theories of regulatory origins, processes, and impact. Ideally, as well, these theories can explain not just regulation but also deregulation and reregulation. This is a tall order, but the seeds have been planted in scholarship like that of Vogel (1996), which is equally sensitive to economic and organizational interests and resources, to political structures and rules, and to regulatory cultures (see also the empirically informed analytic frameworks offered in, e.g., Scharpf 1997b; Stryker 1996). Seeds also have been planted in research programs, like Vogel’s (1996), that are sensitive to periods or cycles in which different economic and other institutional arrangements, incentives, and constraints operate, and to feedback effects from past to future regulatory policies and processes (see also Boyer 1996).

Whether or not such an integrative and synthetic theory is achieved, a combination of unfolding social processes, including globalization, court-led European integration, and democratization and marketization in eastern Europe and elsewhere all will continue to enhance interest in the study of government regulation. All these processes simultaneously promote economic liberalization and the regulatory state. Whatever else these current political-economic changes bring, they certainly should enhance scholarly dialogue and also synergy across national borders in the study of regulation.

GROUP COHESIVENESS

See Interpersonal Attraction; Small Groups.

GROUP CONFLICT RESOLUTION

To understand conflict resolution among groups it is helpful first to consider the role of conflict in and among groups. Conflict analysis of groups is divided between the study of *intragroup* conflict, that which happens within a group among its members, and *intergroup* conflict, that which happens between one or more groups where the conflict is viewed as involving the group as a whole. The study of these phenomena is closely related to the study of both group dynamics and cross-cultural relations. A further distinction is made according to the group level being studied. Here the separation is generally between group conflicts and international conflicts. Group conflicts include both communal group conflicts and workplace conflicts. Communal group conflicts can involve just about any group that provides people with social identity. Social identity is itself a group-level concept, since it is defined as the identity we gain from being part of a collectivity, a group. Since most of the hours of our days are organized around group membership, the study of groups and their interactions is central to the work of sociologists.

When groups are in conflict, the very presence of the group intensifies and changes the way conflict between individuals is perceived. Membership in the group affords the individual two perceptions that impact on the conflict: (1) that the individual is right and justified to engage in and

attempt to win the conflict and (2) that the individual will be evaluated and either further embraced or rejected based on his or her performance in a conflict situation. Within groups, conflict often results in patterns of splintering or perhaps a coup d'état and expulsion. Between groups, conflict can encourage deindividuation, ethnocentrism, and diabolical imaging of the enemy. Groups often provide individuals with a way to rationalize their involvement in a conflict and perhaps to take actions they might otherwise avoid. Conflict resolution is likewise changed in a group situation.

Defining exactly what a conflict is has also been an important part of the analysis of conflict and its resolution. There are generally two accepted ways of defining "conflict": (1) realistic and (2) perceived. The former involves tangible, verifiable competing interests. The latter refers to situations where it is believed by one or both parties that the other stands in the way of achieving what is desired. Conflicts occur over resources, power distribution, and values. They are classified as latent (yet to be noticed) or manifest. A final method of defining "conflict" is as destructive or constructive. Although viewed by most people as risky and something to be avoided, conflict is often seen differently by conflict analysts. Most who study conflict and its resolution argue that conflict holds the potential to be constructive, to create positive social change. These theorists and practitioners argue that how one copes with conflict is the important distinction. If the proper structures exist (such as skilled trainers or participants), conflict can actually have creative and constructive outcomes.

CONFLICT RESOLUTION

The area of conflict resolution is itself an interdisciplinary field of research. Despite the great diversity of scholars involved in this work, they are brought together by a common interest in understanding how and when conflicts are resolved. What to call the work varies, including such terms as "conflict management," "conflict resolution," and "conflict transformation." A variable here is to what extent and in what way one might get involved to eliminate a conflict. Scholars in this area favor searching for nonviolent and noncontentious methods for ending conflicts, perhaps because these methods are felt to be more

permanent than the cycle of escalation likely to emerge with aggressive measures for “ending” conflicts. Avoidance and repression are also considered to be negative responses to conflict.

Here we focus not generally on the field of conflict resolution but specifically on it in relation to groups. While there is much application of theory and research across the levels of study, there is not much agreement on the transferability of ideas from the interpersonal level to the group or international level. Conflict resolution among groups remains an important but understudied social process. Great strides have been taken in developing various models of conflict resolution at the interpersonal level, but among groups the process remains less easily identifiable. At the international level, only small inroads have been made in developing and testing possible methods. War or military threats remain the most common responses to conflict among nations.

Another variable is when and how conflict might be a positive social phenomenon. Functionalists may wonder about the purpose of the conflict in the larger social construct. Although much more writing exists on the negative impact of conflicts, there are many who argue for the creative potential of conflict. The positive view generally takes one of two tacks. Most common are those scholars who argue that conflict leads to greater understanding, relaying of information, and potentially new ideas and stronger relationships. For them, what matters is how conflict is handled. With proper training and skills, one can learn to turn conflict into a creative interaction. A second group argues that conflict in the form of competition can improve work quality, increase production, and improve unity. They are quick to point out that task conflict especially has this effect; interpersonal conflict rarely yields this positive effect.

INTERPERSONAL VERSUS GROUP CONFLICT

Conflicts happen at all levels of society. The major classifications of levels of conflict include interpersonal, intergroup, and international. The primary distinction between intergroup and international conflicts is that nationalism provides a particular framework for and gives an intensity to conflicts that distinguish them from group conflicts in general. Intergroup conflicts may be organization based

or community based, or they may stem from racial, ethnic, or class differences among groups not recognized at the nation-state level. Fisher (1990) argues that the study of group and international conflict is not nearly as well developed as the research on conflict at the interpersonal level. He cautions against assuming that analysis derived from interpersonal experiences can be generalized to other levels. He points to basic information about how groups affect conflict and suggests that these differences necessitate different strategies for addressing and reducing conflict among groups and nations.

IMPACT OF GROUPS ON CONFLICT

Group conflict is typically divided into two categories: (1) intragroup and (2) intergroup. Conflict within groups is viewed as potentially harmful since it can lead to competition for leadership, loss of focus on group purpose, and membership loss. Intragroup conflicts are typically about power and control over content, purpose, and goals. It can also emerge out of recognition of intragroup inequalities that are found unacceptable by those with less power.

The primary means of limiting intragroup conflict is maintaining a strong normative structure with effective member socialization. When conflicts arise, avoidance often leads the group to dissolve. Methods for solving conflicts within groups include facilitation or problem solving led by an external professional or perhaps a skilled insider, capitulation by one party, subdivision of the group, or re-prioritization of group goals. The latter often occurs in the presence of an outside threat. In fact, a useful response to internal conflict is the identification of a common fear or enemy. External threat increases the sense of homogeneity within the group, encourages commitment to ensuring group survival, and rationalizes stern measures to limit internal challenges to the status quo.

Intergroup conflicts are typically about control and distribution of resources (objective conflicts) or threats to identity or values (perceptual, or subjective, conflicts). Realistic group conflict theory (RCT) focuses on rational mechanisms for understanding group conflict. Social identity theory (SIT) focuses on the idea that the mere perception of belonging to a discrete group is sufficient to produce intergroup discrimination. According

to SIT, groups are the major basis for the formation of an individual's sense of identity. And groups produce a positive social identity by being favorably compared to other groups (Fisher 1990). As suggested above, intergroup conflicts can also emerge when there is a desire to quell intragroup conflict through the creation of an enemy.

Usually intergroup conflict is considered more dynamic, more likely to be intractable, quicker to escalate, and more in need of external intervention than interpersonal conflict. According to White, escalation of intergroup conflict is fed by (1) a diabolical image of the enemy, (2) a virile self-image, and (3) a moral self-image (cited in Fisher 1990). Misperceptions and stereotypes of those outside the group are confirmed by group members in an effort to solidify group identity and establish the boundaries of membership. According to balance theory, groups tend to minimize intragroup differences and exaggerate intergroup differences.

Social psychologists suggest that the magnification process stems from an audience effect. In a group, one has confirmation and support for one's position as right and justified. In a group, a clear leader often emerges as external threats grow. Because groups in conflict tend to prefer more aggressive leaders, leaders of groups find themselves pushed to take stances more extreme than they would as individuals. They are expected to succeed (win) or lose power or membership in the group. Leaders often find it difficult to negotiate on behalf of a group with diverse opinions about priorities. Members of the group are more inclined to follow orders in the face of an external threat and to be convinced to commit acts (sometimes heinous) to ensure group survival. This may help individuals' involvement in genocide, torture, and other crimes they would not consider participating in for individual gain.

RESPONSES TO CONFLICT

Scholars in the field point to five possible responses to conflict. The actual names of these responses vary, but they are well represented by the following terms: contending, yielding, avoiding, compromising, and problem solving (integrative solutions). These categories are appropriate for all

levels of conflict—interpersonal, intergroup, and international. The first three (contending, yielding, and avoiding) tend to escalate conflict. The last two fall clearly within the purview of creative conflict resolution.

Contending behavior is when a party to a conflict seeks to solve the conflict at the other party's expense. Rubin and colleagues (1994) suggest that contentious tactics range from light to heavy, where "light" tactics result in acceptable or neutral consequences for the other party and "heavy" tactics impose or threaten severe consequences. Contending behavior is a key part of the upward spiral of escalation, since it usually evokes a defensive response from the other party. As long as a party believes it can win (benefits outweigh costs), it is likely to practice contending behavior.

Yielding responses are sometimes the partner to contending behavior. A party will yield when it is more important that the conflict be over than that the party wins. Yielding may be an initial strategy to lay the basis for getting something else that is a priority at a later time. Or perhaps the concern is just not an issue for the party that yields.

Avoiding conflict is practiced by a party that does not want to encourage the conflict to become manifest. Usually the hope is that if avoided, the conflict will become unimportant over time. While sometimes avoiding does allow space for conflict to fade, it rarely works to actually resolve those issues underlying the conflict. Therefore there is commonly a resurgence of conflict in another way or at a later time. Avoiding conflict can also be perceived by the initiating party as an act of escalation. As such, it can cause the upward spiral of conflict to begin.

Compromising about a conflict is the outcome that most people associate with conflict resolution processes. For some analysts, compromise is a sufficient method to diffuse conflict; others argue that it still falls short of the goal of a "win-win" solution. In a compromise, parties to the conflict are expected to give up some part of their needs or goals if they stand in the way of the other party's reaching important needs or goals. Each party is partially successful in achieving what it sets out to gain or protect at the beginning of the conflict. Neither one completely loses and neither one completely wins.

Problem-solving behavior entails engaging in a process with the goal of achieving a win-win solution to the conflict. A win-win solution is also called an “integrated solution” when the parties’ needs and goals are different but a resolution is found that meets the concerns of both. The process of problem solving is designed to encourage conflicting parties to think creatively to establish possible joint needs and goals and to work cooperatively to solve their problems. There are various methods, such as log-rolling, expanding the pie, and bridging, that can assist in achieving a win-win solution. Log-rolling encourages parties to prioritize their needs and preferences so that lower priority requirements can be negotiated as trade offs in a win-win solution. Expanding the pie requires the infusion of additional resources—often by a party external to the conflict. This makes it possible to satisfy competing needs. In bridging, parties discover mutual definitions of their needs and a single solution leave both satisfied.

ACHIEVING CONFLICT RESOLUTION

A central question in the study of conflict and its resolution involves the conditions that support constructive outcomes to conflict. According to Deutsch (1973), a cooperative environment breeds cooperation and a competitive environment encourages groups to compete. He also suggests that there are three conditions that encourage problem-solving behavior: (1) the arousal of the desire to solve the conflict; (2) conditions that permit reformulation of the issues of the conflict; and (3) the availability of diverse and flexible ideas. Rubin and colleagues (1994) suggest (as do many other scholars) that to turn from contentious behavior to problem solving, the parties must believe that the costs outweigh the benefits if they continue to fight. This may happen because resources are scarce, because the parties fear a permanent loss of their relationship, or perhaps because another party intervenes and provides an incentive (or threat) that encourages seeking a resolution. Sometimes parties in conflict are moved to problem solving by the introduction of a superordinate goal or by the emergence of a common or shared threat.

Establishing communication between the parties is an essential part of turning competitive conflict into cooperative problem solving. The

dynamics of groups can make this particularly challenging to accomplish. Leaders will not want to admit that they exaggerated stereotypes and negative associations to encourage diabolical imaging of the enemy. And leaders that emerged during the escalation of conflict will worry about damaging their credibility by agreeing to enter negotiations. For most people, negotiations mean compromise, which means appearing to have lost, at least partially. Communication and understanding can also be challenging across cultures. Lederach (1995) suggests that while the general progression of a conflict and its resolution remains fairly similar from one culture to the next, the specific processes and techniques for solving problems are dramatically different from one cultural group to the next.

Although it might prove challenging to establish, in any conflict communication is essential to building trust, eliciting interests, and defining the problems and possible solutions. Trust is also built through reciprocity of positive initiatives. As Kriesberg (1998) suggests, changes at three levels—within the group, between the groups, and in the larger social context—all contribute to the initiation of deescalation. Ongoing case studies help us understand how seemingly intractable conflicts can be softened through the transformation of interparty relationships and the intraparty absorption of those changes.

APPLICATIONS OF CONFLICT RESOLUTION FOR GROUPS

Contact Theory. Much effort has gone into identifying conditions that encourage the deescalation of conflict. Organized and well-structured contact between group members is regarded as essential for breaking down stereotypes and assumptions that prevent initiating discussion of the conflict(s). It is thought that this contact needs to be not simply positive but genuinely cooperative, so that new methods of interacting can be learned. Also, the parties need to enter into the contract as equals. Two studies of groups—by Sherif and by Blake and Mouton—suggest that building trust between competing groups requires the creation of superordinate goals if the groups are to move beyond stereotypes and negative assumptions (cited in Fisher 1990). Furthermore, many researchers (Fisher 1990; Rubin et al. 1994) point to the

positive function of superordinate goals or shared tasks in reducing intergroup tensions, especially bias or ethnocentrism. The cooperative nature of this structured contact can decrease perceived threat from the other group, thus supporting the reduction of bias and ethnocentrism. Much of the work in cross-cultural conflict resolution and sensitivity or diversity training operates from this belief that structured contact can be used to challenge people's assumptions about other groups.

Third-Party Intervention (Intermediaries).

Here, an intermediary intercedes with the goal of influencing or facilitating the settlement of a conflict. Historically force has been the common form of intervention. However, Princen (1992) argues that the intermediary role is becoming much more diverse in the contemporary international system. As an intermediary, a party does not impose a solution or have a direct stake in the outcome. However, it is possible that an intermediary has an indirect interest that the problem be solved. Thus Princen (1992) distinguishes those with an indirect stake (principal mediator) from those with no stake at all (neutral mediator). He suggests that the motivation to intervene shapes the form and content of the intervention made by a third party.

A typology of the forms of third-party intervention in conflict resolution would certainly include the following:

- **Peacekeeping.** Placement of military forces from a third party within another country on behalf of the third party or an international organization (e.g., the United Nations) to enforce or maintain a cease-fire and/or a peace agreement. While soldiers are typically armed, they limit their use of weapons to self-defense and defense of the peace agreement.
- **Arbitration.** An individual or a board of arbitrators is appointed (usually by a court or someone in a position of higher power) to listen to the concerns of the parties and elicit their suggested solutions. The arbitrator crafts an agreement to address these concerns. Parties who go to an arbitrator agree to abide by the decision, regardless of whether the outcome is considered favorable to one's concerns (binding arbitration).
- **Mediation.** Parties in conflict meet with an intermediary who facilitates a discussion about the conflict and each party's concerns. The mediator is expected to be neutral on the outcome of the issue and typically is a stranger to each party. There are exceptions in some international situations, where it is often a preference of the parties to know and trust the mediator prior to the meeting. And in some cases the international mediator may have an indirect interest in the outcome of the conflict (principal mediator). Regardless, the philosophy of mediation is that the parties solve their own conflict while the mediator encourages the process, especially the initiation of communication early in the discussions.
- **Conciliation.** Sometimes also known as "shuttle diplomacy" or "track-two diplomacy," this is mediation work that happens without bringing the parties face-to-face. Often this is the first step in developing enough trust for the parties to meet (especially at the international level). These intermediaries must establish high levels of trust and legitimacy with the parties in order to be successful. Often they are known to the parties, or are powerful international players, or are generally recognized for their success in international mediation.
- **Consultation.** In this approach, parties are brought together by a conflict resolution specialist in a workshop format to learn problem-solving skills. Usually the entire group (or significant leadership in the group) is involved. The workshop leader works with the groups to encourage a positive motivation for solving the conflict, to improve communication between the members of the groups, to help the groups define the conflict, and to regulate interaction as the groups discuss their problems. Whereas in much arbitration and mediation the concern is for agreement, here the concern is for building new, positive relationships between the parties by changing their interactions in a controlled setting (Fisher 1990).

These workshops are commonly organized around issues such as communication skills, group decision making, and cross-cultural understanding. They are commonly used with community groups or in work settings where a long-term cooperative relationship is either necessary or desirable.

Unilateral Mechanisms. Even without the intervention by a third party, sometimes a player in a conflict will initiate the deescalation process. This most likely occurs when there is apparently little to be gained (and much to be lost) by continuing the conflict. Unilateral moves typically begin with small confidence-building measures. These actions stand on their own and are done without the requirement of reciprocation (although that may be the hope). The goal is to break the upward spiral of conflict by opening a channel of communication or establishing a foundation for trust.

- **GRIT.** This is the acronym for “graduated and reciprocated initiatives in tension-reduction,” a strategy designed by Charles Osgood in the early 1960s that is intended to streamline unilateral measures (cited in Rubin et al. 1994). Some of his guidelines include announcing the series of unilateral initiatives ahead of time with a clear time line and continuing the announced steps even if the other party does not reciprocate. At the same time, the initiating party maintains its ability to retaliate in case the opposition responds with contentious behavior. The initiatives should reward the other party for cooperating and thus become increasingly favorable to the other party (Fisher 1990; Kreisberg 1998; Rubin et al. 1994).
- **Dialogue groups.** This long-term approach to building understanding between groups entails bringing members of groups together on a regular basis for general discussion. Often these meetings bring together people not directly engaged in the conflict. Hubbard (1997) reports the use of these groups in many communities in the United States to bring together Israelis and Palestinians. The groups typically also include members unrelated to either of the conflict groups. The groups

discuss issues generally or specifically, depending on local, national, or international events. Dialogue groups have also been used in international conflicts to bring together the “average, everyday” people who must learn once again to live side-by-side once the hostilities have ceased.

CURRENT STATUS OF THE FIELD AND RECOMMENDATIONS FOR FURTHER RESEARCH

The field of conflict resolution is clearly interdisciplinary. With the end of the Cold War and the changing nature of conflict internationally, the field has become increasingly influential. Sociologists and social psychologists have contributed to theory building and the development of practical applications at all levels (interpersonal, group, international). The particular concern that sociologists have for group relations and for the alleviation of social inequalities (a common source of conflict) has made a natural fit between the areas of research. Conflict analysts are heirs to the work of Marx, Weber, Simmel, and many other influential sociologists.

A primary interest in both research and in the application of the field is in the area of ethnic conflict. Sociologists are working on these issues both in urban communities and at the international level. Another important area of interest is teaching conflict resolution theory and skills to young people. Mediation became well established both in the schools (elementary through university levels) and in the judicial system in the 1990s. There is also interest in an alternative to the adjudication system, an approach called “restorative justice.”

A challenge to researchers and practitioners is that each conflict has its unique elements. While we have been able to isolate basic concepts and “rules” of the escalation and deescalation of conflict, the nature of human beings resists a single approach to the science of conflict resolution. Most scholars acknowledge that there is more need for study of individual cases of conflicts and for the comparison of specific conflict and conflict resolution processes. This would certainly provide

more resources for the teachers and learners of conflict resolution techniques. At the same time, there is strong resistance to developing a monolithic model, since cultural, historical, and individual characteristics must be taken into account with each conflict. Much of the success of the application of the knowledge gained in the field is dependent upon the skill of the conflict resolution specialist and his or her willingness to respond to case-specific information. There is also a concern that while research is necessary to increase our understanding, the most significant work is done by those who work as practitioners of the conflict resolution process.

GROUP PROBLEM SOLVING

See Decision Making Theory and Research; Group Conflict Resolution; Interpersonal Conflict Resolution; Small Groups; Social Psychology.

GROUP SIZE

Some of the earliest and most basic ideas about groups in sociology concern group size. Cooley (1922) described how people universally are members of primary groups, which are small in size, face-to-face, highly intimate, cooperative, and enduring. Prototypes include families and groups of friends. Although people also participate in secondary groups, which are typically larger, less personal, more formally organized, and more limited in duration and purpose, primary group participation appears necessary for teaching children the requisites for participating in society, including language, basic social skills, values, and identities. Simmel (1950) described the profound effects on interpersonal relations when the smallest group, the dyad (pair), expands to a triad. The dyad is unique because it can be destroyed by the loss of a single member, and this feature often leads to a degree of intimacy and closeness not found in larger groups. Adding another person, a third party, to form a triad dramatically transforms the character of the relations. Simmel noted three different roles served by a third party. One role is as a nonpartisan or mediator, which can serve to draw the members of the pair closer together. For example, the birth of a child may enhance the emotional bond between the parents, or a third person may try to settle a dispute between two friends. Another role is as the *tertius gaudens* ("the third party who enjoys"). The third party benefits when two members in conflict try to win the third party's support. For example, parents who are in conflict may compete to win the affection of their child by using gifts and favors. A third role is to divide and conquer. Here the third party benefits by actively encouraging conflict in the pair. For example, a parent may gain greater control over two children by having them compete for the parent's favors and affection. Simmel thus drew attention to the fact that the triad (and larger groups) brings into play processes that are impossible in the dyad. A systematic account of the effects of group size, however, awaited the emergence of an experimental research tradition.

In sociology the term *group* has been used very loosely, referring at one extreme to small aggregations of people whose members are mutually aware of each other and can potentially interact (McGrath

1984) and at the other extreme to enormous aggregations whose members simply share some characteristic, as in the case of an "ethnic group." In studies of group processes, the more restricted definition has been used. The groups studied have generally been created explicitly for the purpose of research, rather than being ones that existed naturally for other purposes.

Group size has been studied in groups facing two very different circumstances. The first concerns groups that are formed to achieve some common purpose or goal. Interest has focused on how people behave in such groups and conditions that enhance or impede their effectiveness in achieving the goal. The second concerns groups facing collective dilemmas, where each member chooses between two actions with contrasting consequences. One action maximizes each member's own interest, whereas the other action maximizes collective interests, that is, the interests of the group as a whole. The dilemma is that each member profits more from the selfish choice, but if all members make that selfish choice each is worse off than if all chose to maximize collective interests (Komorita and Parks 1994).

GOAL-ORIENTED GROUPS

As Steiner (1972) notes, purposes for which groups are formed can vary on a continuum from task performance at one extreme (e.g., solving a problem, creating some product) to sociability at the other (e.g., simply enjoying one another's company). Groups whose purpose is primarily sociability have been little studied. Assuming that sociability is defined by spontaneous, reciprocal conversation, enjoyment should be highest in groups with no more than five or six members, the largest group size in which this kind of interaction occurs easily. This rule may be qualified in larger groups, however, if the situation is arranged so that people interact in smaller subgroups.

Most experimental research has focused on groups that are more task oriented. Here the most consequential feature is the nature of the task, or *task structure*. The first major program studying task-oriented groups experimentally was conducted by Bales and associates (Bales 1950). Bales and other early researchers focused on groups attempting to solve decision or judgmental tasks, problems for which there is no correct answer and

where differences of opinion are likely regarding the resolution (e.g., a personnel issue facing an administrator in an organization). Groups were told to discuss the assigned problem for a few minutes and then arrive at a group recommendation. Bales's method of interaction process analysis (IPA) coded verbal and nonverbal communication among group members as they addressed two basic ongoing concerns: the task and the relationships among the members. Research by Bales and associates showed the feasibility of measuring ongoing behavior in discussion groups and was instrumental in the emergence of small-group research as a distinctive field in the social sciences.

Group size is a fundamental consideration in discussion groups because the number of possible symmetrical relations between pairs of members increases much more rapidly than the number of members added to the group. The formula is where x =the number of symmetrical relationships and n =number of members (Bossard 1945). In addition to the pair relations, there are also relations between each group member and the group as a whole. If group members interact for a fixed amount of time, adding group members forces changes in the nature of existing relations and limits the number and nature of new relations (e.g., time available with each member, degree to which conversation is reciprocal).

As group size increases, groups tend to adopt a more direct and organized approach in soliciting information, and a task leader is more likely to emerge or be chosen. The top communicator initiates a greater proportion of the group's communications, and the differences in amount of communication by other members diminish (Bales et al. 1951). An increasing proportion of communication is directed toward the group as a whole, and the number of members who participate minimally by simply listening and giving emotional expressions increases (Bales and Borgatta 1955). In addition, the larger the group, the greater the conflict, the less likely members are to reach agreement on controversial issues, the less the conformity to group norms is, and the less the members are satisfied with the group and its activities (Levine and Moreland 1998; Thomas and Fink 1961).

Latané and L'Herrou (1996) suggest that group size is important in determining whether or not

subgroups holding a minority opinion are likely to form and persist over time. As the number of members grows larger, the larger the number of members who may hold minority views, and hence the greater the opportunity for them to interact with each other and avoid exposure to majority views. The emergence of minority subgroups in groups is also affected by whether the group has an odd or even number of members. When opinion is divided, odd-numbered groups (e.g. 3, 5, or 7 members) are more likely to break into majorities and minorities, avoiding the possible even splits of even-numbered groups. With this pattern, odd-numbered groups should have fewer deadlocks and should reach decisions more quickly than even-numbered ones (Bales and Borgatta 1955).

The ideal size of discussion groups is often considered to be four to six members, a number large enough to ensure some diversity in member resources but small enough so that everyone can participate. Groups naturally occurring in public are rarely larger than five or six people, and more often contain two or three (Moreland et al. 1996).

Juries are discussion groups entrusted by the state to make decisions of the utmost consequence for the accused. Because legislation now permits juries smaller than twelve members, jury size has emerged as a variable of interest in studies of actual and mock (experimenter-created) juries. Although twelve-person juries should be less likely to reach unanimous verdicts (or verdicts based on a two-thirds majority) than smaller juries (e.g., six or eight members), the predicted difference is small and it has not been found in the studies themselves (Davis 1989).

Group size affects performance for other types of tasks as well. Steiner (1972) describes the effects for tasks having products or solutions whose adequacy can be judged objectively. Tasks are *unitary* when they cannot be readily divided into subtasks and where mutual assistance is impractical (e.g., working one arithmetic problem, hammering a nail). Tasks are *divisible* when they can be divided into subtasks, allowing different group members to work on the parts before the final product is assembled (e.g., working ten arithmetic problems, assembly-line production). Steiner identified several types of unitary tasks. A task is *disjunctive* when any single member can supply the group's product (e.g., the answer to a question). Here potential

group productivity depends on the resources of the most competent member. The larger the group, the greater the likelihood that at least one member will have the needed resources. As the group grows larger, however, each additional person adds a smaller increment to the group's potential. Productivity gains are thus a decelerating function of group size. A task is *conjunctive* when the resources of the least competent member determine group productivity (e.g., mountain climbers trying to reach the summit while roped together). Here the larger the group, the greater the likelihood that at least one member will be low in competence. As the group grows larger, productivity decreases, with each additional person adding a smaller decrement to the group's potential. Productivity losses are thus a decelerating function of group size. A task is *additive* when individual resources are added to obtain the group product (e.g., stacking firewood, offering ideas to improve a product). Here, the larger the group, the greater the group productivity.

For divisible tasks, variation can occur both in the nature of the subtasks and in the way that subtasks are combined to form the final product. A subtask can be disjunctive, conjunctive, or additive if two or more group members are working on it, and the process of assembling the subtasks can be disjunctive, conjunctive, or additive, thus creating a large number of possibilities. Where the rule for combining subtasks is additive or disjunctive, group productivity should be a positive, decelerating function of group size. The larger the group, the more likely it is that the subgroups can be staffed optimally, but communication, coordination, and matching members to the subtasks most appropriate for their interests and skills can become increasing problems. An increase in group size has the opposite effect, however, where the rule for combining subtasks is conjunctive. For tasks where the labor is divided and it is critical that each member make the correct response (e.g., an airline crew, a team of surgeons), the larger the group, the greater the chance that one of the critical members (or subgroups) will fail to perform adequately, and hence the group will perform poorly.

Steiner notes that actual task productivity often fails to reach potential productivity because groups use faulty or limiting processes to address

the task and may also fail to motivate members sufficiently. Both problems typically increase with group size. With divisible tasks, for example, assignments given to members may not provide a good match between member skills and the sub-tasks they are to perform. In face-to-face groups where each member contributes orally (e.g., giving novel ideas on some topic), larger groups derive decreasing benefits as group size increases simply because only one person can talk at a time. The best-studied example of motivational losses involves additive tasks where individual performances are simultaneous and anonymous. For example, where group members each make some response on cue (e.g., pulling on a rope, shouting), individual contributions are smaller the larger the group, an effect that is termed “social loafing.”

In addition to a task structure, most groups also have a *reward structure*—the arrangement of payoffs or rewards that motivate members to work on the task. The type and nature of the reward structure may be imposed by a third party (e.g., a supervisor, leader), be part of the group’s history, or be chosen by the group itself. In most experimental studies of task-oriented groups, the reward structure is *cooperative*: The payoff or reward is a result of the group’s efforts in meeting some criterion and is shared by all members (although not necessarily equally). The payoff may be intangible (e.g., the satisfaction of solving the problem or completing the product) or tangible (e.g., money or prizes). Reward structures can also be *competitive*, where rewards are distributed unequally to members based on *relative* individual performance. Cooperative and competitive contingencies are often compared with a third alternative, *individual* contingency, where a member receives a reward when he or she meets an individual performance criterion; this is the case in most work-for-pay groups in industry.

These reward structures are not equally appropriate for all tasks. In particular, cooperative rewards are effective across a range of tasks (Johnson et al. 1981; Qin-Zhining et al. 1995) and are uniquely appropriate when the task requires collaborative activities such as response coordination, task subdivision, or information sharing. Collaboration is rewarded with cooperative rewards, increasing the likelihood that the criterion for the group reward will be met. By contrast, competitive

rewards are effective only where task responses can be made independently by each person. With competitive rewards, blocking another’s responses, not collaboration, is likely to lead to winning. When competition is appropriate, though, it is often more cost-effective (more responses made per unit of reward), easier to implement, and capable of producing short-term performance rates that are higher than those of the other conditions (Schmitt 1987). Competitive motivation can also arise outside of the formal reward structure. Under cooperative conditions, members may work harder simply to be the best performer in the group.

A group member’s motivation to perform a task can vary greatly depending on reward structure, and group size affects important aspects of that structure. With a cooperative structure, all members are rewarded, but inequities may exist in the size of the rewards received (e.g., some people contributing to a task may get more money than others). In general, people working on tasks expect their rewards to be proportional to their contributions (Homans 1974; Walster et al. 1978). Thus, if person A and person B have similar task skills, A will be upset if A and B contributed equally to the task but A received a reward half the size of B’s. Person A will not be upset, however, if A made a contribution half the size of B’s to the task. People who are inequitably underpaid relative to their contributions often work less hard on future tasks and may choose to leave the group (Marwell and Schmitt 1975). In the 1990s professional sports revealed a number of cases where athletes earning millions of dollars per year refused to play for their teams (or played less energetically) because comparable performers on their own or other teams earned more. In cases where the total amount of the cooperative reward for completing a task is proportional to the number of group members (e.g., \$50 for a five-member group and \$100 for a ten-member group), the larger the group, the greater the potential for larger inequities, that is, several of the members receiving a large share of the reward. If large inequities are present, productivity gains are likely to be a decelerating function of group size (and member discontent may provoke a change in distribution).

In arranging for competition, the reward structure is defined by the unequal rewards distributed to winners and losers at the end of the contest. In

most contests the distribution is fixed in advance and is known to the competitors. As with inequitable cooperative structures, the variety of competitive structures depends on the number of competitors in the group, assuming that the total contest amount is proportional to the number of group members (i.e., the larger the group, the larger the contest amount). Two properties of the distribution are relevant. One is the proportion of competitors receiving rewards in each contest. At one extreme, only one competitor receives a reward; at the other extreme, all competitors are rewarded, but in varying amounts. With a single winner, the larger the size of the group, the larger the competitive reward. As has been shown with large lottery prizes, the larger the competitive reward, the greater the motivation of group members to compete, at least in a single contest. However, if there is a series of contests and a difference in competitive skills causes some members to lose continually, the lack of earnings will lead to their withdraw from the group, thus lowering group productivity (Schmitt 1998). Maximizing the proportion of competitors rewarded should encourage poorer performers to remain in contests regardless of group size. When more than one competitor is rewarded, variation can occur in a second property—reward differential or spread, that is, the difference between the highest and lowest reward amounts in each contest. Again, the larger the size of the group, the larger the total competitive reward, hence the larger the possible differential. Maximizing reward differential more highly motivates those who have a chance of winning but gives those who lose frequently less incentive to continue over a series of contests. In sum, group size is a factor when competitive reward structures specify that few are rewarded or have reward differentials that are extreme. Although increasing group size (and the reward pool) is likely to increase member motivation and productivity in initial contests, over a series of contests these gains are likely to be a decelerating function of group size, as those who earn little contribute less or quit.

With individual reward structures, the potential effects of group size are similar to those for cooperative structures. Again assuming that the total reward amount for the group is proportional to the number of members, the larger the group, the greater the size of the reward inequities that are possible in arranging the individual rewards.

With large inequities, productivity gains are likely to be a decelerating function of group size.

SOCIAL DILEMMAS

Several types of social dilemmas have been investigated. The best-known type is prisoners' dilemma. Originally conceived as a two-person game, an n -party prisoners' dilemma in which the number playing the game can be varied has been used to study the effects of group size (Komorita and Parks 1994). Each group member has two choices: to cooperate (C), which maximizes payoffs for the group as a whole, or to defect (D), which maximizes the individual's own payoff. The actual payoffs for each member depend both on own and others' choices. Payoffs for each choice increase with the proportion of members who make the C choice, but the D always produces the higher individual payoff. Finally, the payoff if everyone chooses C is greater than the payoff if everyone chooses D, the selfish choice. Each group member chooses repeatedly over a number of trials. This basic dilemma has numerous everyday counterparts, as when commuters each prefer to use a private automobile instead of a bus, but if each does so the resulting chaos leaves everyone dissatisfied.

Other types of social dilemmas involve a pool of sources to which the group members have access (Pruitt 1998). One is the commons dilemma, based on the Tragedy of the Commons (Hardin 1968), in which a village's common land is overgrazed because of the selfish actions of the individual herdsmen. As studied experimentally, subjects take turns removing resources (e.g., money) from a pool that is replenished periodically based on the amount remaining. The pool can be productive indefinitely, provided that the subjects don't destroy it by taking all the resources. Another is the public goods dilemma, in which the resource pool is built up through individual contributions, as when people contribute money to support public television or some charity. Here the temptation is for individuals to "free ride" and let others make the contribution. As studied experimentally, subjects take turns contributing resources to a pool that is later enhanced by the experimenter and then divided equally.

Studies have found that the larger the group in social dilemmas, the less the cooperation and the greater the selfish behavior, although there is

little change in groups larger than eight members (Pruitt 1998). Various explanations of this relation have been proposed (Komorita and Parks 1994; Pruitt 1998). One possibility is that any defection breaches the trust required for cooperation, and that if one person defects, others view cooperation as unlikely and follow suit. The possibility of one person defecting increases as the group grows larger. In addition, as the group grows larger, each selfish individual response becomes less identifiable and may be seen as less responsible for the lower group payoffs. By the same logic, a cooperative response may also be seen as contributing less to the group product as the group grows larger. Finally, any opportunities by the group to communicate the group's cooperative interests or to sanction defectors are more difficult to carry out in larger groups.

CONTEXT

Any social interaction among group members must take place in some context, for example, people standing, seated at a table, at stations on an assembly line, or in separate offices linked by a computer network. Physical contexts are very important because they affect both the nature of the interaction among members and the ease with which various members can interact. The nature of interaction among group members is determined in part by the number and kind of stimuli presented by those who interact. Stimuli may be verbal in the form of oral or written communication, or they may be nonverbal—information transmitted without using language (e.g., facial expressions, gestures, posture, appearance, voice quality, rate and temporal patterning of speaking).

The context in which a group functions determines whether verbal and nonverbal stimuli are transmitted among group members. If the context includes face-to-face contact, speakers can deliver messages using both verbal and nonverbal stimuli. Nonverbal stimuli add elements that can be both enriching and distracting. For example, a speaker's facial expressions and gestures can reveal the strength with which a position is held, the truthfulness of a message, or the degree of intimacy sought by the speaker. Aspects of the speaker's demeanor or appearance can also distract listeners from paying close attention to the message.

People differ, however, in how they use such stimuli and hence the meaning given to a message. This variability is greatly reduced if the messages are written. In addition, the quality of interaction may differ, depending on the presence of the verbal and nonverbal stimuli. For example, people are more likely to harm others (e.g., deliver punishment or bad news) when communication is restricted and nonverbal behavior is absent compared with face-to-face contact (where people are more fully personalized). In general, restricted communication does not lead to the full development of interpersonal relations, and it minimizes cues that reveal differences in status, power, and prestige among group members. Hence, differences in interaction and influence among group members tend to be less extreme than those in face-to-face groups (McGrath, 1984). Restricted communication is more likely as groups become large and more formally organized.

Another aspect of context concerns the timing of information transmitted among group members. When people interact, verbal and nonverbal stimuli may be presented synchronously (i.e., immediately and in real time), or asynchronously (i.e., at the member's own time, place, and pace). Face-to-face interaction, telephone conversations, and video conferences are synchronous. Letters, memos, videotapes, electronic mail, and answering machine messages are asynchronous. Synchronous interaction, whether in person or electronically mediated, constrains interaction because only one person normally talks at a time. With an increase in group size, a few members typically lead or dominate the conversation. Asynchronous interaction, by contrast, typically permits any number of messages to any or all members, and the fact that the messages are necessarily recorded means that they are normally available for comparison and review later.

Asynchronous communication has increased enormously in popularity in recent years as computer-mediated electronic mail has become available in all organizations and many households. Computer-mediated communication has unique facilitating features: the ability to link anyone who has a network connection and the opportunity to send messages instantaneously to any number of people at very low logistical and social cost. For

some tasks, the use of asynchronous communication changes the effects of group size on productivity, compared with traditional face-to-face synchronous communication. For example, Valacich and associates (1995) investigated groups formed to generate new ideas, that is, to “brainstorm,” where different group members have the potential for generating different ideas. In face-to-face interaction, larger groups derived decreasing benefits as group size increased from five to ten members. In computer-mediated groups, where members communicated via typed messages, larger groups derived increasing benefits as group size increased. Computer-mediated groups appear to use the advantage of reviewing the ideas of others to avoid redundant ideas and build new ones. The study of computer-mediated groups with other tasks promises to reveal further distinctions between synchronous and asynchronous interaction (see Kiesler 1997 for discussion of a number of computer- and Internet-related issues).

An intriguing and potentially distinguishing feature of computer-mediated compared with face-to-face groups is that group size itself may become difficult to define and detect (Sproull and Faraj 1997). People in face-to-face groups take up space, and their physical presence and nonverbal reactions can affect others’ behavior even if a group member says nothing. By contrast, the readers of computer-mediated messages are typically invisible, and speakers may have little notion of who has seen or read a message.

In both industry and education, computers have been used to create humanlike partners who interact with people in various ways. Kiesler and associates (1996) investigated subjects’ responses in a prisoners’ dilemma game where the “partner” was known by the subject to be either a person or computer based. In both conditions, the subject and partner discussed options on each trial, and the partner asked the subject for commitments. For both types of partners, discussion and agreements with the subjects facilitated cooperation, although the effect was stronger with the human partner. Thus, nonhuman partners can produce “social” responses in people provided that the partners make humanlike use of social stimuli and responses.

Much of the early research on context concerned constraints on who could communicate

with whom in small groups. These constraints determine the group’s communication network (for a summary, see Shaw 1981). For example, two contrasting networks in groups of three or more members are the circle, where each member can communicate with two adjacent members, and the wheel, where one member occupies a central position and others can communicate only with that central person (the “hub”). Wheels and circles are examples of highly centralized and decentralized networks, respectively. Groups studied in such networks have typically been small (e.g., three to five members), and communication has usually occurred via written notes. Comparisons of group problem solving using various networks have found that when tasks are relatively simple and require that members collect their information, centralized networks are more efficient than decentralized ones (with fewer messages and errors). Where tasks are more complex and require that members perform additional operations on their information, decentralized networks are more efficient than centralized ones (Shaw 1981). With complex tasks the communication overload (termed “saturation”) experienced by the member in the central position slows the attainment of a solution. Saturation is likely to be a problem in all networks as the group increases in size, and it should emerge more rapidly when interaction is synchronous.

Communication networks arrange the contacts among group members in a decisive manner, but even where members are in face-to-face contact, aspects of the setting can make interaction between some members more likely than others, thus producing networklike effects. Seating arrangement is an example. Groups discussing problems are frequently seated at tables. One of the earliest findings was that people tend to communicate with others across the table and facing them instead of with those seated alongside them (Steinzor 1950). As groups grow larger, people are frequently seated at rectangular tables. Studies have found that people at the table’s end positions tend to participate more, are seen as having more influence, and are more likely to be chosen as leaders than those on the sides (for a summary, see Shaw 1981). Networklike arrangements can also be created if group members are instructed to follow a particular communication pattern in a discussion (e.g., “Talk only with the leader.”). Instructions can also be used to limit style of expression (e.g.,

“Give ideas for solving the problem but don’t criticize others’ ideas.”).

In conclusion, differences in group size pose both opportunities and problems for the members. Because the nature of the consequences depends on the type of group task, reward structure, context, and the skills of the group members, little can be said about a group if only its size is known. Under certain circumstances, however, group size is highly consequential for the group’s performance and stability. It should be noted that for groups that form in everyday life, unlike those created for experimental purposes, problems posed by size do not necessarily condemn a group to subpar performance. Everyday groups usually have both pasts and futures, and are often skillful in identifying problems and in making changes that help mitigate them.

HEALTH AND ILLNESS BEHAVIOR

Health and illness behaviors are associated with level of disability, quality of life, patterns of illness, and risk of death. It is tempting to view such health-related outcomes solely through the lenses provided by the biomedical sciences; however, the behaviors that importantly shape individuals' experiences of sickness or wellness, and life or death, are more completely understood from a sociological perspective. The confluence of individuals' life histories, their personality characteristics and social experiences, and their social positions influences health and illness behaviors and tells us much about how to enhance health and well-being, and mitigate disability and sickness. An examination of health and illness behaviors, therefore, has important public health implications.

HEALTH BEHAVIORS

Health behavior usually refers to preventive orientations and the positive steps people take to enhance their physical well-being and vitality. Traditionally, work in health behavior has focused on the use of preventive services such as immunizations, medical checkups, hypertension screening, and

prophylactic dentistry (Becker 1974). It also includes research on such behaviors as cigarette smoking, seat-belt use, medication adherence, substance abuse, nutritional practices, and exercise (Janz and Becker 1994).

The conventional approach to health behavior has been limited, focusing on the origins of particular behaviors damaging to health and strategies to modify them. The most widely used general model—the health belief model—conceptualizes preventive health action within a psychological cost-benefit analysis (Rosenstock 1974). The health belief model conceptualizes decisions to take positive health actions as motivated by perceived threat (either susceptibility to a particularly condition or perceptions that the condition is severe) and judgments about the barriers and benefits associated with specific changes in behavior. Behavior change is seen as following motives that are salient, in situations where people have conflicting motives, following those that are perceived as yielding valuable benefits. An important component of the model involves cues to action, since an activating stimulus often appears to be necessary in the initiation of a new behavioral sequence. Both internal (e.g., feelings of symptoms) and external (e.g., suggestions from doctors, peers, or the media) stimuli may act as cues motivating change. Over the years, this model has been expanded (Becker and Maiman 1983), but it serves more as an organizing framework for the study of preventive health behavior than as a successful predictive model. An analysis of studies that have used the health belief model to explain a variety of health

behaviors indicates that the predictive value of the model is, at best, modest; the average variance in health behaviors explained is approximately 20 percent (Harrison, Mullen and Green 1992).

A second commonly used model to explain health decisions is the theory of planned behavior, originally developed as the theory of reasoned action (Ajzen 1991; Ajzen and Fishbein 1977). Like the health belief model, the theory of planned behavior conceptualizes changes in behavior as products of the saliency of individuals' beliefs about the potential costs and benefits associated with an outcome or action. The theory of planned behavior, however, places greater weight on persons' intentions, arguing that behavior is centrally motivated by intentions that are shaped by normative beliefs, feelings of control, and judgments about the barriers and benefits associated with potential change. Again, however, the model has had only modest success in predicting an array of health behavior; the association between intentions and behavior is typically about .40 (Conner and Norman 1994).

There are many other models and theories proposed to predict health behaviors, and much has been written comparing the relative efficacy of each for predicting health behaviors (Conner and Norman 1994; Mullen et al. 1987; Weinstein 1993). It appears that efforts to develop a general theory are limited by the fact that behavior conducive to health derives from diverse and sometimes conflicting motives. Consistently, research indicates that health behavior, or a healthy lifestyle, is not a unitary construct (Johnson et al. 1998; Sobal et al. 1992). One study of health behaviors among a nationally representative sample of adult Americans examined the clustering of four health behaviors: diet quality, alcohol use, tobacco use, and physical exercise (Patterson et al. 1994). The results (based on data from the late 1980s) suggest that approximately 10 percent of Americans live a "healthy" lifestyle, defined by a good diet, low use of tobacco and alcohol, and engaging in regular physical exercise. In comparison, about 2 percent of the population practice unhealthy behavior on all four of these dimensions. Thus, most Americans fall somewhere between the two extremes, practicing some positive health behaviors while neglecting others. Research that has attempted to

establish specific clusters of related health behaviors has proved inconclusive. Some studies have identified many apparently interrelated clusters of behaviors—for example, smoking/drinking and exercise/diet—and others have identified few (cf. Johnson et al. 1998; Sobal et al. 1992). In short, the research indicates that there is no simple identifiable positive health orientation that can serve as a basis for promoting risk aversion and health maintenance.

The lack of such a general orientation results because most behaviors with important implications for health arise from motives not related to health and are significantly programmed into the daily patterns and institutional life of communities and families (Mechanic 1990). Health-protective behaviors that are consequences of accepted, everyday, conventional activities require neither conscious motivation nor special efforts to be sustained. The favorable health experience of Mormons, for example, is a product of their belief systems and patterns of activity reinforced by the way of life of this cultural community (Mechanic 1990). To the extent that health behaviors are more the result of habits than cognitive decisions, we might expect that past health behaviors are robust predictors of current health behaviors. Yet neither the theory of reasoned action nor the health belief model adequately incorporates past behavior in its model, an omission that might partially explain their lack of predictive power (Conner and Norman 1994).

Promoting health may be more a matter of changing culture and social structure than of modifying personal motives or intentions. Patterns of behavior that depend on sustained conscious motivation are less stable than those that are a natural consequence of the accepted norms and understandings within a community. Expectations not only affect the prevalence of varying behaviors but also establish constraints on the acquired behaviors of children and adolescents. Changes in the social constraints on smoking, and the growing unacceptability of smoking in varying social contexts, may have more significance than any program to change personal behavior for explaining the dramatic decline from about 42 percent of the U.S. adult population being current smokers in 1965 to 25 percent in 1995 (National Center for Health Statistics 1998).

Although there is no evidence for a unitary health orientation, some social factors, particularly socioeconomic status (SES), predict good outcomes across a wide range of health indicators (Bunker et al. 1989; Marmot 1998; Ross and Wu 1995). Occupational status, income, and education each reflect some part of SES, and all are associated with health behaviors, whether one is comparing the health behaviors of populations or of individuals. Generally, wealthy nations show the highest rates of preventative health practices, such as child immunization, routine dental care, and the use of mammography, compared with less wealthy nations. But the importance of SES may be indirect, through social conditions. Indeed, as Caldwell (1986, 1993) has argued, mothers' educational attainment appears to be particularly important, influencing health outcomes net of its relationship to per capita income. Caldwell suggests that maternal education increases women's autonomy, enhances their ability to interact efficaciously with available health services and technology (even when such technology is not advanced), and enables women to increasingly control their own health and that of family members.

Within nations, there are also important SES differences in health behaviors. Table 1 presents some examples of SES differences in the U.S. population; the behaviors presented are meant to illustrate the gap and are not an exhaustive list of possible health behaviors. As shown in Table 1, Americans with lower SES are more likely to engage in health-risk behaviors and less likely to engage in health-promoting behaviors. The precise ways in which SES affects these outcomes are not fully understood, but the consistent findings point to an explanation of health behaviors that goes beyond personal responsibility and free choice. Research that examines the impact of SES over the life course illustrates the fallacy of relying on "choice" explanations to account for SES differences in health behaviors. In a sample of Finnish men, Lynch and his colleagues (1997) examined the effects of SES during childhood (parents' occupation), adolescence (education), and adulthood (occupation) on psychosocial characteristics, such as hostility and hopelessness, that are important to health and on health behaviors, including smoking and alcohol use. They found that lower SES in childhood and adolescence is associated with greater health-risk behaviors in adulthood, in addition

to greater feelings of hopelessness and hostility. Given that childhood SES is not a matter of choice, their findings support an explanation of SES differences in health behavior rooted in persistent structural disadvantages and the accompanying differential opportunities and constraints. Others have also demonstrated that higher SES provides not only obvious economic advantages and related opportunities but also enhanced personal autonomy, increased sense of control, and greater social participation (Marmot 1998; Ross and Wu 1995, 1996), all of which also influence health outcomes.

A variety of behaviors noxious to health (smoking, drug use, and drinking) develop or increase during adolescence and young adulthood. However, young people who have a good relationship with their parents and who are attuned to parent-oriented values—as measured by school performance, attendance at religious services, and participation in meals with parents—do relatively well across a variety of health measures (Hansell and Mechanic 1990). In contrast, high engagement with peer-oriented social activities is associated with increases in behavior associated with health risk. In addition, children model their parents' health behaviors, an effect that persists at least into young adulthood (Lau et al. 1990).

Although it is apparent that adolescence is a time of life where there are likely to be changes in health behaviors, we know very little about other stages of the life course or the life transitions that may be especially important (Prohaska and Clark 1997). Prohaska and his colleagues propose a "stages of change" model that recognizes important transitions in the life course as explanations for changes in health practices (Prohaska and Clark 1997; Prohaska et al. 1994). They argue that individuals go through a number of steps, from not thinking there is a need for change to maintaining the new behavior after change. Public health efforts, therefore, could benefit from understanding what motivates or hinders a person's progression through the steps. For instance, life transitions such as motherhood may motivate progression toward positive health practices, while transitions such as death of a spouse may make it difficult to maintain health practices and, therefore, may explain deterioration of positive health behaviors among persons recently widowed. Moreover, according to this model, persons may be differently prepared to progress through the steps depending

Socioeconomic Status and Health Behaviors in the United States

Behavior	Education		Year
	Less Than 12 Years %	16 or More Years %	
Cigarette smoking (person 25 years and older)	35.7	13.6	1995
Dental visit last year (persons 25 years and older)*	38.0	73.8	1993
Prenatal care in first trimester (mothers 20 years and older)	68.0	93.9	1996
Heavy alcohol use (men 25–49 years)	16.3	6.1	1994/96
Overweight (women 25–74 years)	45.8	26.3	1988/94

Behavior	Income/Poverty		Year
	Below Poverty %	At or Above Poverty %	
Mammography use past two years (women 40 years and older)	44.4	64.8	1994
Dental visit past year (persons 25 years and older)	35.9	64.3	1993
No physician visit in last year (children under 6 years)**	11.2	5.2	1994/1995
Vaccination (children 19–35 months)	69.0	80.0	1996

Table 1

NOTE: *Comparison is less than 12 years versus 13+ years.

**Comparison is poor versus nonpoor.

on their stage in the life course; for example, older persons may be better prepared to contemplate the health risks of smoking or heavy alcohol use, while adolescents are not. The important point for our purposes is that understanding how to modify health practices requires appreciation of how stages in the life course and transitions may influence when people are willing or able to make changes.

ILLNESS BEHAVIOR

The study of illness behavior, in contrast to health behavior, is concerned with the way people monitor their bodies, define and interpret bodily indications, make decisions about needed treatment, and use informal and formal sources of care (Mechanic 1986, 1995). Like other behavior, illness behavior is learned through socialization in families and peer groups and through exposure to the mass media and education. There is great diversity of attitudes, beliefs, knowledge, and behavior, all of which affect the definitions of problematic symptoms, the meanings and causal attributions that

explain them, socially anticipated responses, and the definition of appropriate remedies and sources of care. Motivation and learning affect the initial recognition of symptoms, reactions to pain, the extent of stoicism and hypochondriasis, and the readiness to seek release from work, school, and other obligations and to seek help (Mechanic 1978).

Illness behavior begins prior to the use of services with the recognition of illness or sickness. While a complex array of variables might explain variations in interpretation of sickness, they can be summarized in ten general categories: (1) the visibility, recognizability, or perceptual salience of deviant signs and symptoms; (2) the extent to which the person perceives the symptoms as serious (that is, the person's estimate of the present and future probabilities of danger); (3) the extent to which symptoms disrupt family, work, and other social activities; (4) the frequency of the appearance of deviant signs and symptoms, or their persistence, or their frequency of recurrence; (5) the tolerance threshold of those who are exposed

to and evaluate the deviance signs of symptoms; (6) the information available to, the knowledge of, and the cultural assumptions and understanding of the evaluator; (7) the degree to which autistic psychological processes (perceptual processes that distort reality) are present; (8) the presence of needs that conflict with the recognition of illness or the assumptions of the sick role; (9) the possibility that competing interpretations can be assigned to the symptoms once they are recognized; and (10) the availability of treatment resources, their physical proximity, and the psychological and monetary costs of taking action (including not only physical distance and costs of time, money, and effort, but also stigmatization, resulting social distance, and feelings of humiliation resulting from a particular illness decision) (Mechanic 1978).

In short, illness appraisal is a two-step process (Mechanic 1972). In the initial step, persons monitor their bodies to assess the location, duration, intensity, and persistence of discomfort. In the second stage, which may occur almost concurrently, they seek explanations for perceived changes. If an obvious explanation is not available, or is disconfirmed by further checking, individuals look to their environment for new cues and explanations. These interpretations, in light of knowledge and other beliefs, may then play a role in the formal initiation of care.

Individuals' appraisals of symptoms vary importantly. Processes of symptom appraisal are influenced by the manner in which symptoms occur and their characteristics, by knowledge, and by past experiences with illness (Leventhal 1986; Mechanic 1972). Some symptoms are so painful and incapacitating that they inevitably lead to intervention without significant inquiry. Others are so familiar and generally understood as self-limited that they also are dealt with routinely. Many symptoms, however, are neither familiar nor easily understood, resulting in a process of interpretation within the context of personality, situational cues and stressors, and environmental influences. Only a small proportion of symptoms lead to formal consultation or care. The vast majority are denied, normalized, or evaluated as having little significance

Much research has focused on how persons come to make judgments of their own health status. One approach is to study health appraisals

among children and adolescents who have little serious illness. In a prospective study of adolescents, those who were more competent and more engaged in age-related activities, as measured by school performance and participation in sports and other exercise, rated their health more highly (Mechanic and Hansell 1987). Adolescents' health assessments are shaped by their overall sense of functioning, and they do not seem to differentiate among physical and psychological aspects of well-being in making general assessments of how they feel.

This finding is consistent with the body of research examining the impact of global judgments of health on mortality and disability. Several longitudinal studies of the elderly have found that subjective self-assessments of health predict future mortality after taking account of known risk factors and sociodemographic measures (Idler and Angel 1990; Idler and Benyamini 1997; Idler and Kasl 1995; Mossey and Shapiro 1982). Likewise, some research suggests that global assessments of health predict future level of functioning or disability (Farmer and Ferraro 1997; Idler and Kasl 1995). It is remarkable that simple self-assessments of health prospectively predict longevity and disability better than physicians' assessments or known health-risk factors. Many studies suggest that judgments of health and well-being and interpretations of sickness are shaped by factors beyond those traditionally captured by biomedical conceptions of illness. Individuals' appraisals of their health appear to depend as much on their global sense of well-being as they do on specific patterns of illness. The identification of the exact psychological and social factors responsible for self-assessed health, however, remains elusive. Some have suggested that individuals take into account important social and psychological resources, such as social support, feelings of control, and optimism, when making judgments of their own health—and that these psychosocial resources provide protection against morbidity and mortality (Idler and Benyamini 1997; Kaplan and Camacho 1983).

One of the most consistent research findings has been that perceptions of physical illness depend on the person's psychological well-being or level of psychological distress (Aneshensel et al. 1984; Farmer and Ferraro 1997; Tessler and Mechanic 1978). Individuals tend to assess their health

holistically in terms of vitality and capacity to perform their social activities and roles. Psychological distress often diminishes vitality and functioning as much as serious medical conditions. The RAND Medical Outcomes Study found that depressive symptoms were more disabling than many chronic physical conditions that physicians view as extremely serious (Wells et al. 1989).

Persons seeking medical care commonly express their distress and lowered sense of well-being through many diffuse physical complaints, such as fatigue, insomnia, and aches and pains in different bodily systems, a process referred to as somatization (Kleinman 1986). Although much of the existing literature focuses on somatization as a problematic process, it is by far the predominant pattern for expressing distress. Until the last forty or fifty years, it was uncommon to conceptualize distress in psychological terms, and even now such expressions are used primarily among well-educated populations receptive to psychological interpretations. General distress has both physical and psychological concomitants; the language that people use to characterize distress depends on the cultural context, the perceived appropriateness of psychological complaints, and the stigma attached to emotional disorder.

There is controversy as to whether psychological idioms are inaccessible to many people due to cultural factors or limited schooling, or whether somatization represents a choice among alternative idioms because such presentations are seen as more consistent with the medical care context. Rates of reported depression in Chinese cultures, for example, are extremely low, although "neurasthenia" is a common diagnosis in Chinese medical care settings (Kleinman 1986). Psychiatrists in China routinely view neurasthenia as a "disorder of brain function involving asthenia of cerebral cortical activity," but the symptoms reported are strikingly similar to the physical manifestations of depressive disorders more commonly seen in Western countries. It remains unclear whether these diagnoses characterize the same underlying disorders that are expressed differently in varying cultural groups or whether they are fundamentally different. Kleinman (1986) treated Chinese patients diagnosed as neurasthenic who met the American diagnostic criteria for major

depression with antidepressant drugs but found on follow-up that while a majority showed significant improvements in clinical psychiatric symptoms, they continued to be impaired, to function badly, and to seek help for their condition. They also remained skeptical of the drug treatment they received. Kleinman links these responses to the patients' needs for the medical legitimization of their "illness" to explain past failures and to justify continuing difficulties in meeting social expectations.

Similar examples are provided within the American context when "new" disorders become part of our popular understanding of what is (and is not) physical illness. For example, in recent years we have seen much debate around the legitimacy of chronic fatigue syndrome and Gulf War illness as physical disorders (Abbey and Garfinkel 1991; NIH 1994; Presidential Advisory Committee 1996). The case definitions associated with these conditions are not well specified, and the etiology of each remains undetermined. Those suffering from the symptoms of each condition have benefited greatly from the efforts of interest groups who have lobbied to have the conditions treated as unique clinical disorders. The status of disorder often brings access to insurance coverage and other entitlement programs. Equally important, recognition of a group of symptoms as a specific disorder or distinct illness acts to reduce stigma for those suffering and provides some legitimacy to persons disabled by the symptoms. Studies of patients diagnosed with chronic fatigue syndrome highlight the important role of attribution in the experience of illness. Some research indicates that patients who view their illness as essentially physical have less favorable outcomes than those who attribute the cause of their illness to social or psychological factors (Joyce et al. 1997).

In situations where there are no obvious explanations for the occurrence of symptoms, individuals seek meanings for changes in their feeling states. The commonsense theories they apply may either be idiosyncratic or drawn from socially prevalent conventional explanations such as stress, lack of sleep, overwork, and overeating. These lay explanations are influential on subsequent behavior such as care seeking and use of medication (Kleinman 1980; Leventhal et al. 1980; Leventhal et al. 1985). For example, it is commonly believed that stress

increases blood pressure and that relaxation reduces it. Most individuals, however, cannot assess whether their blood pressure is high or low on the basis of available cues, yet many believe they can. Persons with hypertension, an asymptomatic condition, commonly use self-assessments of their stress levels or relaxation as an indicator of their blood pressure levels and adjust their medication accordingly, despite medical advice to the contrary (Leventhal et al. 1985). Similarly, many patients with limited understanding of the biological processes through which drugs such as antibiotics or antidepressants act increase or decrease medication in relation to changes in how they feel and environmental cues.

The decision to seek medical care in response to symptoms also depends on prevailing norms about the conditions that are within the purview of the medical field. Such norms differ across cultures and time. In recent years, the role of the popular media in influencing help-seeking appears to have increased. In the late 1980s, Prozac was widely advertised and discussed as a treatment for a wide range of symptoms ranging from clinical depression to shyness, self-criticism, low self-esteem, or just feeling blue (Barondes 1994; Kramer 1993). It became the most quickly accepted drug in U.S. history (Kramer 1993). In April 1998 Viagra was introduced to the market, and the popular press was inundated with stories of the potential of the drug to increase sexual pleasure. It replaced Prozac as the fastest-selling pharmaceutical in history, and by the end of the year approximately 7 million prescriptions had been written for some 3 million patients in the United States (Pfizer Inc. 1999). Unmet need partially explains the rapid acceptance of both drugs. However, it is also likely that variations in human feelings or behavior that would previously have been normalized were more likely to be viewed as medical conditions requiring treatment.

Sickness is an accepted role in society, bringing sympathetic attention and legitimate release from expected performance (Parsons 1951). Determinations of what is (and what is not) illness may involve intense negotiations about individuals' claims that, when legitimized, may justify failure to meet expectations or allow escape from onerous obligations (Mechanic 1978). In some

situations, the sick role becomes a point of tension and conflict between the claimant, who seeks legitimation of sickness with its special privileges, and other interested parties, including families, employers, and welfare administrators, who may seek to limit release from social obligations or diminish special privileges granted to the sick and disabled (Field 1957). Most illness situations are neither problematic nor sources of conflict, but the contested cases make evident the social assumptions and expectations around which illness is organized.

Certification of illness becomes a public issue when physicians, government bureaucrats, or managed care companies have moral and legal authority to define illness and disability and to sanction the sick role. Such influence is found in certifying justified absenteeism for employers, in litigation, and in decisions on eligibility in insurance and disability entitlement programs. Efforts are often made to maintain the illusion that these are objective decisions based solely on medical expertise and clinical experience, but judgments often depend on whom the physician represents. The state or other formal organizations may thus attempt to control physicians by limiting their discretion, as happened in the Soviet Union when physicians were viewed as allowing people excuses to escape work too easily (Field 1957).

American examples of the processes involved in legitimation of illness come from observations of legislative changes affecting definitions of what is (and is not) disability. For example, in 1996 Congress passed legislation that removed substance use as a disability qualifying for Supplemental Insurance Income (SSI). Approximately 140,000 people lost their official status as "disabled" under the Social Security Act and concomitantly lost the right to income and medical benefits (Gresenz et al. 1998). Similarly, substance-use disorders associated with illegal drugs are explicitly excluded from the classes of disorders covered by the Americans with Disability Act (Mechanic 1998a). The removal or exclusion of a class of illness from the definition of disability highlights the importance of societal norms and values in sanctioning which groups of persons may legitimately occupy the sick role. Moreover, much of the debate surrounding implementation of both acts concerned judgments of

personal responsibility and “badness” and “goodness,” rather than the clinical significance of substance-use disorders as disabling conditions. In contrast, veterans of the Persian Gulf War have been awarded medical and disability entitlements based on Gulf War illness, despite the weight of medical evidence suggesting that there is no such unique clinical entity (NIH 1994; Presidential Advisory Committee 1996). Both examples illustrate the point that the certification of persons as legitimately sick (and thus deserving of public benefits) is not always the result of clinical judgments. Definition of illness and disability is the “rope” in a tug of war in which competing parties seek determinations in their own interest.

The study of illness behavior has many applications in research, clinical care, public health, and social policy (Mechanic 1998b). Such patterns of behavior substantially affect pathways into care and selectively shape the samples studied in clinical contexts. Failure to understand these selection effects and how they operate leads to erroneous conclusions about the nature of basic disease processes. A common error is to attribute to the etiology of the illness influences triggering use of services, a problem that plagues much research on stress and illness. At the clinical level, awareness of how people construe illness, present symptoms, and respond to care can improve understanding and communication and help health professionals to guide the treatment regimen more effectively.

Health and illness behavior studies make clear that the forces affecting health and treatment outcomes transcend medical care and the transactions that take place between doctor and patient. In recent decades there have been increasing tendencies toward the medicalization of social problems and a failure to address the complicated attitudinal needs of patients with serious chronic conditions and disabilities. Moreover, the problems in managing the frailties of old age, characterized by a combination of medical, instrumental, and social needs, increasingly challenge assumptions of treatment focused on narrow definitions of disease and care. Studies of health and illness behavior teach the importance of moving beyond initial complaints and narrow definitions of problems and toward examining the broad context of individuals' lives and the factors that affect social

functioning and quality of life. They point to the diverse adaptations among persons with comparable social and physical debility and potential. They reinforce the need to take account of the environmental and social context of people's lives, their potential assets, and their disease. A medical care system responsive to these broad concerns would be better prepared for the impending health care challenges of the new millennium.

HEALTH AND THE LIFE COURSE

Health and *the life course* are two broad concepts of interest to sociologists. Each of these concepts must be nominally defined.

CONCEPTIONS OF HEALTH

Health can be conceptualized in three major ways: the medical model (or physical definition); the functional model (or social definition); and the psychological model (or the subjective evaluation of health: Liang 1986). In the medical model, health is defined as the absence of disease. The presence of any disease condition is determined by reports from the patient, observations by health practitioners, or medical tests. The social definition of health is derived from Parsons's (1951) work and refers to an individual's ability to perform roles, that is, to function socially. Illness or impairment is a function of reduced capacity to perform expected roles, commonly measured in terms of activities of daily living (ADLs—eating, dressing, bathing, walking, grooming, etc). The psychological model, or the subjective evaluation of health, is often based on the response to a single question asking one to rate one's health on a scale from poor to excellent. The definition of health used by the World Health Organization since 1946 reflects this multidimensional perspective: "a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity."

It has been suggested (e.g., Schroots 1988) that a distinction be made between *disease* and *illness*. It is argued that disease refers to an objective diagnosis of a disorder, while illness refers to the presence of a disease plus the individual's

perception of and response to the disease. Thus, one may have a disease, but as long as one does not acknowledge it and behave accordingly (e.g., take medicine), one will perceive oneself as healthy (Birren and Zarit 1985).

A distinction should also be made between *acute* and *chronic* conditions. These two types of health conditions are differentially related to older and younger age groups (discussed more below). That is, there is a morbidity shift from acute to chronic diseases as an individual ages. In addition, Western societies experienced a dramatic shift from infectious diseases (a form of acute condition) to chronic, degenerative diseases in the late nineteenth century and the first half of the twentieth century.

CONCEPTIONS OF THE LIFE COURSE

The life course is a progression through time (Clausen 1986), in particular, social time. Social time is a set of norms governing life transitions for particular social groups. These transitions may vary from one group to another (e.g., working class versus middle class) and from one historical period to another. The life-course approach focuses on “age related transitions that are *socially created, socially recognized, and shared*” (Hagestad and Neugarten 1985, p. 35). Historical time plays a key role in life-course analysis because of the emphasis on social time and social transitions (Elder 1977; Hareven 1978). Changes that take place in society lead to a restructuring of individual life courses. Thus, life courses will vary from one cohort (generation) to the next.

The life-course perspective should be differentiated from the life-span perspective or other developmental models of psychology. In these latter approaches the focus is on the individual, especially on personality, cognition, and other intrapsychic phenomena (George 1982). In these developmental approaches, change results from within the individual, and this change is universal—it is a function of human nature. Typically, developmental changes are linked to chronological age, with little or no reference to the social context or the sociohistorical or individual-historical context. The life-course perspective, in contrast, focuses on transitions when the “social persona” (Hagestad and Neugarten 1985, p. 35) undergoes change.

CONCEPTIONS OF AGING

In order to understand health and the life course it is also important to understand the aging process. Aging is best understood in a life-course perspective. Persons do not suddenly become old at age sixty or sixty-five or at retirement. Aging is the result of a lifetime of social, behavioral, and biological processes interacting with one another. While genetics may play a part in predisposing individuals to certain diseases or impairments, length and quality of life have been found to be highly dependent on behaviors, lifestyles, and health-related attitudes (e.g., Haug and Ory 1987).

A distinction is often made between primary and secondary aging (see Schroots 1988). Primary aging, or normal aging, refers to the steady declines in functioning in the absence of disease or despite good health. Secondary aging, or pathological aging, refers to the declines that are due to illnesses associated with age but not to aging itself. This suggests that secondary aging can be reversed, at least in principle (Kohn 1985).

VARIATIONS IN HEALTH AND LIFE EXPECTANCY

The largest cause of death in America for people under age forty-five is accidents and adverse effects (National Center for Health Statistics [NCHS] 1999). For people five to fourteen years of age and twenty-five to forty-four years of age, malignant neoplasms (tumors) rank second as a cause of death. For persons fifteen to twenty-four years of age, homicide, followed closely by suicide, are the next leading causes of death.

For adults ages sixty-five and over the causes of death are quite different. Cardiovascular disease, malignant neoplasms, cerebrovascular disease, and chronic obstructive pulmonary disease are the most common causes of death (NCHS, 1999). Older persons, too, are more likely to suffer from chronic, and often limiting, conditions. Most common among these are arthritis, hypertension, hearing impairments, heart conditions, chronic sinusitis, visual impairments, and orthopedic impairments (e.g., back). Interestingly, these same conditions are among the most commonly mentioned by persons ages forty-five to sixty-four,

though their prevalence is generally considerably less than among persons sixty-five and older.

At the turn of the century, life expectancy was about 48 years. By 1950, life expectancy was 68 years (66 years for males and 71 years for females). By 1997, life expectancy had increased to 76.5 years (74 years for males and 79 for females). Many of the improvements in life expectancy came about before large-scale immunization programs. These programs largely affected the health of those born during the 1940s and 1950s. These programs have, however, reduced infant mortality and reduced the likelihood of certain debilitating diseases (e.g., polio).

The chance of surviving to old age with few functional disabilities is strongly related to socioeconomic position, educational level, and race (Berkman 1988). People in lower classes and with less education have higher mortality risk and have higher incidence and prevalence of diseases and injuries. They have more hospitalizations, disability days, and functional limitations.

Life expectancy also varies by social class. At age twenty-five life expectancy, for those with four or fewer years of education, is forty-four years for men and almost forty-seven years for women. For men and women with some college education, life expectancy is forty-seven years and fifty-six years respectively. After age sixty-five, however, this relationship becomes less clear-cut, suggesting that for older cohorts a different set of factors is involved.

Another area where health and the life course intersect is that of health inequalities in the life course. Increasing evidence indicates that many illnesses in middle and later life have their beginnings in childhood or prior to birth (Wadsworth 1997). For example, low birthweight indicates poor prenatal growth, and both are associated with higher risk of respiratory problems in adult life. Further, lower birthweight is associated with poorer health practices of expectant mothers, suggesting that these babies will be born into family/household/social environments that do not facilitate optimal health.

Life course trajectories vary by key social characteristics such as age, gender, race, and socioeconomic status (SES) (Bartley et al. 1997). Further,

these life-course trajectories are related to disease risk. For example, an individual born into a poorer or working-class family will have a different trajectory of disease over the life course than an individual born into a family with better financial and social means. The former individual accumulates risks or disadvantages over the life course that begin to show up in adulthood.

ISSUES AND IMPLICATIONS

Differences in health conditions by age raise at least two issues regarding the analysis and understanding of health. First, it has been suggested that in trying to understand the health and health behavior of the elderly, especially as our models become more complex, the *individual* is the critical unit of analysis (Wolinsky and Arnold 1988). That is, we must focus on individual differentiation over the life course. Aging is a highly individual process, resulting from large inter- and intraindividual differences in health and functioning.

The second issue concerns the extent to which many processes thought to be life-course processes may in fact be cohort differences (see Dannefer 1988). An assumption is often made that the heterogeneity within older cohorts is an intracohort, life-course process: Age peers become increasingly dissimilar as they grow older. This conclusion is, however, often based on cross-sectional data and may lead to a life-course fallacy. Age differences may reduce to cohort differences. If each succeeding cohort becomes more homogeneous, older cohorts will display greater heterogeneity compared to younger cohorts. Evidence suggests that for several cohort characteristics this may be the case. For example, there has been increasing standardization of years of education, age of labor-force entry and exit, age at first marriage, number of children, and so on. Thus, younger age groups would exhibit less diversity than older cohorts.

Not all health deterioration is a normal process of aging. Some of it appears to be the result of an accumulation of life experiences and behaviors. Many of the experiences and behaviors are different for older and younger cohorts, suggesting that an understanding of factors affecting health for older cohorts may not hold for younger cohorts as they age.

Two possible scenarios exist. One is that older people in the future will experience less morbidity than today's elderly, even though later life will be longer. That is, they will be older longer, sick for a very short period of time, and then die. An alternative situation is one in which elderly live longer and are sick or impaired for many of those years. That is, they will be sick for an extensive period of their later life. Given the fact that more people are living longer, the general expectation is that the demand for health care by the elderly will be greater in the future. The extent of the demand will depend, in part, on which of these two scenarios is closer to the truth. The conservative approach, and the one generally adopted, is that estimates of tomorrow's needs for care are based on data from today's elderly. However, a life-course perspective might yield quite a different picture because the life experiences, behaviors, and health attitudes of today's elderly may be quite different from those of younger cohorts, tomorrow's elderly.

Health is a lifelong experience of an individual, composed of accumulations of risk. Logically, reducing health problems in middle and later years will be more successful the earlier attempts are made to reduce these risks (Wadsworth 1997). Similarly, health inequalities exist, and these are associated with social and biological characteristics of individuals (e.g., gender, race, SES). Reducing health inequalities will require reducing risk factors for these different groups of individuals and doing so early in life.

HEALTH CARE FINANCING

See Health Care Utilization and Expenditures; Health Policy Analysis; Medical Sociology.

HEALTH CARE UTILIZATION AND EXPENDITURES

The U.S. health care system is unique among industrialized nations because it lacks a national health insurance program. The United States relies instead on private health insurance that individuals or companies must purchase. The public insurance system is limited to those who are aged or disabled (Medicare) and to some individuals who are poor (Medicaid). The delivery system for health care in the United States is almost entirely private, with only a small sector of government providers who primarily target the poor and uninsured population. Moreover, the U.S. health care system is largely unplanned and has limited regulation, even though the government is a large payer of services. In contrast, other industrialized nations have national health systems that provide coverage for their populations that are generally independent of employment (Blendon et al. 1995). These systems are more comprehensive and less expensive than the U.S. system, which excludes 43 million people (U.S. Bureau of the Census 1998b). This article examines the factors that have contributed to a system that severely limits access to millions of individuals in the United States.

We first examine health care utilization and expenditure patterns at the macro level. This approach is used by public policy makers at the federal, state, and local levels and by private insurers in decision making about the allocation and control of public and private resources for health care services. The second approach is a micro-level focus on the patterns of use and expenditures by individuals or groups of people in society and the factors that limit (or improve) access to services.

GROWTH IN EXPENDITURES

The most significant feature of health care in the United States during the 1980s and 1990s was its overall high growth rates and its total expenditures. Total national health expenditures increased by 283 percent between 1980 and 1990 (Smith et al.

1998). Although the annual growth rate in spending slowed from 11 percent in 1990 to 4.8 percent in 1997 (Levit et al. 1998), expenditures were over \$1 trillion in 1996 and are projected to exceed \$2 trillion by the year 2007 (Smith et al. 1998). Health care expenditures in 1997 amounted to \$4,000 per capita (Table 1).

Health expenditures increased from 12.2 percent of the gross domestic product (GDP) to 13.5 percent in 1997 (Levit et al. 1998), and they are expected to reach 16.6 percent of GDP in the year 2007 (Smith et al. 1998). The devotion of a large percentage of the total GDP to health costs is a concern because such dollars are then not available for other needs.

Factors Increasing Expenditure Growth. Levit and colleagues (1998) have examined three basic components in the growth of health spending. The first component is the economy-wide increase in prices and inflation (about half of the total increases in the 1995–1997 period). The second is the change in volume and intensity of services. Levit and colleagues (1998) found that the volume and intensity of service use were about the same in the 1990s (about one-third of the total expenditure increases in 1997). Finally, there is medical price inflation over and above these other factors. In the 1990–1995 period, excess medical prices were important factors—almost one-third of the total increases. Between 1995 and 1997, this factor was only about one-sixth of the total increase (Levit et al. 1998). Even so, excess medical prices, or the “greed factors,” are an important focus for policy makers because they represent the area where savings may be targeted.

Although health economists rarely focus on administrative costs, some scholars are now paying attention to the role of high administrative costs in the United States. For example, Hellander and colleagues (1994) estimated that administrative overhead accounted for 25 percent of total U.S. health system expenditures in 1993. This included the costs of insurance overhead, hospital administration, nursing home administration, and physicians’ billing and overhead. There is some evidence that such costs are increasing. The excess bureaucracy is related to the complex payment and billing systems that have been created in the United States. Consolidating the 1,500 insurers in the United States could reduce overhead costs.

Other expenditures not included above			
Program administration and net cost of private health insurance	40.5	50.0	151.3
Government public health	19.6	38.5	74.9

Table 1

SOURCE: Adapted from *Levit et al. (1998); **Smith et al. (1998).

Kenkel (1993) found that health maintenance organizations (HMOs) reported that 18 percent of their revenues were used for overhead and profits, compared with traditional insurance plans (14 percent) and Medicare (only 3.5 percent).

Economic analysts argue that the slower spending during the latter part of the 1990s reflected several factors. First, where employers sponsored health plans, there was a shift of many workers from indemnity health plans into managed care (Levit et al. 1998), where premiums may have been lower. Second, managed care was successful in negotiating discounts with providers because there was an excess capacity of providers. Growth in managed care enrollment was found to have only a small effect on the volume and intensity of services. Finally, the general and medical-specific inflation rates declined (Levit et al. 1998).

Ginsburg and Gabel (1998) argue that spending was down in the 1990s because of a sharp decline in provider revenues and payrolls. They show that hospital and physician spending increases in 1997 were less than the growth rate in the GDP (which was 2.8 percent in 1997). Although there was a slight increase in payroll costs between 1996 and 1997 in hospitals, most of the growth was

due to increases in hours worked, and not in number of employees. At the same time, drug costs had increased by 11.5 percent, primarily because of increases in the use of drugs rather than the price (Ginsburg and Gabel 1998). Premiums for health insurance increased by only 3.3 percent between 1997 and 1998 (Ginsburg and Gabel 1998). The premium increases showed substantial profit margins in 1992–1994, but lagged behind expenditures while profit margins in health plans dropped in 1996–1997 (Ginsburg and Gabel 1998).

Health care spending increases are expected to continue because of the growing demand for medical services, continued economy-wide inflation, and medical price inflation. See Table 1. Most of the expenditure growth is expected to take place in the private sector, with lower spending in the public sector (Smith et al. 1998).

The high growth rate for health expenditures has had several consequences. First, the growth rate has dominated the attention of policy makers at all levels as they have attempted to struggle with cost containment. Most policy efforts have been directed toward reducing program utilization and expenditures. This focus on cost containment has

set the national political agenda, relegating issues of access to health care and the quality of care to a second level of consideration. This agenda is of great concern because the number of uninsured is increasing and the quality of health care urgently needs to be improved (Chassin et al. 1998). Moreover, the high expenditure rates continue to be used as a rationale by some policy makers for why the expansion of public programs and a national health insurance policy are not financially feasible in the United States.

Growth Through Consolidations, Mergers, and Acquisitions. Overall health expenditures are increasing in part because of the changing structure of health care financing and delivery systems. Kassirer (1996) documented the rapid trends in consolidation of the health care industry, creating larger corporations during the 1990s. Srinivasan and colleagues (1998) reported that, in 1997 alone, there were 483 mergers and acquisitions involving health services companies totaling \$27 billion and 33 mergers and acquisitions involving HMOs totaling \$13 billion. The big winners in mergers and acquisitions are the corporate executives of these large organizations, the stockholders, the lawyers who broker the consolidations, and the health care consultants. The losers are the physicians and nurses who may lose income and even jobs. It is not clear that these mergers and acquisitions are resulting in any overall savings to the system or in improvements in the quality of care. Rather, they appear to be increasing profits and market power (Kassirer 1996).

Srinivasan and colleagues (1998) reported that the growth rate in for-profit health service companies and HMOs has increased rapidly in recent years. Between 1981 and 1997, for-profit HMOs grew from 12 to 62 percent of total HMO enrollees and from 18 to 75 percent of all health plans. Between 1987 and 1997, there were 210 offerings for health services companies valued at \$6.7 billion and 23 HMO public offerings for \$1.4 billion. Health services capitalization was \$113 billion and HMO capitalization was \$39 billion in 1997, showing dramatic growth rates. Stock prices for health care industry firms generally outperformed the overall stock market over the decade. As these changes occurred, there were also many conversions of nonprofit health care organizations to for-profit status in order to obtain capital and survive in a highly competitive environment. In 1997, there

were 81 conversion foundations with assets of \$9 billion as a result of the conversions to for-profit status (Srinivasan et al. 1998).

Every year *Forbes* magazine lists the largest health care corporations in the United States and details their stock performance. Gallagher (1999) reported \$10 billion in mergers and acquisitions in 1998, including many in the HMO and long term care sectors. The managed care stocks were reportedly healthy in 1998, climbing 15 percent over 1997 (Gallagher 1999). HMO mergers and acquisitions were slower in 1998 than in the previous year. By comparison, hospital stocks were off 22 percent on average and long-term care providers were off 56 percent (Gallagher 1999).

What scholars and policy makers have generally thus far ignored are both the economic and the social costs of these changes in the structure of the health care system. The costs associated with mergers, consolidations, and profits are not identified in the analyses of health care costs (Levit et al. 1997). As long as the health industry is profitable, we can expect growth in the private profit-making sector.

PRIVATE PAYERS

The payers of health services dominate the policy decision-making process in the United States. At the same time, the payers of health care have shifted over the past decade.

Private health insurance corporations dominate the health system because they have the lion's share of the resources and power in the health industry. For instance, private health insurance firms earned \$348 billion in premium income in 1997 in the United States (Levit et al. 1998). See Table 2. Private health insurance companies include both the traditional indemnity insurance plans as well as managed care plans. The private health insurance industry—including managed care organizations—spent \$34.5 billion (or 10 percent) of their premium income in 1997 on administration and profits.

Light (1992) has documented many of the problems with private indemnity health insurance plans. These plans have practice medical underwriting that excludes individuals with medical problems (e.g., chronic diseases) or raises the premiums for such policies to levels where individuals

**National Health Expenditures by Source of Funds for 1990, 1997

cannot afford to purchase them. There are indirect approaches to reducing risk, such as waiting periods, copayments, and payment ceilings, along with the exclusion of certain procedures, tests, or drugs. Light (1992) also documented the problems with inaccurate or manipulative premiums and discrimination, which includes policy churning (switching policies before the waiting period ends) within group underwriting for those individuals at high risk, renewal underwriting (increasing the costs for those with new medical conditions), and selective marketing. There are many techniques to deny or delay payment for services. All these practices have negative consequences for individuals and groups seeking insurance. These problems are the result of a health care system geared toward profit and cost containment and of ineffective regulation of health insurance companies at the state level, although states do vary in their regulatory activities.

In 1996, Congress passed the Health Insurance Portability and Accountability Act (HIPAA). This legislation, sponsored by Senators Edward Kennedy and Nancy Kassebaum, was designed to address some of the problems with health insurance by making it easier for persons who have lost employer-provided insurance to qualify for other coverage. However, Kuttner (1999) concludes that HIPAA is of little help because there are no regulatory controls on insurance premiums and no subsidies for those persons who need the insurance because most have lost their jobs and the ability to

pay for the insurance. Similarly, the 1985 Consolidated Omnibus Budget Reconciliation Act (COBRA) allowed people leaving employment to pay insurance premiums out of pocket for up to eighteen months to retain their coverage, but again, this is of little help for those without the resources to pay for the insurance (Kuttner 1999).

Managed care organizations (MCOs) had the most dramatic growth in health care in the 1990s. As one study reported, "Managed care isn't coming; it has arrived" (Jensen et al. 1997). In 1995, 73 percent of insured U.S. workers received their coverage through an HMO, a preferred provider organization (PPO), or a point-of-service plan (POS) (Jensen et al. 1997, p. 126). See Table 3. HMOs are health plans that provide care from an established panel of providers to an enrolled population on a prepaid basis. PPOs are health plan arrangements where networks of providers agree to accept plan payment rates and utilization controls. POS plans are HMOs where members may self-refer outside the established network but are required to pay deductibles and other costs. This means that conventional, or fee-for-service (FFS), plans have experienced a precipitous decline in recent years. Between 1993 and 1995, the percentage of workers in conventional health plans dropped from 49 to 27 percent (22 percent), while significant growth occurred in HMOs (6 percent), PPOs (5 percent), and POSs (11 percent) (Jensen et al. 1997, p. 126). Eighty-five percent of the U.S. work force was covered by some type of managed care plan in 1997 (Levit et al. 1997).

Percentage of Workers in Various Types of Plans, 1993-1995

Plan Type	Year	
	1993	1995
Conventional	48.9%	27.4%
Health maintenance organization (HMO)	22.4%	27.5%
Preferred provider organization (PPO)	19.6%	25.0%
Point-of-service plan (POS)	9.1%	20.1%

Table 3

SOURCE: Jenson et al. (1997).

There have been numerous studies of HMOs and their performance (Miller 1998; Miller and Luft, 1994, 1997). Davis and colleagues (1995) surveyed individuals in FFS plans in comparison to those in managed care. They found that many individuals (54 percent) had changed plans within the past three years. Of those who changed plans, 73 percent had done so involuntarily, either because of employment coverage changes or changes in jobs or moves. Of those persons in managed care who had changed plans, 41 percent also reporting having to change physicians involuntarily, compared with only 12 percent of enrollees in fee-for-service coverage.

Although most respondents were reasonably satisfied with their health insurance, those in managed care were more likely to rate their plan as "fair" or "poor" and were less like to rate their plan as "excellent." Those individuals in managed care plans reported less access to specialty care, less availability of emergency care, more waiting times for appointments, and less overall plan satisfaction (Davis et al. 1995).

Other research on the quality of managed care services points to concerns for populations with particular health needs. Miller (1998) found mixed results for access to care in HMOs among enrollees with chronic conditions and diseases. He found enough negative results to raise serious concerns about access. Nelson and colleagues (1997) found less satisfaction with the amount of services received among enrollees who used HMO services. For populations with a variety of needs, the concerns are also mounting. For example, studies of elderly ill persons revealed that HMO enrollees report poor quality of care and lower utilization

than FFS enrollees (Clement et al. 1994; Shaughnessy et al. 1994). The problems that the elderly confront reveal spaces where government programs (i.e., Medicare) and private institutional practices (HMOs) need expanded coverage and improved coordination.

Between 1989 and 1995, the enrollment of Medicare beneficiaries in HMOs grew rapidly, so that HMOs covered about 10 percent of the total beneficiaries and the remaining persons received traditional FFS care (Welch, 1996). The Balanced Budget Act of 1997 made a number of changes in the Medicare program, called Medicare+Choice, that were intended to expand Medicare beneficiaries' options (Christensen 1998). These included: (1) PPOs, where networks of providers agree to accept plan payment rates and utilization controls; (2) provider-sponsored organizations (PSOs), which are plans organized by affiliated health care providers; and (3) medical saving accounts (MSAs) established by enrollees to receive the Medicare amount that would be paid to an HMO. Enrollees must pay all costs out of the MSA that would be covered by Medicare as well as out-of-pocket expenses (Christensen 1998). Congress expected that the Balanced Budget Act would accelerate the growth in HMO enrollment to nearly 34 percent by 2005. In spite of these changes to implement this new program, growth may be slower than projected because some HMOs are unwilling to accept Medicare members because they consider Medicare rates to be too low. In 1998, HMOs announced that they were dropping approximately 400,000 of their 6 million enrollees because they consider the rates too low (Pear 1998).

There are two advantages of HMO enrollment for Medicare beneficiaries. The first is that premium costs have generally been minimal and the second is that some HMOs include prescription drug coverage and other benefits not covered by Medicare. Recently, however, drug benefits for Medicare beneficiaries have been reduced or capped by a number of HMOs (Kuttner 1999).

HMOs have also dramatically captured the Medicaid enrollment in many states. President Bill Clinton streamlined the process that allowed states to have waivers of the federal regulations that provide mandatory enrollment of Medicaid beneficiaries in HMOs (Iglehart 1995). The expectation

was that HMOs would control Medicaid costs and encourage more coordinated forms of care by increasing the likelihood of having a primary care physician. The Kaiser Commission on the Future of Medicaid (1995) summarized 139 articles, books, and reports on Medicaid managed care and found mixed results. They found that the use of specialty services and emergency room care declined, but there was not a consistent increase or decrease in use of physicians' services or hospital care. The issue of cost savings was mixed, and quality and satisfaction rates were considered to be comparable. On the other hand, Iglehart (1995) documented serious problems with the implementation of Medicaid managed care in some states, including Florida and Tennessee.

Pauly (1998) argues that for-profit health plans enjoy monopsony power in the health care market. And while a monopsony can result in lower provider premiums, it may also reduce benefits as the providers reduce their spending on care. Pauly concludes that traditional antitrust policies have not addressed the problem of monopsony or monopoly power.

Woolhandler and Himmelstein (1995) view the growth in HMOs as a transformation that not only places physicians at financial risk because of cost-containment practices but also pressures physicians to withhold needed care. These financial arrangements encourage physicians to collaborate in risk selection by seeking to avoid patients who may have high care needs. Mechanic and Schlesinger (1996) have argued that the impact of managed care has had a negative impact on patients' trust of medical care and their physicians. The insurance industry and the managed care organizations hold great power and authority over the care provided to individuals and groups. They also have a great deal of influence over physicians, other health professionals, and health care workers. The current trends can have serious negative consequences for access and the health status of the population.

PUBLIC PAYERS

The two major public payers are Medicare and Medicaid, programs established in 1965. Medicare pays for those individuals who are aged or disabled under Title 18 of the Social Security Act. Medicaid

is generally provided to persons age 65 and over who are entitled to Social Security and to individuals who are disabled for a period of at least 24 months. There were 38 million people eligible in 1997. Medicaid, under Title 19 of the Social Security Act, is funded jointly by federal, state, and local governments. It provides coverage to those persons who are eligible for Supplemental Security Income, for low-income individuals who are aged, blind, or disabled. It also pays for recipients and their children under the Aid to Families with Dependent Children, which is now the Temporary Assistance for Needy Families program. The program provided assistance to 36 million persons in 1996 (Waid 1998). There are other public payers, such as the Veterans' Administration and local governments, that are not discussed here in detail.

Medicare. In 1997, Medicare paid \$214.6 billion for its 38.4 million aged and disabled enrollees (Levit et al. 1998). Medicare is the single largest public program, accounting for 20 percent of the nation's health expenditures. See Table 2. The growth rates in Medicare spending declined from 12.2 percent in 1994 to 7.2 percent in 1997. This decline was the result of slower price inflation and policy changes. Physician payments were limited, and fraud and abuse detection programs were increased. Limits on payments and aggressive abuse detection programs are credited with decreasing home health care spending (Levit et al. 1998). Future declines in nursing home spending are expected because of the adoption of a prospective payment system that was implemented in 1998.

In the 1980s and 1990s, Medicare spending growth had been much lower than private health insurance annual growth rates. But in 1997, Medicare spending growth rates were 5.8 percent compared with 3.8 percent for private health insurance (Levit et al. 1998). Unfortunately, this growth in spending has contributed to public policy attention on reducing spending for the Medicare program.

And although spending for Medicare has increased, the program pays for only a limited amount of health insurance for those who are aged and disabled. Data from the 1997 Current Population Survey indicate that Medicare beneficiaries paid 67 percent of their total expenditures. Private insurance paid for only 10 percent of the bills,

even though a large proportion of beneficiaries have private supplemental insurance. The remainder was paid out of pocket by beneficiaries (Carrasquillo et al. 1999).

When the Medicare, Medicaid, and other public programs are combined, their expenditures represent 46 percent of total national expenditures. Because this is such a large percentage of the total, the large increases in public spending per year contribute to the public policy focus on cost containment.

Medicaid. Medicaid is a program designed for the poor as a safety net. Medicaid spending was \$159.9 billion in 1997, or a 3.8 percent increase over the previous year (Levit et al. 1998). Other governmental expenditures for health care (federal, state, and local) totaled \$132.7 billion. These public programs represented 27 percent of total U.S. expenditures. See Table 2. There was a rapid growth in Medicaid expenditures in the 1988–1994 period, related to the growth in (1) the number of enrollees, (2) the spending per enrollee, and (3) increases in spending for hospitals with disproportionate shares of Medicaid patients. The spending slowed in the 1994–1997 period because the number of Medicaid enrollees dropped during this period. The states also were allowed to have waivers to implement mandatory enrollment in managed care plans.

Congress passed welfare reform legislation in 1996 that replaced the Aid to Families With Dependent Children (AFDC) with Temporary Assistance for Needy Families (TANF). This legislation broke the link between welfare and Medicaid eligibility, but states must continue to provide benefits to persons who met the eligibility requirements for Medicaid prior to the legislation. The law changed the definition of childhood disability under the Supplemental Security Income (SSI) program, curtailed benefits to legal immigrants, and banned Medicaid eligibility for qualified aliens admitted to the United States after the legislation. Some benefits were restored to legal immigrants under the Balanced Budget Act of 1997 (Levit et al. 1998).

The passage of TANF means that welfare limits will gradually become effective in most states during 1999, and millions of women will lose their eligibility for welfare benefits. Although states may

continue to offer Medicaid eligibility to those individuals who go off welfare and are working in low-income jobs, many former welfare recipients are not informed of their eligibility for Medicaid services and thus have not retained their benefits. Those former welfare recipients who successfully obtain employment will generally be placed in relatively low-wage occupations that will probably not offer health insurance or job security. Overall, the legislation will result in a loss of health insurance for many women and children (Kuttner 1999).

In response to the health needs of children, Congress passed the Children's Health Insurance Program (CHIP) as a part of the 1997 Balanced Budget Act. This program provided states with \$24 billion over five years to expand coverage of Medicaid for children or to establish a new children's health insurance program. The new insurance program is complex and difficult for people to understand and gain access to. In 1998, it was reported that the program was dramatically undersubscribed for a number of reasons across the country. California, for example, had enrolled only about 4 percent of the 580,000 children eligible for the program (Kuttner 1999). Some immigrants were reported to be concerned that enrollment of their children could affect their immigration status.

Several barriers restrict access to this program, particularly for immigrant populations. First, a large state bureaucracy and complicated application process have limited access to services. Second, eligibility coverage varies for children of different ages, so that one child may be covered while another is not in a single family. Many immigrant parents declined to participate in the program because they felt that providing health care for one child while not obtaining coverage for another was immoral (Altman 1998). Finally, eligibility for this program was initially tied to citizenship, which created access problems because, although their children were often documented and legal residents, undocumented immigrant parents declined to apply to the program for fear of deportation by immigration authorities (Korenbrodt et al. 1999).

The Congressional Budget Office estimated that the Children's Health Insurance Program and the Medicaid expansions could extend coverage to

2 million of the 10.6 million uninsured children in 1997 (Kuttner 1999). It is uncertain if more than a fraction of this total will ever receive coverage.

CONSUMER POWER

Consumers have seen a drop in their out-of-pocket spending for medical care over the past two decades. In 1980, out-of-pocket spending was 24 percent of the total expenditures in contrast with 17 percent of spending in 1997 (Levit et al. 1998). The total out-of-pocket spending was \$187.6 billion in 1997. Out-of-pocket costs include premiums for insurance, copayments, and deductibles for services use, and direct costs for services not covered by insurance, such as outpatient drugs and long-term care. The reason that out-of-pocket spending is lower is that some consumers are also paying a lower proportion of their income on premiums for health insurance. Managed care plans generally had more limited copayments and deductibles than indemnity insurance, and more individuals were enrolled in managed care (Ginsburg and Gabel 1998). Out-of-pocket costs did, however, go up in 1997 because some HMOs were reportedly increasing their copayment and deductible charges (Levit et al. 1998). Consumer spending for drugs increased as well.

Some studies have reported that 61 percent of the population has employment related coverage (AHCPR 1998; Levit et al. 1998). These estimates group individuals who have public and private employment together and tend to count anyone with private insurance even if that insurance is not the primary payer of health care. New data from the 1997 Current Population Survey showed that only 43 percent of the population had their health insurance paid for by private-sector employers, 34 percent have publicly funded insurance, 7 percent purchased their own insurance, and 16 percent were uninsured (Carrasquillo et al. 1999). Employers also contribute to the Medicare Hospital Insurance Trust Fund through Social Security payroll taxes, but these account for only a small amount of the total expenditures.

Carrasquillo and colleagues (1999) point out that the role of employers in paying for insurance has been exaggerated and, as a consequence, employers have played a dominant role in public policy discussions related to health insurance. For

example, President Clinton's national health insurance plan proposed to link health insurance to that paid for by private employers, even though employers are not the major payers of insurance. Employers played a role, along with many other interest groups, in defeating the Clinton plan because of fears that their costs would be increased and they would lose control over their work force (Navarro 1995). At the same time, employers are given an estimated \$100 billion in tax subsidies in order to cover the costs of employer-sponsored health insurance (Reinhardt 1997). The \$100 billion in subsidies could be eliminated if a national health insurance plan were paid directly by the government.

TYPES OF UTILIZATION AND EXPENDITURES

National expenditures for health care reveal how health resources are utilized and allocated to provide care in the United States. The patterns are not necessarily the way the public would allocate the resources. Instead, the expenditure patterns reflect historical decisions about how public and private dollars should be spent.

The patterns of expenditures changed rapidly in the latter half of the 1990s because of the growth in managed care. Managed care plans have instituted their own cost controls on the providers that they pay. The health industry has also been consolidating through a large number of mergers and acquisitions. These changes have resulted in fewer larger health care provider organizations.

Hospital Care. Hospital care has historically been and continues to be the largest component of health spending, accounting for 38 percent of total spending (\$371 billion) in 1997. See Table 1. The spending for inpatient care dropped considerably and marked increases occurred in outpatient services. This shift represents a restructuring to outpatient care, which is less costly. In the 1990–1997 period, there was a 6-percent reduction in hospital admissions per capita and a 16-percent decline in inpatient days in community hospitals (American Healthcare Infosource 1998).

As result of the restructuring and downsizing, U.S. hospitals closed 88,000 beds (10 percent) and occupancy rates fell from 64.5 percent in 1990 to 59.6 percent in 1997 (Levit et al. 1998). Although

utilization fell and price increases were controlled, hospitals were able to keep profit margins high, since almost all their revenue is from third-party insurance (consumers paid directly for only 3 percent of hospital costs).

Physician Services. Costs of physicians' services were \$218 billion in 1997, or 21 percent of total health services and supplies. Spending increases for physicians were associated with the increasing dominance of managed care organizations. The American Medical Association (AMA) reported that 92 percent of all physicians were in managed care, and these contracts accounted for 49 percent of their income (Levit et al. 1998). Physicians are also expected to pay for an increasing share of ancillary services under the capitated managed care contracts. Physicians have reacted to managed care cost controls by expanding the sizes of their practices to large group practices. These practices allow for greater leverage in negotiating contracts, economies of scale, and increases in capital. More research on the effects of the changing structure of medical practices on health care access, costs, and quality is needed.

Drugs and Medical Nondurables. Drugs and medical nondurables accounted for \$108.9 billion in 1997, or 10 percent of total national expenditures (Levit et al. 1998). Prescription drugs as a subset grew faster than other types of health care. These costs grew at 14.1 percent in 1997 compared to 4.8 percent for health spending in 1989. Out-of-pocket drug costs were 51 percent of total payments in 1989, later dropping to only 29 percent in 1997, and the rest were paid by third parties. The switch to managed care has increased the amount of covered outpatient drugs with relatively low copayments (Levit et al. 1998). Thus, the growth in drug costs was associated with increases in the number of prescriptions—not price increases, as had been the case in the 1980s (Levit et al. 1998).

The demand for drugs continues to increase. The Food and Drug Administration (FDA) approved fifty-three new drugs in 1996 and thirty-nine in 1997—both record highs. These approvals, along with increased advertising efforts by pharmaceutical firms, may lead to increases in demand. Drug makers reported spending \$21 billion on research and development in 1998, compared with \$8 billion in 1990 (Herrera 1999). They also increased spending on advertising to \$1.3 billion

in 1998, having great successes with Viagra (for impotence), Claritin (for allergies), and Propecia (for baldness) (Herrera 1999).

Other Services. Nursing homes represented about 8 percent of total health service and supply expenditures in 1997, and this is projected to decline to 7 percent in 2007. Other professional services were 4.6 percent of expenditures, home health care was 3 percent, dental services were 4.6 percent, and vision products and other durable medical equipment were only 1.4 percent in 1996. These expenditures were expected to remain about the same percentage of the total over the next ten-year period (Smith et al. 1998). Governmental public health activities were estimated to be about \$35.5 billion in 1996, representing 3.4 percent of total U.S. health expenditures. Research expenditures were 1.6 percent of the total in 1996, and construction was 1.4 percent of the total (Smith et al. 1998); these were also projected to remain the same over the next ten-year period.

LONG-TERM CARE IN THE UNITED STATES

The only segment of the U.S. population whose cost of long-term care is fully covered is made up of those individuals below the poverty threshold who are enrolled in the state-run, federally supported Medicaid plans (Harrington et al. 1991). Many persons of moderate incomes needing long-term care are unable to afford the costs of long-term care services, which can be as much as \$50,000 per year for nursing home care. If individuals “spend down” to the poverty threshold, they can become Medicaid eligible as a last resort (Wiener 1996). This not only constitutes a hardship to the patient but creates dependence on federal and state assistance, which would be unnecessary if the entire population were insured, with premiums derived from sources other than the government.

In contrast, the nonpoor elderly enrolled in Medicare are entitled only to a limited number of skilled nursing care days (up to 100 days) if medically required following hospitalization. With some exceptions, the rest of the population must either pay for care out of pocket or purchase private long-term care insurance (Levit et al. 1997).

In 1996, national estimates for long-term care spending were \$125.5 billion (Levit et al. 1997). Of

the total expenditures, 30 percent (\$38 billion) was for home health care (including hospitals and freestanding agencies) and 70 percent was for nursing home care (\$87.5 billion; including hospital and freestanding facilities) (Levit et al. 1997). Home health expenditures are expected to double between 1996 and 2007, while nursing homes are expected to grow by 50 percent during the same period (Smith et al. 1998).

Medicaid paid for 48 percent of all nursing home care and 14 percent of all home health care in 1996 (Levit et al. 1997). Medicare paid for 45 percent of home health care and 11 percent of nursing home care. Overall, the government paid 59 percent of home health costs and 61.5 percent of nursing home costs (Levit et al. 1997). Most of the burden for government spending is from general taxes used to pay for Medicaid and a combination of general taxes and payroll taxes that support the Medicare program.

Private health insurance paid only an estimated 5 percent of nursing home care and 10.6 percent of home health care expenditures in 1996 (Levit et al. 1997). The remainder of the expenditures was paid directly out of pocket by those needing long-term care (31.5 percent for nursing home care and 19.5 percent for home health care) (Levit et al. 1997).

Private, voluntary long-term care insurance is not a viable approach to financing long-term care (Wiener 1994). Although private long-term care insurance has been available since the late 1980s, only 4.5 million long-term care insurance policies had been sold by 1994 (and not all of these policies were still in effect) (Cohen and Kumar 1997). Sold on an individual basis, private long-term care insurance is primarily attractive to persons whose health condition places them at high risk and makes them likely candidates for long-term care. Only about 10 to 20 percent of the elderly can afford to purchase long-term care insurance (Wiener 1994). Premiums for two policies purchased at age 65 were estimated to cost an average of \$3,500 per year, which would be about 13 percent of a median elderly couple's income (Consumer Reports 1997, p. 46). These models determined that private long-term care insurance is unlikely to have a significant impact on public spending for long-term care, even though such insurance is expected

to increase (Wiener and Illston 1994; Wiener et al. 1994).

A mandatory social insurance program for long-term care would have many advantages (Harrington et al. 1991). If everyone paid into the system, then individuals would have access to coverage when they are chronically ill or disabled without the humiliation of having to become poor (i.e., to "spend down") to receive services. The program might be more appealing if enrollees could have the advantage of paying in advance (prefunding) so that services would be available when needed. No stigma would be attached to receiving services, and such a program should have wide public support. The program could also reduce the access problems that are currently experienced by those who are in the Medicaid program. The financial risk would be spread across the entire population so that individual premium costs or taxes would be relatively low, in comparison to the costs of insurance purchased when individuals are older and at risk of needing long-term care.

Although many have argued that the United States cannot afford to adopt a public social insurance program, Germany mandated a social insurance program for long-term care in 1995 (Geraedts et al. 1999). This program was funded through a combination of public taxes and payroll taxes paid by employers and employees (.08 percent of wages for each or a total of 1.6 percent) (Geraedts et al. 1999). During the first three years of this program, it maintained its financial solvency and expanded long-term care to the entire population who have disabilities. This example demonstrates that such public insurance programs, if paid for by the entire population, can ensure coverage at a reasonable cost. This approach avoids restricted access, the stigma, and the stress placed on those individuals needing long term care and their families who do not have sufficient funds to pay for them in the United States (Harrington et al. 1999).

THE UNINSURED AND THEIR HEALTH: MICRO-LEVEL ISSUES

An estimated 43 million individuals in the United States have no private health care insurance (Kuttner 1999; U.S. Bureau of the Census 1998b). These individuals have no Medicare, Medicaid, or other public insurance coverage. The percent of

the population without insurance increased from 14.2 in 1995, to 15.3 percent in 1996, and to 16.1 percent in 1997 (Kuttner 1999). This represents a steady increase in the number of uninsured since the 1980s, when the Reagan administration first began cutbacks in public health expenditures. The U.S. Bureau of the Census (1998b) also estimated that about 71.5 million individuals lacked insurance for at least part of the year in 1996.

The uninsured are primarily those who are poor and members of minority groups. Of those with incomes of less than \$25,000, 24 percent had no health insurance compared with only 8 percent of those with incomes over \$75,000 (Kuttner 1999). For those from minority groups, 50 percent of Hispanics and 37 percent of blacks had at least one month without insurance coverage compared to only 25 percent of whites (Kuttner 1999). Moreover, approximately one in three children had no health insurance for part of the year during 1995 and 1996 (Families USA 1997). The rate of children lacking insurance rose between 1989 and 1996 (U.S. Bureau of the Census 1998a). Lack of insurance for children was closely correlated with income. The group with the highest uninsured rate was young adults (38 percent, or twice the rate for other Americans), because many of them are dependent on their parents, who are working in low-wage jobs (AHCPR, 1998).

REASONS FOR THE GROWING NUMBERS OF UNINSURED

There are many reasons why individuals do not have health insurance, but the primary one is that private health insurance rates are too high relative to the incomes of those who are poor. The costs of insurance would represent about 26 to 40 percent of incomes of those who are poor, so many of these individuals are unable to afford coverage (Kuttner 1999). Another major problem is that 44 percent of those individuals who lost their jobs in the 1993–1995 period also lost their health insurance coverage.

The Medicaid program does not provide health insurance to all those individuals living below the U.S. poverty rate. State Medicaid programs are allowed to establish their own eligibility standards for those on welfare (TANF) in order to limit the number who can be served. The Census Bureau reported that 49 percent of people who were fully

employed but living below the poverty line had no Medicaid or private insurance, and this number increased to 52 percent in 1996 (Kuttner 1999). Due to reductions in Medicaid coverage, the rate of poor children with insurance fell from 16.5 million to 15.5 million between 1995 and 1996 (U.S. Bureau of the Census 1998a). A U.S. General Accounting Office study (1996) found that nearly 3 million children who were eligible for Medicaid were not enrolled in the program because of inadequate outreach, fears by immigrants about immigration problems, and other barriers. Additionally, the combination of immigration reform and welfare reforms has produced a “chilling effect” on many immigrants and their health care providers (Korenbrodt et al. 1999).

Another reason that health insurance coverage is eroding is the rising cost of health insurance premiums, especially for people who purchase individual premiums privately rather than through the job (Kuttner 1999). Kuttner (1999) also cites the trends toward temporary and part-time employment, where most workers do not have insurance. The rising costs of Medigap premiums for the elderly who are on Medicare is also a major problem. Finally, the trend away from community rating of insurance to individual and group ratings makes the costs substantially higher for individuals and some groups that have higher injury or illness rates. Employers are also reducing their supplemental health coverage for retirees (from 60 percent to only 40 percent of retirees in 1995) (Kuttner 1999).

There has been a reduction in benefit coverage, particularly for pharmaceutical benefits. Many health plans are capping their outpatient drug benefits, although prescription drugs are the largest category of out-of-pocket costs for the elderly and the costs are increasing rapidly (Kuttner 1999). As noted earlier, drugs costs have been increasing rapidly (Levit et al. 1997) and many cannot afford to pay these costs. Many HMOs and insurance companies have been reducing drug benefits because of these cost increases. One study found that 84 percent of Medigap policies for the elderly had no drug coverage (McCormack et al. 1996). The result is that many elderly individuals are unable to afford drugs that are prescribed for them.

Another problem has been limited health insurance coverage for persons with mental health

problems and mental illness. Mechanic and Rochefort (1992) document the deinstitutionalization of the mentally ill from public mental hospitals and the problems associated with inadequate mental health services. Inadequate housing and community health services, as well as the limits on mental health insurance coverage have all contributed to a general decline in mental health services.

CONSEQUENCES OF LIMITED ACCESS TO HEALTH CARE

The United States and South Africa continue to hold the unenviable distinction as the only two existing industrialized countries without national health insurance. Thus, when the high U.S. expenditures per capita are compared with those of other industrialized countries, the majority of these nations have their populations covered by insurance, while the United States is excluding 43 million individuals. The lack of health insurance leads to a number of serious problems in access to health care services.

There are many other health-related problems that plague the U.S. population in comparison to those of other nations. Among the top twenty-four industrialized nations, the United States ranks sixteenth in life expectancy for women and seventeenth for men, while it ranks twenty-first in infant mortality (Andrews 1995, p. 38). Although there were substantial reductions in childhood mortality in the United States between 1950 and 1993 (Singh and Yu 1996), the United States is well behind many other industrialized countries in childhood mortality (two to four times higher than Japan and Sweden) not only because of higher mortality from medical causes (e.g., heart disease) but also because of injuries and violence. Moreover, there are large differences across groups, with male children experiencing higher mortality rates and African-American children experiencing rates of more than twice that of white children (Singh and Yu 1996).

A number of studies have been conducted on the barriers to access related to the inability to pay for services (Berk et al. 1995; Braveman et al. 1989; Berk et al. 1995; Hafner-Eaton 1994; Mueller et al. 1998; Weissman et al. 1991). Mueller and colleagues (1998) confirmed that lack of health insurance—regardless of race or ethnicity, or living in a

rural environment—is the major determinant of the utilization of health care services.

Approximately 12 percent of all American families (12.8 million) experienced barriers to receiving needed health care services in 1996. Sixty percent of these families reported that the barrier to care was their inability to afford the care, and 20 percent cited insurance-related problems (AHCPR 1997). The barriers to health care included difficulties finding care, delays, or not receiving the care that was needed.

Nearly 46 million Americans were without a regular source of health care such as a doctor's office, clinic, or health center in 1996 (AHCPR 1997). Those persons without insurance were two to three times more likely to have no regular source of health care and two to three times more likely to have encountered barriers in receiving needed health care than those persons with health insurance (AHCPR 1997). Hispanics (30 percent), the uninsured under age 65 (38 percent), and young adults (34 percent) were more likely to lack a stable source of health care. Those individuals with a history of serious medical illness were twice as likely to be unable to obtain care. African Americans and Hispanics were also more likely to be unable to obtain care than whites and others (Himmelstein and Woolhandler 1995).

OTHER BARRIERS TO HEALTH CARE ACCESS

There are many other barriers to access to care. One is the lack of providers in areas close to people who need care. This is a problem for those persons living in rural areas as well as for those in central- or inner-city areas (Clarke et al. 1995). Weisgrau (1995) reviewed the myriad problems rural Americans confront in obtaining health care and mental health services due to the shortages of health care providers and the continued closures of rural hospitals. The stigma of obtaining mental health services in rural areas was also considered to be a problem.

Studies by Wennberg and colleagues (1989) have documented the wide geographic variations in health outcomes. These outcomes are considered to be, in part, related to variations in provider practices. A recent study by the Department of

Veterans' Affairs found that even though the system predominantly serves low-income men, they found substantial geographic variation in service use for different diagnoses in hospitals and clinic use across the United States which they attribute to different practice styles (Ashton et al. 1999).

Another problem is cultural barriers to care. These include language differences between patients and providers and other communication problems. Escarce and colleagues (1993), Gornick and colleagues (1996), Friedman (1994), and Korenbrot and colleagues (1999) have identified these problems. Many studies have found persistent disparities across racial and ethnic groups in access to care (Escarce et al. 1993). Racial and ethnic minorities and rural residents were less likely to use physician services. This pattern was even stronger for rural Latinos and Asians (Mueller et al. 1998), particularly refugee populations. Mortality rates for black Americans are about 50 percent higher than for white Americans, and Native Americans also show very high death rates, especially among the young (Nickens 1995). In part, the high mortality rates are related to lower socioeconomic status (SES) measured by occupation, income, and education attainment, which are generally lower for minorities. Mortality rates were more strongly related to SES in 1986 than in 1960. The substantial black and white differentials in infant mortality have been well documented (NCHS, 1994). High infant mortality rates for minorities are a function not only of poverty and low SES, but also of racial segregation in housing markets that are in close proximity to industrial pollution generators (incinerators, factories, etc.). These sources of pollution produce poor air quality in many communities of color and have a direct effect on infant mortality rates and adult morbidity (Hurley 1995).

In addition to poverty, low SES, and poor environmental quality, infant mortality rates of minorities are also influenced by continuing discrimination in society. The discrimination accumulates over time and results in perceived powerlessness, frustration, and negative self-images that in turn contribute to higher mortality rates. Discrimination against minority group members by health care providers may be a contributing factor that has not been eliminated. Using simulated video interviews of patients and physicians, a recent study documented that the race and sex of patients

have an independent influence on physician decisions regarding how to manage care for chest pain. Women, blacks, and younger patients were less likely to be referred for diagnostic tests (cardiac catheterization), and the interaction effects were also significant (Schulman et al. 1999).

SOCIOLOGICAL MODELS OF ACCESS TO SERVICE USE

Much of the study of health care utilization and access has been developed using the theoretical model adopted by Andersen, Aday, and colleagues at the University of Chicago (Aday and Andersen 1974, 1991; Andersen 1995; Andersen and Aday 1978).

Andersen's (1995) original model was designed to predict or explain the use of health services. Three major components were developed for the model. First, predisposing characteristics were considered to include those that were endogenous to use including (1) demographics, such as age, gender, and race; (2) social structure, such as education, occupation, and ethnicity; and (3) health beliefs, including attitudes, values, and knowledge about health. Various critics have suggested (and Andersen 1995 agreed) that social networks, social interactions, and culture are all concepts that can be incorporated into the social structural factors. Genetic makeup might also be added to the list of predisposing factors. Second, enabling factors were considered to be those community and personal resources that may enable an individual or family to use health services. These include the supply of health personnel and organizations or facilities to provide care. Enabling factors also include income, health insurance, regular source of care, travel and waiting times, and other such factors. Social relationships, or "social support," are also important enabling factors according to Andersen (1995).

Finally, the original model included the need for health care services. "Need" included both the perceived need and the need as evaluated by health professionals. In the original model, the outcomes included the amount of physician, hospital, and other health services used. This model is one of the most widely used approaches by scholars, with hundreds of articles presenting the results of testing these factors. In Andersen's original model,

access was described as potential access and realized access (actual use) of services. Access could be found to be equitable or inequitable, depending on value judgments. Inequitable access occurred when predisposing factors (such as race, ethnicity, or gender) or enabling factors (e.g., health insurance) determine who receives services rather than services determined by need. In later models, the health care system was incorporated, including national health policy, resources, and organizations. Outcomes of health services were revised to include consumer satisfaction about convenience, availability, financing, providers, and quality (Aday and Andersen 1974). The model was expanded further to include ethical criteria to measure equity, such as freedom of choice, equal treatment, and decent basic minimum care. Subsequently, the model has included understandings of effective and efficient access to services and improved health status as outcomes (Andersen 1995). Finally, Andersen sees the model as interactive and dynamic, with utilization and outcomes influencing predisposing, enabling, and need factors.

As a test of the importance of the behavioral model, a study in the late 1990s examined its use in the social science literature between 1975 and 1995. The study found 139 empirical research articles that used the model; of these articles, 45 percent included environmental variables and 51 percent included provider-related variables (Phillips et al. 1998). Extensive work has been done to examine health status as measures of health service outcomes. These include mortality, morbidity, well-being, and functioning. Outcomes can also include equity of service access. More elaborate conceptual models have been developed by the Institute of Medicine (Gold 1998; Millman 1993).

ISSUES RAISED BY TRENDS IN HEALTH CARE UTILIZATION AND EXPENDITURES

The macro-level and micro-level patterns of health care utilization and expenditure suggest that consumers, workers, the poor, people of color, the elderly, nurses, and even physicians are losing ground with respect to access to care and decision making within the health care system. Each year—indeed, every month—thousands more individuals join the ranks of the uninsured and thousands more remain *underinsured* (Kuttner 1999). At the same time, expenditures for the nation's health

care system are expected to rise steeply in the first decade of the twenty-first century. While most policy makers and health policy analysts regard the American health care system as characterized by “private insurance,” less than 50 percent of health insurance is in fact paid for by private employers—and these payments are subsidized by the government at a total of \$100 billion (Carrasquillo et al. 1999). Thus, the role of employers in paying for insurance has been overstated and employers have played a prominent role in health policy discussions. And while the number of employers offering their employees health insurance has either remained unchanged or even decreased in recent years, the cost of these plans has been prohibitive for many workers, who then go without coverage. The result is a nationwide decline in persons with employer-sponsored health coverage (NCH Statistics 1994).

These trends raise questions about the role of the U.S. health care system in providing care to the nation's population. What becomes clear is that while the system is heavily supported by public funds, the benefits are accruing more and more to private corporations. Thus, we suggest that in order to understand changing patterns in health care utilization and expenditure, a political economy perspective is useful. A political economy perspective recognizes the enduring underlying conflicts among different interest groups (workers, purchasers, providers, doctors, insurers, nurses, the elderly) in gaining access to the myriad benefits a health care system provides. For example, many scholars argue that while the U.S. medical system is officially designed to provide the best possible care to any person who needs it and can pay for services, health care is actually only a secondary or tertiary function of this system (Navarro 1976; Relman 1980; Waitzkin 1983). Profit, above all else, is the “driving force” behind the health care system (Woolhandler and Himmelstein 1995).

The benefits and costs of health care in the United States are hotly contested, and stakeholders are engaged in a continuous struggle to gain access to the former and to externalize the latter. Doctors and nurses have organized unions; consumers have demanded a “patient's bill of rights” and a long list of other legislative reforms, producing a “managed care backlash”; health care providers

and insurers have consolidated in a flurry of mergers and acquisitions in the 1990s; pharmaceutical and other health care firms have sought out markets around the globe; and managers of health care systems have slashed wages and jobs in an effort to contain costs (Andrews 1995). The results have been: (1) less regulation of the health care industry; (2) increasing profits for industry; (3) declining consumer satisfaction and less access to care and insurance under managed care; (4) loss of control and autonomy by doctors and nurses; (5) rising health care expenditures; and (6) no discernible improvement in the quality of health care. Our health care system is transforming rapidly without a coherent national approach to either the structure of the delivery of care or to the problem of rising expenditures. It is incumbent upon sociologists studying the health care system of this nation and others to provide a counterbalance to the currently dominant economic cost-benefit analytical approach to this topic. A sociological perspective offers a balanced understanding of the social basis on which the health care system operates and can, therefore, lead the way toward improvements in both theory and policy making in the areas of health and health care.

HEALTH POLICY ANALYSIS

Health policy analysis is of increasing interest to sociologists in the areas of medical sociology and health services research. Health policy analysis draws on perspectives from across the social science disciplines: from anthropology and economics to political science and sociology, as well as law, medical ethics, and the applied fields of public health, public administration, and public policy. Leading sources of policy analysis are scholars in twenty to thirty university-based health policy and health services research centers and institutes and the myriad and growing number of private sector "think tanks" such as the Brookings Institution, the Urban Institute, RAND, the National Bureau of Economic Research, Project Hope, and the American Enterprise Institute. An early indicator of advances in the field of policy studies was the publication of the *Policy Studies Review Annual*, which commenced in 1977 (Nagel 1977) and continues to cover the field with an editorial advisory board made up of distinguished social scientists.

Major federal agencies that both sponsor and conduct health policy analysis include the National Center for Health Statistics (NCHS); the Health Care Financing Administration (HCFA); the Agency for Health Care Policy and Research (AHCPR); the Alcohol, Drug Abuse, and Mental Health Administration (ADMHA); the Social Security Administration; the National Institute on Aging (NIA); and the Office of the Assistant Secretary for Planning and Evaluation. Federal research funding is the mother's milk of health policy analysis; although limited, it has assured the slow but gradual accumulation of health services research knowledge.

Several journals are sources for the latest developments in health policy analysis: *Health Affairs*, *Health Care Financing Review*, *Health Services Research*, *Journal of Health and Social Behavior*, *Journal of the American Medical Association*, *Milbank Quarterly*, *International Journal of Health Services*, *New England Journal of Medicine*, and *Journal of Health Politics, Policy and Law*. A recent, comprehensive

text, *Understanding Health Policy* (Bodenheimer and Grumbach 1998), though written by physicians and with a clinical orientation, is nonetheless critical of chronic systemic tensions and inequalities in U.S. health care delivery. The authors integrate social science literature throughout, one indication of a growing consensus regarding salient problems among scholars, practitioners, and "patients" alike, in a nation shaken by unprecedented corporate intrusions into health and medical encounters.

There are multiple paradigms in and approaches to health policy analysis in schools of public policy, public health, public administration, and social work. The same diversity is present in sociology and other social science disciplines. However, we detect and discuss important areas of convergence between current controversies in U.S. health policy and perspectives and methods that are well established in sociology. We believe these areas of convergence are likely to enhance the stature and usefulness of the discipline in the analysis of health policy, in public as well as in academic life.

The various disciplines, substantive specializations, and methodologies represented in such work have contributed an array of perspectives to the definition of health policy analysis, how it is conducted, and how professional training is oriented and organized. As the number of programs offering health and related policy training has increased, the academic respectability of such work has grown apace. In sociology, vestiges of an invidious distinction between "basic" and "applied" research are still with us, and policy research is both less visible and less valued than is warranted, given its potential public impact. Nonetheless, an expanded topical definition of health policy analysis, following from the recent political and cultural tumult over changes in health care, is conducive to research in several vibrant research genres in sociology, including political economy (see, e.g., *International Journal of Health Services*), constructionist approaches to medical encounters and social problems (Brown 1995; Spector and Kitsuse 1987), phenomenology of illness and medical practice (Benner 1994), community-based studies (Israel et al. 1998), and comparative sociocultural studies of health systems (Mechanic 1996; Kleinman 1980). The latter, bordering medical anthropology, encompasses conventional treatment regimen, as

well as “self-help” and various nonbiomedical, “alternative” health practices, be they traditional or sacred (Baer 1995). Such topical breadth is also evident in “mainstream,” medically oriented outlets. In recent years, the *Journal of the American Medical Association (JAMA)* has devoted sustained attention to public health issues such as gun violence (Sinauer et al. 1996), domestic violence, motor vehicle accidents, and terrorism.

For sociologists, the primary point of entry into health policy analysis has been medical sociology, which has long been sustained by its applied relevance to and sponsorship by agencies in government and medicine (Cockerham 1988). Other contributing subfields include aging/social gerontology, political sociology, gender studies, and social stratification. Despite productive cross-pollination between these related fields of scholarship, the number of sociologists working in health policy analysis is small relative to those involved overall in studies of health care and of social policy, broadly conceived. Though medical sociologists continue to comprise one of the largest sections of the American Sociological Association (ASA)—with more than 1,000 members—their presence in the smaller Association for Health Services Research (AHSR), a major professional association, is modest: only 5 percent of its 1,400 members report primary disciplinary training in sociology, compared to 20 percent from medicine and 14 percent from economics (other members were trained in other social sciences, the allied health fields, and business). Health policy analysis is not, however, confined to conventional research roles and careers; many working in health policy analysis hold master’s degrees, are employed on the staffs of governmental and private agencies, and are not oriented toward academic theory or publication (Luft 1999).

Sociologists’ limited involvement in health policy analysis reflects the sources of, and agendas driving, health services research funding. Many problems in the planning and administration of large, complex programs favor orientations and methodological skills others can best provide, primarily those in economics and business. It reflects as well an unfortunate trend in which “the division of intellectual labor in our discipline tends to replicate program divisions. Experts on aging study

Social Security; experts on health care study Medicare; experts on poverty study Aid to Families with Dependent Children” (Quadagno 1999, p. 8). More generally, the American health care system is itself increasingly governed by business principles of cost control and administrative efficiency, under corporate managed care. The dramatic growth of for-profit health maintenance organizations (HMOs), “now accounting for 75 percent of all HMOs and enrolling over 50 percent of all subscribers” (Fein 1998, p. 10), has intensified public debate over quality, access, and humanity in health care.

The products of health policy analysis range from journalistic and descriptive accounts to sophisticated quantitative analyses and projections. But over the last decade or more, health policy analysis has reflected a societal struggle to come to terms with a secular change in the organization and financing of medical care, away from solo, fee-for-service practice toward corporate managed care. Given the current emphasis on cost savings and efficiencies, and on mechanisms for achieving them such as capitation, risk adjustment, and “utilization management” or “practice guides” for physicians’ clinical discretion, economic models and analyses have been paramount in health policy analyses funded by government agencies and large corporate entities. The justification advanced for these competitive efforts has typically been a need to check inflationary costs and “excessive” demands for medical services by consumers, ostensibly free to operate in a “market” for such services.

Consequently, traditional foci of sociological interest—including professional status and autonomy, access to and stratification of health care services, and continuity Federal safety-net policies rooted in the postwar *social contract* (Quadagno 1999; Rubin 1996)—have been pushed to the margins of public and policy debates. However, sociological perspectives are both rejuvenated and needed at this time. One important line of critique has been to challenge attributions of market choice and consumer autonomy in the face of corporate managed care (Freidson 1994; Freund and McGuire 1999). Another is to reject the very notion of “system” in relation to health care and medical coverage in the United States and instead to document, as does Diamond (1995), the collective vulnerability and implications arising from the arbitrary and confusing patchwork quilt that is American

health policy—a paradox of “excess and deprivation” (Bodenheimer and Grumbach 1998). Yet another is to demonstrate how health care professions may act to mediate between users of health services and their often remote provider organizations. In an important analysis of how doctors are implicated in this process, Freidson (1994) argues for a rebirth of *professionalism*, based on client service and trust, as bases for health care reform. Although one may question the likelihood of this scenario, given the mistrust of doctors at the heart of the consumer backlash of recent decades, the answers are sure to be significant both for social theory and policy. These are but a few examples of the distinctive contributions sociologists are making to health policy analysis, broadly defined.

Consistent with this public spotlight, sociological research on health policy and other segments of the welfare state is gaining momentum. The 1998 president of the American Sociological Association devoted her address to a historical analysis of changes in welfare policy provision, including social security and medicare, as central to understanding the erosion of the postwar social contract in the United States (Quadagno 1999). Furthermore, the demographic aging of America, along with a dramatic increase since mid-century in women’s labor-force participation (with resultant strains in traditional sources of familial care), are propelling the neglected problems of chronic illness, community-based care, and allocation of resources—that is, between capital-intensive hospital treatments and more equitable provision of basic health care—to the forefront of the national and research agendas.

In recent years, then, the inventory and scope of topics subsumed under the heading *health policy analysis* have expanded in ways that energize and demand the attention of sociologists. The legislative failure of the Clinton administration’s national health plan demonstrated the necessity for a coherent set of principles—moral and political, as well as technocratic—in order to implement large-scale policy reform; resistance to “environmental racism” by those unduly exposed to hazardous jobs and industrial toxins has assumed global dimensions; and such widely publicized conflicts as those over public versus corporate liability for the expense of tobacco-related illness (Glantz et al.

1996) and firearms and other forms of violence (Prothrow-Stith 1998; Sinauer et al. 1996)—all these have underscored the political, economic, and cultural forces that shape the health problems, as well as the spectrum of policy options, that analysts address. Indeed, health policy analysts have periodically been buffeted directly by political currents. During the Reagan administration, conservative forces in Congress sought to curtail sharply the collection of health-related data at the federal level; and spokespersons for the failed Clinton plan were attacked as proponents of a federal “takeover” of health care. This attack reflected and accelerated the devolution of federal discretion and responsibility for health care and other policies to state and local governments. Thus, health policy analysis, like health policy itself, has become increasingly politicized.

Research in health policy analysis necessarily concerns itself most directly with timeliness, pragmatism, and specificity in an effort to improve health and health care delivery. Research and analysis are conceived to inform social policy by (1) illuminating features of social organization and social action that are relevant to health policy planning, (2) identifying the social and health problems that require formulation in attempts to develop health policy, and (3) organizing and interpreting data that monitor the effects and outcomes of health policy decisions and the relative impact of programmatic alternatives.

In response to this mission, health services research contributes two major types of knowledge: *engineering* and *enlightenment* knowledge (Weiss 1978). In turn, these models imply distinctly different roles for analysts in the policy process (Marris 1990). In the *engineering* model, researchers seek to provide instrumental knowledge for practical assessment of alternatives and problem solving, accepting the values and goals inherent in existing policies largely as givens. Many influential health policy analyses first appear as fugitive documents directed to internal governmental audiences, addressing particularistic needs and interests of government agencies and actors, and are based on reports designed with an evaluative purpose. Policy analysis of this kind is, again, primarily funded and supported by government, with a lesser role played by such private foundations as the Robert Wood Johnson Foundation.

In the *enlightenment* model, researchers critically—even irreverently—scrutinize the implicit empirical, moral, and political assumptions embedded either in discrete policies or in broader debates (e.g., about the “right to die” or national health insurance). Rather than dealing with how policies work in a technical or engineering sense, enlightenment research contributes to the root understanding of how, by whom, and with what unintended consequences problems in health policy are socially constructed. Often, enlightenment research promotes shifts in what Thomas Kuhn (1970) calls “paradigms,” that is, fundamental ways of looking at problems. The enlightenment model is rooted as well in a critical, Weberian tradition in which the *formal rationality* of internal program functioning is juxtaposed with the *substantive rationality* of such programs, as they affect individual freedom and social equity.

As Marris (1990) shows, the engineering model is most effective and appropriate when policies have clear goals, enjoy broad consensual support, and can be linked directly to social outcomes. At the macro level especially, such conditions have rarely obtained regarding health policy in the United States. Moreover, experienced observers have concluded that however well conceived and conducted, research has had a limited direct role on the adoption and implementation of health policy (e.g., Lee 1998; Mechanic 1974). Important, though less often discussed, is that analysts in the engineering model are dependent on access to reliable, comprehensive, and timely data sets. Such a research infrastructure is difficult to develop and maintain, even where data collection is mandated at state or federal levels of government (Mechanic 1974). Given the present trend of privatization in the management and delivery of health services, sources, collection, and linkage of data are correspondingly more varied and less subject to public oversight. For example, while public health departments have a responsibility to serve the population at large, HMOs, however carefully they document utilization of services among their thousands of subscribers, have no such obligation to the public. This poses serious questions regarding the coordination of public and private health entities (Goldberg 1998).

Among other fertile research questions being posed in the expanding, multidisciplinary field of

health policy analysis are the following: How is the global resurgence in infectious disease—termed the *third epidemiologic transition* (Barret et al. 1998)—linked to our more global economy and consumer culture, and what strains is it likely to impose on outdated public health networks? To what extent is globalization leading to convergence in the organization of health care systems internationally (Mechanic 1996)? How are the successes of the American health care system in increasing human longevity creating new conceptions of and practices in medical ethics? Inasmuch as chronic illnesses are often peripheral to direct treatment by doctors, what roles are nurses and other medical practitioners playing in the revision of medical ethics and practice (Thomasma 1994)? What is the place and role of communities in our increasingly corporate health care system? And how might we rethink research practices to better conceptualize and tap community-level perspectives and dynamics (Israel et al. 1998)? Many contemporary problems in health care—from mechanisms by which AIDS and other diseases are transmitted, to discrimination against minority groups seeking care—would seem to rest on understanding community-level dynamics.

Sociology has a long tradition of reformism and interest in finding solutions to applied problems. Robert Lynd’s *Knowledge for What?* (1986) called sociologists to the task, and a long line of American sociologists have worked within the applied tradition. Particular examples are from the Chicago School (Bulmer 1984; Deegan 1988; Deegan and Burger 1981; Park 1952) and Columbia University, where Lazarsfeld and his colleagues advanced the field of applied research after World War II. These efforts were followed by work on the uses of sociology (Lazarsfeld et al. 1967) and a burgeoning of critical scholarship in the wake of the “counterculture” of the 1960s. These forerunners laid the foundation for what has become an increasingly exciting enterprise: the study of health policy. Freeman’s (1978) observation on the nature of health policy analysis as a scientific enterprise remains applicable: that policy studies are rather specialized and “content limited,” demonstrating few attempts to develop overriding conclusions about the policy process; hence, “there is practically no effort at ‘grand theory’ and little at ‘middle-range theory’ either” (Freeman 1978, p.

11). Nevertheless, narrow, highly specialized studies are not policy studies if they have no use beyond the most limited and specialized areas of concern. "Policy studies . . . need to be broad in implications, insightful to those beyond the narrow band of experts in a particular field, and intermeshed with work in related areas" (Freeman 1978, p. 12). The stimulation of and funding for policy analyses has been driven largely by the immediacy of existing (rather than emerging) problems that catch the attention of policy makers. Therefore, there is tension between the need to conduct carefully controlled definitive studies and the need to enlarge the focus of such research to contribute broader application and significance.

The growth of health policy analysis was shaped by the social problem definitions of health care from the 1960s to the 1980s (Rist 1985), and these, in turn, have been shaped by the political and economic exigencies of these periods. Health care was defined in the 1960s by the crisis of access, in the 1970s by the crisis of fragmentation and lack of comprehensive planning, and in the 1980s by the crisis of cost and the resurgence of market forces in health care. The widening reverberations of these forces throughout the 1990s presents sociology with an urgent and relevant research agenda. The cost of medical care continues to rise at two or three times the rate of inflation; the costs to business, government, and individuals skyrocket; more and more Americans are uninsured each year; the annual expenditure on the medical-industrial complex climbs above \$600 billion; and the population is aging. In the wake of these dramatic developments, the health care system and the policies creating it have been increasingly exposed to criticism and investigation. The key health policy issues for the new century are the cost, quality, and outcomes of care; the organization, financing, and delivery of acute and long-term care services; and expanding access to care.

HEALTH PROMOTION AND HEALTH STATUS

Health promotion, a general term, refers to a wide range of health-enhancing activities that seek to maintain health and functional ability, increase longevity, and reduce the prevalence and consequences of disease. These diverse activities include distributing free needles to substance abusers, identifying and modifying genes such as those linked to the development of Alzheimer's disease, proposing laws that seek to deter cigarette smoking, and offering blood pressure and cholesterol screening. They also include personal health practices whereby individuals engage in healthy lifestyles, consume vitamins, and the like. Therefore, these wide-ranging activities are conducted by persons trained in the field of public health, traditional health care workers, practitioners of complementary medicine, basic science researchers, politicians, health policy experts, and the individuals who practice health-enhancing behavior, to name but a few.

Long ignored in favor of medical, surgical, and pharmaceutical treatments that seek to cure or arrest health problems, health promotion information is now a prominent feature of popular magazines and nightly newscasts. Indicative of its rising importance, the United States Public Health Service has expanded the official title of the Centers for Disease Control to the Centers for Disease Control and Prevention.

The significance of health promotion activity is well known to the medical community. It offers the best, if not cheapest, method of reducing the burden of life-threatening conditions and maintaining a healthy, well-functioning, long-lived population (Pope and Tarlov 1991). As has been stated, "many of the most serious disorders. . . can be prevented or postponed by immunizations,

chemoprophylaxis, and health life-styles. To an unprecedented extent, clinicians now have the opportunities, skills, and resources to prevent disease and promote health, as well as cure disease” (Office of Disease Prevention and Health Promotion 1994). Thus, health promotion is the ounce of prevention to avoid the pound of disease/disability/decline.

THE RANGE OF HEALTH PROMOTION ACTIVITIES

Activities that constitute health promotion are conducted on macro and micro levels. They address many spheres of society including: (1) the physical environment, (2) political/economic institutions, (3) health and medical care systems, (4) the social environment, (5) the fields of human biology, molecular medicine, and genetics, and (6) human behavior.

Macro-level efforts range from the international arena (e.g., drafting treaties about water safety), to the national level (e.g., policies about smoking and air pollution standards), and further to the local level (e.g., offering services of the city or county public health agency). They also include the private sector. Some of these activities address the training of medical personnel, the financing and delivery of medical care at private and public sites, the provision of health screening services, the development of active surveillance systems about disease threats, the provision of immunization programs, the offering of health education programs, and the scientific discovery of pathways to disease.

Micro-level health promotion involves individuals and small units. A single person’s actions to maintain a healthy body, forestall the development of disease, achieve a longer life, or reduce emotional stress are micro-level health-promoting activities. Also included in this category are behaviors of the patient–health provider dyad. Such behavior often pertains to establishing a set of health-promoting practices and complying with this plan.

In a narrower approach to health promotion, disease control is the focus. This has resulted in distinguishing health promotion activities according to their potential for primary, secondary, and

tertiary prevention of disease. The terms are used in relationship to the stage of a disease or condition; thus primary prevention includes the pre-disease phase and applies to the period prior to onset or diagnosis of a disease. In contrast, secondary and tertiary prevention occur after a disease has manifested itself. Efforts to detect the disease and keep it controlled, contained, and manageable are included (secondary prevention) as well as medical treatment activity addressed to preventing disability, improving life quality, and delaying death during the course of well-established disease.

Primary prevention can begin at any time during the life course. Directed toward individuals without disease manifestations, it seeks to help them maintain well-functioning, disease-free bodies. One of the oldest primary prevention practices is handwashing to prevent spread of communicable disease. One of the newest is testing women for the BRCA1 gene for breast cancer. If it is detected in an individual, she may be prescribed a drug that has been observed to have cancer-prevention potential. This type of primary prevention activity reflects cutting-edge medical technology from the fields of molecular medicine and genetic therapy. It is growing exponentially as a health promotion strategy. Indeed, \$25 million of macro-level prevention efforts were recently announced to prevent or curb the spread of infectious diseases by using state-of-the-art technology (*New York Times*, December 27, 1998).

Avoiding exposure to agents that cause disease, injury, or defects is clearly the focus of much of the primary prevention activity. Public health agencies achieve this by offering immunization programs to children and adults alike. Health policy and health law personnel propose laws to prohibit cigarette advertisements. Physicians offer general and condition-specific health education, such as teaching patients about the value of weight control. Laboratory personnel seek to develop new vaccines or analyze the genetic characteristics of bacteria linked to certain infectious diseases.

Personal behavior is often the target of primary prevention efforts. Individuals with a family history of heart disease may be advised about dietary change from fatty foods or the need to engage in exercise, stress reduction, smoking cessation, and/or weight reduction programs. Given

recent data, these activities appear to be quite important in preventing the development of a heart attack (myocardial infarction) and blockage of the coronary arteries. Even reducing one of the modifiable risk factors for heart disease (smoking, high blood pressure, obesity, physical deconditioning, high lipid count, impaired glucose tolerance) significantly reduces the risk of developing this disease (Herd et al. 1987; Kannel et al. 1987). Since more than half of the men and women over age 65 currently die of heart disease, such activity could have profound effects. Indeed, the development of a major heart condition may take fifty years, beginning in childhood with unhealthy food and exercise habits (Fries and Crapo 1986). Therefore, the individual is responsible for this type of primary prevention, which can actually begin with parental efforts to offer low-fat diets to their children. The idea is that the person would then carry on healthy living behavior throughout the life cycle.

The importance of personal behavior in health promotion and disease prevention was established in a recent effort to reconceptualize the causative factors for death (mortality). Previously, mortality data listed specific diseases as primary or secondary causes of death. The new approach designates specific health-risk behaviors (e.g., smoking and exercise behavior, food habits, alcohol use) as actual causes of death (McGinnis and Foege 1993). These behaviors accounted for half of all U.S. deaths in 1990. The three leading risk behaviors were tobacco use (400,000 deaths) and diet and activity patterns (300,000 deaths). By now considering this health-risk behavior to be the cause of death, the prevailing disease-centered approach is diminishing in importance. Reducing the prevalence of these behaviors is becoming a goal of interventive efforts and can facilitate the shift to primary prevention efforts.

Secondary prevention is undertaken after a disease has been detected. This may occur a half century after the causal agent or offending behavior initiated the disease process (Fries and Crapo 1986). For example, a heart attack at age 70 may have as its etiology poor dietary habits beginning at age 15, smoking behavior that started at 20, and at ages 30, 40, and 45, respectively, physical deconditioning, job stress, and the development of hypertension.

In contrast to primary prevention, secondary prevention involves control of a disease or condition. Aims are to ensure early detection, follow this with prompt and effective treatment, and educate the individual about risk-reduction behavior. Such efforts seek to halt, slow, or possibly reverse the progression of a condition and to prevent secondary effects or complications. Therefore, the heart patient would not only receive medication that might improve functional capacity of the heart but also receive referral to a smoking-cessation program.

Secondary prevention efforts are addressed to all acute and chronic conditions, but five chronic diseases account for most of the deaths, hospital care, and disability of the U.S. population. In order of prevalence they are arthritis, high blood pressure (hypertension), heart disease, chronic bronchitis, and diabetes. These chronic diseases are readily amenable to preventive action (Pope and Tarlov 1991). Physicians can treat these conditions medically, pharmaceutically, and surgically to prevent complications or arrest disease progression. The individuals suffering from these conditions can engage in a series of health behaviors and modify their lifestyles. For example, persons with diabetes can be asked to visit their doctor regularly, have frequent tests of blood and urine to detect disease progression, and visit specialists for control of diabetes complications involving eyes, kidneys, nervous system, skin, and so forth. Simultaneously, they can be taught to monitor and control their conditions, engage in dietary change, and actively pursue weight-control and exercise programs.

One of the most important tools for secondary prevention is health screening. This procedure seeks to detect disease, abnormal body states, and sensory loss. It comprises activities as diverse as mammography; Pap smears; and blood pressure, glaucoma, blood sugar, prostate specific antigen (PSA), and hearing tests. These secondary prevention services may be offered in physician's offices, at community sites (such as health fairs or churches on Sunday), or at work sites.

Secondary prevention procedures are immensely valuable, especially if they allow a disease to be detected in its early stages. Through early detection, medical and personal care can begin before the disease has progressed. Complications may be

avoided, dangerous clinical thresholds may be averted, and the downward trajectory to disability and death may be prevented. For example, mammography that detects a small breast tumor may be responsible for saving a woman's life, preventing disfigurement from mastectomy (seldom performed in the early stages of cancer), averting the need for chemotherapy and its severe side effects, and enabling the patient to have hope for complete remission. In contrast, if a tumor is detected by clinical breast examination by a physician or breast self-examination, it will be larger than one identified through mammography. A tiny tumor or precancerous breast tissue change will not be apparent, through clinical breast examination and the cancer detected may be larger or have metastasized.

Physicians and nurses are the predominant practitioners of secondary prevention. Physician assistants, pharmacists, nutritionists, health educators, and physical therapists are among others who form the secondary prevention medical team. Unfortunately, there is much less use of this health promotion strategy than is optimal, or even desirable. Studies have shown that fewer than half of all physicians indicated they schedule proctoscopic examinations and chest x-rays for asymptomatic patients with no personal history of cancer (American Cancer Society 1990). This study also showed that specialists in internal medicine offer their patients the most cancer screening relative to other medical specialties (Pap tests; mammograms; stool blood determinations; chest x-rays; and breast, digital rectal, and proctoscopic examination).

Tertiary prevention is the last type of disease-focused prevention. It seeks to provide good health care to persons with diseases that have progressed beyond their initial stages. Therefore, since it is too late to prevent illness or arrest its progression to a more serious phase, tertiary prevention includes medical and surgical interventions that can prevent functional decline, improve life quality, or delay death.

The U.S. medical care system has focused on tertiary prevention and uses an increasingly large medical and surgical armamentarium. Breakthrough technology is at the basis of these efforts. It features replacement of organs with mechanical, animal, or other human parts; using genetically engineered products to alter disease agents; and cloning

or otherwise duplicating disease-free cells to replace unhealthy tissue. These efforts are unprecedented and unique to the U.S. health care system. No other nation offers a comparable level of advanced medical care. Unfortunately, these tertiary prevention services have made our health care system the most costly in the world on a per capita basis but have not improved our life expectancy to the level of most of the industrialized world. In 1994 life expectancy at birth in the United States was 75.9 years, compared with 80.1 years in Hong Kong, 79.3 in Japan, 78.2 in France, and 78.1 in our neighbor, Canada (U.S. Bureau of Census 1994). Men, in particular, have failed to experience major gains in life expectancy. Women of all racial groups have outlived men since 1900, and white females currently have a seven-year advantage in length of life (U.S. Bureaus of Census 1994).

The fact that the gender gap in survival is occurring simultaneously with a major decline in mortality from conditions such as heart disease may speak to the limitations of tertiary prevention. Some attribute lower mortality from heart disease to procedures such as replacing valves and arteries, heart transplantation, removing blockages in coronary arteries and introducing stents, or offering pharmacological treatment in the form of clot-reducing drugs. Yet others suggest that medical measures have been less effective than those that involve change in health-risk behavior. It is proposed that the reduction in heart disease mortality has been achieved mainly through primary and secondary prevention practices. Since males are less likely to have good dietary practices, and more likely to ingest foods that contribute to artery blockages, use tobacco and have poor exercise habits, this may be affecting their mortality rates. Men may not be living as long as women because they fail to engage in health-promoting behavior, relying instead on medical treatment for an existing condition.

Tertiary prevention is clearly important. The vast majority of individuals suffering from cancer, severely debilitating disease, or life-threatening heart problems seek, or await the development of, advanced medical care. Medical journal articles about life-saving, and sometimes life-enhancing, treatments, are reported regularly on evening news programs. Only a small number of people refuse

to have organ transplants or kidney dialysis, and many wait for new AIDS or cancer drugs to be offered for clinical trials. Canadian citizens routinely cross the U.S. border to avail themselves of medical, surgical, and technological procedures that are unavailable in their country or subject to waiting lists.

As stated in a classic medical sociology article, medical care in this country has not been responsible for a decline in mortality rates; rather, the primary causes of the reduction are public health measures that lessen the risk of acquiring disease (McKinlay and McKinlay 1977). We need to refocus our efforts toward heavier emphasis on primary and secondary prevention, and reduce our reliance on costly and technology-heavy tertiary interventions.

THE ROLE OF THE INDIVIDUAL IN HEALTH PROMOTION

As presented above, the responsibility for health promotion rests with several agents; the national and international health care systems, health law and health policy experts, public and private health facilities, health professionals, and individuals. However, the individual is often the center of attention as the burden of health promotion is shifted to the person.

This approach rests on the premise that a person's actions account for whether he or she remains healthy and does not experience progression of or complications from disease. The corollary to this is that persons who fail to exert control over health behaviors are contributing to disease, disability, and death. Movements to empower people and help them take charge of their medical conditions reflect this emphasis on the person's responsibility for health.

Indicative of this trend is that patient noncompliance with the medical regimen is considered to be a cause of medical treatment failure. Clearly, many people fail to adhere to the treatment plan prescribed by their physician. They may fail to have their prescriptions filled, take the amount of medication prescribed, keep medical follow-up appointments, or adhere to a dietary program necessary for a controlling a condition. Only 57

percent of persons with elevated cholesterol levels actually visited a physician after being notified of their state. Gender is an important part of compliance. Women visit physicians more than men, especially for preventive care (Verbrugge 1990). They also act as gatekeepers to the medical system for children and husbands, offering suggestions and advice, and sometimes making medical appointments without the consent of the latter.

This line of reasoning—patients are largely responsible for poor health outcomes because they do not follow the doctor's advice—ignores the fact that health professionals may create situations that foster noncompliance. Presenting an ultimatum about smoking cessation to heart patients, informing people with diabetes they must avoid sugar for the rest of their lives, or telling people diagnosed with hypertension they must fill a costly prescription for a condition that does not cause them physical distress seldom results in compliance. People do not like to be given lists of do's and don'ts. If reasons for the recommended procedures, medications, or behavioral changes are not given, compliance may fail to materialize. Asymmetric models of the patient-physician encounter (Bloom 1974) pose physician authority on the one hand and childlike response on the other. These models have lost their impact, especially among educated middle-class patients, and compliant behavior as an automatic response by the patient is becoming much less widespread.

Another reason that health promotion should not be considered the sole responsibility of the individual is that knowledge is the foundation for action. However, individuals may have little knowledge of appropriate health-promoting behavior. They are consumers of health information. As such, they must either depend on others for information or take the initiative for self study. While knowledgeable, enlightened patients can certainly help to control and/or contain their medical problems, only medically trained persons familiar with that patient's health problems can offer appropriate recommendations! To illustrate, the heart patient's physician is responsible for educating the patient about specific exercises to reduce the risk of a second heart attack because it is the physician who is intricately familiar with the functional and/or anatomical state of that person's heart. Physicians

must educate their patients and, in doing so, carefully explain the regimen. It is only when patients receive adequate information and careful explanation about a particular regimen that they can be held accountable.

BARRIERS TO HEALTH PROMOTION

Reducing barriers to health service use helps considerably to promote health and reduce disease prevalence (Orlandi 1987). Analysis of the major barriers to health service utilization shows that they are both societal and individual. Societal impediments are known as structural barriers and refer to variables that originate in the economic, political, and medical organizational spheres of society. Individual, or personal, barriers refer to behavioral variables that seek to avoid, delay, or underutilize health care.

Structural barriers limit access to health promotion programs, as they do to medical service utilization. They can act at several levels. At the economic and health insurance level, absence of such resources make it unlikely that patients will receive some recommended screening or early detection tests. Even for those persons with health insurance coverage, policies may not cover the recommended tests. Constraints on health promotion services are also due to policies or factors that reflect how health care services are organized. To illustrate, political decisions that reduce the availability of public transportation in turn reduce access to sites offering health promotion services. Another example would be health policies that encourage medical sites with state-of-the-art equipment to proliferate in suburban areas. If the newest mammography equipment is available only to women in affluent areas, while inner-city sites have machines that may be old and of poor quality, clearly mammography screening will be less likely in these latter areas.

Personal barriers to health promotion activity include several factors that relate to an individual's perceptions, beliefs about cause and cure, and/or attitudes toward use of formal health care services. These barriers influence whether people will seek health care, follow the advice of medical professionals, and comply with a health promotion regimen and are reflected in the health belief model

(Rosenstock 1974). This model of health services utilization proposes that people seek medical services according to: (1) perception of the threat posed by a health problem, and beliefs about their susceptibility to it (e.g., "heart attacks are serious but no one in my family died of heart disease"); (2) the possible inconvenience of the health-related activity versus potential rewards ("I can't manage without a morning cigarette, and besides my heart can't be in such bad shape since I only smoke half a pack a day"); and (3) response cues ("Did you have your annual prostate cancer checkup?").

Cultural factors affect the likelihood that persons will engage in recommended health promotion activity. Beliefs and practices handed down through the generations prescribe alternative health behaviors and nutrition habits. Some are harmless, others may be beneficial (chicken soup for colds, for example), and still others may exacerbate illness or even cause death (refusing blood transfusions on religious grounds). Beliefs also affect primary prevention; for example, some cultural traditions associate obesity with beauty or strength, not risk for chronic disease.

Denial is a particularly important personal barrier that can be added to this model, since denial of illness is directly related to avoidance of medical care. Many women fail to have a mammogram or delay the procedure because they seek to deny the possible threat of cancer. Some of these women have intense fear of the disease, others believe it is incurable, still others fear the surgical or chemotherapeutic treatment involved (Young 1998). In either case, they avoid thinking about it and feel they are better off not knowing whether they have a breast tumor. Delay in scheduling mammograms is a current interest of people seeking to improve rates of mammography compliance (Rimer et al. 1996).

Belief in one's own ability to control one's life also relates to health promotion. Health locus of control measures indicate whether individuals are internally controlled or whether they believe control is due to chance or the actions of powerful others (Wallston et al. 1978). Thus, individuals with internal health locus of control are the best candidates for health promotion programs because they believe in exerting control over their health status. They represent, on a conceptual level, the action stage of Prochaska and DiClemente's

(1984) transtheoretical model of health behavior. Using this same framework, persons who are not engaging in risk-reduction behavior might be considered to be in precontemplation or contemplation stages and may never move to action.

HEALTH PROMOTION FOR OLDER PEOPLE

Health promotion and disease prevention programs generally target working-age people rather than older adults (Young 1994). This is quite unfortunate, since approximately 85 percent of people aged 65 and over suffer from chronic disease and the three most prevalent conditions are arthritis, high blood pressure, and heart disease (National Center for Health Statistics 1996). When considered simultaneously with the three leading causes of death in this population (heart disease, cancer, and stroke), the need for preventive care is quite apparent. These five conditions are largely amenable to risk-factor reduction practices. Indeed, readily available and well-known health promotion and disease prevention practices can alter the course of most, if not all, chronic and killer diseases of older people. There is great potential for improving the health of older adults by including them in health promotion programs (Pope and Tarlov 1991).

Health promotion efforts for older people should certainly involve risk-reduction behavior. As they are taught about behavioral and lifestyle changes, these efforts can result in a sharp drop in the medical consequences of chronic disease. Heart disease provides an important example. Rates of coronary heart disease are at least ten times as high in persons aged 65 and over as among their counterparts under age 45. Women as well as men show a dramatic rise in heart disease rates after they reach age 65. It has clearly been shown that much heart disease can be prevented by diet, exercise, smoking cessation, and similar healthy living practices. Furthermore, some of these same practices can reduce the likelihood of death, development of secondary complications of heart disease, and occurrence of a second heart attack (Kannel et al. 1987). Such behavioral change also brings psychological and social benefits to heart patients and results in gains in several areas of their lives. Yet

older people recovering from heart attacks have been found to be significantly less likely to receive preventive behavior advice than their younger counterparts (Young et al. 1987). Particularly absent for persons aged 60 and over is advice to cease smoking and enroll in a cardiac rehabilitation exercise program. The question then emerges, "How can older people engage in health-promoting behavior that may prevent another heart attack, if not given the proper information from their physicians?"

Another way health promotion can be achieved is through following recommendations of major authorities for periodic administration of specific tests, examinations, and immunizations. The guidelines for adult preventive care offered by the U.S. Preventive Service Task Force (1989) include specific age-related tests. The set of recommendations for people aged 65 and over includes annual influenza shots; breast, thyroid, mouth, skin, ovarian, testicular, lymph node, rectal, and prostate cancer examinations; and dental examinations. Tests to determine blood pressure and visual ability should be conducted every two years. There are also recommendations for periodic tests of urine, hearing, estrogen levels in women, and cholesterol. Of course all of these recommendations apply to persons without specific health problems (those who are asymptomatic and of normal risk). Cholesterol and blood pressure tests for older people with heart disease would need to be performed frequently.

Thus, health promotion for older people can be achieved if (1) physicians conduct specific examinations and tests at defined periods of time and (2) if older people engage in risk-reduction behavior. For either to be successful, the older person must follow a recommended plan for medical visits and for individual behavior. This plan must be carefully explained to the older patient. However, studies show that patient-physician interaction in later life is poor (Coe 1987), and physicians may communicate poorly with their older patients and fail to offer a recommended illness-management plan (Young et al. 1987). Clearly, if older people are to change poor dietary habits, they must first be informed about good food choices. Since this information is condition-specific, it needs to be provided by the physicians

who treat the individuals or their medical agents, such as nurses or physician assistants.

Older individuals also bear responsibility for behavioral change. They must be willing to engage in health behaviors that prevent illness or modify high-risk profiles. Even when these behaviors represent change in lifelong habits, they must be willing to pursue them. However, for effective risk-reduction practices to be targeted to older people, patient-physician partnerships must be formed (Hess 1991). Including the older patient in the health promotion program is essential.

HEALTH PROMOTION FOR MINORITIES

Significant advances in understanding, managing, and treating chronic disease have failed to eliminate the excess death and disability found in older minorities. African Americans, for example, have a five-year deficit in life expectancy (U.S. Bureau of the Census 1994). They have higher mortality rates for cancer and heart disease (Polednak 1989) and twice the risk of severe complications from diabetes, such as blindness, neurological decline, and illnesses that require dialysis or amputation (Lieberman 1988). Other ethnic minorities such as Hispanic Americans, Native Americans, and some Asian Americans also have a major gap in mortality and morbidity, compared with whites; death rates for heart disease and stroke, two leading causes of death, are twice as high for older minorities as for whites (Polednak 1989). Indeed, the health gap of minorities in the United States is wide and shows no signs of being bridged.

This bleak prognosis is certainly a call for massive efforts at treatment, on the one hand, and extensive health promotion efforts, on the other. Yet despite the fact that health needs vary across populations, health promotion efforts have usually been generic (Young and Olson 1993). Often they focus on the needs of white, middle-class adults (Gottlieb and Green 1987).

Programs to target ethnic minorities must be culturally sensitive; they must also be specific to a particular population (Tseng and Ellyne 1990). One-size-fits-all programs will not fit ethnic minorities as a whole, or individual ethnic groups. The cultural background of the particular target

population must be taken into account, along with educational level, health beliefs, and attitudes toward health providers (Young and Olson 1993).

The need to modify generic health promotion program for minority groups is increasingly recognized. Without targeted programs, it is doubtful that health promotion efforts can achieve high success. Knowledge about and appreciation of specific cultural norms, values, and beliefs should be a major component of health promotion programs for minorities (Leavitt 1990).

An example of a health promotion program that targeted a particular ethnic minority was conducted among African Americans with coexistent diabetes and hypertension (Waller et al. 1994). Sixty subjects were randomly assigned to an educational/self-care intervention group or an observation group. The former were instructed by a health educator, using culturally relevant materials. Diet and food preparation information were specific to the food habits of lower-income African Americans and focused on culturally acceptable food and cooking changes. Materials prepared reflected the average educational level of the target population. After one year, high-risk behavior among the intervention group was significantly less than among the observational group. Risk for complications of diabetes, heart disease, and stroke all declined. Furthermore, the diseases were considered to be controlled.

The determinants of success of health promotion programs are clearly their effect on (1) health-risk behavior and (2) medical outcome (control over the condition, laboratory test values within acceptable ranges, etc.). Programs that can change behavior and also effect better outcome for ethnic minorities cannot be generic. They must be culturally sensitive and appropriate to the population they seek to serve. Otherwise, there will be little effect on the mortality and morbidity status of the minority group.

HEALTH STATUS ASSESSMENT

Health promotion goals are often measured in terms of reduction in the prevalence of specific diseases or decline in death rates for a particular condition. The sciences of epidemiology and

biostatistics and the field of medical sociology propose several ways to determine health status. They use measurements and statistics for populations, subgroups, and individual cases.

Health status data are collected by epidemiologists, agencies, and medical professionals. Among multiple strategies used are disease surveillance, population surveys, and conducting probability and nonprobability studies of the health of subpopulations (Friedman 1988). Surveys that assess health-risk behavior (e.g., Behavioral Risk Factor Surveys from the Centers for Disease Control and Prevention) are well accepted means of collecting health status data.

Measurements often used to assess health status include rates, ratios, counts, proportions, distributions, ranges, and quantiles. These measurements may indicate prevalence of a particular disease (number of persons with the disease in proportion to the total number in the group); incidence (number of new cases in a given period); or number of persons of a particular age, gender, or ethnic group with the disease. They can also indicate ranking systems and represent change over time in disease or death rates.

Rates are often calculated as the number of cases per 1,000, 10,000, or 100,000 persons. They are also standardized to take factors such as age into consideration. Therefore, since age increases risk of lung cancer, epidemiologists can eliminate this potential bias by using appropriate statistical techniques. They may use age adjustment or age standardization procedures to calculate the expected rate of lung cancer (Friedman 1988). This enables them to assume nonsmokers are the same age composition as smokers.

After rate comparisons are made, the relative and attributable risks of a disease can be determined. In these calculations, biostatisticians evaluate prevalence or incidence of a disease in a particular population and may then compare risks of two different populations. Other analyses may be of change in risk over time, or the lifetime risk of acquiring a disease such as cancer.

A frequently encountered health indicator is the proportion of cases that fall into a particular quantile. This generic term refers to several tiers,

each representing a proportion of the population. To illustrate, people may be categorized into four quartiles, representing cholesterol levels. Each 25 percent segment of the population may then be compared. In these analyses, the association of an outcome variable, such as a second heart attack, with membership in a high-cholesterol-level group (quartile 1, for example) is clearly shown.

From a public health perspective, important indicators of health status are infant mortality and life expectancy rates. Low infant mortality and high life expectancy are considered to represent good health in a society. The premise is that societies that can reduce unnecessary maternal and child deaths and increase the average life expectancy at birth have established good medical care procedures and may have health practices that reduce the burden of illness and premature death.

In the United States, infant mortality rates have declined over the past century. In 1991 the overall infant death rate in the United States was 8.9/1,000 births (National Center for Health Statistics 1996). This represented a decline from 20/1,000 in 1970. Among certain subpopulations infant mortality was much higher than for the population at large. Blacks, for example, had infant death rates of 17.6, versus 7.3 for whites.

Life expectancy at birth is approximately 76 years in the United States. However, it is close to 80 years for white women and 73 years for white men. These figures represent a rise in life expectancy for men and women alike, and although there is a major racial gap, nonwhites have also shown an increase over the past 90 years.

In comparison with industrialized countries that offer all or most of their citizens publicly funded health care, U.S. men and women show up to a four-year gap in life expectancy (U.S. Bureau of Census 1994). U.S. infants are also more likely to die than those in several industrialized nations.

Sociologists use a different approach to assess health status than epidemiologists or biostatisticians. They measure functional ability, perceived health status, emotional and psychological health, and quality of life, to name a few. Medical measures are used infrequently, and statistics are seldom expressed in rates. Rather, sociologists assess health

status by tabulating scale scores of health-specific indices and/or calculating frequency distributions of individual health status questions. In the case of the latter, the investigator might determine presence/absence of a specific health problem (e.g., Do you have arthritis?) and measure central tendencies and variance in the data.

Functional ability is considered to an important indicator of health status in a sociological context. While the level of functioning can be measured as physical, mental, or social impairment, most of the interest is in physical functioning. This approach conceptualizes functional ability as ability to conduct activities of daily living (ADLs) or instrumental activities of daily living (IADLs) without assistance from others. Instruments used include measures suitable for older people (e.g., the OARS instrument of Duke University 1978), disease-specific measures (e.g., the arthritis functioning measure of Patrick and Deyo 1989), and instruments that assess cognitive functioning as a component of physical functioning (e.g., Keller et al. 1993).

The individual's perception of his or her health is often measured. In these investigations, the concern is with how the person assesses general health status at the present time or in reference to other people and other times. Thus, they may be asked "Is your health generally excellent, good, fair, poor, bad?" or "How does your health compare with that of people your own age?" or "Is your health better or worse than one year ago?" They may also be asked about perceived functional ability (Duke University 1978; Lawton et al. 1982).

Emotional and psychological health are also measured. Well-validated instruments such as the CES-D of the Center for Epidemiological Studies or the Zung Depression Measure are used for depression (DeForge and Sobal 1988). Investigators also seek to determine mood (Profile of Mood States of McNair et al. 1971), positive and negative affect (Bradburn 1969), morale (Lawton et al. 1982), and subjective well-being (Dupuy 1984).

Quality of life indicators are among the least well validated instruments used to assess health status. There are many different approaches to quality of life that represent medical, psychological, and social models of illness. Since sociologists

prefer a multidimensional view, Levine and Croog (1984) presented five components of quality of life: social-role performance, physiologic state, emotional state, intellectual function, and general satisfaction or feeling of well-being. Also considered to measure quality of life are some subscales of the Sickness Impact Profile (Bergner 1984). The full 134-item instrument assesses physical, social, psychological, and interactional aspects of illness, but some scales are specific to pain or impairment level and tend to reflect a medical, rather than psychosocial, view of quality of life. Indeed, the medical approach may concentrate exclusively on disease-specific or treatment-specific variables. It may measure, for example inability to eat or excessive fatigue among cancer patients undergoing chemotherapy, or frequency of urination among individuals with hypertension who are prescribed medications to expel fluids from the body. Still other medically focused approaches to quality of life may focus on the experience of pain, as in the previously mentioned Sickness Impact Profile.

Health status assessment is clearly a broad field. It includes measurement of disease patterns in a population, self-reports by individuals of generalized health status, and middle-level health measurements. These latter measurements are neither macro level, like population-based mortality and morbidity statistics, nor micro level, like individual reports. Rather, they include validated scales, indices, or series of questions that may be widely used among general or specific populations. Many, if not most, measures have been found to be reliable and valid indicators of health status. The medical sociologist or related researcher thus has a wide range of instruments to assess health status.

CONCLUSION

Health promotion includes a wide-ranging set of activities that (1) enhance health status, (2) prevent disease, (3) seek to control the spread of chronic or infectious disease, and (4) attempt to arrest or delay deterioration that occurs as the result of these conditions. Health-promoting activities occur at the societal and individual levels and include a long list of agents. Essentially, health promotion represents the principle that maintaining health, preventing disease, and avoiding decline or complications of progressive illness are all

achievable goals. For any society to have a healthy, vital citizenry, it must reduce the financial, social, and medical burdens of illness. All these are accomplished with health-promoting practices.

HIERARCHICAL LINEAR MODELS

Hierarchical linear models are applicable in situations where data have been collected from two (or more) different levels. Sociology's initial interest in such multilevel relationships can be traced back to Durkheim's research into the impact of community on suicide (Durkheim [1898] 1951). More recently, these models have been related to the topic of contextual analysis (Boyd and Iversen 1979), where researchers are interested in investigating linkages between micro-level and macro-level variables. Sociological theories have been classified into three groups according to the degree to which they incorporate multilevel variables (Coleman 1986). In one group, variation in a dependent variable is explained through independent variables obtained from the same social level (e.g., country, community, individual). In a second group, attempts are made to account for differences in a dependent variable at one level by examining variation in an independent variable at a higher level; and in a third group, variations in a dependent variable are explained by variations in an independent variable at a lower level. Theories

that fall into either the second or third group are multilevel theories and can be explored using hierarchical linear models.

SPECIFICATION OF THE HIERARCHICAL LINEAR MODEL

A wide variety of hierarchical models can be specified. However, in order to outline the basic features of such models, a simple example will be developed. Assume that a researcher is interested in modeling the length of hospital stay (LOS) for a specific individual (Y_i) as a function of the severity of that individual's illness (X_i) and the bed occupancy rate for the institution in which that individual is hospitalized (G_j). In this hypothetical model we have one criterion (or dependent) variable, Y_i , at the micro level, one micro-level predictor (or independent) variable, X_i , and one macro predictor (or independent) variable, G_j . This produces a two-level hierarchical model. The technique is quite flexible and can be expanded to include multiple predictor variables at either (or both) the micro- and macro-levels and additional levels. In the given example, an index of individual comorbidity could be included as an additional micro-level predictor, type of hospital (e.g., public vs. private) could be included as an additional macro-level predictor, and an additional level of the gross national product (GNP) of the country in which the hospital is located could be added to create a three-level model.

The first step in developing hierarchical models is to specify a model for the micro-level variables that is identical for all contexts. In the present example a linear model relating LOS as a function of severity of illness is specified for each of the hospitals.

$$Y_{ij} = \beta_{0j} + \beta_{1j}X_{1ij} + \varepsilon_{ij} \tag{1}$$

Where $j=1, 2, \dots, j$ denotes the macro-level contexts (e.g., the hospitals) and $i=1, 2, \dots, n_j$ denotes micro-level observations within contexts (e.g., individuals within hospitals). The intercepts from Equation 1 (β_{0j}) provide estimates of the expected LOS for individual i in hospital j whose severity of illness is zero, whereas the slopes (β_{1j}) provide estimates for the effect of a unit change in the severity of the illness for individual i in hospital

j . Finally, the β_{ij} 's represent random errors or residuals. It is assumed that these errors are normally distributed within each context with a mean of zero and a constant variance σ^2 . This is a standard linear model with the exception that the coefficients (i.e., the β_j 's) are allowed to vary across contexts (hospitals).

In situations where separate regression equations are estimated for various contexts, four different patterns can emerge. These patterns are depicted in Figures 1a, 1b, 1c, and 1d. In Figure 1a, the functional relationship between the micro-level variables is identical for all the contexts, and thus the intercepts and slopes are the same for all contexts. In Figure 1b, the degree of linear relationship between the micro-level variables is equivalent across contexts; however, the initial "location" (i.e., the intercept) of this relationship varies across contexts. In Figure 1c, the degree of linear relationship between the micro-level variables varies as a function of context, although the initial "location" is consistent across contexts. Finally, in Figure 1d, both the initial location and the relationship between the micro-level variables vary significantly across contexts.

Systematic differences across contexts are reflected in three of the figures (viz., Figures 1b, 1c, and 1d). The presence of these differences leads to questions of whether there are contextual or macro-level variables that could be associated with the varying micro-level coefficients (i.e., the slopes and/or intercepts). Questions of this type are addressed by specifying a second-level model. For example, if there is significant variation among the micro-level coefficients, then this variation could be modeled as a function of contextual or macro-level variables as follows:

$$\beta_{0j} = \gamma_{00} + \gamma_{01}G_j + U_{0j} \tag{2}$$

$$\beta_{1j} = \gamma_{10} + \gamma_{11}G_j + U_{1j} \tag{3}$$

where G_j is a contextual (or macro-level) variable, γ_{00} and γ_{10} are the intercepts from the second-level models, γ_{01} and γ_{11} are the slopes from the second-level model, and U_{0j} and U_{1j} are the second-level residuals. It is assumed that the residuals are distributed multivariate normal with mean vector $\mathbf{0}$ and variance-covariance matrix \mathbf{T} . In the present example, Equation 2 would be used to model differences across hospitals among the intercepts

of the micro-level equations (cf. Figures 1b and 1d), whereas Equation 3 would be used to model differences across hospitals in the slopes of the micro-level equations (cf. Figures 1c and 1d).

Depending on the actual variability of the micro-level coefficients (i.e., the β_j 's), different second-level models would be justified. For example, in situations where there is no variation in the slopes across contexts (see Figure 1b), the inclusion of G_j in Equation 3 would not be meaningful given that β_{1j} is the same across all contexts. Similarly, in situations where there is no variation in the intercepts across contexts (see Figure 1c), the inclusion of G_j in Equation 2 would not be meaningful given that β_{0j} is the same across all contexts.

By substituting Equations 2 and 3 into Equation 1, we can obtain a single equation form of the hierarchical model as follows:

$$Y_{ij} = \gamma_{00} + \gamma_{01} G_j + \gamma_{10} X_{1ij} + \gamma_{11} G_j X_{1ij} + (U_{0j} + U_{1j} X_{1ij} + \varepsilon_{ij}) \tag{4}$$

The model represented by Equation 4 is a mixed model with both fixed coefficients (viz., the γ 's) and random coefficients (viz., the U 's and the ε 's). Further, since the random coefficients are allowed to covary across contexts, it can be called a variance component model.

The approach to investigating relationships occurring across hierarchical levels represented by the equations above is not new. Burstein and colleagues (1978) discussed a similar approach under the conceptualization of "slopes as outcomes." Conceptually, this is an accurate description, given that the regression coefficients estimated within each context at the micro level are used

as criterion (or dependent) measures in the macro-level (or second-level) model (cf. Equations 2 and 3). However, while this conceptualization of the relationship between micro- and macro-level variables has been understood for a number of years, concerns about the adequacy of estimating such models using traditional statistical techniques (viz., ordinary least squares, OLS) have been expressed. However, separate statistical advances throughout the 1980s improved the estimation procedures for these models (for reviews see Burstein and colleagues 1989; Raudenbush 1988), with the advances resulting in several different software packages being developed specifically for the estimation of hierarchical linear models (e.g., GENMOD, HLM, ML3, and VARCL).

ESTIMATION OF HIERARCHICAL LINEAR MODELS

In estimating the various components of the hierarchical linear model, a distinction is made among fixed effects, random effects, and variance components. Specifically, fixed effects are those parameter estimates that are assumed to be constant across contexts (e.g., the γ 's from Equations 2 and 3), whereas random effects are parameter estimates that are free to vary across contexts (e.g., β_{0j} and β_{1j} from Equation 1). Hierarchical linear models also allow for the estimation of the variance components of the model. These include (1) the variance of the residuals from the micro-level model (i.e., the variance of the ϵ_{ij} 's identified as σ^2 above); (2) the variance of the second-level residuals (i.e., U_{0j} and U_{1j}); and (3) the covariance of the second-level residuals (i.e., the covariance of U_{0j} and U_{1j}). The variance-covariance matrix of the second-level residuals was previously defined as \mathbf{T} .

Estimation of Fixed Effects. One approach that could be used to estimate the γ 's from Equations 2 and 3 is traditional OLS regression. However, because the precision of estimation of these parameters will vary as a function of contexts, the usual OLS assumption of equal error variances (i.e., homoscedasticity) will be violated. In order to deal with this violation the second-level regression coefficients (the γ 's) are estimated using a more sophisticated procedure, generalized least squares (GLS). GLS techniques provide weighted estimates

of the second-level regression coefficients such that the contexts that have more precise estimation of the micro-level parameters receive more weight in the estimation. That is, those contexts in which there is greater precision in estimating the parameters (the slopes and the intercepts) receive more weight in estimating the second-level regressions.

Estimation of Variance-Covariance Components. The components of the variance-covariance matrix \mathbf{T} include the variance of the micro-level residuals, and the variance and covariance of the second-level residuals. These components are used in the GLS estimation of the fixed effects of the second-level model. However, the values of the components of this matrix are typically not known and must be estimated. The best methods for doing this are iterative methods that alternatively estimate the parameters of the models and then estimate the variance-covariance matrix \mathbf{T} until a convergence is reached. Hierarchical linear models adopt the EM algorithm (Dempster et al. 1977) that produces maximum likelihood estimates for the variance-covariance components of \mathbf{T} .

Estimation of Random Effects. The simplest way of estimating the coefficients for the micro-level model (i.e., Equation 1) is to compute an OLS regression for a specific context. In the present example, this would involve obtaining a regression equation relating expected LOS to severity of illness for all individuals within a specific hospital. If there are reasonably large sample sizes within each context, this analysis would provide relatively precise estimates of the coefficients of interest. These estimates will not be stable, however, if sample sizes are smaller. Further, inspection of the second-level models reveals that there is a second estimate of the coefficients from the micro-level models. Thus, for any particular observational unit there are two separate estimates of the micro-level regression coefficients: one from the micro-level regressions themselves and the other from the second-level regression model. The question that this leaves is which of these provides a more accurate estimate of the population parameters for the particular observational unit.

Rather than forcing a choice between one of these two estimates, hierarchical linear models use empirical Bayes estimation procedures (Morris

1983) to compute an optimally weighted combination of the two estimates. The empirical Bayes estimates are a weighted composite of the two estimates discussed above. The micro-level regression coefficients (the β_j 's) estimated by OLS are weighted according to the precision with which they are estimated (i.e., their reliability). In cases where the OLS estimates are not very reliable (e.g., due to small sample size), the empirical Bayes procedure allots greater weight to the second-level estimates. Essentially, then, the weighted composite "shrinks" the micro-level estimate toward the second-level estimate, with the level of shrinkage being determined by the reliability of the micro-level estimate. It has been demonstrated that, in general, the empirical Bayes estimates have smaller mean squared errors than OLS estimates.

Statistical Tests. A variety of statistical tests for hypothesis testing are provided by the various computer programs used to estimate hierarchical linear model. For example, HLM (Bryk et al. 1994) computes a *t*-test to evaluate the hypothesis that the second-level regression parameters depart significantly from zero. In addition, chi-square tests are provided for tests of whether or not there is significant variation in the second-level residuals. These latter tests allow the researcher to determine the model that best fits the observed data. For example, it might be that there is no significant variation in the slopes across contexts; however, there might be significant variation in the intercepts (as in Figure 1b).

FURTHER ISSUES WITH HIERARCHICAL LINEAR MODELS

Centering. Often, as in the present example, interpretation of the intercepts is not straightforward, since a value of zero for the independent variable (in the present case, severity of illness) is not meaningful. In situations like this, it is possible to "center" the independent variable as a deviation from the mean level of that variable in the sample as follows.

$$Y_{ij} = \beta_{0j} + \beta_{1j}(X_{1ij} - \bar{X}_{1j}) + \varepsilon_{ij} \quad (5)$$

With this specification, the intercepts now represent estimates of the expected length of stay for individuals in a specific hospital whose severity of

illness is at the mean. The interpretation of the other parameters remain unaltered.

Longitudinal Data. Hierarchical linear models can also be used to analyze longitudinal data collected in order to examine questions regarding the assessment of change (Bryk and Raudenbush 1987). Under this approach, there are repeated observations within an observational unit and there is a sample of different units. This allows for a two-level conceptualization of development such that change in the individual units is modeled as a function of time and differences in the patterns of change across individual units can be modeled as a function of measurable characteristics of the individual units. Under this conceptualization, interest is in between-individual (unit) differences in within-individual (unit) change.

Statistical Software. As previously noted, a number of different software programs have been specifically developed in order to estimate hierarchical linear models. Kreft and colleagues (1994) reviewed five of the then-available packages. While they recommended ML3 (Prosser et al. 1991) for the "serious" user, they concluded that HLM's main advantage is its ease of use. Since that time, both programs have been updated and now versions for Windows '95 are available (viz., HLM 4 and MlwiN. Information on the latest version of these programs is available from the following Web sites: go to <http://www.ssicentral.com/hlm/mainhlm.htm> for information on HLM 4; go to <http://www.ioe.ac.uk/mlwin> for information on MlwiN.).

CONCLUSION

Hierarchical linear models provide statistically sophisticated ways for dealing with analyses in which data are obtained from multiple levels. Such data are common in sociological research, especially if the investigation deals with contextual effects or longitudinal designs. For more detailed discussions of hierarchical linear models, the interested reader is directed to the following sources that provide more in-depth coverage: Bryk and Raudenbush (1992); Goldstein (1995); or Hox (1995). (At the time of publication, a complete, online version of this text was available from: <http://ioe.ac.uk/multilevel.what-new.html>.)

HIGHER EDUCATION

Colleges and universities seem to defy the maxim that only highly rationalized institutions can succeed in the modern world. Only the Catholic Church has a longer continuous existence among Western institutions. Higher education has done more than survive; it is in many ways a pivot of key developments in the social structure and culture. It is central for the generation of research and technological innovations. It is also central in the selection, training, and credentialing of young men and women for higher-level positions in the occupational structure.

Among the most important sociological questions surrounding higher education are the following: (1) To what extent have advanced industrial societies become based on a "knowledge economy" closely related to university research and training? Related to this question is another: To what extent do we see the rise of a "new class" of "knowledge workers" with advanced training—differing in interest and outlook from both business elites and earlier aristocracies of labor? (2) To what extent do institutions of higher education reproduce social inequalities by certifying the cultural advantages of children from the upper classes, or reshuffle the social hierarchy by rewarding intellect and ability independent of students' social-class background? (3) Do institutions of higher education, with their traditions of collegial control and tenure, represent an alternative model to corporate forms of organization? These issues can be addressed only after examining the historical development, the existing organizational structures, and the contemporary pressures on higher education.

First, it is necessary to define the dimensions of higher education. Formal educational systems are conventionally divided between primary (the first six years), secondary (the next four to six years), and postsecondary education. Some postsecondary schools offer courses of study that are narrowly vocational and very short in duration. These institutions (including secretarial, business, and vocational-technical colleges) are not usually considered to be part of higher education. Institutions must award degrees that are recognized by baccalaureate-granting colleges and universities to be considered part of higher education. By this criterion, community colleges in the United States,

Fachhochschulen in Germany, and the “further education” colleges in the United Kingdom represent bottom tiers of their respective national higher education systems. These are all short-cycle, vocationally oriented institutions, but some of their degrees are transferable to higher-level colleges and universities. Above these lower-tier institutions are a vast array of colleges, universities, and specialized institutions (for example, seminaries and art schools) that constitute the core of the higher education sector in all contemporary societies. Levels in this institutional hierarchy are structured, most fundamentally, by the type of credentials offered. In the United States, for example, levels are marked by movement from the associate to the baccalaureate to the master’s to the doctoral degree.

HISTORICAL DEVELOPMENT

The distant relatives of today’s institutions of higher education go back in the West to the Greek academies of the fourth and fifth centuries B.C.E. In these academies, young men from the governing classes studied rhetoric and philosophy (and lesser subjects) as training for public life (Marrou [1948] 1982). In the East, the roots of higher education go back to the training of future government bureaucrats at the feet of masters of Confucian philosophy, poetry, and calligraphy. In both East and West, a close relationship existed among social class, high culture, and preparation for public life.

However, modern institutions of higher education trace a more direct lineage from the medieval *studium generale*. In the first European universities of the twelfth and early thirteenth centuries (notably Salerno, Bologna, and Paris), students and masters came together to pore over the new knowledge discovered in ancient texts and developed by the Arab scholars of Spain. These gatherings of students and teachers were a product of the revival of scholarly inquiry in what has been called the “twelfth-century Renaissance.” The medieval universities were similar to modern higher education in that they were permanent institutions of learning with at least a rudimentary formal organization. Courses of study were formally organized, lectures and examinations were given at scheduled times, administrative officials presided, graduation ceremonies were held, and students lived in

lodgings near the university buildings. The *studium generale*, or leading universities, were recognized as such because they housed at least one of the “higher faculties” in law, medicine, or theology in addition to faculties of the arts. Courses in the arts, typically with an emphasis on logic and philosophy, were common preparation for study in the three learned professions. Thus, from the beginning, a certain vocational emphasis is evident in the university. Degrees awarded on the completion of professional studies certified accomplishments that made their recipients worthy of entry into professional life. Nevertheless, the spirit of inquiry was equally important in the medieval universities; these were places renowned for famous teachers, such as Abelard in Paris and Irnerius in Bologna. Civic competition led to a proliferation of universities. By the end of the Middle Ages, eighty had been founded in different parts of Europe (Rashdall [1985] 1936).

In the seventeenth and eighteenth centuries, the fortunes of colleges and universities waned. The causes for decline are numerous, including the attractiveness of commercial over scholarly careers, the interference (in some places) of religious and political authorities, and the insularity of faculty who jealously guarded their guild privileges but resisted new currents of thought. During this period, colleges and universities became places concerned with the transmission of ancient texts rather than the further advance of knowledge. Professional training moved out of the universities: into Inns of Court, medical colleges, and seminaries. New elites interested in technical and scientific progress established entirely new institutions rather than allying with the colleges and universities. Napoleon, for example, founded elite professional training institutions, the *grandes ecoles*, and the early investigators in the natural sciences created separate elite societies to encourage research and discussion.

The revived university is the product of nineteenth-century European reform movements, led in the beginning by intellectually oriented aristocrats and eminent philosophers and theologians. The University of Berlin, founded in 1810, was the first reformed university, and others shortly followed in its wake. The new university was founded on the “Humboldtian principles” of the unity of teaching and research (meaning that both functions were performed by the professoriate) and

the freedom to teach and learn without fear of outside interference. The development of new academic components, such as the research seminar and the specialized lecture, created an environment in which path-breaking researchers, such as Leopold Ranke in history and Justus von Liebig in chemistry, emerged (McClelland 1980). By mid-century, the German research universities had become a model for reformers throughout Europe and from as far away as the United States and Japan. The first research university in the United States, Johns Hopkins University, founded in 1876, was explicitly modeled on the German research university.

Higher education's current emphasis on training for a wide range of applied fields has an equally important history. Here the United States, rather than Germany, was the decisive innovator. The Morrill Acts (passed in 1862 and 1890) provided funds for states to establish "land grant" universities to provide both general education and practical training in agricultural and mechanical arts for all qualified applicants. Such institutions encouraged both the democratization of American higher education and a closer connection between universities and emerging markets for educated labor. The American university's role in society was further enhanced by its willingness to work collaboratively with government, professional associations, and (somewhat later) business and community organizations. The "Wisconsin Idea" encouraged close connection between university experts and government officials during the period before World War I. Universities also cooperated closely with professional associations to raise educational training standards. Connections between university and state were extended, particularly in the sciences, during World War II and the Cold War, when government grants for university-based scientific research became a very large source of support. These developments encouraged a new view of higher education. In the 1960s, Clark Kerr (1963) coined the term "multiversity" to describe institutions, like his own University of California, as service-based enterprises specializing in training, research, and advice for all major sectors of society. Junior colleges, first established just after the turn of the twentieth century, were by the 1960s even more systematically tied than universities to local and regional markets for semiprofessional and technical labor (Brint and Karabel

1989). In terms of growth, these two-year colleges are the great success story of twentieth-century higher education, and their influence is now evident even in four-year institutions. The utilitarian approach of American educators was resisted for some time in Europe and Asia, where access to higher education was strictly limited to those students who passed rigorous examinations and where higher degrees had long served as important badges of social status linked to cultural refinement. However, by the last quarter of the twentieth century, the entrepreneurial multiversity had become an important model throughout the developed world (Clark 1998).

Institutions of higher education rarely shed their earlier identities completely; instead, they incorporate new emphases through reorganizing and adding new components and new role expectations. Today, all major historical stages of university development remain very much in evidence. Much of the nomenclature, hierarchy, and ritual of the medieval university remains and is in full display at graduation ceremonies. Although the major fields of study have changed dramatically, the underlying liberal arts emphasis of the ancient academies has remained central in the first two years of undergraduate study (the lower division). The nineteenth-century emphasis on specialization is evident in the second two years of undergraduate study (the upper division) and in graduate and professional programs. The nineteenth-century emphasis on research remains an absorbing occupation of faculty and graduate students. The twentieth-century emphases on ancillary training, service, and advisory activities are organized in separate components (as in the case of university extension programs, agricultural experiment stations, university-based hospitals, and collegiate sports teams) or performed by research faculty in their capacity as consultants and lecturers in the community.

ACADEMIC ORGANIZATION

Contemporary institutions of higher education are organized horizontally by divisions among fields of knowledge and vertically by ranks of authority. The dual hierarchy of professors and administrators is a structural feature of academic organization with particularly important consequences.

Knowledge is divided among discipline-based departments and interdisciplinary programs and research centers. Interdisciplinary programs have become increasingly important in the organization of research activity. However, academic appointments remain based in departments. For this reason, departments must be considered fundamental to academic organization. In chair systems, characteristic of continental European universities, one or two senior professors hold chairs and organize research programs, while the other professors serve in subsidiary roles under the direction of the chair. In American universities, departmental faculty operate independently, pursuing their own research programs, only occasionally in collaboration.

The larger structures of knowledge-based organization are the colleges and professional schools. A college of humanities will, for example, typically include all departments in the fine arts (such as music and theatre) and the humanities disciplines (such as philosophy and English). Colleges and professional schools are administrative units. The number of colleges and professional schools varies by the size of the campus. A very large campus will have separate divisions for the arts, humanities, social sciences, biological sciences, and physical sciences. It may also have half a dozen or more professional schools. A small campus may have only a single college of arts and sciences.

Colleges and universities are under no obligation to represent all fields of basic and applied knowledge, and most do not. (The term “university” does not, as many believe, refer to the universe of all fields of knowledge. Originally, it meant simply “an aggregate of persons.”) New disciplines must fight for a place in the university, and old disciplines sometimes fragment or disappear altogether. Sociology and psychology, for example, both broke away from philosophy, while the nineteenth-century discipline of political economy eventually divided into political science and economics. Today the fate of disciplines in particular colleges and universities depends on a number of factors, including, most notably, student demand for courses in the department, the strength of the departmental faculty in national ratings, the ability of faculty to bring in grants and contracts, the exodus or retirement of “star” faculty, and the effectiveness of the department in making its case for new hiring. These factors have little to do with

any purely objective intellectual principles of value. Over the long run, disciplines with a strong profile in the labor market and those with access to large research grants have been least vulnerable to retrenchments. One might even argue that the modern university is moving away from a liberal arts core in the direction of a “practical arts core” composed of departments closely tied to technological and economic advance or to national security (such as economics, molecular biology, physics, and international affairs) and professional schools providing training for the highest-income occupations (such as medicine, law, and finance). Strength in this practical arts core does not necessarily come at the expense of strength in traditional liberal arts disciplines, however. In the larger universities, powerful disciplines help to subsidize less powerful ones, which, in turn, may teach a disproportionate share of students.

Modern institutions of higher education are far from *collegiua* in their authority structure, but they also do not fit an ideal-type corporate model of top-down control. Instead, decision-making practices are based, at least in principle, on divided spheres of power and ongoing consultation among the major “branches” of institutional governances. In this dual structure, both administrative and knowledge-based authority are represented. The authority structure of knowledge is constituted by the departments and, within the departments, by the professorial ranks. Advancement in the professorial hierarchy is based in principle on the quality of a faculty member’s professional accomplishments (typically involving assessments of research, teaching, and service). Differences in rank are associated with both deference and income. This hierarchy moves from the temporary ranks of lecturer and instructor to the regular ranks of assistant, associate, and full professor. Highly visible full professors may be appointed to named chairs that provide both additional symbolic recognition and a separate budget for research and travel.

The top level of the administrative hierarchy is composed of a president or chancellor, who is responsible for fund-raising and interaction with important resource providers as well as overall supervision; a provost or executive vice chancellor, who is responsible for internal academic matters; and the deans of the colleges and schools. Top administrators are usually drawn from members of the faculty, although an increasing number

of lower-tier institutions now hire professional managers at the presidential level. Top administrators make the ultimate decisions about budget allocations, hiring and promotion, and planning for the future. However, the faculty, at the leading authorities in their specialized domains of knowledge, retain a decisive say at least in the better institutions, over all decisions involving curricular organization and instruction. They also retain the predominant say in hiring and promotion decisions within the academic departments, expecting only very rare overrules by administrators. The faculty typically play a significant advisory role in the development of new programs and centers and in discussions of institutional priorities. Top universities depend for prestige and resources on the accomplishments of their faculty; as a general rule, the less distinguished the faculty, the more powerful the administration (Blan 1973). Faculty in nonelite institutions have, consequently, sometimes chosen to organize in collective bargaining units to control administrative discretion through contractual means (Rhoades 1998).

The unique institution of tenure greatly enhances the influence of faculty. After a six-year probationary period, assistant professors come up for a decision on promotion to tenure and accompanying advancement in rank. Tenure, a conventional rather than a legal status, guarantees lifetime employment for those who continue to hold classes and act within broad bounds of moral acceptability. Together, dual authority and tenure guarantee opposition to any administrative efforts to abandon existing programs or to downgrade the work conditions and privileges of faculty.

The primary funding for colleges and universities varies by national circumstances. Most institutions of higher education in Europe and in the developing world are state-supported. Modest fees are sometimes charged students enrolling in expensive or high-demand fields. However, the idea of tuition is only now developing. In the United States, public colleges and universities are primarily supported by state appropriations, but they also charge tuition and fees. Private colleges and universities, lacking state appropriations, charge substantially higher tuitions and, therefore, attract a larger proportion of students from the higher social classes. They also use interest from their investments to support the operating budget. In

both public and private universities, research contracts and grants are another important source of funds.

COMPARISON OF NATIONAL SYSTEMS

Sociologists frequently use the term “system” to describe national patterns of higher education. This term should be used advisedly, since many national “systems” are not in fact highly coordinated. Societies with strong traditions of state planning have relatively centralized systems. The Russian, French, and Swedish systems remain among the most centralized today. But even in these countries, some private institutions operate independently of the centrally organized public system. Societies with weak traditions of state planning and strong traditions of voluntarism have decentralized and highly diverse systems. American higher education is a clear example of this pattern. Colleges and universities have been organized by religious bodies, secular elites, state legislators, and individual entrepreneurs. The result is a system of some 4,000 largely independent institutions. Institutions emulate and compete with one another in a complex ecological setting whose major dimensions are defined by level of selectivity, by institutional identity (for example, denominational or nondenominational, residential or commuter), and, perhaps most of all, by geography. One of the few forms of regulation is the requirement that curricular programs meet accreditation standards.

It is possible to classify national systems in many ways. Clark (1965) proposed dividing them by the primary influence on the coordination of the system. He placed the former Soviet Union near the pole of state-based coordination and the United States near the pole of market-based coordination. He classified Italy as the clearest example of coordination by an “academic oligarchy.” Here powerful academics were the decisive influence in the development of rules and policies for the system as a whole. Clark argued further that the dominant mode of coordination has important consequences for the ethos and structure of the system. State-based systems place a strong and focused emphasis on manpower planning objectives and scientific and technical development. Market-coordinated systems place consumer interests first and compete to satisfy simultaneously

the social, vocational, and educational interests of students. In "oligarchical" systems, faculty traditions and privileges are jealously preserved and institutions do not change easily.

Clark's framework remains useful. Depending on the question of interest, however, other dimensions of comparison may be equally important. National systems, for example, can also be characterized in relation to their (1) size and openness, (2) institutional diversity, and (3) interinstitutional stratification structure. Countries vary significantly across these three dimensions. The United States represents an unusually large, diverse, and stratified system. Two-thirds of secondary school students enter higher education, but they enter a very heterogeneous set of institutions that are highly stratified by acceptance rates. Germany, by contrast, represents a still relatively small, homogeneous, and unstratified structure. About one-third of German high school students enter higher education. Four-year institutions are designed to be quite similar to one another, and there is no clear ranking system among them. In the United States, therefore, life fates are determined within the system; in Germany, they are determined to a greater degree by inclusion in or exclusion from the system. Some systems in the industrialized world remain relatively small but nonetheless include also a highly differentiated elite track. This is true, for example, in France, where the *grandes écoles* represent a clearly defined upper tier reserved for the very best students. It is also true in Japan, where an institution such as the University of Tokyo retains very close linkages to elite positions in the Japanese state and private economy. Differences across these dimensions have important implications for student consciousness. The highly educated are, for example, more likely to be seen as a separate status group in societies in which access to higher education is relatively restricted. By contrast, opportunity consciousness tends to replace class consciousness in more open systems.

SOURCES AND CONSEQUENCES OF GROWTH

Since the 1960s, the trend in the industrialized world has been in the direction of the American model, with an increasing proportion of students entering higher education but with stratification

among institutions and major subjects also increasing. In most countries of Europe, for example, access to higher education is now possible from all secondary school tracks (including vocational tracks) and once-rigorous secondary school-leaving examinations have been relaxed to allow a larger flow of students into higher education. Nevertheless, both attendance and graduation rates in most of the industrialized world remain at about half that in the United States. Thus, higher education in Europe and East Asia is no longer class education, but it has not reached the level of mass education found in the United States.

Theorists of postindustrial society have suggested that the growth of the knowledge sector in the economy is behind this expansion of higher education. Estimates vary on the rate of growth of the "knowledge sector," depending on the definition used. Industries employing high proportions of professionals are growing faster, by and large, than other industries, but some estimates show them slowing down over time (Rubin and Huber 1986). Every estimate shows that they do not as yet contribute a dominant share of the gross national product or even a dominant share of the most dynamic export industries.

The growth of the knowledge sector is undoubtedly an important factor in the expansion of graduate and professional education. Its importance at the undergraduate level is more debatable. In relation to undergraduate enrollments, at least three other sources of growth must be given proper emphasis. One is the interest of states in expanding educational opportunities for their citizens. Another is the interest of students, given these opportunities, to differentiate themselves in the labor market. As secondary school completion approaches universality and higher education attendance becomes more feasible, more students have a motive to differentiate themselves by pursuing higher degrees (Meyer et al. 1979). Finally, and perhaps most important, is the increasing role played by educational credentials as a means of access to desirable jobs in the economy. Credentials are not simply (or in many cases primarily) a guarantee of technical skills. They also signal that their holders are likely to have cultural and personality characteristics sought by employers. These characteristics include middle-class manners, a competitive outlook, literacy and communication skills,

and persistence. Colleges both reward and inculcate these qualities (Collins 1979).

Sociologists agree that restrictive systems of higher education tend to reproduce the social inequalities of the larger society, because the cultural information, motivation, and academic skills needed to pass rigorous examinations are highly correlated with social class. Social-class advantages do not disappear in more open systems, but these systems do generally allow a higher proportion of academically able students from the lower classes to advance. The sheer size of a system does not, however, guarantee decreasing inequality (Blossfeld and Shavit 1993). Much depends on the circumstances of students in the system and the levels of stratification within in the system. Since 1980, the number of college graduates in the United States has continued to grow, but this growth has occurred almost exclusively from among students whose families are in the top quartile of household income. Students from families in the bottom quartiles are entering at higher rates, but they have not graduated at higher rates. The reasons are clear: These students are often less prepared and less motivated to succeed, more likely to feel the press of work and family responsibilities, and more likely to struggle financially with the high cost of four years of college. They are also more likely to enter two-year institutions emphasizing job-related training.

CONTEMPORARY PRESSURES

Colleges and universities are increasingly costly operations. In state-organized systems, growth is subject to fiscal circumstances and state priorities. In market-organized systems, developments are pushed to a considerable degree by the value of college degrees in the labor market and by competition among colleges and universities. To finance the growth that allows for development of new fields without sharp cutbacks in older fields, colleges and universities compete vigorously for research funds, private gifts, and preeminence in markets for educational services. They also compete vigorously for top faculty and students, the foundations for an institution's reputation.

The high costs of operation and the increasingly competitive environment have led to several

important developments. In the broad field of institutions of higher education, two quite separate market segments tend to develop: one for largely well-to-do students who can afford an expensive four-year residential experience and another for largely moderate- to lower-income students who desire convenience and flexibility as they juggle school, family, and work. In the former, the liberal arts tradition remains strong at the undergraduate level. In the latter, the emphasis is on practical, "consumer-friendly" job-relevant training. As a result of this bifurcation of market segments, the lower tier of liberal arts colleges has begun to disappear in the United States. In most cases, these institutions have transformed themselves into comprehensive colleges with large undergraduate professional programs in areas such as business, engineering, technology, and education (Breneman 1994). The same general trend toward practical, job-relevant training is evident at all but the most selective public four-year colleges and universities.

The size of operations and the increasing competition among institutions have strengthened the influence of top administrators. Managers have started to think strategically about areas of comparative advantage, a striking departure from the model of the past, which emphasized representation of all major fields of study. As a result of this strategic thinking, most departments can no longer depend on automatic replacements for departing faculty, even at the senior level. Administrators have also added resources to student services and development offices to strengthen their relations with key resource providers. For the first time in the postwar period, close partnerships have been developed at some institutions with private firms, which can provide new sources of research funding (Cohen et al. 1998). The ability to attract top students and sizable research grants has improved the position of some departments and schools while weakening the relative position of others. Within institutions, power and influence has continued to shift in the direction of the major professional school faculties and faculties in scientific disciplines with access to large federal research grants. Although still far from completely rationalized along market and bureaucratic-hierarchical lines, institutions of higher education moved significantly in this direction in the last decades of the

twentieth century. Far from reinforcing the position of universities as an alternative to corporate organizations, this movement suggests a tendency for academic institutions to become more like corporations, with power concentrated in the hands of managers, who are conscious, above all, of the markets for their organization's services. Nevertheless, as long as subject-area experts remain central to research and instruction, dual authority will be necessary for academic organization—and academic and corporate forms of organization will never completely converge.

These organizational developments help to explain weaknesses of “new-class” theories. “Knowledge workers” (including professors) do not represent a stratum with social and political interests distinct from those of business elites and nonprofessional workers. Instead, the interests of the knowledge workers are decisively influenced by their particular occupational, organizational, and market circumstances (Brint 1994). This is also true within universities. Those faculty located in professional programs are usually closely allied with top administrators, as are “star” faculty, while those in traditional liberal arts are more likely to express an independent, and somewhat critical, outlook.

All segments of the faculty do, however, share certain guild-like interests in maintaining control over recruitment, employment, and working conditions. The development of new electronic technologies of learning (such as distance learning, “virtual universities,” and Web-based courses) may pose a more significant long-run threat to these guild interests than any of the recent managerial efforts to rationalize campus operations. Studies thus far have not shown consistently significant differences in learning between students taking courses off-site in technologically mediated settings and those taking conventional, on-site courses. This tends to raise questions about the most powerful faculty rationale for the current campus-based organization of academic work. In the future, campuses will undoubtedly continue to exist for elite students, because of the importance of face-to-face contact for building networks that carry over into adult life. They will also be necessary for coursework and research requiring laboratory equipment. It is possible, however, that the number of campuses serving nonelite students will

shrink over the long run, with campus-based instruction shifting toward still more convenient and flexible computer-mediated technologies.

HISPANIC AMERICANS

Despite their common linguistic heritage, Hispanic Americans are a heterogeneous and rapidly growing population that includes no less than twenty-three distinct national identities and combines recent legal and undocumented immigrants with groups whose ancestors predate the formation of the United States as we know it today. The label *Hispanic* is derived from *Hispania*, the Latin word for Iberia. In 1973 the U.S. Department of Health, Education and Welfare adopted the term “Hispanic” at the recommendation of the Task Force on Racial/Ethnic Categories to designate U.S. residents who trace their origins to a Spanish-speaking country. Following suit, the U.S. Census Bureau adopted this label as a statistical shorthand for the Hispanic national-origin groups (del Pinal and Singer 1997; Haverluk 1997). Originating in the western United States, the term “Latino” has been adopted as an alternative by groups that view “Hispanic” as a conservative pan-ethnic label imposed by the government that ignores their political and economic struggles for equality and representation. These distinctions notwithstanding, both labels serve as umbrellas for a highly diverse segment of the U.S. population.

Hispanics are one of the fastest growing segments of the U.S. population. High levels of immigration combined with high fertility rates yield a growth rate for Hispanics that is seven times that of the non-Hispanic population (U.S. Department of Commerce 1993). In 1990 the U.S. Census Bureau enumerated 22.4 million Hispanics, representing 9 percent of the aggregate population, but the 1997 population estimate reached 29.7 million, accounting for 11 percent of the national total (U.S. Department of Commerce 1998). Hispanics accounted for about one-third of national population growth during the 1980s, and their

contribution to aggregate demographic growth is expected to increase in the future. Census Bureau projections made in 1995 predicted that by the year 2000 the Hispanic population would reach 31.4 million, but this estimate is conservative because annual estimates since that time have consistently been exceeded (U.S. Department of Commerce 1996). Hispanics are projected to surpass blacks as the largest minority by 2003—perhaps sooner, depending on the volume of legal and undocumented immigration from Central and South America and the Spanish-speaking Caribbean. Already in 1998, Hispanic children outnumbered black children.

Although immigration has figured prominently in the growth of the Hispanic population since 1941, its influence on demographic growth, ethnic diversification and renewal, and population replenishment has been especially pronounced during the 1980s and 1990s. Immigration was responsible for approximately one-third of the phenomenal growth of the Hispanic population in the 1980s and 1990s. At the end of the 1990s, two-thirds of the population were immigrants or children of immigrants (del Pinal and Singer 1997), and trends in fertility and immigration suggested higher growth of the Hispanic population well into the twenty-first century. By the year 2020, the U.S. Hispanic population is projected to reach 52.6 million, representing approximately 16 percent of the national total (U.S. Department of Commerce 1996).

Nearly two-thirds of all U.S. Hispanics (64 percent) are of Mexican origin, while 11 percent trace their origins to Puerto Rico, 4 percent to Cuba, and 14 percent to other Central and South American nations. An additional 7 percent of Hispanics are of unspecified national origin, which includes mixed Spanish-speaking nationalities, Spaniards, and “Hispanos,” the descendants of the original Spanish settlers in what came to be known as Colorado and New Mexico. This national-origin profile of the Hispanic population has evolved since 1970 because of the differential growth of selected groups. In particular, since 1970 the Mexican, Central American, and South American population shares have increased, while the Cuban, Puerto Rican, and other Hispanic shares have declined (Bean and Tienda 1987; del Pinal and Singer 1997). Differential growth rates derive from rising immigration flows combined with high fertility among the foreign-born.

Defining features of the U.S. Hispanic population, in addition to vigorous growth, include increasing diversity, segmented integration, and rising political influence. Among the more salient aspects of diversity are immigrant and generational status, national origin, residential distribution, socioeconomic status, political participation, and reproductive behavior. Segmented integration is evident in the emergence of a solid middle class coupled with rising poverty, especially among children and immigrants, and greater geographic dispersion coupled with persisting residential concentration—nationally in a few large metropolitan areas and locally in ethnic neighborhoods within major cities (Haverluk 1997). As the number of Hispanics increases, politics also becomes increasingly important in determining their social and economic destiny. Greater political influence is already evident in the growing presence of Hispanics among elected officials. However, Hispanic voter turnout remains exceedingly low, suggesting that the potential political impacts of population growth have not fully unfolded.

The continued rapid growth of U.S. Hispanic population coupled with increased diversification raises concerns about long-term prospects for their social integration, particularly recent arrivals from Mexico, Central and South America, and the Spanish-speaking Caribbean. Among casual observers who note the emergence of ethnic neighborhoods where Spanish is spoken publicly as well as privately, the growing Hispanic presence has raised fears about the potential “Latinization” or “Hispanicization” of the United States. However, larger numbers are not likely to be the most decisive force shaping the Hispanic imprint on the U.S. social and economic landscape, for size automatically confers neither power nor status. Therefore, to evaluate the recent past and future imprint of Hispanics in the United States, what follows summarizes several themes that have developed in the sociological literature on Hispanic Americans. These include: (1) the origin of current ethnic labels, (2) the roots of diversification, (3) the changing social, demographic, and economic composition of the population, and (4) the implications for societal integration of recent social and economic trends. A concluding section summarizes key lessons from existing studies and identifies areas for future investigation.

EVOLVING LABELS

Ethnic labels are partly imposed by the host society and partly chosen by immigrant groups who wish to preserve their national identity. The labels “Spanish origin” and “Hispanic” originally were coined as terms of convenience for official reporting purposes. Before the mid-1960s, Hispanics were unfamiliar to most observers outside the Southwest, where persons of Mexican ancestry were well represented, and the Northeast, where Puerto Rican communities began to flourish after World War II. Therefore, until 1960 the “Spanish surname” concept was adequate for identifying persons of Mexican origin residing in the Southwest, and “Puerto Rican stock” was used to identify persons who resided in the Northeast (predominantly New York) and who were born in or whose parents were born in Puerto Rico. However, with increasing intermarriage, residential dispersion, and generational succession, these concepts became progressively less viable to identify persons from Mexico and Puerto Rico. Furthermore, the influx of immigrants from Central and South America and the Spanish-speaking Caribbean into areas traditionally inhabited by Mexicans and Puerto Ricans necessitated labels that could more adequately represent the growing diversity along national-origin lines.

In recognition of the growing residential, marital, and generational heterogeneity of the Spanish-speaking population, in 1970 the U.S. Census Bureau adopted the “Spanish origin” concept, which was based on self-identification and could be administered to the U.S. population on a national level (Bean and Tienda 1987). Symbolically, this decision, which was also an important political gesture, recognized Hispanics as a national minority group rather than as regionally distributed subgroups. And in 1980 the term “Hispanic” accompanied the “Spanish origin” item on the census schedule to identify persons from Latin America, Spain, and the Spanish-speaking Caribbean. However, through the 1980s the term “Latino” came into popular use as an alternative to “Hispanic.” As a symbol of self-determination and self-definition, “Latino” is the label preferred by many ethnic scholars.

Despite their popular use and administrative legitimacy, pan-ethnic terms such as “Latino” or “Hispanic” are less desirable than specific national-origin designations, such as Puerto Rican,

Venezuelan, Cuban, or Mexican, which better reveal the appreciable socioeconomic and generational diversity of Hispanic Americans. Not surprisingly, diversity along national-origin lines became a major intellectual theme in the scholarly writings about Hispanics during the mid- to late 1980s and remained so at the turn of the century as the powerful forces of international and internal migration continued to diversify the composition of this rapidly growing population.

ROOTS OF DIVERSIFICATION

Social science interest in Hispanic Americans has increased greatly since 1960, and the scope of topics investigated has expanded accordingly. Whereas studies conducted during the 1960s and through the mid-1970s tended to focus on regionally localized populations, the 1980s witnessed a proliferation of designs that compare group experiences. This shift in the research agenda, which coincided with the designation of Hispanics as a national population, also brought into focus the theme of diversity and inequality among national-origin groups. More recent studies have focused on economic opportunities afforded by geographic dispersal and the changing fortunes of the burgeoning second generation—especially the children of recent immigrants.

The Hispanic presence in the United States predates the formation of the nation as we currently know it. Over a decade before the Pilgrims landed at Plymouth Rock, Spaniards had already settled in present-day New Mexico. Several subsequent events shaped the Hispanic imprint on the United States. These include (1) the Louisiana Purchase, which provided a powerful impetus for westward expansion during the 1800s; (2) the Treaty of Guadalupe Hidalgo, which ended the Mexican-American War and ceded all Mexican territories north of the Rio Grande to the United States; (3) the Mexican Revolution, which propelled thousands of Mexicans north to seek refuge from the bloody conflict; (4) the Cuban Revolution, which provided the impetus for several unprecedented refugee flows; (5) the political instability in Central America during the 1980s, which has augmented legal and undocumented migrant streams from El Salvador, Guatemala, and Nicaragua; and (6) the economic crisis of the 1980s, which encouraged higher levels of documented

and undocumented migration from South America, especially Colombia, Peru, and Ecuador (U.S. Department of Commerce 1993). International events in Latin America continue to influence the U.S. Hispanic population by altering immigration streams and their reception as refugees or labor migrants.

The uneven integration experiences of the various national-origin groups are as powerful in diversifying the U.S. Hispanic population as are migration streams of largely unskilled workers from Latin America. The cultural and socioeconomic diversity of Hispanic Americans can be traced partly to the diverse modes of their incorporation into the United States and partly to the changing opportunities to become Americanized. Nelson and Tienda (1985) proposed a framework for conceptualizing the emergence, consolidation, and persistence of distinct Hispanic ethnic groups. They identified three domains of immigrant incorporation that are pertinent for understanding the socioeconomic stratification of Hispanics: (1) the mode of entry, namely, the conditions of migration as voluntary labor or as political migrants; (2) the mode of integration, that is, the climate of reception at the time of mass entrance to the host society; and (3) the circumstances that precipitate reaffirmation of national origin. The latter emphasizes the distinction between the cultural or symbolic content of Hispanic origin and the economic consequences of ethnicity that result in the formation of minority groups. This distinction between the economic and the cultural underpinnings of Hispanic ethnicity is pertinent for theorizing about the long-term integration prospects of specific nationality groups.

Along these three domains of ethnic incorporation, the major national-origin groups exhibit considerable diversity. For example, the origin of the Mexican and Puerto Rican communities can be traced to annexation, although the timing and particulars of the two cases were quite distinct. The annexation of Mexican territory resulted from a political settlement subsequent to military struggle and was followed by massive and voluntary wage-labor migration throughout the twentieth century, but particularly after 1960. The Puerto Rican annexation, which was formalized at the culmination of the Spanish-American War, will remain an incomplete process until statehood or

independence is achieved. However, like the Mexican experience, the Puerto Rican presence on the U.S. mainland was characterized by a massive wage-labor flow after World War II that has ebbed and flowed according to economic conditions on both the island and the mainland.

Mexico has been the leading source country for Latin American immigrants since 1820, but the Mexican flow began in earnest during the time of the Mexican Revolution. The Bracero Program, which was a binational agreement that allowed entry of temporary agricultural workers, institutionalized migrant streams that persisted long after the formal agreement was terminated in 1964. Also, Mexico is the leading source of undocumented migrants to the United States. Although 2.3 million Mexicans obtained legal status under the provisions of the Immigration Reform and Control Act (IRCA) of 1986, undocumented migrant workers continue to enter the United States and are currently settling in such nontraditional areas as North Carolina, Atlanta, New Jersey, and New York.

These distinct modes of incorporation are sharpened by the experience of Cubans, whose socioeconomic success is as striking as the limited socioeconomic achievements of Puerto Ricans and Mexicans. Although the U.S. Cuban community was established before Fidel Castro's rise to power, Cuba's internal politics are largely responsible for the dramatic growth of the Cuban population in the United States since 1960. The Cuban Revolution created a wave of U.S.-bound political refugees who were themselves differentiated by social classes. The so-called golden exile cohort, which virtually gutted the Cuban middle class, was followed by the exodus of skilled and semiskilled workers who made up the vast majority of Cuban emigrés. Although the distinction between political and economic migrants is murky, political refugees, unlike wage-labor migrants, usually command immediate acceptance from the host society. The Cuban experience, however, stands in sharp contrast to that of later political refugees from Central America (primarily El Salvador, Nicaragua, and Guatemala), whose refugee story is one of clandestine entry and extended legal and political struggles for recognition. Probably this difference reflects the fact that Cubans were fleeing a communist regime while this was not the case for Central American refugees.

Immigration from Central and South America and the Spanish-speaking Caribbean has continued to diversify not only the national-origin composition of the Hispanic population but also the socioeconomic position of the various groups. The Dominican Republic, a country of only 8 million inhabitants, was the fourth-largest source of U.S. immigrants in 1995, including many who entered without documentation (del Pinal and Singer 1997). Although internal political problems precipitated Dominican emigration after 1960, declining economic conditions fueled the migrant stream during the 1970s. Likewise, the Central American wage labor-flow has been propelled by poor economic conditions coupled with political upheavals, especially during the 1980s and 1990s. That more than two-thirds of Central Americans residing in the United States in 1995 entered after 1980 testifies to the recency and intensity of this wage-labor flow. South American immigration to the United States derives mainly from Colombia, but there is a growing presence of Ecuadorians and Argentineans among this stream. Compared to Mexican, Central American, and Dominican flows, undocumented migrants are less common among South American immigrants.

The future role of immigration in stratifying the Hispanic population is highly uncertain, as it depends both on changes in U.S. foreign policy toward Central and South America and on revisions in immigration policy concerning the disposition of undocumented aliens and quotas on admissions of close family members of legal residents. Equally important is the role of expanded social networks in drawing new migrants to U.S. shores. Trends in the 1990s indicate that these flows are likely to continue into the foreseeable future. A comparison of wage-labor migration histories of Hispanics clearly illustrates how diverse modes of entry and integration have fueled the diversification of Hispanic Americans.

Ethnic reaffirmation and consolidation can best be understood as immigrant minority communities define themselves vis-à-vis the host society. For groups that were relatively successful in adapting to the host society, such as Cubans, national heritage acquired a highly symbolic character that is used for economic relationships when expedient and downplayed otherwise. Alternatively, class position and national origin become inextricably linked when immigrants are destined for

the lower ranks of the social hierarchy, as seems to have occurred for Mexicans, Puerto Ricans, and Central Americans, or when illegal status forces many underground. Thus, the distinction between symbolic ethnicity and minority status revolves around the degree of choice groups have in controlling their socioeconomic destiny (Vincent 1974).

SOCIAL, DEMOGRAPHIC, AND ECONOMIC TRENDS

Until the 1960s, the U.S. Hispanic population was overwhelmingly Mexican and almost exclusively located in the Southwest (Haverluk 1997). But migration from Puerto Rico to the Northeast during the 1950s and the arrival of thousands of Cubans in south Florida and the Northeast following the 1959 Cuban Revolution led to the establishment of distinct Hispanic communities in Miami and New York City. Heavy migration from Mexico and other Latin American countries since the 1970s has altered the regional landscape and created a more geographically and socially heterogeneous Hispanic population whose imprint reaches well beyond the traditional states of residence.

Although Hispanics reside in all states, historically the population has been concentrated in nine states, where 85 percent of Latinos reside. These include the five southwestern states of California, Texas, Arizona, New Mexico, and Colorado, as well as New York, Florida, Illinois, and New Jersey. Two states—California and Texas—were home to more than half of all Hispanics in 1995, with Mexicans and Central Americans disproportionately concentrated in these states. Despite residential dispersion of Hispanics during the 1980s and 1990s, the visibility of distinct Hispanic communities is reinforced by persisting regional concentration along national origin lines. Puerto Ricans remain concentrated in the Northeast—predominantly in major cities of New York and New Jersey—while Cubans have become bimodally distributed in south Florida and large northeastern cities (Bean and Tienda 1987). Mexicans remain disproportionately concentrated in the major cities of the Southwest and Chicago.

Cities with large Hispanic populations witnessed the greatest growth during the 1990s (Frey 1998). The ten metro areas with the largest Hispanic populations experienced the largest population gains. These include Miami, New York City,

and Chicago as well as others close to the Mexican border. In San Antonio, Miami, and El Paso, Hispanics are the majority population. In 1996, more than 6 million Hispanics resided in Los Angeles, making it the second largest Latino city in the world (behind Mexico City). Residential segregation further compounds geographic concentration by spatially isolating Hispanics of low socioeconomic status and recent immigrants from non-Hispanic whites. This segregation reinforces the cultural distinctiveness of Hispanics in regions where visible communities have been established even as increased residential dispersion concurrently fosters national integration. It is in this sense—increasing geographic dispersion combined with persisting concentration—that Hispanics experience segmented residential integration.

The demography of the Hispanic population helps in understanding other characteristics, such as educational standing and economic well-being. For instance, the high immigrant composition of the population means that many have not had the opportunity to acquire a U.S. education, or much education at all. The youthful age structure also means that Hispanic school enrollment rates are higher and retirement rates lower compared to other population groups.

A social and economic profile of the Hispanic population since 1960 provides signals of both optimism and pessimism for the long-term economic prospects of distinct nationality groups. Because education is key for economic and social mobility, as well as for integration of new arrivals, trends in educational attainment are quite revealing about the diverse futures facing Hispanics. On the one hand, from 1960 to 1996 Hispanics witnessed an unmistakable improvement in their educational attainment. Whereas only 30 percent of Hispanics aged 25 and over had completed a high school education or more in 1970, by 1996 more than 53 percent had done so (del Pinal and Singer 1997; U.S. Department of Commerce 1993). However, there have been very modest gains in educational progress since 1980. More disturbing is evidence that educational gaps between Hispanics and non-Hispanics have widened because gains of the latter have been faster. These widened gaps are evident at all levels of educational attainment, beginning in preschool. Because Hispanics average less pre-school experience, they begin elementary school with fewer social skills. Furthermore,

high school noncompletion rates remain distressingly high for Mexicans and Puerto Ricans—the two groups with the longest history in the United States.

That Cubans outperform Mexicans and Puerto Ricans in educational attainment undermines simplistic explanations that immigration and language are the reasons for the continued educational underachievement of the latter. The continued arrival of new immigrants with very low levels of education also contributes to the slow educational progress of Hispanics. However, this is only a partial explanation because even among the native-born, Hispanics lag behind African Americans and non-Hispanic whites in educational attainment. Low socioeconomic status and especially the preponderance of parents with low educational attainment are major forces driving the persisting educational underachievement of Mexicans and Puerto Ricans (Bean and Tienda 1987). Most research shows that Hispanics with family backgrounds comparable to those of non-Hispanic whites are less likely to withdraw from high school and as likely to continue on to college. Unfortunately, the current educational distribution implies intergenerational perpetuation of educational disadvantages well into the future.

These educational disadvantages carry over into the labor market, yet Hispanics have higher age-specific labor-force participation rates than most groups. This labor-market advantage exists largely because immigrants have very high rates of labor-force participation and they comprise a large and growing share of the working-age Hispanic population (Bean and Tienda 1987). However, relatively low skills and limited proficiency in English channel Hispanic immigrants to low-wage jobs with few benefits. Yet because Hispanic immigrants themselves are highly diverse along national origin lines, group experiences in the U.S. labor market are equally varied.

The 1960s and 1970s witnessed a deterioration of the labor-market standing of Puerto Rican men and women, while Cubans became virtually indistinguishable from non-Hispanic whites in terms of participation rates, unemployment rates, and occupational profiles. Mexicans stand somewhere between these extremes, with greater success than Puerto Ricans in securing employment, but usually at low wages owing to their low levels of

human capital. Therefore, Mexicans are more highly represented among the working poor than are non-Hispanic whites, but Puerto Ricans are more likely than other Hispanic groups to join the ranks of the nonworking poor. Puerto Rican men witnessed unusually high rates of labor-force withdrawal during the 1970s, and their labor-force behavior converged with that of economically disadvantaged blacks (Tienda, 1989).

Numerous explanations have been provided for the deteriorating labor-market position of Puerto Ricans. These include the unusually sharp decline of manufacturing jobs in the Northeast; the decline of union jobs in which Puerto Ricans traditionally concentrated; increased labor-market competition with Colombian and Dominican immigrants; and the placement of Puerto Rican workers at the bottom of a labor queue. Direct empirical tests of these working hypotheses—all with merit—have not been forthcoming. However, the dramatic improvement in the labor-market standing of Puerto Ricans during the 1990s as a result of tight labor markets and vigorous economic growth suggest that Puerto Ricans are, like blacks, located at the bottom of a hiring queue and hence more vulnerable to dislocation in accordance with the business cycle.

Less debatable than the causes of Hispanics' labor-market status are the associated economic consequences. The median family incomes of Hispanic families place them below white and above African-American families (Bean and Tienda 1987). Although this socioeconomic ranking by groups has been in place since the 1970s, in 1995 Hispanic median family income actually fell below that of African Americans (del Pinal and Singer 1997). However, the emergence of a solid middle class supports the view of segmented economic integration wherein some groups experience upward mobility while others do not.

Trends in poverty rates also indicate that Hispanics are losing ground relative to African Americans. Not only have Hispanic poverty rates risen over time, but they appear resistant to improvement when the economy rebounds. Although black poverty rates have historically exceeded Hispanic poverty rates, this situation changed during the 1990s, when black poverty dropped faster than Hispanic poverty. Thus, by 1995 black and Hispanic family poverty rates had converged, and for

some population subgroups (e.g., single-mother families and children), Hispanic poverty rates exceeded those of blacks for the first time.

Poverty rates are higher among immigrants compared to native-born Hispanics; and, among specific national origin groups, Mexicans and Puerto Ricans experience the highest risk of poverty. In 1995 more than one in three Puerto Rican families had incomes below the poverty level, compared to 22 to 28 percent for the other Hispanic groups. Even Cubans, the most highly educated of the Hispanic groups, experienced poverty rates double those of non-Hispanic whites in 1995—16 versus 6 percent, respectively (del Pinal and Singer 1997). Puerto Rican families headed by single women have the highest poverty rates, as nearly two of every three such families were poor in 1995 compared to only 30 percent of Cuban and 50 percent of Mexican mother-only families. In part, these differences among national origin groups reflect the groups' nativity composition. That is, because recent arrivals have relatively low skills, even their high rates of labor-force participation cannot shield them from poverty wages. A working poverty explanation also is consistent with the failure of Hispanic poverty to rebound during periods of economic recovery. Puerto Ricans are a possible exception, inasmuch as their poverty derives more from nonwork than that of Mexicans or Central/South Americans.

INTEGRATION PROSPECTS

The changing demography of Hispanics has direct implications for the integration of Hispanic immigrant minority groups and raises questions about assimilation prospects. The rapid growth and residential concentration of the groups, coupled with the rising salience of immigration as a component of demographic growth, revitalizes Hispanic cultures and fosters maintenance of Spanish. That Hispanics have some of the lowest naturalization rates of all immigrant groups hinders their political participation and, for some observers, raises questions about their commitment to becoming American.

Puerto Ricans are U.S. citizens by birth and enjoy most of the privileges that citizenship confers, while Mexican and other Latin American immigrants who enter legally must wait at least five

years to apply for citizenship. Those who enter illegally have an uncertain status in the United States as long as they remain undocumented. That Puerto Ricans have been less successful economically than Mexicans raises questions about the significance of citizenship as a requisite for socioeconomic integration. The newest wage-labor migrants—Colombians, Dominicans, and Central Americans—appear to fare better than Puerto Ricans, posing yet another challenge to conventional understandings about immigrant assimilation processes. However, it is too early to determine their long-term prospects, which likely will depend more on changes in labor market opportunities and the educational achievement of the second generation than on processes of discrimination and social exclusion. Furthermore, the growing number of undocumented migrants among these groups could undermine their social and political leverage over the short to medium term.

Although it is difficult to predict the long-term integration prospects of any group, the diversity of the Hispanic experience complicates this task further because of the uncertain future of immigration and the economy, and because the political participation of Hispanics has traditionally been low. While the spatial concentration of Hispanics allows native languages to flourish and under some circumstances promotes ethnic cohesion, some observers interpret the rise and proliferation of ethnic neighborhoods as evidence of limited integration prospects, irrespective of whether the segregation is voluntary or involuntary. An alternative interpretation of high levels of residential segregation among Hispanics, particularly recent arrivals, is that of ethnic resilience. This perspective maintains that in the face of inter-ethnic tensions and economic adversity, individuals rely on their ethnic compatriots for social supports and hence promote solidarity along ethnic lines. One implication of this view is that ethnic resilience is the *consequence* rather than the *cause* of unequal integration prospects—that Hispanics' tendency toward elaborate ethnic ties reflects their tentative acceptance by the dominant society. As such, ethnic traits become enduring rather than transitional features of Hispanic neighborhoods.

A similar debate over the integration prospects of Hispanics clouds the issue of Spanish-language retention, which is politically significant

because it provides a ready target for policies designed to assimilate linguistically diverse populations and because Spanish-language retention is a ready scapegoat for the poor educational achievement of Hispanics. Spanish is the second most common language spoken at home in the United States, but it is also a limiting attribute because two of five Hispanics reported that they did not speak English well or at all in 1990 (del Pinal and Singer 1997). Although this circumstance could prohibit labor-market integration, this is not necessarily the case in ethnic neighborhoods where virtually all business transactions can be conducted in Spanish. According to Lopez (1996), in Los Angeles, Spanish has become the *lingua franca* of the city's working class. As such, the public use of Spanish symbolizes and reinforces the ethnic stratification of the Hispanic population, particularly in areas of high residential concentration. Public use of Spanish by the poorer segments of the Hispanic population not only reinforces stereotypes about poverty and immigration but also reinforces beliefs about the limited integration prospects of Hispanics.

Furthermore, considerable controversy about the socioeconomic consequences of bilingualism exists, yet the preponderance of research shows that Spanish retention and bilingualism per se are not the sources of Hispanic underachievement. Rather, the failure to acquire proficiency in English is the principal culprit (Bean and Tienda 1987). In support of the distinction between bilingualism and lack of proficiency in English, there is some evidence that bilingualism may be an asset, albeit only among the middle classes who are able to convert this skill into social and financial resources (Tienda 1982). The failure of many Hispanics to achieve proficiency in English certainly limits their economic opportunities, but it is facile to equate lack of proficiency in English with bilingualism, which does not preclude proficiency in English. Although Spanish maintenance among Hispanics is more pervasive than is the maintenance of Asian languages among respective national origin groups, language shifts clearly indicate linguistic assimilation toward English dominance (Lopez 1996). Bilingualism is pervasive among second-generation Hispanics, but by the third generation bilingualism is less common than English monolingualism (Lopez 1997b). In short, language trends indicate that Hispanics are becoming assimilated to U.S. society and culture.

Finally, the long-term integration prospects of Hispanics depend on whether and how groups from specific localities or national-origin groups mobilize themselves to serve ethnic interests. Despite the convenience of the pan-ethnic label for statistical reporting purposes, Hispanics do not represent a unified political force nationally, and the fragility of their coalitions is easily undermined by demographic, economic, and social diversification. Hispanic populations of all ages and citizenship statuses affect routine electoral politics and contribute to the electoral power of registered Hispanic voters by the weight of numbers, which is the basis of redistricting. However, greater numbers are insufficient to guarantee increased representation, particularly for a population with a large number of persons under voting age, low rates of naturalization and voter registration, and, among registered voters, a dismal record of turning out at the polls. Most important is the low adult citizenship rate of 54 percent, compared to 95 percent for non-Hispanic whites and 92 percent for blacks (Rosenfeld 1998). That voter turnout also varies by national origin further divides the fragile Hispanic political alliances, such as the Hispanic congressional caucus, by splitting the Hispanic vote along class and party lines.

In the 1992 U.S. elections, Mexican Americans cast only about 16 votes per 100 persons compared to 50 for every 100 non-Hispanic whites. Cubans cast 29 votes for every 100 persons in the 1992 election; and despite their high citizenship rate (93 percent), Puerto Ricans cast only 24 votes for every 100 residents on the U.S. mainland. Other Hispanics, with an adult citizenship rate of 43 percent, cast 17 votes for every 100 residents in 1992. Despite low rates of voting relative to population shares, Hispanics have increased their representation at all levels of political office. Rosenfeld (1998) analyzed changes in Hispanic elected officials in the five southwest states from 1960 to 1995, a period that captures the entire trajectory of Hispanic electoralism in all states except New Mexico. The analysis considered the universe of elected officials in each state, including statewide and legislative offices as well as U.S. House and Senate seats relative to the voting-age population. Empirical trends indicate the emergence of Hispanic electoralism, which he characterizes as the achievement of a steady and significant level of

Hispanic representation throughout the political system.

Thus, political behavior also points to greater political integration, albeit slow and with some uncertainty for the future. This is because most of the gains in political representation and Hispanic electoralism occurred prior to 1980, and the rapidly changing demographic and socioeconomic profile is less predictable. The political status of Hispanics underwent rapid changes during the 1990s, and the eventual outcomes are far from certain. Low rates of naturalization are beginning to reverse. For Mexicans, this has been facilitated by changes in Mexican law that permit dual citizenship in Mexico and the United States. Furthermore, legislative changes that tie access to welfare benefits to citizenship status have also encouraged many immigrants to naturalize. Finally, the higher priority given to citizens in sponsoring relatives for admission to the United States also intensified demand for naturalization. However, there persist large differentials by national origin (del Pinal and Singer 1997), with Mexicans lagging far behind Cubans and Central/South Americans.

CONCLUSIONS

Several lessons can be culled from the scholarly literature and public discourse about the social and economic future of Hispanic Americans. One is that generic labels, such as "Hispanic" and "Latino," are not useful for portraying the heterogeneous socioeconomic integration experiences of specific national-origin groups. A second major lesson is that the evolving differentials in economic standing of Hispanic national origin groups are rooted in the distinct *modes of incorporation* of each group, which in turn have profound implications for short- and long-term integration prospects. A third major lesson, which is related to the second, is that the socioeconomic imprint of Hispanic Americans will be as varied as the population itself. Changes in immigrant composition and residential segregation will play decisive parts in determining how Hispanics shape the ethnic landscape of the United States into the twenty-first century.

The nagging question is: Why does there persist a close association between Hispanic national origin and low social standing? On this matter there is much debate, but both sides accord great emphasis to the role of immigration in deciding

the socioeconomic destiny of Hispanic Americans. One interpretation—the replenishment argument—emphasizes how immigration continues to diversify the composition of the population by introducing new arrivals on the lower steps of the social escalator, even as earlier arrivals experience gradual improvements in their economic and social statuses. The recency of immigration of a large share of the Hispanic population has direct implications for other demographic, social, and economic characteristics. They are younger, and less proficient in English, and many cannot vote because they are not citizens. Immigrants are also more likely than native-born Hispanics to be working class and to have lower education levels. Consistent with the predictions of classical assimilation theory, the replenishment hypothesis implies that observed differences in socioeconomic standing among Hispanics will disappear with time, irrespective of country of origin or period of arrival. Lending support to this prediction is a growing body of evidence showing that later arrivals fare better in the U.S. labor market and social institutions than do earlier arrivals.

Despite some compelling aspects of the replenishment argument, it falls short of accounting for the limited social mobility of Mexicans and Puerto Ricans, the two groups with the longest exposure to U.S. institutions and traditions. These experiences challenge the immigrant-replenishment hypothesis and place greater emphasis on the complex set of circumstances that define distinct modes of incorporation for the major national-origin groups and subsequent entry cohorts. The structural interpretation emphasizes the role of unique historical circumstances in which each national origin group established its presence in the United States and acknowledges that social opportunities depend greatly on the state of the economy and public receptiveness toward new arrivals.

Unfortunately, it is too early to evaluate the relative merits of the two hypotheses, especially in the absence of the longitudinal data required to trace socioeconomic trajectories of successive generations. That the future of immigration (its volume, source countries, and composition) is highly indeterminate further aggravates the difficulties of assessing these hypotheses. Of course, the greatest uncertainty about immigration concerns the volume and sources of illegal migrants. Finally, the socioeconomic fate of Hispanic Americans as a

whole and as separate national origin groups will also depend on the extent to which Hispanic elected and appointed officials use ethnicity as a criterion for defining their political agendas. The early decades of the twenty-first century will be pivotal in resolving these uncertainties.

HISTORICAL ANALYSIS

See Comparative-Historical Analysis; Event-History Analysis; Historical Sociology.

HISTORICAL SOCIOLOGY

Used as a category to identify social scientific research that constructs or illustrates theory by careful attention to culturally, geographically, and temporally located facts, historical sociology (or, from the historian's vantage point, sociological history) exists as a self-conscious research orientation within both of its parent disciplines. Popular assertions in the 1950s and 1960s that history involved the study of particular facts while sociology involved the formulation of general hypotheses (see Franzosi and Mohr 1997, pp. 133-139 [for the historians' view]; Lipset 1968, pp. 22-23; McDonald 1996; cf. Mills 1959, pp. 143-164) had turned around by the early 1980s, at which time Abrams claimed that "sociological explanation is necessarily historical" (Abrams 1982, p. 2; see Burke 1980, p. 28). While this integrative interpretation of the two disciplines reflects the attitudes of many researchers in the respective disciplines, a few persons remain extremely cautious about the merits of integrating them (see Ferrarotti 1997, pp. 12-13).

Abrams's claim is true for much of sociological theorizing, and sociologists realize that seminal research in their discipline has been informed by careful attention to historical information. Nonetheless, fundamental differences exist between history and sociology regarding the choice of research strategies and methodologies. Historical research emphasizes the sociocultural context of events and actors within the broad range of human culture, and when examining events that occurred in early periods of the human record it borrows from archaeology and cultural anthropology, two

companion disciplines. Historians, therefore, who examine premodern material often borrow anthropological rather than sociological insights to elucidate areas where the historical record is weak, under the assumption that preindustrialized societies share basic similarities that sociological theory rarely addresses (Thomas 1963, 1971; cf. Thompson 1972). Historians are likely to choose research topics that are culturally and temporally delimited and that emerge “from the logic of events of a given place and period” (Smelser 1968, p. 35; see Bonnell 1980, p. 159). They tend to supplement secondary sources with primary texts or archival data (see Tilly 1981, p. 12).

In contrast, sociological research stresses theory construction and development, and its heavy emphasis on quantification limits most of its research to issues that affect societies after they begin to modernize or industrialize (and hence develop accurate record keeping that researchers can translate into data [see Burke 1980, p. 22]). Many of their methodological techniques—including surveys, interviews, qualitative fieldwork, questionnaires, various statistical procedures, and social-psychological experimentation—have little if any applicability to historians (Wilson 1971, p. 106). (Interestingly, however, a number of historical sociologists are utilizing narratives to elucidate sociologically traditional issues like capital–state relations and urban development [Gotham and Staples 1996; see Isaac 1997; Kiser 1996.]) Given their orientation toward theory, sociologists are likely to choose research topics that are “rooted in and generated by some conceptual apparatus” (Smelser 1968, p. 35; see Bonnell 1980, p. 159). Their data sources infrequently involve archival searches (see Schwartz 1987, p. 12) or heavy dependence on primary texts. Sociologists seem more willing than historians both to “undertake comparative analysis across national and temporal boundaries” and to present generalizations that relate to either a number of cases or universal phenomena (as opposed to a single case [Bonnell 1980, p. 159]). Reflecting these basic differences, social history, which developed out of the historical discipline, concentrates on speaking about lived experiences, while traditional historical sociologists concentrate on analysing structural transformations (Skocpol 1987, p. 28).

Although some historical sociological studies attempt either to refine concepts or rigorously to

test existing theoretical explanations, more often they attempt “to develop new theories capable of providing more convincing and comprehensive explanations for historical patterns and structures” (Bonnell 1980, p. 161). When testing existing theories, historical sociologists argue deductively (by attempting to locate evidence that supports or refutes theoretical propositions), case-comparatively (by juxtaposing examples from equivalent units), or case-illustratively (by comparing cases to a single theory or concept [Bonnell 1980, pp. 162–167]). Both case comparisons and case illustrations can show either that cases share a common set of “hypothesized causal factors” that adequately explain similar historical outcomes or that they contain crucial differences that lead to divergent historical results (Skocpol 1984, pp. 378–379). In any case, historical sociologists occasionally need reminding that, in both their quantitative and qualitative research, they must avoid the “common tendency . . . to play fast and loose with time” (Jensen 1997, p. 50), since the temporal dimensions of events have profound implications for the validity of comparisons.

Sociology’s founding figures—Marx and Engels, Weber, Tocqueville, and, to a limited degree, Durkheim—utilized history in the formulation of concepts and research agendas that still influence the discipline. In various works Marx and Engels demonstrated adroit sociohistorical skills, particularly in *The Eighteenth Brumaire of Louis Bonaparte* (Marx [1885] 1963) and *The Peasant War in Germany* (Engels [1870] 1926). In these studies they moved deftly among analyses of “short-term, day-to-day phenomena” of sociopolitical life, the underlying structure of that life, and “the level of the social structure as a whole” (Abrams 1982, p. 59) to provide powerful examples of historically grounded materialist analysis (see Abrams 1982, p. 63; Sztompka 1986, p. 325).

Weber, who was steeped in the ancient and medieval history of both the East and West, believed that, through the use of heuristically useful ideal types, researchers could “understand on the one hand the relationships and cultural significance of individual events in their contemporary manifestations and on the other the causes of their being historically *so* and not *otherwise*” (Weber 1949, p. 72). However much contemporary researchers have faulted his *Protestant Ethic and the Spirit Of Capitalism* (1930) for misunderstanding

Puritan religious traditions (Kent 1990; MacKinnon 1988a, 1988b) and interpreting them through preexisting philosophical categories (Kent 1983, 1985), it remains the quintessential example of his historically informed sociological studies (see Marshall 1982). Weber's extensive contribution to many aspects of historical sociology (including the linkage between "agency and structure," multicausality, ideal types, and various methodology and substantive issues) receives extensive attention in Kalberg (1994).

Variouly assessed as a historian and a political scientist, Tocqueville also contributed to historical sociology with books that examined two processes—democratization (in the United States) and political centralization (in France)—that remain standard topics of historical sociological research (Tocqueville [1835] 1969, [1858] 1955; see Poggi 1972; Sztompka 1986, p. 325). Similar praise for historical sensitivity, however, has not always gone to a fellow Frenchman of a later era, Emile Durkheim, whose concepts were scornfully called by one historical sociologist an "early form of ahistoricism" (Sztompka 1986, p. 324). Bellah, nevertheless, asserted that "history was always of central importance in Durkheim's sociological work" (Bellah 1959, p. 153) and even argued that, "at several points Durkheim went so far as to question whether or not sociology and history could in fact be considered two separate disciplines" (Bellah 1959, p. 154). Indeed, recent research has identified Durkheim's cross-disciplinary sensitivity in his analysis of the history of French education (Emirbayer 1996a) and "the structures and processes of civil society" (Emirbayer 1996b, p. 112). Nevertheless, Abrams's compromise interpretation may be most accurate concerning most of Durkheim's work. He acknowledges that Durkheim identified the broad process of the Western transition to industrialization, even though his "extremely general framework" demands specific historical elaboration (Abrams 1982, p. 32).

Despite the prominence of history within major studies by sociology's founding figures, subsequent sociologists produced few historically informed works until the late 1950s (cf. Merton 1938). Also during this period (in 1958) the historian Sylvia Thrupp founded the *Journal of Comparative Studies in Society and History*, and since then other journals have followed that are sympathetic

to historical sociology (including *Journal of Family History*, *Journal of Interdisciplinary History*, *Journal of Social History*, *Labor History*, *Past and Present*, *Social History*, and *Social Science History* [Bart and Frankel 1986, pp. 114–116]). The output of interdisciplinary books continued growing throughout the 1960s, and by the 1970s "the sociological study of history achieved full status within the discipline" (Bonnell 1980, p. 157, see p. 156; see Smith, 1991 [for a clear historical overview]).

Studies of capitalist expansion examine such topics as the emergence and consequences of the Industrial Revolution, the rise of the working class, population growth, and the developmental operations of the modern world system. Exemplary studies include Smelser's *Social Change in the Industrial Revolution* (1959) and Wallerstein's *The Modern World System* (1974). Basing his middle-range model on Parsons's general theory of action, Smelser deduced a supposedly universal sequence through which all changes move that involve structural differentiation in industrializing societies (see Bonnell 1980, p. 162; Skocpol 1984, p. 363). He illustrated the applicability of his framework by drawing examples from the economic changes within the British cotton industry during the nineteenth century, followed by additional examples of changes to the lives and activities of workers in that industry. These historical facts, however, were secondary to the model itself.

Wallerstein borrowed from Marxism and functionalism to devise a "world system" theory of the global economy that purports to be universal in its interpretive and explanatory power. He argued that after the late fifteenth and early sixteenth centuries, a "world economy" developed in which economically advantaged and politically strong areas, called "core states," dominated other economically nondiversified and politically weak "peripheral areas." Through "semi-peripheral areas" that serve as "middle trading groups in an empire," resources flow out of the peripheral areas and into the core states for capitalist development, consumption, and often export back to their areas of origin (Wallerstein 1974, pp. 348–350). Within this model Wallerstein mustered a phalanx of historical facts in order to demonstrate the emergence of the world economy above the limited events in various nation-states, and in doing so he "has promoted serious historical work within sociology" (Tilly 1981, p. 42).

E.P. Thompson's exemplary study (1963) took the sociological concept of "class" and presented its historical unfolding in England between 1780 and passage of the parliamentary Reform Bill in 1832 (Thompson 1963, p. 11). He argued that "the finest-meshed sociological net cannot give us a pure specimen of class The relationship [of class] must always be embodied in real people and in a real context" (p. 9). By the end of the era that he examined, "a more clearly-defined class consciousness, in the customary Marxist sense, was maturing, in which working people were aware of continuing both old and new battles on their own" (p. 712). His study stands among the finest examples of historically careful development of a sociological concept.

In contrast to the economic focus on issues involving capitalist expansion, studies of the growth of national states and systems of states examine political topics such as state bureaucratization, the democratization of politics, revolutions, and the interaction of nations in the international arena. Three heralded historical sociology studies in this genre are Eisenstadt (1963), Moore (1966), and Skocpol (1979). Eisenstadt studied twenty-two preindustrial states that had centralized, impersonal, bureaucratic empires through which political power operated. After a tightly woven and systematic analysis of comparative social, political, and bureaucratic patterns, he concluded that "in any of the historical bureaucratic societies, their continued prominence was dependent upon the nature of the political process that developed in the society: first, on the policies of the rulers; second, on the orientations, goals, and political activities of the principal strata; and third, on the interrelations between these two" (Eisenstadt 1963, p. 362).

Moore's case studies of revolutions in England, France, the United States, China, Japan, and India sought "to understand the role of the landed upper classes and peasants in the bourgeois revolutions leading to capitalist democracy, the abortive bourgeois revolutions leading to fascism, and the peasant revolutions leading to communism" (Moore 1966, p. xvii). His own sympathies, however, lay in the development of political and social systems that fostered freedom, and he realized the importance of "a violent past" in the development of English, French, and American democracies

(pp. 39, 108, 153). He concluded "that an independent nobility is an essential ingredient in the growth of democracy" (p. 417) yet realized that a nobility's efforts to free itself from royal controls "is highly unfavorable to the Western version of democracy," unless these efforts occur in the context of a bourgeois revolution (p. 418).

Skocpol scrutinized the "causes and processes" of social revolutions in France, Russia, and China "from a nonvoluntarist, structural perspective, attending to international and world-historical, as well as intranational, structures and processes." While doing so she moved "states—understood as potentially autonomous organizations located at the interface of class structures and international situations—to the very center of attention" (Skocpol 1979, p. 33). She concluded that "revolutionary political crises, culminating in administrative and military breakdowns, emerged because the imperial states became caught in cross-pressures between intensified military competition or intrusions from abroad and constraints imposed on monarchical responses by the existing agrarian class structures and political institutions" (p. 285).

Underappreciated by theorists of historical sociology is the growing number of studies that apply sociological categories and concepts to the emergence and development of historically significant religious traditions (see Swatos 1977). By doing so, these scholars have surpassed the traditional sociological and historical colleagues who limit their efforts primarily to political and structural issues, especially ones arising during the late eighteenth to twentieth centuries. Swanson (1960), for example, coded material on fifty hunting-and-gathering societies in an effort to connect religion and magic to social structure, and subsequently analyzed relationships between constitutional structures and religious beliefs around the period of the Protestant Reformation (Swanson 1967). The emergence and early development of major religious traditions has received considerable sociological attention. They include, for example, analyses of early Christianity as a social movement (Blasi 1988), as a millenarian movement (Gager 1975; see Lang 1989, p. 339; Meeks 1983, pp. 173–180), and as a dramatically expansive young religion during the first centuries of the Common Era (Stark 1996). Concepts from sociological studies of modern sectarianism have informed historical studies of Mahayana Buddhism (Kent 1982) and

Valentinian Gnosticism (Green 1982). Weberian examinations continue to influence historically grounded studies of numerous world religions, including ancient Judaism (Zeitlin 1984), Islam (Turner 1974), and other religious traditions from around the world (see Swatos 1990). On a grand scale, religion figures prominently in the work of globalization theorist Roland Robertson (e.g., Robertson 1985; see Robertson 1992).

The historically grounded research in the sociology of religion, along with the works of Eisenstadt and others, suggests that future historical sociological studies will continue pushing beyond the confines of modern, macrosociological topics and into a wide range of premodern historical areas. Likewise, historical issues likely will become more consciously developed in microsociological studies (see Abrams 1982, pp. 227–266), and there will appear more sociologically informed historical examinations of cultural development (still exemplified by Elias 1978). Nonetheless, considerable macrosociological research still needs to be performed on historical issues affecting preindustrializing and Third World countries as well as on recent international realignments between forms of capitalism and communism.

Sometimes coupled with communism's collapse is the reappearance of nationalism and ethnic violence in various parts of the world. The deterioration of the Balkans in what (under Soviet influence) was Yugoslavia, for example, prompted Veljko Vujacic (1996) to develop "a comparative examination of contemporary Russian and Serbian nationalism" by attempting "to demonstrate the usefulness of some of Weber's key theoretical ideas on nations, nationalism, and imperialism" (p. 789). Specifically, he tried "to show how long-term historical and institutional legacies, shared memories, and defining political experiences, played themselves out in the contemporary period, influencing the different availability of mass constituencies in Russia and Serbia for nationalist mobilization under the auspices of new 'empire-saving coalitions'" (p. 789). Despite being faced with the difficult task of utilizing Weberian theory in this comparative context, Vujacic warned, "there is no need to gloss over the frequently bloody and unpredictable consequences of [people's] struggles with unduly abstract sociological generalizations. Instead, we should theorize our narrative, while giving contingency its place" (p. 790). In essence,

narrative accuracy must not be compromised by the demands of theory building.

Innovative methodological techniques continue to enter the historical sociology realm. As outlined by Roberto Franzosi and John Mohr, two such methodologies are network analysis (mapping "the connectivities among people, groups, and organizations" [Franzosi and Mohr 1997, pp. 145–154]) and content analysis ("the use of formal methods for extracting meanings from textual materials" [Franzosi and Mohr 1997, p. 149; see Tilly 1997, pp. 219ff.]). These and other methodologies contribute to the production of respected historical sociology studies on such topics as capitalist expansion, "the growth of national states and systems of states," collective action (Tilly 1981, p. 44; and see Tarrow 1996 for a review of Tilly's work), and the sociology of religious development. (Not to be overlooked, however, are studies of both capital-state relations and urban development and poverty [Gotham and Staples 1996].) Discussion will continue over the relative merits of globalization theory, world systems theory, and modernization theories (see Mandaliou 1996), and globalization theory likely will expand and modify to include greater emphasis on regional world systems, particularly in East-Southeast Asia (Ikeda 1996). The extent to which Michel Foucault's historically grounded, poststructuralist work on the relationships among cultural meanings, self-identities, and social control extend into the historical sociology corpus (for example, Foucault 1979, 1980; Dean 1994; see Seidman 1994, pp. 212–233) remains to be seen.

As older sociological methodologies disseminate within history and newer ones enter the discipline, we will continue to appreciate "the importance of historical sociology in enlarging our understanding of the historical variations in class, gender, revolutions, state formation, religion, and cultural identity" (Somers 1996, p. 53). On a practical level, the profile of historical sociology in its respective disciplines will be enhanced as universities extend cross-appointments of faculty, cross-list courses in methodologies and other topics, share theses and dissertation supervisory responsibilities among history and sociology faculties; encourage interdepartmental co-sponsorship of visiting speakers, and generally enhance the learning and training environments for graduate

students and staff. On a professional level, the American Sociological Association continues to sponsor a section in its annual conference entitled "Comparative and Historical Society."

STEPHEN A. KENT

HOMELESSNESS

Literal homelessness—lacking permanent housing of one's own—is a condition that has been present throughout human history. It has always been dangerous as well, given the necessity of shelter for survival. Nevertheless, the routine occurrence of homelessness in the past probably prevented the problem from generating any extraordinary degree of collective concern. Members of premodern societies often experienced losses or disruptions of residence as a result of food scarcity, natural disaster, epidemic disease, warfare, and other environmental and self-inflicted circumstances. Such forces contributed to the likelihood, if not the expectation, that most people would be homeless at some point in the life cycle.

Ironically, now that homelessness is relatively rare in Western societies, it has achieved a special notoriety. When shelter security becomes the norm, the significance of housing evolves beyond the purely functional. Homes, like jobs, constitute master statuses, anchoring their occupants in the stratification system. Hence, being without a home portends a more general and threatening *disaffiliation*, defined as "a detachment from society characterized by the absence or attenuation of the

affiliative bonds that link settled persons to a network of interconnected social structures" (Caplow et al. 1968, p. 494). This is the broadest meaning associated with the concept of homelessness, at the opposite end of the continuum from its literal definition.

Homelessness, broadly construed, first appeared on the American scene during the early stages of colonial settlement, with paupers, indentured servants, petty criminals, unemployed seamen, and the mentally impaired forming a pool of individuals at risk of vagrancy. It began to assume major proportions as a social problem in the United States near the end of the nineteenth century. Over the several preceding decades, urban homeless populations had emerged in response to a series of events at the national level, including Civil War displacement; the arrival of impoverished European immigrants; seasonal employment patterns in agriculture, construction, and the extractive industries; and severe economic setbacks in the early 1870s and 1890s (Rooney 1970).

As a makeshift remedy, downtown warehouses and old hotels were converted into inexpensive, dormitory-style lodging facilities. The proximity of the lodging facilities to one another, along with the distinctive mix of commercial and recreational establishments growing up around them, helped to concentrate the homeless physically in areas that came to be known as *skid rows* (supposedly named for a "skid road" in Seattle used to slide logs downhill). At the turn of the century, these areas were less burdened by the seedy images later evoked by the term "skid row." Instead, they were vibrant neighborhoods offering a temporary resting place and a range of services to thousands of tramps, the mobile workers who laid the foundation for the U.S. industrial economy.

The manpower needs created by World War I subsequently drained skid row districts, but a pool of footloose veterans replenished them at war's end. An even greater surge in homelessness—one extending well beyond the boundaries of skid row—was soon sparked by the Great Depression. The widespread hardship of the period forced previously domiciled individuals into a migrant lifestyle, and shantytowns (dubbed "Hooverilles") sprang up in urban and rural settings alike. These new manifestations of homelessness in turn stimulated the first generation of sustained research on

the subject among sociologists. Anderson (1940), Sutherland and Locke (1936), and other scholars conducted studies of different segments of the homeless population as part of the Depression-era relief effort.

A second generation of research started in the 1950s. Large-scale single-city surveys—many of which were funded by urban renewal agencies—formed the debate over what to do about deteriorating skid row areas (Bahr and Caplow 1974; Bogue 1963). Demographic data obtained during the surveys showed homeless respondents to be predominantly male, white, single, older, and of local origins. The surveys also lent credibility to the popular view of the homeless as deviant “outsiders.” Depending on the city under examination, between one-fourth and one-half reportedly were problem drinkers, a higher percentage had spent time in jail or prison, most were unable or unwilling to hold down steady employment, many suffered from poor health, and few were enmeshed in supportive social networks. This negative profile based on the survey findings was countered by a parallel body of ethnographic evidence. Field observers like Wallace (1965) portrayed the homeless of skid row in subcultural terms, as a cohesive group with their own language, norms, and status hierarchy. Participation in the subculture was believed to help members cope with a problem more serious than their presumed deviance: extreme poverty.

In the 1970s, almost a century after skid row became a recognizable entity in the American city, its demise seemed imminent. Urban renewal and redevelopment projects had eliminated much of the infrastructure of skid row, while slackening demand for short-term unskilled labor was eroding one of the few legitimate economic roles the area could claim to play. Consequently, several investigators predicted skid row’s disappearance and, by implication, the decline of the U.S. homeless population (Lee 1980). Yet within a decade of such forecasts, homelessness had resurfaced as an important national issue. During the 1980s media coverage of the so-called *new homeless* increased dramatically, and federal legislation (most notably the McKinney Act) was formulated to address their plight. The amount of social scientific inquiry rose as well. Indeed, the recent outpouring of scholarly monographs on the topic has surpassed that of any prior generation of research.

Despite this renewed interest, what is known about contemporary homelessness remains limited, for several reasons. Unlike most groups surveyed by sociologists, the homeless are not easily reached at residential addresses or telephone numbers. The demolition of skid row districts in general and of single-room-occupancy (SRO) hotels in particular, accompanied by social control measures designed to reduce the public visibility of drunks, panhandlers, and other “undesirables,” has intensified the difficulties involved in finding homeless people, pushing a higher percentage of them into more dispersed, obscure locations. Those referred to as the *doubled up*, who stay with settled relatives or friends, are virtually inaccessible to investigators. Also poorly captured by surveys are the many individuals for whom homelessness is of brief duration or episodic in character. Even among the homeless who can be found, participation rates fall far short of perfect. The prospect of further stigma and humiliation keeps some from admitting their condition, thus excluding them from sample membership, while others are too suspicious or incoherent to take part in an interview.

Finally, the political context surrounding the latest wave of research magnifies the significance of each methodological obstacle just identified. Because the homelessness issue has been transformed into a referendum on the ability of the state to meet its citizens’ needs, liberals and conservatives both use the slightest technical shortcoming as ammunition with which to attack any study unfavorable to their own position. Similarly, members of both camps—not to mention the media, advocacy groups, government agencies, and other actors—selectively draw on research results to frame the homelessness problem in a way that attracts (or diverts) public attention. Thus, apparently straightforward “facts” about homelessness—and there are few of these to begin with—become matters open to debate.

“Snapshot,” or single-point-in-time, data on the size of the national homeless population illustrate the uncertain nature of the existing knowledge base. According to an early assertion by advocates, the number of homeless in the United States as of 1982 stood at 2.2 million, or approximately 1 percent of the total population of the country (Hombs and Snyder 1982). However, only two years later the U.S. Department of Housing and Urban Development (HUD) (1984) compiled

a series of estimates, extrapolated from street counts and surveys of informants and shelter operators, that yielded a "most reliable" range of 250,000 to 350,000. A 1987 Urban Institute study arrived at a figure—500,000 to 600,000 homeless nationwide on a single day—that fell between the advocate and HUD extremes (Burt and Cohen 1989). More recently, the Census Bureau enumerated 240,000 homeless people in the course of its massive yet heavily criticized 1990 S-night (street and shelter) operation (U.S. Bureau of the Census 1992).

Although most experts now dismiss the advocate-generated 2 million figure as groundless, the remaining estimates vary considerably. One explanation for this variation is that all are *point estimates*, depicting the size of the homeless population at a specific moment (e.g., a particular day or week). To the extent that the number of homeless changed during the 1980s, studies conducted on different dates should produce different results. Indeed, the trend retrospectively uncovered by several investigators (Jencks 1994)—slow growth early in the decade, rapid increase in the middle, and decline after 1987–1988—seems consistent with the magnitudes of the HUD, Urban Institute, and Census estimates. Others believe that the homeless population grew rapidly throughout the decade, by as much as 25 percent annually in some places. That growth rate could be inflated, though, given the relative stability documented in one of the few large cities (Nashville, Tennessee) for which longitudinal observations are available (Lee 1989).

It is hard to know whether the most credible point estimates accurately reflect the true scope of homelessness. If the homeless population is marked by high turnover, with many people entering and exiting quickly, the total number who experience homelessness over a longer period will be grossly underestimated by a point estimate. Two recent *period-prevalence* studies illustrate this dynamic. In the first study, counts of unduplicated shelter users in New York and Philadelphia suggest that roughly 1 percent of the residents of both cities are homeless each year, and the figure rises to 3 percent for a three-to-five-year interval (Culhane et al. 1994). In the second, 15 percent of the respondents to a nationally representative telephone survey reported that they had been literally homeless or had doubled up with someone else during their lifetimes (Link et al. 1995).

While definitional and methodological differences underlie much of the disagreement over the magnitude of the homeless population, generalizations about its composition have been complicated by (1) the selective emphasis of many inquiries on atypical "slices" of the whole (homeless veterans, the mentally ill, etc.) and (2) real variation in the characteristics of the homeless across communities. Contrary to media reports and popular perceptions, the modal homeless individual is still an unattached male with local roots, similar in fundamental ways to his skid row counterpart of the 1950s or 1960s. Yet there clearly have been significant compositional shifts during the intervening period. Blacks and other minorities, rarely found on skid row, are now overrepresented among the homeless, and women, children, young adults, and high school graduates constitute larger segments of the population both absolutely and proportionally than they once did (Burt 1992; Rossi 1989). Family groupings, usually headed by the mother alone, have become more common as well. Taking these elements of demographic continuity and change together, perhaps the safest conclusion to be drawn is that a trend toward greater diversity distinguishes the new homelessness from the old.

The same conclusion applies with respect to deviant characteristics. Alcoholism, which previously constituted the most noticeable form of deviance among the homeless, is now rivaled by other kinds of substance abuse, and mental illness has surpassed physical illness as an object of public concern. Beyond a rough consensus regarding the greater variety of such problems in the current homeless population, little of a definitive nature is known about them. For example, a review of nine studies cited mental illness prevalence rates that run from a low of one-tenth to a high of one-half of all homeless (U.S. General Accounting Office 1988), and occasional reports suggest that as many as 90 percent are at least mildly clinically impaired. This wide range leaves room for opposing arguments: on the one hand, that pervasive mental illness is the principal cause of contemporary homelessness; on the other, that its presumed causal role represents a stereotypic myth created by the visibility of a small minority of disturbed folk.

Even if the extent of mental illness has been exaggerated, there can be no doubt that the general well-being of the homeless remains low. This is

hardly surprising in light of the stresses that accompany life on the street. The absence of shelter exposes homeless persons to the weather, violence, and other threatening conditions. They have trouble fulfilling basic needs that most Americans take for granted, such as finding a job, obtaining nutritionally adequate meals, getting around town, washing clothes, storing belongings, and locating toilet and bathing facilities. To cope with these difficulties, homeless people draw on a repertoire of subsistence strategies (Snow and Anderson 1993). One of the most common is temporary low-wage employment, often as a day laborer. For some, *shadow work*—engaging in unconventional activities outside the formal economy (scavenging, pan-handling, selling blood, trading junk)—offers a means of survival. Others resort to crime, especially petty theft, prostitution, and drug dealing, or become dependent on service providers.

While frequently creative, such strategies heighten the physical health risks to which the homeless are subjected. Compared to the settled population, a larger percentage of homeless individuals suffer from chronic disorders, and rates for most infectious diseases are at least five to six times greater (Wright et al. 1998). The collective consequence of these conditions is a drastically shortened life expectancy. However, to identify homelessness as the direct cause of higher morbidity and mortality would be an oversimplification. Preexisting health problems can reduce a person's employability, prompting a downward "drift" toward homelessness and lessening the chances of returning to a normal life. Homelessness can also be a complicating factor in the provision of health care. In part because of their circumstances (e.g., lacking transportation, distrusting authorities, being unable to store medicine), many homeless miss appointments and do not follow through with their prescribed treatment. They are, in short, less than ideal patients from the perspective of health professionals, whose goal is to insure continuity of care.

Poor health and other disadvantages associated with homelessness tend to worsen as the length of time on the streets increases. Some people still experience the longer-duration bouts common in the skid row era; close to 10 percent may be homeless for five continuous years or more. These "chronics," by virtue of their visibility, disproportionately influence public perceptions of who the

homeless are, but they now constitute the exception rather than the rule. Results from most surveys indicate that the median episode of homelessness lasts between two months and one year (Burt 1992; Link et al. 1995). Of the persons who fall into this "temporary" category, some are homeless only once in their lives. Many, though, exhibit a more complex pattern marked by frequent exits from and returns to homelessness (Piliavin et al. 1996). For such individuals, being without shelter is just one manifestation of prolonged residential instability.

Whether temporarily or chronically homeless, few prefer to be in that state. But if preference can be ruled out, what forces account for the new homelessness? Among the numerous answers elicited by this question so far, two general classes are discernible. *Structural* explanations treat homelessness as a function of large-scale trends that constrain people's chances for success and that are beyond their immediate control. Scholars point in particular to (1) the decreasing availability of affordable housing; (2) the growth of the poverty population; (3) changes in the economy (e.g., deindustrialization and the expansion of the service sector) resulting in fewer decent-paying, limited-skill jobs; (4) intensifying competition among members of the baby boom cohort during their adult years; (5) the declining appeal of marriage (and the heightened vulnerability of unmarried women and men); (6) the deinstitutionalization movement in mental health care policy; and (7) wider access to controlled substances, dramatically illustrated by the crack cocaine "epidemic" (Burt 1992; Jencks 1994; Wright et al. 1998). The rise of the new homeless is typically attributed to the convergence of two or more of these trends in the 1980s.

The availability of affordable housing has probably received the most attention of any structural factor, in part because all the other trends are thought to operate in conjunction with this one to produce homelessness. The thrust of the housing thesis is that government action, a supply-demand imbalance, inner-city revitalization, and related events have not only priced many low-income households out of rental status but have also eliminated a key fallback option historically open to them: SRO units in downtown residential hotels (Hoch and Slayton 1989; Ringheim 1990). With the depletion of the SRO stock, displacement

from other sectors of the housing market may lead directly to a homeless outcome.

In contrast to the structural approach, *individualistic* explanations posit traits, orientations, or experiences specific to the person as the main causes of homelessness. Few researchers have found much evidence that lacking permanent residence is a freely chosen lifestyle. Nevertheless, the enlargement of the emergency shelter system in recent years has made it easier for poor people who are exposed to domestic conflict or doubled up in a crowded unit to voluntarily head for a shelter as a way of coping with their untenable housing situations. In similar fashion, older thinking about the inherent immorality and wanderlust of skid row denizens has given way to revisionist claims that the primary antecedents of homelessness are deficits in talent or motivation or the debilitating effects of mental illness or substance abuse. Traumatic life events, either in childhood (e.g., sexual violence, placement in foster care or an orphanage) or adulthood (divorce, job loss, a serious health problem), can increase the likelihood of homelessness as well.

Interestingly, many experts who subscribe to some version of the individualistic view have had to invoke associated structural trends—deinstitutionalization in the case of mental illness, for example—in order to explain the size and compositional changes that have occurred in the homeless population in recent years. The tendency to draw on both individualistic and structural perspectives has grown more pronounced with the realization that a theory of homelessness, like that of any social phenomenon, can never be fully satisfying when cast in exclusively micro- or macro-level terms. To date, the work of Rossi (1989) offers the most compelling cross-level synthesis. He contends that structural changes have put everyone in extreme poverty at higher risk of becoming homeless, especially those poor people who exhibit an “accumulation of disabilities,” such as drug abuse, bad health, unemployment, and a criminal record. Being “disabled” forces one to rely on a network of friends and family for support, often over prolonged periods. If the strain placed on this support network is too great and it collapses, homelessness is the likely result.

Though Rossi’s central idea—that structural factors and individual problems combine to make

certain segments of the poor more vulnerable to homelessness than others—seems reasonable to social scientists, it could prove less acceptable to members of the general public. Based on previous research into public beliefs about the causes of poverty, most Americans might be expected to hold the homeless responsible for their lot. However, the small amount of evidence that bears directly on this expectation contradicts rather than confirms it. Findings from a local survey, supplemented with data from a national opinion poll, indicate that (1) more people blame homelessness on structural variables and bad luck than on individualistic causes and (2) many hold a mixture of structural and individualistic beliefs, consistent with the complex roots of the condition (Lee et al. 1990).

The relative frequency of the two types of beliefs is a matter of substantial political significance, since the study just cited shows that each type implies a distinctive set of policy attitudes. As a rule, members of the public who believe in structural causes consider homelessness a very important problem, feel that the response to it has been inadequate, and endorse a variety of corrective proposals, including a tax increase and government-subsidized housing. This policy orientation stands at odds with that for individualistic believers, who tend to devalue homelessness as an issue and favor restrictive measures (vagrancy enforcement, access limitation, etc.) over service provision. Regardless of which orientation ultimately registers the greatest impact on policy making, the sharp contrast between them says much about how homelessness has managed to stay near the top of the U.S. domestic social agenda for the past two decades.

Homelessness also persists as an issue because it is so hard to solve. Out of frustration, many communities have resorted to controlling the homeless. Historically, mechanisms to achieve this goal have included expulsion, spatial containment, and institutionalization (the latter for the sake of monitoring, rehabilitation, or punishment). Other efforts have been aimed at amelioration. For example, the Stewart B. McKinney Homeless Assistance Act recognizes the responsibility of the federal government to meet the basic needs of the “down and out.” Since the McKinney Act was signed into law in 1987, it has authorized billions of dollars for

food, shelter, health care, and other forms of aid (Foscarinis 1996). However, most of the funding is used to support emergency relief programs. The act designates only modest amounts for reintegration initiatives (for example, moving people into transitional or permanent housing) and virtually nothing for prevention. In short, it treats symptoms but not causes.

The effectiveness of legislation like the McKinney Act is further hindered by our federal system of government, which requires an unrealistically high degree of coordination among units at different levels to insure successful and equitable implementation. The current political climate does not bode well for such legislation, either. Repeated challenges have been made to the McKinney Act; critics want to reduce the size of the federal commitment, redirect the homeless toward existing social services (although many do not appear eligible to receive benefits), and give local government more flexibility. In practice, this is likely to mean a continuation of the piecemeal approach already taken in many places, with an assortment of non-profit organizations, religious groups, advocates, volunteers, and state and municipal agencies attempting to do their part. As long as communities lack specific intervention strategies for keeping at-risk residents from losing their housing and for equipping them with essential skills, there will be little change in the status quo.

The United Nations' designation of 1987 as the "Year of Shelter for the Homeless" attests that homelessness has been an international as well as an American concern. The situation in Europe resembles that in the United States in several respects. Although rates of homelessness appear to be slightly lower across the dozen or so European countries for which data are available, the number of people affected annually (at least 2.5 million) is large (Wright et al. 1998). The compositional profile of the European homeless population looks familiar: Its members are disproportionately single, male, from disadvantaged socioeconomic backgrounds, and in poor physical and mental health. Like their American counterparts, they have become homeless as a result of both structural pressures (e.g., a poverty and affordable housing "squeeze") and individual experiences (family breakup, substance abuse, etc.). Remedies for these causes are no easier to come by in Europe than

they are in the United States. The primary response thus far has been to offer emergency relief, with the burden of service provision falling on the private sector.

Homelessness takes a different, more acute form in the developing countries of the Third World, where rapid population growth outstrips the expansion of the housing stock and the economy by a wide margin. Compounding the growth-housing mismatch are prevailing patterns of spatial redistribution: Rural-to-urban migration streams have created huge pools of homeless people in tenements, in squatter communities, and on the streets of many large cities. Besides such demographic trends, periodic events of the kind that once created literal homelessness in premodern societies—drought, earthquakes, food shortages, and the like—still contribute to the problem today outside the West. War (including "ethnic cleansing") and political instability add to the toll.

What is perhaps most striking about homelessness in the Third World context is its youthful face. Visitors to developing nations cannot help but notice the ubiquitous street children; UNICEF estimates that there may be as many as 100 million globally (Glasser 1994). A majority are "on the street" during the daytime, typically performing some sort of economic activity (begging, vending, etc.), but they have a family and dwelling to return to at night. Perhaps 10 percent qualify as literally homeless or "of the street." The children belonging to this group may have run away from difficult family circumstances, been discarded as "surplus kids" by parents unable or unwilling to care for them, or been discharged from an orphanage or other institutional setting. Because children of the street must hustle to survive, they are occasionally romanticized as savvy and resilient. But they also lack adequate diets, are susceptible to criminal victimization, and engage in behaviors such as drug use and prostitution that jeopardize their health.

Sadly, the prospects for weaving a safety net to catch homeless children and adults—let alone for targeting the sources of the problem—must be judged slim in the face of the financial debts, service demands, and other burdens under which Third World governments operate. Possibly because these burdens are so overwhelming,

homelessness—while important—has yet to achieve dominant-issue standing. As one informed observer put the matter, “neither the resources to address the plight of the homeless nor the degree of aroused public sympathy present in the United States are in evidence in the developing world” (Knight 1987, p. 268). However, that is the sector of the world in which a vast majority of all homeless persons will continue to live for the foreseeable future.

HUMAN ECOLOGY AND ENVIRONMENTAL ANALYSIS

With the growing awareness of the critical environmental problems facing the world today, ecology, the scientific study of the complex web of interdependent relationships in ecosystems, has moved to the center stage of academic and public discourse. The term *ecology* comes from the Greek word *oikos* (“house”) and, significantly, has the same Greek root as the word *economics*, from *oikonomos* (“household manager”). Ernst Haeckel, the German biologist who coined the word *ecology* in 1868, viewed ecology as a body of knowledge concerning the economy of nature, highlighting its roots in economics and evolutionary theory. He defined *ecology* as the study of all those complex interrelations referred to by Darwin as the conditions of the struggle for existence.

Ecologists like to look at the environment as an ecosystem of interlocking relationships and exchanges that constitute the web of life. Populations of organisms occupying the same environment (habitat) are said to constitute a *community*. Together, the communities and their abiotic environments constitute an *ecosystem*. The various ecosystems taken together constitute the *ecosphere*, the largest ecological unit. Living organisms exist in the much narrower range of the *biosphere*, which extends a few hundred feet above the land or under the sea. On its fragile film of air, water, and soil, all life depends. For the sociologist, the most important ecological concepts are diversity and

dominance, competition and cooperation, succession and adaptation, evolution and expansion, and carrying capacity and the balance of nature. Over the years, the human ecological, the neo-Malthusian, and the political economy approaches and their variants have come to characterize the field of human ecology.

CLASSICAL HUMAN ECOLOGY

The Chicago sociologists Louis Wirth, Robert Ezra Park, Ernest W. Burgess, and Roderick McKenzie are recognized as the founders of the human ecological approach in sociology. In the early decades of the twentieth century, American cities were passing through a period of great turbulence due to the effects of rapid industrialization and urbanization. The urban commercial world, with its fierce competition for territory and survival, appeared to mirror the very life-world studied by plant ecologists. In their search for the principles of order, human ecologists turned to the fundamental process of *cooperative competition* and its two dependent ecological principles of *dominance* and *succession*. For classical human ecologists, such as Park (1936), these processes determine the distribution of population and the location and limits of residential areas. City development is then understood in terms of succession—an orderly series of invasion—resistance—succession cycles in the course of which a biotic community moves from a relatively unstable (primary) to a more or less permanent (climax) stage. If resistance fails and the local population withdraws, the neighborhood eventually turns over and the local group is succeeded by the invading social, economic, or racial population. Each individual and every community thus finds its appropriate *niche* in the physical and living environment. In the hands of the classical human ecologists, human ecology became synonymous with the ecology of space. Park and Burgess identified the natural areas of land use, which come into existence without a preconceived design. Quite influential and popular for a while was the “Burgess hypothesis” regarding the spatial order of the city as a series of concentric zones emanating from the central business district. However, Hawley (1984) has pointed out that with urban characteristics now diffused throughout society, one in effect deals with a system of cities in which the urban hierarchy is cast in terms of functional rather than spatial relations.

Since competition among humans is regulated by culture, Park (1936) made a distinction between the biotic and cultural levels of society: above the symbiotic society based upon competition stands the cultural society based upon communication and consensus. Park identified the problematic of human ecology as the investigation of the processes by which biotic balance and social equilibrium are maintained by the interaction of the three factors constituting what he termed the *social complex* (population, technological culture [artifacts], and nonmaterial culture [customs and beliefs]), to which he also added a fourth, the natural resources of the habitat. However, while human ecology is here defined as the study of how the interaction of these elements helps maintain or disrupts the biotic balance and the social equilibrium, human agency and the cultural level are left out of consideration by Park and other human ecologists.

NEOCLASSICAL HUMAN ECOLOGY

Essentially the same factors reappear as the four POET variables (population, organization, environment, and technology) in Otis Dudley Duncan's (1964) *ecological complex*, indicating its point of contact with the early human ecological approach. In any case, it was McKenzie who, by shifting attention from spatial relations to the analysis of sustenance relations, provided the thread of continuity between the classical and the neoclassical approaches. His student Amos Hawley, who has been the "exemplar" of neoclassical human ecology since the 1940s, defines human ecology as the attempt to deal holistically with the phenomenon of organization.

Hawley (1986) views the *ecosystem* as the adaptive mechanism that emerges out of the interaction of population, organization, and the environment. *Organization* is the adaptive form that enables a population to act as a unit. The process of system *adaptation* involves members in relations of interdependence in order to secure sustenance from the environment. *Growth* is the development of the system's inner potential to the maximum size and complexity afforded by the existing technology for transportation and communication. *Evolution* is the creation of greater potential for resumption of system development through the incorporation of new information that enhances the capacity for

the movement of people, materials, and messages. In this manner, the system moves from simple to more complex forms.

Hawley (1984) has identified the following propositions, which affirm the interdependence of the demographic and structural factors, as constituting the core of the human ecological paradigm:

1. Adaptation to environment proceeds through the formation of a system of interdependences among the members of a population,
2. system development continues, *ceteris paribus*, to the maximum size and complexity afforded by the existing facilities for transportation and communication,
3. system development is resumed with the introduction of new information that increases the capacity for movement of materials, people, and messages and continues until that capacity is fully utilized. (p. 905)

The four ecological principles of *interdependence*, *key function*, *differentiation*, and *dominance* define the processes of system functioning and change. A system is viewed as made up of functioning parts that are related to one another. Adaptation to the environment involves the development of interdependence among members, which increases their collective capacity for action. Differentiation then allows human populations to restore the balance between population and environment that has been upset by competition or improvements in communication and transportation technologies. As adaptation proceeds through a differentiation of environmental relationships, one or a few functions come to mediate environmental inputs to all other functions. Since power follows function in Hawley's view, dominance attaches to those units that control the flow of sustenance into the ecosystem. The productivity of the key function, which controls the flow of sustenance, determines the extent of functional differentiation. As a result, the dominant units in the system are likely to be economic rather than political.

Since the environment is always in a state of flux, every social system is continuously subject to change. Change alters the life condition of all participants, an alteration to which they must adapt in order to remain in the system. One of the most

significant nonrecurrent alterations is *cumulative change*, involving both endogenous and exogenous changes as complementary phases of a single process. While evolution implies a movement from simple to complex, proceeding through variation and natural selection, cumulative change refers to an increase in scale and complexity as a result of increases in population and territory. Whether the process leads to growth or evolution depends on the concurrent nature of the advances in scale and complexity.

Generalizing the process of cumulative change as a principle of *expansion*, Hawley (1979, 1986) applies this framework to account for growth phases that intervene between stages of development. When scale and complexity advance together, the normal conditions for growth or expansion arise from the colonization process itself. Expansion, driven by increases in population and in knowledge, involves the growth of a center of activity from which dominance is exercised. The evolution of the system takes place when its scale and complexity do not go hand in hand. Change is resumed as the system acquires new items of information, especially those that reduce the costs of movement away from its environment. Thus an imbalance between population and the carrying capacity of the environment may create external pressures for branching off into colonies and establishing niches in a new environment. Since efficiencies in transportation and communication determine the size of a population, the scope of territorial access, and the opportunity for participation in information flows, Hawley (1979) identifies the technology of movement as the most critical variable. In addition to governing accessibility and, therefore, the spread of settlements and the creation of interaction networks among them, it determines the changes in hierarchy and division of labor. In general, the above process can work on any scale and is limited only by the level of development of the technologies of communication and transportation.

Hawley (1986, pp. 104–106) points out how with the growth of a new regional and international division of labor, states now draw sustenance from a single biophysical environment and are converted to subsystems in a more inclusive world system by the expansive process. In this way, free trade and resocialization of cultures create a far more efficient and cost-effective global reach. The result is a global system thoroughly interlinked by

transportation and communication networks. The key positions in this international network are occupied by the technologically advanced nations with their monopoly of information and rich resource bases. However, as larger portions of system territories are brought under their jurisdiction, the management of scale becomes highly problematic. In the absence of a supranational polity, a multipolar international pecking order is then subject to increasing instability, challenge, and change. With mounting costs of administration, the system again tends to return to scale, resulting in some degree of decentralization and local autonomy, but new information and improvements in the technologies of movement put the system back into gear and start the growth process all over again. In the modern period of “ecological transition,” a large portion of the biophysical environment has progressively come under the control of the social system. Hawley, therefore, believes that the growth of social systems has now reached a point at which the evolutionary model has lost its usefulness in explaining cumulative change.

Hawley points out that while expansionism in the past relied on political domination, its modern variant aims at structural convergence along economic and cultural axes to obviate the need for direct rule by the center. The process of modernization and the activities of multinational corporations are a prime example of this type of system expansion, which undermines traditional modes of life and results in the loss of autonomy and sovereignty by individual states. Convergence of divergent patterns of urbanization is brought about by increased economic interdependence among nations and the development of compatible organizational forms and institutional arrangements. This approach, as Wilson (1984, p. 300) points out, is based on the assumption that convergence is mainly a result of market forces that allow countries to compete in the world on an equal basis. He cites evidence that shows how the subordinate status of non-Western nations has hindered their socioeconomic development, sharpened inequalities, increased rural-to-urban migration and rural-urban disparities, and led to the expansion of squatter settlements.

Human ecological theory accounts for the existence of an international hierarchy in terms of functional differences and the operation of its

universal principles of ecosystem domination and expansion. Quite understandably, underdevelopment is defined by Hawley simply in terms of inferiority in this network. Since not all can enjoy equal position on scales of size, resources, and centrality with respect to information flows, Hawley believes that the resulting “inequality among polities might well be an unavoidable condition of an international division of labor, whether built on private or state capitalist principles” (1986, pp. 106, 119).

As the process moves toward a world system, all the limiting conditions of cumulative change are reasserted at a higher level. On the one hand, a single world order with only a small tolerance for errors harbors the seeds of totalitarianism (Giddens 1990). On the other, there is also the grave danger that a fatal error may destroy the whole system. Human ecologists, however, rely on further expansion as the sure remedy for the problems created by expansion. To restore ecological balance, they put their faith in the creation of value consensus, rational planning, trickle-downs, market mechanisms, technological fixes and breakthroughs, native “know-how,” and sheer luck.

The real irony of this relentless global expansion elaborated by Hawley lies, however, in the coexistence of the extreme opulence and affluence of the few with the stark poverty and misery of the majority at home and abroad. The large metropolitan centers provide a very poor quality of life. The very scale of urban decay underscores the huge problems facing the city—congestion, polluted air, untreated sewage, high crime rates, dilapidated housing, domestic violence, and broken lives. One therefore needs to ask: What prospect does this scale and level of complexity hold for the future?

HUMAN ECOLOGY AND THE PROBLEMATICS OF “CHAOS”

Chaos theory is the latest attempt to unravel the hidden structure in apparently random systems and to handle chaos within and between systems. In this view, order and disorder (chaos) are seen as two dimensions of the same process: Order generates chaos and chaos generates order (Baker 1993, p. 123). At the heart of both lies a dynamic element, an “attractor,” that creates the turbulence

as well as re-creates the order. In the human–social realm, Baker has identified center–periphery, or *centriphery*, as the attractor. Baker, however, uses the concepts of center and periphery more broadly to cover not only their application in the dependency approach (which views the exploitation and impoverishment of the non-Western peripheral societies as basic to the rise of the dominant Western capitalist center), but also to carry the connotation of humans as “world-constructors.” Centriphery is, then, the universal dynamic process that creates both order and disorder, as well as accounts for the pattern of human social evolution. The center has an entropic effect on the periphery, causing increasing randomness and denuding it of its resources. But as the entropic effects mount, they are fed back to the center. Beyond a certain point, the costs of controlling the periphery become prohibitive. Should the center fail to come up with new centering strategies, it may split off into subcenters or be absorbed by another more powerful center. Baker is thus led to conclude that “although the effect of feedback is unpredictable, the iteration of a pattern leads to turbulence. The mechanism for change and evolution are endemic to the centriphery process” (Baker 1993, p. 141).

Several things need to be noted about this approach. For one, since these eruptive episodes are random, “the emergence of repeated patterns . . . must be seen as random . . . not as mechanically predictable occurrences. Among other things, the precise character of the emergent pattern cannot be predicted, even though we would no longer be surprised to find a new thing emerging” (Francis 1993, p. 239). For another, Baker’s centriphery theory is essentially Hawley’s human ecological theory recast in the language of chaos theory, with the important difference that a specific reference is now made both to the role of *agency* as “world-constructors” involved in “categorizing, controlling, dominating, manipulating, absorbing, transforming, and so on,” and to their devastating impact on the peripheralized “others,” the victims of progress, who suffer maximum entropy, exploitation, impoverishment, death, and devastation. Even so, Baker’s is the latest, though undoubtedly unintended, attempt to generalize and rationalize Western expansionism and its “chaotic (unpredictable) . . . devastating, and now increasingly well known, impact on native peoples” (Baker

1993, p. 137). As such, the centripetal process, said to explain both order (stability) and disorder (change), is presented not only as evolutionary and irreversible, but also as natural and universal: "Thus, the Western world became a center through the peripheralization of the non-Western world. And within the Western world, particularly in North America, the city, which peripheralized the rural hinterland, became the megapolis whose peripheralizing effects were simultaneously wider and greater." (p. 136)]

Not only the recurrent iteration of this pattern but even its "unpredictable" outcomes (new strategies of control, splitting off into new subcenters, absorption into a larger center, etc.), are also prefigured in Hawley (1986). Its process is expansion, and its "attractor" is none other than the old master principle of sociology: domination or control (Gibbs 1989). While Friedmann and Wolff (1982) characterize world cities as the material manifestation of the control functions of transnational capital in its attempt to organize the world for the efficient extraction of surplus, Lechner (1985) leaves little doubt that Western "[materialism] and the emphasis on man's relation to nature are not simply analytical or philosophical devices, but are logically part of an effort to restore world-mastery" (p. 182).

"ECOLOGICAL DEMOGRAPHY"?

Since the study of organizational dynamics as well as the structure and dynamics of population are at the core of sociology, Namboodiri (1988) claims that rather than being peripheral to sociology, human ecology and demography constitute its core. As a result, he contends that the hybrid "ecological demography" promises a more systematic and comprehensive handling of a common core of sociological problems—such as the analysis of power relations, conflict processes, social stratification, societal evolution, and the like—than any other competing sociological paradigm. However, although human ecologists recognize the possibility of other pairwise interactions in addition to competition, and even highlight the points of convergence between the human ecological and the Marxist point of view (Hawley 1984), human ecology as such does not directly focus on conflict in a central way. In this connection, Namboodiri (1988) points out how the very

expansionist imperative of human and social systems, identified as a central postulate by human ecologists, generates the possibility of conflict between the haves and the have-nots far more in a milieu of frustrated expectations, felt injustice, and a growing awareness of entitlements, which includes claims to their own resources by nations and to a higher standard of living by deprived populations. How these factors affect the development of and distribution of resources and the relationships among populations by sex, race, ethnicity, and other stratifiers should obviously be of concern to a socially responsible human ecology, one that moreover should be responsive to Borgatta's call for a "proactive sociology" (1989, 1996).

The general neglect of cultural factors and the role of norms and agency in human and organizational interaction has also been a cause for concern to many sociologists. While some latitude is provided for incorporating social norms in specific analyses (e.g., in the relationship between group membership and fertility behavior), their macro-orientation and focus on whole populations compels human ecologists and demographers to ignore the role of the subjective values and purposes of individual actors in ecological and demographic processes (Namboodiri 1988, pp. 625–627).

THE HUMAN ECOLOGICAL APPROACH: AN EVALUATION

While the human ecological approach has strong theoretical underpinnings and proven heuristic value in describing Western expansionism and the colonizing process in supposedly objective terms, its central problem is one of ideology. Like structural functionalism, it is a theory of the status quo that supports existing institutions and arrangements by explaining them as the outcome of invariant principles: "Its concerns are the concerns of the dominant groups in society—it talks about maximizing efficiency but has nothing to say about increasing accountability, it talks of maintaining equilibrium through gradual change and readjustment and rules out even the possibility of fundamental restructuring" (Saunders 1986, pp. 80–81). Not surprisingly, human ecologists downplay the role of social class by subsuming it under the abstract concept of a "categorical unit." They also fail to analyze the role of the state and of the interlocking power of the political, military, and

economic establishment, which are centrally involved in the process of expansion and colonization of peoples and cultures. These omissions account for their total lack of concern for the fate of the “excluded others” and the “dark side of expansionism”: colonial exploitation, war, genocide, poverty, pollution, environmental degradation, and ecological destruction. Hutchinson (1993) blames the human ecologists for neglecting or downplaying the role of socioeconomic practices and government policies in creating rental, economic resource, and other differentials. He claims that their analyses tend to be descriptive because they take for granted the existence of phenomena such as socioeconomic or racial and ethnic segregation rather than looking at them in terms of spatial processes that result from the competition between capital and labor.

ENVIRONMENTAL SOCIOLOGY AND THE NEW HUMAN ECOLOGY

The mounting public concern since the 1970s about fuel shortages, oil spills, nuclear power plant accidents, acid rain, dying lakes, urban smog, famine and death in the Sahel, rainforest destruction, and the like has made social scientists realize that overexploitation of the ecosystem may destroy the very basis of our planetary survival. Many environmentalists have blamed the voracious appetite of industrial societies and their obsession with growth for the destruction of the fragile balance among the components of the ecological complex.

Having encountered a seemingly unlimited frontier and an expanding economy, the West has come to believe that expansion is in the nature of things. A major reason for the neglect of the physical environment by American sociologists has, therefore, been the anti-ecological worldview of the dominant social paradigm that has been shaped by this belief. At the same time, the exaggerated emphasis by human ecologists on culture, science, and technology as “exceptional” human achievements has led to the illusion that humans are “exempt” from bioecological constraints to which all species are subject. This awareness has led Catton and Dunlap (1978) to develop the fields of new human ecology (Buttel 1987) and environmental sociology to deal with the reciprocal interaction between human activities and the physical

environment. They believe that the POET model, broadened to include the role of human agency and culture, provides a useful analytical framework for grounding environmental sociology in the ecological perspective.

In a comprehensive review of the new field, Buttel (1987) has pressed for shifting the focus of environmental sociology from the imbalance of population and resources, emphasized by Catton, to the reality of the unequal distribution of these resources. Allan Schnaiberg’s idea of the “treadmill of production” (1980), which emerges from a dialectical relationship between economic growth and ecological structures, points to the need to focus on production institutions as the primary determinants of economic expansion and to incorporate a conflict dimension in environmental analysis. Buttel’s own work in environmental sociology draws on the “political economy tradition” of the neo-Marxists and the neo-Weberians. Catton’s major contributions, on the other hand, are in the neo-Malthusian tradition. While the problem of order created by the harsh realities of industrial life and expansionism had earlier defined the central problematic of sociology and human ecology, the problem of survival now defines the central problematic of environmental sociology and the neo-Malthusian new human ecology: to the earlier question of how social order is possible is now added the more urgent concern with survival itself.

THE POLITICAL ECONOMY APPROACH AND THE NEW URBAN SOCIOLOGY

The conservative nature of the classical and neoclassical human ecology paradigms has also come under attack from theorists who focus on the internal contradictions and the global reach of capitalism to understand urban phenomena.

Smith (1995) has argued that a new urban sociology paradigm, which draws on neo-Marxist sociological theory, urban political economy, dependency theory, world-system analysis, and critical theory, has now become dominant and largely supplanted human ecology and the old urban sociology approach to the study of urban phenomena. The conflict between the two approaches is an aspect of the old conflict between the structural-functional and the neo-Marxist (conflict) perspectives in the field of sociology generally. Whereas

human ecology's main concern is with how technological change enables population aggregates to adapt to their environment through changes in social and spatial organization, the new perspective underplays the role of technological determinants or functional imperatives in shaping the urban landscape. It focuses instead on social inequality and conflict, and highlights the role of economic and political elites, states and other institutional actors, and powerful global forces in order to analyze the problematic "underside" of modern city life: urban poverty, housing segregation by race and social class, urban fiscal crises, deindustrialization, structured inequality in the built environment, and the massive level of human misery associated with the rapid growth of megacities in the Third World (Smith 1995, p. 432.) The new approach looks at urban growth within the context of the international division of labor engendered by the global reach of the expansionary logic of competitive capitalism. This process, which translates aspects of competitive capitalism into geographic space, involves "the creation and destruction of land and built environments we term 'cities.' [Moreover,] this leads to concentrations and locational shifts of human populations, infrastructure, and buildings within the urban landscape (resulting in suburbs, neighborhoods, slums, etc.)" (Feagin 1988, p. 23, quoted in Smith 1995, p. 438).

A "new urban paradigm" in the political economy tradition has been put forward by Gottdiener and Feagin (1988) as an alternative to the human ecological and the expansionist paradigms discussed earlier. Rather than treating societies as mere population aggregates or as unified biotic communities, the new urban paradigm treats them as specified by their mode of production. In this view, crisis tendencies and profit generation constitute the core of societal development, which is seen as dominated by the process of capital accumulation. Thus, to take one example, conventional human ecologists like to regard central-city restructuring as a consequence of adaptation to increasing population size and the growing complexity of social organization. They then relate these changes to the size of the metropolitan hinterland. The new urban paradigm, on the other hand, emphasizes the impact of the global economy, multinational corporations, the shift to functional specialization in world-system financial and

administrative activities, the constant subsidization by the state, the efforts of pro-growth coalitions, and changes in labor-force requirements leading to some renovation and central-city gentrification. It tends to focus on power and inequality, the production and reproduction of capital accumulation, crisis adjustment in sociospatial organizations, and such other processes. The following are some of the basic questions that the new urban sociology paradigm seeks to answer: What is the character of power and inequality? How do they relate to "ecological" patterns? How do production and reproduction processes of capital accumulation, as well as the processes of crisis adjustment, manifest themselves in sociospatial organization?

THE CRISIS OF THE NEW URBAN SOCIOLOGY

However, having apparently supplanted human ecology, the new urban sociology itself appears to be in a state of deep crisis (Hutchinson 1993). Among other things, many of its practitioners are now claiming that the new urban sociology lacks a paradigm equivalent to that of human ecology; that its contribution is critical rather than substantive; that its viewpoint is far more ideological than empirical; and that it lacks a unifying focus, there being as many new urban sociologies as there are its practitioners (La Gory 1993, p. 113). At the same time, while asserting that "what is most salient about the new approach is . . . its direct challenge to the theory and method of ecology," Gottdiener and Feagin (1988) deride the attempt "to pick and choose from some of the new literature . . . areas of compatibility, thereby turning the new approach into a mere footnote of the old" (p. 167). However, in view of the inadequacy of both approaches, La Gory (1993) suggests the use of network analysis as the preferred strategy for devising a revised urban paradigm that is informed by both the strengths and shortcomings of these two perspectives. And noting the considerable conceptual convergence between the two approaches, Smith (1995) argues for a *synthesized* urban theory that will require the fleshing out of Hawley's theory of social organization, technology, and population distributions by incorporating the contributions of the new urban theory regarding the nature and content of the global competitive capitalist system. Thus, Smith claims that while the new

urban sociology can provide human ecology with a better understanding of power and dominance and how class interests play a central role in shaping urbanization, human ecology can help the new urban theory pay more attention to the demographic processes and variables in order to develop a theory of demographic change under global capitalism.

ECO-CATASTROPHE AND ENVIRONMENTAL COLLAPSE

Industrial and industrializing nations are now beset with more or less the same devastating problems of air, land, and water pollution and environmental destruction. Large numbers of lakes and rivers that were not naturally eutrophic have now become so as a result of pollution and chemical runoffs. In the United States, Love Canal and Times Beach, Missouri, made headlines in the 1980s as much as Chernobyl did in 1986 in the Soviet Union. Sulfur dioxide emissions from industrial and power plants cause acid rain that inflicts irreparable damage on buildings, monuments, marine life, trees, and plants. More than 60,000 synthetic chemicals are now on the market, of which a sizable number contaminate the environment and pose health hazards. Over half a million tons of toxic wastes are produced each year in the United States, while the five-year cost of cleaning nuclear waste, which remains dangerously radioactive for thousands of years, may well exceed \$30 billion. The soil, lake water, and groundwater near nuclear power and weapons plants are heavily contaminated with such toxins as mercury, arsenic, and many types of solvents, as well as with deadly radioactive materials such as plutonium, tritium, and strontium-90. The contamination is so bad in eight states that huge tracts of land are said to be totally unfit for human habitation and pose serious health hazards for the surrounding communities. The siting of dump sites in minority communities and the international shipment of hazardous waste to non-Western nations raise serious issues of environmental justice. With an annual production of solid waste that doubled between 1960 and the late 1990s to nearly 225 million tons, the United States is producing more garbage than any other nation in the world and will soon be facing a huge problem of disposal as its 2,300 landfills run out of room and their leachates pose serious threats of toxicity.

The environmental destruction is far more serious and widespread in eastern Europe and the republics of the former Soviet Union. These countries are the sites of some of the world's worst pollution. Lakes and rivers are dead or dying. Water is so contaminated in some areas that it is undrinkable. Chemical runoff and sewage and wastewater dumping have created serious groundwater contamination. Lignite (brown coal), the major source of energy for industry and homes in some of these nations, is responsible for the heavy concentration of sulfur dioxide and dust in the air that has caused serious respiratory problems and additional health damage. The haze-covered cities are an environmental disaster. According to Worldwatch estimates, the former Soviet Union alone accounted for a fifth each of global carbon dioxide and sulfur dioxide emissions—the former are implicated in global warming; the latter are the principal ingredient of acid rain. These environmental problems thus not only span transboundaries, they also cut across ideological labels.

In non-Western nations, a million people suffer acute poisoning and 20,000 persons die every year from pesticides. Pesticides are a major source of environmental and health problems in the United States as well. But the United States alone exports more than half a billion pounds of pesticides that are restricted in or banned from domestic use. The ecology, natural environment, and resources of these non-Western nations are being destroyed and contaminated at a frightening rate. Irreversible damage is being done by large-scale destruction of rainforests and the intensive use of marginal lands, as well as by the imbalances that result from population pressures and the practices of multinational firms and national elites. Desertification now threatens a third of the earth's land surface. Poverty, hunger, starvation, famine, and death are endemic throughout much of the world.

RELATION BETWEEN POPULATION AND THE ENVIRONMENT

What lends urgency to the current population-resource crisis for the West is the fact that while human numbers are declining or standing still at most in industrial societies, they are increasing disproportionately in the rest of the world, a

world divided today not only economically and sociopolitically, but also demographically. The technological mastery of the world has resulted in a higher material standard of living in the West, but it has also spelled economic polarization, ecological ruin, and environmental disasters worldwide. At the same time, hunger, famine, poverty, and overpopulation in the rest of the world have raised critical issues of equity, justice, security, and human survival. While the close link among poverty, population growth, and environmental degradation is invariably highlighted by the neo-Malthusians and the media, the impact of unsustainable patterns of consumption and production on the environment does not receive equal emphasis. Much more disconcerting is the fact that the use of the population argument tends to divert attention away from the role of exploitative and oppressive social institutions and arrangements. Schnaiberg and Gould (1994) find the lack of control over industrial production systems rather than population growth to be the main factor contributing to the underdevelopment of Southern societies. Without minimizing the danger of overpopulation, they find clear historical evidence that the worldwide environmental disruption has been caused not by population growth but by the enormous expansion of production, profits, and surplus in the past century. And based on available evidence, Humphrey and Buttel (1982) have been led to conclude that “[one] of the most important findings to come from the study of the relationship between population size and the environment is the misplaced importance given to world population size as cause of natural resource scarcities and pollution . . . [We do not] imply that world population growth should be . . . neglected as a cause of environmental problems, [but] a fixation on it as the major reason for pollution and energy crises would be sociologically misguided” (p. 60).

Depending on their consensus or conflict orientation, we find that the dominant perspectives on the population–resource dynamic place differential emphasis on the alternative modes of resolving competition over scarce resources. In this respect, the modern division of labor, highlighted by Durkheim, is but one of several modes of resolving competition over scarce resources. Schnore (1965, pp. 12–13) offers a number of alternative survival strategies, which may involve one or a combination of the following: (1) demographic

changes resulting in the elimination of excess numbers (increase in the death rate, decrease in the birthrate, and migration); (2) technological changes that allow for the expansion of the resource base (the exploitation of unused or existing resources, availability of new areas and new resources, resource substitutions, etc.); and (3) organizational changes that allow for the support of larger numbers (occupational and territorial differentiation, revolutionary changes that redistribute the surplus among the many, and reduction in the general level of living to support increased numbers).

For human ecology, the most salient aspect of the population–environment relationship is the way it affects human survival and the quality of human life. Under the impact of the interlocking crises of overpopulation, resource depletion, and environmental degradation, issues of sustainability and survival have come to occupy center stage. Corresponding to the main approaches in human ecology, three broad positions may be identified for discussion: the pro-growth (expansionist), the neo-Malthusian, and the political economy perspectives. Our discussion of these positions is followed by a consideration of the Brundtland Report, issued by the World Commission on Environment and Development, and of the traditional-Gandhian view of the ecological crisis. Extended treatment of the issues involved may be found in Catton (1980), de la Court (1990), Humphrey and Buttel (1982), Mellos (1988), and Schnaiberg and Gould (1994).

The Pro-Growth (Expansionist) Perspective.

To explain the growth patterns of modern society, this approach builds on the foundations of “the new synthetic theory developed in the biological sciences in the last forty years, . . . mixing in elements of neo-Malthusian theory, Marx’s historical materialism, and modern systems theory” (Lenski 1979, p. 14). It seems quite likely, however, that the basic elements of expansionism, now presented as a natural universal process, were derived from the fundamental American experience of abundance and an open frontier conceived as a process. As Avery O. Craven (1937) put it more than sixty years ago, the basic idea was “that American history . . . presents a series of recurring social evolutions in diverse geographical areas as a people advance to colonize a continent. The chief characteristic is

expansion; the chief peculiarity of institutions, constant readjustment . . . Into . . . raw and differing areas men and institutions and ideas poured from older basins, there to return to a more or less primitive state and then to climb slowly back toward complexity The process was similar in each case, with some common results but always with ‘essential differences’ due to time and place” (quoted in Potter 1954, p. 145–146.)

In expansionist thinking, scale, complexity, and acceleration—that is, the constant broadening of the limits of the maximum permitted by prevailing circumstances—mark the human–environment encounter. Hawley’s version of human ecology, with its focus on population growth and differentiation as significant processes of continuous change, provides a concise exposition of the pro-growth or expansionist view on the population–resource problematic. Hawley believes that industrial systems have no known upper limits on either the number of specializations or the size of the populations that can be supported. Similar pro-growth sentiments are expressed by other expansionist thinkers. Asserting that resource supplies are finite but unbounded, Hawley (1986, pp. 110–111) questions the neo-Malthusian assumption that overpopulation and overuse will soon exhaust a declining supply of fixed resources. While acknowledging the threat of overpopulation and pollution to the quality of the environment, he points to the inherently expansive nature of populations, technology, and organization that has resulted in a long history of resource expansion through more efficient extraction and use of new and existing resources, new resource development, and resource substitutions. With regard to global food-producing resources, he presents evidence to show that the size of arable land, its productivity, and its agricultural output can be increased beyond the rate of population growth. He blames poverty and the structural conditions that generate it for the chronic food shortages in parts of the world and points to the indispensability of further increments of growth and the creation of central organizations capable of tackling these and other environmental problems. Contrary to the view of the Malthusians, he holds that the expansive power of populations by itself does not cause war, resource depletion, or environmental degradation; it does so only under specific organizational circumstances. Hawley (1986, p. 26) views

these outcomes as the result of the maladaptation or malfunctioning of organization, with disequilibrium opening the possibility for evolutionary change through a movement to a higher level of complexity.

While Colin Clark directly links population numbers to power, Herman Kahn (1974) views population increase as a necessary stimulus to economic growth and believes the earth can easily support 15 billion people at \$20,000 per capita for a millennium. In fact, he believes that the wider the gap between the rich and the poor, the more the riches will percolate downward. In any case, he is unconvinced that the rich would agree to part with their income to ensure a more equitable distribution of wealth. Roger Revelle (1974) believes the earth can actually support nearly thirty times the present population in terms of food supplies and that it would take almost 150 years to hit that mark. While economic development is necessary to provide people with the basis to control their fertility, Revelle is certain the world would drown in its own filth if most of the people in the world were to live at Western standards. Finally, the postindustrial sociologist Daniel Bell (1977) is convinced that economic growth is necessary to reduce the gap between the rich and poor nations. He has little doubt that the “super-productivity society,” with less than 4 percent of its labor force devoted to agriculture, could feed the whole population of the United States, and most of the world as well. In his opinion, pollution exists because the market principle has never been applied to the use of collective goods. Actually, Bell suggests that the government itself could utilize the market to demand a public accounting from all parties on issues of public interest, levy effluent charges for pollutants, and bring effective compliance through the price mechanism.

However, while corporations have shown greater sensitivity and self-regulation, there is evidence that attempts to enforce the “polluter-pays” principle are likely to be resisted or the costs passed on to the public. The negative impact of governmental policies that alleviate energy and resource scarcities is more likely to be felt at the lower socioeconomic levels (Morrison 1976). Dunlap (1979) presents evidence to show that the effects of pollution and the costs of cleaning the environment are borne disproportionately by the poor and may actually serve to reinforce class inequalities.

The Neo-Malthusian Perspective. Within the context of actual and perceived resource scarcities worldwide, neo-Malthusianism has gained ascendance since the 1970s over the earlier theories of demographic transition and neoclassical human ecology (expansionism), which were dominant through the 1960s. Based on the Malthusian notion that population invariably outruns food supply because of a lag between the simple arithmetical increases in resources and the exponential rates of population growth, the neo-Malthusians bring in the notion of *carrying capacity* to identify overpopulation as the main threat to human planetary survival. However, in spite of the fact that there is no exact or objective formula for determining the *optimum population*, the neo-Malthusians tie in the notion of carrying capacity—the optimum population that a given environmental resource base can support at a given time—with the idea of an acceptable quality of life that one *insists* on living. Sometimes the theory of demographic transition, discussed below, is also invoked to explain why Western societies have been able to avoid the Malthusian apocalypse by joining declining death rates and birthrates with increasing standards of living, while non-Western societies cannot, given the least likelihood of their ever achieving Western levels of industrial and economic development, and the sheer impossibility of the whole world living at U.S. standards within the constraints imposed by the finite nature of the earth's resources (Daly 1979).

Compounding the environmental effects of the poverty-stricken and “food-hungry” populations of the world are the impacts of massive consumption and pollution by the “energy hungry” nations (Miller 1972, p. 117). The latter rise sharply with even a slight growth in the population of Western nations, where one-quarter of the world's population is responsible for more than 85 percent of worldwide consumption of natural resources and the environmental sinks. Within the United States, a bare 6 percent of the world's population consumes more than half of the world's nonrenewable resources and more than a third of all the raw materials produced. G. Tyler Miller, Jr. (1972, p. 122) believes that the real threat to our life-support system, therefore, comes not from the poor but from the affluent megaconsumers and megapolluters who occupy more space, consume more natural resources, disturb the ecology more,

and directly and indirectly pollute the land, air, and water with ever-increasing amounts of thermal, chemical, and radioactive wastes. While the Club of Rome (Meadows et al. 1972) and the other neo-Malthusians gave a grace period of thirty or so years, Catton (1980) believes we have already overshoot the maximum carrying capacity and are now on a catastrophic downward crash course. In any case, he is convinced that our best bet would be to act as if a crash were imminent and to take advance measures to minimize its impact.

However, the basic premises of Malthusian theory have not stood the test of time. With each technological breakthrough, the Western nations have so far been able to raise their carrying capacity through extending their territorial and environmental reach, which now reaches to the ends of the globe. The social and economic forces unleashed by the Industrial Revolution not only telescoped the doubling of human population within a shorter time span, they also brought about ever-rising material standards of living due to astronomical increases in the scale and speed of agricultural and industrial production in the advanced nations. While the Malthusian theory predicts the fall in growth rates of population as a result of rising death rates, this prediction failed to apply during the period of industrial growth. The theory of *demographic transition* was proposed to cover the anomalous results. The theory specifies declining fertility as a consequence of modernization and economic development. However, in the West itself, smaller families became a clear option only after the newly affluent had suffered a major setback in higher living standards during the Great Depression. On the other hand, the downward transition of fertility worldwide appears to be the result of a complex of factors, including the declining role of tradition and religion, rising levels of income, the increasing role of women's education and outside employment, urban residence and industrialization, and the awareness and availability of fertility-control measures (Weinstein 1976, p. 85). Many of the generalizations based on the demographic-transition theory have thus proved to be culturally and historically specific.

At the same time, the “development” of poor nations has created a new set of claimants for the resources needed to maintain the high material standard of living of affluent nations. As the poor nations begin to assert control over their own

resources, try to set terms of their exchange, or resist outside pressures to transform them into “environmental preserves” or the “global commons,” the prospects of conflict, particularly over critical water, mineral, forest, and energy resources, are greatly magnified. Amartya Sen (1981) has looked at the famine situation as essentially a “crisis of entitlement,” not so much because there is lack of food but because many are denied any claims to it because of the very nature of the market economy. In the West, the entitlement revolution has entailed huge welfare expenditures, which could be financed either by economic growth or by direct redistribution of income (Bell 1976, p. 20). For Bell and the neo-Malthusians, the latter is out of the question.

To restore the population–resource balance—with global economic development, equitable distribution of resources, and the perfectibility of man and society now largely ruled out—the neo-Malthusians rely on sophisticated computer models to predict the end to development and limits to economic and demographic growth for the non-Western nations; others favor “sustained environment development”. Still others despair of the effort to avert disaster through population control or the *preventive checks* of moral restraint proposed by Malthus. Instead, they invoke the operation of the Malthusian *positive checks* (wars, famines, pestilence, and natural disasters) and raise the specter of massive famines and die-offs to justify triage, war, secessionist movements, adding sterilants to drinking water, forced sterilization, violent and coercive contraceptive technologies for women, even genocide. In a piece published in 1969 in the Stanford Alumni Almanac, and appropriately titled “The Immorality of Being Softhearted,” Garrett Hardin is quite clear that food would be the worst thing to send to the poor. Nothing short of the final solution will do. “Atomic bombs would be kinder. For a few moments the misery would be acute, but it would soon come to an end for most of the people, leaving a very few survivors to suffer thereafter.” These solutions, which would bring about the decimation of entire populations, have been called *ecofascist*. Such sentiments are by no means uncommon among the neo-Malthusians.

To revert to the neo-Malthusian argument: The tragedy of numbers is compounded by the “free rider,” who derives personal benefits from

the collective efforts of others, and the more serious “tragedy of the commons” (Hardin 1966), where each herdsman will add cattle without limit, ignoring the costs imposed on the others and degrading the land held in common. The “tragedy of the commons” is really the tragedy of individualism run amuck, an individualism from which all constraints of private and common morality have been removed. However, others have been quick to point to the equal or far greater extent of environment pollution and ecological destruction in socialist countries as one more evidence of the inevitable convergence of capitalism and socialism!

Many environmental problems are clearly transideological and transnational. Acid rain, oil spills, the destruction of the ozone layer, the threat of global warming—all call for common responsibility and joint regulation. Ironically, it appears that the expressed concern about the destruction of the global commons through overpopulation or industrial pollution is seldom matched by a parallel commitment by powerful nations to preserve or clean up the environment or provide support for international population-control efforts. Instead, one witnesses a mad scramble to divide up the remaining oceanic and other planetary resources without regard to equity, ecology, or environment. As a result, the air and the oceans, as well as the forests and lands of other nations, are being overexploited or used as garbage and toxic dumps with impunity.

Of no small consequence globally is the environmental impact of waste, widespread corruption at all levels, hoarding and price-fixing, and poor storage, distribution, and transportation networks. Not surprisingly, “formidable mafias based on a triangular alliance between the corrupt bureaucrat, the corrupt politician and the corrupt businessman emerged in all [Indian] States and became a most powerful threat to the conservation of the country’s tree cover” (Vohra 1985, p. 50). When one adds to this list the role of political and economic elites and multinational corporations, and of huge debts, huge dams, and huge arms stockpiles, it becomes clear that poverty, hunger, malnutrition, and starvation may have far more to do with political, cultural, and socioeconomic components of food shortages than with sheer numbers alone. This is not to underestimate the immensity of the population problem or to minimize the difficulty of its solution.

The Political Economy Perspective. With the rise of the “consumer society” and the “welfare state” in the West, and the coupling of the “revolution of rising expectations” and the “entitlement revolution” with the impossibility of generalizing Western levels of consumption worldwide, the problematic nature of the relationship between consumption and production has again come to the fore. On the one hand, food aid and food supply have become powerful political weapons globally; on the other, welfare programs constitute a potentially deprivational means of control (Gibbs 1989, p. 453). Saunders points out that today the basic class divisions centered in the relations of production are increasingly being overlaid by “a division, which cuts right across the class structure, between those with access to individual forms of consumption and those who are reliant on collective provision” (1986, p. 232).

Arguing that the issues of collective consumption must be separated from issues of production and class struggle and that urban struggles develop around the question of social consumption, Saunders contends that by recognizing that consumption may generate its own effects, Castells (1985) opens up the possibility of identifying nonclass bases of power and popular mobilization, as well as nonclass forms of popular aspiration and identity (Saunders 1986, p. 226). It is precisely for this reason that the anticommunism of the counterculture during the 1960s was both hailed as a true “revolution without Marx or Jesus” and also seen as a threat to the very existence of a mass-production society. On the other hand, the current neo-Malthusian demands centered on the impossibility of generalizing Western standards of living (level of consumption) to the rest of the world, or on stabilizing consumption at some “optimum” level for achieving a steady state within western societies, also rest on the possibility of regulating production by manipulating mass-consumption patterns.

Barry Commoner (1974) faults socialist as much as capitalist economic theories for neglecting the biosphere as a major factor of production but regards both poverty and population growth as outcomes of colonial exploitation. The world, he believes, has enough food and resources to support nearly twice its present population. The problem, in his view, is a result of gross distributive imbalances between the rich and the poor, and

requires a massive redistribution of wealth and resources to abolish poverty and raise standards of living in order to wipe out the root cause of overpopulation. The alternative to this humane solution is the unsavory one of genocide or natural destruction. A study of environmental destruction in southern Honduras by Susan Stonich (1989) illustrates the power of a perspective that combines the concerns of political economy, ecology, and demography. Her conclusion is that environmental degradation arises from fundamental social structures and is intricately connected to problems of land tenure, unemployment, poverty, and demography.

Stonich identifies political and economic factors and export-promotion policies of international lending institutions and aid agencies as the key elements of a development policy for the whole of Central America that is likely to lead to destruction of the remaining tropical forests, worsen poverty and malnutrition, and increase inequality and conflicts within and between nations. Government policies encourage commercial agriculture in order to earn foreign exchange in the face of mounting external debt, which rose by 170 percent in just seven years to equal three-fourths of the 1986 gross national product. The expansion of export-oriented agriculture and the integration of resource-poor rural households into the capitalist sector, often by ruthless and violent means, concentrates the highest population densities in the most marginal highland areas and encourages intensive land-use and adaptive strategies that accelerate ecological decline. Between 1952 and 1974, as a result of changes in land-use patterns, forest land declined by more than two-fifths and the area lying fallow by three-fifths. In the same period, food-crop production was reduced drastically while pasture area rose by more than half regionally and by more than 150 percent in the highlands, where the number of cattle rose by about 70 percent. By 1974, a third of all rural families were landless; two-fifths were below the subsistence level in 1979.

The result has been the evolution of a class of rich peasants raising export-oriented cattle and cash crops, a class of land-poor and landless peasants and wage laborers, and a class of middlemen operatives who serve as transportation links in an expanding regional and national network. The whole socioeconomic structure has an extremely deleterious effect on the regional ecology and

environment. These patterns are being repeated all over Africa and Asia. Even the “green revolution,” which uses the model of American agribusiness to commercialize agriculture in non-Western countries, provides only a temporary respite. Its recurrent and increasingly high capital requirements for seed, fertilizer, insecticide, water, land, and machinery wipe out the small farmers and landless laborers. It destroys peasant agriculture, exposes the monocultures to destruction by disease and pests, magnifies inequality, and sows the seeds of social instability and rural strife. To those who subscribe to the political economy perspective, the bioecological explanation thus appears to be too simplistic. It overlooks the social context of development and land distribution within which worldwide destruction of traditional agriculture and the rainforests is now occurring.

In sum, these considerations bring out the fact that debates surrounding resource distribution and the control of population and consumption patterns are neither entirely scientific nor purely ecologically inspired. As Barry Commoner (1974) points out, they are political value positions. Will the changes come voluntarily, or will they involve totalitarian nightmares? “Sustainable development” and “traditional ecology” hold out two contrasting possibilities for the future.

THE BRUNDTLAND REPORT AND THE PROMISE OF SUSTAINABLE DEVELOPMENT

At the heart of the Brundtland Report of the World Commission on Environment and Development (1987) is the idea of *sustainable development* that has become the rallying point for diverse agendas linking poverty, underdevelopment, and overpopulation to environmental degradation and “environmental security.” The report defines sustainable development as “development which meets the needs of the present without compromising the ability of future generations to meet their own needs.” Its popularity lies in its ability to accommodate the opposing idea of limits to growth within the context of economic expansion, but with a new twist. As pointed out by Gro Brundtland (1989), the “central pivot” of the notion of sustainable development remains “progress, growth, the generation of wealth, and the use of resources.” The imposition of limits on consumption is then

justified in order to protect the resource base of the environment both locally and globally. At the same time, continuous economic growth is considered essential to meeting the needs of the world’s neediest. In fact, the Brundtland Report indicates that “a five-to-tenfold increase in world industrial output can be anticipated by the time world population stabilizes sometime in the next century” (World Commission on Environment and Development 1997).

Sustainable development is also seen as a strategy to enhance global security by reducing the threat posed by conflict and violence in an inequitable and resource-hungry world. To this end, it promotes a commitment to multilateralism, with a call for strong international institutions to ward off the new threats to security and for the collective management of global interdependence (Brundtland 1989, p. 14). As a result, the interests of economic growth and the environment are seen as mutually reinforcing rather than contradictory. The World Commission Report (1987) duly notes that ecology and economy “are becoming ever more interwoven—locally, regionally, nationally, and globally—into a seamless net of causes and effects.” And the 1990 Worldwatch Institute Report predicts that the world will have a sustainable society by the year 2030 (Brown et al. 1990, p. 175). Meanwhile, the challenge, as Arnold (1989, p. 22) states, is to ensure that the sustainability vision “is not trivialized or, worse, used as one more way to legitimize the exploitation of the weak and vulnerable in the name of global interest and solidarity.”

To its credit, the Brundtland Report singled out some forms of economic growth that destroy resources and the environment. The present \$1 trillion expenditure on armaments, for example, constitutes “more than the total income of the poorest half of humanity.” According to 1990 United Nations estimates, military expenditures in developing countries, which account for 75 percent of the arms trade, had multiplied by seven times since 1965 to almost \$200 billion, compared with a doubling by the industrialized countries. In addition, burgeoning debt, adverse trade policies, and internal instability constitute the overwhelming obstacles to sustained development. The fifty-two poorest nations of the world are now burdened with nearly a \$400 billion debt. With Africa’s total debt approaching \$200 billion (half of its overall gross national product and three to four

times its annual income from exports), its average debt repayments amount to more than half the export income. The debt burden forces the African nations to concentrate on monocrop export agriculture to the detriment of food-crop production and pushes hungry and landless farmers and nomads to marginal lands that they overgraze and overexploit in order to survive. However, with respect to fixing the responsibility for deforestation, the Brundtland Report appears to be of two minds (de la Court 1990). In asserting that to most farmers, especially the poor ones, "wood is a 'free good' until the last available tree is cut down," the report partly sides with the "tragedy of the commons" argument, accusing the poor farmers of being "both victims and agents of destruction." On the other hand, it also points to a different cause: "The fuelwood crisis and deforestation—although related—are not the same problems. Wood fuels destined for urban and industrial consumers do tend to come from the forests. But only a small proportion of that used by the rural poor comes from forests. Even in these cases, villagers rarely chop down trees; most collect dead branches or cut them from trees" (quoted in de la Court 1990, p. 68). In any case, the Brundtland Report became the focal point for global environmental efforts in the 1990s, even though in the United States it remained "America's best-kept secret." It undoubtedly played a crucial role in the United Nations conference on the global environment held in Brazil in 1992.

SOCIAL CHAOS AND THE PROBLEMATICS OF SOCIAL AND ECOLOGICAL INTEGRATION

Dennis Wrong (1994, pp. 295–296) has pointed out how the globalization of the world economy and the accompanying spread of communication and transportation systems to embrace more of the world represent an unprecedented increase in the dissociation of system from social integration, and how the fear of disorder has become more acute in a greatly interdependent world suffering from persistent economic scarcity and a limited capacity for human sympathy with others.

To Scott Greer (1979), the rapid growth of American society, made possible by the increase in societal scale, has led to the following Durkheimian

dilemma: "Increasing interdependence requires more cultural integration than we can manage; growth itself has undermined the cultural support system. While bureaucratization may increase order within a segment of the society, what is to guarantee order among segments?" In the absence of the spirit of consensus generated by war, economic disaster, or a universalized humanity, Greer feels that symbiosis rather than cultural integration may best remedy the fragmentation accompanying the discontinuities of societal growth. Such an approach would not only emphasize trading partners, controlled markets, and formal and informal co-optation, but "given the increasing number of role players who do not 'know their place,' from white working-class men to black college-educated women, such a system will take an awful lot of work by leaders, middlemen, and fixers, as well as some luck" (Greer 1979, pp. 315–316).

Daniel Bell (1976) has made the critical point that while the dominant nineteenth-century view of society as an interrelated web, a structured whole unified by some inner principle, still rules Marxist and functionalist thought, it is no longer applicable. On the contrary, society today is composed of three distinct realms—the technoeconomic structure, the polity, and the culture—each obedient to a different axial (value) principle, each having different rhythms of change, and each following different norms that legitimate different and even contradictory types of behavior. The discordances between these realms are responsible for various contradictions within society. Bell has proposed the creation of a "public household" to overcome the disjunctions among the family, the economy, and the state through the use of modified market mechanisms to further social goals. And given his conviction that the crisis is really a spiritual one of belief and meaning, he recommends the return in Western society of some conception of religion to restore the continuity of generations and provide a ground for humility and care for others. This presents a formidable challenge, however, for Bell is painfully aware that one can neither manufacture such a continuity nor engineer a cultural revolution.

It is doubtful that the problems of order created by the "normal" but dangerous nonrelation between the life-sustaining (ecology–economy) and

order-maintaining (sociopolitical) systems of contemporary society can be corrected, as Bell believes, by the creation of a miraculous hybrid—a “public household”—protected and nurtured by both the polity and the household to serve the interests of the technoeconomic structure and by the side-door entry of the “religious” to provide for the integrative and “higher-order” needs of a socially disjointed and spiritually vacuous society. Even the frantic use of a “holistic” ecological approach is bound to fail if its actual goal is somehow to dominate or desperately hold on to a sundered reality in which everything is so hopelessly *unrelated* to everything else. Since a dependent part cannot grow infinitely at the expense of the others, or usurp the whole for its own purposes without undermining the very conditions of its own existence, the high-powered technoeconomic structure, driven by the insatiable demand for energy, resources, and markets, is inherently disorder-producing and anti-ecological. Its immensity of scale and utilitarian thrust not only destroy traditional structures and sociocultural diversity but also set in motion irreversible and ecologically damaging global processes whose attempted solutions greatly magnify the problems.

That the philosophy and ideology of progress may promote activities inconsistent with sound ecological management and the prospects of human survival is also increasingly being recognized (Peck 1987). But the fact that “‘history’ is not on our side, has no teleology, and supplies us with no guarantees” does not mean to Giddens (1990) “that we should, or that we can, give up in our attempts to steer the juggernaut . . . For we can envisage alternative futures whose very propagation might help them be realised. What is needed is the creation of models of utopian realism” (p. 154). Unwilling and unable to abandon the world-constructionist project, he offers a “post-scarcity” system as perhaps the only possibility but is also bothered by the “dark side of modernity,” the creation of totalitarian power, based on his original insight that totalitarianism and modernity are not just contingently but inherently connected (Giddens 1990, p. 172).

In the stark asymmetry between the disorder-producing and the order-creating powers of the centriphery lies the real “nightmare of reason” and the roots of the current crisis and worldwide chaos. The process is not only incomprehensible

(“complex”), but totally out of control. In this state of affairs, “what is there to love or preserve in a universe of chaos? How are people supposed to behave in such a universe? If that is the kind of place we inhabit, why not go ahead with all our private ambitions, free of any fear that we may be doing special damage” (Worster 1994, p. A3).

TRADITIONAL ECOLOGY AND THE ENVIRONMENT

Patterns of human social organization and technology use reflect the vision a people have of themselves and of their place in the universe. According to Karl Polanyi ([1947] 1974), the question of how to organize human life in a machine society confronts us with a new urgency:

Behind the fading fabric of competitive capitalism there looms the portent of an industrial civilization with its paralyzing division of labor, standardization of life, supremacy of mechanism over organism, and organization over spontaneity. Science itself is haunted by insanity. This is the abiding concern.” (pp. 213–214)

A. K. Saran (1978) does not doubt in the least that the ecological crisis is a self-inflicted one, because an entropic environmental system and an infinitely expanding economy and technology are mutually incompatible. His main argument is that the modern system does not provide a coherent worldview or the proper regulative principle to satisfy the needs of the different orders in a unitive way. In such a system, only a technological solution to the problem of order in the sociopolitical realm can be contemplated, and a piecemeal approach will be relied on to deal with the consequences of a discordant and disharmonious order. In addition to generating tremendous violence, universal disorder, and planetary destruction in the desperate attempt to hold the parts together under its hegemony, such an approach is bound to fail. Since the symbolic is not an integral part of the modern literal consciousness, the attempt to appropriate Mother Earth or other symbols, such as that by the proponents of Gaia, may be ideologically seductive but is both scientifically irrelevant and spiritually vacuous. Neo-Malthusian disclaimers notwithstanding, since evolution has been the master concept to organize and rearrange the world in human terms, the ontology of modern

science is necessarily anthropocentric. Saran's conclusion, therefore, is that there can be no ecological science unless it is grounded in traditional cosmology.

In a study of the Tukano Indians of the northwest Amazon, G. Reichel-Dolmatoff (1977) shows how aboriginal cosmologies, myths, and rituals

represent in all respects a set of ecological principles . . . that formulate a system of social and economic rules that have a highly adaptive value in the continuous endeavor to maintain a viable equilibrium between the resources of the environment and the demands of society. The cosmological myths which express the Tukano world-view do not describe Man's Place in Nature in terms of dominion, or mastery over a subordinate environment, nor do they in any way express the notion of what some of us might call a sense of "harmony with nature". Nature, in their view, is not a physical entity apart from man and, therefore, he cannot confront it or oppose it or harmonize with it as a separate entity. Occasionally man can unbalance it by his personal malfunctioning as a component, but he never stands apart from it. Man is taken to be a part of a set of supra-individual systems which—be they biological or cultural—transcend our individual lives and within which survival and maintenance of a certain quality of life are possible only if all other life forms too are allowed to evolve according to their specific needs, as stated in cosmological myths and traditions. . . . This cosmological model . . . constitutes a religious proposition which is ultimately connected with the social and economic organization of the group. In this way, the general balance of energy flow becomes a religious objective in which native ecological concepts play a dominant organizational role. To understand the structure and functioning of the ecosystem becomes therefore a vital task to the Tukano. (pp. 9–11)

However, modernity in its essence has been totally destructive of the traditional vision of human nature, our proper place in the "web of life," and our conception of the ultimate good. Polanyi ([1947] 1974) points out how with the modern separation of "economy" as the realm of hunger and gain,

[our] animal dependence upon food has been bared and the naked fear of starvation permitted to run loose. Our humiliating enslavement to the "material", which all human culture is designed to mitigate, was deliberately made more rigorous. This is the root of the "sickness" of an acquisitive society that Tawney warned of . . . [The task of] adapting life in such surroundings to the requirements of human existence must be resolved if man is to continue on earth. (p. 219)

The post-World War II creation of the global economy through the idea of "development" is the other half of the story. As pointed out by Wolfgang Sachs (1990), and in line with Hawley's observation, the concept of development provided the United States with the vision of a new global order in which the former colonies were held together not through political domination but through economic interdependence. But to "define the economic exploitation of the land and its treasures as 'development' was a heritage of the productivist arrogance of the 19th century. Through the trick of a biological metaphor, a simple economic activity turns into a natural and evolutionary process. [Soon] traditions, hierarchies, mental habits—the whole texture of societies—were all dissolved in the planner's mechanistic models . . . patterned on the American way of life" (p. 42).

However, even after nearly two decades of development work, the results were far from heartening. Instead of declining, inequality, poverty, unemployment, hunger, and squalor actually increased manifold in all "developing" countries. To summarize: While the expansionist vision tries to tie ecology, economy, and polity together, and the neo-Malthusians add biology to the list, it is in *sustainable development* that all these orders are firmly knit together—but at a price. The paradoxical nature of the term *sustainable development* arises from the fact that it attempts to combine the contradictory notions of limits to growth and active growth promotion. However, if the key to maintaining ecological integrity is economic self-sufficiency and production for use, then the problem today is surely one of the inhuman scale of enterprise based on the "techniques of degradation" (Marcel 1952), which serve nothing higher than human self-interest, and of the concept of

man as having an economically rather than a spiritually determined nature (Coomaraswamy 1946, p. 2).

Roy Rappaport (1976) has documented how the Maring of New Guinea support as many as 200 people per square mile by cultivating nearly forty-five acres of cleared forest at a time without damaging the environment. But then they look at the world and its "resources" through very different eyes!

A PROACTIVE ENVIRONMENTAL SOCIOLOGY

Heightened concern with ecology and the environment has now moved into the mainstream of public life as a major priority at the national and international levels. This provides important opportunities for environmental sociologists to contribute to the understanding and solution of these problems. Constance Holden (1989) has highlighted the report of the National Academy of Sciences that outlines an agenda for both micro and macro social scientific studies of "anthropogenic" stresses on the resources and the environment in the north circumpolar region and that has general application. The fragile Arctic region has a great wealth of natural resources. It comprises one-tenth of the earth's area and has a population of 8 million people, of whom a quarter are natives. The report placed major emphasis on interdisciplinary studies, particularly those linking the social and physical sciences and basic and applied research. It emphasized the need for drawing on native knowledge and put urgent priority on issues such as cultural survival and the allocation of scarce resources. It also asked the social scientists to come up with models generalizable to other areas.

An interesting insight concerns how each of the several identities of the Arctic (e.g., as homeland for the natives, as a "colony" exploited for its natural resources, and as the last wilderness) results in a distinctive approach to human-environment relationships. "These approaches have come increasingly into conflict as subsistence hunters and commercial interests vie for limited stocks of fish and game; communities are shaken by boom and bust cycles in scrambles for mineral resources; and rapid modernization has inflicted trauma on native cultures" (Holden 1989, p. 883). The committee identified three areas of interest to the social scientist. In the area of human-environment

relationships, there is a need for studies on conflict resolution to strike a balance between commercial needs and the interests of subsistence hunters, sportsmen, and conservation. The second area pertains to community viability, for which a systematic approach is needed to help develop a physical and social services infrastructure to meet the special climatic needs of the region. A final area pertains to the study of the impact of rapid social change (single-industry cash economy, the snowmobile revolution), which is exacting a heavy price from the local inhabitants in terms of higher rates of alcoholism, suicide, stress, loneliness, accidents, and violence.

The shift from expansionist to neo-Malthusian thinking seemingly implies an attempt to come to terms with the finitude of the total ecosphere and changed global realities, but the underlying assumptions and contradictions are again not made explicit. The overriding concern has been with the protection of industrial and commercial interests, even where these interests clearly come in conflict with the interests of individuals, communities, and their environment. The commitment to protect growth or a certain way of life at any cost has led human ecologists and neo-Malthusians to disregard the minimum well-being or sheer survival of the rest of humankind. In fact, Hawley (1986) admits that while "competition," resulting from demand exceeding the carrying capacity, may account for the exclusion of some contestants from access to their share of a limited resource, it does not shed "any light on what happens to the excluded members of a population after their exclusion" (p. 127). This serious neglect of the concern for the underdog and the undermined is matched by the self admitted tendency of the human ecologists "not [to] confront policy matters directly" (Hawley 1986, p. 127). Given its reliance on large-scale macro forces to explain other macro-level phenomena, the human ecological approach does not readily lend itself to policy considerations. Even otherwise, since it views spatial patterns as the natural outcome of ecological processes rather than the result of power relations, it becomes a conservative force in policy applications (La Gory 1993, p. 112).

Edgar Borgatta (1989, 1996) has sought to develop an important field called "proactive sociology," with a view to closing the wide gap between sociological theory and practice and to save

sociology from sheer irrelevance. Sociological approaches, even when application-oriented, have been largely timid, inactive, or merely reactive. They have restricted their focus to studying how changes in social policy may alter behavior and social situations, but they have refrained from making policy recommendations for designing social structures to serve accepted values. Proactive sociologists, on the other hand, would have the task not only of clarifying values and specifying their meaning but also of assuming the responsibility for making policy recommendations based on an understanding of appropriate models of change. In stark contrast to the pretended value-neutral and value-free stance of mainstream sociology, Borgatta (1996) would, therefore, push to include the consideration of values, as well as the examination of possible structures to implement preferred values, among the central tasks for proactive sociologists.

In human ecology, for instance, it is with reference to the population-consumption problematic that questions of value and their interpretation become evident. Rather than waiting to study only the aftereffects of “all in the path”—the Three Mile Island radiation leak or the Exxon Valdez oil spill—or stepping in at the end of the “issue-attention” cycle, when the problem is historically interesting but socially irrelevant, a proactive sociology would concern itself with the dynamics out of which problems arise, anticipating potential problem areas and their alternative solutions as the means to translate desired values into effective policy. This would involve identifying possible futures and the consequences of action or inaction for their attainment—a policy dimension ignored by sociologists, despite their belief that this may make all the difference in a fast-changing and turbulent world in which the ability to handle and manage change requires the ability to anticipate change and to adapt social structures to changing requirements. To this end, the sociologist would need to ask whether what he or she was doing would make an impact and be useful to society. The fundamental assumption here is that if we know something about the impact of social structure on behavior, we should be able to propose models for changes in social structures that will effectively implement values that have priority status in society (Borgatta 1989, p. 15). Sociologists would then be obligated to “address societal

values more directly by providing alternate models of potential changes and exploring the consequences these changes may produce if identified values are implemented” (Borgatta and Hatch 1988, p. 354).

Following this lead, a “proactive environmental sociology” would have particular application to the “sociology of environmental issues,” which is concerned with the study of environmental movements, resource management problems, and the like. It would broaden the scope of the sociology of environmental issues by focusing specifically on the changes that are required to effectively implement stated values such as equity, environmental justice, rights of the deprived and of “future generations,” resource conservation, equitable sharing of the global commons, the right to clean and healthy environment, sustainable lifestyles and consumption patterns, and the like, and by exploring the possible consequences of these changes. Thus David Mahar, an adviser to the World Bank, has argued that blaming peasant colonists for deforestation is “tantamount to blaming the victim” for “misguided public policies” that promote road building, official colonization of the forest, and extensive live-stock development, and that “purposely or inadvertently encourage rapid depletion of the forest.” This *definition of the situation* led Mahar to propose an “alternative development model” that would put government action on hold so that, based on land-use surveys, lands “found to have limited agricultural potential—virtually whole of terra firme [*sic*] of Amazonia—would be held in perpetuity as forest reserves.” These and other unconventional conclusions are stated by Mahar as his own and carry the disclaimer that they do not necessarily represent the views and policies of the World Bank itself (cited in Hildyard 1989).

This example also brings out Borgatta’s point that a proactive stance may involve the espousing of unpopular positions. It may lead a proactive environmental sociologist to examine the role of established institutions and values (crass individualism and the impact of “anthropocentric,” “cowboy,” “superpower,” and “commercialized conservation” approaches to the use of finite resources and a fragile environment; wasteful consumption patterns; draconian measures of population control; corporate nonaccountability and the global impact of multinationals, the state, and the like) in

order to facilitate the creation of ecologically sustainable social structures that implement positive environmental values. On this basis, a systematic concern with morality and the application of knowledge would lead to a "proactive environmental sociology" that would prompt the sociologist to formulate alternative policies with respect to the set of environmental values or goals that are to be implemented (Borgatta and Cook 1988, p. 17). This approach would also ensure that the applied aspects of "environmental sociology" would flourish within the discipline and not become detached from sociology, as has been the fate of industrial sociology and many other areas in the past (Borgatta 1989).

OVERVIEW

Environmental sociologists have complained of the lack of a unifying focus within the field and have noted its specialized, fragmented, and dualistic tendencies, which hinder concept and theory development (Buttel 1987, p. 466). This should be a cause for serious concern insofar as the new human ecology is supposed to provide a holistic, integrated understanding of human-environment interactions. In addition to the problems surrounding functionalist as well as Marxist categories and assumptions is the difficulty of adapting bioecological concepts to the human context. Notions such as ecosystem, niche, succession, climax communities, balance of nature, even evolution—none have clear social referents and all pose formidable problems of inappropriate or illegitimate transferal of concepts. Thus, while one finds constant reference to urban or social "ecosystems" in the literature, the wide-ranging, even global, energy-exchange patterns make the boundaries so diffuse that it becomes impossible to locate an urban ecosystem in time and space, at least in biological terms (Young 1983, p. 195). Or, if humans are defined as niche dwellers, the term *niche*, "if adopted directly from biology would produce only one worldwide niche for the entire global species, a result that would render the concept useless. How can the species problem be overcome in adapting such a concept to human ecology?" (Young 1983, p. 795).

Terms such as *the environment* are not easy to define or conceptualize; nor are ecological chain reactions, multiple causal paths, and feedback

mechanisms in complex ecosystems easy to delineate. In recognition of the substantial difference between human and bioecological orders, some human ecologists, such as Hawley, have moved away from bioecological models. Thus, Hawley (1986) is highly critical of the neo-Malthusian application of the "carrying-capacity" notion, on the ground that "while the argument may be suitable for plants and animals, its transfer to the human species is highly questionable" (p. 53). While still shying away from assigning a critical role to human agency, or even a policy-making role to the human ecologist, Hawley has nonetheless broadened the scope of his theory by incorporating culture and norms as ecosystem variables. However, as a commentary on Western-style development and its total disregard for limits, Rappaport has raised more basic objections: To treat the components of the environment as if they were mere resources is to view them exclusively in economic terms and invite "the use and abuse of biological systems of all classes and the neglect of moral and aesthetic considerations in general. Whatever may be meant by the phrase 'quality of life,' exploitation does not enhance it" (1978, pp. 266-267).

Human ecologists, in general, have not dealt adequately with such concerns, nor with the problems of power, domination, and the role of the state and of "values" in human-environmental relationships. At a minimum, one needs to know the role of the state in the regulation, maintenance, expansion, suppression, and "resocialization" of peoples and societies. If ecosystems are constituted of interdependent parts, one needs to know the nature of the reciprocal relationships among the parts and among the parts and the ecosystem. Rappaport (1978) has drawn attention to the maladaptive tendency of subsystems to become increasingly powerful and to dominate and use the larger system for their own benefit, to the detriment of the general interest and the adaptive flexibility of the system. He mentions the dominating positions occupied by huge corporations and the "military industrial complex" as examples. More broadly, Rappaport ties pollution, "resource" depletion, and the diminution of the quality of life and the destruction of its meanings to the scale of modern societies and the voracious appetites of their industrial metabolisms. Thus, while he does

not deny that population increase may have a negative impact on the quality of life, he has little doubt that the real cause of ecosystem destruction and the deterioration of the quality of life is to be found in the way societies are organized, not in their population trends. If that is so, what alternative do humans have?

Within the human ecological perspectives, environmental problems are seen as arising either from the unplanned nature of growth and expansionism, from its attendant externalities and "commons" tragedies, from growth and market restrictions (the pro-growth, expansionist perspective), or from the excess of population over the carrying capacity of the environment (the neo-Malthusian perspective). To restore ecological balance and environmental health, human ecologists place their faith in value consensus, rational planning, systems theory, computer models, economic growth, trickle-downs, market mechanisms, and technological fixes (the pro-growth perspective) or in limits to growth, sustainable development, sticks and carrots, benign neglect, triage, die-offs, outright compulsion, and even genocide (the neo-Malthusian perspective). Within the political economy perspective, on the other hand, the emphasis is on internal contradictions, uneven development, center-periphery relations, capitalist exploitation, the role of multinationals and the state, trade imbalances, and the treadmill of production. To ensure environmental and ecological protection, equitable distribution, and social justice, the proposals from a political economy standpoint range from social revolution to conflict and confrontation, from redistribution to social welfarism and mixed economies.

The political economy perspective is critical of the basic assumption of the Chicago ecologists that changes in population, organization, and the technologies of movement explain expansionary movements and territorial arrangements. By allowing planners to alter spatial forms to dissipate class conflict and social unrest, Smith (1979, p. 255) believes, the perspective becomes a powerful depoliticizing weapon in their hands. He favors "client-centered" planning, which does not assume that "physical structure determines social structure," but holds that both are shaped by the economic and political structures of society, which

provide selective access to opportunities and further discriminatory patterns of land use and investment. Smith therefore offers "conflictual planning" on behalf of the poor and the powerless in order to call attention to the hidden social costs of development and to increase the political costs of pursuing repressive policies disguised as rationally planned allocational, locational, and investment choices. This approach poses three basic questions: "Whose values, interests, and social actions will determine the purpose, pace, and direction of historical change? Can the costs and benefits of historical change be distributed fairly? Can the changes that do occur further the cause of social justice?" (Smith 1979, p. 288).

Schnaiberg (1980) has identified three responses to the contradiction between production expansion and ecological limits: (1) the expansionist, which will be temporary, increasingly unequal, environmentally stressful, and authoritarian; (2) the business-as-usual, which will be unstable, socially regressive, unequal, and of limited environmental value; and (3) the ecological, involving appropriate technology, reduced consumption, and reduced inequality, which will be the most durable but also the most socially disruptive and the least desirable. Schnaiberg's own preference, short of a social revolution, is for a mixed social democratic system like Sweden's, with some production expansion and improved welfare distribution under close state supervision.

However, this solution does not quite address the critical concerns of the environment or the needs of three-fourths of humanity. It presents to the world the anti-ecological model of the "treadmill of production" under a more benign form. It ignores the reality of global inequity, environmental injustice, and global-resource wars—the fact that behind every environmental struggle of today lies a struggle over the expansion of the treadmill of production. It is worth noting that at least in the case of sustainable-yield forestry, Schnaiberg and Gould (1994) no longer look to Sweden as the model. With more than 90 percent of Sweden's native forest now extinct, and its native species replaced by North American tree species, the authors decry that "native plants and animals have been exterminated, sacrificed for an economically-sustainable industry. The Swedish treadmill is

sustained at the expense of the Swedish environment" (1994, p. 210). The real thrust, therefore, is not sustainable development at all but what Vandana Shiva (1990) has called *commercialized conservation*, which puts a dollar value on biodiversity and "justifies conservation in terms of present or future commercial returns" (p. 14). Smith (1979) believes that the environmental problem, like the problem of poverty, has arisen and remains insoluble because of our commitment to existing economic arrangements and institutions and because wealth and power are valued over persons and human need. In fact, the global treadmill operates in such a way that the poor countries often end up financing the development of the rich ones. Thus, during the period from 1982 to 1990, Foster (1995) reports how Third World nations became a net exporter of hard currency to developed countries to the tune of about \$30 billion per year, while also remitting almost \$12.5 billion in monthly payments on debt alone to their creditors in wealthy nations.

While the West is busy presiding over a general reorganization of the global economy and the ways of living throughout the world, the common problem, as Hilary French (1990) points out, is that of finding the proper balance between sufficiency and excess, which she says will be as difficult for the former socialist nations as it has been for the West. In this context, she points out how Czechoslovakia's president, Vaclav Havel, has identified the omnipresent dictatorship of consumption, production, advertising, commerce, and consumer culture as the common enemy.

The uncontrolled greed of the global treadmill has been blamed for the frightening global environmental degradation and for overpowering our sense of responsibility to future generations. "How much is enough" for living a good life (Durning 1992) has become the critical issue today. This concern with sufficiency should lead us to question the equation of consumption with meaningful existence and of the good life with the material standard of living. But such an equation cannot be avoided in a society of abundance, which has to follow the imperative of consumption if its expanding productive capacities are to be put to use. However, since redistribution or any real systemic changes are ruled out, Daly (1979) recommends a control from within based on obedience

to objective value, warning that "if interior restraints on will and appetite diminish, then exterior restraints, coercive police powers, and Malthusian positive checks must increase." (p. 53)

Gandhi, aware both of the fatal attraction and the destructive potential of wanton materialism, saw it as constituting the gravest threat to human freedom, survival, and environmental security. He therefore opted for a simple, nonexploitative, and ecologically sustainable social order. Such a decentralized social order, based on truth and nonviolence, was to be governed by the metaphysically determined optimum levels of wants, technology, and resource use fitted to the requirements of the human scale. In the interim, he demanded that the rich become trustees of the poor in order to serve justice, to mitigate the negative impacts of the differentials of wealth and power, and to avoid class conflicts. His radical vision of a normal social order, nowhere realized as yet, provides a useful yardstick for measuring how ecologically sound and environmentally sustainable a society is in its actual operation. Noting that the world has enough for everyone's needs but not for everyone's greed, Gandhi was convinced that such a social order would come about

only if the means of production of the elementary necessities of life remain in the control of the masses. These should be freely available to all as God's air and water are or ought to be; they should not be made a vehicle of traffic for the exploitation of others. Their monopolization by any country, nation or group of persons would be unjust. The neglect of this simple principle is the cause of the destitution that we witness today not only in this unhappy land but in other parts of the world too. (quoted in Sinha 1976, p. 81.)

From this point of view, while there is little disagreement that overpopulation aggravates environmental and other problems, the attempts to eradicate the root causes of social instability, inequality, and poverty are bound to be far more effective in the long run than the impressive but partially effective approaches to population control. Brian Tokar (1988) has pointed out that, historically, rapid increases in population occur when people become dislocated from their traditional land base and become less secure about their personal and family survival. On the other

hand, populations become stable when the future is secure, the infant mortality rate is low, social choices for women are expanding, and parents are not worried about who will support them in their old age.

How to effect the radical changes required to restore the proper ecological balance and preserve the biocultural integrity and diversity of the global "household," but "without the most fantastic 'bust' of all time" (Ehrlich 1968, p. 169), is the formidable challenge and the urgent task facing humankind. This will involve a redirection of the vast, creative human energies away from a self-defeating and ecodestructive expansionist and wasteful orientation, and their rechanneling into life-giving and life-promoting forms of human action and human social organization.

LAKSHMI K. BHARADWAJ

HUMAN NATURE

Debates over the nature of human nature have characterized social theory since it emerged in the Renaissance. As Thomas Sowell has argued, these debates generally take two forms: the optimistic and the pessimistic (Sowell 1987). The former position, associated with Rousseau and anarchists such as William Goodwin, holds that humans are essentially good but are turned bad by the institutions of their society. The latter position is rooted

in the assumption that humans are fundamentally egoistic and selfish, thereby requiring either a strong state to regulate them or, in a less pessimistic account, an institution like the market to guide their affairs toward an optimal result.

For sociologists, neither position became the dominant way of thinking about human nature; instead, the plasticity of human experience was emphasized. Durkheim (1973) wrote the most important defense of a pluralistic approach to the subject, one that remains unsurpassed to this day in its clarity of presentation. Human nature is dualistic, he argued, speaking to the needs of both body and soul, the sacred and the profane, the emotional and the cognitive, and other such dualities. We are, in short, what we make ourselves. This version of a flexible approach to human nature would come to characterize contemporary theorists such as Parsons, who spoke of "much discussed 'plasticity' of the human organism, its capacity to learn any one of a large number of alternative patterns of behavior instead of being bound by its generic constitution to a very limited range of alternatives" (1951, p. 32).

In current sociological debates, the plasticity of human nature is emphasized by the general term *social construction*. If one argues that we ought to speak of gender roles rather than sex roles—the former is recognized to be the product of how people arrange their cultural rules, whereas the latter is understood to be fixed biologically—one is making a case for plasticity (Epstein 1988). Indeed, given the importance of feminism in contemporary theory, which tends to argue that "nothing about the body, including women's reproductive organs, determines univocally how social divisions will be shaped" (Scott 1988, p. 2), the strength of a plasticity approach to human nature is probably stronger than ever before.

Current research in many areas of sociology is premised on a social construction approach. Work stimulated by ethnomethodology is one clear case. In contrast to a Chomskian understanding of language as originating in rules hard-wired in the brain, the tradition of conversation analysis examines how human beings in real conversation twist and shape their utterances to account for context and nuance (Schegloff and Sacks 1979; Scheff 1986). Moreover, since the language we use is a

reflection of the way we think, it is possible to argue that the mind itself is socially constructed, that the a priori nature of the way we think is relatively minimal (Coulter 1979). Accounts of sociological practice based on the assumption of plasticity do not end there. It has been argued that homosexuality is not driven by biological destiny but is a socially constructed phenomenon (Greenberg 1988). Morality, as well, can be understood as socially constructed (Wolfe 1989). Underlying a wide variety of approaches to sociology—from symbolic interactionism to social problems—is an underlying premise that human nature is not driven by any one thing.

The only dissent from a general consensus about human nature's plasticity is rational choice theory. At least among economists who believe that economic methodologies can be used to study social institutions such as the family, there is a belief that "human behavior is not compartmentalized, sometimes based on maximizing, sometimes not, sometimes motivated by stable preferences, sometimes by volatile ones, sometimes resulting in an optimal accumulation, sometimes not" (Becker 1976, p. 14). Yet there are many versions of rational choice theory; at least one of them, that associated with Jon Elster, is committed to methodological individualism but is also willing to concede the existence of a "multiple self" (Elster 1986). It is far more common in contemporary sociology to speak of egoism and altruism as existing in some kind of unstable combination rather than giving the priority totally to one or the other (Etzioni 1988).

Arguments about human nature, in turn, are related to the philosophical anthropology that shaped so much social theory. It has been a consistent theme of the sociological enterprise to argue that humans are different from other species. From the emphasis on *homo faber* in Marx and Engels, through Weber's notions about the advantages of culture, to Mead's account of why dogs and other animals are incapable of exchanging significant symbols, humans have been understood to possess unique characteristics that determine the organization of their society. Twentieth-century theorists such as Arnold Gehlen or Helmuth Plessner carried forward this tradition and are increasingly translated and read (for an overview, see Honneth and Joas 1988). Even Niklas Luhmann,

whose work is heavily influenced by biology and cybernetics, can still claim that "the decisive advantage of human interaction over animal interaction stems from this elemental achievement of language" (1982, p. 72).

The most important shift in philosophical anthropology in recent years is a shift from an essentially materialist understanding of human capacities to an essentially mental one. Powers of interpretation and narrative, it has been argued, constitute the essential features of the human self (Taylor 1989). Just as an argument about the plasticity of human nature enables sociology to avoid reduction into psychological categories, an emphasis on the interpretive powers of humans prevents a reduction of sociology to sociobiology and other basically algorithmic ways of thinking about evolution.

As with the issue of plasticity, not all sociologists agree either that there are specific human characteristics or that, if there are, they ought to be understood as primarily mental and interpretive. Sociobiologists argue not only that humans are driven by their genetic structure more than they would like to believe but also that other animals also possess cultural skills. There is therefore no fundamental difference between human and nonhuman species, they are merely points along a continuum (Lumsden and Wilson 1981). Both sociologists and anthropologists, consequently, have argued for the use of sociobiological approaches in the social sciences (Lopreato 1984; Rindos 1986; Wozniak 1984), although there are also critics who question such an enterprise (Blute 1987).

In the 1990s, sociobiology, now often called evolutionary psychology, was something of a growth industry. Edward O. Wilson, who did so much to originate the field, sees the possibility of a unified approach to knowledge, one in which the laws of human interaction could eventually be deduced from the physical and the biological sciences (Wilson 1998). In the meantime, others influenced by evolutionary psychology have argued that cultural products such as language and mind can be understood through the laws of evolution (Blackmore 1999; Lynch 1996). Even such specific cultural products as novels and works of art are formed by processes of cultural selection, it has been argued (Taylor 1996). While still something of a minority point of view, trends such as these are premised on

the idea that the natural sciences, especially biology, offer a better model for understanding human societies than the sociological tradition as derived from Durkheim, Weber, and Mead.

Another challenge to the anthropocentric view that social scientists have taken toward humans has arisen with cognitive science and artificial intelligence. Whereas classical sociological theory compared humans to other animal species, we can now compare them to machines. Computers, after all, process information just as human brains do, use language to communicate, and reason, and can, especially in new approaches to artificial intelligence called connectionist, learn from their mistakes. There are, consequently, some efforts to apply artificial intelligence to sociology just as there are efforts to use the insights of sociobiology (Gilbert and Heath 1986), although here, again, there are strong critical voices (Wolfe 1991; Woolger 1985). In the more recent work of Niklas Luhmann, as well as in the writings of some other theorists, emphasis is placed on information science, systems theory, even thermodynamics—all of which are approaches based on a denial that human systems require special ways of understanding that are different from other systems (Bailey 1990; Beniger 1986; Luhmann 1989).

In spite of efforts to develop sociological theory on the basis of algorithmic self-reproducing systems, it is unlikely that assumptions about the unique, interpretative, meaning-producing capacities of humans will be seriously challenged. It is the capacity to recognize the contexts in which messages are transmitted and thereby to interpret those messages that make human mental capacities distinct from any organism, whether natural or artificial, that is preprogrammed to follow explicit instructions. One reason humans are able to recognize contexts is precisely the plasticity of their mental capacities. The plastic theory of human nature, in short, overlaps with an emphasis on philosophical anthropology to produce an understanding of human behavior that does not so much follow already-existing rules so much as it alters and bends rules as it goes along.

Both understandings of human nature and accounts of specifically human capacities will be relevant to future efforts in sociological theory to reconcile micro and macro approaches. Although there has been a good deal of effort to establish a

micro-macro link (Alexander et al. 1987), the more interesting question may turn out not to be not whether it can be done but whether (and how) it ought to be done. Systems theory and the information sciences provide a relatively easy way to make a link between parts and wholes: Each part is understood to have as little autonomy as possible, so that the system as a whole can function autonomously with respect to other systems. The micro, like a bit of information in a computer program, would be structured to be as dumb as possible so that the macro system itself can be intelligent. Nonhuman enterprises—computers on the one hand and the structure of DNA in other animal species on the other—show that there is a major bridge between the macro and the micro. But the cost of constructing that bridge is the denial of the autonomy of the parts, a high cost for humans to pay.

But the conception of human beings as preprogrammed rule followers is not the only way to conceptualize micro sociological processes. The traditions of ethnomethodology and symbolic interactionism, which are more compatible with notions emphasizing the plasticity of human nature, imagine the human parts of any social system as engaged in a constant process of renegotiating the rules that govern the system. When the micro is understood as plastic, the macro can be understood as capable of existing even in imperfect, entropy-producing states of disorder. Indeed, for human systems, as opposed to those of machines and other species, disorder is the norm, integration the exception. If there is going to be a micro-macro link in sociology, it may well come about not by denying human plasticity and uniqueness, but rather by accounting for the particular and special property humans possess of having no fixed nature but rather a repertoire of social practices that in turn make human society different from any other kind of system.

HUMAN RIGHTS, CHILDREN'S RIGHTS, AND DEMOCRACY

Sociology has existed in universities and as a research and scholarly profession for more than a century, but it has serious problems in justifying its existence in terms of demonstrating that the knowledge it produces is useful. In its early stages of development, sociology was often coupled with social work or with other fields such as anthropology, political science, and economics. However, as universities grew, the social and behavioral science fields became differentiated, and in the post-World War II period sociology not only grew but flourished and developed a major identity in the universities. However, more important, within the field applied interests were often disparaged. In

large part, fields such as social work, family studies, industrial relations, systems analysis, administration, criminology, penology, and others became independent major entities as sociologists denigrated the notion of being involved in applied research and practice. In fact, in the last decades of the twentieth century sociologists appear more often to be seen as possible peripheral members in social research rather than the organizers of major social research, which is frequently motivated by practical, applied considerations.

Still, it is occasionally noted that sociology has been useful, but it is frequently and necessarily a quite modest statement. For example, it is often pointed out that sociology led much of the development and diffusion of statistical and other analytic procedures in the social sciences. Sociology also led the way in developing procedures for systematic data collection, which it has not only shared with other academic disciplines but which has become a part of common daily life, such as polling, investigative reporting, and so on. And the interest in social problems, consistent but peripheral for sociology over the years, has led to some involvement in race and ethnic relations, women's rights, and human rights more generally. Incidentally, while sociology has failed to move in the direction of applied science, psychology has virtually exploded in that direction, leading to concern over the years that that discipline might detach its academic and research interests from the applied professional and clinical aspects. Indeed, the field of psychology has moved into areas of application neglected by sociology, such as family relations, group counseling and therapy, and environmental and ecological studies; other sister disciplines, such as anthropology, economics, and political science have made a similar move in order to increase the scope of development of applied interests.

THE RELEVANCE OF SOCIOLOGY

It is not unreasonable to raise the question: If sociology is presumed to be adding to the knowledge of the world, how can it be useful? This question has been raised throughout the history of the discipline, but that does not mean it has gotten serious attention. As a recent positive example, note the work of Turner (1998) and the subsequent comments on the topic. Another recent

consideration of "The Value of Sociology" that provides perspective is the article by Snow (1999), but to some extent much of the discussion about the value of sociology is abstract, albeit broader than some earlier particularistic orientations, which took the view that if sociology was not valuable, it would not be in the college or university curriculum. Two sentences from the abstract of Turner's article (p.243) provide an orientation to answering the question: "It is argued that sociological theory and its applications to real world problems should constitute the core of the discipline Sociology should redefine and reorient its practice to create an engineering discipline where abstract theoretical principles are boiled down to rules of thumb and used to build or tear down social structures" (p. 243). This is a more direct statement of the idea that sociology should be useful.

Part of the reason for the hesitancy of sociologists to become interested in applied research is the way the field was defined—as "the science of society." Scientists study and analyze their subject matter, but they do not determine what is right and proper for society. The task of determining laws, custom, and mores is not seen by them as being their task, and indeed there is commonly great concern that the values of social scientists should not influence their research and scholarly work. Thus, applied research in sociology has often been defined as examining what is going on in a social situation, in order to determine the underlying social forces at work. If a social policy is involved, the aim of the research may be to see if it is working; with the introduction of a new social policy, research is most typically aimed at seeing whether stated objectives can be confirmed. Much of the interest in applied research in the social sciences became associated with the concept of "evaluation research," particularly in the post-World War II period, with stimulus from sociologists such as Donald Young and Leonard S. Cottrell, Jr., at Russell Sage Foundation. However, stimulus for evaluation research occurred in other ways as well, such as through laboratories and research centers in educational psychology, social psychology, and other behavioral and social sciences, with research often being supported by such government agencies as the National Institute of Mental Health. These thrusts led to two important developments for the social and behavioral sciences.

The first was the growth of methodological sophistication, often identified with the classic codifying work on quasi-experimental research design by Campbell and Stanley (1963) and Cook and Campbell (1979). The second was the notion that evaluation research could be of two types: conventional research, in which the disinterested researcher merely seeks to describe what happens when policy changes are introduced, and "formative" research, wherein the social scientist is not only involved in the evaluation of the consequences of policy changes but is a consultant in the process of identifying the changes needed to accomplish the goals of proposed policy, often with sequential evaluations and changes when the desired results do not materialize with the initial changes.

Throughout this history of social science involvement in applied research, evaluations have often produced negative (i.e., no change) findings, and in some cases even retrogression or reversal on the intended change direction and/or unintended consequences. But, independently of all these results, it can be asked whether the presumed knowledge of sociology and the social sciences is being used effectively, and the answer has been that this does not appear to be the case, at least in the context of one type of criticism. This critique has been advanced many times in different ways, and in the context of this article it will be phrased as not satisfying options of "proactive sociology" (see Borgatta 1991, 1994, 1996). In particular, do sociologists evaluate the social and behavioral structures that exist in society and put them in a comparative perspective? Do sociologists examine the values that exist and describe them objectively, presumably correctly interpreting what they are? Do sociologists examine stated values and see how well social structures that exist implement the identified values? Before proceeding to further consideration of these questions, consider one relevant case.

DEMOCRACY AND INDIVIDUAL RIGHTS

While no form of government can effectively be defined as maximizing the provision of human rights and children's rights, there is a strong basis for arguing that democratic forms are more likely to do so in the long run than other governmental forms. There are a fair number of nations that at this juncture appear to be reasonably well oriented

to protecting human and children's rights, but attention to a little bit of history should keep one from becoming complaisant about the prospect. For example, in the United States slavery existed until the end of the Civil War, less than a century and a half ago. Until the amendments that followed the Civil War, if one read the Constitution of the United States one might have thought women were entitled to the same rights as men, but they were not. The assumption that women were not entitled to the same rights as men was so ingrained in the culture that it was not even necessary that it be made explicit. It was a world in which men governed; women did not even get the right to vote until half a century after the end of the Civil War. And the history of the expansion of the United States and its relationship with Mexico and with the American Indians may give pause to those who think that simply having a government that is labeled a democracy is one in which "social justice" writ small and large is to be expected.

In a democracy the de facto rules do not necessarily provide equal protection under the law for all persons, and the majority or even a smaller segment of society may define the rules. In more recent times, there have been examples of restrictive abuse in the United States, as in the passing of the constitutional amendment that established "prohibition" of alcohol. Aside from attempting to restrict the choice behavior of citizens, the amendment created the era of gangsters and racketeers. Although that constitutional amendment was repealed, there remain numerous laws prohibiting access to certain substances among the most obvious of which are the laws restricting "drugs." More than the outlawing of alcohol during prohibition, the drug laws have created the circumstances leading to the incarceration of the overwhelming majority of the roughly 1.5 million people in the U.S. prison system today. But more generally, in a democracy, all kinds of laws may be passed that restrict individual rights. Germany's progression from a democratic government to Hitler's dictatorship, although an extreme case, should never be forgotten. Similarly, the cases in which liberal or "socialist" regimes have been overthrown with the help of the great American Democracy, only to be followed by totalitarian regimes, may be seen as disturbing.

To continue with the example of the United States, the McCarthy period in the 1950s is an

example of rampant political witch hunts. But consider even the more recent partisan political situation, also termed a witch hunt by some, involving a person as powerful as the president of the United States. A Republican majority in the House of Representatives voted to impeach the president, sending two articles of impeachment to the Senate, which was to "try" the president to determine his guilt or innocence, with a guilty finding by two-thirds of the Senate requiring removal from office. Here we will not discuss the constitutional issues involved, or the moral and legal failings of the president in the matter, but only pay analytical attention to the strange articles of impeachment to show how subtly the power of a majority can create a situation that counters "fairness" and fails to protect even the rights of a president (see *Congressional Record*, December 19, 1998).

Two articles of impeachment were passed in the House of Representatives by an essentially partisan vote of the Republican majority; here *attention will be given only to the question of what is minimally necessary to arrive at a guilty verdict by two-thirds, or 67, of the 100 senators*. Article I states in part: "Contrary to that oath, William Jefferson Clinton willfully provided perjurious, false and misleading testimony to the grand jury concerning one or more of the following . . ." Then four alleged "testimonies" were noted. Now, any sociologist or statistician should be able to analyze the charge and ask the question, "What would the minimum guilt attribution be to create a majority of 67 senators voting guilty?" Simple, since only one alleged testimony is required to judge the president guilty, if 16 senators voted guilty on the first testimony and 17 different (nonoverlapping) senators voted guilty on each of the three other testimonies, the majority of 67 would be created to judge the president guilty of Article I. Thus, the extraordinary situation exists that *theoretically the president could be judged guilty by no more than 17 senators on any of the four testimonies, but he could be judged guilty by 67 senators because of the way the question was formulated!* What a strange way for a democracy to operate. Of course, the situation is even more ridiculous with regard to Article II, which is also defined in the "one or more" fashion, but involves seven "acts," leading to the situation that theoretically the minimum number of senators needed (nonoverlapping) is 9 for three "acts"

and 10 for each of the other four to get a cumulative majority of 67 senators voting guilty. Thus, it can be seen how the Republican congressmen were able to structure a vote in any way they wished, since they constituted the majority in the House of Representatives. It has been said many times that an effective democracy requires constant attention to how power is used and how the rights of all individuals, even of the president, are protected.

Democracy is a common topic of study, and topics relevant to issues of human rights are implicit in many presentations, as, for example, those in a special issue of *International Sociology* ("Democratic Culture," 1999).

HUMAN RIGHTS AND CHILDREN'S RIGHTS

With regard to human rights and children's rights, attention must be given to providing, as much as possible, for the protection for all persons, and presumably this can happen most dependably in a democracy. However, some things need to be emphasized. Special rights can be legislated for particular individuals or groups, and because they are often accepted as reasonable, this may lead to some abuses and strange situations. For example, *it has been repeatedly stated that with regard to human rights, the attribution of status on an inherited basis does not correspond to a concept of equal opportunity and equal treatment*. If this is the case, then how do equal opportunity and equal treatment operate with regard to other aspects of inheritance? If a parent is rich, owning \$70 billion of assets, the child could inherit roughly \$30 billion in the United States under current law. If the parent is poor, the child may not inherit anything. Further, in being raised in the rich family, the child may have extraordinary forms of support and access to resources that the poor child does not have. The capitalist system may provide the possibility of upward mobility in a democracy, but considering the advantages of the wealthy, the playing fields for the rich and the poor are not equal. Thus, even if the state mandates a strong support system for all children, human rights and children's rights are still subject to a relative notion of the importance of inherited status. *Question: How much attention do sociologists give to this kind of analysis and identification of the values involved?* The sociologist, of course,

should be able to note that the general system even in a democracy can provide a very strong support of inherited status. The acceptance of inherited status is still rampant in much of the world, beginning with any nation in which there is a notion of royalty, which of course includes Great Britain and some other developed nations that are classed as democracies.

This article began by noting that sociologists and other social scientists should become more concerned with the possibility of proactive involvement in social change. As regards the above example, a major concern of the sociologist would be not only to consider and analyze the consequences of existing social policy, but also to *realistically represent* the value system that presumably underlies the social policy. As has been implicit thus far, social policy often does not correspond to the values that are espoused. There is reason for concern in being involved in this proactive orientation, since often values are not consistently aligned and may conflict. *Most dramatically, a traditional view of the family may conflict with the notion that children are due equal opportunity and access to resources in society, the provision of which necessarily becomes a community or state function. The tradition of parental "ownership" of children simply may conflict with providing children with equal access to the resources that exist in the society.* Thus, the analysis of values becomes a critical area for sociological research. Beyond this, if there is a thrust for moving toward "universal" values regarding human and children's rights, then in the proactive orientation sociologists and other social scientists who are ostensibly knowledgeable about how social structures operate should be able to model and propose social structures in order to implement these values.

HUMAN RIGHTS

Human rights, or the rights and privileges that every person should expect and receive in a just or "good" society, have been a concern of philosophers through the ages, and commonly this interest has been reassociated with such concepts as "social justice." Although this philosophical topic has also been addressed in religious and political codes and documents, the first really broad and broadly supported international statement on the topic is

to be found in the United Nations Universal Declaration of Human Rights (1949), which was approved by the U.N. General Assembly on 10 December 1948. Sociologists might give this document critical attention. Are the rights that are noted consistent with each other; if not, what are the inconsistencies and how might they be resolved? Thus, the study of implicit values becomes a vital area for sociologists. Questions that become obvious include questions about the priorities of the values. The Universal Declaration begins with a preamble that states: "Whereas recognition of the inherent dignity and of the equal and inalienable rights of all members of the human family is the foundation of freedom, justice and peace in the world . . ." It goes on to elaborate on these rights and then states: "The General Assembly proclaims this Universal Declaration of Human Rights as a common standard of achievement for all peoples and all nations, to the end that every individual and every organ of society, keeping this Declaration constantly in mind, shall strive by teaching and education to promote respect for these rights and freedoms and by progressive measures, national and international, to secure their universal and effective recognition and observance, both among the peoples of Member States themselves and among the peoples of territories under their jurisdiction." There followed thirty articles that can be summarized as follows:

1. "All human beings are born free and equal in dignity and rights . . ."
2. All are entitled ". . . without distinction of any kind, such as race, colour, sex, language, religion, political or other opinion, national or social origin, property, birth or other status . . ."
3. "Everyone has the right to life, liberty and the security of person."
4. "No one shall be held in slavery or servitude; slavery and the slave trade shall be prohibited in all their forms."
5. "No one shall be subjected to torture or to cruel, inhuman or degrading treatment or punishment."
6. "Everyone has the right to recognition everywhere as a person before the law."
7. "All are equal before the law and . . . equal protection before the law . . ."

|---|---|
| <p>8. "Everyone has the right to . . . national tribunals . . ."</p> <p>9. "No one shall be subjected to arbitrary arrest, detention or exile."</p> <p>10. Elaboration is provided for entitlement to ". . . fair and public hearing . . ."</p> <p>11. "Everyone charged with a penal offence has the right to be presumed innocent until proved guilty . . . No one shall be held guilty of any penal offence on account of any act or omission which did not constitute a penal offence . . ."</p> <p>12. "No one shall be subjected to arbitrary interference with his privacy, family, home or correspondence, nor to attacks upon his honour and reputation . . ."</p> <p>13. "Everyone has the right to freedom of movement and residence within the borders of each state. Everyone has the right to leave any country, including his own, and to return to his country."</p> <p>14. "Everyone has the right to seek and to enjoy in other countries asylum from persecution."</p> <p>15. "Everyone has the right to a nationality . . ."</p> <p>16. "Men and women of full age, without any limitation due to race, nationality, or religion, have the right to marry and to found a family. They are entitled to equal rights . . . entered into only with the free and full consent of the intending spouses. The family is the natural and fundamental group unit of society and is entitled to protection by society and the State."</p> <p>17. "Everyone has the right to own property alone as well as in association with others . . ."</p> <p>18. "Everyone has the right to freedom of thought, conscience and religion . . ."</p> <p>19. "Everyone has the right to freedom of opinion and expression . . ."</p> <p>20. "Everyone has the right to freedom of peaceful assembly and association . . ."</p> <p>21. "Everyone has the right to take part in the government . . ."</p> | <p>22. "Everyone . . . has the right to social security . . ."</p> <p>23. "Everyone has the right to work, to free choice of employment, to just and favourable conditions of work and to protection against unemployment . . ."</p> <p>24. "Everyone has the right to rest and leisure . . ."</p> <p>25. "Everyone has the right to a standard of living adequate for health and well-being . . ."</p> <p>26. "Everyone has the right to education. Education shall be free, at least in the elementary and fundamental stages. Elementary education shall be compulsory. Technical and professional education shall be made generally available and higher education shall be equally accessible to all on the basis of merit. Education shall be directed to the full development of the human personality and to the strengthening of respect for human right and fundamental freedoms . . . Parents have a prior right to choose the kind of education that shall be given to their children."</p> <p>27. "Everyone has the right freely to participate in the cultural life . . . Everyone has the right to the protection of the moral and material interests resulting from any scientific, literary or artistic production of which he is the author."</p> |
|---|---|
- Articles 28 to 30 deal with (1) the rights to an international community in which these rights are realized; (2) respect for the rights and freedoms of others; and (3) maintenance of morality, public order, and the general welfare of a democratic society, in a manner that is not contrary to the purposes and principles of the United Nations.
- It is not until Article 29 that one realizes that the Universal Declaration of Human Rights implicitly assumes a democratic form of government in all nations. Therefore, the approval of the Universal Declaration in 1948 by a vote of 48 to 0 with 8 abstentions—from the U.S.S.R., Ukraine, Byelorussia, Poland, Czechoslovakia, Yugoslavia, Saudi Arabia, and the Union of South Africa—is not ununderstandable. However, what is important for sociologists is that this is an attempt at identifying of universals, which presumably can be the
-

basis for examining existing social structures and dealing with explorations of how social structures can be made to support the values involved. But before getting into such an enterprise, it is necessary to reiterate the idea that the values incorporated into the Universal Declaration themselves need to be made explicit.

Before going on to subsequent developments in the area of human rights, a few remarks about the Universal Declaration are appropriate. First, human rights in this document are allocated specifically to individuals. This is in keeping with the notion that only individuals have status before the law. Of course, throughout history, particularly with the beginning of industrialization, the law has given status to entities other than individuals, most obviously corporate structures, including religious organizations, schools and foundations, and unions. Provision of rights before the law to such entities has consequences for individual human rights. Second—and this is a consideration that will become more prominent in subsequent comments—the rights provided are ambiguously allocated to adults, but the Universal Declaration provides no definition of adult status. Thus the definition of a vital concept is omitted—but quite a few other important concepts are also named but not defined. Implicitly, the concepts are subject to definition in the state where the individual resides. To give an example of the ambiguity, let us look at Article 16: “Men and women of full age, without limitation due to race, nationality or religion, have the right to marry and to found a family.” It is not clear what full age means. Is it twelve years of age, fifteen, sixteen, eighteen, or twenty-one? Men and women have a right to marry, but does that mean one of each, or any combination of men and women? In terms of history and ethnic/religious variations, this is not a trivial question. “The family is the natural and fundamental group unit of society and is entitled to protection by society and the State.” What is a family? There is so much variation in any anthropological view of the family as to make this a very vague concept, and the definition is continuing to change in modern industrial societies, what with the arrival of birth control and divorce and sequential multiple marriage. Sociologists and other social scientists obviously can provide some bases for clarification of these statements of rights and values. Other issues

that arise with United Nations documents are emphasized in subsequent sections.

At this point it is appropriate to note that when the Universal Declaration of Human Rights was voted on, it was emphasized that it did not have the status of a treaty. A treaty was in preparation, however, and the International Covenant on Civil and Political Rights (1966), which incorporated much of the Universal Declaration, was adopted by the U.N. General Assembly, in 1966. By 1985, 80 of the 159 members had ratified the treaty. The treaty changed some of the orientation, however, as can be seen by Article 1, which states: “All people have the right to self-determination. By virtue of that right they freely determine their political status and freely pursue their economic, social and cultural development. The States . . . shall promote the realization of the right of self-determination . . .” The treaty begins with an ambiguous statement on how states are to operate, not on individual human rights. Unfortunately, it also contains language that responds to political entities, and one radical interpretation of the language suggests that any political entity effectively has the right to become independent. It needs to be emphasized that human rights—and closely topics related such as genocide, women’s rights, and children’s rights (to be considered below)—have been the subject of many actions in the U.N. General Assembly.

The literature in the field of human rights does not appear to have a major sociological component, but some sociological studies do exist (Buerghenthal 1997; Gros Espeill 1998; Magnarella 1995; Pace 1998).

CHILDREN'S RIGHTS

The issues associated with children’s rights are anticipated in part in the movement from the Universal Declaration to the International Covenant. Article 26 of the Universal Declaration states that everyone has the right to education but that parents have a prior right to choose the kind of education to be given to their children. In the International Covenant, more is said about the parental role. Article 18, for example, states: “The States . . . undertake to have respect for the liberty of parents . . . to ensure the religious and moral education of their children in conformity with their own convictions.” Further, Article 23 states:

"Every child shall have . . . the right to such measures of protection required by his status as a minor, on the part of his family, the society and the State." This elaboration on the involvement of the society and the State raises many questions about the rights of children. Let us look at this in terms of education issues.

First, some attention must be given to the question of what constitutes education. A primary concept obviously is that there should be access to literacy—the ability to read and write. But other skills can also be important, as is exposure to what is classed as knowledge. Using a simplistic index, such as the one used in "Why Family Planning Matters" (1999), it is estimated that, of 4.8 billion people in developing countries, 45 percent of females and 54 percent of males of the relevant age group are in secondary school, suggesting that education is still relatively primitive in most of the world. Possibly more striking is that in twenty-six of the thirty-nine sub-Saharan African nations for which data are reported, less than 20 percent of females of the relevant age group are in secondary school. So, somehow much of the world is not yet in tune with the values in the U.N. treaties with regard to education. For sociologists, even these facts can be a challenge. Assuming that the value of education is seen as an important "universal" value, what is necessary to implement it in developing countries?

The question of the education of children goes beyond such components as literacy, and basic knowledge bases to other values that need attention to be clarified. For example, consider the allocation of rights ". . . of parents . . . to ensure the religious and moral education of the their children in conformity with their own convictions." This is indoctrination, and it is directly inconsistent with the notion that the children should be educated. To state the matter crassly, children are subject to indoctrination into specific belief systems, with no opportunity for choice. Children are not exposed to competing belief systems. Beyond indoctrination into belief systems, children are subject to behavior restrictions and physical practices. For example, circumcision of male children is a common form of irreversible mutilation that is imposed by parents and often by the dominant culture. Health-based rationale are sometimes advanced for the practice, without apparent support, and in addition it is suggested that the

practice does little harm. The same cannot be said about the "circumcision" of female children, in which the mutilation involves the removal of sensitive sexual tissue. While there has been substantial negative reaction to female circumcision, it is prevalent in a number of less developed countries. It has to be noted that the "community" and the governing bodies in these countries often support the indoctrination of children. This is not surprising, since many of these countries tend to be either formally or informally theocratic and children are indoctrinated not only through their parents but also through other community support systems. By contrast, in developed countries, where education is more widespread and substantial, belief systems may persist through parents and some community support systems, but modifications are obvious. For example, in Italy, where most of the population are Roman Catholic, the birthrate is the lowest among all developed countries, in spite of the papal condemnation of birth control methods other than abstinence or rhythm. It would be naive to believe that Italians are not using modern techniques of birth control.

The treaty basis for children's rights, the Convention on the Rights of the Child (1989), was adopted by the U.N. General Assembly on 20 November 1989. The document contains fifty-four articles, but the greater detail does not alter the problem of value clarification, and in some ways some of the statements of rights create greater ambiguity. For example, Article 14 states: "States . . . shall respect the right of the child to freedom of thought, conscience and religion." From where will the child have acquired thought, conscience and religion?" Note also the role of the parents in Article 18: "Parents . . . have the primary responsibilities for upbringing and development of the child." Much of the document seems to consist of platitudinous statements that the parents will be good and the state will help them. However, sociologists and other social scientists may find it challenging to try to assess structures that might facilitate this. Situations in different nations may be quite different because of underlying differences in the social and economic circumstances. For example, much current political rhetoric in the United States focuses on strengthening the family so that it can better serve children. How is this to be done? Presumably, sociologists would examine the current dichotomy between reality

and rhetoric, noting the shift over the course of the twentieth century from large families with a single working head to small families, sometimes with two working parents, sometimes with single parent. How could the family be strengthened? The conventional/conservative notion of the mother staying home might not be the right answer. One possible answer that needs to be looked at is discarding school patterns that have their roots in the rural past and replacing them with patterns that meet current needs, such as full-day, year-long schooling, which recognizes that parents are not available until the end of the workday and do not have three-month summer vacations. Another possible answer would be to provide supervision and instruction at a level that corresponds to what research says is needed: rather than acquiescing to the economics of minimum support and unrealistic expectations about what schools as now constituted can produce. When something like the latter is suggested, too often the response is that it is not realistic because of cost and convention. On the contrary, and this is an important point: *If that is what the analysis of social scientists finds, there should be insistence that it is realistic.*

While there has been a substantial amount written about the rights of the child, one particularly accessible source is especially recommended—the 1996 issue of the *American Psychologist* that is devoted in large part to the topic (Limber and Wilcox 1996; Melton 1996; Murphy-Berman and Weisz 1996; Saks 1996) With regard to the Convention on the Rights of the Child, it should be noted that at this writing the treaty has been ratified by all member nations of the United Nations except two: Somalia and the United States.

CONCLUSION

Human rights and children's rights are topics that provide rich potential for research and applied involvement for sociologists and other social scientists. The United Nations has given considerable attention to issues of human rights, and this brief consideration has barely scratched the surface. Sociologists have given attention to some aspects of human rights in detail, including issues of women's rights and racial and other discrimination, but even in these topics the focus has often been narrow considering the varieties of problems and issues in the world.

Special circumstances bring issues of human rights to prominence, and at the end of the twentieth century the issue of genocide has been given substantial attention. Even this issue should be carefully examined by sociologists and social scientists. For example, in a syndicated column Alexander Cockburn wrote: "In 1996, [Madeleine] Albright was asked the following question on CBS-TV's '60 Minutes' by Lesley Stahl: 'We have heard that half a million children have died [in Iraq]. I mean, that's more children than died in Hiroshima. And you know, is the price worth it?' Albright infamously replied, 'I think this is a very hard choice, but the price—we think the price is worth it.' So, back in Nuremberg time, Albright would certainly have been condemned and maybe hanged, if the standards applied to Seyss-Inquart had been leveled against her and if she had been on the losing side. So would her commanding officer, Bill Clinton" (*Seattle Times*, June 3, 1999). The winning side has always defined what is acceptable, but its actions should be subject to objective analysis. Cockburn went on to note: "The protocols of the Geneva Convention of 1949 prohibit bombing not justified by clear military necessity. If there is any likelihood the target has a civilian function, then bombing is forbidden. NATO's bombers have damaged and often destroyed hospitals and health-care centers, public housing, infrastructure vital to the well-being of civilians, refineries, warehouses, agricultural facilities, schools, road and railways. If Slobodan Milosevic goes on trial before before the International Criminal Court, Clinton, Albright and Defense Secretary William Cohen should have their place on the court's calendar, too." It has also been pointed out that the NATO bombings in Serbia were carried out with the defined expectation that there would be no NATO military casualties, and there were none. The Serb military was to be reduced in effectiveness, meaning the destruction not only of military physical resources but also of personnel in barracks and persons in government centers and other related circumstances; there was also the expectation that there would be "collateral damage," that is, civilian casualties. Of course, the Serbs killed Kosovo Albanians during the forced expulsion, but the irony was that after the collapse of the Serbs, the process was reversed. The agenda for social scientists in such matters is one of requiring objectivity in the analysis of the values and the documents and in the reporting of the events. While Cockburn's critique may be

rejected, it should be done so on the basis of the objective facts and the relevance of defined values, not on the basis of the interpretation of the winning side. History is full of uncomfortable facts, and in retrospectively looking at questions of human rights, we have to remember such things as that victory over Japan in World War II came by means of nuclear destruction of two Japanese cities, not two Japanese armies.

Sociologists have not focused sufficiently on human and children's rights with regard to clarifying the "universal" values that the United Nations has promulgated and in which the international community has concurred. Some issues are very complex, loaded with traditional and religious values that directly conflict with those in the Universal Declaration, which tend to be stated in broad and/or general humanistic terms. For example, in a nation that is dominated by a single religion—one that is virtually actually a theocracy—dogmas and traditions supported by the community and in families, may dictate highly restricted status for behavior by women. In a modern industrial nation, this may be viewed as depriving women of their human rights.

The conflict between values that emphasize the good of the broader community and those presumed to be individual human rights is also a critical area for attention by sociologists. One such conflict exists in the values involved in family planning and fertility control. From the community point of view, which may be phrased as "for the good of the society at large," there may be a need for fertility control. For example, although the world (or a nation) may be able to support a tremendous increase in population, such population growth also carries the potential for catastrophic famines and epidemics. The potential problems may result in a general value being placed on the importance of family planning and fertility control by both developed and less developed nations. How is population growth to be attenuated? "Educational" programs have had some success in less developed nations, especially those with a potential for modernization and industrialization. In China, with a tradition of valuing large families, especially male children, the government decided that a strict policy of one child only was necessary to stay population growth. When this policy was implemented, the population was about

90 percent rural, and it currently is still predominantly so. Is such a policy reasonable, and how can it be implemented? The implementation was possible through the form of government that existed, but not without some abuses and also some relaxations of the policy. Here the sociologist can be asked the practical question. How could the policy be implemented without some problems, that is, what would the sociologist instruct the policy makers to do to get the same effect as was accomplished? How are people to be made to adhere to a "one-child-family" policy? Many different types of suggestions can be advanced, including questioning the premise that such a policy is necessary or even appropriate. The argument may shift to empirical questions and estimates, and the like, while the world population continues to increase from 6 billion at the beginning of the twenty-first century to estimates as high as 15 billion by the year 2050. Then the question of quality of life comes into play. At this point, roughly 1.5 billion people live in more or less developed nations and 4.5 billion in less developed nations. What would happen if those in less developed nations used resources at the same rate as those in developed nations? What would happen if, in fifty years, 15 billion people used resources at the level they are currently used in the United States today? The critical analyst might point out that population control is more essential in developed nations, since one additional person there might use twenty (or as much as one hundred) times the resources as one person in a less developed nation. Sociologists obviously have fertile ground for research in examining how social structures might support values that are advanced as "universals" for human and children's rights.

EDGAR F. BORGATTA

HUMANISM

Humanism in its broadest sense can be traced to the philosophical movement that originated in Italy in the second half of the fourteenth century and that affirmed the dignity of the human being. Although over the centuries there have been numerous varieties of humanism, both religious and nonreligious, all have been in agreement on the basic tenet that every human being has dignity and worth and therefore should be the measure of all things.

Humanism, as practiced in sociology, starts from two fundamental assumptions. The first of these is that sociology should be a moral enterprise, one whose fundamental purpose is to challenge the views and conditions that restrain human potential in a given society. The second is that sociology should not be defined as a scientific discipline that embraces "positivism"—the position that facts exist independently of the observer and that the observer should be a value-neutral compiler of facts.

Sociologists operating in the humanist tradition hold that the study of society begins with the premise that human beings are free to create their social world and that whatever impinges on that freedom is ultimately negative and destructive. They argue that the use of one of the traditional methodological tools of science—dispassionate observation—has not only taken sociology away from its Enlightenment origins in moral philosophy but is based on a faulty epistemology.

Although diverse theoretical frameworks, such as Marxism, conflict theory, phenomenology, symbolic interaction, and feminist sociology, can all be said to have some form of a humanistic orientation

as a part of their overall framework's, humanism in sociology is most readily identified with those sociologists who in their teaching, research, and activism gravitate around the Association for Humanist Sociology (AHS), which was founded in 1976 by Alfred McClung Lee, Elizabeth McClung Lee, and Charles Flynn.

The fundamental underpinnings of sociological humanism can be traced back to two traditions that came out of the Enlightenment: moral philosophy and empiricism. Although Modern sociologists see these traditions as separate, to the Enlightenment French and Scottish philosophers (collectively known as the *philosophes*) they were intertwined and interdependent. The *philosophes* called for a fusion of morals and science, for a social science that sought to liberate the human spirit and ensure the fullest development of the person. It is this emphasis on moral philosophy and empiricism, as modified by German idealism and more recently by the American philosophical tradition of pragmatism, that constitutes the foundations of humanism in sociology, today.

THE ENLIGHTENMENT AND THE LEGACY OF SOCIOLOGICAL HUMANISM

Although the Enlightenment *philosophes* initiated the enterprise of modern sociology through their call for the application of scientific principles to the study of human behavior (Rossides 1998), humanist sociologists stress that the *philosophes* were first and foremost moral philosophers. Science and morality were to be fused, not separated; the "is" and the "ought" were to be merged into a moral science, a science for the betterment of humankind. It was Jean Jacques Rousseau, with his arguments against inequality and for the dignity of the person, who best represents this tradition of moral science tradition Rousseau (1755–1985) started with the fundamental assumption that all people are created equal and from this formulated a radical system of politics. Rousseau and the *philosophes* were wedded to the idea that individual liberty and freedom prospered only under conditions of minimal external constraint that had to be consensually based. In the eighteenth century, the *philosophes* articulated their doctrine of individual liberty and freedom chiefly in the idiom of natural rights (Seidman 1983).

The *philosophes* held that the most important value was the freedom of the individual in a humane society that ensured this freedom. Not having any developed psychology of the individual, of the subjective side of human behavior, or of how institutions are formed, they could not go beyond this modest beginning. They could not fashion a full-blown vision of the free individual within a society based on the principle of human freedom.

This tradition of a moral science is overlooked by contemporary sociologists, who instead focus on the empiricism of the *philosophes*; but although empiricism without doubt played the greatest role in the rise of social science, it is only one part of what the *philosophes* advocated. In their dismissal of the moral science tradition and in their virtually unquestioning embrace of the positivism of Comte, Spenser, Durkheim, and the other early founders of sociology as a discipline, contemporary sociologists overlook the *philosophes*' concern that there was an epistemological dilemma inherent in the new empirical science they envisioned. If a social science was to arise out of the Enlightenment, it had to have a new conception of knowledge, one that rejected Greek and medieval Christian epistemology. The Aristotelian view held that a definite entity resided within the human body, an entity that passively observed what was going on in the world, just as a spectator does. The observer sees a picture of the world, and it is this passive observation that constitutes *experience*. Science, in the Aristotelian model, was the process of observing objects as they were thought to be conceived in the human mind. Following Newton, the world was to be understood in terms of mathematical equations by means of axioms that were put in the minds of humans by God and that enabled the mind to picture reality. John Locke's *Essay Concerning Human Understanding* ([1690] 1894) represented an early attempt to show that the extreme rationalist notion that the world precisely followed mathematical axioms was in error. Locke argued that first principles did not exist a priori but came from the facts of experience. Locke, however, became caught up in the epistemological dilemma that experience was mental, and not physical, and therefore still had to be located in the "unscientific" concept of mind. This led Locke, like David Hume (1711–1776), to conclude that an exact science of human behavior was unattainable (Randall 1976). Only probabilistic knowledge could be arrived at,

and this could only modestly be used to guide humankind.

Although the epistemological dilemma posed by Locke and other Enlightenment thinkers was real to them, the development of sociology in France, England, and later in the United States discarded these concerns and embraced positivism as the cornerstones of the discipline. Sociology, however, developed differently in Germany, and it is through German social science that the tradition of humanism in sociology was kept alive.

GERMAN IDEALISM

German social science, unlike its English, French, and later American counterparts, was much more influenced by idealism than by empiricism. This influence is due to two giants of philosophy: Immanuel Kant and Georg William Freidrich Hegel.

Immanuel Kant (1724–1804). Kant ([1781] 1965) was interested in answering the basic question of how autonomy and free will were possible in a deterministic Newtonian universe. His answer led him back to Locke's epistemological dilemma. According to Kant, there is a *phenomenal* and a *neumenological* self. Kant called the world as experienced by the individual *phenomena* and the thing in itself *neumena*. Since science is concerned with experience, Kant relegated it to the study of phenomena. The neumenon is beyond the scientist's realm of inquiry, because Kant wanted to claim the neumenon for the moral philosopher. For Kant, the basis of moral philosophy was to be found in the human mind; moral law located a priori in the mind and can be deduced rationally. Kant, like Locke before him, was faced with the dilemma of how the mind works.

Kant's explanation was that objects of scientific investigation are not simply discovered in the world but are constituted and synthesized a priori in the human mind. The external world that human beings experience is not a copy of reality, but something that can only be experienced and understood in light of a priori forms and categories. According to Kant, these forms and categories determine the form but not the content of external reality. Causation is a product of the mind and is a necessary precondition for the conception of an orderly universe.

Kant believed that he had solved the problem of knowledge through the forms and that he could do the same for ethics. Morally right action, too, is located in the mind. Going back to Rousseau and before him to the fourteenth-century humanists, Kant ([1788] 1949) focused on the dignity of the human being. His notion of the *categorical imperative*, that each person be treated as an end and never as a means, solidifies the importance of the person as the cornerstone of philosophical inquiry and of humanism. Natural rights are part of the neumenal world, part of the moral self. Kant thus began to look to the mind, to the self, as the primary origin of society. Moral values come from human consciousness: but, lacking a viable theory of consciousness, Kant could go only so far. It was Hegel who took up the challenge and subsequently made further progress toward the development of a humanistic orientation in sociology.

Georg Wilhelm Freidrich Hegel (1770–1831). Hegel was well versed in the social and moral philosophy of his day, and was particularly steeped in the work of Kant, who was the dominant figure in Germany philosophy at the time. Although Hegel ([1821] 1967) held that Kant's epistemology was successful in explaining how scientific knowledge was possible, he differed with Kant by rejecting Kant's belief that the categories were innate and therefore ahistorical. For Hegel, the human mind has to be understood in the context of human history. Human reasons is the product of collective action and as such is constantly evolving toward an ultimate understanding of its own consciousness. There are adumbrations of the sociology of knowledge in Hegel's view, specifically in his arguments that the Kantian categories, which are used to make sense of the world, change as the political and social climate changes. Hegel is very close to modern sociology in other aspects of his thought, and it is extremely unfortunate that he is so often dismissed because of his ultimate reliance on the metaphysical assumption that total understanding would only come with the realization of the absolute spirit in human history. When Hegel's contributions are mentioned, it is usually only as having had an influence on Marx, and even then it is inevitably pointed out that Marx turned Hegel "upside down." These interpretations overlook the fact that Hegel was the first modern theorist to develop an antipositivistic critical approach to society. Hegel rejected positivism because of its

overreliance on empiricism, which forces the individual to find sense impressions meaningful. As was Kant's philosophy, Hegel's philosophy was humanist at its core.

Also overlooked is the fact that Hegel not only offered an active epistemology but a social one as well. This socially based epistemology (the categories are conditioned by social and political factors) also led him to conceive of a socially based moral philosophy. Whereas Kant held that the concept of freedom was based in the mind of the individual, Hegel, like Rousseau, believed that freedom could only be expressed in terms of a supportive community.

Perhaps Hegel's most important contribution to modern social science is that he was among the first theorists to look at the social development of self, something that makes him a forerunner of humanist sociology. For Hegel ([1807] 1967), the self must be understood as a process, not as a static reality. The self develops as the mind negotiates intersubjectivity. We experience ourselves as both an intending subject and as an object of experience. The mind develops and strives for ultimate truth in this context, which, to Hegel, is freedom. The essence of being is, therefore, a self-reflexive struggle for freedom. Hegel's idealism led him to conclude that objective analysis is always mediated by subjective factors and points toward freedom. In Hegel, there is the outline of a critical, humanistic sociology. He offered an active, antipositivistic, socially conditioned epistemology, with an emphasis upon freedom through the seeking of self knowledge, along with a critique of any non-morally based society.

PRAGMATISM AND HUMANISM

The importance of pragmatism for a humanistic orientation in sociology lies in its assumption of an active epistemology that undergirds an active theory of the mind, thereby challenging the positivistic behaviorism of the time made popular by the likes of John B. Watson. For the pragmatists, how the mind comes to know cannot be separated from how the mind actually develops.

George Herbert Mead ([1934] 1974) exemplifies the pragmatists' view concerning the development of mind. Consciousness and will arise from problems. Individuals ascertain the intentions of

others and then respond on the basis of their interpretations. If there were no interactions with others, there would be no development of the mind. Individuals possess the ability to modify their own behavior; they are subjects who construct their acts rather than simply responding in predetermined ways. Human beings are capable of reflexive behavior: that is, they can turn back and think about their experiences. The individual is not a passive agent who merely reacts to external constraints, but someone who actively chooses among alternative courses of action. Individuals interpret data furnished to them in social situation. Choices of potential solutions are only limited by the given facts of the individual's presence in the larger network of society. This ability to choose among alternatives makes individuals both determined and determiners (Meltzer et al. 1977).

What Mead and the pragmatists stressed was the important notion that the determination of ideas—in particular, the impact of social structure on the mind of an individual—is a social-psychological process. Thinking follows the pattern of language. Language is the mechanism through which humans develop a self and mind, and language is social because words assume meaning only when they are interpreted by social behavior. Social patterns establish meanings. Language sets the basis for reason, logic, and by extension all scientific and moral endeavors. One is logical when one is in agreement with one's universe of discourse; one is moral when one is in agreement with one's community. Language is a mediator of social behavior in that with a language come values and norms. Value judgments and collective patterns exist behind words; meaning is socially bestowed.

Although Mead was the most important pragmatist for understanding the development of self, the epistemology of pragmatism was most precisely formulated by John Dewey (1929, 1931). Dewey's epistemology represented a final break with the notion that the mind knows because it is a spectator to reality. For Dewey, thought is spatiotemporal. Eternal truths, universals, *a priori* systems are all suspect. Experience is the experience of the environment—an environment that is physical, biological, and cultural. Ideas are not Platonic essences but rather are functional to the experience of the individual (Dewey 1931). This position is antipositivistic in that the mind deals

only with ideas and, therefore, does not ponder reality, but only ideas about reality. Truth is not absolute but is simply what is consistent with experience.

The individual is engaged in an active confrontation with the world; mind and self develop in a social process. The pragmatists provided an epistemological justification for freedom (the basic tenet of humanism). The mind develops in a social context and comes to know as it comes into being. Any restriction on the freedom of the mind to inquire and know implies a restriction on the mind to fully develop. The pragmatists rounded out Hegel's ([1807] 1967) view that ultimate truth is freedom by showing that the mind needs freedom to develop in a social context. Epistemology and freedom are inseparable.

Pragmatism, by joining epistemology and freedom via the social development of mind, also provides a solution for the seeming incompatibility between an instrumental and an intrinsic approach to values. The value of freedom is instrumental in that it is created in action (the action of the developing mind); but it is also intrinsic in that the mind cannot fully develop without the creation of an environment that ensures freedom. This integrated epistemological framework provides the basis for a humanistic methodology for sociology.

PRAGMATISM, METHODOLOGY, AND HUMANISM

Dewey and Mead developed a methodology that gave social scientists a different frame of reference from that of the "traditional scientific methodology." Flexibility was the main characteristic of their pragmatic methodology—it did not offer specific forms or languages to which social problems had to be adapted. Instead, the form and language of the method grew out of the problem itself. The social scientist, thus, fashions his or her own methodology depending upon the problem studied. New concepts and methodologies arise from efforts to overcome obstacles to successful research. Techniques are developed that enable the researcher to be both a participant in and observer of social structures. There is an instrumentalist linkage between theory and practice as it is incorporated into the humanist sociologist's life. This is what Alfred McClung Lee (1978), a leading humanist sociologist, meant when he wrote: "Sociologists cannot

be persons apart from the human condition they presumably seek to understand" (p. 35). This is what C. Wright Mills (1959) meant when he wrote: "The most admirable thinkers within the scholarly community . . . do not split their work from their lives." (p. 195).

For the humanist sociologist, the main purpose in amassing a body of knowledge is to serve human needs; knowledge must be useful. By accepting this dictum, humanist sociologists extend the analysis of what *is* to the analysis of what *ought* to be. Knowledge should provide answers for bringing about a desired future state of affairs, a plan that can be achieved through the methodological insights of pragmatism whereby the researcher is both participant and observer.

The dilemma of which values to choose is answered by opting for the pragmatist's emphasis upon responsibility as a moral standard which assumes that a fundamental quality of human beings is their potentiality for ethical autonomy. People not only *are* but *ought* to be in charge of their own destiny within the limits permitted by their environment. Individual character development takes place to the extent that persons can and do decide on alternative courses of action (Dewey 1939).

Pragmatism is grounded upon an assumption of freedom of choice. However, choice among alternatives is always limited. It is in pointing out these limitations in the form of power relations and vested interests behind social structures that humanist sociology builds upon pragmatism and thereby confronts the basic sociological criticism of pragmatism—that it lacks a viable notion of social structure. Humanist sociology seeks to fashion a full-blown vision of the free individual within a society based on the principle of human freedom.

HUMANIST SOCIOLOGY TODAY

Humanist sociology has moved beyond pragmatism via its attempt to spell out the social structural conditions for the maximization of freedom. Humanist sociology is based on moral precepts, the foremost of which is that of *freedom*—"the maximization of alternatives" (Scimecca 1995, p.1). This is assumed to be *the* most desirable state for human beings—and the goal of sociology is to work toward the realization of conditions that insure this

freedom. Given its Meadian theory of self (an active theory of self that chooses between alternatives), humanist sociology is concerned with how this is best realized within a community. Humanist sociology begins with the fundamental assumption that all varieties of humanism hold—that individuals are the measure of all things. Using a nonpositivistic epistemological foundation, humanist sociologists employ their methods of research to answer the most important question that can be asked by a humanist sociologist about human behavior, the one originally raised by the Enlightenment *philosophes*: How can social science help to fashion a humane society in which freedom can best be realized?

IDENTITY THEORY

Identity theory, in the present context, has its referent in a specific and delimited literature that seeks to develop and empirically examine a theoretical explanation, derived from what has been called a structural symbolic interactionist perspective (Stryker 1980), of role choice behavior. It is only one of a large number of formulations—social scientific, therapeutic, humanistic—in which the concept of identity plays a central role, formulations having their roots in a variety of disciplines ranging from theology through philosophy to political science, psychology, social psychology, and sociology. Further mention of these diverse formulations will be forgone in order to focus on identity theory as specified above; those who desire leads into the literature of sociology and social psychology to which identity theory most closely relates will find them in McCall and Simmons (1978); Stryker (1980); Weigert (1983); Stryker and Statham (1985); Hewitt (1997a, 1997b); MacKinnon (1994); and Burke and Gecas (1995).

The prototypical question addressed by identity theory, phrased illustratively, is: Why is it that one person, given a free weekend afternoon, chooses to take his or her children to the zoo while another person opts to spend that time on the golf course with friends? The language of this prototypical question implies a scope limitation of the

theory that is important to recognize at the outset of the discussion. The theory is intended to apply to situations where alternative courses of action are reasonably, and reasonably equivalently, open to the actor. A defining assumption of the symbolic interactionist theoretical framework is that human beings are actors, not merely reactors. Identity theory shares this assumption, which recognizes the possibility of choice as a ubiquitous feature of human existence. At the same time, however, identity theory recognizes the sociological truth that social structure and social interaction are equally ubiquitous in constraining—not in a strict sense “determining”—human action. That constraint is variable. It may be true in an abstract and philosophical sense that people are “free” to act in any way they choose in any situation in which they may find themselves, including choosing to endure great punishment or even death rather than to behave in ways demanded by others; but surely it is entirely reasonable to presume that jailed prisoners have no viable options with respect to many—likely most—facets of life and in any event have fewer viable options than persons who are not jailed. Identity theory has more to say on those the latter persons than on the former, and more to say on those—perhaps few—aspects of life about which the former do have reasonable choice than on those many aspects of prisoner life where options, as a practical matter, do not exist.

As a derivative of a symbolic interactionist theoretical framework, identity theory shares a number of the assumptions or premises of

interactionist thought in general. One, that human beings are actors as well as reactors, has already been suggested. A second is that human action and interaction are critically shaped by definitions or interpretations of the situations of action and interaction, which definitions and interpretations are based on shared meanings developed in the course of interaction with others. A third premise is that the meanings which persons attribute to themselves, their self-conceptions, are especially critical to the process producing their action and interaction. And a fourth premise is that self-conceptions, like other meanings, are shaped in the course of interaction with others and are, at least in the initial instance and at least largely, the outcomes of others' responses to the person.

The fourth premise has sometimes been phrased as "self reflects society." Taken in conjunction with the third premise, it gives rise to the basic theoretical proposition or formula of symbolic interactionism: Society shapes self, which shapes social behavior. That formula, it must be noted, admits of and, indeed, insists upon the possibility of reciprocity among its components—social behavior impacts self and society, and self can impact society. Identity theory builds upon refinements of the traditional symbolic interactionist framework and specifications of its basic formula.

The refinements essentially have to do with three facets of the traditional symbolic interactionist framework as it evolved from Mead ([1934] 1962), Cooley ([1902] 1983), Blumer (1969), and others: the conceptualization of society, the conceptualization of self, and the relative weight to be accorded social structure versus interpretive processes in accounts of human behavior. The traditional framework tends to view "society" as unitary, as a relatively undifferentiated and unorganized phenomenon with few, if any, internal barriers to the evolution of universally shared meanings. It also tends to a view "society" as an unstable and ephemeral reflection, even reification, of relatively transient, ever-shifting patterns of interaction. In this view of society, social structures, as these are typically conceived of by sociologists, have little place in accounts of persons' behaviors. These accounts tend to be innocent of a coherent sense of extant social constraints on those behaviors, and there are few means of linking the dynamics of social

interaction in reasonably precise ways to the broader social settings that serve as context for persons' action and interaction.

Further, and enlarging this theme of an inadequate conceptualization and consequent neglect of social structure, this view of society tends to dissolve social structure in the universal solvent of subjective definitions and interpretations, thus missing the obdurate reality of social forms whose impact on behavior is undeniable. To say this does not deny the import for social life of the definitional and interpretative processes central to interactionist thinking and explanation. It is, however, to say that seeing these processes as in large degree unanchored and without bounds, as open to any possibility whatsoever without recognizing that some are much more probable than others, results in visualizing social life as less a product of external constraints and more a product of persons' phenomenology than is likely warranted. Finally, on the premise that self reflects society, this view of society leads directly to a view of self as unitary, as equivalently internally undifferentiated, unorganized, unstable, and ephemeral.

Contemporary sociology's image of society is considerably different from that contained in traditional symbolic interactionism, and it is the contemporary sociological conceptualization of society that is incorporated into the structural symbolic interactionist frame from which identity theory derives. This contemporary conceptualization emphasizes the durability of the patterned interactions and relationships that are at the heart of sociology's sense of social structure. It emphasizes social structure's resistance to change and its tendency to reproduce itself. The contemporary image differs as well by visualizing societies as highly differentiated yet organized systems of interactions and relationships; as complex mosaics of groups, communities, organizations, institutions; and as encompassing a wide variety of crosscutting lines of social demarcation based upon social class, age, gender, ethnicity, religion, and more. This vast diversity of parts is seen as organized in multiple and overlapping ways—interactionally, functionally, and hierarchically. At the same time, the diverse parts of society are taken to be sometimes highly interdependent and sometimes relatively independent of one another, sometimes implicated in close and cooperative interaction and sometimes conflicting.

The symbolic interactionist premise that self reflects society now requires a very different conceptualization of self, one that mirrors the altered conception of society. Self must be seen as multifaceted, as comprised of a variety of parts that are sometimes interdependent and sometimes independent of other parts, sometimes mutually reinforcing and sometimes conflicting, and that are organized in multiple ways. It requires a sense of self in keeping with James's ([1890] 1990) view that persons have as many selves as there are other persons who react to them, or at least as many as there are groups of others who do so.

Equally important, viewing both society and self as complex and multifaceted as well as organized opens the way to escaping the overly general, almost banal, and essentially untestable qualities of the basic symbolic interactionist formula by permitting theorization of the relations between particular parts of society and particular parts of self, and by permitting reasonable operationalizations of those parts.

In identity theory, this theorization proceeds by specifying the terms of the basic symbolic interactionist formula, doing so by focusing on particulars hypothesized as especially likely to be important in impacting role choice. That is, first of all, the general category of social behavior is specified by taking role choice—opting to pursue action meeting the expectations contained in one role rather than another—as the object of explanation. Role choice is hypothesized to be a consequence of identity salience, a specification of the general category of self, and identity salience is hypothesized to be a consequence of commitment, a specification of society. Identity theory's fundamental proposition, then, is: Commitment impacts identity salience impacts role choice.

The concept of identity salience develops from the multifaceted view of self articulated above. Self is conceptualized as comprised of a set of discrete identities, or internalized role designations, with persons potentially having as many identities as there are organized systems of role relationships in which they participate. Identities require both that persons be placed as social objects by having others assign a positional designation to them and that the persons accept that designation (Stone 1962; Stryker 1968). By this usage, identities are

self-cognitions tied to roles and, through roles, to positions in organized social relationships; one may speak of the identities of mother, husband, child, doctor, salesman, employee, senator, candidate, priest, tennis player, churchgoer, and so on. By this usage, too, identities are cognitive schemas (Markus 1977), structures of cognitive associations, with the capacity of such schemas to impact ongoing cognitive and perceptual processes (Stryker and Serpe 1994).

Self is not only multifaceted; it is also postulated to be organized. Identity theory takes hierarchy as a principal mode of organization of identities; in particular, it assumes that identities, given their properties as cognitive schemas, will vary in their salience, and that self is a structure of identities organized in a salience hierarchy. Identity salience is defined as the probability that a given identity will be invoked, or called into play, in a variety of situations; alternatively, it can be defined as the differential probability, across persons, that a given identity will be invoked in a given situation. Identity theory's fundamental proposition hypothesizes that choice between or among behaviors expressive of particular roles will reflect the relative location in the identity salience hierarchy of the identities associated with those roles.

The concept of commitment has its basic referent in the networks of social relationships in which persons participate; as such, commitment is a social structural term. Associated with the "complex mosaic of differentiated parts" image of society is the recognition that persons conduct their lives not in the context of society as a whole but, rather, in the many contexts of relatively small and specialized social networks, networks made up of persons to whom they relate by virtue of occupancy of particular social positions and the playing of the associated roles. To say that persons are committed to some social network is to say that their relationships to the other members of that network depend on their playing particular roles and having particular identities: To the degree that one's relationships to specific others depend on being a particular kind of person, one is committed to being that kind of person. Thus, commitment is measured by the costs of giving up meaningful relations to others should an alternative course of action be pursued. Commitment, so

defined and measured, is hypothesized by identity theory to be the source of the salience attached to given identities (Stryker 1968, 1980, 1987a).

Two analytically distinct and possibly independent dimensions or forms of commitment have been discerned: interactional and affective (Serpe 1987; Stryker 1968). The former has its referent in the number of relationships entered by virtue of having a given identity and by the ties across various networks of relationships (for instance, one may relate as husband not only to one's spouse, her friends, and her relatives but also to members of a couples' bridge club and other such groups). The latter has its referent in the depth of emotional attachment to particular sets of others.

Reciprocity among the three terms of the identity theory formula is again recognized; but the dominant thrust of the process is hypothesized to be as stated by the proposition, on the grounds that identity, as a strictly cognitive phenomenon, can change more readily than can commitment, whose conceptual core is interaction rather than cognition.

The empirical evidence brought to bear on the hypotheses contained in the fundamental identity theory formula has been supportive. Stryker and Serpe (1982) demonstrate that both time spent acting out a religious role and preferred distribution of time to that role are tied to the salience of the identity associated with the role; they demonstrate as well that the salience of the religious identity is tied to commitment (in this case, the measure of commitment combines interactional and affective commitment) to others known through religious activities. Burke and various associates (Burke and Hoelter 1988; Burke and Reitzes 1981; Burke and Tully 1977) show the link between identity and gender, academic attainment and aspirations, and occupational aspirations, finding evidence that the linkage reflects the commonality of meaning of identity and behavior. Lee (1998) finds that the correspondence of meanings of students' personal identities and meanings they attach to those occupying positions in scientific disciplines predicts interest in science as well as appreciably accounting for gender differences in intention to become scientists. Serpe and Stryker (1987), using data on student-related identities obtained at three points in time from students

entering a residential college, provide evidence that the salience of these identities is reasonably stable over time; that in a situation in which earlier commitments have been attenuated by a move to a residential university, high identity salience leads to efforts to reconstruct social relationships that permit playing the role associated with the salient identity, efforts taking the form of joining appropriate organizations; and that when such efforts are not successful, the level of salience of the identity subsequently drops and self-structure is altered. Callero (1985), Callero and associates (1987), and Charng and associates (1988) show that commitment and identity salience add appreciably to the ability to account for the behavior of repeated blood donors. Sparks and Shepherd (1992) find, to their considerable surprise, that identity theory-based predictions stand up well in accounting for behavioral intentions with regard to green consumerism, the predicted relationships holding when examined in the context of the variables of a theory of planned behavior. Serpe (1987) shows that over time there is indeed a reciprocal relationship between commitment to various student role relationships and the salience of identities associated with those roles, and that the identity theory hypothesis arguing the greater impact over time of commitment on salience than vice versa is correct.

The success of identity theory attested to in this brief and incomplete review of empirical evidence notwithstanding, however, there is reason to believe that the theory requires development and extension beyond the basic proposition that has been the major focus of attention to this point. Indeed, such work has begun; and it has a variety of thrusts. How to incorporate varying degrees of situational constraint into the theory—the impact that variations in “choice” have on the ways in which the relationships among commitment, identity salience, and role performances play themselves out—is one such thrust (Serpe 1987). Another seeks to explore mechanisms underlying the linkages among commitment and identity salience, and identity salience and behavior; to this end, work (especially by Burke and Reitzes 1981, 1991) exploits the basic symbolic interactionist idea that it is commonality of meaning which makes social life possible. Some attention has been given to extending the applicability and predictive power

of identity theory by incorporating into it other than strictly role-based identities; in particular, the concern has been with what have been termed “master statuses” (such as age, gender, and class) and personal traits (such as aggressiveness and honesty), and the suggestion is that master statuses and traits may affect identity processes by modifying the meaning of the roles from which identities derive (Stryker 1987a). Stryker and Serpe (1994) treat the conceptual and measurement confusion of the importance ranking of identities and identity salience, in the process showing that both importance and salience respond to commitment, that importance and salience are related, and that both contribute to the prediction of role-related behavior.

An effort is being made to correct the almost totally cognitive focus of identity theory (as well as its parent and grandparent interactionist frameworks) by recognizing the importance of affect and emotion to the processes with which the theory is concerned. The earliest statement of the theory (Stryker 1968) posited a cathectic modality of self that parallels the cognitive modality from which the emphasis on identity flows; however, subsequent work on the theory has not pursued that idea. Stryker (1987b) has attempted to integrate emotion into the theory by arguing, with Hochschild (1979), that emotional expressions carry important messages from self and, beyond Hochschild, that the experiences of emotions are messages to self informing those who experience those emotions of the strength of commitments and the salience of identities.

Finally—and here work has barely begun—it is time to make good on the promise to provide more adequate conceptualization of the linkages between identity theory processes and the wider social structures within which these processes are embedded. From the point of view of structural symbolic interactionism, structures of class, ethnicity, age, gender, and so on operate as social boundaries making it more or less probable that particular persons will form interactional networks; in this way, such social structures enter identity theory directly through their impact on commitments. However, the relation of such structures to identity processes clearly goes beyond this direct impact; they affect not only the probabilities of

interaction but also the content (meanings) of the roles entailed in interaction and, thus, the meanings of identities, the symbolic and material resources available to those who enter interaction with others, and the objectives or ends to which interactions are oriented. Explication of these impacts, both direct and indirect, of social structure on the processes that relate commitment, identity salience, and role performance remains to be accomplished.

SHELDON STRYKER

ILLEGAL ALIENS/ UNDOCUMENTED IMMIGRANTS

See International Migration.

ILLEGITIMACY

Until the 1960s, it was widely assumed that marriage was a universal or nearly universal institution for licensing parenthood. Marriage assigned paternity rights to fathers (and their families) and guaranteed social recognition and economic support to mothers and their offspring. According to Malinowski (1930), who first articulated "the principle of legitimacy," and to Davis (1939, 1949), who extended Malinowski's theory into sociology, marriage provides the added benefit to children of connecting them to a wider network of adults who have a stake in their long-term development.

This functional explanation for the universality of marriage as a mechanism for legitimating parenthood became a source of intense debate in anthropology and sociology in the 1960s. Evidence accumulated from cross-cultural investigations showed considerable variation in marriage forms and differing levels of commitment to the norm of legitimacy (Bell and Vogel 1968; Blake 1961; Coser 1964; Goode 1961). More recently, historical evidence indicates that the institution of marriage was not firmly in place in parts of Western Europe until the end of the Middle Ages (Glendon 1989; Goody 1983).

The accumulation of contradictory data led Goode (1960, 1971) to modify Malinowski's theory to take account of high rates of informal unions

and nonmarital childbearing in many New World nations and among dispossessed cultural minorities. Goode (1971) argued that the norm of legitimacy was likely to be enforced only when fathers possessed wealth and property or when their potential economic investment in child rearing was high. Therefore, he predicted that when "giving a name" to children offers few material, social, or cultural benefits, the norms upholding marriage will become attenuated.

So vast have been the changes in the perceived benefits of marriage since the 1960s in the United States and most Western nations that even Goode's modification of Malinowski's theory of legitimacy now seems to be in doubt (Cherlin 1992; Davis 1985). Indeed, the term "illegitimacy" has fallen into disfavor precisely because it implies inferior status to children born out of wedlock. Both legal and feminist scholars have been critical of the notion that the presence of a father confers status on the child (Burns and Scott 1994; Mason et al. 1998). The nuclear unit (biological parents and their offspring)—once regarded as the cornerstone of our kinship system—remains the model family form, but it no longer represents the exclusive cultural ideal, as was the case in the mid-1960s. The incentives for marriage in the event of premarital pregnancy have declined, and the sanctions against remaining single have diminished (Cherlin 1999; McLanahan and Casper 1995). In the 1990s, considerable scholarly attention and public policy debate has been devoted to ways of restoring and reinvesting in the institution of marriage (Furstenberg 1996; McLanahan and Sandefur 1994; Popenoe et al. 1996).

TRENDS IN NONMARITAL CHILDBEARING

Premarital pregnancy has never been rare in the United States or in most Western European nations (Burns and Scott 1994; Goode 1961; Smith 1978; Vinovskis 1988). Apparently, the tolerance for pregnancy before marriage has varied over time and varies geographically at any given time. Throughout the first half of the twentieth century, premarital pregnancy almost always led to hasty marriages rather than out-of-wedlock births—even for very young women (O'Connell and Moore 1981; Vincent 1961). In 1940, illegitimacy was

uncommon in the United States, at least among whites. Nonmarital births were estimated at about 3.6 per 1,000 unmarried white women, while the comparable rate for nonwhites was 35.6. For all age groups, among whites and nonwhites alike, a spectacular rise occurred over the next five decades (Clague and Ventura 1968; Cutright 1972; McLanahan and Casper 1995).

In the 1960s and the 1970s, nonmarital childbearing rates continued to increase for younger women, albeit at a slower pace, while for women in their late twenties and thirties rates temporarily declined. Then, in the late 1970, nonmarital childbearing rates rose again for all age groups and among both whites and African Americans. This rise continued until the mid-1990s, when levels of nonmarital childbearing stabilized or even declined (Ventura et al. 1996). Since the early 1970s, rates of marriage and marital childbearing have fallen precipitously. Thus, the ratio of total births to single women has climbed continuously (Smith et al. 1996). Nearly a third of all births (32.4 percent) in 1996 occurred out of wedlock, more than seven times the proportion in 1955 (4.5 percent) and more than twice that in 1975 (14.3 percent). The declining connection between marriage and parenthood is evident among all age groups but is especially pronounced among women in their teens and early twenties. Three out of four births to teens and nearly half of all births to women ages twenty to twenty-four occurred out of wedlock. Virtually all younger blacks who had children in 1995 (more than 95 percent) were unmarried, while two-thirds of white teens and more than a third of white women twenty to twenty-four were single when they gave birth.

Nonmarital childbearing was initially defined as a problem among teenagers and black women (Furstenberg 1991). But these recent trends strongly suggest that disintegration of the norm of legitimacy has spread to all segments of the population. First the link between marriage and sexual initiation dissolved, and now the link between marriage and parenthood has become weak. Whether this trend is temporary or a more permanent feature of the Western family system is not known. But public opinion data suggest that a high proportion of the population finds single parenthood acceptable. A Roper study ("Virginia Slims American

Women's Opinion Poll" 1985) revealed that 49 percent of women agreed that "There is no reason why single women should not have children and raise them if they want to."

Citing similar attitudinal evidence from the National Survey of Families and Households in 1987–1988, Bumpass (1990) concludes that there has been an "erosion of norms" proscribing nonmarital childbearing. He concludes that this behavior is not so much motivated by the desire to have children out of wedlock as it is by the reduced commitment to marriage and the limited sanctions forbidding nonmarital childbearing. Bumpass argues that much of the nonmarital childbearing is unplanned and ill timed.

THE CONSEQUENCES OF NONMARITAL CHILDBEARING

Although extensive research exists on the economic, social, and psychological sequelae of single parenthood for adults and children, relatively little of this research has distinguished between the consequences of marital disruption and nonmarriage (Furstenberg 1989; Furstenberg and Cherlin 1991; Garfinkel and McLanahan 1986; Maynard 1997). A substantial literature exists on the consequences of nonmarital childbearing, but it is almost entirely restricted to teenage childbearers (Chilman 1983; Hofferth and Hayes 1987; Institute of Medicine 1995; Miller and Moore 1990; Moore et al. 1986). It is difficult, then, to sort out the separate effects of premature parenthood, marital disruption, and out-of-wedlock childbearing on parents and their offspring.

Nonmarital childbearing most certainly places mothers and their children at risk of long-term economic disadvantage (Institute of Medicine 1995; Maynard 1997; McLanahan and Booth 1989). Out-of-wedlock childbearing increases the odds of going on welfare and of long-term welfare dependency (Duncan and Hoffman 1990). The link between nonmarital childbearing and poverty can probably be traced to two separate sources. The first is "selective recruitment," that is, women who bear children out of wedlock have poor economic prospects before they become pregnant, and their willingness to bear a child out of wedlock may reflect the bleak future prospects of many unmarried pregnant women, especially younger women

(Furstenberg 1990; Geronimus 1987; Hayes 1987; Hogan and Kitagawa 1985; Maynard 1997). But is also likely that out-of-wedlock childbearing—particularly when it occurs early in life—directly contributes to economic vulnerability because it reduces educational attainment and may limit a young woman's prospects of entering a stable union (Furstenberg 1991; Hofferth and Hayes 1987; Hoffman et al. 1993; Trussell 1988).

If nonmarital childbearing increases the risk of lengthy periods of poverty for women and their children, it is also likely that it restricts the opportunities for intra- and intergenerational mobility of families formed as single-parent units. Growing up in poverty restricts access to health, high-quality schools, and community resources that may promote success in later life (Ellwood 1988; Wilson 1987). Apart from the risks associated with poverty, some studies have shown that growing up in a single-parent family may put children at greater risk because they receive less parental supervision and support (Amato and Booth 1997; Dornbush 1989; McLanahan and Booth 1989; McLanahan and Sandefur 1994). As yet, however, researchers have not carefully distinguished between the separate sources of disadvantage that may be tied to nonmarital childbearing: economic disadvantage (which could restrict social opportunities or increase social isolation) and psychological disadvantage (which could foster poor parenting practices or limit family support).

Even though nonmarital childbearing may put children at risk of long-term disadvantage, it is also possible that over time the advantages conferred by marriage may be decreasing in those segments of the population that experience high rates of marital disruption (Bumpass 1990; Edin 1998; Furstenberg 1995). Moreover, the social and legal stigmata once associated with nonmarital childbearing have all but disappeared in the United States and many other Western nations (Glendon 1989). Over time, then, the hazards associated with nonmarital childbearing (compared with ill-timed marital childbearing) for women and their children may have declined. Whatever the reasons for these trends, it appears that nonmarital childbearing may have peaked by the mid-1990s. Whether the leveling off in rates of nonmarital childbearing signals a shift in family formation patterns or is

merely a response to the robust economy of the 1990s remains to be seen.

NONMARITAL CHILDBEARING AND PUBLIC POLICY

Growing rates of nonmarital childbearing in the United States and many other Western nations suggest the possibility that the pattern of childbearing before marriage or between marriages may be spreading upward into the middle class. In Scandinavia, where marriage has declined most dramatically, it is difficult to discern whether formal matrimony is being replaced by a *de facto* system of informal marriage (Hoem and Hoem 1988). If this were to happen, the impact on the kinship system or the circumstances of children might not be as dramatic as some have speculated. But if the institution of marriage is in serious decline, then we may be in the midst of a major transformation in the Western family.

The weakening of marriage has created confusion and dispute over parenting rights and responsibilities. A growing body of evidence indicates that most nonresidential biological fathers, especially those who never marry, typically become disengaged from their children (Arendell 1995; King and Heard 1999; Seltzer 1991; Teachman 1990). Most are unwilling or unable to pay regular child support, and relatively few have constant relationships with their children. Instead, the costs of child rearing have been largely assumed by mothers and their families, aided by public assistance. A minority of fathers do manage to fulfill economic and social obligations, and some argue that many others would do so if they had the means and social support for continuing a relationship with their children (Marsiglio 1998; Smollar and Ooms 1987).

The uncertain relationship between biological fathers and their children has created a demand for public policies to shore up the family system (Garfinkel et al. 1996; Popenoe 1996). Widespread disagreement exists over specific policies for addressing current problems. Advocates who accept the current reality of high levels of nonmarriage and marital instability propose more generous economic allowances and extensive social support to women and their children to offset the limited

economic role of men in disadvantaged families (Ellwood 1988). Critics of this approach contend that such policies may further erode the marriage system (Vinovskis and Chase-Lansdale 1987). Yet few realistic measures have been advanced for strengthening the institution of marriage (Furstenberg and Cherline 1991).

Enforcement of child support has attracted broad public support. A series of legislative initiatives culminating in the Family Support Act of 1988 have increased the role of federal and state governments in collecting child support from absent parents (typically fathers) and standardizing levels of child support. There has been a steady but modest improvement in the collection of child support in the 1990s. It is much less clear whether the strengthening of child support has worked to the benefit of children (Furstenberg et al. 1992; Garfinkel et al. 1996). It is too early to tell whether these sweeping measures will succeed in strengthening the economic contributions of fathers who live apart from their children. And, if it does, will greater economic support by absent parents reinforce social and psychological bonds to their children (Furstenberg 1989; Garfinkel and McLanahan 1990)? The other great experiment of the 1990s was the Welfare Reform Act in 1996, which replaced the longstanding entitlements to public assistance with temporary provisional support. It is much too early to tell what, if any, the effects of this policy will be on marriage and fertility practices. Advocates of welfare reform claimed that it would reduce out-of-wedlock childbearing and help restore marriage (Murray 1984). But the link between welfare payments and marriage patterns has never been strong (Moffitt 1998). Still, it may be possible to devise a test of the consequences of the different policies given the large state variations in program implementation.

As for the future of marriage, few, if any, sociologists and demographers are predicting a return to the status quo or a restoration of the norm of legitimacy. Short of a strong ideological swing favoring marriage and condemning nonmarital sexual activity and childbearing, it is difficult to foresee a sharp reversal in present trends (Blankenhorn et al. 1990). Predicting the future, however, has never been a strong point of demographic and sociological research.

IMPERIALISM, COLONIALISM, AND DECOLONIZATION

The colonial expansion of European states into the Americas, Asia, Africa, and the Pacific, followed by the collapse of these empires and their replacement by sovereign nation-states, is a double movement of great historical importance. The following briefly reviews the larger contours of this history and outlines some central arguments about its causes and consequences.

IMPERIALISM AND COLONIALISM

The term "imperialism" was first used in the 1830s to recall Napoleonic ambitions. It gained its core contemporary meaning around the turn of the century as a description of the feverish colonial expansion of Britain, France, Germany, Russia, the United States, and Italy. But the term is not confined to formal colonial expansion; in particular, the continuing dependence of much of the Third World on Western states and multinational corporations is often understood as neocolonialism or neoimperialism (Magdoff 1969; Nkrumah 1966).

Contemporary efforts to distill these diverse usages generally define imperialism as the construction and maintenance of relationships of domination between political communities. Such relations are often seen as explicitly political, either in the narrow sense of direct administrative control or more broadly as formal or informal control over state policy. Economic conceptions of imperialism sometimes develop an analogue to these notions, where relations of economic control or exploitation replace political domination.

"Imperialism" has also been appropriated in a much narrower sense to support particular lines of argument. Lenin's statement that "imperialism is the monopoly stage of capitalism" ([1917] 1939, p. 88) may be understood as a move of this sort. Arrighi, among others, argues that Lenin is better understood as formulating a substantive proposition; he suggests the interpretation "imperialism,

or the tendency to war between capitalist countries, is a necessary consequence of the transformation of capitalism into monopoly or finance capital" (1978, p. 14).

Even when imperialism is equated with the establishment and maintenance of political domination, an awkward relationship between *imperialism* and *empire* persists. Classically, "empire" refers to the great agrarian bureaucracies that dominated antiquity, from the Aztec to the Chinese, from ancient Sumer to Imperial Rome. It is not clear how much these structures have in common with the overseas colonial empires of Western states, much less with contemporary structures of dependence on foreign investment. Agrarian bureaucracies involved ethnic divisions that separated classes (most importantly separating warriors and peasant producers) rather than entire communities or nations (Gellner 1983).

A second historical use of "empire" is the medieval image of a temporal parallel to the Roman Church (Folz 1969; Guenee 1985). Rather than an alien and illegitimate structure, empire was seen as a political order unifying the Christian world. Revived by Charlemagne, the notion of a universal polity lived on, in an increasingly ghostly fashion, through the Holy Roman Empire. It receded into the background as a real political force with the construction of absolutist states and was lost as a compelling image with the rise of the nation-state.

In contrast to these historical understandings of empire, modern conceptions of imperialism rest on the notion that popular sovereignty forms the basis of political community. Only with the notion of popular sovereignty does domination refer to relationships between rather than within communities. If the criteria that the United Nations uses today to identify colonialism were to be applied before 1700, all territories would be parts of empires and all peoples would be dependent subjects. It is thus no accident that the notion of imperialism arose with the nation-state; it connotes the expansionary drive of a community that is internally organized around (the myth of) popular sovereignty.

European Political Expansion. European overseas expansion can be described crudely as occurring in two stages, the colonial and the imperial. In the fifteenth and sixteenth centuries, seagoing

powers constructed networks of colonial enclaves along the route to the East Indies. Less than half a century after the voyages of Columbus, the conquistadores had laid waste to the Incan and Aztec empires and were sending gold and silver back to Spain. In the following two centuries, Spain, Portugal, Great Britain, France, and the Netherlands colonized virtually the whole of the Caribbean, Central and South America, and the North Atlantic seaboard. The colonial period per se came to a close with the wars of national independence in the Americas between 1776 and 1830, leaving European states in control of little more than trading posts and exhausted sugar plantations.

The second period of expansion, one of imperial rather than colonial expansion, began after an interregnum marked by British naval hegemony. In the three decades after 1880, a scramble for territory partitioned Africa, Southeast Asia, and the Pacific among Great Britain, France, Germany, Belgium, and Portugal, while the United States annexed the remains of the Spanish Empire. None of this expansion involved much metropolitan emigration; colonial officials, traders, planters, and missionaries formed a thin veneer on indigenous societies.

The sources of the political structures of imperial rule lie in both metropolitan and indigenous traditions. Colonies tended to be formally organized along metropolitan lines (Fieldhouse 1966). Settler colonies mirrored domestic political structures quite directly (Lang 1975), while nonsettler colonies recall metropolitan structures in a more abstract fashion. For example, the British tried to fashion systems of local rule (Lugard [1922] 1965), while the French strove to create a unified, centralized administration. But the superficiality of most imperial rule led to great variation in actual administrative arrangements. Even empires whose guiding rationale was assimilation (the French and the Portuguese, especially) depended heavily on indigenous authorities and traditions.

Overseas colonies also varied in the strength and character of their economic relationship to the metropolis. Only a few colonies were the source of great riches for the metropolitan economy: most prominently, the American settler and plantation colonies, British India, and the Dutch East Indies. Others had a largely strategic value; much

of the British Empire, for instance, was acquired in the effort to maintain lines of communication to India. The great majority of colonies acquired after 1880 had rather little importance for the metropolis, either as markets for imperial products or as sources of raw materials (Fieldhouse 1973).

Theories of Imperialism. The starting point for modern theories of imperialism is John Hobson's *Imperialism: A Study* ([1902] 1965). A liberal critic of the Boer War, Hobson saw imperial expansion as a search for new outlets for investment. He found the source of this search in the surplus capital amassed by increasingly monopolistic corporate trusts. Hobson viewed imperial expansion as costly for the nation as a whole and sought to expose the special interests promoting imperialism. He also contended that capital surpluses could be consumed domestically by equalizing the distribution of income.

Lenin's *Imperialism: The Highest Stage of Capitalism* ([1917] 1939) provides the most influential statement of an economic analysis of imperialism. Lenin agreed with Hobson that imperialism flowed from the need to invest outside the domestic economy, drawing explicitly on Hilferding's ([1910] 1981) analysis of finance capital as a stage of capitalism. He was concerned to show that imperialism was a necessary consequence of the dynamics of capitalism (in contrast to Hobson's anticipation of Keynes) and that the expansionary impulse could not be globally coordinated (versus Kautsky's notion of an ultra-imperialism). Lenin argued that the unevenness of development makes imperialist war inevitable, as "late starters" demand their own place in the sun.

More contemporary writers like Baran and Sweezy (1966), Frank (1967), and Wallerstein (1974) drew upon both the Marxist tradition and Latin American theories of *dependencia* to suggest an alternative economic analysis of imperialism. They argued that international economic relations involve a net transfer of capital from the "periphery" to the "core" of the economic system and point to the continuities in this process from early colonial expansion to contemporary neoimperialism. This is in sharp contrast with the Leninist tradition, which argues that colonial forays bring noncapitalist societies into the world economy.

Other writers consider political ambitions or relationships to be the taproot of imperialism. In

perhaps the most interesting account of this sort, Schumpeter (1951) turned the Marxist perspective on its head. He noted that the characteristic motif of the ancient empires is military expansion for its own sake. Schumpeter argued that imperialism appears as an atavistic trait in the landed aristocracy of modern societies, stressing the mismatch between the social psychology of the warrior and the industrious, calculating spirit of the entrepreneur. A more political perspective treats imperial activity as flowing from the anarchical structure of the Western state system (Cohen 1973; Waltz 1979). In the absence of an enforceable legal order, states are motivated to expand when possible or endure decline relative to more aggressive states. This perspective explains European imperialism in the nineteenth century as the product of increasing levels of international competition and conflict.

Whether economic or political, most analyses of imperialism find its sources in the logic of the West, ignoring indigenous peoples in the process. John Gallagher and Ronald Robinson led a historiographic revision aiming to redress this imbalance. Their seminal essay "The Imperialism of Free Trade" (1953) emphasized the continuity in British policy between the informal imperialism of the mid-eighteenth century and the rush for colonies after 1880. In *Africa and the Victorians*, Robinson and colleagues (1961) argued that it was increasing indigenous resistance to European influence that led Britain to replace informal domination with formal empire. In later work, Robinson (1972) emphasized the other side of the coin—the extent to which Western empires as political systems were dependent on local collaboration.

DECOLONIZATION

"Decolonization" refers to a polity's movement from a status of political dependence or subordination to a status of formal autonomy or sovereignty. In modern usage, it is generally assumed that the imperial or metropolitan center is physically separated from the dependency and that the two societies are ethnically distinct. The term refers specifically to the disintegration of Western overseas empires and their replacement by sovereign states in the Americas, Asia, and Africa.

There are several routes by which decolonization can take place. Most frequently, the dependency

becomes a new sovereign state, a political entity recognized in the international arena as independent of other states and as possessing final jurisdiction over a defined territory and population. Less often, decolonization may occur through the dependency's full incorporation into an existing polity, such that it is no longer separate and subordinate.

It is often unclear when (or whether) decolonization has occurred. Puerto Rico's relation to the United States can be described as one of colonial dependency or as free association. In the 1960s, Portugal claimed to have no colonies, only overseas territories formally incorporated into a unitary Portuguese state (Nogueira 1963). And where political relations are not contested, the absence of overt conflict makes it difficult to know when sovereignty has been achieved. For example, arguments can be made for dating Canadian independence at 1867, 1919, 1926, or 1931.

European Political Contraction. Virtually all of the decolonization of Western overseas empires occurred in two historical eras (Bergesen and Schoenberg 1980). The major American colonies became independent during the late eighteenth and early nineteenth centuries. The mid-twentieth century witnessed a more rapid and complete wave of decolonization worldwide. The types of colonies in existence in each period and the nature of the decolonization process varied greatly across the two periods (Fieldhouse 1966; Strang 1991a).

The first wave of decolonization began with the independence of Britain's thirteen continental colonies as the United States of America. The French Revolution touched off a slave uprising that led ultimately to the independence of the French colony of Saint Domingue as Haiti. Portuguese Brazil and Spanish Central and South America became independent after the Napoleonic Wars, which had cut Latin America off from the Iberian peninsula.

While the first period of decolonization was limited to the Americas, twentieth-century decolonization was global in scope. It included the independence of most of the Indian subcontinent, Southeast Asia and Australasia, the Middle East, Africa, and the Caribbean. Between the world wars, some of Britain's settler colonies and a number of loosely held protectorates became fully sovereign. Soon after World War II, the major

Asian colonies—India, Indonesia, Indochina, and the Philippines—achieved independence. The pace of change rapidly accelerated during the 1960s, which saw the decolonization of nearly all of Africa. By the 1980s, nearly all Western colonies had become independent or had been fully incorporated into sovereign states.

One fundamental difference between the two eras of decolonization has to do with who sought independence. Early American decolonizations were creole revolutions, as the descendants of European settlers sought political autonomy from the “mother country.” The American Revolution and the Spanish Wars for Independence were political rather than social revolutions. Slave revolt in Haiti provided the sole exception, to the horror of creole nationalists as well as loyalists elsewhere.

By contrast, twentieth-century decolonization was rooted in indigenous rather than creole movements for independence, as decolonization came to mean freedom from racially alien rule. After World War II, settler minorities opposed decolonization, since national independence spelled an end to their privileged political, economic, and social position. Only in South Africa did a racist minority regime survive decolonization.

The first and second waves of decolonization also differed importantly in the amount of violence involved. Early decolonization in the Americas was won through military combat between settler and imperial forces. Wars for independence raged in Britain’s thirteen continental colonies, in Spanish Central and South America, and in Haiti. Only in Portuguese Brazil was independence achieved without a fight, largely because Brazil was several times richer and more populous than Portugal.

During the twentieth century, protracted wars for independence were fought in Indochina, Indonesia, Algeria, and Angola. But these were the exceptions to the rule. Most colonies became independent with little or no organized violence between the imperial state and colonial nationalists. In much of Africa, imperial powers virtually abandoned colonies at the first sign of popular opposition to the colonial regime. By the mid-1960s, decolonization had become a rather routine activity for many imperial powers, often achieved through institutionalized expressions of popular will such as plebiscites.

Causes of Decolonization. A variety of arguments have been developed about factors contributing to decolonization. While most treatments have dealt with a single dependency or empire, there have been a number of efforts to develop explicitly comparative analyses (see Albertini 1982; Anderson 1983; Bergesen and Schoenberg 1980; Boswell 1989; Emerson 1960; Grimal 1978; Lang 1975; Smith 1978; Strang 1990).

Decolonization is often seen as the result of structural change in the dependency itself. Settler colonies are thought to undergo a natural process of maturation, well expressed in the physiocratic maxim that colonies are like fruit that fall from the tree when they are ripe. Indigenous populations are also importantly affected by contact with Western economic and political structures.

In both kinds of colonies, the specific condition that seems to precipitate decolonization is the emergence of peripheral nationalism. Settler colonies generally began as economic corporations chartered by European states. Non-Western peoples were generally tribal or segmental societies prior to colonization, and imperial structures were fundamentally dependent on the collaboration of indigenous elites (Robinson 1972). Decolonization required a new vision of the colonial dependency as a national society (Anderson 1983; Diamond 1958).

Colonial powers contributed unintentionally to the formulation of a national vision. They did so partly by spurring the rise of new social groups—indigenous bourgeois, landless workers, civil servants, teachers—who proved to be the carriers of colonial nationalism and independence. Contact with the colonial power exposed these groups to the notions and institutions of the Western nation-state while simultaneously denying them participation rights. Settlers, of course, carried notions of these rights with them (see Bailyn 1967 and Greene 1986 on the ideological origins of the American Revolution). Under these conditions, nationalism was a weapon easily turned on its creators (Emerson 1960; Strang 1992).

While pressures for decolonization invariably stemmed from the dependency itself, the response of the metropolitan power played a crucial role in the outcome. The classic contrast in imperial policy is between British “association” and French “assimilation” (though parallel contrasts between

the imperial policies of the United States and Portugal are even more striking). The British empire was administratively structured around indirect rule and local autonomy, which permitted considerable flexibility in the imperial reaction to pressures for decolonization. By contrast, the French aimed at the assimilation of their colonies into a unitary republic, which led to firmer resistance to decolonization.

Some decolonization occurred because the balance of military capacity shifted against metropolitan states. This was crucial to the decolonization of the Americas, as increasingly vigorous creole societies could not be controlled from across the Atlantic. After World War II, metropolitan weakness was a contributing factor as European colonial states found themselves reduced to the position of second-rate powers. At critical junctures after 1945, metropolitan governments were unable to project sufficient military power abroad to control events: the British in Suez, the French in Indochina and Algeria, the Dutch in Indonesia.

Finally, several systemic factors or processes may be linked to decolonization. One is the presence of a state that is economically and politically dominant on the world stage. It has been argued that "hegemonic" states seek to construct a global free-market system that provides them access to markets more cheaply than does formal control (Bergesen and Schoenberg 1980; Boswell 1989; Krasner 1976). This argument has much in common with Gallagher and Robinson's (1953) notion of an "imperialism of free trade" that metropolitan states preferred to the overhead costs of empire. Both Britain and the United States supported the collapse of rival empires and avoided empire building themselves during the periods of their global hegemony.

A second systemic factor is the contagiousness of decolonization. The American Revolution served as a model for insurrection in both Haiti and Latin America. After World War II, the independence of India, Indochina, and Indonesia had a substantial impact on colonized peoples everywhere. The contagiousness of independence is most apparent in the rapidity with which decolonization swept across Africa, where thirty-three colonies became independent between 1957 and 1966.

Finally, global political understandings and discourse play a critical role in decolonization

(Strang 1990). After 1945, the two superpowers were ideologically opposed to colonialism, though each accused the other of imperialism. Even the major imperial powers (Great Britain, France, the Netherlands) found it difficult to reconcile colonial possessions with the political ideas and institutions of the evolving national polity. As a result, the rationale for colonialism crumbled under pressure, with imperialism being formally denounced by the United Nations in 1960.

The social construction of a society or administrative unit as a "colonial dependency" is thus crucially important to mobilization around national independence, particularly given contemporary political understandings. A sharp distinction is generally drawn between the overseas empires of European states and "internal colonies" such as Wales, Armenia, or Eritrea. While the empirical basis for such a distinction is sometimes shaky, it is real in its consequences. Identification as a colonial dependency greatly increases the chances of mobilizing internal and external support for indigenous nationalism; it also vastly reduces the compulsion that the metropolitan state can legitimately bring to bear.

Consequences of Decolonization. The implications of decolonization for more general notions of international domination or exploitation are strongly contested. Dependency and world systems theorists view decolonization as producing change in the mere form, but not the content, of core-periphery relations (Chase-Dunn and Rubinson 1979). The argument is that contact between more and less developed economies tends generally to reinforce the differential between them, even in the absence of explicit political controls. Dependence on foreign capital has been argued to slow long-term economic growth (Bornschiefer et al. 1978) and more generally to shape the political and economic structure of the dependent society (Amin 1973; Cardoso and Faletto 1979).

Despite these concerns, it is clear that decolonization involves a fundamental shift in the structures regulating international exchange, especially in the post-World War II era. Contemporary states are armed with widely accepted rights to control economic activity within their boundaries, including rights to nationalize foreign-owned

industries and renegotiate contracts with multinational corporations (Krasner 1978; Lipson 1985). Third World nations mobilize around these rights (Krasner 1985), and the negative impact of economic dependency seems to decrease when the peripheral state is strong (Delacroix and Ragin 1981).

While notions of dependency and neocolonialism are the subject of vigorous debate, a straightforward consequence of decolonization is the worldwide expansion of an originally European state society. Most of the present members of the United Nations became sovereign through decolonization (McNeely 1995). And historically, the political units emerging from decolonization have been strikingly stable. Few ex-dependencies have been recolonized or annexed or have merged or dissolved (Jackson and Rosberg 1982; Strang 1991b). Against much expectation, decolonization has produced states that figure as core players in the contemporary international economic and political order.

IMPRESSION FORMATION

See Affect Control Theory and Impression Formation; Social Psychology.

INCEST

Incest is illicit sex or marriage between persons socially or legally defined as related too closely to one another. All societies have rules regarding incest. Incest is conceptualized in four ways: as a proscribed or prescribed marriage form, as a taboo, as prohibited coitus, and as child abuse. The first three conceptualizations are most closely related to early scholars (mid-1800s to mid-1900s), who tended to overlap them. The last conceptualization has become prominent more recently.

Incest-as-marriage rules are usually proscriptive ("Thou shalt not"). Prescriptive ("Thou shalt") incestuous marriage rules have been documented for royalty in Old Iran and ancient Egypt and for Mormons in the United States (Lester 1972). Some groups historically encouraged brother-sister incest. Cases in point were the ruling families of Egypt and Polynesia, where preservation of family resources and ethnic identity took precedence over political alliances with other groups (Firth 1936, 1994).

That some groups proscribe while others prescribe incestuous marriages has caused some to be skeptical of many theories about incest, especially theories that assume that incest avoidance is natural, that close inbreeding is genetically disadvantageous, or that there is an incest taboo. John F. McLennan ([1865] 1876), a lawyer, coined the terms *endogamy* (within-the-group marriage) and

exogamy (outside-the-group marriage). He defined incest as endogamy. Based on his analyses of marriage in Ireland, Australia, ancient Greece, and other societies, he concluded that rules proscribing endogamy evolved as a group survival mechanism. He reasoned that as members of one tribe or group married into others, “blood ties” emerged. These blood ties encouraged reciprocity between groups and cooperation and harmony within groups.

Anthropologist Lewis Henry Morgan ([1877] 1964) generally agreed with McLennan’s definition of incest as endogamy and with McLennan’s assumption that proscribing incest promoted both exogamy and group survival. Morgan assumed, however, that incest originally became prohibited due to the presumed deleterious effects of inbreeding. That is, Morgan assumed that at some point, humans developed the capacity to see that exogamy increased the “vigor of the stock” (p. 65). Moreover, in agreement with sociologist Herbert Spencer’s ([1876] 1898, pp. 623–642) earlier critique of McLennan’s application of the terms “endogamy” and “exogamy,” Morgan ([1877] 1964) contended that given the very contradictory nature by which kinship is recognized and organized among humans, McLennan’s “terms and his conclusions are of little value” (p. 432). Finally, Morgan contended that practices such as brother-sister and father-daughter marriage among Hawaiians, for instance, spoke to earlier, savage stages of human existence. To Morgan, human groups evolve through three basic epochs: savagery, barbarism, and civilization. The first two epochs each have two stages, the last one only one stage. In Morgan’s schema of the evolution of humankind, at the very first stage there is promiscuous intercourse and the marriage of brothers and sisters. In the second stage, brother-sister marriage is prohibited. The third stage of evolution sees prominence given to the Gentile pattern of social organization, which includes monogamy. The patriarchal family characterizes the fourth stage. The fifth, and final, stage in the schema, arising with the concept of property, is hallmarked by the monogamian family and the superiority of the “Aryan, Semitic, and Uralian system of consanguinity and affinity” (Morgan [1877] 1964, pp. 421–422). To Morgan, the Aryan family represented the highest level of human evolution, and thus the epitome of civilized humans. This high civilization was attributed to the “providence of God” (p.

468). To Morgan, in this civilized arrangement, cousin marriage is prohibited. In reading Morgan’s work, one gets the impression that he saw this last stage as the best and the highest, and seemed to personally identify with it. Thus, it is somewhat curious that he married his cousin, Mary Elizabeth Steele.

Tylor (1889) elaborated on McLennan’s notion of exchange and reciprocity among exogamous groups. He noted that men made political alliances with men in other groups by exchanging women in marriage. Spencer ([1876] 1898) argued that endogamy was probably the original practice among early peoples, especially among peaceful tribes. Exogamy probably began through wife stealing. He assumed that some early groups probably stole wives from other groups because they faced a scarcity of women. Other groups forcefully captured wives in the process of war. Thus, Spencer positioned exogamy as originally speaking to extremely brutal treatment of women. He assumed that as time passed and circumstances changed, exogamy would be seen as advantageous to groups who could make the linkages between sexual intercourse and procreation. That is, these groups might come to see exogamy as leading to a healthier stock of people. In addition, he assumed that, over time, such exchanges also would be seen as creating bonds among groups who otherwise might compete for scarce resources or else annihilate each other through warfare.

The common thread among these theories is the focus on incest rules as social organizational principles. A shared weakness is the reliance on analyses of primitive or premodern groups. These inclinations are also found in varying degrees in writings by Sir James Frazer (1927), Brenda Seligman (1929, 1932), Robert Briffault (1930), Bronislaw Malinowski (1922, 1927, 1929), George Murdock (1949), and Claude Levi-Strauss ([1949] 1969). Many of these and other writers also fail to differentiate between incest rules and exogamy rules. What one group calls incestuous marriage may not biologically be such. Likewise, some groups’ exogamy rules permit biologically incestuous marriage. Recognizing that incest rules are socially defined, Sumner (1906) presaged today’s sociobiologists. Sumner argued that incest rules should be modified as researchers gathered genetic evidence that

dispelled fallacious beliefs that all incestuous matings are deleterious.

Sociologist Emile Durkheim's *Incest: The Nature and Origin of the Taboo* ([1898] 1963) is an infrequently cited magnum opus. Based on ethnographic research in Australia, this book emphasized and illustrated the social and moral origins of incest taboos. Durkheim noted the ways in which prohibitions against incest and penalties for rule violations organize social groups internally. Cooperation and alliances with other groups via exogamy are consequently prompted. Durkheim contended that the incest taboo has a religious origin. It is derived from the clan's sentiments surrounding blood, specifically menstrual blood. While blood is taboo in a general way, contact with the blood of the clan is taboo in specific ways. Durkheim reasoned that menstrual blood represents a flowing away of the clan's lifeblood. This renders women taboo for and inferior to men of the same clan. The taboo relates to intercourse in general and to marriage in particular. Blood and incest are presumed to be related such that a man violating the taboo is seen as a murderer. Thus, in a real sense, Durkheim posited women as having a dual nature, being at once both sacred and profane. That women bear children, thus rendering a clan immortal, made them sacred. However, since they spilt blood, which itself is sacred, they had a profane nature to them. To marry a clan's women to another group kept the clan sacred, while at the same making it possible for other clans to perpetuate themselves.

Durkheim contended that the origin of the taboo is lost to the consciousness of clans over time but that the taboo itself is replaced by a generalized repugnance of incest. This repugnance prompts men to exchange women with other groups, thus facilitating political alliances between men of different groups. In addition, in his *The Division of Labor in Society* ([1893] 1963), Durkheim posited that when incest loses its religiously based criminal status, prohibitions against it are or will be codified into law.

While brother-sister marriages are negatively sanctioned in many parts of the world, the United States contrasts sharply with European and other nations in having civil laws that prohibit cousin marriage as well (Ottenheimer 1990). Roughly 60

percent of U.S. states prohibit cousin marriage. Many of the states have prohibitions placed on marriages other than brother-sister or cousin-cousin. For instance, Alaska prohibits marriage to persons more closely related than the fourth degree of consanguinity, regardless of whether this relationship is whole- or half-blood. Both Rhode Island and South Carolina forbid men to marry their stepmother, grandfather's wife, wife's daughter, and various other affinal or blood kin. Both states forbid women to marry their husband's grandfather, son's daughter's husband, daughter's husband, stepfather, or grandmother's husband (Kessinger 1990). Many of these laws no doubt were influenced by persons such as Morgan, with his emphasis on social evolution and his contention that civilized people simply don't engage in incestuous pairings. It is probably also the case that the eugenics movement, of the late 1800s through roughly the early 1900s, had some effect on maintaining such laws. The word "eugenics" was coined by biologist Francis Galton and meant improvement in the human race through selective breeding (Parrinder 1997). Galton and his followers were concerned with an array of social issues that they thought could be minimized if not eradicated through eugenics. These included overpopulation caused by high fertility rates of immigrants, poor people, and other classes of people deemed to be of inferior stock. Given a belief that criminals biologically inherited their antisocial tendencies, proponents of eugenics also believed that sterilization and birth control were necessary among some people so that they did not bring forth more generations of criminals (Rafter 1997). Fears of the negative effects of human inbreeding were also high at this time, resulting in several U.S. states passing laws that made cousin-cousin marriage a criminal offense (Gibbons 1993). The eugenics movement is also associated with social Darwinism and the Nazi regime. However, both of these topics are beyond the purview of this article.

Marriage laws and moral crusades aside, endogamous unions have continued to occur in the United States. An analysis of marriage patterns in Madison County, Virginia, 1850-1939, revealed a rather high rate of marriage between first cousins and first cousins once-removed (Frankenberg 1990). Possible reasons for these patterns may include restricted physical mobility and preference for

socially similar others. Relying on U.S. Census data, another study revealed a fairly high rate of endogamy among Louisiana Cajuns (Bankston and Henry 1999). Partial explanations for this endogamy include restricted residential mobility, ethnic identity emphases of the subculture, and a preference for social-class homogamy. The rate of biologically incestuous unions among this group, however, was not made clear in the report.

The concern over genetic transmission of physical and mental defects through marriage to close relatives continues today. In an analysis of consanguineous marriage and health profiles of offspring from these unions, researchers in Dammam City, Eastern Province, Kingdom of Saudi Arabia, found that of the 1,307 unions studied, 52 percent were consanguineous. The most common consanguineous union was among first cousins. These consanguineous unions are associated with culture values and efforts to keep property and resources in the family. The study revealed that babies born of a consanguineous union tended to be smaller than those born of a nonconsanguineous union (Al-Abdulkareem and Ballal 1998). A recent American study focused on the relationship between consanguinity and childhood mortality in an Old Order Amish settlement. It was found that the Amish in the Lancaster, Pennsylvania, area are at risk for genetically transmitted defects that result in increased mortality rates. In addition, consanguineous unions resulted in higher neonatal and postnatal death rates than did nonconsanguineous unions (Dorsten et al. 1999).

Sigmund Freud focused on the incest taboo ([1913] 1950) and infantile sexuality ([1905] 1962). Through his tale of the primal horde, Freud posited that in the original family there was a jealous and violent father who engaged his daughters in incest. The jealous brothers banded together, killed, and ate the father. Horrified by their deeds, the brothers made incest taboo. For Freud, this (the moment when humans created incest rules) was when humans became social. He assumed that very young (Oedipal) children sexually desire their opposite-sex parent. Little boys then suffer from castration anxiety, fearing that the father will become aware of their desires and punish them. While little girls see their mothers as inferior to men, they also know them to be more powerful than they are.

Thus, little girls resignedly align themselves with their mothers, repress their incestuous impulses, and experience penis envy. Even though Freud's theories were based on conjecture and focused on the bourgeois nuclear family of his day, they have nonetheless influenced many social scientists, including French anthropologist Jean Claude Levi-Strauss ([1949] 1969) and American sociologist Talcott Parsons (1954).

Levi-Strauss agreed with Freud that humans became social with the creation of incest rules. Borrowing from the emphasis on the exchange of women, found in the works of Durkheim and Marcel Mauss, and Durkheim's assumption that women of a clan become the symbol (totem) for the clan, Levi-Strauss posited that exogamy represents a special form of alliance-creating reciprocity. Since incest involves sexuality, incest rules and the exchange of women represent a unique social connection between the biological and the cultural. Although frequently lauded by social scientists, the work of Levi-Strauss adds little to previous theories about incest.

Parsons incorporated Freud's theory of infantile sexuality into his structural-functionalist view of the American nuclear family. Like functionalists before him, he assumed that incest rules exist to prevent role confusion within the nuclear family and to encourage alliances with other families (see also Malinowski 1927, 1929). He contended that the mother was to exploit her son's Oedipal desires as if she had him on a rope. At earlier ages she was to pull him toward her, encouraging heterosexuality. At later ages she was to push him away, encouraging him to establish relationships with nonrelated females. Tugging and pulling on the rope were also designed to assist the son in internalizing society's incest rules and guide him in creating his own nuclear family. Parsons assumed that little girls also experience an erotic attachment to their mothers. He argued that as the mother severed this attachment, it was her responsibility to instill in the daughter an aversion to both father-daughter and brother-sister incest. Failure to do this would result in family disorganization and in the daughter's inability to become a normatively functioning adult. Parsons contended that incest aversion would be realized if the mother kept the erotic bond with her husband intact.

Parsons's analysis has thus assisted in perpetuating what child abuse researchers have sought to eradicate: placing blame on mothers when fathers incestuously abuse their daughters (see Finkelhor 1984; Russell 1986; Vander Mey and Neff 1986).

Psychologist Edward Westermarck ([1891] 1922) contended that family and clan members develop a sexual aversion to one another due to the dulling effects of daily interaction and the sharing of mundane tasks. This aversion prompts the development of laws and customs proscribing incest among persons with a shared ancestor and set of obligations based on clan membership. Westermarck noted that failure to develop this aversion and the propensity to violate incest laws were due to alcoholism, membership in the lower social classes, inability to control the sex drive, lack of alternative sexual outlets, social and geographic isolation, and failure to have developed normative, family-like feelings of duty. Variations on Westermarck's thesis appear in writings today. Some focus on a learned aversion that Oedipal children develop because their fantasies cannot be realized, due to their lack of full sexual maturation. Westermarck's thesis is weak because if there were a natural aversion to incest, then laws prohibiting it would be unnecessary. Furthermore, a growing body of literature suggests that persons who share mundane tasks and interact daily do not necessarily develop a sexual aversion to one another (see Vander Mey and Neff 1986).

Sociobiologists (e.g., Parker 1976; van den Berghe 1980) variously incorporate Freudian theses, Westermarck's thesis, and the assumption that human social behavior follows a fitness maxim to argue that groups establish prescriptive or proscriptive incest rules to enhance a group's survival by facilitating genetic advantages. Sociobiologists typically use the functionalist assumption that incest rules regulate the internal dynamics of the procreating group and encourage affiliation with other nuclear groups. Violations of incest rules are assumed to be caused by the factors identified by Westermarck. Many sociobiologists link intercourse directly to procreation. The assumption has no merit when one tries to explain why adult-child and child-child intercourse occurs. Equally problematic is the frequent reliance on the rules prescribing incest among royals. Dismissed is the role that

ethnocentrism plays in such rules. Finally, serious questions arise when research on primates, birds, or other nonhumans is extrapolated to human social behavior and organization. In sum, it is questionable whether the sociobiological arguments for, and data supporting the existence of, incest-avoidance mechanisms in humans can be confidentially accepted (Leavitt 1990).

A new twist on sociobiological discourse on the incest taboo comes from the field of genetic psychology. It is proposed that the taboo exists to protect children's "mating-strategy template." It is assumed that humans have a mating-strategy template that effectively gears females toward attracting men who can provide for them and their children. The human biogram also orients males toward being able to garner valuable resources for themselves, which they can then share with mates and children. It is assumed that should adult-child incest occur, male and female children who experience it will have disruptions in their mating-strategy template. In effect, if incest occurs, then the developing girl child will suffer various psychopathologies and will be unable to adequately compete for suitable mates. This will make her less attractive as a potential mate. Boys who experience father-son incest will lose the ability to be instigators of mating since it already has been imposed on them. Boys then become targets. It is assumed that by lowering children's attractiveness as mates, their reproductive success is also lowered. With this lowered reproductive success, future generations are negatively affected as well. Therefore, it is argued that incest taboos have been instituted as a way to avoid these long-term consequences for greater intergenerational success in mating outside one's own group (Immerman and Mackey 1997).

Prefiguring more recent research on incest as child abuse, Durkheim wrote that incest violations are most likely to occur in families in which members do not feel morally obligated to be dutiful to one another and to practice moral restraint ([1898] 1963). In many parts of the world today, incest is seen as a serious and severe type of child abuse. As child abuse, incest is any form of sexual touching, talking, or attempted or actual intercourse between an adult and a child or between two children when the perpetrator is significantly older than the victim or forces the victim to engage in actions against his or her will. The perpetrator and victim

are related either by consanguinity or affinity. Incest is abuse because it harms the victim and violates the child's basic human rights. Its negative effects linger throughout victims' lives (Russell 1986). That the sexual victimization of children is nothing new, but rather ancient, is well documented (deMause 1982; Rush 1980). Public recognition of incest as child abuse, however, has its roots in research and public discourse dating from roughly the early 1970s.

Had Freud not abandoned his first psychoanalytical paper, "The Aetiology of Hysteria" ([1896] 1946), he could have been heralded as the savior of children. In this paper he described incest and other sexual abuse experienced by eighteen patients when they were children. He linked his adult patients' problems to their experiences of childhood sexual trauma. However, when his paper was coldly received and then ignored by senior psychologists, and Freud faced professional ostracism, he dismissed these findings (see Jurjevich 1974; Masson 1984). He reasoned that his patients were incorrectly recalling masturbatory childhood fantasies of sexual encounters with adults (Freud [1905] 1962). Freud then associated adult neurosis and hysteria with unfulfilled childhood incest fantasies.

Freud's revamped theories quickly became popular. Several writers then recounted case studies of children who had experienced sex with an adult. The children were described as seductive and provocative. They were not seen as victims; rather, they were seen as sexual initiators (see Vander Mey and Neff 1986). Although Swedish sociologist Svend Riemer (1940) and American sociologist S. Kirson Weinberg (1955) tried to bring attention to incest as a form of family deviance that sometimes resulted in harm to victims, Freudian theory held fast until the late 1960s. The "discovery" of child abuse, in conjunction with the civil rights movement, the anti-Vietnam War movement, and the resurgence of the women's rights movement, refocused attention such that the physical abuse of children and rape of women became seen as serious wrongs inflicted on other humans and as special types of social problems (Vander Mey and Neff 1986). Since that time, theories and research have explored in great detail why and how incestuous abuse occurs and its lasting negative effects. Laws protecting children against such abuse have been enacted. These laws mandate that

treatment services be available for victims, perpetrators, and families (Fraser 1987). They also stipulate penalties (fines, imprisonment) for convicted abusers. These operate on a sliding scale, with harsher penalties applied to cases in which the victim is very young or has suffered serious physical or psychological trauma because of the abuse. Some cases are handled in family courts. Others, especially those involving serious harm to the child, are heard in criminal courts. Although variable in scope, laws in European nations prohibit and punish incestuous child abuse (Doek 1987). As with statutes in the United States, applicable penalties often depend on the victim-perpetrator relationship, the age of the victim, and the seriousness of harm to the victim. Efforts to refine legal statutes and penalties continue. Laws are also needed that more specifically define and punish child-child incestuous abuse. While the bulk of research on incestuous abuse has focused on adult-child incest, there is accumulating evidence to the effect that sibling incest is more common than previously thought and also can be traumatizing (Adler and Schutz 1995; Vander Mey 1988).

Feminists usually focus on father-daughter incest. They refer to it as rape to emphasize the specific type of abuse that it is. The term "rape" also illustrates the point that if an adult male forced another person to engage in intercourse with him, he could be arrested. However, if he rapes his own child, it is called incest, which is often seen as a disgusting, private, family problem (Brownmiller 1975). Feminists see incest as commonplace, originating in and perpetuated by patriarchy (Rush 1980). A general feminist approach to father-daughter incest incorporates a discussion of the sex-role socialization of males and the male-as-superior patriarchal ideology as causal factors in incest. The contention is that females ultimately are rendered second-class citizens, the property of men, and sexual outlets for men (see Rush 1980). Problems with a general feminist perspective on incest include a focus limited to father-daughter incest, the monocausal linkage of patriarchy to incest, the portrayal of all incest perpetrators as male and all incest victims as female, and the oversimplified view of male sex-role socialization (Vander Mey 1992; see also Nelson and Oliver 1998). American feminist sociologist Diana Russell (1986) extends and refines the general feminist approach to incest. She argues that males are

socialized to sexualize the power given them by virtue of the fact that they are male. This includes sexualizing the power they have over their own children. Moreover, Russell recognizes that mothers and children can be incest perpetrators. She advocates androgynous socialization of children, more equality between men and women, and more public awareness of the harsh realities of incestuous abuse.

Welsh psychologist Neil Frude (1982) relied on existing empirical and clinical research to articulate a five-factor explanatory model of father-daughter incest. These five factors are sexual need (of the perpetrator), attractive partner, opportunity, disinhibition, and sexual behavior. A strength of Frude's model is the attention paid to the interweaving of sex and power. Weaknesses include the fact that incest perpetrators are not usually sexually deprived, victim attractiveness is often irrelevant, and families are not usually closed systems today. American sociologist David Finkelhor (1984) offers a somewhat similar model, although it differs from Frude's model in that Finkelhor pays keen attention to the myriad ways in which larger social forces and cultural ideology are related to child sexual abuse. Finkelhor's model has the added strength of being applicable to several types of incest and other sexual abuse.

American sociologists Brenda Vander Mey and Ronald Neff (1986) constructed a research-based ecological model of father-daughter incest. They begin with the assumption that there is no incest taboo. Rather, there are rules proscribing adult-child incest. They contend that characteristics of the society, the neighborhood, the family and the marital dyad, and the father-daughter dyad differentially affect the probability that a daughter will be sexually abused by her father. These levels of influence interact in complicated ways. Father-daughter incest is associated with dominance in society and in the family, residence in a violent neighborhood, social isolation of the family, family disorganization, and the father's lack of empathy for his wife and children. Mitigating factors decreasing the likelihood of incest include a father's conformity to rules against incest, sex education of the daughter, and media attention to adult-child incest as wrong and illegal. This model is strong in its reliance on research and theoretical principles. Although this model is limited to father-daughter incest, it does provide

information that can assist in identifying children at risk for incestuous abuse.

Incestuous abuse of children, male and female alike, is associated with an array of problems for victims. These problems include bulimia, self-mutilation, alcohol abuse, criminal behavior such as assault and shoplifting, psychological impairment, sexually aggressive behavior, and sexual hyperarousal (Araji 1997; Green 1993; Kinzl and Biebl 1992; Ryan et al. 1996; Wonderlich et al. 1996).

Incestuous abuse is seen as an international social problem today. At least four journals frequently carry the latest research on this topic: *Child Abuse and Neglect*, *Journal of Family Violence*, *The Journal of Interpersonal Violence*, and *The Journal of Child Sexual Abuse*.

However, not everyone sees adult-child sexual contact as abusive. It has been argued that American and European cultures have long tended to deny that children have a sexuality. That is, experts on child development have for many decades focused on every other aspect of human development but have ignored child sexuality. In addition, audiences have been less than receptive to the idea that children might enjoy sexual contact with other children—or with adults—and that this contact might be conducive to their development in a constructive way. It has been argued that taking the cultural constraints away from children's need to develop their sexuality is part of a child's right (Martinson 1973, 1994; Yates 1978). Due to the very sensitive nature of the topic, few empirical studies on child sexuality have been conducted. Of the few available studies, one was a longitudinal study of sexual experiences in early childhood. It revealed that most of the children focused on in the study had engaged in some form of sex play by age six (Okami et al. 1997). However, another extensive study of college students revealed that among those who had experienced sexual contact while children, sexual contact with an adult was more often seen as unwanted, unwelcome, and/or abusive (Nelson and Oliver 1998).

Organizations such as the North American Man Boy Love Association contend that the child abuse laws constrain children's liberty. Some parents, particularly in the United States and Europe, have resisted the child sexual abuse laws as infringing on their right to rear their children in ways they see as most appropriate (for elaboration, see Beckett

1996; Hechler 1988). Thus, just as marriage laws and cultural groups vary in their definitions of what constitutes incestuous marriage, we now are seeing public discourse on how best to define sexual contact with children.

BRENDA J. VANDER MEY

INCOME DISTRIBUTION IN THE UNITED STATES

As the twentieth century drew to a close, the gap between rich and poor in the United States, and between the wealthy and impoverished nations of the world, continued to widen. This entry extends the analysis presented in the 1992 edition of the

Encyclopedia (largely based on 1988 data) to include information on income, wealth, and poverty gathered from studies conducted in the mid- and late 1990s by various government departments, academic economists, and private research institutions.

INCOME DISTRIBUTION

Data on money income for households, families, and persons in the United States are collected yearly by the Bureau of the Census, based on a national probability sample of approximately 50,000 households. The official definition of “income” is money income before taxes, including some government transfers (Social Security benefits, welfare payments, worker’s compensation), returns on investments, and pensions, but excluding capital gains or health insurance supplements paid by employers. In recent years, the Census Bureau has also published computations based on fourteen alternative definitions of income; for example, after deducting a range of taxes or after adding the earned income credit, the value of noncash government benefits such as food stamps, school lunches, and Medicare or Medicaid reimbursements to providers. Some of these alternative measures reduced the level of income inequality, while others increased it, but the general finding is that government transfers have a significantly stronger effect on reducing inequality than does the current tax system. For the sake of simplicity and consistency, this entry will primarily use data based on the official definition.

Household Income. In 1997, the median income for all 102 million U.S. households was \$37,005, an increase of almost 2 percent over 1996, continuing an upward trend from a low of \$34,700 in 1993. Adjusted for inflation, however, the 1997 median was slightly lower than the previous high of \$37,303 in 1989. As Table 1 indicates, there are significant differences among subgroups in median income, and while all but male nonfamily householders and Asian/Pacific Islanders experienced an increase in real income over the previous year, data covering the entire period 1989–1997 present a mixed picture. Gains between 1989 and 1997 were highest for black households, for both married-couple family households and those headed by a female householder, and for persons aged

55–64. Losing ground over the eight years were male family householders without a wife, male nonfamily householders, Hispanic households, and households headed by young adults age 15–24 as well as by those 35–54 years old.

With respect to region and place of residence, households outside metropolitan areas and in the South and Midwest experienced income gains; metropolitan households and those in the Northeast and West suffered declines. In absolute numbers, however, the South continues to lag well behind the Northeast, while at the extremes of the distribution, median household income in Alaska is almost twice that in West Virginia.

Because a “household” can consist of one person, often a young adult at the onset of the work life or an elderly retiree, household medians are typically lower than those for families, officially defined as two or more persons related by blood, marriage, or adoption. The advantages of family households, especially those comprising a married couple, over nonfamily households is shown in Table 1. Clearly, some of the other differences seen in Table 1—by race, ethnicity, region, and residence—can be accounted for variations in the proportion of married-couple family households.

Per Capita Income. Table 1 also reports on per person income, which has risen by close to 7 percent since 1989 in constant dollars, with black gains outstripping those for whites, although white per capita income remains roughly 40 percent higher than that of blacks. In addition, that part of per capita income which is accounted for by earnings continues to show a gender gap in wages, but one that has narrowed from a 31 percent advantage for male workers in 1989 to 25.8 percent in 1997. In part, this narrowing is due to a 3 percent increase in real earnings for women over the eight years, but also an even more significant decline of more than 4 percent for men during the same period. The loss in real earnings for men reflects the general decline in employment in high-paying unionized jobs in the blue-collar sector as well as corporate downsizing at the managerial level.

Although not shown in Table 1, per capita income also varies directly with years of schooling. Since 1980, the adjusted median wage for workers with only a high school education fell by 6 percent, while the median for college graduates rose by 12

INCOME DISTRIBUTION IN THE UNITED STATES

Summary Measure of Income by Selected Characteristics: 1989, 1996, and 1997

CHARACTERISTICS	1997	Median income (in 1997 dollars)		Percent change in real income 1996 to 1997	Percent change in real income 1989 to 1997
	Median income (dollars)	1996	1989		
HOUSEHOLDS					
All households	37,005	36,306	37,303	*1.9	-0.8
Type of Household					
Family households	45,347	44,071	44,647	*2.9	*1.6
Married-couple families	51,681	51,002	49,925	*1.3	*3.5
Female householder, no husband present	23,040	22,059	22,315	*4.4	3.3
Male householder, no wife present	36,634	36,476	39,108	0.4	*-6.3
Nonfamily households	21,705	21,454	22,221	1.2	*-2.3
Female householder	17,613	16,774	17,865	*5.0	-1.4
Male householder	27,592	27,892	29,036	-1.1	*-5.0
Race and Hispanic origin of householder					
White	38,972	38,014	39,241	*2.5	-0.7
White, not Hispanic	40,577	39,677	40,166	*2.3	1.0
Black	25,050	24,021	23,583	*4.3	*6.2
Asian and Pacific Islander	45,249	44,269	46,611	2.2	-2.9
Hispanic origin ¹	26,628	25,477	28,192	*4.5	*-5.5
Age of Householder					
15 to 24 years	22,583	21,930	24,027	3.0	*-6.0
25 to 34 years	38,174	36,711	38,442	*4.0	-0.7
35 to 44 years	46,359	45,439	48,554	*2.0	*-4.5
45 to 54 years	51,875	51,630	53,738	0.5	*-3.5
55 to 64 years	41,356	40,729	39,946	1.5	*3.5
65 years and over	20,761	19,894	20,402	*4.4	1.8
EARNINGS OF FULL-TIME, YEAR-ROUND WORKERS					
Male	33,674	32,882	35,179	*2.4	*-4.3
Female	24,973	24,254	24,237	*3.0	*3.0
PER CAPITA INCOME					
All races	19,241	18,552	17,999	*3.7	*6.9
White	20,425	19,621	19,088	*4.1	*7.0
White, not Hispanic	21,905	20,991	(NA)	*4.4	(X)
Black	12,351	12,172	11,231	1.5	*10.0
Asian and Pacific Islander	18,226	18,332	(NA)	-0.6	(X)
Hispanic origin ¹	10,773	10,279	10,605	*4.8	1.6

Table 1

SOURCE: U.S. Bureau of the Census (1998d): vii.

percent. This differential signifies the growing wage gap between unskilled and skilled workers in an economy increasingly geared to processing information rather than to manual labor. For example, according to the Bureau of Labor Statistics, in 1982 workers in the top decile earned roughly four times the wages of workers in the lowest decile; by 1996, this difference had spread to almost five times (Pierce 1998).

Income Dispersion by Households. In 1997, 11 percent of households had income below \$9,000, while 9.4 percent reported income of \$100,000 or more. Adjusted for inflation, these numbers indicate a decline of 9 percent in households at the lowest level and an increase of 21 percent in the proportion at the top over the decade since 1987. Also showing a slight increase were households with incomes in both the \$75,000–\$99,999 and \$10,000–\$14,999 brackets. In contrast, the proportion of households with incomes between \$15,000 and \$50,000 declined from 45.2 percent of the total to 44.5 percent. It would appear, then, that the “middle” continues to “disappear,” but that the overall distribution of household income moved upward, with the greatest gains among those in the highest income categories (U.S. Bureau of the Census 1998d, Table B-2).

Income Dispersion by Families. A similar pattern characterizes the distribution of income by families rather than households: a modest decline in the proportion with incomes below \$10,000, from 7.3 percent in 1987 to 6.8 percent in 1997, a 20 percent increase, from 9.3 to 11.8 percent, at the \$100,000+ level, and declines in the proportion in the \$25,000–74,999 range (U.S. Bureau of the Census 1998d, Table B-4). For both families and households at the lower end of the distribution, much of the gain in income over the decade can be attributed to the longer hours worked by both wives and husbands, as well as the tight labor market that allowed workers to bargain for higher wages (Mishel et al. 1998). Nonetheless, the major gains in family income accrued to the top 10 percent, who realized 85 percent of the increase in the value of stocks.

Income Inequality. Although the Census Bureau’s press releases in the late 1990s focused almost entirely on the overall gain in median household income since 1994, especially for black

and female-headed households, the data also showed a marked increase in inequality on the two measures tabulated by the Bureau.

1. *Shares of aggregate income received by households.* When income groups are divided into quintiles, the share of aggregate income received by the lowest one-fifth of households fell from a high of 4.4 percent in 1977 to a low of 3.6 percent in 1997, while the share going to the highest fifth rose from 43.6 to 49.4 percent. Declines over the past two decades also characterized the three middle quintiles. In other words, the top 20 percent of households accounted for an ever-higher share of the nation’s aggregate income, with that of the top 5 percent increasing from 16.1 to 21.7 percent.
2. *Index of income concentration.* Another way of measuring inequality is through an index of income concentration called the Gini coefficient or ratio. A Gini score of 0 would indicate complete equality, where there are no differences among units; a score of 1 indicates complete inequality, whereby one unit has all of whatever is being measured and the other units have none. Figure 1 tracks the percentage change in Gini ratios for household income since 1967. As you can see, the period from 1967 to 1980 was one in which income differences among households rose slowly, held in check largely by increases in government transfers to the poor and a relatively progressive tax structure. Inequality rose more sharply between 1978 and 1989, stabilized briefly during the recession of 1990–1992, and then shot upward in the mid- and late 1990s. Some of this increase can be accounted for by a change in Census methodology, but most is very real, and there was no indication that the trend had abated in 1998.

As striking as are the data on household income inequality shown in Figure 1, the story for *family* income is even more dramatic. After declining during the 1960s, the percent change in Gini coefficients for family income has risen sharply higher than for households, reaching the 20–25

Figure 1. Percent change in Household Gini Coefficients: 1967–1997

SOURCE: U.S. Bureau of the Census (1998d): xiii.

NOTE: *Computer-assisted personal interviewing (CAPI) was introduced in January 1994. As part of the conversion, increases were made in the limits for some income sources. This change in methodology increased measured income in 1993 for the highest income households by considerably more than their actual incomes rose. See Current Population Reports, Series P60–191, “A Brief Look at Postwar U.S. Income Inequality.”

percent range by the mid-1990s (U.S. Bureau of the Census 1996, 1998a).

Other Benefits. In addition to money income and government transfers, the well-being of households and families is also affected by employee benefits such as health insurance coverage, vacation pay, sick leave, and pensions. Although it was once thought that fringe benefits would tend to reduce inequality within the labor force, since such compensation represents a larger proportion of lower-wage workers’ income than of high-income earners, quite the opposite appears to be the case.

While government-sponsored programs such as Social Security and workers’ compensation insurance do indeed have an equalizing effect throughout the labor force, employer-sponsored benefits, in contrast, have “substantially increased compensation dispersion,” especially at the lower end of the wage scale, according to data from the Bureau of Labor Statistics (Pierce 1998). This is so because less skilled workers are most likely to be employed

in jobs that do not provide benefits, particularly in the small businesses providing most of the new jobs and in workplaces where employers can find a number of ways to limit coverage and/or exclude dependents. Benefits can be denied to entry-level employees and to those classified as “contingent.” This latter category—covering all types of part-time employment—also accounts for growing numbers of white-collar workers without employer-sponsored health insurance and pension plans.

As Table 2 indicates, even the proportion of workers at the top of the wage scale with health insurance coverage has declined since 1982, while that of low-wage employees has shrunk from half to one-fourth.

Taxes and Transfers. Thus, although government transfers, most notably Social Security and the earned income credit, have had a moderating effect on income dispersion, the impact of the tax system has been less so, as rates have become less progressive than in the 1960s. At the federal level, the Taxpayer Relief Act of 1997 might benefit

Percentage of Employees with Employer-Provided Health Insurance

	1982	1996
Bottom 10% of wage earners	49	26
Middle 50% of wage earners	90	84
Top 10% of wage earners	98	90

Table 2

SOURCE: Pierce (1998); see also U.S. Bureau of the Census (1998b).

lower-income taxpayers through a \$500 per child tax credit, but the major new programs—education and retirement savings accounts—will lighten the tax burden only of those who can afford to put money aside for the future. The big winners are the top 1 percent of wealthholders, who will receive, on average, more than \$7,300 in tax relief from a cut in the capital gains rate, compared with savings of about \$7 for the lower 60 percent of taxpayers (Congressional Budget Office 1998).

In addition, the FICA payroll tax, which takes a bigger bite out of the incomes of a majority of American families than does the federal income tax, is regressive in that most workers will pay the tax on 100 percent of income, while higher-income earners will be taxed on only the first \$72,600 of wages. Also regressive in their impact are the types of levies currently favored by state governments—sales and sin taxes. As a consequence, the current tax structure has done more to reinforce than to moderate the trend toward income inequality in the United States.

Explanatory Variables. A number of other secular trends have been advanced to explain the long-term increase in income inequality in family and household income.

1. *Labor-market factors.* One set of explanatory variables focuses on changes in the economy: (a) the shift in employment from manufacturing to service-related jobs, and the further division among service jobs between high- and low-skilled; (b) a concomitant decline in organized labor and the power of unions to negotiate favorable wage and benefit packages; (c) global competition and immigration patterns that depress wages of low-skill workers; and (d)

growth of the contingent labor force, such as temporary, part-time, and contract workers, who are typically ineligible for fringe benefits.

All these trends have contributed to an extremely skewed wage structure in which a few at the top crowd out the rest of the field, a “winner take all” situation that characterizes all occupations but is most notable in professional sports and in the compensation package of chief executive officers (Frank and Cook 1995). With the exception of a handful of millionaire athletes, almost all the benefits of economic growth and changes in tax system since the mid-1970s have been reaped by a small stratum of Americans already enriched by education, opportunity, and social capital.

2. *Lifestyle factors.* A second set of variables concerns long-term changes in patterns of marriage and living arrangements: (a) an increase in nonfamily and single-parent households due to later age at first marriage, high rates of divorce and separation, nonmarital births, and increased life expectancy, especially for widows in single-person households; and (b) the tendency toward endogamy among high-earning men and women, thus concentrating incomes and widening the split between the few at the top and the rest of the population.

Interestingly, the widening gap between top and bottom in income shares is not fully reflected in data on the distribution of wealth.

WEALTH

The methodological difficulties in measuring income are minor compared to those encountered in the study of *net worth*: the total value of all assets owned by a household, family, or person, less the debt owed by that unit. Such assets include investment portfolios, bank accounts, trusts, businesses, real estate, homes and their furnishings, insurance policies, annuities, pension equity, vehicles, works of art, jewelry, and other contents of safe deposit boxes. Because public records of such assets are minimal and/or difficult to trace, researchers are largely dependent on self-reports. In addition,

because very few extremely wealthy units would appear in a national random sample, special frames must be constructed. As a result, data reported by the Bureau of the Census, the Federal Reserve Board, and the Internal Revenue Service are not always comparable because of differences in sampling, the type of assets being counted, and the way in which they are measured and weighted. In this section, we will briefly review the history of studying wealth in America, current data, and the generalizations that can be most confidently drawn.

The first systematic study of wealthholding was conducted in 1963 by the Federal Reserve Board (FRB), which found that the wealthiest one-half of 1 percent of households (“superrich”) owned 25 percent of the aggregate net assets of the nation. The next one-half of 1 percent (“very rich”) accounted for an additional 7 percent of net worth, and the next 9 percent (plain “rich”), accounted for one-third of the total, leaving 35 percent of the total net worth in the hands of the remaining 90 percent of households.

Although comparable data were not collected until 1983, evidence from the Internal Revenue Service (IRS) estate tax records suggests that the share of assets owned by the superrich declined between 1965 and 1976 to a low of 14.4 percent. This drop was due in part to an extended stock market slump and in part to changes in tax policy, as well as the growth of social welfare programs such as Aid to Families with Dependent Children, Medicare and Medicaid, and the liberalization of Social Security benefits, all of which shifted resources from the affluent to the more needy.

Interest in research on wealth picked up again in the mid-1980s, when both the Bureau of the Census and the FRB conducted studies designed to yield data comparable to the 1963 survey, although with different sampling frames and asset measures. The common finding, however, was that between 1976 and 1983 the downward trend of asset ownership by the superrich was dramatically reversed: from owning less than 15 percent of aggregate wealth to accounting for more than 30 percent just six years later. This doubling of asset ownership reflected an upward swing in the value of stocks, reinforced by Reagan administration policies on taxes and welfare favoring the more affluent. It must be noted, however, that these

numbers are subject to considerable error due to sampling, nonresponse, and missing data.

Recent Studies of Household Wealth. In a major effort to standardize research findings, the FRB adopted a consistent weighting formula for adjusting data on household wealth from the Board’s Survey of Consumer Finances for 1989, 1992, and 1995 (Kennickell and Woodburn 1997). According to these calculations, shown in Table 3, the share of net worth held by the superrich remained constant between 1989 and 1992 at about 23 percent, then rose to 27.5 percent between 1992 and 1995. At the other end of the distribution, the share owned by the 90 percent less well-off households also remained stable—at about 32 percent—over the entire 1989–1995 period. The 1992–1995 increase in the share of net worth of the top one-half of one percent, then, has come largely from the share of the 90–99 percentile “plain rich,” which declined from 37 to 33 percent. In other words, there is little evidence that the rich have become richer at the expense of nonaffluent households.

There are marked contrasts between the few at the top and the rest of American households in the types of assets held. Wealth for the bottom 90 percent consists primarily of a principal residence, vehicles, and cash-value life insurance, and has been considerably diluted by rising debt (mortgage and credit card) in the 1990s. In contrast, stocks and bonds, trusts, and equity in businesses account for the bulk of the accumulated wealth of the top decile. By 1997, when stock ownership replaced the value of real estate as the leading component of aggregate wealth, the top 1 percent held more than half of all such investment instruments, with the bottom 80 percent holding 3 percent of the total value (Wyatt 1998). Yet even at this relatively low level of stock ownership, primarily through pension plans, low-wealth households will be especially vulnerable to sudden downturns in the market value of their investments.

Another set of numbers comes from the Bureau of the Census, which has, since 1990, conducted a panel study of households—the Survey of Income and Program Participation (SIPP)—that permits following the economic status of units over time. These data differ from those collected by the FRB in three crucial respects: the sample

**Percentage of Total Net Worth Held by
Different Percentiles: 1989, 1992, and 1995**

YEAR	Percentile of Net Worth			
	0-89.9	90-99	99-99.5	99.5-100
1989	32.5	37.1	7.3	23.0
1992	31.9	36.9	7.5	22.7
1995	31.5	33.2	7.6	27.5

Table 3

SOURCE: Kennickell and Woodburn (1997): 22.

frame does not yield many very high income households; a different set of assets are counted; and the distribution of wealth is measured differently. In the SIPP study, the distribution of “asset ownership” is computed on the basis of the median net worth of households at each quintile of monthly income. For both 1991 and 1993, the one-fifth of households with the lowest monthly income owned about 7 percent of the total net worth of all households, while those in the top fifth owned 44 percent (U.S. Bureau of the Census 1995). Unfortunately, comparable data for the next wave (1995-1996) have not yet been published, nor can the SIPP numbers be used for historical comparisons.

Personal Wealth. In addition to studies of household wealth by the Census and Federal Reserve Board, the Internal Revenue Service periodically publishes reports on individual wealth-holding, based on estate tax returns. These data are also subject to error—from sampling, from calculating mortality rates, and from underreporting, since not all assets can be tracked and since high-income earners have ways of dispersing and hiding assets prior to death. The most recent data come from surveys of estate tax returns of the very wealthy carried out by the IRS’s Statistics of Income Division (SID) in 1992 and 1995 (Johnson 1997).

In 1992, it was estimated that 3.7 million adults, or 2 percent of Americans aged 21 or older, had gross assets of at least \$600,000, which accounted for 28 percent of the aggregate personal wealth of the nation. In 1995, the number of wealthy persons had increased (to 4.1 million), as had their total net worth, but once adjusted for inflation, these differences were minimal. Indeed, looking at the very wealthiest—persons with a net

worth of at least \$1 million—in terms of numbers, total assets, and net worth, there was a sharp decline between 1989 and 1992, due primarily to the recession of 1990-1992. Between 1992 and 1995, however, the number of millionaires increased slightly (to 1.32 million), as did their total assets and net worth, but both still remained below the levels of 1989.

The SID also computed the percent of total U.S. net worth held by the top 1 percent and one-half of 1 percent of individual wealthholders. As shown in Figure 2, the share of total wealth owned by the wealthiest individuals rose from 1989 to 1992 before declining to 1989 levels. Clearly, according to these data, there was no dramatic shift in net worth from the less affluent to the top, although the dollar amount of their assets did appreciate. Between 1989 and 1995, then, the pattern for individual wealthholders was similar to that for household net worth in showing minimal increases in the concentration of wealth.

At the time of publication, detailed reports from the IRS and FRB on trends between 1995 and the end of the decade were unavailable, but material from *Forbes* magazine’s yearly compilation of the 400 wealthiest individuals suggests that the fortunes of the very affluent have increased significantly (*Forbes*, October 12, 1998). In 1998, the minimum needed to appear on the list of the 400 wealthiest individuals in the United States was \$500 million, up 5 percent from 1997 and more than double that of a decade earlier. Most dramatic was the increase in the proportion with a net worth of more than \$1 billion, up from 170 persons in 1997 to 186 in 1998, almost half the total, compared to only 23 in 1986. Ten of the billionaires had fortunes in excess of \$10 billion, including the five children of the founder of Walmart Stores, and Bill Gates, the founder of Microsoft, whose net worth almost equals the gross domestic product of New Zealand. Thus, while the very rich may not be getting richer at the expense of the less affluent, they received the lion’s share of wealth created in the economic boom years of the mid-1990s.

POVERTY

Interesting changes are also taking place at the lower end of the income distribution, among the persons, families, and households officially designated as living below the poverty threshold. In the

Figure 2. Percent of Total U.S. Net Worth Held by the Top 1 Percent and Top 1/2 Percent of the U.S. Population

SOURCE: Johnson (1997: 79).

early 1930s, Franklin Delano Roosevelt could speak movingly of one-third of the nation being ill-housed, ill-clad, and ill-nourished in a society without an extensive social welfare system. Yet three decades later, in the early 1960s, despite the introduction of Social Security and other programs designed to minimize the effects of unemployment, more than 20 percent of Americans could still be defined as lacking a minimally adequate standard of living.

Defining Poverty. By 1964, as the nation geared up for Lyndon Johnson's War on Poverty, the Social Security Administration (SSA) was pressed to construct clear parameters for measuring impoverishment. The SSA turned to research conducted by the Department of Agriculture (DoA) in 1955, which found that families typically spent one-third of their income on food and which also computed the cost of a least expensive nutritionally adequate food plan. The SSA simply multiplied the cost of the DoA's food basket by three and, with some corrections for family size, age and sex of householder, and rural/urban residence, arrived at a dollar figure for yearly income—that neatly demarcated the poor from the nonpoor.

The value of the minimal food plan is adjusted each year to the cost-of-living index, but it no longer distinguishes rural from urban residence (the rural threshold had been higher, since it was thought that country folk could grow some of their own food) or female from male heads of household (on the grounds that women ate less than men). Only number of children and age of householder have been retained in the calculations. Nor has there been an adjustment for the fact that the cost of housing today typically exceeds that for food.

By the official yardstick, the poverty threshold for a single person in 1997 was \$8,183, slightly higher for those under age 64 and slightly lower for someone aged 65 or older on the assumption that an older person eats precisely \$276 worth less food per year than does a younger person. The poverty line was \$12,802 for a family of three and \$16,400 for a family of four. These are the dollar amounts considered adequate to house, feed, and clothe household members. Income in excess of the threshold officially lifts the unit out of poverty and therefore makes the unit ineligible for additional benefits, including both income supports (the former Aid to Families with Dependent Children and its successors, and Supplemental Security Income) and in-kind programs (food stamps, Medicaid, school lunch assistance, and housing subsidies). At the urging of conservative critics, the Bureau of the Census also publishes computations that include the cash value of these in-kind benefits in the definition of income, thus automatically reducing the poverty rate by about 25 percent. Nonetheless, at this writing, the official poverty level is still calculated on the basis of money income earned or received.

As Figure 3 indicates, the number of people below the poverty level was cut in half between 1959 and 1973—from 22.4 to 11.1 percent of the population—as a result of federal programs designed to assist the elderly, low-income families, and single-parent households. As the domestic War on Poverty fell hostage to the war in Vietnam, poverty rates began to rise, reaching a high of 15.2 percent during the recession of the early 1980s, and again in 1993, before declining to the current 13.3 percent, or 35.5 million persons.

In its 1998 report, the Census Bureau drew special attention to the fact that poverty declines in 1995–1997 have been much steeper for black

Figure 3. Percent of Persons Below the Poverty Level, by Race and Ethnicity

SOURCE: U.S. Bureau of the Census (1998):45.

and Hispanic persons than for Asian/Pacific Islanders and whites, but this effect is partly due to the fact that blacks and Hispanics were much further behind to begin with, so that any income increase will translate into a higher percentage compared to those initially less disadvantaged. Nonetheless, poverty among African Americans is at an all-time low, though the rate remains more than twice that for whites. The three factors most responsible for declining poverty rates today are: (1) The rise in the minimum wage that took effect in 1996, which accounts for the increased incomes of black and Hispanic single mothers, most of whom are hourly workers; (2) the earned income tax credit (EITC) now available to low-income workers, which has been particularly helpful to low-wage married-couple families; and (3) the economic boom that has generated a large number of jobs at the lower-skill level of the service sector, thus reducing unemployment and allowing low-wage workers to bargain for higher wages and benefits. In 1998, however, Congress voted down

further raises in the minimum wage and failed to expand the EITC, thus leaving low-skill workers increasingly dependent on market forces.

The Census also computes the “ratio of income to poverty level”; that is, the number of Americans in families whose income is under half the poverty level, the “severely poor,” as well as those with incomes 25 percent above the threshold, the “near poor.” In 1997, 14.6 million persons, or 41 percent of the poor, were “severely poor.” Another 12.3 million were “near poor,” including many full-time workers, since the earnings of a year-round, full-time minimum-wage-worker would still fall below the poverty threshold for a couple with one child.

Who are America’s poor? Forty percent are children under age 18, whose poverty rate of about 20 percent is unchanged since 1989. Especially disadvantaged are the 59 percent of children under age six living with a female householder, no husband present. And while the poverty rate for all

such households has hovered at slightly under one-third since 1987, there was a significant decline in poverty from 1996 to 1997 for black female householders. Even so, four in ten black female householders and almost half of Hispanic female householders were officially poor in 1997.

The most powerful variable affecting poverty status, however, is not race or ethnicity, but sex. It is women of all ages, especially those without husbands, from teenage mothers to elderly widows, who are most at risk of being poor. If economic well-being depends on working full time, remaining married, and being free of child-care responsibilities, then single mothers with limited education and job skills will be especially disadvantaged (U.S. Bureau of the Census 1998e). Yet it is precisely these women, many of whom were dependent for survival upon the income provided by Aid to Families with Dependent Children (AFDC), who came to be blamed for their own misfortune and to symbolize the failure of public welfare programs.

The Poverty Debate of the Mid-1990s. Although poverty programs absorbed less than 5 percent of the national and state budgets, they became a focal point for political debate in the mid-1990s. The public had come to believe, contrary to empirical studies, that AFDC families remained on the welfare rolls for generations, that poor women had additional children in order to increase their monthly benefit, and that it was characteristics of the poor themselves (laziness, substance abuse, sexual immorality) that accounted for poverty. In fact, fewer than 10 percent of the poor can be considered long-term welfare recipients, primarily women who entered the system as very young unwed mothers and who have been unable to develop the job skills or to find employment near their home that pays enough to lift the family above the poverty level. Nor is there any consistent relationship between benefit levels and the fertility of poor women.

As the SIPP data clearly show, poverty is a transitory state for the great majority who fall below the threshold. For example, although 21.4 percent of Americans were poor at some point in 1994, the proportion who were poor for all of 1993 and 1994 was only 5.3 percent. Almost half of all spells in poverty (47.3 percent) lasted 2–4 months, and 75 percent lasted less than one year (U.S.

Bureau of the Census 1988f). People fall into poverty when a marriage ends, when employment stops, or when children become ill; they are lifted out of poverty when they remarry, when they are employed, and when family members are restored to health.

As part of their attack on all government programs to which entire classes of citizens are entitled, conservative critics of the American social welfare system have long maintained that there is a “culture of poverty,” whereby maladaptive attitudes toward work and family are transmitted across generations (e.g. Murray 1984). In this view, welfare dependency itself is the problem, and the solution is to remove income supports, so that employment becomes the more attractive alternative. In contrast, most sociologists would focus on the structural conditions that produce unemployment, family dissolution, educational failure, and homelessness, with people’s behavior perceived more as a response to than as a cause of their situation.

The debate was won by those seeking radical change in the welfare system, and in 1996 the Personal Responsibility and Work Opportunity Act replaced AFDC and several other federal assistance programs with block grants to the states for Temporary Assistance for Needy Families (TANF). The states were given relative freedom to construct their own programs for moving former welfare recipients into the paid labor force.

It is too early to tell what effect the new systems will have on poor women and their children. Some states will be more effective than others in providing the job training and child care required for full-time labor-force participation; others will be more or less punitive. It will also be very difficult to disentangle the effects of the business cycle from those of public policy, or to determine whether people leaving welfare would have done so anyway given the transitory nature of most poverty spells. At the moment, welfare rolls have dropped dramatically, as a function of both economic growth and tighter eligibility requirements. And although the poverty rate also fell in 1997, the decline was minimal. Much will depend on whether the private sector can continue to generate jobs that former recipients can find and hold—and that will pay a family wage.

COMPARATIVE PERSPECTIVES

Any discussion of wealth, poverty, and income inequality within a society must take into account the vast differences between modern industrial and the less developed nations. Poor people in high-income societies are rarely as deprived of the basic necessities of survival as are most people in the Third World, where income inequality is typically much greater than in the industrialized countries. But Americans do not compare themselves to Sudanese; rather, they compare themselves to other Americans to whom they feel similar. It is a sense of relative rather than absolute deprivation that tends to fuel resentment. At this writing, despite the extent of income inequality in the United States, there are few appreciable signs of anger directed toward the top wealthholders. Rather, whatever ill will has been generated by blocked opportunity appears to be directed toward racial and ethnic minorities at the same or lower social-class level.

Yet, when compared with other Western democracies, the United States has the most unequal distribution of income and highest poverty rate. For example, while the percentage of American children in poverty was among the highest in the developed world, proportionately fewer were lifted out of poverty by government aid (Atkinson et al. 1995; United Nations 1998). This is so because the United States has the least extensive social welfare system of any modern state, and since 1996 even this limited “safety net” has been reduced. Alone among its industrialized peers, the United States is without a comprehensive family policy, lacks a national health insurance system, and provides minimal assistance to the most needy. As a consequence, there are few institutionalized mechanisms other than Social Security—which has also come under attack from those who would turn it into a private rather than public responsibility—for the redistribution of income that might narrow the gap between the very rich and very poor or that might substantially reduce both the likelihood and impact of poverty. In the absence of a revitalization of a sense of collective responsibility, income inequality will continue to characterize the United States. Indeed, all signs point to a continuation of economic, social, and political trends that elevate individual over collective interests and that reinforce the power of the market and weaken that of government.

INDIAN SOCIOLOGY

The reviewers of Indian sociology generally trace its origin to the works of several British civil servants, missionaries, and Western scholars during the eighteenth and nineteenth centuries (Dhanagere 1985; Mukherjee 1979; Rao 1978; Singh 1986; Srinivas and Panini 1973). British administrators wanted to understand the customs, manners and institutions of the people of India to ensure the smooth running of their administration. Christian missionaries were interested in learning local languages, folklore, and culture to carry out their activities. The origin, development, and functioning of the various customs and traditions, the Hindu systems of caste and joint family, and the economy and polity of the village/tribal community were some of the prominent themes of study by the British administrators and missionaries as well as other British, European, and Indian intellectuals. The first all-India census was conducted in 1871. Several ethnographic surveys, monographs, census documents, and gazetteers produced during this period constitute a wealth of information that is of interest to sociologists even today. Mukherjee (1979) observes that the works of the civil servants, missionaries, and others during the colonial rule in India "provided the elements from which the British policy for ruling the subcontinent crystallized and also in turn helped to produce the pioneers in Indian sociology" (p. 24). Further, the available studies of Indian society and

culture became an important source for testing various theories by scholars such as Marx and Engles, Maine, and Weber.

Although the first universities in India were established in 1857 in Bombay, Calcutta and Madras, formal teaching of sociology began only in the second decade of the twentieth century—at the University of Bombay in 1914, at Calcutta University in 1917 and at Lucknow University in 1921. By this time the observations and impressions of the census commissioners and civil service officials about the caste system, family structure and functions, age at marriage and widowhood, and so forth, had already begun to be published, along with statistical tables based on the population counts. Prior to India's independence in 1947, only three other universities (Mysore, Osmania, and Poona) were teaching sociology. There was no separate department of sociology; it was joined with the department of economics (Bombay and Lucknow), economics and political science (Calcutta), anthropology (Poona), or philosophy (Mysore). Almost all the pioneers in sociology in the first half of the twentieth century were trained in disciplines other than sociology. Only a limited number of courses in sociology, as fashioned by teachers according to their interest, were taught. Sociology courses included such topics as social biology, social problems (such as crime, prostitution, and beggary), social psychology, civilization, and prehistory. "In the case of teaching of Indian social institutions the orientation showed more Indological and philosophical emphasis on the one hand and a concern for the social pathological problems and ethnological description on the other. Strong scientific empirical traditions had not emerged before Independence" (Rao 1978, pp. 2–3).

Although many of the pioneers in sociology were educated at Calcutta, substantial impact on Indian sociology during the first half of the twentieth century was made at Bombay University and Lucknow University. Patrick Geddes, the first chairperson of the department of sociology and civics at Bombay University, was a city planner and human geographer. His reports on the city planning of Calcutta, Indore, and the temple cities of south India contain much useful information and demonstrate his keen awareness of the problems of urban disorganization and renewal (Srinivas and Panini 1973, p. 187). G. S. Ghurye succeeded

Geddes in 1924. During his thirty-five year teaching career at Bombay University, he guided about eighty research students. Several of his students (e.g., M. N. Srinivas, K. M. Kapadia, I. P. Desai, Y. B. Damle, A. R. Desai, and M. S. A. Rao) later on had a great impact on the development of sociology in India. Trained as a social anthropologist at Cambridge University, he addressed a wide range of themes in his research work and writings: from castes, races, and tribes in India to cities and civilization, from Shakespeare on conscience and justice to Rajput architecture, and from Indian Sadhus to sex habits of a sample of middle-class people of Bombay. He drew attention to several unexplored dimensions of Indian society, culture, and social institutions.

R. K. Mukherjee and D. P. Mukherji, both trained in economics at Calcutta University, taught sociology at Lucknow University. R. K. Mukherjee made a series of micro-level analyses of problems concerning rural economy, land, population, and the working class in India as well as the deteriorating agrarian relations and conditions of the peasantry, intercaste tensions, and urbanization. D.P.Mukherji's interest was diverse; they ranged from music and fine arts as peculiar creations of the Indian culture to the Indian tradition in relation to modernity. A professed Marxist, he attempted a dialectical interpretation of the encounter between the Indian tradition and modernity, which unleashed many forces of cultural contradiction during the colonial era (Dhanagare 1985).

B. N. Seal and B.K. Sarkar were two of the leading sociologists of that time at Calcutta University. Seal was a philosopher, interested in comparative sociology. He wrote on the origin of race, positive sciences, and the physicochemical theories of the ancient Hindus, as well as made a comparative analysis of Vishnavism and Christianity. He stressed the need for a statistical approach, inductive logic, and methodology to appraise the contextual reality comprehensively. Sarkar, a historian and economist by training, opposed the persistent general belief that Hinduism is "other worldly." He was also one of the few who discussed Marx, Weber, and Pareto at a time when they were not fashionable with sociologists either in India or abroad (Mukherjee 1979). S. V. Ketkar and B. N. Dutt, both of whom specialized in Indological studies in United States, and K.P.

Chattopadhyay, a social anthropologist trained in the United Kingdom, are some of the other noteworthy pioneers of Indian sociology.

Mukherjee (1979) points out that the goals set by the pioneers ranged from an idealized version of Oriental culture to the materialist view of social development. They were involved in bibliographical research to establish the historical database and strongly advocated empirical research. But in the days of the pioneers, the interaction between theoretical formulations and the database remained at a preliminary stage.

Some of the outstanding trends in the development of Indian sociology since India's independence have been the organization of professional bodies of sociologists, a lack of rigid distinction between sociology and social anthropology, debates regarding the need for indigenization of sociology and the relevance of Indian sociology, diversification and specialization into various subfields, and participation of sociologists in interdisciplinary research.

There has been a tremendous increase in the number of universities, colleges, and institutes teaching sociology. In most universities, the teaching of sociology started first at the graduate level and then at the undergraduate level. Universities and institutions offering degrees in interdisciplinary areas—such as management, rural development, planning, communication, and nursing—include some sociology courses in their training program. In the 1990s, some states have also introduced sociology courses at the higher secondary level. There was no professional body of sociologists during the colonial period. Ghurye was instrumental in establishing the Indian Sociological Society in 1951, and R. N. Saksena was instrumental in organizing the first All-India Sociological Conference in 1956. These organizations merged in 1967 as a single all-India professional body of sociologists. The Indian Sociological Society has more than a thousand life members. Several regional associations of sociologists was also formed during the 1980s and 1990s.

The development of sociology in India, from the viewpoint of theory, methodology, and research interests, has been significantly influenced by sociology in Western countries. Several Western scholars, a majority of them initially from the

United Kingdom and Europe, and later on also from the United States, have carried out studies in India. Similarly, many of the leading sociologists in India have been trained in the United Kingdom and the United States. However, with a rise in the cost of higher education and a fall in the availability of financial assistance in the Western universities, there has been of late a decline in the number of Indian students going to the United Kingdom and the United States for advanced study in sociology. There has, however, been a steady increase in the participation of Indian sociologists in various international seminars, workshops, and conferences. The holding of the eleventh World Congress of Sociology in New Delhi in 1986 is indicative of the recognition of the development of Indian sociology and its contribution.

Two journals of sociology—*The Indian Journal of Sociology*, started in 1921 by Alban G. Widgery (a British professor at Baroda College), and *The Indian Sociological Review*, started in 1934 with R. K. Mukherjee as its editor—were short-lived. There are now only a few all-India journals of sociology: *Sociological Bulletin* (a biannual journal of the Indian Sociological Society since 1952), *Contributions to Indian Sociology* (edited by two French scholars, Louis Dumont and D. F. Pocock, from its inception in 1957 to 1963, when its editorship was passed on to Indian sociologists), and *Social Change* (published by the Council for Social Development since 1971). Occasionally, articles with sociological content and relevance are published in other journals, such as *Economic and Political Weekly* and the journals published by some universities and regional associations. Several sociological articles are published in the journals of some institutions and university departments with a focus on interdisciplinary training and research. For example, since the beginning of the 1980s, the National Institute of Rural Development in Hyderabad has published a quarterly (*Journal of Rural Development*), and the National Institute of Urban Affairs in New Delhi has published a biannual journal (*Urban India*). Also, the Center for Women's Development Studies in New Delhi publishes a biannual journal called *Indian Journal of Gender Studies*.

Initially, no rigid distinction was made between social anthropology and sociology, but they separated as teaching disciplines in the 1950s. In the field of research, however, the distinction

between social anthropology and sociology continues to be blurred. Ghurye, Srinivas, S. C. Dube, and Andre Beteille, among others, have argued that sociologists in the Indian context cannot afford to make any artificial distinction between the study of tribal and folk society on the one hand and advanced sections of the population on the other; nor can they confine themselves to any single set of techniques. Yogesh Atal (1985) points out that this is true of several countries in Asia and the Pacific; social anthropologists have extended the scope of their investigation to micro communities in rural as well as urban settings in their own country, and sociologists have found the anthropological method of fieldwork and participant observation useful in their research. Even the Indian Council of Social Science Research (ICSSR) treats both these disciplines together in its two surveys of research, the first covering the period upto 1969 (ICSSR 1972–1974) and the other from 1969 to 1979 (ICSSR 1985–1986); the same approach continues for the third survey, now under way, for the period 1979 to 1987.

There have been continuous debates regarding the need for indigenization of sociology, or “sociology for India” and the relevance of Indian sociology (Sharma 1985; Unnithan et al. 1967). One side of the debate started with the suggestion of Dumont and Pocock (1957) that “in principle, . . . a sociology of India lies at the point of confluence of Sociology and Indology” (p. 7). The proponents of an Indological approach in sociology emphasize that the contextual specificity of Indian social realities could be grasped better from the scriptural writings. Gupta (1974) points out the need for separating normative and actual behavior. Oommen (1983) pleads that “if sociology is to be relevant for India as a discipline it should endorse and its practitioners should internalize the value-package contained in the Indian Constitution” (p. 130), that is, socialism, secularism, and democracy rather than hierarchy, holism, pluralism, and so forth as pointed out by the Indologists. Another side of the debate is identified with a paradigm of Indian sociology free from academic colonialism—that is, borrowed packages of concepts and methods from other cultures, particularly the West, that supposedly do not have relevance for the Indian social, historical, and cultural situation (Singh 1986). However, although most sociologists are not hostile to using Western concepts,

models, and analytical categories, they want their adaptations to suit the Indian sociocultural setting. Singh (1986) analyzes the contents and salient orientations of the presidential addresses delivered by M. N. Srinivas, R. N. Saksena, Ramkrishna Mukherjee, S. C. Dube, A. R. Desai, and M. S. Gore at the conferences of the Indian Sociological Society. He observes that there is a deep concern with the issue of relevance in the contexts of social policies, normative analysis of these policies, and the role of sociologists in understanding, critical appraisal, and/or promotion of these normative objectives of development and change in India.

In the 1950s and 1960s, several micro-level studies of caste, joint families, and village communities, mostly from the viewpoint of structural-functional aspects and change, were carried out. Srinivas introduced the concepts of dominant caste, Sanskritization, Westernization, and secularization to understand the realities of intercaste relations and their dynamics (Dhanagare 1985). Change in the structural and functional aspects of family in different parts of India was the focal point of most studies in the area of marriage, family, and kinship. The village studies focused on stratification and mobility, factionalism and leadership, the *jajmani* (patron-client) relationship, contrasting characteristics of rural and urban communities, and linkages with the outside world.

Indian sociology in the last quarter of the twentieth century shows both continuity and change in research. Caste and stratification, village communities, and social change have continued to be themes of research, but the approach has shifted from the functional to the conflict viewpoint. Descriptive studies of a single village community or other unit in a single social setting have been replaced by analytical comparative studies of social structure across time and space. Interest in the area of marriage, family, and kinship has declined. Women's studies have increased greatly. Several studies have been conducted in the fields of education, urban sociology, social movements, voting behavior, communication, and industrial relations. Sociologies of medicine, law, science, and other professions have also begun to develop. Now the thrust is on studying various processes. For example, with a concern for equality and distributive justice, there is an increasing emphasis on examining the process of education as a vehicle of social

change as it affects the existing system of stratification, women, and less favored segments of the population.

A steady trend of out-migration of entrepreneurial and educated Indians, particularly to Western countries, has led to a modest beginning of sociological studies of the Indian diaspora (Motwani et al. 1993). Such studies attempt to understand the sociocultural dynamics of the Indian diaspora. Some of these studies are influenced primarily by the phenomenological and the symbolic interactionist perspectives (Jayaram, 1998). Interest in the study of changing patterns of marriage and family relations due to international migration, both among the out-migrants and among the aged and others who continue to reside in India, is slowly increasing. A genealogical study of an Asian Indian, covering nineteen generations, is a notable illustration of efforts to trace roots and study intergenerational socioeconomic changes (Desai 1997).

India started its first Five-Year Plan in 1952. Since then social scientists, particularly economists, sociologists, and demographers, have been involved in conducting diagnostic, monitoring, and evaluative studies concerning a variety of developmental programs at micro as well as macro levels. For example, the interest and financial support of the Indian government and international agencies have been instrumental, since the early 1950s, in encouraging and sponsoring research in the field of population and family planning (Visaria and Visaria 1995, 1996). Policies and programs concerning urban and rural community development, Panchayati Raj, education, abolition of untouchability, uplift of weaker sections (scheduled castes, scheduled tribes, and other backward castes), and rehabilitation of people affected by large-scale projects (constructions of large dams, industrial estates, capital cities, etc.) have been some of the other important areas of research by sociologists. At times, the various ministries of the central and the state governments, the ICSSR, and other funding agencies have sponsored all-India studies that have tended, albeit in a small way, to strengthen interdisciplinary approaches in social research. For example, in 1975-1976 the Indian Space Research Organization conducted a one-year satellite instructional television experiment in 2,330 villages spread over twenty districts of six states (Agrawal et al. 1977); the ICSSR sponsored a

nationwide study of the educational problems of students from scheduled castes and tribes (Shah 1982).

During the 1970s and 1980s, several social research institutes were established in different parts of India. Also, many universities established interdisciplinary women's studies. Most prominent sociology departments and/or social research institutes are located in Delhi, Bombay, Ahmedabad, Jaipur, Chandigarh, Poona, Bangalore, Hyderabad, and Trivandrum.

Several universities have gradually switched over to the use of the regional language as a medium of instruction at the undergraduate level, and some at the graduate level also; however, inadequate availability of textbooks in regional languages has been a major handicap in the teaching-learning process. Statistics has as yet not become an integral component of sociology curricula in a large number of colleges and universities. Although the survey approach is widely used in sociological research, most research publications hardly go beyond the use of descriptive statistics. There has been a strong plea for developing concepts and measurements that fit the Indian situation, but concerted efforts in this matter are still lacking. At the end of the twentieth-century, there is a frequently mentioned concern about an emergent paradoxical trend in sociological teaching and research in India. On the one hand, sociology has been accepted as one of the core subjects in almost all colleges and universities and several interdisciplinary institutions; on the other hand, a severe problem obstructing the growth and development of sociology in India due to a dearth of qualified teachers and falling standards, which may be due to a lack of teaching material in the regional languages and the inability of a large number of students to read textbooks and reference material in English. With a democratic polity, a developing economy, and a socioculturally diversified population, questions of applying even fairly good social science research findings get shrouded in the complex processes of the state policy and administration.

INDIGENOUS PEOPLES

For well over a century claims have been advanced that Native Americans, and indigenous peoples in general, are about to vanish (Bodley 1990, 1994; Dippie 1982). Apparently, however, indigenous peoples have neither read nor followed these scripts. In fact, quite the opposite has occurred. In the United States and around the world there has been a resurgence of indigenous consciousness, political mobilization, and cultural renewal (Cornell 1988; Nagel 1996; Snipp 1988a, 1989, 1992; Thornton 1987; Wilmer 1993). Groups in Canada, the United States, Australia, Brazil, Southeast Asia, and elsewhere are making land claims, petitioning for political rights, and demanding control of resources with remarkable success given their nearly universal paucity of votes, money, or military means. Interestingly, these indigenous movements are occurring while the number of people who live “traditional” or “tribal” lifestyles has diminished under the onslaught of expanding national and global industrialism and capitalism. A full description and explanation of these contradictory trends would require several volumes. Here we offer a summary of current understanding of the state of indigenous peoples in North America and around the world, and we suggest why such issues are of vital concern to sociology.

TERMINOLOGY

Ethnic terminology is notoriously politically controversial and loaded. Terms such as “tribe,” “clan,” “ethnic entity,” and “nation” have been used over the last few centuries as weapons of both the strong and the weak in wars of words, laws, and often guns, to attack or defend the rights and survival of indigenous peoples. Even the term “indigenous peoples” is problematic—after all, everyone is indigenous to some place, and indigenousness sometimes can be a matter of

when the clock starts. We use the term “indigenous” to refer to those peoples who either live, or have lived within the past several centuries, in nonstate societies, although these indigenous societies may well have existed within the boundaries of state societies. We eschew the term “pre-state” because it implies, even sometimes unintentionally, that there is a necessary, progressive evolution from nonstate to state societies. We hasten to add that although some states have existed for several millennia (Sanderson 1999) in a variety of forms, the diversity of types among nonstate societies is far greater. This why there is a plethora of terms to refer to them: clans, bands, macrobands, tribelets, tribes, chiefdoms, segmentary lineages, and so forth. Virtually all these terms entail an attempt to organize this diversity (for discussion of the terms and concordance of the various meanings, see Chase-Dunn and Hall 1997, chs. 4, 7).

The most problematic in this litany of terms is “tribe.” As much as anthropologists and others have argued that “tribe” has become so general as to be useless (Fried 1975), it often is used in efforts to communicate with the general public or beginning students. The problem is especially salient for those peoples who inhabited North America before Europeans arrived, since the tribe–nation distinction has often been used politically to support or to deny autonomy or sovereignty for indigenous groups. To further confuse matters some, indigenous communities officially and legally call themselves “tribes,” though many have replaced “tribe” with “nation.” Even the designation “Native American” is not without problems, since legally, anyone born in the United States is a “native”[-born] American. For all these reasons we use “nonstate society” as a generic term, and for those peoples indigenous to the Americas, we alternate among Native Americans, American Indians, native peoples, and indigenous peoples.

When referring to a specific indigenous community, we use the name of the group—but even that is often problematic. There are four broad problems in regard to group names that we discuss here because of the light these difficulties shed on the issues facing indigenous peoples generally. Our discussion deals specifically with North America, although the issues we raise often are faced by native peoples elsewhere. First, membership in indigenous groups may change over time as various forms of identity and political organization

change in response to internal processes or encounters with outsiders. In early periods of contact with Europeans, North American native peoples often shared a broad sense of identity but were not ruled by any single social or political organization (Cornell 1988). Through years of contact, this situation frequently reversed itself. The need for unified resistance to European, then American, encroachments often necessitated the formation of sociopolitical structures that encompassed individuals and communities that had not necessarily shared historical cultures or identities (for examples, see Champagne 1989, 1992; Dunaway 1996; Faiman-Silva 1997; Fenelon 1998; Hall 1989; Himmel 1999; Meyer 1994).

Second, many historical indigenous cultures and communities have been destroyed, either by outright genocide, the devastations of disease, assimilation into European societies, or merger or amalgamation with other indigenous groups. As a survival strategy, many native groups found themselves greatly transformed, in particular through the consolidation of diverse individuals and communities. At times these amalgamated communities represented a form of “ethnogenesis,” that is, the creation of new native groups.

Third, a great deal of ethnographic and ethnohistorical investigation shows that the symbolic, demographic, and social boundaries of nonstate groups are extremely permeable (as, indeed, are those of many states and empires). Thus, the expectation of fixed, clear, rigid boundaries or borders is an artifact of the creation of the modern European nation-state, and of the needs of European and American negotiators to identify “leaders” of native societies for purposes of treaty-making and land acquisition. Hence naming a group often gave a false sense of unity, solidity, and organization.

Finally, there are the historical accidents of naming and the vagaries of spelling that stemmed from a lack of clear understanding of indigenous languages. One of the most notorious is the naming of the Lakota peoples as “Sioux,” which is a French corruption of an Anishinaabe [Chippewa or Ojibwa] word, “nadowasieux,” which translates into something like “slimy snake people” (Tanner 1987, p. 4)—certainly, not a name many Lakotas would wish to be known by. Many Native American groups are shifting back to their own names

for themselves, rather than continuing to use those assigned them by outsiders. For instance, Diné is increasingly used to refer to Navajo institutions and people, and the former “Winnebagos” of Wisconsin are now officially the “Ho Chunks.”

SOCIOLOGICAL SIGNIFICANCE OF INDIGENOUS PEOPLES

There are several reasons that the study and understanding of indigenous peoples and the challenges they face are of special interests to sociology and to sociologists. First, in the United States (and every country in the Americas and in many others elsewhere) indigenous peoples are part of an ethnically diverse social, political, cultural, and economic landscape. Despite their often relatively small numbers, placing indigenous peoples into the ethnic mosaic of contemporary nations and states puts later settler and immigrant groups into a more accurate and larger historical context. This is a point that goes beyond “political correctness” or broad “multiculturalism.” The history and current conditions of native peoples often highlight questions of group rights, nation formation, justice, and social change that are relevant to all ethnic communities, not just indigenous groups. To ignore any group in academic discussion of majority–minority relations is itself a form of racism that denies the existence or legitimacy of that group.

Second, of considerable importance in developing general theoretical accounts of intergroup relations is the fact that indigenous peoples present a wide variety of social structures that are not found among state groups, such as Americans, or immigrant groups within states, such as Cuban Americans. Thus, all theories of intergroup relations that study only state peoples will lack dimensions unique to indigenous peoples, such as particular spiritual traditions or patterns of social relations. For instance, most sociologists are familiar with the U.S. racial classification norm called the “one-drop rule”: If an individual has any African ancestry, then that person is considered African American no matter what the person’s appearance or skintone. But for Native Americans—another colonized, conquered, and oppressed group—the same rule does not apply. Often standards require much more than “one drop” for an individual to be officially considered an “Indian.”

A common standard requires one-quarter Indian ancestry (or “blood quantum”), that is, that an individual must have one grandparent or two great-grandparents who are American Indian to qualify as a “real” Indian. Sometimes such ancestry rules are official U.S. government regulations, and more than occasionally they are tribal government rules (see Meyer 1994 for a detailed discussion). No such “one drop” or “blood quantum” rules apply to other U.S. immigrant or ethnic groups.

Third, since the formation of the United States, Native Americans have had a very special political and social relationship with the U.S. government. They are the only ethnic community that has legal right to direct federal action and accountability that bypass city, county, and state governmental authority. This “government-to-government” tribal-federal relationship generates many politically and sociologically interesting interactions and exceptions. One example can be found in the controversies about gaming on Indian reservations that emerged in the last quarter of the twentieth century; another involves treaty-based Indian hunting and fishing rights.

Fourth, theories of long-term social change and social evolution that do not include analysis of indigenous peoples will be inherently defective due to a biased sample of societies examined. There is another danger—that of assuming that surviving indigenous people, even those who live “traditionally,” are models or “living artifacts” of earlier societies. Contemporary indigenous peoples have survived centuries—and in parts of Asia, millennia—of contact and interaction with state societies. Their contemporary social structures have been shaped by their responses to those interactions. Indeed, Ferguson and Whitehead (1992) argue persuasively that these state/nonstate contacts so profoundly change both types of societies that scholars must view even the earliest first-hand accounts of indigenous societies with considerable skepticism. This is because typically by the time a representative of state society who produces written records observes an indigenous group, there has already been considerable interaction, and what that observer sees already has been shaped by that interaction. This is not denying that there are occasional observations that reflect very little interaction and change, but they are very rare. This raises questions, for example, about the accuracy

of depictions of western U.S. tribes by such early travelers (1804) as Meriwether Lewis and William Clark.

In summary, to ignore indigenous peoples leads to bad sociology in the form of theories and explanations that are based on biased samples, that cover only a truncated range of processes and relations found in societies, and that lead to a distorted picture of ethnic, cultural, social, political, and economic diversity in any society with indigenous communities. This is why it is important to overcome the nineteenth century legacy of the division of labor between anthropology and sociology in their objects of study. This is no easy task given the great diversity of indigenous groups in the world, or even in the continental United States.

DEMOGRAPHIC ISSUES

One of the more formidable problems in studying indigenous peoples is describing their demography. Here, too, there are several interesting challenges, even if discussion is restricted to the United States. First, there is the politics of numbers. This derives from changes, and in some cases, improvements in historical demography in the twentieth century and the uses to which numbers are put. Stiffarm and Lane (1992) argue persuasively that there is an inherent tendency to minimize the historical population of Native Americans prior to European contact in order to support the argument that destruction of the indigenous American population was not extreme and mostly accidental. While estimates for the indigenous population of North American (United States and Canada) range from 1 million to 30 million, Thornton (1987) argues for a figure in the neighborhood of 7 million, based on careful reconstruction of population densities, early population counts, and the effects of known epidemics. From 1492 on, Native populations declined drastically, primarily, but not exclusively, because of exposure to “Old World” diseases. For the continental United States, the absolute population nadir of about a quarter million was reached around the turn of the twentieth century. Thereafter, population has grown steadily, so that at the end of the twentieth century the Native American population is approximately 2 million, or between one-third and

one-half of what it likely was in 1492. An important point here is that various studies show that more than disease was involved in the initial depopulation. That outright genocide contributed to the nearly total destruction of the Native American population is now well-documented (see Thornton 1987; Stannard 1992).

The impressive population recovery of the post-Second World War period is worth some mention. From 1960 to 1970, the number of Americans who reported their race to be "American Indian" in the U.S. census grew by 51 percent (from 523,591 to 792,730); from 1970 to 1980, the American Indian population grew faster, by 72 percent (to 1,364,033); and from 1980 to 1990, the American Indian population increased by 37 percent (to 1,878,285). Several reasons are given for this growth, including improved enumeration techniques, a decreasing death rate, and an increasing willingness of individuals to identify themselves as Native American. An important feature of the contemporary Native American population is the extensive intermarriage of indigenous peoples with non-Indians. Intermarriage has given rise to three distinct types of U.S. Indian population (Snipp 1986). First, there are "American Indians," persons who claim to be Indian racially and ethnically (having a specific tribal identification). Second, there are "American Indians of multiple ancestry," persons who claim to be Indian racially but have significant non-Indian ancestry. Third, there are "Americans of Indian descent," who do *not* claim to be Indian racially but report an Indian component in their background. The second two categories contain a number of individuals whose ethnic and racial identities readily shift with political, economic, and social contexts. By 1990 many, if not most, Indians were marrying outside their tribal group, and many were marrying non-Indians. As the number of individuals of ambiguous, and often ambivalent, Indian identity has increased, questions about membership in Indian tribes and definitions of who is and is not really an Indian have been raised by tribal governments, federal officials, and Indian communities and individuals. "Indianness" has become an empirical measurement issue, a political issue, and a theoretical issue. With the financial successes of some native community enterprises (in gaming, natural resources, and tourism), questions of tribal membership have become an economic issue as well.

ECONOMIC DEVELOPMENT

In the twentieth century, political incorporation, assimilation, and economic interaction have tended to attenuate cultural processes and heighten political processes of tribal governments (Cornell 1988; Cornell and Kalt 1999). Access to wealth from mineral resources, gaming, and tourism has helped economic development. Snipp (1988b) shows, however, that many differences between Indian nations with energy resources and those without such resources tend to be minimal. A key problem in economic development—and one that is especially salient among indigenous communities—is how to participate in and benefit from economic development without simultaneously undermining or destroying traditional Indian values (Cornell and Kalt 1992; Ward and Snipp 1996, especially Ward's chapter). Not surprisingly, these issues are enmeshed in indigenous political action globally (Wilmer 1993).

AMERICAN INDIAN POLITICAL ACTIVISM

The urbanization, intermarriage, education, increased participation in the paid labor force, and bicultural character of the American Indian population during the post-Second World War period gave rise to the most politically active period in American Indian history. The 1960s, 1970s, 1980s, and 1990s saw Native Americans organize themselves into political activist organizations (the American Indian Movement, Women of All Red Nations), protest movements ("Red Power," Camp Yellow Thunder in the Black Hills), legal defense organizations (Native American Rights Fund, Native Action), and lobbying groups (National Congress of American Indians, National Tribal Chairmen's Association). These organizations and movements were established and grew in the fertile political soil of the civil rights era ethnic politics in the United States. The following decades were marked by a range of Native American protest events, from the "fish-ins" in the Pacific northwest in the mid-1960s, to the nineteen-month occupation of Alcatraz Island beginning in 1969, to the seventy-one-day siege at Wounded Knee on the Pine Ridge Reservation in South Dakota in 1973, to the occupation of Camp Yellow Thunder in the Black Hills in the 1980s, to the protests against Indian athletic mascots of the 1980s and 1990s (see Johnson 1996; Nagel 1996). Against this

backdrop of marches, occupations, protests, and sometimes open conflict, many legal battles were waged in U.S. and tribal courtrooms across the country. Out of both the protest and the legal battles came a new “self-determination” era in federal Indian policy. Self-determination opened the way to increased tribal control of budgets and decision making, to the development of tribally owned natural resources, to the establishment of casinos and gaming on tribal land, and to opportunities for self-rule and economic development by Indian communities. These political and economic opportunities have raised social questions about the rules for tribal membership, which will remain a subject for debate well into the twenty-first century because of the projected continued growth of the Indian population.

OTHER CONTEMPORARY NATIVE ISSUES

Two of the major contemporary issues facing Native Americans are debates over gaming and renewed interest in indigenous religion. Because of their special relationship with the U.S. federal government, reservation governments are able to sponsor gaming over the opposition of state authorities; to sell gasoline and cigarettes without paying local and state taxes; and to sell other products, such as fireworks, that are typically regulated or made illegal by state or local governments. Of all these, the most controversial has been the establishment of gaming facilities. Indeed, these bingo parlors and casinos have spawned social movements that are nominally antigaming but are often very thinly disguised anti-Indian movements, and in some cases reflecting a conflict of interest, as when state authorities see Indian gaming as unfair competition to state-run lotteries and other gaming enterprises. Similar non-Indian opposition has resulted from renewed Indian land claims (such as by the Oneidas in upstate New York in 1998–1999). These controversies have heightened the stakes of identity politics both within native groups and between native groups and the general population.

Initially, one might expect that renewed interest in and presumably respect for native religions by non-Indians might have been received positively by Native Americans. However, this is generally *not* the case. Often non-Indian appropriation of Indian spiritual traditions is perceived by native

people as a final theft. After stealing Indian land, mineral rights, water rights, and fishing rights, the final non-Indian assault on native peoples is to usurp and subvert Indian culture. This has not been helped by the number of charlatans and hucksters (a few of whom are of native ancestry) involved in assorted “New Age” appropriations of Indian cultural elements, typically lifted entirely out of their indigenous context (see Churchill 1994, 1996; Rose 1992). The spread of New Age and “world” music, which uses elements and occasionally performers from various indigenous populations, has spawned analogous controversies at a global level (Feld 1991). Not the least of the subcontroversies is that it is non-Indian performers and producers who are making the large profits from the use of indigenous instruments, themes, music, and performances. Such controversies will not disappear quickly. They have, however, generated a new interest in relations with indigenous peoples and new attempts to reexamine the long and often tawdry history of Indian/non-Indian relations.

CONCLUSION

The sociology of indigenous peoples, including their relations to state peoples, is multifaceted, and fascinating. It is also a vital and necessary component to the study of the sociology of intergroup relations. Many complex and important sociological processes occur primarily, and sometimes only, in relations between state and nonstate peoples. In order to develop robust theories of intergroup relations, of social movements, and of globalization and resistance to its negative consequences, the study of indigenous peoples is indispensable. Theories built solely on the study of immigrant populations are necessarily flawed; those that include indigenous peoples are much richer.

A NOTE ON REFERENCES

The literature on indigenous peoples is immense, even in sociology. We have cited works which contain extensive bibliographies. We also suggest that those interested in this area use the World Wide Web to search for information on Native American studies, American Indian studies, and individual tribes—many of which have their own Web pages. The History Net list, H-AMINDIAN, is also an excellent resource. Some useful scholarly

journals are: *American Indian Culture and Research Journal*, *American Indian Quarterly*, *Native America*, *Wicazo Sa Review*, and *Cultural Survival Quarterly*.

INDIVIDUALISM

Individualism is a doctrine concerning both the composition of human society and the constitution of sociocultural actors. The term was invented in the 1820s, apparently, in France (Swart 1962). Its first appearance in English dates from the 1835 translation of Alexis de Tocqueville's study of the United States (Tocqueville [1850] 1969, p. 506). The basic notion conveyed by the newly coined word, that the individual is sovereign vis-à-vis society, was intensely controversial, for it stood on the grave of one established order, proclaiming the rise of another. As an early French critic saw it, individualism "destroys the very idea of obedience and of duty, thereby destroying both power and law," leaving nothing "but a terrifying confusion of interests, passions and diverse opinions" (cited in Lukes 1973, p. 6).

Individualism should be distinguished from historically specific constitutions of the individuality of human beings. The word "individual," used to discriminate a particular human being from collectivities ("family," "state"), had been in circulation for centuries prior to Tocqueville (albeit mainly as an adjective), and individualizations had been practiced under one description or another long before that, at least as evidenced in the oldest surviving texts of human history. However, premodern constitutions of individuality did not become the foci of a distinctive doctrine of individualism. That development came in response to

the profound changes of social structure and consciousness that had been slowly accumulating during the seventeenth and eighteenth centuries. In the transformation from a medieval to a modern world, new transparencies of meaning evolved—among the most important, a particular conception of "the individual." The enormous power of that conception is reflected in the fact that people of modern society have generally had no doubt as to what an "individual" is. The reference has been self-evident because the object referred to, an *individual*, has been self-evident, pregiven, natural.

But one must remember that "the individual" is a construct. Like all constructs, it is historically variable. The meaning of individualism's "individual" was formed under specific historical circumstances that, in practice as well as in ideology, increasingly prized values of rational calculation, mastery, and experimentation; deliberate efforts toward betterment of the human condition; and a universalism anchored in the conviction that "human nature" is basically the same everywhere at all times and that rationality is singular in number. These commitments were manifested in the doctrine of individualism (as, indeed, in the formation of the modern social sciences). By the time of Tocqueville and the newly coined word, individualism's individual had become integral to much of the practical consciousness of modern society. Human beings were being objectified as instances of "the individual"—that is, as instances of a *particular kind* of individuality.

The forces created during that formative period wrought great changes in the fabric of society, many of which continue to reverberate. Of course, as historical circumstances have changed, both "the individual" of individualism and the constitution of individuality have changed. Nonetheless, a certain transparency of meaning remains still today in our practical consciousness of "the individual," and it is still informed by a doctrine of individualism. Thus, when a sociologist says that "a natural unit of observation is the individual" (Coleman 1990, p. 1), he can assume without fear of failure that most of his readers will know exactly what he means.

The remainder of this article offers brief accounts of (1) the development of individualism during the seventeenth, eighteenth, and nineteenth

centuries, (2) recent shifts of emphases in individualism's conception of "the individual," and (3) some current issues and concerns. More extended treatments can be found in Macpherson (1962), Lukes (1973), Abercrombie and colleagues (1986), Heller and colleagues (1986), and Hazelrigg (1991), among others.

THE SELF-REPRESENTING INDIVIDUAL

While elements of individualism can be seen in expressions of practical affairs as early as the twelfth-century renaissance (Macfarlane 1978; Ullmann 1966), the first more or less systematic statement of the doctrine came during the 1600s. Scholars such as René Descartes, Thomas Hobbes, and John Locke believed that in order to understand a whole (e.g., society) one had first to understand the parts of which it is composed. In the case of society, those parts, the building blocks of a society, were instances of "the individual." Although disagreeing on various specific issues—for example, whether human agency is distinct from a natural world of causal necessity (Descartes) or a product of that causal necessity (Hobbes)—these seventeenth-century scholars displayed a remarkable confidence in their understandings of "the individual" as a presocial atom. Their individual was a highly abstract being, squatting outside the world.

In the premodern order of European society, social relations had been organic, corporate, and mainly ascriptive. Sovereignty was a complex relation of duty, responsibility, and charity, focused on a specific location in the hierarchical order of organic community. Certainly members of the community were individualized, but the distinction was constituted primarily by ascriptive position in the hierarchical order. It is clear from surviving documents of the twelfth century, for example, that one individual knight was discriminable from any other in ways that we would describe as "personality." With rare exceptions, however, the discrimination was local. Otherwise, knights were discriminable mainly by pedigree, lines of fealty, and quality of chivalry. Individuals could rise (and fall) through gradations of rank, but vertical movement was first within the family or household group. A knight who aspired to still higher standing had first to be retained in another, more powerful family. Similarly, while there is no reason

to doubt that residents of a twelfth-century village or town could reliably discriminate one another by physiognomic features, the portrayal of human beings in paintings concentrated on matters of costume, placement, and posture to signal social distinctions among virtually lifeless mannequins. Even in the revolutionary works attributed to Giotto (1267–1337), whose use of subtle gestures and glances began to individualize portrayals sufficiently to be called portraits in the modern sense, such facial features as warts, wens, moles, wrinkles, lines, scars, and sagging skin were still quite irrelevant to, and therefore absent in, the visualized identity or character of a person. But by the end of the 1400s we see, most notably in Domenico Ghirlandaio's *Portrait of Old Man and Boy* (c. 1490), depictions that to the modern sensibility count as realistically individualized faces. The art of portraiture gradually developed into advertisements of a new actor, front and center—modernity's sovereign individual (Haskell 1993).

In this new order, by contrast to its predecessor, social relations were conceived as contractual rather than organic, based on achieved rather than ascribed traits of individuals liberated from constraints of community. City life was once again the center of gravity in territorial organization, having displaced the manorial system. What would become the modern nation-state was beginning to take shape during the period of relative peace inaugurated by the several Treaties of Westphalia in 1648. Within this context of invention and experimentation with new (or renewed) organizational forms, the new individual was conceived as a wholly separate entity of self-identical integrity, a "bare individual" who could freely consent to enter into concert with other, equivalently constituted individuals, each propelled by self-interest. This was, as Macpherson (1962) described it, the advent of "possessive individualism," and it correlated well with the developing motivations of capitalism.

By the end of the eighteenth century, individualism had attained mature statement in treatises by David Hume, Adam Smith, and Immanuel Kant, among others. This mature statement, worked out in the context of rapidly changing political-economic institutions, emphasized the centrality of a "self-representing individual." The chief claim—that "every individual appears as the autonomous subject of his [or her, but primarily his] decisions

and actions” (Goldmann [1968] 1973, p. 20)—served as the linchpin to formalized explanations of the political and economic rights of members of society, especially the propertied members. Expressions of the chief claim in moral and legal rights of the individual became enshrined in newly invented traditions, in legitimizing principles such as “popular sovereignty” and “inalienable rights,” and in documents of public culture such as the Declaration of the Rights of Man and the Constitution of the United States of America (Hobsbawm and Ranger 1983; Morgan 1988). The prayerful injunction “God bless the squire and his relations and keep us in our proper stations” had been replaced by the almost wholly secular “*I* pledge allegiance to the flag” (i.e., to an abstract sign). While the claim of autonomy emphasized the universality of rights and the particularity of the “*I*,” the practical emphasis on a self-representing individual was formulated in political-economic terms that “necessitated” elaborate definitions and procedures for the defense of “property rights” long before equivalent attention would be given to, say, “rights of the handicapped.”

Much like the individual of organic community, the self-representing individual is a substantial presence, manifest as the embodiment of a uniform human nature, and as such is the bearer of various traits, dispositions, and predications. However, the site of the self-representing individual’s capacity of agency and potential for autonomy is neither the community nor the accumulated traits, dispositions, and predications. Rather, it is deeply interior to what became a new “inner nature” of the human being. Beneath the faculty of reason, beneath all feeling and emotion and belief, there is “the will.” Emile Durkheim ([1914] 1973) described it as the egoistic will of the individual pole of *homo duplex*, for George Herbert Mead (1934) it was “the principle of action.” But before either of those sociologists, the master theorizer of the self-representing individual, Immanuel Kant, had formulated the basic principle as the pure functioning of the “*I*” through time. Only because *I* can unite a variety of given representations of objects in *one* consciousness, Kant ([1787] 1929, B133) argued, is it possible that *I* can “represent to myself the *identity of consciousness*,” throughout those representations. In other words, the very possibility of a knowledge of the external world is dependent on the temporal continuity of the “*I*.”

The individual is absolute proprietor of this pure functionality, this willing of the “*I*” as basic principle of action; the individual owes absolutely nothing to society for it.

By conceiving the essential core of human individuality to be a deeply interiorized, radically isolated pure functionality, connections between the individual and the substantive traits that he or she bears become arbitrary. The individual is formally free to exercise choice in which traits to bear, free to be mobile geographically, socially, culturally, personally. Ascriptive traits are devalued in favor of achieved traits, and one set of achieved traits can always be exchanged for yet another set. This principle of freely exchangeable traits, an aspiration directing progress toward “the good society,” depended on new means of socialization (or “internalization of norms”), so as to insure sufficient regularity in processes of exchange. Indeed, the self-representing individual was central to a distinctive regimen of behavior, a new practical meaning of “discipline” (Foucault [1975] 1977). As the doctrine of individualism saw it, the contractual, associative forms of social relation, though looser fitting in their normative constraints than the old organic community, were complemented by the figure of “the self-made man” who had internalized all the norms of rectitude and propriety so nicely as to merit life in an unprecedentedly free society. When reality failed the image, there were courts and legal actions for deciding conflicts of interest and the clash of individuals’ rights. Notably, not a single book on the law of torts had been published in English by the mid-1800s; the explosive growth of tort law and third-party rules was only beginning (Friedman 1985, pp. 53–54).

Because the doctrine of individualism provided a set of answers to questions that were foundational to sociology (as to the social sciences in general)—What is the individual? How is society possible? and so forth—virtually every topic subsequently addressed by sociology has in one way or another involved aspects of individualism. Given the composition of individualism’s self-representing individual, the most prominent issues have often centered on questions of relationship between the rise of individualism and the development of new forms of political-economic organization as manifested in capitalism, bureaucracy, and the modern state. Indeed, that relationship was

focus of one of the great controversies occupying many early sociologists (Abercrombie et al. 1986). Hardly anyone doubted the existence or importance of a relationship. Rather, the debates were about such issues as causal direction (which caused which?), periodizations (e.g., when did capitalism begin?), and whether ideas or material conditions (each category conceived as devoid of the other) were the primary motive force. In many respects the debates were a continuation of the struggles they were about.

Other, more specific topics addressed by sociologists have also involved aspects of the rise of individualism. Several have already been mentioned (e.g., a new regimen of discipline). Additional examples are the development of sectarian (as opposed to churchly) religions, followed by an even more highly privatized mystical-religious consciousness of the isolated individual; changes in domestic architecture, such as greater emphasis on individualized spaces of privacy and functionally specialized rooms; changes in table manners, rules of courtesy, and other “refinements of taste”; the emergence of a “confessional self” and practices of diarykeeping; increased emphasis on romantic love (“affective individualism”) in mate selection; new forms of literary discourse, such as the novel and autobiography; the rise of professionalism; and the rise of the modern corporation as an organizational form that, having gained standing as a legal actor comparable to a flesh-and-blood person, cast into doubt reliance on understandings of “the will” as foundation and motive force of contractual relations (see Abercrombie et al. 1986; Horwitz 1992; Perrot [1987] 1990).

THE SELF-EXPRESSING INDIVIDUAL

The figure of the self-representing individual proved to be unstable, even as the meaning of representation gradually changed. This was mainly because the same factors that had produced this version of individualism’s individual also led to dissolution of the transparent sign. For example, whereas clothing, manners, bodily comportment, and similar traits had been, in the old order, reliable signs (representations) of a person’s rank or station in life, the sign became increasingly arbitrary in its relationship to ground. This loosening of the sign, together with a proliferation of signs in exchange,

led to a new universalism of “the empty sign.” The prototype was money and the commodity form: Devoid of intrinsic value and capable of representing everything, it represents nothing in particular. As one recent scholar has described the process, borrowing a clause from Karl Marx, “all that is solid melts into air” (Berman 1983).

At the same time, the rhetoric of transhistorical forms of value (e.g., the commodity, inalienable rights) allows for an enormous amount of individual variation in the sociocultural conditions under which it can succeed. Individualism’s emphasis on the bare individual was being increasingly generalized, further reducing the import of group-based relations and traits. In the mid-1800s, for instance, the distinction between public affairs and private matters was drawn at the door of home and family. Family life provided the chief “haven” of organic relations, nurturant domesticity, and refuge from the trials of work and politics. But soon the haven itself became a site of struggle toward still greater individuation. Of the many factors contributing to this rebellion against the traditional restraints of family, one of the most important was a new culture of sexuality, which manifested a more general and growing concern for the interior interests and needs of the individual.

Precedent for this concern can be seen in Kant’s conception of the self-representing individual (because of the transcendental “I,” every individual has in common a potential for *self-actualization*) as well as in romanticist movements of the early 1800s. However, the development of a new “inner discourse of the individual” has been mostly a twentieth-century phenomenon. The psychology of Sigmund Freud and his disciples formed part of that development, certainly; but another part was formed by the conception of a new “social citizenship” (Marshall 1964), which emphasized an individual’s rights of social welfare in addition to the earlier mandates of political and economic rights. A new figure of individualism’s individual gradually emerged, the “self-expressing individual.”

The individualism of the self-representing individual promoted the idea that all interests are ultimately interests of the bare individual. The new version of individualism both extends and modifies that idea. Whereas the self-representing individual puts a premium on self-control and

hard work, the self-expressing individual generalizes the value of “freedom of choice” from political-economic exchange relations to matters of personal lifestyle and consumption preferences (Inglehart 1990). The central claim holds that “each person has a unique core of feeling and intuition that should unfold or be expressed if individuality is to be realized” (Bellah et al. 1985, p. 336), and each person has the right to develop his or her unique capacities of self-expression. A recent change in divorce law partly illustrates the import of that claim. Prior to the 1960s one of the few organic relations still surviving in modern society was the marital bond; few conditions were deemed grave enough to have legal standing as grounds for breaking it. With the invention of “no fault” divorce (relatively noncontroversial legislation that spread rapidly from state to state; Jacob 1988), the marital relation became a civil contract much like any other, and a spouse’s freedom to choose divorce in the interest of satisfying unfulfilled needs of self-expression gained recognition.

Another manifestation of this self-expressing individual is the recent development of a specialized field, the sociology of emotions (e.g., Barbalet 1998; Thoits 1989). Certainly earlier scholars (e.g., Georg Simmel) had recognized emotive dimensions of sentiment, tradition, trust, and the like, and had assumed motivations such as fear of power, anxiety about salvation, envy of success, frustrated ambition, and eponymous glory. No one imagined that persons of premodern societies did not experience emotions—though usually this would have been in an idiom of “the passions,” and scholars disagreed whether these were in fact ahistorical, noncultural formations. But emotions had rarely been treated as important topics of inquiry by sociologists until the latter decades of the twentieth century. The emotive dimensions of life had typically been regarded as subordinate to other dimensions, just as the passions had been treated as dangerous when unbridled—energies which belonged properly in the harness of reason or “the rational faculty.” (Most of the seven deadly sins, remember, were emotional states or effects of emotional states.) When rightly yoked by reason, emotive energies of the self-representing individual could achieve highly valued public outcomes even if the particular emotion itself was classified as a vice. Thus, avowed Adam Smith among others, private greed or avarice could become, through

the device of market transaction, a public benefit. For the self-expressing individual, on the other hand, emotive aspects of life are, or should be, valued in themselves, not only for what might result from them. Whereas the eighteenth-century “pursuit of happiness” (one of the self-representing individual’s inalienable rights) was idiomatic for the unfettered formal liberty of the individual to pursue self-interest in commerce (an inherently outward-looking, social activity), for the self-expressing individual the pursuit of happiness refers to a much more introspective, privately evaluated emotional state, “being happy with who one is.”

Individualism’s self-expressing individual remains a trait-bearing substantial entity, to be sure. The variety of bearable traits is greatly expanded by the shift in emphasis from self-control to self-expression through lifestyle experimentation (“the person as work-in-progress-from-within,” as it were). Moreover, this shift in emphasis is accompanied by the stipulation that only those traits that an individual can freely choose to assume, and then jettison, should be relevant criteria by which to discriminate and evaluate individuals. Criteria falling outside the bounds of individual choice (“immutable” traits, whether biological or sociocultural) are deemed to be both irrelevant and, increasingly, a violation of an individual’s rights. In conjunction with the “entitlements” logic of social citizenship, this stipulation of a radically individualistic freedom of reversible choice has been linked to the emergence of a generalized expectation of “total justice” (Friedman 1985).

By the same token, the doctrine of individualism has always contained a large fictive component. Long after the doctrine proclaimed the sovereignty of the bare individual, for example, the actual individuality of human beings continued to be heavily marked by ascriptive traits (e.g., gender, race) and by sociocultural inheritances from one’s parents. The shift to an expressive individualism reflects efforts to situate the agency of a “free individual” outside the separately conceived domain of relations of domination. Rather than attempt to change those relations, the self-expressing individual would “transcend” them by concentrating on a logic of rights pertaining to the free expression of individual will in a domain of “personal culture” (Marcuse [1937] 1968).

Fictions can be productive in various ways, however. The fictions of individualism have often been made taskmasters, as women, African Americans, persons with disabilities, and other human beings discriminated primarily by ascriptive or group-based criteria have struggled to make reality conform to doctrinal image.

SOME CURRENT ISSUES

Because individualism has been one of the professional ideologies of the social sciences (“methodological individualism”), a perennial issue concerns the proper structure of explanation—specifically, whether explanation of any sociocultural phenomenon must ultimately refer to facts about individuals, and if so, what precisely that means (Coleman 1990; Hazelrigg 1991; Lukes 1973). No one denies that collectivities are composed of individuals. But that truism settles neither the question of how “composition” is to be understood nor the question of what constitutes “the individual.” In short, the methodological issue involves a number of theoretical-conceptual issues, including several that are located at the intersection between individualism’s “individual” and historical variations in the actual constitution of individuality (Heller et al. 1986). The doctrine of individualism has consistently conceptualized “the individual” as a distinct and self-contained agent who acts within, yet separate from, a constraining social structure. Rather than being an ensemble of social relations, individualism’s individual is the substantial atom out of which any possible social relations are composed. This has certain implications for the empirical field.

How, for instance, does one understand the category “rational action”? What minimal criteria must be satisfied in order that a particular action can count as “rational”? The individual who stands forth in individualism tends to the heroic—self-made, self-reliant, and self-governing, rising above circumstances, taking charge of one’s own destiny, and, in the aggregate of similar atoms, building a better world. This individual was soon accorded central place as the chief fount of rational action. Whereas late eighteenth-century scholars such as Adam Smith continued to remind readers that rational action could and did stem from nonrational motivations (e.g., moral sentiment, the ethos of tradition, even the simple inertia of habit), pride of

place in the list of motivational sources increasingly shifted to that part of the “faculties of mind” called “the rational faculty,” conceived as an instrument of the will. The emphasis on rationality as faculty, an “instrumental rationality,” was no doubt encouraged by, and at the same time promoted, a growing list of successes in the inventiveness of carefully deliberated, calculated designs, plans, and projects of human engineering. (Recall the success of Dutch efforts, beginning on an ever larger scale in the 1600s and 1700s, to push back the sea and create thousands of square miles of new land—for most of us a barely remembered fact of history, but in those earlier times a truly audacious undertaking.) Are the limits of rational action therefore as closely circumscribed as the limits of an individual actor’s rational deliberations, calculations, and intentions? Most sociologists today are agreed in answering “no” to that question, although they diverge, sometimes sharply, in particulars of the answer (Coleman 1990; Kuran 1995; Sica 1988).

Social action can be highly rational in the aggregate, both in outcome and in process, even when individual actors, attending more to nonrational or irrational than to rational motivations and intentions, behave in ways that hardly fit the doctrinal image of “heroic actor.” People do learn from experience (if fitfully and slowly), and part of the accumulated fund from that learning consists in organizational forms that have rationalities built into them. This “rationality as form”—a materialized intelligence in the same way that a hand-held calculator, an airplane, or a magnetic resonance imager is a materialized solution to a set of problems—enables many more people to use, benefit from, and even operate the rationalities built into such devices than have the understanding (“rationality as faculty”) required to design their architectures or to convert design into working product. Moreover, whereas the examples just cited can be readily interpreted as immediate and punctual products of some specific individual’s rational faculty (thus fitting the heroic-actor model of the inventor or discoverer as genius), many other examples of rationality-invested organizational forms—family structures, markets, bureaucracy, and so forth—are as much or more the gradual accretions of indirection, sentiment, habituation, and happenstance than the intended consequences of rationally deliberated, calculated, instrumental

actions of particular individuals. The doctrine of individualism has often slighted the importance of these latter wellsprings of rational action, as if the actions they motivate do not quite count, or do not count in quite the same way, as action that directly manifests the willful force of an individual's reasoned intentions.

In a related vein, if the individual owes nothing to society for the "I" as principle of action, where should the distinction be drawn between determinants of action that are social and those that are psychological? Consider, for instance, a person suffering the characteristics clinically (and thus socially) categorized as "depression." Are these characteristics proper to the individual only, or are they also in some way descriptive of a social condition that is integral to the individual so characterized? If Willy Loman, of Arthur Miller's *Death of a Salesman*, is depressed, does that description say anything about the circumstances of a life Loman shared with countless others, or is it the description only of a misery interior to an isolated individual? Each of these accounts of what is under description has had its proponents. The popularity of a medicative regimen that emphasizes direct palliation or amelioration of psychic state (as in chemical applications, whether Prozac or psilocybin) suggests a growing preference for the second account.

Some sociologists contend that individualism's self-expressing individual is an accurate depiction of contemporary reconstitutions of individuality, and that in this new form of "the individual" the substance of selfhood, an individual's self-identical integrity, is being evacuated. Bellah and colleagues (1985) indict the emergence of "a language of radical individual autonomy" in which people "cannot think about themselves or others except as arbitrary centers of volition (p. 81)." Others argue that the emphasis on individual autonomy and separation is an expression of masculine, patriarchal values, as contrasted to feminine values of social attachment (Gilligan 1982). Still others see the development of an entirely new "order of simulacra" (Baudrillard [1976] 1983), in which simulation or the simulacrum substitutes for and then vanquishes the real (e.g., television images establish the parameters of reality). The alleged result is a collapse of "the social" into the indifference of "the masses," who no longer care to discriminate among "messages" (beyond their

entertainment effects) since one simulation is as good as another.

Equally contentious issues surround the evident growth in people's sense of entitlement and in the array of legal rights claimed and often won on behalf of "individual choice." Individualism's figure of the self-expressing individual is held by some to be the harbinger of a new age of democracy, by others to be the confirmation of a continuing trend toward greater atomization (Friedman 1985). Both assessments point to the emergence of a "rights industry" that promotes the invention of new categories of legal right pertaining to everything from a guaranteed freedom to experiment with unconventional lifestyles without risk of discrimination or retribution, to the rights of animals both individually and at the species level, to the possibility of endowing genes with "subject-like powers" and thus legal standing (Glendon 1991; Norton 1987; Oyama 1985). Some critics contend that the expansion of concern for increasingly particularized and "arbitrary" individual choices comes at the expense of a diminished concern for social outcomes. "Unless people regain the sense that the practices of society represent some sort of natural order instead of a set of arbitrary choices, they cannot hope to escape from the dilemma of unjustified power" (Unger 1976, p. 240). The conviction recalls that of the early French critic quoted in the opening paragraph.

LAWRENCE HAZELRIGG

INDUSTRIAL SOCIOLOGY

The term *industrialization* connotes the development of social organizations, generally in nation-states in which large manufacturing enterprises loom large and in which adjunctive legal institutions supporting laissez-faire philosophies of market relationships and providential public and private services grow with them in tandem. Adam Smith's *Wealth of Nations* became early on, after its appearance in 1776, a kind of founding blueprint for the exploitation of private interests and initiatives in the service of the "general good." Industrial sociological studies accordingly focus on the "causes" or prerequisites for, the correlates of (in family, community, and other social settings), and the consequences of the industrialization process, largely in social systems governed in accord with eighteenth-century liberalism, with its emphases on the economic rights of property owners and their agents.

The key consequences under examination have been the "rights, privileges, and immunities" of parties to labor contracts; the characteristic social

and economic relationships among investors, producers, workers, and consumers in Western societies and, in turn, the circumstances of dependents, communities, and regions; and, finally, the resulting stabilities and changes in the social, economic, and political structures of the nations in which all these persons live.

Those whose research and teaching agendas include several of these broad domains draw very heavily on specialists in “world systems,” economic development, economic determinism, legal institutions, social stratification, public policy, organizations, urban sociology and community studies, labor markets, and economic sociology. A number of issues treated elliptically in these lines of research, especially those addressed by French, German, British, Italian and Japanese scholars, are discussed in relevant articles in this Encyclopedia.

Industrial sociology as a distinguishable if very broad field of study may truly be said to have been born in the late 1770s, so continuous with their forebearers’ interests have been many of the specific subjects of concern of modern investigators. Systematic studies of social organizations in industrial societies date from the long-celebrated if not always carefully read analyses by Adam Smith, who addressed philosophical issues having to do with economic activities and related “moral sentiments” early in his writings and then turned to his widely known and enduring work on the social (macroscopic) and organizational (microscopic) roles in society of capitalists and, more famously, of labor. Smith regarded labor and its effective mobilization and utilization, not the fruits of mercantilism (i.e., the quantity of gold and silver imported from colonies and the exportation of finished goods), as the real sources of what he termed the wealth of nations. Smith’s studies of the superiority of specialized divisions of labor in a pin factory became a template for studies of the personal and social costs and benefits of manufacturing enterprises by scholars of all political colors.

Furthermore, Smith’s analyses and urgings about the benefits of free trade, of constraining the role of government in economic affairs, of the critical roles of increasingly differentiated divisions of labor, and of the emergence of the “factory system” in late-seventeenth and early-eighteenth-century England staked out most of the basic subjects of modern industrial sociologists’ research

studies: economic organizations; managers’ and workers’ ways; the correlates of technology and divisions of labor; economic exchange and trade; questions about the roles of central governments in economies, and about innumerable regulatory measures affecting workplaces; and, finally, the distributive effects of industrialization on national stratification systems.

Industrial sociologists can also trace their roots to Charles Dickens’s very popular literary treatments of life in early-nineteenth-century England and to other early and more pointedly social, economic, and political reformers in Europe. Thus, investigators now undertake studies with debts to English and French critics, commentators, and philosophers whose works are captured in the term “the Enlightenment”; to Henri St. Simon’s urgings about the application of scientific rationality to social organization; to Karl Marx’s historicist treatments of capitalism’s problematical “maturer” states; to the pros and cons in arguments about nascent trade union movements; to debaters arguing over alternative welfare, trade, and other initiatives by governments; and to assessments of the philosophical legitimacy of the emerging stratification of societies, as variant forms of aristocracy gave way to variant forms of more representative governments. Dickens’s characterization of an employers’ association that resisted safety guards on moving machine parts as “The Association for the Mangling of Operatives” and his and his audiences’ concerns about the improvement of working conditions presaged a great deal of the work of industrial sociologists in the twentieth century, most of whom have been critical of unfettered markets. Continuities since the nineteenth century, meantime, in all but methods of research, have been notable. The subjects pursued include the forces that virtually compel ever more differentiated divisions of labor; the effects of different patterns of national income distribution; and the contributions of these forces to the rise, expansion, and characters of both “blue-collar” labor forces and, overlapping with them, the expansion of middle classes in urban centers; the forces that contribute to the rise of trade unions and the resulting growth of new systems of law that have changed the nature of property and property claims to include more than physical capital and realty; the forces that have contributed to the decline in small agricultural holdings, small towns, and rural

areas; and, withal, the forces that generally make social life more secular, political life more democratic or undemocratic, and working life more bureaucratic.

During the period from 1900 to 1950, much of the macro-level research that continued to add to present-day conceptions of the body of industrial sociological literature was actually performed by institutional economists—in the United States principally students of labor, management, and the “legal foundations of capitalism”, in the tradition of the “Wisconsin” or (J.R.) “Commons School” (Commons and associates 1926, 1935, 1936). These investigators also founded the field of industrial relations, whose practitioners’ work has perennially overlapped with that of industrial sociologists. In more recent times, sociologists have essentially inherited what has come to be seen as the “institutional tradition” in economics, a longtime tradition in that discipline that has given way, in the post-World War II world, to mathematical modeling and econometrics. Parallel works in western Europe have similarly been informed by Sydney and Beatrice Webb and by pre-World War I Christian democratic and secular left-liberal traditions in France and Germany.

In the period after World War I, industrial sociologists gave increasing attention to the positive and negative social effects of business cycles: “Busts” undoubtedly helped to purge national economies of many types of waste and inefficiencies and thus contributed to subsequent “booms.” At the same time, however, busts sparked unwelcome recessions and depressions, with their subversive effects on growth, employment levels, and thus on the living standards, attitudes, and behavior of most citizens. Researchers’ attentions, in the 1930s especially, focused correlatively on the growth of large corporations in the Western democracies; the pros and cons of aggressive price competition; and the possibly leavening effects of unions and of interventions by the “positive state” against the centralization of economic and thus, potentially, of political power in private hands, such that some of the less admirable correlates of capitalist systems could be controlled. Generally the researchers sought not so much to traduce “big business” as to identify constraints on private economic power that would not reduce the benefits to societies of large corporations’ productive capacities. The emergence of fascism in Germany in the

1930s embodied widespread apprehensions about both big government and the reach of the communist revolution in what became the USSR.

Systematic attention toward the middle of this period was also given to what is now termed the global economy, often in the form of studies of the effects of the international trade barriers that contributed so significantly to the collapse of the Western industrial economies—the so-called Crash of 1929 and the Great Depression. The political and economic interdependencies among nations—and those among classes of economic actors within them—became increasingly palpable to researchers, who began to see economies more clearly in terms of the structures of individual industries and industry groupings—new chapters in the all-important story of the causes and correlates of the division of labor (Brady 1943). Additionally, unions were gaining in their appeal, beyond skilled tradesmen, to industrial, “mass-production” assembly workers. Among the questions pursued by sociologists were those having to do with the prospects that a coherent working class would emerge in the United States out of the ferment of the pre-World War II era. Incipient “class warfare” could be tamed, if not quashed, by reforms that are collectively referred to nowadays as revisions in the (Jean-Jacques Rousseau’s) “social contract” and by the construction of social “safety nets” of types that are currently being critically assessed in both the United States and in western Europe; renewed and very vigorous industrial price competition has contributed significantly to concerns about expansion of central government “welfare” budgets in competition with funds for private investment.

Finally, by the 1920s and into the 1940s, there were growing concerns about whether Benito Mussolini’s “corporate state” and Adolf Hitler’s Third Reich represented a kind of conspiracy of fascists with Italy’s and Germany’s financial and manufacturing leaders (Neumann 1942) against those, especially in the three Communists Internationals, who were perceived by conservatives to be urging workers to turn to the revolutionary political left. This subject earned much increased attention after World War II; joined by historians’ work in the 1950s, the social scientific literature on the social sources of totalitarian systems has become extensive, one of the recurring questions in this literature being whether the seeds

of “totalitarianism of the right” germinate especially well in “capitalist” soil (Moore 1973). The answers from sociologists’ studies, however, have tended to focus on the fragility of support for democratic institutions in most societies. These studies have analyzed the vulnerabilities of democracies to losses of the confidence of large numbers of citizens victimized by major and long-enduring economic collapses, rather than on markets’ preoccupation with putative contradictions in capitalism per se, as a key reason for the appeal of social movements on the political right. Suffering from traumatic social, political, and economic discontinuities, sociologists reported, could all too easily contribute to the delivery of the loyalties of many—from Rome and Naples in Italy, to Marienthal in Austria, to Berlin in Germany, and to Buenos Aires in Argentina—to demagogues and “scapegoaters”. Indeed, these studies led social psychologists among sociologists to important and widely influential discoveries about scapegoating phenomena that could generate poisonous race and ethnic relations (Adorno et al. 1950).

At what we may call the “mesoscopic”—middle—levels of analyses, industrial sociologists, in loose confederation with the more institutionally oriented scholars among labor economists, turned their attention in the pre-World War II period to the implications of the levels of aggregate demand (and deficiencies thereof) for the structures and experiences of communities before and during the Great Depression [as in Muncie, (“Middletown”), Indiana, in the United States]; to the disinclinations of unemployed Americans to “blame the system” (rather than themselves) for their sad circumstances during the Great Depression; and to the pros and cons of government intervention in national economies and of the construction of the aforementioned “safety nets” for victims of economic downturns.

Not least among sociologists’ interests were those in the stratification of societies, especially respecting the distribution of wealth and income among individuals and families; the behavior of economic elites in local communities; and the causes and correlates of social mobility. In the latter matter, evidence mounted that the economic successes and failures of individuals could not be attributed simply to their ambition, “drive,” and hard work—or their lack of these oft-praised qualities. Indeed, many successes and failures are

grounded in opportunity structures, not the least important of which are individuals’ access to third-party “bonding” agents and access to formal education and training. While most economists have equated their educational achievement, or lack thereof, to earners’ incomes without further ado, sociologists have urged that imperfections in markets enabled American employers to assume that better-educated workers were more productive and to pass on the costs of such an assumption to consumers (Berg 1970). For economists, better-educated workers are paid more because they are more productive, but their measure of productivity is income, not actual output, as a supposedly valid measure of output.

The advent of World War II brought many industrial sociologists to focus, not without a degree of patriotic fervor, on organizational arrangements in relation to the need to heighten productivity gains in what President Franklin D. Roosevelt called the world’s arsenal of democracy. Studies of workers’ groups in industry in the late 1920s, many conducted by applied sociologists linked to academic business schools (at Harvard University especially), had already indicated that most workers were as responsive to work-group “peer pressures” to fix production quotas at rates below those contemplated by managers and by their time-and-motion experts as they were to economic incentives. These findings were replicated many times between 1929 and 1985. This view of workers’ motives continues to inform the urging by many sociologists that we go beyond conventional economic studies of wage administration in seeking to understand the ways of citizens in their workplaces. At issue are the respective roles of communitarian and of individualistic predispositions among workers.

With a few very noble exceptions, and for the majority’s own good reasons, economists conceive of production organizations as essentially unproblematic “givens” into which resources are pumped and from which outputs flow. Sociologists’ lessons about organizations as social systems, which balanced the valuable lessons taught by economists, were widely applied in the electrical appliances industry, the airframes industry, and in automobile, steel, and other industrial settings. The lesson: Identify work groups and win over workers’ groups and their leaders to corporate aims; then reap the benefits of the support of not-so-rugged

individualists in workplaces, who often respond more favorably to group norms than to group-disrupting industrial incentive-type pay plans. As it turned out, these lessons were perhaps applied somewhat more assiduously from 1960 to 1990 in Japan than in the United States, where worker participation in organizational decision making and work reforms have appealed to comparatively fewer employers despite the possible benefits of “humanized” personnel policies. Researchers have discovered that U. S. managers’ interest in worker participation tends to wax when there labor market conditions are “tight”—that is, high demand for workers—and wane when they are “loose.” In Western managers’ theory at least, human resources are factors of production—commodities—and the treatments of these factors are functions more of short-run market conditions than of long-term concern about the qualities of work life (O’Toole 1974). The latter concerns find more expression in collective bargaining relationships and in remedial legislation, with the endorsement and help of many sociologists who are skeptical of managers as patrons, than in initiatives by employers who are skeptical of the benefits of “codeterminative” relations with workers, such as those requiring worker representations on boards of directors under laws in Germany and the Scandinavian countries.

THE CONTEMPORARY SCENE

In present-day industrial sociology, the main subjects of study have been (1) the increasingly important roles of education and training in shaping Americans’ opportunities (Jencks et al. 1979); (2) the relationships between the significant differences in circumstances between managers and workers in “core” industries and managers and workers in “internal labor markets” on the one hand, and the lower-paid, appreciably less capitalized, smaller, more vulnerable establishments in the “peripheries” of economies on the other (Kalleberg 1983); (3) in the correlates—income and otherwise—of discrimination against women and minorities; and (4) the problems of those who simply are not well integrated into the labor force, the so-called underclass (Wilson 1987). These newer topics have taken their places with continuing studies of work groups; industrial conflict; mobility patterns; the evolving roles of public policies and the state; the politics of income distribution;

and intramural studies of organizations, their decision-making arrangements, and, more recently, their “cultures.”

Studies by industrial sociologists are increasingly comparative in character, as these researchers seek to identify cultural and political factors—such as belief systems and constitutional arrangements, respectively—that influence the effectiveness of different nations’ populations in efforts to mobilize human and other resources, motivate leaders and their human charges, design productive organizations, and make and provide goods and services (Cole 1989; Lincoln and Kalleberg 1990).

Overall, industrial sociologists have contributed to the delineation of options facing leaders in government but less so to enterprises, unions, and urban communities. During the period until 1970, industrial sociologists’ investigations moved in increasingly specialized directions.

One thrust brought a large group of the field’s leaders to concentrate on organizations (Coleman 1982; Stinchcombe 1990; Thompson 1967). In rich elaborations and embellishments on Max Weber’s pioneering work on bureaucracies, sociologists in the United States and western Europe have ventured into “the Japanese factory”; the Tennessee Valley Authority; banks; mental hospitals; British coal mines; a gypsum mine; a state employment agency; schools, prisons and equivalent “total institutions”; a foundry; the U.S. Military Academy; steel mills (in the United States and Europe); German, Soviet, and Czech manufactories; the military establishment; French family firms; social movements; labor unions; merchant ships; American soldiers’ organized experiences in and out of World War II combat; and the YMCA—to mention just a few contexts and populations about which studies were completed (Hall 1987; Perrow 1986).

While the vast body of literature produced by the observers in this disparate array of organizations has received little acclaim in the media, it is a sign of the importance of these investigators’ findings, assessments, and consequent theories that their work is basic to the curricula of the very influential graduate schools of business and management, from Harvard to Berkeley, from Seattle to Miami, and from Maine to Los Angeles—and in Scandinavia; Germany; France; the United Kingdom; Japan; and, by the 1990s, Moscow. The

lessons learned: It is possible to design a great many optional variations on the specific structures of hierarchical organizations, their intramural arrangements, and the “production relations” therein, to meet the exigencies confronting managers and their charges in dealings with each other; with competitors, clients, customers, suppliers, subcontractors, regulators, third-party insurers, and community forces; and with labor market developments.

Industrial sociologists—whether “majors” from colleges or holders of masters and doctoral degrees, some of whom work as consultants or as technicians or managers in corporate settings—offer prescriptions for improving employee morale and marketing programs (from demographic assessments to surveys of customer attitudes); for designing optimal “mixes” of wage and salary schedules with supplementary benefits; for reducing supplementary benefits; for reducing absenteeism and turnover; for productivity “enhancement”; for designing therapeutic (rather than custodial) environments in mental health care agencies; and for constructing occupational safety programs, grievance machinery, and quality control programs.

A second group moved away from these more microscopic studies of organizations to study the social, economic, and political development of whole societies, some in historical terms during the post-World War II era, including India’s, China’s, Italy’s, Japan’s, and Germany’s (actually “redevelopment” in the latter two cases), and the USSR’s systems. Among the lessons were important guidelines to understanding the stabilities of some and the flexibilities of other social-cultural values that gave distinctive national shape to individual countries’ brands of industrialization. It is clear that while the “common denominators” in the paths to both growth and development—the latter a matter of the degree of distributive justice in a society and the former a matter of increases in gross national product—are numerous, there are instructive differences as well (Inkeles and Smith 1974).

Indeed, a consortium of scholars, many of them sociologists studying “industrialization and industrial man” in comparative-international terms, produced well over forty volumes and a great many shorter pieces on the convergences and

divergences among industrial and industrializing nations over the period 1955–1975 (Dunlop et al. 1975; Kerr and Dunlop 1973). These works of scholarship have helped thousands of leaders in governments, large corporations, labor unions, and international agencies to make judgments about investments (both public and private); social, political, and economic policies; and the aptness of designs of organizations in what is now truly a global economy in which nations’ planning efforts are turning, more and more, toward market and away from command economies (Yergin and Stanislaw, 1998). The conclusions at the end of 1990, in a continuing body of research following the preceding twenty-four months of changes in eastern Europe and the USSR, were that the “marketizing” and democratization movements in previously planned economies would assuredly reduce divergences among industrial systems but would by no means eliminate entirely the influence of discrete national cultures in shaping the practices and institutions, from child rearing to legal structures, that help, in turn, to shape social relations in a given nation’s enterprises, as some sociologists have long argued.

A third constituency moved “below” organizational levels to study the dynamics of work groups within organizations, picking up on the work of the previously mentioned human relations school before, during, and after World War II. This group of scholars drew heavily on earlier sociologists’ insights and theories—from Georg Simmel, Charles Cooley, and George Herbert Mead, and especially from the massive number of post-World War II publications of data and analyses from one of the first very-large-sample and sophisticated social scientific surveys of wartime American soldiers (Inkeles 1964). These reports gave abundant corroboration to the findings in industry, by earlier human relations investigators, concerning the critical importance of small groups and their norms in efforts to understand individual attitudes and behavior (Homans 1950). The applications of these findings—in studies of satisfaction, leadership, morale, productivity, grievances, absenteeism, turnover, and incentive systems—have become staples in training programs for supervisors and foremen in the United States and in delineating jobs and designing work flows across American industries (Perrow 1986; Porter et al. 1975). A new group of business school educators in western Europe has

generated very similar programs tailored to take account of the historical and cultural imperatives of managers and workers in different countries. The growing integration of Europe's economies and the mobility of their citizen promises to add to the convergence in the ways and means of financing and directing economic organizations.

A fourth group has focused on industries and occupations as special and highly significant aspects of organizations' "external environments" and as subsets of America's systems of social stratification. Sociological studies of whole industries—their personnel and collective bargaining policies especially—have often informed public agencies' regulations, legislators' bills, and judges' decisions. Analyses of differences among industries and occupations have helped leaders in government, business, and labor unions to understand better the dynamics of industrial conflict; the character and effectiveness of organizations; and the complexities in identifying the effects of physical technology—capital—in the spinning of "webs of rules" (Kerr et al. 1973) that, for all of their *de facto* and even informal character, function very much like governance systems in the workaday world (Kalleberg and Berg 1987). In their most formal states, these systems—arbitration procedures, for example—sometime mature into what the U. S. Supreme Court in 1960, in a "trilogy" of cases that defined the role of arbitration in industrial relations, called "systems of industrial common law" (i.e., as legal systems virtually unto themselves). Otherwise, more implicitly, as with work rules that establish "how fast is fast, how fair is fair, and how reasonable is reasonable", the webs of rules define relationships and codes applicable to both employers and employees that afford a kind of lubrication to the mechanics of human interactions in bureaucratic machines, with their close tolerances, involving millions of persons in hundreds of thousands of workplaces. Sociological studies of the costs and benefits to employees and employers (and ultimately to the public) of work rules, for example, have helped transform emotionally charged arguments about "featherbedding", "soldiering," and "goldbricking" (all efforts to escape irksome chores) into coherent and constructive debates about nonmonetary dimensions of working conditions. Studies of work rules suggest that "informal organizations" within parent organizations are really not so much informal as they are what Durkheim

long ago called "the noncontractual element of contracts"; sociologists have demonstrated that though these patterned, enduring, and bilaterally honored arrangements do not appear on an organization's wall charts, they are significant components of organizational life unto themselves, not mere shadows of more familiar and more palpable structures.

Meanwhile, the discoveries in international comparisons of data on grievances and strikes—that there are numerous short strikes and many grievances in the United States and few but long strikes and virtually no grievance procedures in western Europe for example—have led researchers, employers, and union leaders to appreciate the value of expeditious "on-site" bargaining relationships, on a day-to-day basis, such that emotional affect in disagreements may be drawn off and tensions relaxed before out-and-out conflicts disrupt production and social relations. It seems clear that these day-to-day adjustments and accommodations occur even as the efficacy of unions has declined in the United States and will likely wane in the "Euro" countries.

At the same time, the costs as well as the benefits of federal laws requiring that unions be democratic have helped us to make more realistic estimates about democratic arrangements' capacities to function as panaceas; democracy, for example, offers no guarantees against corruption, nor does it assure harmonious relations between parties to collective bargaining agreements. Sociologists have also documented a kind of (perhaps understandable) hypocrisy regarding democracy: Many lay observers and most labor columnists are delighted by unionists who vote to ratify contracts or to "decertify" their bargaining agents but are appalled by "strike votes."

Still another group of specialists have concentrated their attentions on worker satisfactions, dissatisfactions, and work experiences, by use of survey research designs that involve both periodic "snapshots" of different working Americans (and Japanese and west Europeans) and repeated observations of these same respondents, in "panel studies," over long time periods. These designs also make it possible to study "cohort effects," that is, the effects of reaching a given age in different time periods, each with their different qualities regarding a variety of social realities (Quinn et al.

1974). Thus there are significant differences, for example, in the experiences (and their attitudes about them) of workers, depending on whether they entered the labor force in 1960, 1970, 1980, or 1990. Sociologists can accordingly raise thoughtful questions about the implications, for public and private policies, of changing *social* definitions of aging, for example, in juxtaposition and contrast with essentially arbitrary public *policies* that fix eligibilities for a number of services and benefits on the basis of the chronological ages of individuals; not all those now 65 years old think, act, or want to be treated as a homogeneous class of senior citizens, nor have they had the same life histories, on average, as those who reached that age in 1940, 1960, or 1980.

Finally, the advent and continuing engagements of the civil rights movements have sparked the expenditure of a great deal of research effort on the comparative socioeconomic opportunities of men and women, and of minority group members in these groups (Jacobs 1989; Jaynes and Williams 1989). The findings by sociologists in these investigations have figured prominently in the drafting of legislation, legal suits, and employment policies, as well as in landmark civil rights decisions in courts at all levels.

In their work, as noted at the outset, a shrinking population of traditional industrial sociologists have drawn on work by sociologists in virtually every one of the profession's own major areas of interest with alacrity and have, in turn, seen much of their work inform the work of these other specialists. There has been similar intellectual commerce with social psychologists, industrial relations practitioners, and with full-time nonacademic social scientist practitioners in private enterprises, public agencies, universities, and research and other organizations in foreign lands, especially in the United Kingdom; Yugoslavia; Germany; Japan; France; Scandinavia; Canada; Italy; and what has, for so long, been called eastern Europe (Adams 1991; Barr, 1994; Freeman, 1994).

Industrial sociologists will likely grow in numbers in the years ahead, despite the growth of service sectors and information technology across the globe, as the global economy's structures will tend to be more related to multilateral regional pacts among nations with shared currencies, laws, and macroeconomic policies that will reshape the

political, economic, and social characters of member nations.

IVAR BERG

INDUSTRIALIZATION IN LESS DEVELOPED COUNTRIES

In the two and a half centuries since the Industrial Revolution in England, the process of industrialization has perhaps had more impact on all the nations of the world than any other complex set of forces. This process has not been uniformly introduced in all countries, nor has it occurred at the same time or at the same rate. Despite the common features of industrialization, these differences in its introduction and adoption have produced

inequities among nations and among people on a scale never before experienced.

In describing various countries and regions of the world, certain terms have been adopted, first by official agencies such as the United Nations and national governments, and then more generally by scholars, journalists, and those interested in making sense of international relations. According to a now commonly used United Nations classification, *more developed countries* (MDCs, or developed countries) comprise all of Europe, North America (excluding Mexico), Japan, Australia, and New Zealand. Other countries (e.g., Singapore, Taiwan, and Israel) constitute recent additions, while many of the former Soviet-bloc countries (including the Russian Federation) are now in a developing, or "transition," phase. *Less developed countries* (LDCs, or developing countries) make up the remainder. The distinction between MDCs and LDCs mirrors the famous "North-South divide," a phrase coined by former West German chancellor Willy Brandt (1980) in his Commission's report to the World Bank. LDCs have also been referred to as the Third World, a term devised in post-World War II Europe to distinguish the politically nonaligned, underdeveloped nations of the world from the industrialized capitalist nations (First World) and the industrialized communist countries (Second World) (Worsley 1984, pp. 306-315).

In some cases, the underlying variable upon which these distinctions are based is economic, in other cases it is political, and in still others it is unspecified. However, generally speaking, MDCs are "rich" and LDCs are "poor." In 1996, the per capita gross national product (GNP) among all MDCs was US\$25,870, while in the LDCs it was only US\$1,183 (World Bank 1998, p. 38). The major explanation for this vast discrepancy is that MDCs are fully industrialized whereas LDCs are not. In 1994, the industrial market economies produced 81.4 percent of total world manufactures (World Bank 1997, p. 152). Considering that LDCs comprise 84 percent of the world's population (World Bank 1997, p. 36), their industrial output and, consequently, their standard of living are dramatically lower than in MDCs.

INDUSTRIALIZATION DEFINED

Industrialization is a complex process comprised of a number of interrelated dimensions (Hedley

1992, pp. 128–132). Historically, it represents a transition from an economy based on agriculture to one in which manufacturing represents the principal means of subsistence. Consequently, two dimensions of industrialization are the work that people do for a living (economic activity) and the actual goods they produce (economic output). Other dimensions include the manner in which economic activity is organized (organization), the energy or power source used (mechanization), and the systematic methods and innovative practices employed to accomplish work (technology). Table 1 specifies these dimensions and also lists indicators commonly used to measure them.

According to these indicators, MDCs are fully industrialized. On average, close to one-third of the labor forces in these countries are employed in industry (three-fifths work in the service sector); manufacturing makes up approximately one-quarter of the gross domestic product; the overwhelming majority of workers are employees of organizations; commercial energy consumption is high (5,100 kilograms of oil equivalent per capita); and professional and technical workers comprise on average 15 percent of the work force. Furthermore, more than 95 percent of all receipts for royalty and license fees are collected in the MDCs (Hedley 1992, pp. 128–133; United Nations Development Programme [UNDP] 1998; World Bank 1997). Industrial activity and the services associated with it constitute the major driving force and source of income in these more developed economies.

In contrast, none of the LDCs is fully industrialized as measured by these five dimensions of industrialization. Although manufacturing accounts for a significant proportion of many of these countries' total output, most do not achieve industrial status on any of the other dimensions. Manufacturing in these countries is accomplished largely by traditional methods that have varied little over successive generations. Consequently, although manufacturing (transforming raw materials into finished goods) is an essential component of industrialization, there is considerably more to the process. Because industrialization is multidimensional, it cannot be measured by only one indicator.

In general, LDCs may be classified into three major groups according to how industrialized they are. The first and smallest group, referred to as

newly industrializing countries (NICs), contains the most industrialized countries in that they achieve industrial status on at least two dimensions listed in Table 1. Located mainly in East Asia (e.g., South Korea, Malaysia, Thailand, Indonesia) and Latin America (e.g., Mexico, Brazil, Argentina, Venezuela), these eight NICs accounted for more than 40 percent of all merchandise exports from developing countries in 1995 (World Bank 1997, pp. 158–160). Although China and, to a lesser degree, India (because of their huge population bases) contribute significantly to the merchandise exports of LDCs, they have not developed their industrial infrastructures to the same extent as these NICs and therefore do not belong in the most industrialized group of LDCs.

A subgroup of NICs are high-income, oil-exporting nations (e.g., the United Arab Emirates, Qatar, Bahrain, Kuwait, and Saudi Arabia). Although they do not have large manufacturing bases, they do have significant proportions of their labor forces involved in industry (oil exploration and refining), a substantial component of professional and technical workers (many of them imported), and high per capita commercial energy consumption (World Bank 1998, pp. 34–35, 42–43). Although concentrated in just one industry, they are more industrialized than most other LDCs according to the criteria specified in Table 1. As a result of their petrodollars, they have acquired an industrial infrastructure that in other countries has taken many decades to establish.

The second, very large group of LDCs in terms of industrialization are those with a traditionally strong manufacturing base that also have a substantial agricultural component. Their economies straddle the agricultural and industrial modes of production. China and India are in this group, as are most of the non-European nations that form the Mediterranean basin. The goods that these LDCs predominantly manufacture (e.g., apparel, footwear, textiles, and consumer electronics) are essential to their own domestic markets and, because they are labor-intensive, also compete very well in the international market. In addition, they export natural resources and agricultural products. Other countries included in this semi-industrial group are most of the nations in Central and South America as well as many in South and East Asia.

Dimensions and Measures of Industrialization

1. Economic Activity

- a. Percentage of labor force in manufacturing
- b. Percentage of labor force in industry

2. Economic Output

- a. Manufacturing as a percentage of gross domestic product (GPD)
- b. Industry as a percentage of gross domestic product
- c. Gross output per employee in manufacturing
- d. Earnings per employee in manufacturing

3. Organization

- a. Wage and salary earners as a percentage of the labor force
- b. Number of manufacturing establishments employing fifty or more workers per capita

4. Mechanization

- a. Commercial energy consumption per capita
- b. Total cost of fuels and electrical energy per employee in manufacturing

5. Technology

- a. Percentage of professional and technical workers in labor force
- b. Registered patents in force per capita
- c. Registered industrial designs in force per capita

Table 1

The third and final group of LDCs are not industrialized on any of the five dimensions listed in Table 1. On average, less than 10 percent of their labor forces are employed in industry; most (76 percent) work in agriculture. Manufacturing contributes only 20 percent to their national economies; the bulk of income derives from natural resources and cash crops grown exclusively for export. Per capita gross national product is very low (US\$215). Most of these nonindustrial LDCs are located in sub-Saharan Africa and Asia (UNDP 1998).

Of these groups of LDCs, the semi-industrial cluster of nations is by far the largest, constituting just over half the world's population. China and India alone make up two-thirds of this group. The second-largest group, comprising between 10 and 15 percent of the world population, is the nonindustrial countries; NICs (including high-income oil exporters) comprise less than 10 percent. Thus, approximately one-quarter of the world is fully industrialized, another 10 percent are industrializing, half are semi-industrial, and the remaining 15 percent are nonindustrial.

CORRELATES OF INDUSTRIALIZATION

Research has demonstrated that industrialization is directly related to national and individual income, urbanization, the development of an

infrastructure (e.g., communication and transportation networks, education, and health and welfare programs), and the overall quality of life (Hedley 1992, pp. 133–146). These relationships occur because industrialization results in huge productivity gains, which in turn raise individual and national income. For example, when Britain was industrializing, total national income increased by more than 600 percent between 1801 and 1901 (Mitchell 1962, p. 366). In 1850, workers in industrial nations earned eleven times more than their counterparts in nonindustrial countries. Moreover, the advantages of industrialization have been cumulative: today per capita income is more than fifty-two times greater in developed than less developed countries (World Bank 1995, p. 53), thus magnifying what one author has termed a *Global Rift* (Stavrianos 1981). For a variety of reasons, the direct relationship between industrialization and income is continuing to increase.

In an annual survey of all countries in the world, the United Nations Development Programme (UNDP) measures “human development” based on the combination of three, admittedly crude, criteria: longevity, knowledge, and a decent standard of living. Table 2 provides a summary of its most recent results grouped by level of industrialization. Of the 174 countries examined, MDCs consistently scored at the top of all three dimensions that comprise human development, while LDCs, particularly the *least* developed (nonindustrial)

countries, scored at the bottom of the scales. The composite Human Development Index ranged from a high of 0.960 for Canada to a low of 0.185 for Sierra Leone.

According to the UNDP (1998, p. 2):
