* That this figuring was not arbitrary was confirmed by the International Geophysical Year 1957–58 geodetic research with orbiting vehicles, which obtained a figure of 3949.89 miles for the polar radius of the earth. Divided by 10,000,000 British inches, this gives 25.02614284, or the length of Taylor's and Newton's "sacred cubit" correct to the third point of decimal.

† Corroborative evidence for Taylor's conclusion was recently produced by Algernon E. Berriman in his *Historical Metrology,* published by E. P. Dutton in New York in 1953. "The English acre," writes Berriman, who is an engineer and an architect, "is the most intriguing of ancient measures because it is virtually equal to a hypothetical geodetic acre defined as one myriad-millionth of the square on the terrestrial radius." Berriman noted that the geodetic acre could also be defined as measuring one myriad square cubits of a hypothetical cubit equal to one ten-millionth of the terrestrial radius. Berriman gave a value to this cubit of 25.064 inches, saying "its former existence is as plausible (or as incredible) as a cubit derived from the sexagesimal division of the Earth's circumference." Berriman also noted that the slightly larger Scottish and Irish acres are related to each other and to the basic English acre as a square to an inscribed circle.

hogsheads, butts, barrels, gills, pecks, faggots, and chaldrons—all in the hope of finding an ancient unit of measure that could be used as a standard, and from which others could have been derived or corrupted.

Pursuing Jomard's theory that the King's Chamber and its sarcophagus might have been designed not so much as a tomb as to monumentalize a system of weights and measure, Taylor was amazed to find that the cubic capacity of the granite coffer was almost precisely four times what the British farmer still used as a standard measure for grain: the *quarter*, or eight bushels.

From all his studies, Taylor concluded that the proportions of the Pyramid had definitely been intended to incorporate geometric and astronomical laws simply and easily expressed, and that its purpose had been to preserve and pass on this knowledge to future generations.

However, as there was nothing in Taylor's philosophy to indicate the existence in such remote antiquity of any civilization which could have had a knowledge of the true shape of the planet, its actual size, and its motion in the solar system; and as the conceit was not then current that this planet might have been visited by superior beings from some other part of the universe, Taylor was hard put to explain the sources of science he found incorporated in the Pyramid. More than a scholar and a mathematician, Taylor was also a profoundly religious man, thoroughly steeped in the Old Testament which he believed to be literally true. To Taylor the creation of Adam had occurred in 4000 B.C. and the Flood in 2400 B.C. It seemed to him hard to believe that in a mere 300 years man could have redeveloped to the point of building so complex a structure as the Great Pyramid. Taylor could come to but one conclusion: whoever had built the Pyramid must have done so under the direct influence of Divine Revelation as Noah had built the Ark. In his own words: "It is probable that to some human beings in the earliest ages of society, a degree of intellectual power was given by the Creator, which raised them far above the level of those succeeding inhabitants of the earth."

Taylor even ventured the hypothesis that the builders of the Pyramid were of "the *chosen race* in the line of, though preceding Abraham; so early indeed as to be closer to Noah than to Abraham."

Because of the close similarity of the British inch to the "Pyramid inch," his idea was to give impetus to the theory that the British were related to the Lost Tribes of Israel, "which during their captivity and wanderings preserved a knowledge of the wisdom of the Egyptians."

As might have been expected, Taylor, who had been known as a benign and dignified old gentleman, had a hard time convincing his quiet Victorian contemporaries of such wild and revolutionary theories, especially as they were just then being rocked by Darwin's theory of the descent of man.

A paper on the Pyramid which he presented to the prestigious Royal Society was rejected with the suggestion that such a paper might be more appropriate for the Society of Antiquarians.

Growing older and more infirm, Taylor was afraid he would die without developing any audience for his theories which by 1859 he had formulated into a volume entitled *The Great Pyramid: Why Was It Built & Who Built It?*

Nearing his death, he had the luck to find the support of an eminent academician with the reputation of having an excellent and sober mathematical mind: Professor Charles Piazzi Smyth, the Astronomer Royal of Scotland.

VII. FIRST CONFIRMATION OF SCIENTIFIC THEORIES

Piazzi Smyth, who was born in Naples to Admiral William Henry Smyth (and named for his godfather, the renowned Sicilian astronomer, Father Giuseppe Piazzi, discoverer of the first known asteroid), was enough of a mathematician not to mock at Taylor's reasoning. Carefully studying Taylor's figures, Piazzi Smyth decided to support them with a paper which he presented to the Royal Society of Edinburgh, of which he had become a member because of his important contribution to the new science of spectroscopy.

It was Smyth's conclusion that the sacred cubit used by the builders of the Great Pyramid was the same length (25.025 British inches) as the one used by Moses to construct the tabernacle and by Noah when he built his Ark, and because the twenty-fifth part of this cubit was within a thousandth part of being the same as a British inch, Smyth also concluded that the British had inherited this "sacred" inch down through the ages.*

Smyth's fellow academicians treated him no better than they had treated Taylor.

During the last few weeks of Taylor's life, there was an animated correspondence between Smyth and Taylor. When Taylor died in 1864 Piazzi Smyth decided that the only way definitely to confirm or refute Taylor's theories about the π relation, and the Pyramid cubit, would be to go to Egypt and carefully measure the Pyramid.

In "utmost straits for funds," Smyth asked his fellows of the Royal Society in London for help; though the Society

* Attributing to Newton the original discovery of the presence of the sacred cubit in the Pyramid, Smyth wrote: "How thankful should we be that it pleased God to raise up the spirit of Newton amongst us; and enable him to make one of the most important discoveries of his riper years—though the opposition of the Church of England has caused it to remain unread almost to the present day—that while there undoubtedly was in ancient times a cubit of 20.7 inches nearly . . . and which Newton calls "the profane cubit" there was another which he equally unhesitatingly speaks of as the *sacred* cubit, decidedly longer."

C. Piazzi Smyth, Astronomer Royal for Scotland.

was "in receipt of a large annual grant from the government for the assistance of precisely such special efforts in science, it not only gave nothing to my semi-pauperized expedition, but actually sent back part of that year's grant to the government on the plea that there was nothing going on that needed it."

That same December, Piazzi Smyth and his wife—then in their early forties—set sail for Egypt with a vast number of boxes containing scientific instruments more accurate than any yet taken to the Pyramid, and with stores and equipment enough for several months.

Despite a series of mishaps, and the almost ruinous expense of everything in Egypt—which was in the midst of a cotton boom engendered by the American Civil War—the Smyths eventually arrived in Cairo, where they were obliged to hang around waiting for permits and local supplies. In his diary Smyth morosely entered exotic descriptions of "the abominations of the worst city in the world," where the food reeked of garlic, lard and African macaroni, the air was fetid from mounds of desiccated human excrement, where he was infested with flies by day and mosquitoes by night, and woken up by a predawn cacophany of howling cats and dogs which roused the pigs which roused the geese and turkeys "just before the disk of the sun comes up like a ball of liquid fire."

Poignantly he described little girls "diving between the hind feet of colossal camels to pick up its hideous droppings, pat them into nicely shaped cakes . . . to make high-scented ammonia-filled fuel for the cooks . . . of the resplendent city."

Smyth was so well received by Ismail Pasha (who a few years later was to commission Verdi's opera *Aïda* which opened in Cairo in 1871) that he tried to buttonhole the viceroy into providing men and funds to remove the great mounds of debris around the base of the Pyramid, to have a 3-inch hole carved through the center of the granite plugs in the Ascending Passage (so as to ascertain its true meridian), to have the ventilating ducts to the King's Chamber cleared, and to sink a shaft through the hole in the pit down to the level of the Nile.

The pasha shook his head, promising to provide twenty men for two weeks to clean and wash the main chambers of the Pyramid so that Piazzi Smyth might take some measurements. The pasha also kindly agreed to provide the Smyths with donkeys and a camel train to bear them and their luggage to the Great Pyramid.

Leaving "the purse-proud modern Muslim city with its tulip-clothed individuals struggling for wealth," the Piazzi

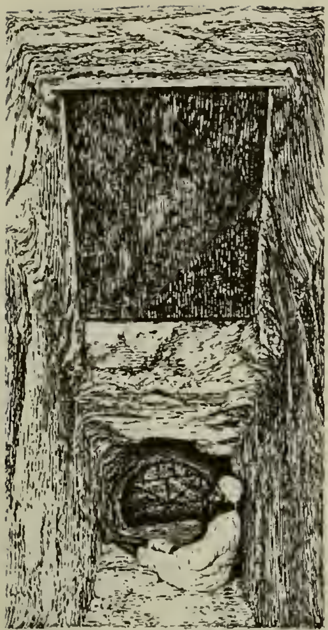
Sandstorm in the desert.

Smyths set off for the Pyramid. On the way they stopped to eat buns "from Mrs. Smyth's commissary" and refresh themselves with Nile water "muddy and opaque as milk with suspended clay" but celebrated, says Smyth, for its health-giving qualities, the best cure for "the windy melancholy arising from the shorter ribs."

The pyramids, tinted by the golden rays of the setting sun "embalmed in the intense azure of the western heaven," appeared to grow no larger as the caravan approached. Only in the immediate vicinity did they suddenly tower so completely as "to take possession of the mind."

Looking up at the vast stepped sides toward the "dizzy apex 480 feet above in perpendicular height, the mind slowly and almost painfully began to realize the enormous size of the mountainous buildings."



Descending Passage blocked by Arab guides below the level of the granite plug.

As a place to live within reach of the Pyramid, the Smyths selected an abandoned tomb in the eastern cliff of the Giza hill which had previously been used as a storeroom by Howard-Vyse. It proved to be an agreeable residence: the solid rock was the best possible protection against the midday heat, and the orientation of the cave protected it from the sandstorms and the clouds of multicolored locusts that otherwise made life in the desert a misery.

To assist Smyth in his measurements, and to help with the general chores, he found a whiskered Arab called Ali Gabri who had carried baskets for Colonel Howard-Vyse a generation earlier.

At twilight Professor and Mrs. Smyth sat on campstools and watched with amazement as flock after flock of bats flew out of the Pyramid, "for almost twenty minutes without any cessation," to be pounced on by hawks or owls.

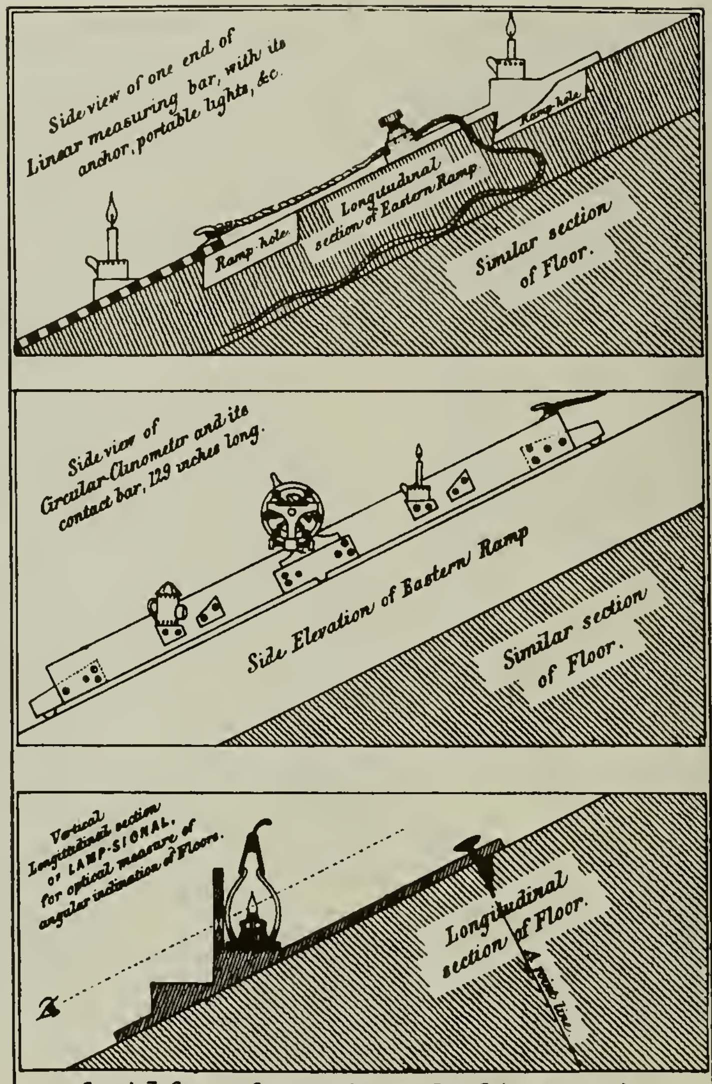
Several days were wasted while Ali Gabri impressed a gang of Arabs to clean the chambers of the Great Pyramid, but at last, in late January, the day came for Smyth to enter what he called "the largest building in the world by the smallest of all doorways."

As Smyth picked his way down the Descending Passage, partly on his seat and partly on hands and knees, he was relieved to find that shallow notches had been dug by Howard-Vyse every 2 or 3 feet so as to keep from slipping on the steep incline. However, each step raised a cloud of fine white dust that made it almost impossible to breathe. To his distress, Smyth also found that the passage leading down to the "pit," which had been cleared by Caviglia, was once more blocked with sand and stones, and barred by a grill just below Al Mamun's hole to the Ascending Passage.

It was explained to Smyth that it cost the Arab guides too much time and candle grease to accompany tourists all the way down to the "pit" before making the long climb back up to the King's Chamber, so they had blocked the passage and informed gullible tourists there was nothing but sand beyond the barrier.

Bent on finding proof that the Great Pyramid had been built on units of his "sacred cubit," Smyth had brought from England a 105-inch metal bar with built-in thermometers at either end to indicate the slightest variation in temperature with which to measure the available passages. A mere change of .01 degree Fahrenheit was enough to produce a sensible change in the length of the standard bars.

To obtain the exact angle of the Descending Passage, Smyth had a specially designed clinometer equipped with a gunmetal circle 8 inches in diameter, divided into units of



Special forms of apparatus, employed in measuring in the Grand Gallery.

10 seconds, and fitted with three pairs of verniers. The slope he calculated was the most precise to date: 26° 27′.

For measuring the individual stones of the floors, walls and ceilings, Smyth had mahogany and teak rods tipped with brass, carefully painted or waxed to prevent variation from humidity or temperature. One special ruler, remarkable for its straight, fine grain, had been obtained from an antique musical organ dating from the reign of Queen Anne. To fashion these measuring instruments, Smyth had obtained the services of an expert optician.

Each rod was checked daily for atmospheric shrinkage

"Miniature" camera, 8 inches long, used by Piazzi Smyth to photograph the interior and exterior of the Great Pyramid. On the right is a tiny container for the vulcanite nitrate bath which held the exposed wet-collodion plates which measured an inch square. Some two hundred microscope negatives, packed in a storage box, are still missing, but 48 lantern slides, 24 transparencies and 23 stereotypes are in the possession of the Royal Society of Edinburgh, examples of which are reproduced with their permission.

The camera is in the possession of the present Astronomer Royal for Scotland, Prof. H. A. Brück, and is here reproduced by kind permission.

or enlargement against a basic fine-grained clinkstone which could be measured with a magnifying glass to 1/100 inch.*

Thus began the first really systematic analysis of the Pyramid with modern measuring equipment. For weeks on end Smyth measured and remeasured whatever he could reach in the interior of the Pyramid, counting the stones in passages and chambers, computing angles and declinations.

Measuring the coffer in the King's Chamber, Smyth concluded that Taylor had been correct in recognizing it as a standard of linear and cubic measure. Unlike the European standards, such as the yardstick kept at Whitehall, which vary with temperature and barometric pressure, shrink, decompose, tarnish or oxidize with time, the coffer appeared to be designed to remain at a constant temperature and barometric pressure, its polished sides unaffected by decomposition over a period of thousands of years, subject only to the vandalism of man.†

* A clinkstone is a compact grayish-blue felspathic rock little subject to atmospheric changes which makes a clink sound when struck.

† Smyth echoed Herschel's complaint about the standard yard at Whitehall. Herschel had called it "a purely individual object, multiplied and perpetuated by careful copying, from which all reference to a natural origin is studiously excluded, as much as if it had dropped from the clouds."

Today our yard is related to the meter, which is determined by a finite number of wavelengths per second in vacuum of an atom of Krypton 86—measured by means of light waves. A second is no longer defined as the 3600th part of an hour but as the duration of cycles of radiation in a cesium atom.

Photograph of Mrs. Piazzi Smyth taken by her husband outside their tomb apartment in the Giza Hill, which Piazzi Smyth characterized as "a quiet nook, looking out over the green Egyptian plain."

For outside measurements Smyth used a 500-inch cord, and for elevations he had theodolites, sextants and telescopes, which were laboriously carted from spot to spot, up and around the Pyramid, to measure all that could be measured, despite the mounds of debris.

With his long and varied experience in observational astronomy, Smyth had brought the requisite apparatus for obtaining astronomical observations with a high degree of precision.

To obtain the correct latitude of the Great Pyramid without having his plumb line diverted from the perpendicular

Photograph of Ali Gabri (sometimes spelt Alee Dobree) seated outside the tomb in the east bank of Pyramid Hill where Piazzi Smyth, who is handling the camera, had his quarters.

by the attraction of the huge bulk of the Pyramid, Smyth made his observations from the very summit; there the Pyramid's pull of gravity would be directly downward.

Smyth and his wife spent several nights on the circumscribed platform, close to the stars, along with Ali Gabri, who complained he could not sleep because of indigestion. Smyth described the first night as eerie but wonderful, with the ghostlike summit of Kephren's pyramid lurking in the misty darkness. At daybreak he saw "a broad pinioned eagle floating serenely along looking downwards on other things, as we were looking down on him."

From the vantage of the summit Smyth figured the latitude of the Pyramid to be 29° 58′ 51″. From this he concluded that the designers might have purposely not placed the Pyramid directly on the thirtieth parallel because of the atmospheric refraction, which would have caused an error in their observations of about that much. Later he attributed the displacement to a gradual shifting of latitude, registered at Greenwich as 1.38″ per century.*

As for the extraordinarily precise orientation of the Pyramid—which Smyth found to be far superior to that of the world-renowned observatory of the sixteenth-century Danish astronomer Tycho Brahe—the Scottish astronomer concluded that for such refinement a meridian must have been obtained by observing a polar star along the Descending Passage.

When Caviglia had cleared this passage of the rubble left by Al Mamun, he noticed one night that the North Star was observable in the small patch of sky—about 1° square—of the opening. Intrigued by this phenomenon, Howard-Vyse had asked Sir John Herschel whether the direction of the passage could have been determined by the polestar. Herschel replied that 4000 years earlier Ursa Minor could *not* have been seen from the passage at any time throughout the twenty-four hours. He added, however, that alpha Draconis, the leading star in the constellation of Drago, would have been near the pole, and that though a comparatively insignificant star of less than the third magnitude, it could nevertheless have been clearly seen by an observer at the bottom of the passage at the moment of its inferior culmination, when its circumpolar orbit was at its lowest.

Smyth proceeded to subtract the 26° 17′ angle he had found for the Descending Passage from the Pyramid's latitude of 30° (or height of a true North Star above the horizon as seen from 30° of latitude) and obtained an angle of 3° 43′. Calculating that alpha Draconis would have been 3°43′ from the pole at its lower culmination in 2123 B.C. and again in 3440 B.C., Smyth concluded that either date might be taken as the one when the Great Pyramid had been laid out.

* Other pyramid experts have attributed the slight displacement to the fact that the Pyramid needed the solid basis of the Giza plateau for a foundation, and could not have been built any farther north, in the soft sand of the Nile valley. The astronomer Richard A. Proctor suggests that the emplacement was the result of the mean latitude obtained from observing sun shadows and star elevations, which are affected in opposite directions by the atmospheric refraction. An interesting explanation was produced by Dr. Everett W. Fish of Chicago who suggested at the turn of the century that the deviation of the Pyramid's latitude from 30° is neither an error in instrumentation, nor in polar axis, or latitude, but compensates for the spheroidal shape of the earth as postulated by Newton.

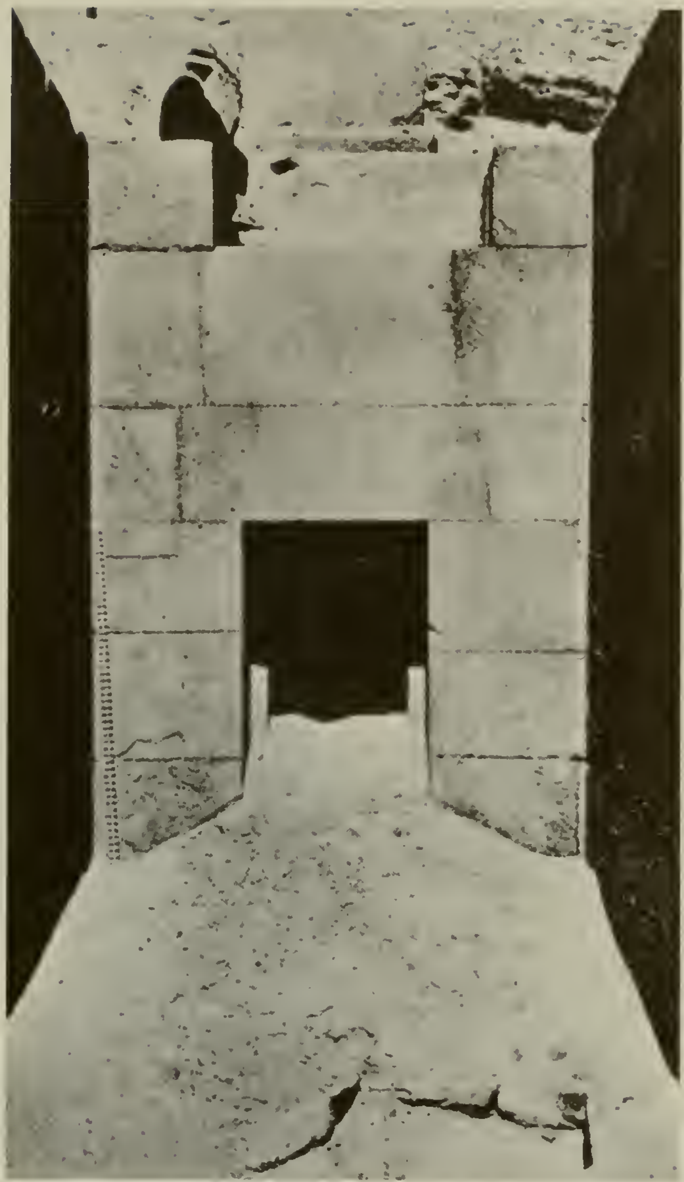
This photograph was taken by Piazzi Smyth and sold at auction after his death. It shows Mrs. Smyth sitting on the edge of what Smyth calls Shafre's burial chamber north of the Great Sphinx. It was taken at high noon to show that the tomb was correctly oriented along the meridian so that with the sun at its zenith, no light would fall on either the east or the west wall.

To ascertain the correct moment for noon Piazzi Smyth spent the previous night observing the stars with his telescope.

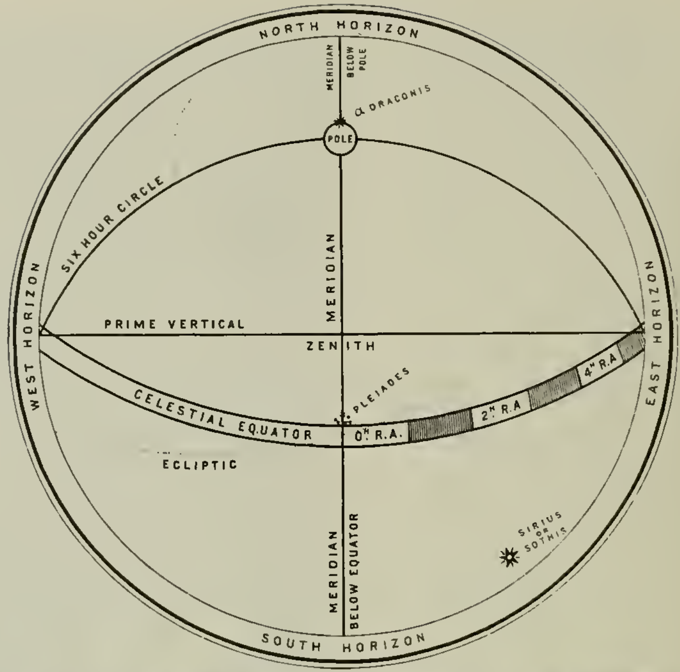
Piazzi Smyth photographed the Great Pyramid with the same scientific thoroughness with which he measured it, despite the difficulties of developing in the desert. He brought all his own chemicals, and used a special 1-inch plate "as small as an ordinary microscopic slide," which gave results that could be blown up with almost the detail of the larger photographic plate. To light the interiors of the Pyramid he used magnesium flares, experimenting with varying amounts so as to obtain the best exposure and the clearest detail. He had to wait hours between exposures in the King's Chamber, which filled up with smoke from each magnesium flare.

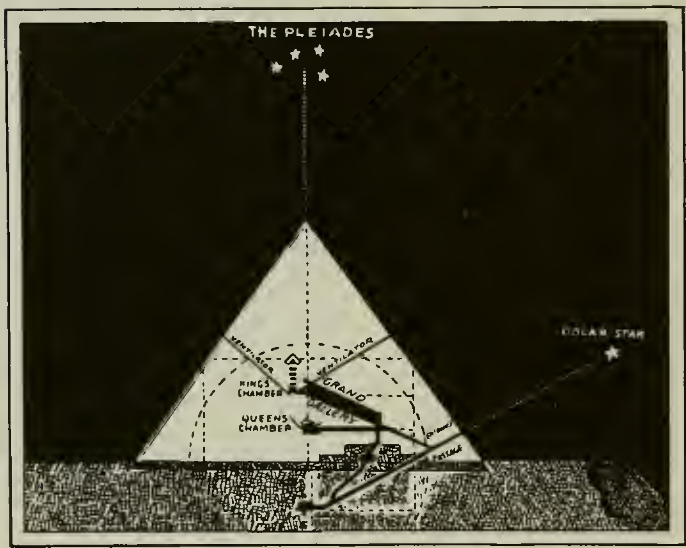
Smyth also achieved some remarkable stereoscopic effects by shooting with two cameras, and is responsible for the innovation of placing his cameras much farther apart than the standard 2 inches.

For lack of funds Smyth was unable to publish some fourscore photographs thus obtained at the Great Pyramid. The positive prints which he made were lent to scientific exhibitions or donated to friends interested in pyramidology, and gradually became lost, with the exception of this rather poor reproduction.



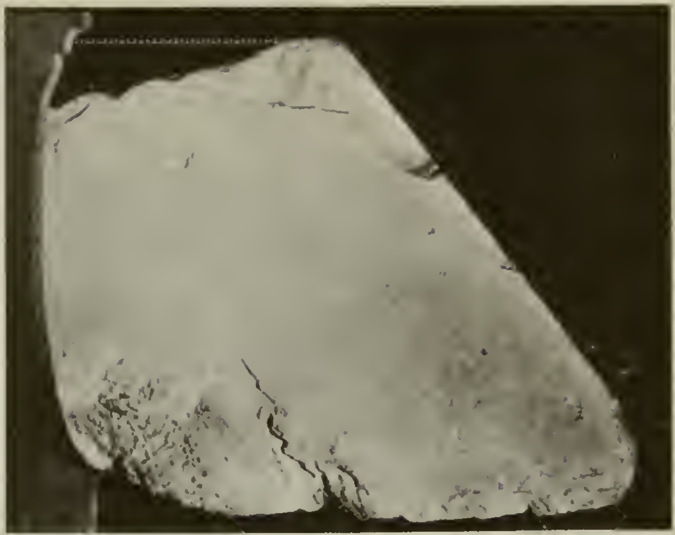
In support of the later date Smyth worked out that if the foundation of the Pyramid had occurred at midnight of the equinox in 2170 B.C., when alpha Draconis was at meridian below the pole, another very important star would have been crossing the meridian above the pole: *n*-Tauri, or Alcyone, of the Pleiades. In other words, when alpha Draconis was visible down the Descending Passage, the chief star of the Pleiades, *n*-Tauri, would have been crossing the meridian in the vertical plane of the Grand Gallery, at the moment of the autumn equinox.





Piazzi Smyth's ground plan of the circles of the heavens above the Great Pyramid, at the epoch when he believed it was founded: midnight of the autumnal equinox 2170 B.C. Smyth noted that *alpha* Draconis was on the meridian below the pole while the Pleiades were on the meridian above the pole, coincidentally with the vernal equinox.

Piazzi Smyth figured that the Great Pyramid might have been built so its Descending Passage was aligned with the polestar and at a time when the Pleiades were at the zenith at midnight.



Casing stones donated by Smyth to the Edinburgh Museum, showing the angle of the slope of the Great Pyramid.

Smyth considered this a very important date in history, as many ancient peoples dated the beginning of their year at Halloween, when the Pleiades and the equinoctial point were on the meridian together at midnight.

But Smyth's prime preoccupation was still with establishing whether Taylor's π proportion was really incorporated in the structure.

Along the face of the Pyramid, Smyth checked the angle of the casing stones discovered by Howard-Vyse. Unfortunately the sharp lines had already been almost obliterated by the Arabs and by the chipping away of souvenir hunters. But searching through the debris piled high round the base, Smyth was able to find fragments of casing stones with the angles still intact.

Invariably the angle checked out at about 52°, or its complement of 128°, confirming Taylor's theory that the height of the Pyramid was designed to be in relation to the perimeter of its base as the radius of a circle is to its circumference.

To see if he could refine this angle, Smyth observed the silhouette of all the backing stones against the sky by means of a very accurate altitude azimuth circle which had been donated to his friend and mentor Professor Lyon Playfair by his students in 1806 and in turn lent to Smyth.

By this method Smyth obtained an angle of 51° 49′. Meanwhile Sir John Herschel had obtained a figure of 51° 52′ 15.5″ from the dimensions of the casing stones as reported by Howard-Vyse. Smyth chose to take the mean of these available measures as 51° 51′ 14.3″—a difference of less than a minute from either figure. He also chose to take the mean of the 763.62-foot base line measured by the

Magnesium-light photography had been developed only a few months before Piazzi Smyth took this double exposure of the coffer in the King's Chamber. The apparent reflections are those of Ali Gabri and another Arab. Mrs. Smyth's head appears beyond the coffer. Smyth's method of burning magnesium powder in a spirit-lamp flame was an innovation in photography.

French and the 764 feet measured by Howard-Vyse, and got 763.81—a difference of barely 2 inches on a length of 763 feet.

This was an arbitrary act, but the result produced an astounding value for π in the Great Pyramid proportions of 3.14159+.

Searching for a reason for the incorporation in the Pyramid of this relation of the radius of a circle to its circumference, Smyth pursued Taylor's theory of the base being divided into 366 units to coincide with the number of days in the year.

To have been absolutely precise, the perimeter should have measured 365,24.2 Pyramid inches. This would require that each side be 9140.18 British inches. The measure obtained by Howard-Vyse and the French savants, though within 6 inches of each other, were both about 2 feet too long.

The only solution appeared to be to dig up the sockets and remeasure the base line more accurately; but time and money were running short. Fortunately two engineers from Glasgow, Messrs. Inglis and Aiton, happened to pass through Egypt on their way from a tour of the Holy Land. Cajoled by their fellow Scot, they agreed to help him uncover the sockets originally found by the French (which had once more become covered with debris in the intervening half century) and make a truly accurate survey.

Following Smyth's complex computations, the engineers were able to uncover not only the sockets but a perfectly leveled stretch of pavement at the perimeter of the base.

Stereographic photo taken by Piazzi Smyth of Mr. Inglis and Arab workers in the northeast socket cleared in April of 1865. The Royal Engineer surveyor went all over the floor of the socket with a spirit level and found it absolutely level.

To measure the distance between the sockets, up and around the debris, required a great deal of digging and moving of rocks. But Smyth could not tarry. His own instruments were already packed and his passage had been booked by the British consul. When the engineers promised to take great care in their measurements and forward the results to Scotland, Smyth disconsolately agreed to depart as scheduled.

All that remained to be done was to dispense the customary baksheesh to the neighboring Arabs who had helped during four months' stay. The Smyths gave each man a gold sovereign plus a present depending on the willingness with which he had served his Scottish employers: the best got globe lamps mounted in copper; the middling got frying pans; and the worst got mousetraps.

When the ancient Arab who guarded their cave by night appeared for his just reward, Piazzi Smyth puritanically noted that the old man "seized on the money with such an agony of clutch, and his eyes brightened with so strange a fire, that alas for perverted human nature! we feared we had done more harm to his soul than good to his body."

As the camel train was prepared for departure, the faithful Ali Gabri stood silent for a time, "then suddenly putting his fingers to his eyes" rushed into the desert to conceal his crying.

Back in Scotland, Piazzi Smyth received the results of the engineers' survey; these gave a much shorter length of 9110 inches for a side of the Pyramid. Smyth concluded that the true length must be the mean between this figure and the

longer one of 9168 inches obtained by Howard-Vyse, or 9140 inches, which was just 1 inch less than was required for Smyth's theory, resulting in a year of 365.2 days instead of the precise 365.24 required by theory.

A great deal now hung on the exactness of these figures. If Smyth's theory could be proved correct, it could mean that the ancient Egyptians had produced a structure whose basic unit, the Pyramid inch, incorporated not only a system for linear measurement—with the cubit and the inch—but also for temporal measurement, with a year of 365.24 days, both based on the most sensible foundation: the polar axis of the planet around which it rotates once in a day.

In Smyth's opinion "the linear measure of the base of this colossal monument, viewed in the light of the philosophical connexion between time and space, has yielded a standard measure of length which is more admirably and learnedly earth-commensurable than anything which has ever yet entered into the mind of man to conceive. . . ."

Smyth summed up his work: the Pyramid "revealed a most surprisingly accurate knowledge of high astronomical and geographical physics . . . nearly 1500 years earlier than the extremely infantine beginning of such things among the ancient Greeks."

From the Royal Society of Edinburgh, Smyth received a gold medal for the careful measurements he had taken in Egypt; these he published in monographs, and in a three-volume opus running to 1600 pages entitled *Life and Work at the Great Pyramid of Jeezeh during the Months of January, February, March and April, A.D. 1865.*

The work was not well received. As much of a religious zealot as had been his predecessor Taylor, Smyth was unable to account for the mathematics displayed by the ancient Egyptians. Like Taylor he was obliged to attribute this science to Divine Wisdom, somehow imparted to an earthly architect who had constructed the Pyramid under the direct influence of revelation. "The Bible," said Smyth, "tells us that in very early historic days, wisdom, and metrical instructions for buildings, were occasionally imparted perfect and complete, for some special and unknown purpose, to chosen men, by the Author of all wisdom."

The idea was received by some with derision, by others with acrimonious opposition. One reviewer remarked that Smyth's book contained "more extraordinary hallucinations than had appeared in any other three volumes published during the past or present century." A friendly reviewer summed up reaction to the book saying "it evoked numerous illustrations of envy, hatred, malice, and much uncharitableness from vain, flippant, and unqualified writers, the author being scoffed at, traduced, worried and all but *argued* with, by opponents who only succeeded in proving their egotistic inefficiency to apprehend the truth."

To make things worse another Scot, a religious enthusiast called Robert Menzies, advanced the theory that the passage system in the Great Pyramid was nothing less than a chronological representation of prophecy, corroborating the Bible, built on a scale of one pyramid inch to the solar year.*

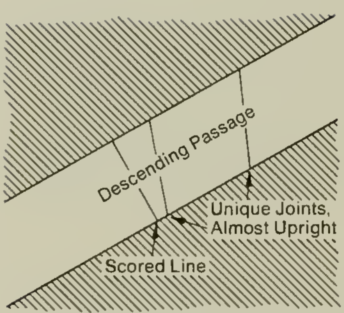
As Menzies' theory was formulated before anything was known of ancient Egyptian messianic prophecy, such as *The Book of the Dead,* the texts of which had not yet been deciphered, this new contribution merely added to Smyth's problems. Smyth was further derided and lampooned by his

* Menzies, knowing that Smyth had made an approximate calculation of the date at which alpha Draconis shone exactly down the Descending Passage, put forward the theory that the date of this important astronomical phenomenon should be clearly marked some way in the Descending Passage itself, at the place representing the said date on the chronological scale. To Menzies' delight, Smyth replied that he had discovered two scored lines on each side of the passage at the very spot indicated. Although the joints in the walls of the Descending Passage were perpendicular to the floor, said Smyth, there were two joints on each wall, immediately to the north of the scored lines, that were not so: these were peculiarly vertical joints, as if intended to draw attention to something of importance: in Smyth's and Menzies' opinion, evidently the scored lines.

fellow academicians. Sir James Y. Simpson, an eminent member of the Royal Society of Edinburgh, publicly ridiculed Smyth before his fellow members, saying, "the whole of Professor Smyth's theory about the Great Pyramid is a series of strange hallucinations, which only a few weak women believe, and perhaps a few womenly men, but no more." Simpson added that he had "talked about it to a great many engineers, mathematicians, and others, and found them scoffing at and despising it."

Smyth's mixing of religious and prophetic conclusions with sound scientific discoveries caused his entire theory to be discarded by skeptics. To this day, the lampooning persists. One modern writer on pyramidology still refers to Smyth as the world's "pyramidiot," and laments that "such a first-class mathematical brain should have wasted its energies in so unprofitable a field."

But Piazzi Smyth was far from being quashed. He continued to produce even more fantastic theories from the results of his measurements of the Pyramid. Recomputing the height of the Pyramid, Smyth found it to be about 6 inches longer than Taylor's figure of 5813 inches from base rock to apex. The new measurement revealed that the Pyramid rose from its base in a proportion of 10:9, that is, for every 10 units of height, the Pyramid extended 9 units in width. To Smyth this was an indication that the proportions were intended to symbolize in yet another way the earth's circuit round the sun. Multiplying the height by 10^9, he obtained an astonishing result. Reduced to British miles, the answer was 91,840.000—or a very good figure for the mean radius of the earth's orbit round the sun. The present figure varies between 91 and 92 million miles. Was this mere coincidence? The argument between the supporters of Smyth's theories and the entrenched academicians who opposed them became intensely heated.



Scored lines in Descending Passage.

Basic to the whole argument was the fact that no one had a series of absolutely reliable measurements for the *exterior* of the building, especially beneath its debris where the base line must actually be measured. Even a new survey by the Ordnance surveyors made in 1869, which gave a length of 9130 inches, was made on the basis of cumulative measurements up and down and around the piles of debris that still clogged part of the base of the Pyramid between the exposed sockets. Results which varied by even 3 or 4 inches could not be considered accurate enough to prove or disprove the theories of Taylor and Smyth. So long as the *actual* dimensions of the Pyramid, both interior and exterior, were not obtained, correct to a fraction of an inch, there would be no real way of *knowing* if Smyth had a point or not.

VIII. FIRST REFUTATION OF SCIENTIFIC THEORIES

To resolve the problem of the dimensions of the Pyramid once and for all, a mechanical engineer by the name of William Petrie, who had become fascinated by the theories of both Taylor and Smyth, set about designing and constructing even more specialized sextants, theodolites, and verniers with which to tackle the technical problems encountered by Smyth. It was no easy job. Smyth had gone a long way in perfecting his own equipment, and it was to take William Petrie all of twenty years to accomplish the task to his own satisfaction. Petrie stressed the importance of further exploration of the Pyramid because of its "paleologic, chronologic, metrologic, geodetic, geologic and astronomic interest to mankind," and above all "for its symbolic interest relating to the higher ideas intentionally embodied therein by its originator." Yet Petrie kept tinkering with the new instruments and postponing his departure for Egypt.

His young son, William Flinders Petrie, perhaps because of a spirit of adventure inherited from his maternal grandfather, the great explorer Matthew Flinders, became so impatient he finally decided to prime the pump by leaving ahead of his father, convinced that his father would quickly follow.

Fascinated by the varied standards of measure used in different parts of the world, young Petrie had read all he could on the subject; instead of going to school, he tramped around England, becoming proficient as a surveyor by measuring churches, buildings and ancient megalithic ruins such as Stonehenge, about which he was to write the first of his several score books.

At the age of thirteen, young Petrie had read Piazzi Smyth's *Our Inheritance in the Great Pyramid*. It had not only revived in him the ideas of Greaves and Burattini, but convinced him that a real history of measures might be deduced from a careful measurement of surviving monuments and objects. He was also determined to prove, one way or another, whether or not Taylor and Smyth had been correct in their theories regarding the Pyramid. To do so he would have to resurvey and measure the entire building.

William Flinders Petrie.

On a stormy day in November of 1880, Flinders Petrie, now a bearded professional surveyor of twenty-six, set off from Liverpool with a vast quantity of boxes containing the rare instruments designed by his father to eliminate the defects revealed by Smyth's experience. He also had with him the necessary supplies with which to survive for a long period in the inhospitable, bandit-infested desert. The gale blew so hard Petrie slept on the engine grating, too seasick to go below deck. Within a week of landing at Alexandria, Petrie had transported his equipment to Cairo, where he managed to get hold of Ali Gabri to help transport his food and instruments to the Giza plateau.

Ali Gabri was now a veteran of 40 years' service with Caviglia, Howard-Vyse and Piazzi Smyth. Reaching the Pyramid in December, Petrie followed the established practice of setting up house in an abandoned tomb.

Ali helped Petrie furnish his quarters with shelves and a hammock, helped him stock the larder with ship's biscuits,

Petrie standing before his living quarters in a tomb on the Giza plateau.

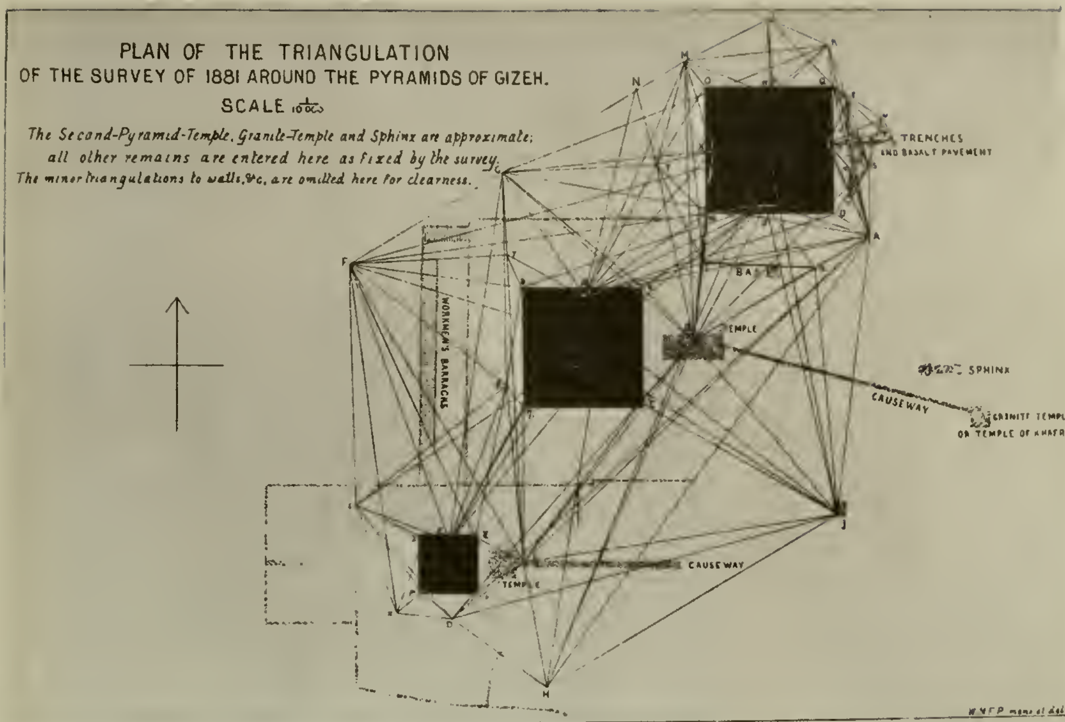
canned soups, tapioca and chocolate. To cook his evening meal Petrie had brought along a kerosene stove. Like his predecessors, Petrie found the solid rock of the tomb an extremely hospitable home, remarking that it seemed "as good as a fire in cold weather, and deliciously cool in the heat."

Petrie's day started with the lighting of his kerosene stove and the ritual boiling of tea water while he enjoyed a makeshift bath.

Breakfast was the time he accorded to reception. Men and women would look in at the door of his tomb, and if a special Arab friend paid a visit, Petrie would brew some coffee in his honor on the little stove by the door.

Petrie got along well with the Arabs, noting that "the smallest entering into their ways pleases them enormously; only sit squat, return the proper replies to salutations, catch their tricks of manner, and imitate their voice, and they will laugh heartily and treat you as a friend."

Petrie's first preoccupation was to accomplish what had been beyond the means of Smyth: a very precise triangulation all over the hill of Giza, including points around all three large pyramids, as well as the surrounding temples and walls which belonged to the complex. Though he couldn't remove the rubble, Petrie hoped to establish the dimensions of the pyramids by triangulation to within a fraction of an inch.



Petrie accomplished his triangulation of the Great Pyramid over a period of months, by means of a ten-inch French theodolite, "a splendid theodolite by Gambay" with a ×35 telescope. Some of the angles were read as many as 14 times from as many as 50 fixed stations. Petrie estimated the probable error in his base measurement of the Pyramid to be ±.03 inch, or 1/260.000 of the whole. But because of the debris and the fact that the cornerstones were missing, Petrie could not establish where the original corners had actually been placed.

Using a highly accurate theodolite by means of which single seconds of angle could be read, Petrie repeated his observations so many times that it would take him from dawn till sunset to accomplish the work at a single station. A second of arc is so fine that it is commonly referred to as the angle subtended by a dime at the distance of a mile.

All the while Ali Gabri held a huge parasol over the theodolite to keep the sun from shining on the metal circle and expanding it unevenly. Once the sun had gone down Petrie would have a solitary meal, washing his own dishes—because he distrusted the Arab's idea of cleanliness—and then sit down to meticulously write up his figures, laying the groundwork for that scientific archeology of which he was to become the prime promoter. His sole entertainment was the "indescribable" tunes played on a reed flute by Ali Gabri's nephew, whose job was to guard him from a neighboring tomb through the night.

Choosing good days, with cool air but no wind, and working for ten hours at a stretch without food, Petrie was able to get a figure to within a quarter of an inch, and usually to within a tenth of an inch, for the actual layout of the three large pyramids at Giza. He was amazed to find the layout of the Great Pyramid "a triumph of skill. Its errors, both in length and in angles, could be covered by placing one's thumb on them."

Victorian tourist and her escort being helped up the Pyramid courses by Arab guides.

The Great Pyramid was so precisely aligned with the cardinal points of the compass that it surpassed in accuracy any human construction to date.

As the weeks wore on, Petrie realized he would not complete the exteriors before springtime and the arrival of the tourist season; so he had the way prepared for his indoor measurements by having a gang of Arab workmen clear the Descending Passage down to the lower "pit" which Smyth had been unable to reach because of the rubble. Armed with baskets, a chain of workers were able to carry the debris up and out of the main entrance.

When the tourists did begin to trickle toward the Pyramid, Petrie devised a system to avoid being bothered by going about outside the Pyramid in nothing but his pink underwear. At the sight of him, the good Victorian ladies kept a safe distance.

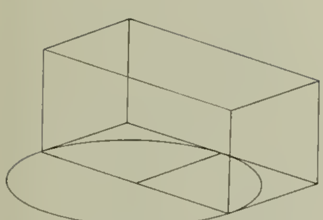
That the tourists were a formidable menace to the pursuit of science had been made clear by Piazzi Smyth, who described "many and multitudinous scenes of lurid-lighted revelry, indulged in by many smoking, tobacco-stinking gentlemen and a few ladies, from some vulgar steamer" who performed "whirling dances over King Cheops' tombstone with ignorant cursing of his ancient name . . . and the painful thunder of the coffer being banged, to close upon breaking, with a big stone swung by their Arab helps."

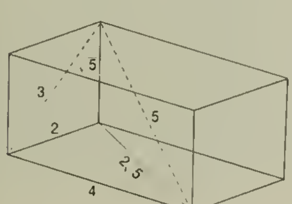
For lack of salacious statues or pictorial attractions at the Pyramid, the more boisterous tourists would amuse themselves by removing loose blocks from the summit which they would send crashing down to the already vast heaps of rubble accumulated round the base.

At the end of the day, once the tourists had left, Petrie would work in the intense accumulated heat of the Pyramid, often till midnight and sometimes right through till morning, like "the Japanese carpenter who had nothing on but a pair of spectacles, except that I do not need the spectacles." The ventilating shafts in the King's Chamber, which had been opened by Howard-Vyse, had once more been clogged by vandals, making the air unwholesome. After the first few hours the dust which was raised at every move caused Petrie feverish headaches; but he persevered in his task.

With steel tapes and special chains 1200 inches long, as well as self-compensating accessory appliances, Petrie set about measuring with a far finer accuracy than Smyth could obtain all that was worth noting. Most of Petrie's instruments allowed him to measure to within 1/100 inch, and some, for really careful work, enabled him to do so to within 1/1000 inch.

To measure upright surfaces he used plumb lines; for horizontal surfaces a leveling instrument. Thus he could find the dimensions of a room at any level, and establish where any faults might lie.





To measure the straightness of the sides of the Descending Passage Petrie used fine observations of Polaris at elongation—when it was farthest east and west from the pole. He was amazed to find that the average error in the part built of masonry was an infinitesimal 1/50 inch in 150 feet; and over the entire length of 350 feet the sides were within 1/4 inch of being absolutely straight.

In the King's Chamber, Petrie established to his satisfaction that the walls had been constructed on the basis of the same π proportion which ruled the exterior of the building. Its length was to the circuit of its side wall as 1 is to π.

This value was not immediately evident, because the floor of the chamber had been inserted between the walls so as to cut off a fraction at the bottom. But the cut was cunning in

President Ulysses S. Grant visited the Pyramid as part of a world tour.

In the archives of the Library of Congress lies a faded daguerreotype, with the unmistakable features of the general.

Piazzi Smyth describes the arrival of a party of enthusiastic Yankee tourists atop the Great Pyramid while Smyth was making early-morning observations. "In the short time they were there," writes Smyth, the Americans "arranged themselves into a meeting on constitutional principles of Anglo-Saxon derivation, with a chairman, secretary and audience; wherein a resolution was proposed, recorded and carried unanimously, to the effect—'that whereas this here pile whips everything in the way of building we've seen in all our grand tour through the used-up, worn-out world, yet we calculate King Cheops, its builder, must have been such a horrid old tyrant and cruel oppressor of the people, that it is hereby resolved by us free and independent citizens of the *Unyted* States that we *won't* give him a cheer.' "

After offering thanks to their "excellent chairman for his well-balanced conduct and impartial attitude on his very elevated seat," says Piazzi Smyth, "the gentlemen liquored up, the ladies, as they bashfully expressed it, consented to take a swallow, and the whole party disappeared down the steep slope of the pyramid . . . every man of them with little Confederate flags picked out on the soles of their boots, so that they might have pleasure in trampling on the hated ensign of the South wherever they went."

As an indication of how *tutto il mondo è paese*, Cheops is said (by Sir Gardiner Wilkinson) to have engraved the figures of the Gods of Egypt on the public roads "in order that they might be trodden under foot by man and beast."

that it thus incorporated in the chamber both the 2– $\sqrt{5}$ –3 and the 3–4–5 Pythagorean triangles.

Checking to see if the π proportion could also apply to the coffer, Petrie found that its dimensions appeared to be all multiples of a square fifth of a cubit. The difference between the requirements of the theory and the actual squares being a mere 1/1500.*

All of this tended to corroborate Smyth's theory that the builders of the Pyramid had been possessed of an advanced science of mathematics. But Petrie also found in the Pyramid an extraordinary mixture of brilliant workmanship and astonishing clumsiness. He was amazed to find that the granite in the antechamber had never been dressed: many of the stones had been left unfinished and some were even defective. From such indications Petrie concluded that "the original architect, a true master of accuracy and fine methods, must have ceased to superintend the work when it was but half done."

From a careful scrutiny of the coffer in the King's Chamber, Petrie established that the ancients had used saws with 9-foot blades, their teeth made of hard jewels, to cut the sides of the coffer out of a single solid block. To hollow it out they had used drills with fixed cutting points also made of hard jewels, probably diamond or corundum.

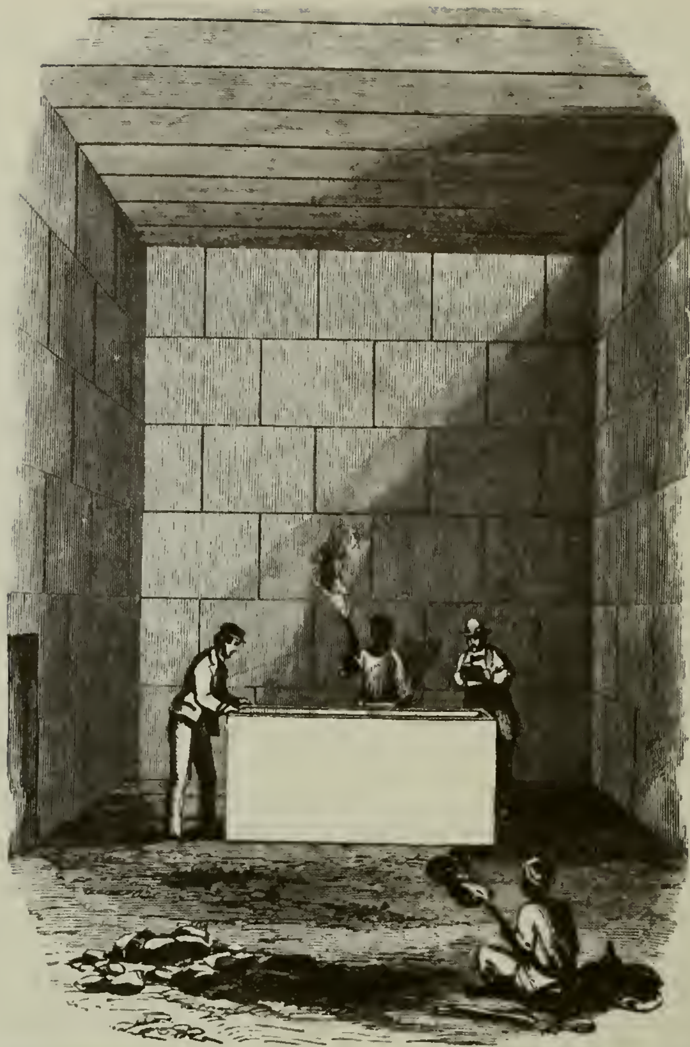
Petrie estimated that in order to cut through the hard granite a pressure of 2 tons would have had to be placed on the drill. How this could be done was a mystery to Petrie, who concluded: "Truth to tell, modern drill cores cannot hold a candle to the Egyptians . . . their fine work shows the marks of such tools as we have only now reinvented."

With such tools the ancient Egyptians were somehow able to cut sharp hieroglyphs into incredibly hard diorite, and also to turn stone bowls to paper-thin surfaces.

To measure the bottom of the coffer and to see if there were any secret opening beneath it, Petrie had its 3 tons raised about 8 inches, but found no sign of any opening. When raised and struck, the coffer produced a deep bell-like sound of extraordinary, eerie beauty.

Outside the building Petrie searched for more casing stones still in their original position such as had been

* Petrie also noted that the squares of the dimensions of the King's Chamber, Queen's Chamber, antechamber and subterranean chamber were all even numbers of cubits, nearly all multiples of ten. From this it followed that the squares of the diagonals were likewise multiples of 10 square cubits. And the King's and Queen's Chambers were so arranged that the cubic diagonals were in even hundreds of square cubits, or multiples of 10 square cubits.



Measuring the granite coffer before it was vandalized.

The coffer showing corner chipped away by tourists.

uncovered by Howard-Vyse at the base of the Pyramid. It was a painstaking and dangerous job to dig down through the accumulated debris. The rubble kept sliding back into the holes dug by the Arabs, and at one point Petrie nearly was killed.

Eventually he did manage to uncover more casing stones, as well as the base of the Pyramid. Petrie found the workmanship on the original casing stones, some of which weighed over 15 tons, quite as remarkable as Howard-Vyse had described it. The faces were so straight and so truly square that when the stones had been placed together the film of mortar left between them was on the average no thicker than a man's nail, or 1/50 inch over an area of 35 square feet.

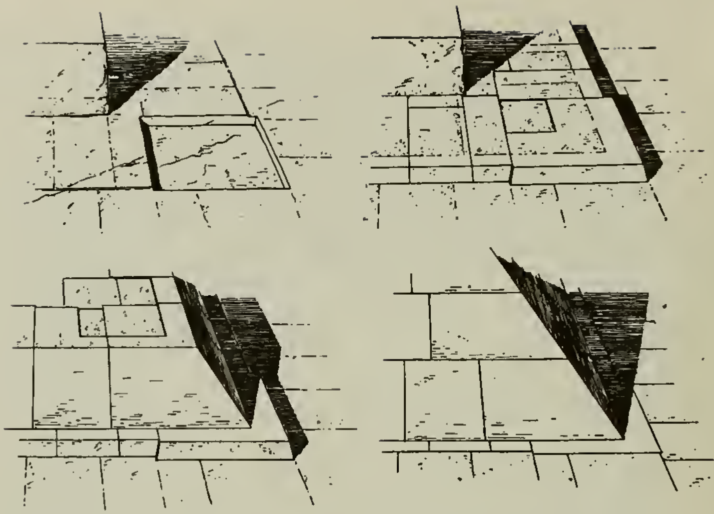
Petrie found that the mean variation of the casings from a straight line and a true square was but 1/100 inch on a length of 75 inches. This staggering accuracy was equivalent to the most modern optician's straight edges.

As Petrie remarked, "Merely to place such stones in exact contact would be careful work, but to do so with cement in the joint seems almost impossible: it is to be compared to the finest opticians' work on a scale of acres."

So fine was the texture of the cement that after millennia of exposure to the elements, the stones shattered before the cement would yield.

The casing stones of the Great Pyramid (looking east), showing the platform on which they rest, the pavement in front, and the leveled natural rock.

Shallow sockets dug into the rock at the corners of the Pyramid were designed to hold the four cornerstones for the base, and were apparently cut through the pavement at these points. This has engendered an argument among pyramidologists as to whether the base circuit should be measured from the edge of the pavement or the edge or bottom of the sockets.
It was at first assumed that the bottom of the Pyramid cornerstones had been fitted into these sockets so as to counterbalance any eventual thrust produced by sliding away from the center of the structure, but modern archeologists discount the assumption because at the northeast corner, the depth of the socket is virtually zero; and the outer edge of the southwest socket is merely an incised line in the rock, more for measurement than for structural support.



But the principal result of Petrie's survey was to prove a little abstruse. He considered the true base length of the Pyramid to be defined *not* by the limit of the sockets as measured by Smyth, but by the edge of the pavement 20 inches higher.

According to Petrie's measurements, the base of the Pyramid at the *pavement* was shorter than the distance between the outer corners of the sockets, as estimated by Smyth. Instead of measuring the 9140 British inches claimed by the Scottish astronomer, Petrie obtained a length of only 9069 inches for the base line.

Discarding Piazzi Smyth's theory that the Pyramid had been designed on an extra-long pyramidal cubit of 25.025 inches, Petrie showed by his own careful measurements that the builders of the Pyramid had used the royal cubit of 20.63 inches in order to produce a base line of 440 cubits and a height of 280 cubits. This confirmed Taylor's theory to the extent that the Pyramid was intended to symbolize the globe by giving a very effective π value of 22/7, or 3.14285, but apparently nullified Smyth's theories about the perimeter of the Pyramid giving the exact number of days in the year. The new product gave only 362.76 days.

Summing up the results of his measurements in a book entitled *The Pyramids and Temples of Gizeh* (which he was able to publish with a fortuitous grant of £100 from the Royal Society in London), Petrie remarked that he had never suspected, 15 years earlier, when he had first read Smyth's fascinating theory, that it would be he who "would reach the ugly little fact which killed the beautiful theory."

With success and recognition, Petrie turned from the romantic exploits of discovery to the prosaic minutiae of scientific archeology.

In the wake of Petrie's demolition of Smyth's basic contention about the length of the year being incorporated in the Pyramid's perimeter, soured academicians were happy to bury Smyth along with his theories. Foremost among such undertakers was Professor F. A. P. Barnard, president of Columbia College in New York, whose spadework in the 1890s consisted in arguing that the value of π was a modern discovery and therefore could *not* have been known to the ancients. In long-winded pieces for small periodicals, Barnard attacked Smyth for his "folly," and the builders of the Pyramid for the "stupidly idiotic task of heaping up a pile of massive rock a million-and-a-half cubic yards in volume."

In Barnard's opinion the Pyramids "originated before anything like intellectual culture existed; have been constructed without thought of scientific method, and have owed their earliest forms to accident and caprice."

Other academicians mocked the theory that the ancient Egyptians could have had an advanced knowledge of geometry, geodesy or astronomy. As recently as 1963 an eminent engineer in Baltimore, author of an expensive privately printed booklet, *Designing and Building the Great Pyramid,* was to write: "Because the sides of the Great Pyramid faced the four cardinal points almost precisely it is usually assumed that the designers intended they should, but it is unlikely that they had more than a vague idea, if any, of the four cardinal points. Like all peoples, the ancient Egyptians knew east and west from seeing the heavenly bodies rise in one and set in the other, but north and south were probably only known to them as general directions. There is no evidence in the Great Pyramid that they had any conception of true north or knew that a north-south line was perpendicular to an east-west line."

For years Smyth's painstaking measurements, carefully collected and illustrated in several large volumes (which went through several editions in his lifetime), were labeled by the academicians so much "trash and fancy."

In the conflict of opinions between biblical scholars and men of science, the true purpose of the Great Pyramid was buried in a rubble of verbiage.

Petrie had become Sir Flinders, and was on his way to becoming the dean of academic archeologists. Had it not been for the careful work of some conscientious scholars, Smyth and Taylor would have suffered the fate of Paracelsus and Mesmer, being relegated in the history books to the role of mountebanks.

IX. SCIENTIFIC THEORY DEVELOPED

Ironically, the next great investigator to throw light on the question of the Pyramid was a man whose object was to destroy and dispose of the theories of Robert Menzies, whose ideas about the prophetic revelations in the passage system had added to the difficulties of Piazzi Smyth.

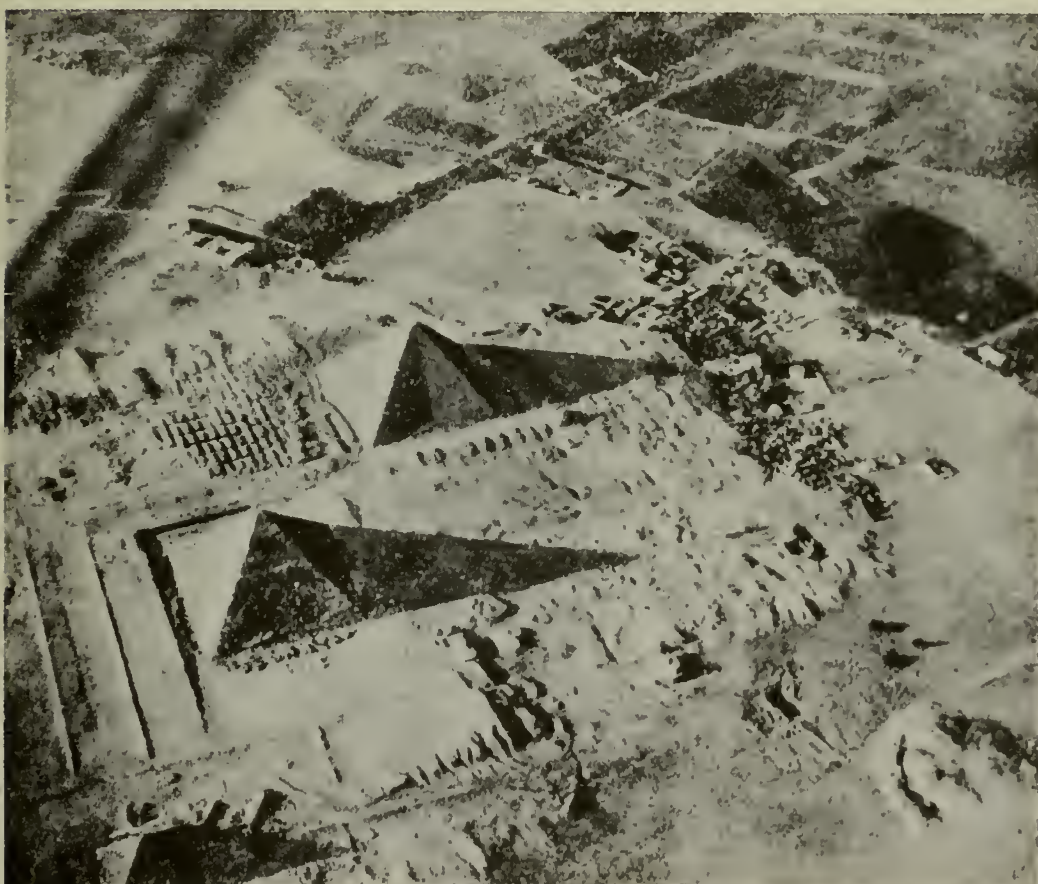
An agnostic and a sober structural engineer from Leeds, in the north of England, David Davidson was determined to destroy Menzies' prophetic theory. But the more he attacked the data, the more he was obliged to assimilate it. In the end he was to produce an encyclopedic literature in support of Menzies' own idea, and to become convinced that the Pyramid was "an expression of the Truth in structural form" and that it "establishes the Bible as the inspired work of God."

From further analysis of the Pyramid, Davidson believed he could confirm Taylor's premise that the science of weights and measures of the ancients was founded upon two functions of the earth and its orbit, the standard time unit being the solar year, and the standard linear unit a decimal fraction of the polar axis about which the earth rotates.

On the question of the length of the Pyramid's base, Davidson was to vindicate Smyth, yet avoid harming Petrie. According to Davidson, not only was Petrie's survey correct, so was Smyth's theory that the Pyramid's base incorporated the length of the solar year.

Petrie, with his meticulously careful measurements, had managed to observe a definite hollowing of the core masonry on each side of the Pyramid. The accuracy of this observation, normally invisible to the human eye, was revealed in Petrie's lifetime in a dramatic aerial photograph taken accidentally at a specific time and angle by Brigadier P. R. C. Groves, the British prophet of air power. A similar line along the apothem, visible in an etching made by Napoleon's savants, had been ignored for a century.

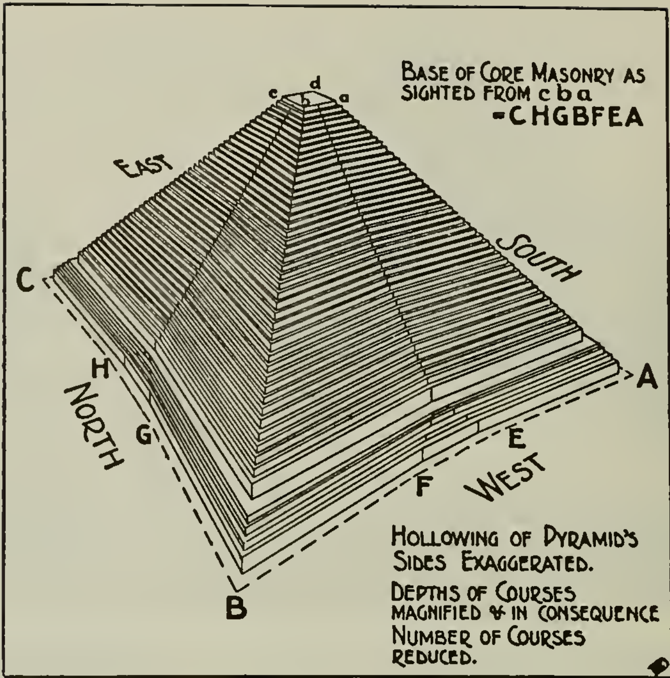
Davidson noted that Petrie had failed to extend this hollowing feature of the core material to his measurement of the outside casing. If this were done, a base length was obtained which fitted Smyth's theoretical length to account for the solar year, to four points of decimal.



Sir Flinders Petrie noted a distinct hollowing of the core masonry in the central portion of each face of the Pyramid. Though the hollowing amounts to as much as 37 inches on the north face, it is not directly observable unless special lines of sight are taken.

Petrie found no evidence of hollowing along the lower-level casing stones, running along the base of the Pyramid, which have now been completely uncovered.

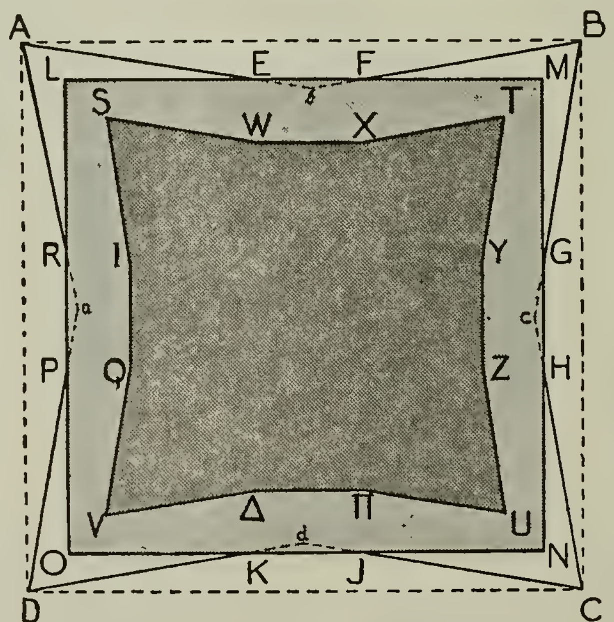
A recent survey by two Italian scholars, Maragioglio and Rinaldi, indicates the casing stones *above* the base line may have been slightly sloped toward a central line.



Davidson's plan of the base of the Pyramid, showing three different ways of measuring the year's length.

CONSTRUCTION OF THE GREAT PYRAMID'S BASE.

(Hollowing-in of core masonry GREATLY EXAGGERATED to show effect.)



LMNO—Base as actually built.
SWXTYZUΠΔVQI—Base of core masonry.

As Davidson put it: "By reason of this unfortunate omission, scientists have been led to believe that the theory of the late Astronomer Royal of Scotland—Professor Piazzi Smyth—requiring a Great Pyramid base circuit of 36,524 inches, was nothing more than a delusion."

The ideal length postulated by Smyth for each side of the base in order to obtain the required length of 9131.5 Pyramid inches was 9141.1 British inches. Petrie's figure, revised by Davidson, came out to 9141.4, or about a third of an inch too long.

According to Davidson, the hollowing effect would give three basic lengths of the year as recorded in the base of the Pyramid: an outer or shortest length, from corner to corner, bypassing the hollowing, a second, slightly longer, which included part of the indentation of the four hollowed faces at the base; and a third, which included the entire angle within each hollowed face. These three measurements, which could have been performed by the ancients at their leisure, could have given the equivalents, according to Davidson, of the three lengths of the year as computed by modern science: the solar, the sidereal, and the anomalistic years, each of which is dependent on the system used for observation.*

The academicians rebutted that all this was purely attributable to chance. An American naval officer who dabbled in digging at Giza remarked that "if a suitable unit of measurement is found—say versts, hands or cables—an exact equivalent to the distance of Timbuctu is certain to be found in the roof girder work of the Crystal Palace, or in the number of street lamps in Bond Street, or the Specific Gravity of mud, or the mean weight of an adult goldfish."

But Davidson's conclusions were to reopen the entire subject of Pyramid measurements and breed a whole new school of pyramidologists.

* The solar year is obtained by observing the exact time between two successive vernal or autumnal equinoxes, when the day is exactly as long as the night. It is now 365 days, 5 hours, 8 minutes and 49.7 seconds, or in decimals: 365.2242. The sidereal year (from the Latin *sidus,* for star) is the time it takes a star to reappear in the same spot in the sky, as seen by an earth observer. It is about 20 minutes longer than the solar year, or 365.25636 days. This 20-minute lag causes what is known as the precession of the equinoxes, which come 20 minutes earlier each year in relation to the stars behind the equinoctial point. The anomalistic, or orbital, year is the time it takes the earth to return to the point in its elliptical orbit nearest the sun, or perihelion. This is about 4 3/4 minutes longer than the sidereal year. According to Davidson, not only does the Pyramid give this value, but it gives the number of solar years it takes for the perihelion to complete a full circle of 360°.

The president of the French College of Astrologers, D. Neroman, a mining engineer by profession, showed in his *La Clé Secrète de la Pyramide,* published shortly after World War I, that Smyth's sacred cubit and Petrie's royal cubit were mathematically related. Neroman revived Newton's conclusion that the Pyramid had been built with both basic cubits, Petrie's shorter cubit for the common workmen, and Smyth's longer cubit for the hermetic science of the designers. Neroman showed that the Pyramid was the precise height and width to contain a round number of each unit. As 33 sacred cubits are equal to 40 profane, or royal, ones, the base measured 440 royal cubits or 363 sacred cubits; the height 280 or 221.*

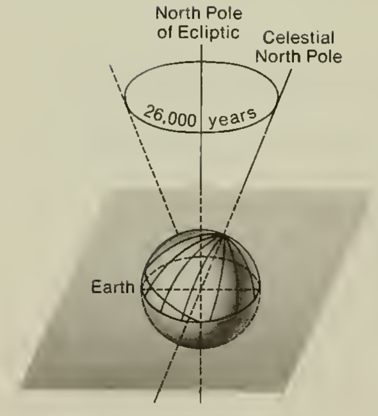
It was suggested that the priests measured the year's length with a sacred cubit so that they alone could make use of the Pyramid's hermetic science. But why this yielded a base of 363 days was not satisfactorily explained.

Another necromantic solution was provided by John B. Schmaltz in a small book entitled *Nuggets from King Solomon's Mines*. Schmaltz demonstrated that the modern deck of cards could be taken as a symbol of the Egyptian year incorporated in the Great Pyramid. According to Schmaltz the 52 cards represent the weeks, the 12 face cards the months, the 13 cards in a suit the lunations, the suits the seasons, the total face value of the cards (counting jack as 11, queen as 12 and king as 13) 364 days, plus the joker as the magic 1.234, for a total of 365.234 days in the year.

A more solid boost to the memory of Piazzi Smyth—quickly made much of by the pyramidologists—was the refined figure for the polar axis of the earth obtained in 1910 by the American geodesist John Fillmore Hayford, who computed it at 6,356,910 meters, the ten-millionth part of which gives a cubit of 635.69 millimeters, or Piazzi Smyth's sacred cubit, correct to .03 millimeter.

Another extraordinary figure found by the pyramidologists in the base of the Pyramid was the sum of its diagonals, which they computed as 25,826.68 pyramid inches. This gave a very close approximation of the number of solar years in what is known as the great year, which is determined by the precession of the equinoxes. The great year is the time it takes the earth to make a complete gyration in the wobble of its axis in relation to the plane of its orbit; this with the solar year, are the two prime standards for astronomical time.

Actually, the rate of precession is far from uniform, and



The precession of the equinoxes.

* 33 × 25.025 = 825.72 and 40 × 20.643 = 825.72. It will be noticed from Neroman's figuring that to obtain this result he arbitrarily lengthened the royal cubit by about 1/100 of an inch.

is at present slowly increasing. According to Davidson, the Great Pyramid recognized this fact and provided a method of sums of diagonals at different levels of the monument to indicate the all-time mean, or average length of the precessional cycle.

To add to the coincidences, Morton Edgar, an ardent supporter of Davidson, who traveled to Egypt just prior to World War I and made extensive measurements and calculations, found that the perimeter of the thirty-fifth course, which is much thicker than any of the other courses, *also* gives a figure for the precession of the equinoxes.

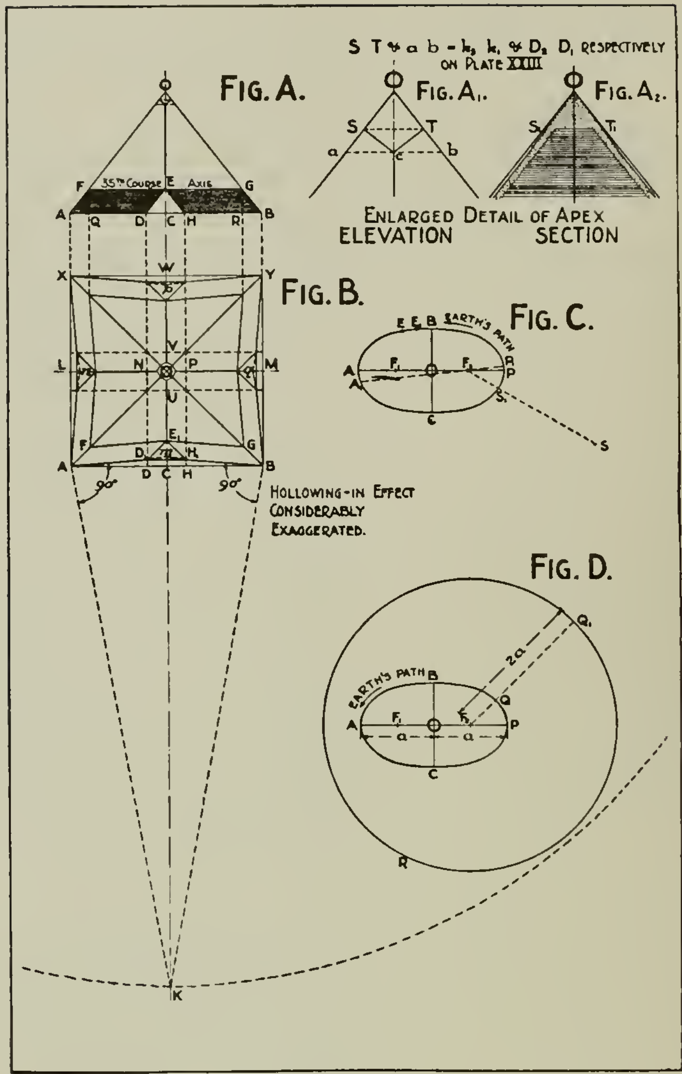
Egyptologists and astronomers argued that if the Pyramid had been designed to incorporate the π proportion, and its base had been designed to be 365.2422 cubits long, the chances of its diagonals being intentionally designed to mark the length of the precession would be simply astronomical.

Davidson replied that to build the Pyramid its designer must have been deeply acquainted with the workings of natural law: that before such a design could be put into effect, the astronomical properties of the solar year would have to be reduced to a simple pyramidical expression.

Davidson claimed that—without getting into higher mathematics—it was evident that if you know the earth's distance from the sun and the length of the sidereal year in seconds, you can compute the rate at which the earth is falling toward the sun. This in turn would lead to finding the specific gravity of the earth, of the sun, of the earth and moon combined, the solar parallax, and even the speed of light.

To Davidson the mathematics of the Pyramid indicate that the former civilization was more highly skilled in the science of gravitational astronomy—and therefore in the mathematical basis of the mechanical arts and sciences—than modern civilization. It was his conclusion "that it has taken man thousands of years to discover by experiment what he knew originally by a surer and simpler method." In Davidson's words: "It means that the whole empirical basis of modern civilization is a makeshift collection of hypotheses compared with the Natural Law basis of the civilization of the past."

As to why the Pyramid was built and its passages carefully secreted, Davidson surmised that the builder intended to monumentalize the science of his time for another civilization far in the future, much as we go about burying time capsules. According to Davidson, the builder knew that the faculties by which he was able to handle the formulas of natural law could atrophy in man, and that by conveying his science to beings of a later civilization he might spur them to recover those powers.

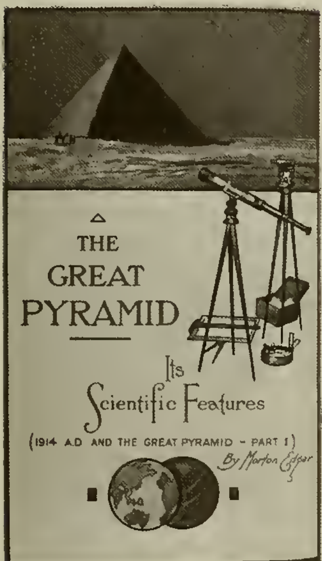


Davidson's computations to show that the Pyramid's base defines the earth and its orbit "in dimensions and motion."

Like Menzies and Smyth before him, all that Davidson managed to accomplish was to antagonize the scientific world with his insistence upon the record-preserving nature of the Pyramid while swamping the average pyramid enthusiast with the overwhelming bulk of his detailed mathematical analyses and computations.

Even worse were the efforts of a succession of pyramidologists who attempted to prove the Great Pyramid contained a six-thousand-year prophetic history of the world commencing in 4000 B.C. and going to A.D. 2045 which coincided with the prophecies of the Bible. They saw in the Pyramid an allegory in stone in which the Descending Passage represented humanity on its way down toward

Morton Edgar, supporter of the prophetic theories about the Pyramid, stooping to enter the King's Chamber. The picture shows how the floor was inserted between the walls so as to obtain both the π value and the 3–4–5 triangle.



ignorance and evil. At the juncture of the Ascending Passage, evil spirits were to continue toward the pit, whereas the rest of humanity, benefiting by the Christian Dispensation, moved upward along the Ascending Passage toward the Light of the Grand Gallery. Having passed the Great Step, humanity must continue bent in submission through the Antechamber of Chaos—representing the modern age—before it could come out into the King's Chamber and the glory of the Second Coming.

The prophetic chronology was supposed to be marked out along the passages and chambers, with one year corresponding to one pyramid inch, commencing with "Adam," or the "first created man," and ending with the "Day of Judgement."

According to Morton Edgar: "By the year 2914, the end of the 1000-year 'Day of Judgement,' mankind will have experienced the full benefit of the sacrificial work of Christ, and will regain that perfect human nature which father Adam lost in the beginning of his disobedience 7040 years previously."

By general agreement the commencement of the Low Passage into the Antechamber was said to mark the beginning of the Great War in 1914. The end of the King's Chamber was supposed to be indicated by the year 1953.

Considering the wide popular acceptance of such medieval prophets as Nostradamus, and such modern prophets as Edgar Cayce and Jeane Dixon, it should not have been harder to believe that some ancient prophet couio

Chronology of the past 6000 years as indicated in the Great Pyramid passages according to Menzies and Piazzi Smyth.

have had prescience of the following 6000 years, and built his vision into the Pyramid passages; but as each prophetic date went by with no appearance of a Second Coming, the idea of the Pyramid as a prophetic calendar became largely discredited.

By 1920, when the waters of the Mediterranean failed to become thick and viscid, and the rivers and fountains of the world failed to turn into blood, as prophesied by Colonel J. Garnier on the basis of the Pyramid chronology, the whole subject became so unpleasant in the halls of academe that few professors dared mention the Pyramid as anything but the supposed resting place of the Pharaoh Cheops.

Nevertheless, a few intrepid investigators kept minds open enough to continue their research into the structure and purpose of the Pyramid, and to put forth some theories that in the end paved the way for a general vindication of much that Jomard, Taylor, Smyth, and even Davidson had propounded.

X. A THEODOLITE FOR SURVEYORS

One basic function of the pyramids on the Giza plateau was discovered by a chief engineer of the Australian railways, Robert T. Ballard, as he watched them from the window of a passing train in the 1880s.

From the constantly changing relative position of their clear-cut lines against the sky, Ballard realized that the pyramids could serve as excellent theodolites for a land surveyor, enabling him to triangulate the land anywhere within sight of the pyramids.

The land of ancient Egypt was parceled out in small lots to individual priests and soldiers, the boundaries of which would regularly vanish with the flooding of the Nile.*

By means of the pyramids, not only could the surrounding country be quickly resurveyed, but boundaries destroyed by the Nile could be readily restored.

From the silhouettes of the pyramids, the engineer realized that lines could be obtained as perfect as can be laid out nowadays with all of our modern instruments. With a string and a stone held in the hand and the clear-cut point of a pyramid 20 miles away against the ball of the sun 90 million miles away, the error in such a line would be trifling.

What's more, the same building could also be used with either moon or stars.

Knowing the latitude of the pyramids, survey lines could be shown all the way to the coast of the Delta—with nothing more than a string and a weight.

As the engineer's train steamed southward along the bank of the Nile, more pyramids appeared on the horizon, and the engineer realized that with a procession of such theodolites it would have been possible to adjust the boundaries of Egypt from one end of the country to the other.

Ballard figured that the simplest portable survey instrument would be a small scale model of the Pyramid of Cheops in the center of a circular graduated board marked like a compass. When the north end of the card was pointed toward the north, and the faces of the model turned to indicate the same light and shade displayed by the Great Pyramid, the

* Statisticians estimate that eight million people were crowded into a space of only 11,500 square miles, giving a density of 695 per square mile—which is more than modern Belgium, the most densely populated part of Europe.

The pattern of shadows cast by the three large pyramids of the Giza plateau can serve to orient the viewer as accurately as a compass or theodolite. Ballard suggests that the smaller pyramid of Mykerinos was intentionally sheathed in red granite, in bold contrast to the other two pyramids, so as to facilitate the work of the surveyor.

The Giza complex of pyramids, as depicted from the air, showing the north-south meridian through the center of the Great Pyramid.

According to Soviet space engineer Alexander Abramov the three large pyramids on the Giza plateau are arranged in a special geometric configuration known in ancient Egypt as an *abaka*. Ballard found that several Pythagorean triangles could be formed by the perimeters and centers of the pyramids.

surveyor could simply read off the angle of bearing. With a model of all three pyramids, the reading would be that much more exact. Furthermore, observation of the next pyramids farther to the south could be tied in with these readings.

The Australian engineer also worked out that the pyramids could be used for surveying by right-angled triangles with sides having whole numbers, such as the 3–4–5 triangle and the 2– $\sqrt{5}$ –3 triangle Petrie had found in the King's Chamber, both of which were fundamental to land surveying. Similarly incorporated in the ziggurat of the Babylonians, the triangles were conceived by the ancients to explain the secret order of the cosmos, a conceit which percolated to Plato. In the *Timaeus* he explains the cosmos as being constructed by the triangle 3–4–5 and the number $\sqrt{5}$–1 or 1.236068 (which in common practice was taken as 1.2345).

For right-angled trigonometry, the Australian engineer realized, true straight lines could be extended from the pyramids in given directions by direct observation, without aid of other instruments, and that with the simplest of instruments, angles could be exactly observed from any point.

In a short time *anyone* might construct a table for himself answering to every degree or so in the circumference of a circle for which only forty or fifty triangles are required.

Such primary triangulation would be useful to men of almost every trade and profession in which tools or instruments were used.

Having come to these conclusions, Ballard incorporated them in a small illustrated volume with the rather grand title of *The Solution of the Pyramid Problem,* published in 1882.

XI. ALMANAC OF THE AGES

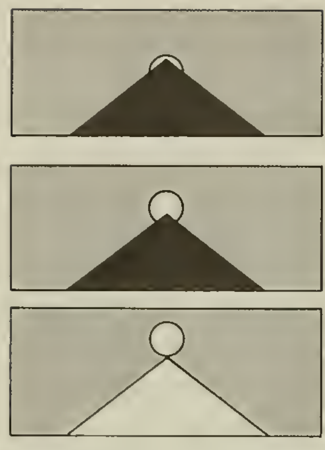
Ballard's little booklet and one of Smyth's discoveries at the Pyramid brought another strange investigator to the scene. Smyth had been astonished that with the advent of spring, when the sun rose high enough to shine down the northern slope of the Pyramid, the structure appeared to swallow its own shadow at noon. Smyth deduced that the Pyramid had been designed as a huge sundial whose shadows could indicate the seasons and the length of the year.

By Smyth's reckoning the Pyramid had been intentionally located, oriented, and sloped for the phenomenon to occur in that latitude at the spring equinox, when at noon the sun is directly over the equator, although for some reason the phenomenon no longer occurred precisely at that particular date.

Unbeknownst to Smyth, the French astronomer Jean Baptiste Biot had been to Egypt in 1853 and noted that "with or without intention by the Egyptians who built the Great Pyramid, it has, since it existed, functioned as an immense sundial which has marked annually the periods of the equinoxes with an error less than one day, and those of the solstices with an error less than a day and three quarters."

The phenomenon had a great impact on an obscure Yorkshireman, Moses B. Cotsworth, a legislative enthusiast whose life's ambition was to reform our present barbarous almanac.*

* The present calendar derives from the early Romans, who had a 10-month year of 334 days: hence our September, October, November, December. In the seventh century B.C. Numa Pompilius is credited with adding January and February for a lunar year of 354 days. The shortage of 11 1/4 days caused the seasons and the calendar to diverge to the point where Julius Caesar was obliged to add 91 days to 46 B.C. and succumb to the suggestion of Cleopatra that he adopt the Egyptian civil calendar of 365 1/4 days. Even so, the difference between the civil calendar and the actual solar year of 365.2422 days added up to an extra day every 128 years, which obliged Pope Gregory XIII to drop 10 days from 1582. When Protestant England refused to go along, Christendom celebrated different Christmases in England and France, till the British finally relented in 1752, though there were street riots in London with shouts of "give us back our ten days." By skipping leap days in centuries which are multiples of 400 and 4000, our calendar is now good for the next 20,000 years, but anyone who troubles to read Cotsworth's impassioned plea for a more rational system than our calendar of floating holidays will find it hard to dispute his logic.



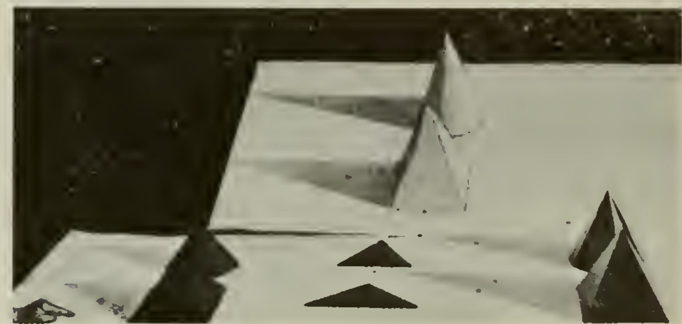
In early spring, when the sun rises just high enough above the apex of the Great Pyramid, the whole shadow on the north face vanishes at the stroke of noon.

Cotsworth was convinced that the designers of the Pyramid had intended their finished structure to serve as a perfect almanac for registering the seasons and the year. To prove his point Cotsworth went in search of further evidence.

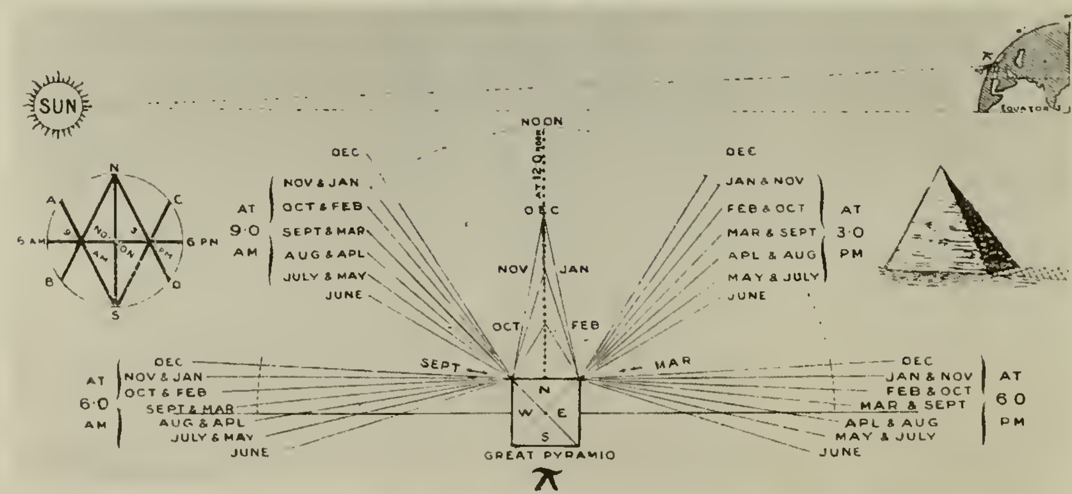
Just before Piazzi Smyth died in 1900, Cotsworth managed to have several conversations with him, and after his death was able to get hold of Smyth's books and papers when they were put up for auction. Though Cotsworth refused to accept Smyth's prophetic theories, he was determined to vindicate the astronomical theories of the ancient Egyptians, so he set about reconstructing with models the sundial system on which he believed the Pyramid had originally been designed.

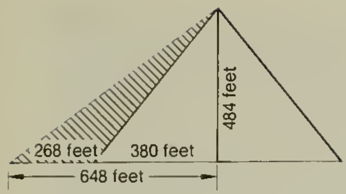
Cotsworth noted that at the latitude of the Pyramid, an ordinary obelisk would serve admirably for telling the time of day, or the general course of the seasons, but could not be built high enough to throw a shadow long enough to detect the length of a whole year of 365 days, let alone throw a shadow fine enough to distinguish the extra quarter of a day to four points of decimal. To obtain the difference in length of 1 foot per day would require an obelisk 450 feet tall, perfectly vertical and precisely oriented.

Cones and pyramids designed by Moses B. Cotsworth to demonstrate how shadow patterns could be used to measure the length of the year.

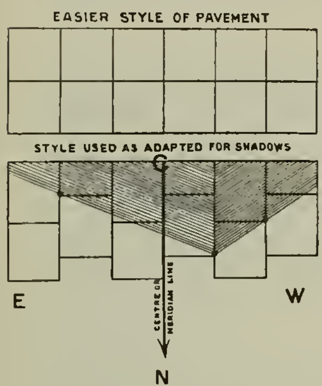


Cotsworth's models show how a square-based pyramid oriented to true north will cast a pointed shadow on the meridan line. A cone, showing no orientation, will not serve the purpose.





With the sun's winter solstice angle of 36° 45′, the Pyramid will throw a shadow of 648 feet. Deduct half the Pyramid's base length of 760 feet, or 380, and the maximum length of the Pyramid's winter shadow will be 268 feet.



Cotsworth found that part of the pavement north of the Pyramid was paved with blocks whose widths were close to the 4 1/2-foot gradation of the sun's shadows on successive days just before the Pyramid consumed its own shadow in the spring.

Cotsworth figured that the dimensions of the Pyramid would be ideal for measuring the six winter months, when the northern slope of the Pyramid is constantly shaded and when the shadow cast at noon onto the northern pavement grows longer up the meridian to a maximum at the winter solstice, gradually decreasing to the point of disappearance at noon on a certain day in March.

To test his theory, Cotsworth made several model pyramids and cones and laid them out on carefully diagrammed paper. On these sheets he marked the outline of the shadow cast by the sun each half hour during a period of several months.

To his satisfaction Cotsworth was able to prove that the pyramid was the best shape for the purpose. The pyramid was more easily oriented to a perfect north, its flat slope was easier to angle, and its sharp edges cast a better shadow. Also, the actual structure would be easier to build to the required height in the form of a pyramid than a cone.

To measure the Pyramid's lengthening and shortening shadows, Cotsworth realized that a wide and perfectly level pavement, or "shadow-floor," should have been constructed on the northern side of the Great Pyramid, presumably with a meridian line running due north, and a pavement laid in some geometric pattern to facilitate the measuring of the shadows.

Cotsworth worked out that a structure 484 feet high, such as the Pyramid of Cheops, would require a "shadow-floor" stretching 268 feet northward of the base in order to include the full length of its shadow at its longest point, at the winter solstice in December.

To verify his theory, Cotsworth sailed for Port Said in November of 1900 aboard the P. & O. liner S.S. *Osiris*. At the Giza plateau he found the north side of the Pyramid of Cheops reasonably clear of rubble and the rocky plateau leveled to the required distance. At the level of the main platform on which the Pyramid rests, he found a pavement, or "shadow-floor," which extended as far as the remains of an old wall which had once surrounded the pyramid complex.

Instead of being paved in adjacent squares, Cotsworth found it laid in alternate half squares, which provided twice the number of junction points by which to measure the daily shadow of the Pyramid along the meridian at noon.

To support his observations, Cotsworth made a series of photographs of these shadows as they grew shorter toward the vernal equinox. To his delight he found that the paving blocks had been cut in widths very close to the 4.45-foot gradation by which each noonday shadow succeeded the former as they approached the vanishing point in March.

Photograph taken by Cotsworth showing shadow cast by the sun close to the base of Pyramid at noon of the last day before the intended equinox. The negative was stolen and the print has suffered in reproduction; but the pattern of shadow can be measured on the northern pavement.

It was only thus, says Cotsworth, "that the ancient priests could have established by physical observation of the shadow on the flagstones, the precise length of a year to .24219 of a day."

William Kingsland, a professor of astronomy, commenting on Cotsworth's conclusions, pointed out that some of the paving stones are actually laid at all kinds of irregular angles and corners; but the corners of these stones are clearly cut out to fit into the adjoining stone—indicating, if anything, an even more sophisticated geometric pattern.*

To make up for the summer half of the year, when there

* According to Kingsland, Cotsworth's leveled rock area did not extend 268 feet north from the northern base of the Pyramid, but ended at a distance of only 33 1/2 feet, where there are the remains of a surrounding wall 9 1/2 feet thick; but there is no way of telling at what time this wall was built, or whether the pavement may not have once continued beyond it, and been dismantled by the Arabs for building blocks.

was no shadow on the northern slope of the Pyramid, Cotsworth figured that the priests could have subdivided and tabulated the intervening months.

In this he failed to realize that the southern face of the Pyramid, being highly polished, could throw a triangle, not of shadow, but of sunlight onto a southern pavement during the summer months, quite as definite as the winter shadows thrown on the northern side.

From May to August the south face would cast a triangular reflection of the sun onto the ground which would shorten as it approached the summer solstice, the shortest being at noon of the solstice, lengthening again till noon of the last day of summer.

Noon reflections would also be projected every day of the year from the east and west faces. But this was to remain for David Davidson to establish.

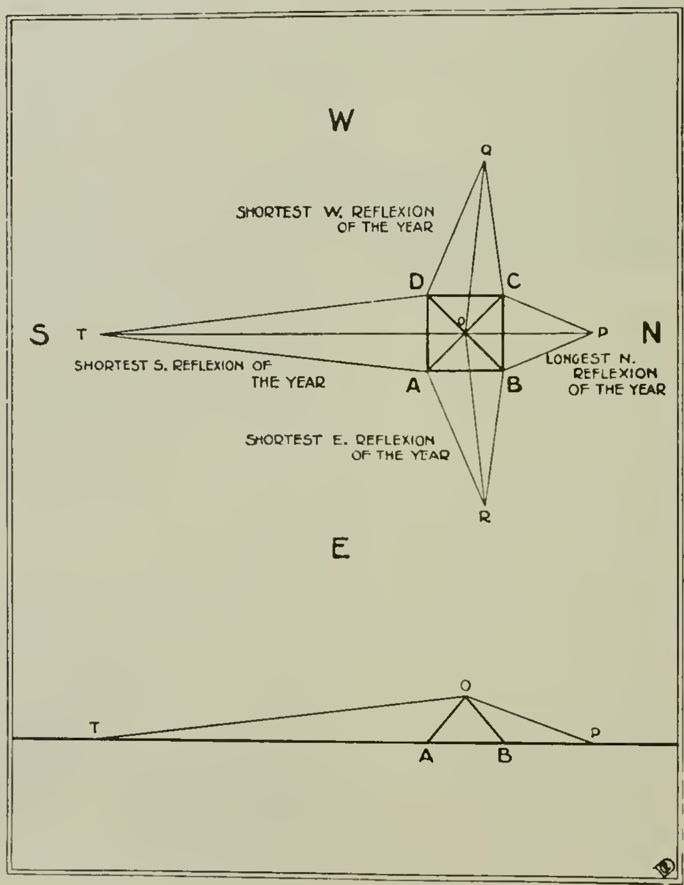
From a study of the sharper slopes of other pyramids, such as of Saqqara, Medûm and Dashur, Cotsworth deduced that their builders may have aimed these slopes not at the equinox, when the sun is midway, but at the summer solstice, when the sun is highest in the sky at noon. Sneferu's pyramid

Deliberately broken pattern of paving stones observed by William Kingsland on the north side of the Great Pyramid, apparently intended for finer mathematical measurement of the sun's shadow on successive days and years.

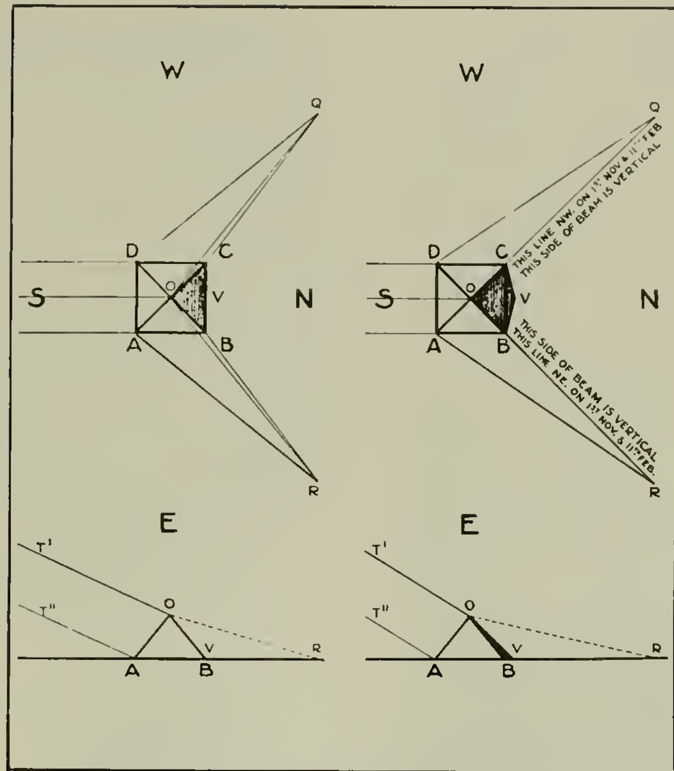
at Dashur, with its milder slope of 43°, may have been aimed at the winter solstice, when the sun is lowest at noon. From the gradually corrected slope of Saqqara and the change in angle in the bent pyramid at Dashur, Cotsworth concluded that the Egyptians may have progressed northward to the "truer" pyramid form, or π-shaped pyramid, at the thirtieth parallel, where morning and afternoon shadows form a series of perfectly straight lines.

In this, Cotsworth was supported by Joseph Norman Lockyer, the eminent British astronomer, who taught astronomical physics at the Royal College of Science. Lockyer noted that pyramids other than that of Cheops appeared to be oriented not to true north but to the rising sun at the solstice, which *changes with the latitude* of the place of construction.

According to Cotsworth the pyramids were originally developed from mastabas or raised terraces built to support an obelisk. To lengthen the shadow, the obelisk was successively raised on higher sloped platforms, which eventually turned into stepped pyramids.



Davidson's diagram of the reflections of sunlight cast by the Pyramid at noon of the summer solstice.



Davidson's diagram of winter shadows and reflections cast by the Great Pyramid. Left figure shows the noon shadow first appearing October 14–15. Other lines indicate reflected sunlight. Right figure shows the noon shadow first disappearing February 27–28. Other lines are pattern of reflected sunlight.

Cotsworth points out that the oldest true pyramid, that of Medûm, was constructed in several stages, as evidenced by the polished casings at each level.

The process, says Cotsworth, was developed to the point where the results no longer increased in proportion to the effort expended. A 60-foot platform which raised a 60-foot obelisk increased its shadow by 100 percent, but an added platform of 40 feet only increased the shadow by 19 percent; eventually the top platform became too small for raising an obelisk. According to Cotsworth, the optimum design turned out to be the solidified Pyramid of Cheops, with its slope set for a particular latitude to swallow the equinoctial shadow. Once this method of establishing the precise length of the year had been found, says Cotsworth, there was no further need for enormous pyramids.

Cotsworth obtained further confirmation of his theory from a comparison of the pyramids with the artificial hills built by ancient inhabitants of Britain who traced the year's end by the longest shadow of the year cast from vertical cones or artificial mounds such as Silbury Hill.

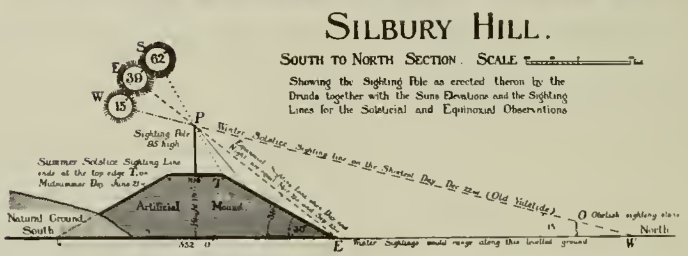
Later inhabitants of Britain, such as the Druids and Goths, continued to count the year's end from Yuletide, the December solstice.

Silbury Hill in Wiltshire, England, covers five acres and is built of over a million tons of hand-moved material. According to archeologists it is at least four thousand years old.

Cotsworth says that Silbury Hill was designed to have a Maypole on top to cast a shadow up and down the truncated hill and onto the level plain to the north, so as to mark the four seasons of the year.

The cone was truncated at a point where the shortest shadow thrown by the Maypole on the longest day of the year indicated the summer solstice. On the level plain north of the hill a stone was placed in the ground to mark the point of the longest shadow cast by the Maypole at the winter solstice, or shortest day of the year.

The juncture at the bottom of the hill, where it touched the plain, marked the spring and autumn equinoxes, when the day was exactly as long as the night.



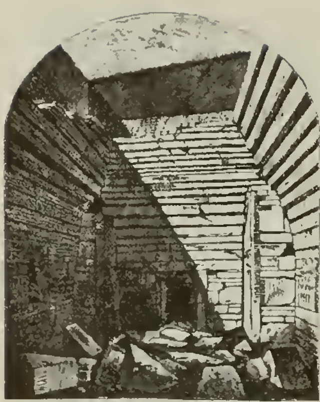
Aerial photograph of Silbury Hill, showing the footpath around the truncated top.

Druid in Old Irish meant "he who knows." Julius Caesar, our earliest source on the subject, considered the Druids highly educated and well organized. In *De Bello Gallico* he commented: "It is especially the object of the Druids to inculcate this—that souls do not perish, but after death pass into other bodies, and they consider that by this belief more than anything else men may be led to cast away the fear of death, and to become courageous. They discuss many points concerning the heavenly bodies and their motion, the extent of the universe and the world, the nature of things, the influence and ability of the immortal gods; and they instruct the youth in these things."

As Cotsworth reconstructed the system, the truncated cone of Silbury Hill enabled the ancient astronomers to measure the length of the seasons and the year by the length of shadow cast by a pine Maypole, which served as an obelisk, atop a hill intentionally truncated so that its edge would also mark the summer solstice, or the shortest shadow of the year.

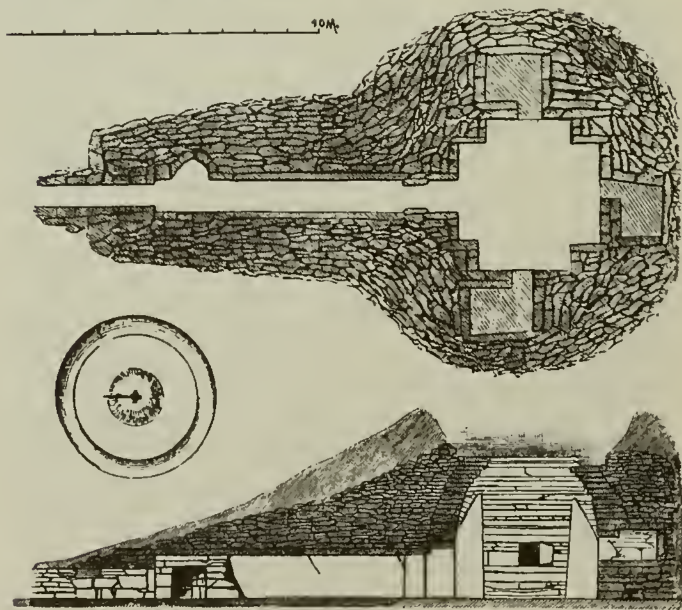
Had these astronomers simply required a great height, says Cotsworth, they would have used the adjacent Abury Hill, with its wide top which could easily have been raised. But this, says Cotsworth, would not do; they required an absolutely level piece of ground on which to mark the progress of the shadow. Hence they had no alternative but to pile up an artificial hill above the level plain. Fortunately, in latitudes of 50° or 60°, such as Brittany or Stonehenge, low mounds would give shadows long enough for detailed measurement. A height of 225 feet in Wiltshire gives a shadow almost equivalent to the shadow of the 484-foot Pyramid of Cheops.

One of the most remarkable of these prehistoric European mounds still exists at Maes-Howe, near Stennes, in the Orkney Islands. It is equipped with a 15-foot square observatory chamber and a 54-foot sighting tunnel. The tube is aimed at a conspicuous man-raised monolith 42 chains (2772 feet) from the entrance, which lines up with a spot on the horizon where the sun now rises 10 days before the winter solstice. Another monolith, to the west, called the Watchstone, indicates the equinoxes. Like the Great Pyramid of Cheops, the observatory chamber is built of huge megaliths and its ceiling is corbeled. There are also three "retiring rooms for the observers," somewhat like the Queen's Chamber in the Great Pyramid.



The main chamber in Maes-Howe, showing corbeled monoliths which could be closed at the top by a single movable slab. The jointing in this prehistoric masterpiece rivals that of the Great Pyramid.

The entrance passage to the Maes-Howe observatory is very similar to that of Egyptian pyramids.

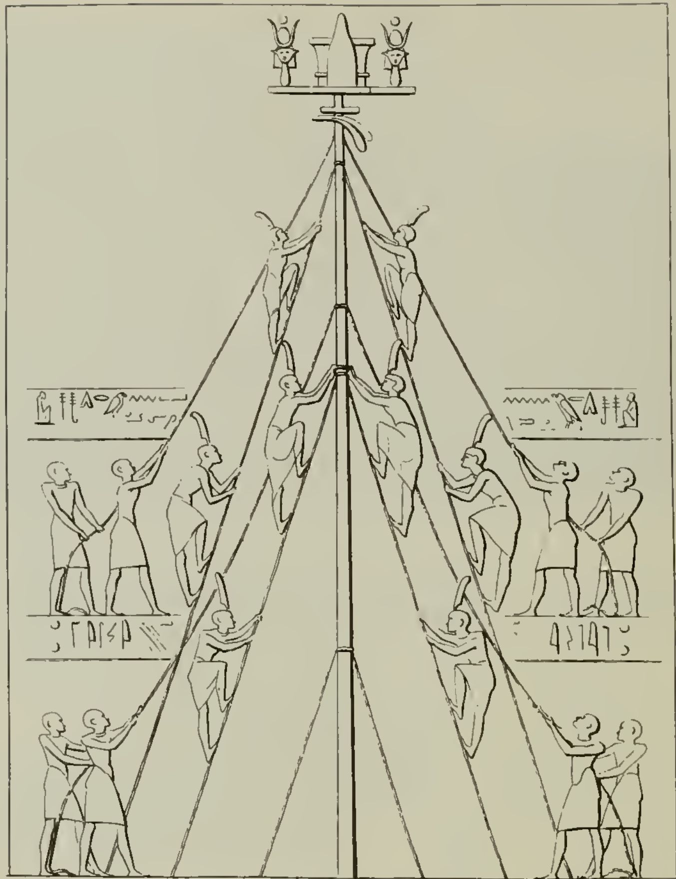


Maes-Howe, near Stennes in the Orkney Islands, is a man-made cone-shaped pyramid 27 feet high and 115 feet across, with an outer circling ditch 45 feet wide and 700 feet in circumference.
It has a 54-foot observation passage aimed like a telescope at a megalithic stone to indicate the summer solstice.
Its central observation chamber, corbeled like the Great Pyramid's Grand Gallery, is built of megaliths weighing 3 tons, carefully leveled, plumbed and so finely jointed they will not admit the blade of a knife.

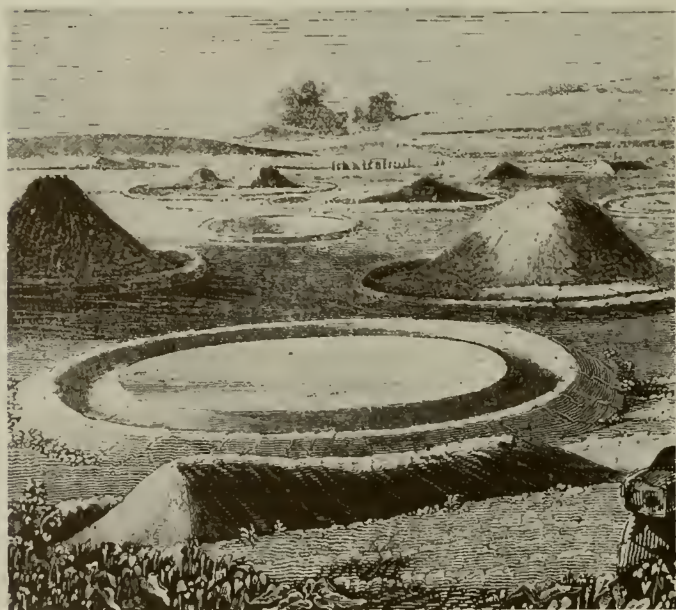
Circular monoliths similar to Stonehenge located at Stennes in the Orkneys near Maes-Howe.

In *Stonehenge, a British Temple Restored to the Druids,* which Piazzi Smyth considered a book "far before its age and perhaps not yet sufficiently appreciated," its author, Dr. William Stukely, attempted to show that such megalithic circles had always been arranged on even and round numbers of the "profane cubit of 20.7 inches nearly," and not in feet or any other known standard of length. Smyth remarked that although the idea "was pooh-poohed by more recent antiquarians, I have never heard of any of them having ascertained by actual measure at the place, that the Stukelian theory would not hold."

Professor Alexander Thom has recently shown they are built on a megalithic yard of 2.72 feet.



An Egyptian Maypole.



Various shaped mounds, or "barrows," were constructed in prehistoric Britain. Cotsworth considered them manmade instruments for observing the movements of heavenly bodies.

Alexander Thom considers Averbury Circle near Stonehenge the greatest and most remarkable circle in Britain, if not in the world. "Its greatness," says Thom, "does not lie in its size alone but in the remarkable manner in which its arcs are built up from a basic Pythagorean triangle so that each retains an integral character, and in the exceedingly high precision of the setting out, a precision only surpassed today in high-class surveying."

The Scottish lairds in residence at Maes-Howe—or Maiden's Mound—still plant a Maypole on the originally flat top, perpetuating the ceremony begun when observations were made of the shadows cast by the pole on the flat terrain to the north of the mound.

In England throughout the Middle Ages and the Renaissance, the Maypole with its tall garlanded and decorated shaft (stowed away for the rest of the year under the eave of a house) was set up on May Day. When Cromwell came to power he banned the Maypole. As the *National Encyclopedia* puts it: "The Puritans, to whom we owe the loss of so many of our public games, and so much of our merriment, ordered all Maypoles to be destroyed by Act of Parliament in 1644, as a 'heathenish vanity, abused to superstition and wickedness,' and fined the constables five shillings weekly as long as they stood."

The custom was revived with the Restoration, and the last Maypole erected in London—all of 100 feet high—stood on the spot where the church in the Strand now stands near Somerset House. It was taken down in 1717 and conveyed to Wanstead Park, in Essex, where it was fixed as part of the support of a large telescope set up by Sir Isaac Newton.

A glance at the outlines and cross sections of the pyramids of Saqqara, Dashur and Medûm will show that, like ancient British observatories, each had a sighting passage, pointed at a northern star. The passage ended in an

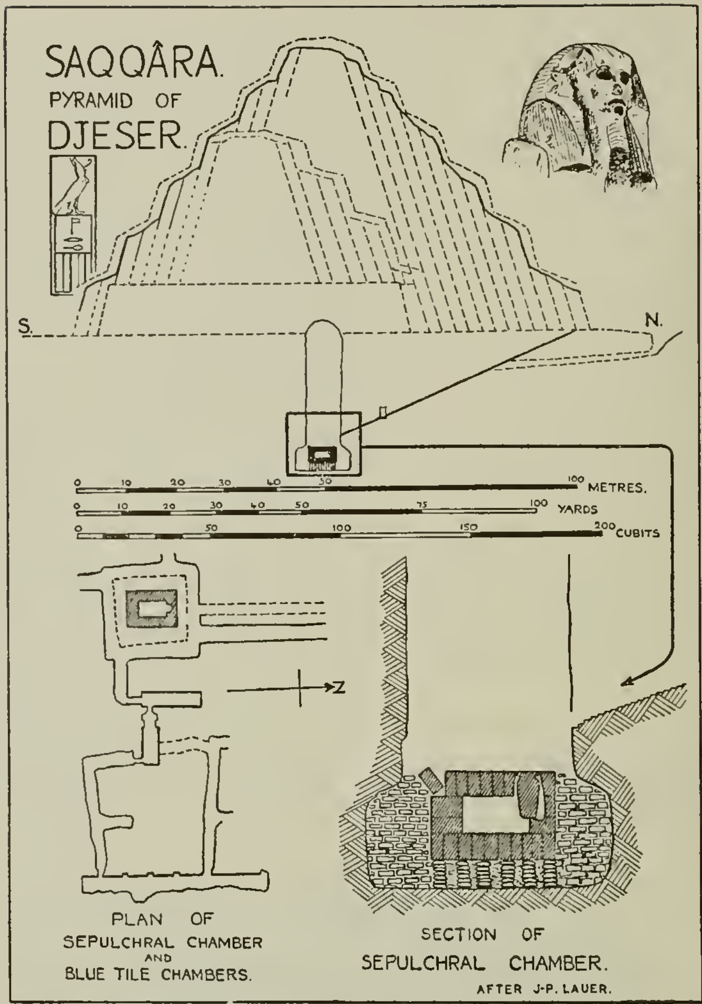
Remains of "Old Sarum," an ancient British stepped pyramid.

The original building of the stepped pyramid was a mastaba 63 meters square built of coarse rubble cased with fine white limestone, above a square pit.

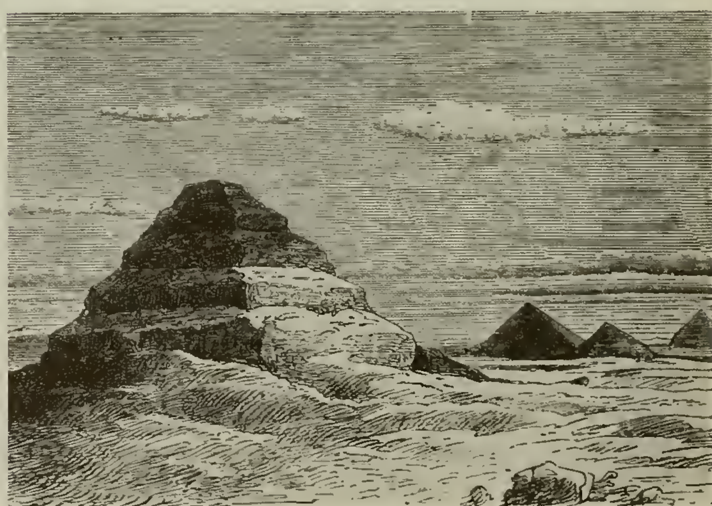
The original entrance was through a hole in the roof directly into a 28-meter shaft lined with granite. The mastaba was subsequently heightened into a stepped pyramid by the superimposition of three more terraces. Extended eastward (ostensibly to include graves for Zoser's family!), the structure was then a rectangle 120 meters by 108. Two more stories were added, so that it became a six-step pyramid, cased with fine limestone, at a slope angle of 72° 30′. A second entrance was placed in the north face leading down a rock-cut flight of steps to a more restricted "sepulchral chamber."

The building was attributed to King Zoser (of the Third Dynasty) on the basis of his cartouche on some stones and is believed to have been erected by his fabulous architect Imhotep.

In 1929 Frith found a bas-relief in the pyramid depicting Zoser, and in the 1950s Prof. Lauer found a mummified foot which he believes to have been Zoser's.



Stepped pyramid of Saqqara, believed to be the oldest Egyptian pyramid.



The pyramid of Medûm, on a square base of 144 meters, rises 92 meters high, and is so situated that it is a landmark for miles in all directions.

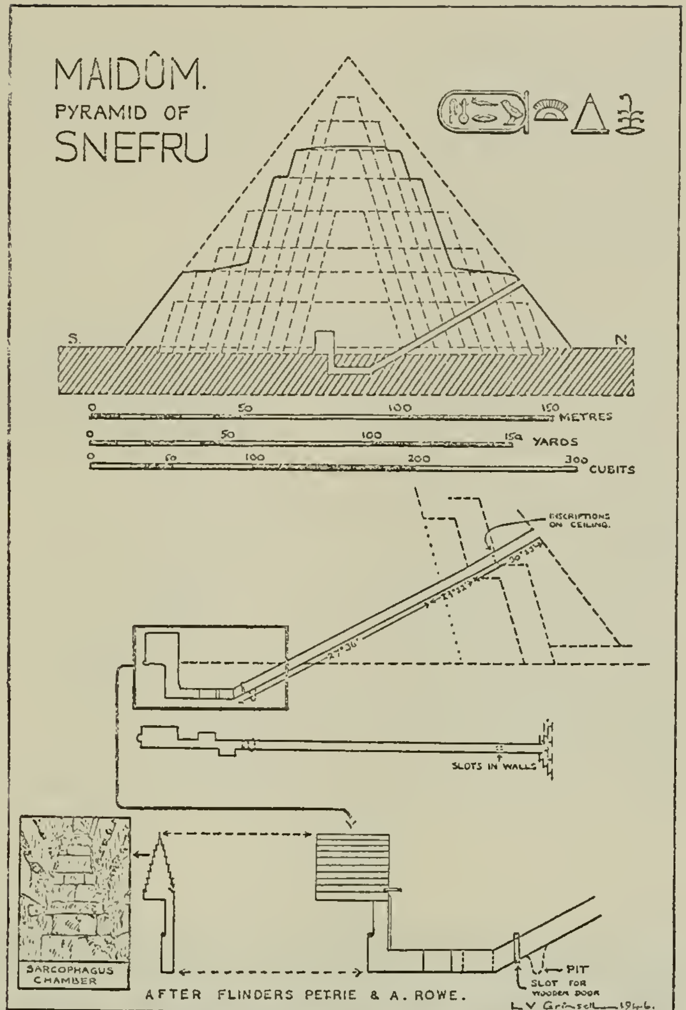
Most of the outside limestone casing, which sloped at 51° 52′, has been removed, showing that the pyramid was built in several stages from an original mastaba about 20 meters long, with slopes of 75°.

The pyramid grew in seven steps by means of a series of accretion walls, each of which was cased in fine white limestone; eventually the spaces between the steps were filled in, and the entire pyramid cased with white limestone, most of which was removed at an early date (possibly during the reign of Rameses II) though portions remain. Three accretion faces are presently visible.

The base is still covered with sand and debris.

An entrance on the north side, 30 meters aboveground, leads down a ramp 57 meters long, sloping at 27° 30′, to two antechambers and a vertical shaft in the center of the building. The shaft rises to the "sarcophagus chamber," which has a fine corbeled roof of limestone built in seven steps.

In 1891 Petrie found fragments of a wooden coffin believed to have belonged to Sneferu; so the pyramid has been attributed to Cheops' father.

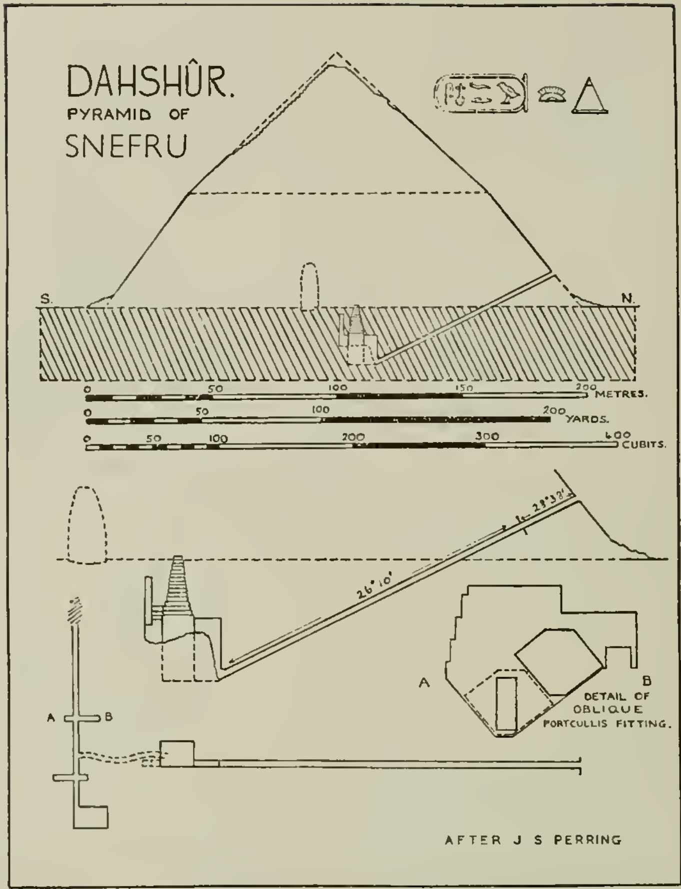


Sneferu's blunted or rhomboidal pyramid at Dashur is 190 meters square at the base and 100 meters high. The lower portion slopes 54° 41′, the upper portion 43°. The casing is of fine white limestone; the body is believed to be of coarser limestone.

There are two entrances, one on the north and one on the west side, leading to two main chambers.

The northern entrance is 11 meters aboveground in the center of the lower face and leads down a ramp inclined at 28° 38′ for the first 13 meters, then at 26° 10′ for the remaining 65 meters. A short horizontal passage 12 meters high leads to a fine chamber whose roof is corbeled on all four sides.

The western entrance, which is 29 meters above the base, leads to a ramp descending at 26° 36′ for 68 meters to a horizontal passage with two portcullis slabs and a chamber with a roughly corbeled roof.

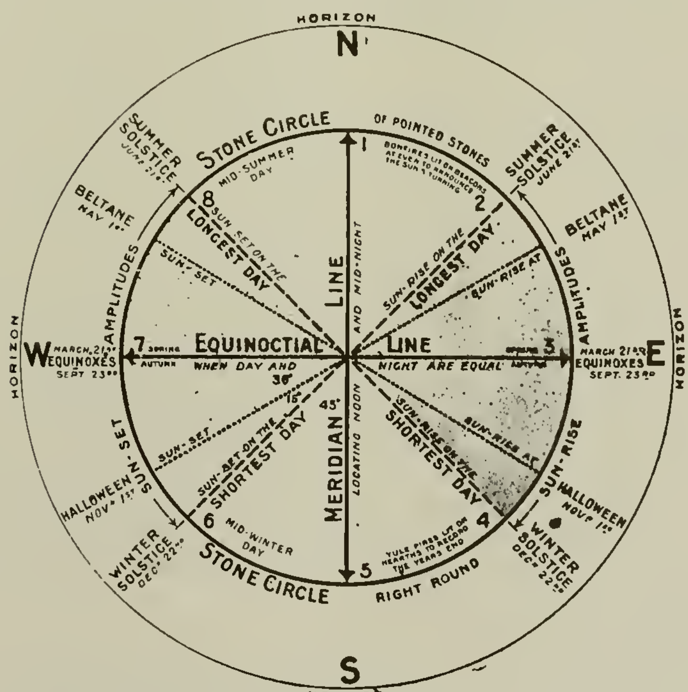


observation chamber with a corbeled roof with a small opening just at ground level, presumably for sighting a star directly overhead at the zenith, or for lowering a plumb line to coincide with a line sighted down the sloping passage. The similarity to the structure at Maes-Howe is indeed amazing. Yet Maes-Howe has also been considered as nothing but a burial chamber. A recent writer on Maes-Howe discarded the theory that the mound might have had astronomical significance, saying that the belief is accepted by no "serious students of archeology."

Scientists of other disciplines are in disagreement, and have produced interesting data on the orientation and purpose of megalithic monuments.

In his *Megalithic Sites in Britain,* published in 1967, Professor Alexander Thom, who for many years held the chair of Engineering Science at Oxford, shows how the stone and wood henges of Britain of the second millennium B.C. were aligned on certain stars, were planned on the basis of a geometry which anticipated Pythagoras, and were uniformly built on a unit of measure which he calls a megalithic yard of 2.72 feet or .829 meter.

According to Thom, megalithic sites in Britain served the purpose of calendars and clocks. During the long winter nights the only indicators of time were the stars. By observing the rising and setting of stars of the first magnitude, or their



Cotsworth's explanation of Druidical circles such as Stonehenge.

transit over the meridian, it was possible to tell the hour of night.

Thom says that in Britain between 2000 and 1600 B.C. there were about ten or twelve stars of the first magnitude whose rising and setting could be clearly observed. Thom also found a great number of stones set to indicate the point of rising and setting of first magnitude stars, and many slabs and alignments which accurately marked the meridian.

For such pointers to be accurate the observer also had to know the date. This was obtained from the sun calendar arrangement of the stones.

As for the accuracy of the alignments, Thom says the ancient engineers managed to raise perhaps ten thousand megaliths from one end of Britain to the other, and set them with an accuracy of 0.1. When they wanted to, says Thom, they could measure with an accuracy of 1 in 500.

R. J. C. Atkinson, professor of archeology at University College, Cardiff, an authority on Stonehenge, and a severe critic in this field, concludes from Thom's data that a high degree of competence in empirical astronomy existed in Britain 4000 years ago.

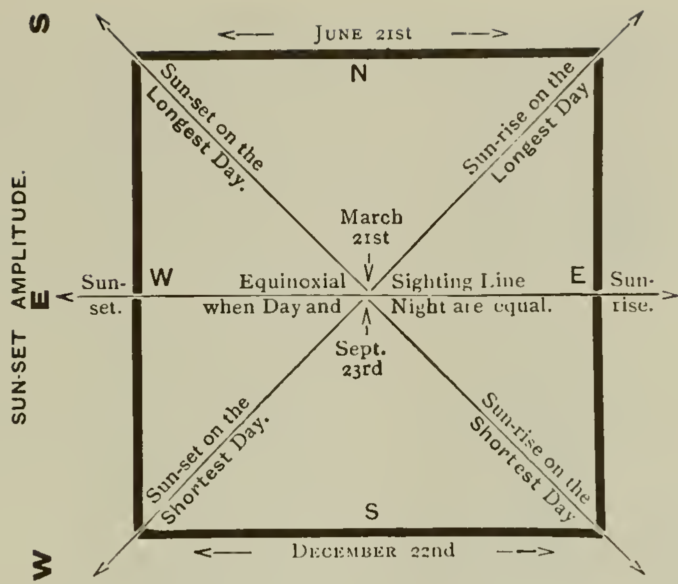
This supports the data of the contemporary Greek astronomer C. S. Chassapis, whose analysis of the Orphic Hymns indicates that the Greeks of the second millennium B.C., also had an advanced knowledge of astronomy.* These ancient Greeks, says Chassapis, knew that the seasons were caused by the earth's rotation around the sun along the ecliptic, and had determined the torrid, temperate and frigid zones. They had established the equinoxes and solstices, and knew that the apparent daily rotation of the stars in the heavens was due to the earth's rotation on its axis, which formed a northern pole in the sky. This knowledge, says Chassapis, was taught by the Orphics to the initiate who distinguished between the "fiery" stars and the seven planets which they called by today's names. The second millennium Greeks used a calendar of twelve conjuctive months from full moon to full moon, and accepted the presence of mountains on the moon. They believed that all phenomena were governed by a universal law, and conceived that space was filled with ether.

Lyle B. Borst, professor of astronomy and physics at New York State University in Buffalo, in an article in *Science* (November, 1969), notes that more than forty churches, mosques and temples have now been identified from Norway

* *Greek Astronomy in the Second Millennium B.C. according to the Orphic Hymns.* Athens, 1967.

Many churches in Europe continued to build with their towers oriented to the cardinal points, or to mark the solstices and equinoxes. Others were oriented to the sunrise of the saint for whom they were named.

St. Peter's Basilica in Rome is oriented due east so that at the vernal equinox the great doors can be thrown open at sunrise and the sun-rays passing through the nave will illuminate the high altar.



to Egypt, all laid out in megalithic yards of .829 to .840 meter.*

Professor Borst, who went to England to make a model of Stonehenge to demonstrate to his students how astronomy was practiced before there were telescopes, suggests that the axes of many early Christian churches in Britain are laid out on top of megalithic foundations originally determined by an alignment with stars; he suggests that Canterbury Cathedral was aligned with the equinoctial rising of Betelguese about 2300 B.C.

Borst also shows that the geometric plans of the megalithic monuments were obtained by means of 3–4–5 triangles and other right-angled triangles laid along the axis of stellar observations.

Alfred Watkins, in his *The Old Straight Track,* published in 1920, pointed out that many churches in England were situated on sight lines between beacon points and that ancient man was inclined to travel in a straight line from beacon to beacon. The churches served as relay points.

Watkins suggested that where topographical features were lacking, observation towers were built, and such geodetic points, initially guarded by the surveyor priesthood, remained hallowed spots even after the reason for them had been forgotten. Later arrivals built churches on these spots, as is indicated by Bede who reports that Pope Greg-

* If .840 meter is taken as a megalithic yard, there are exactly 275 such yards in a 231 meter base of the Great Pyramid of Cheops, 220 in the apothem and 175 in the height.

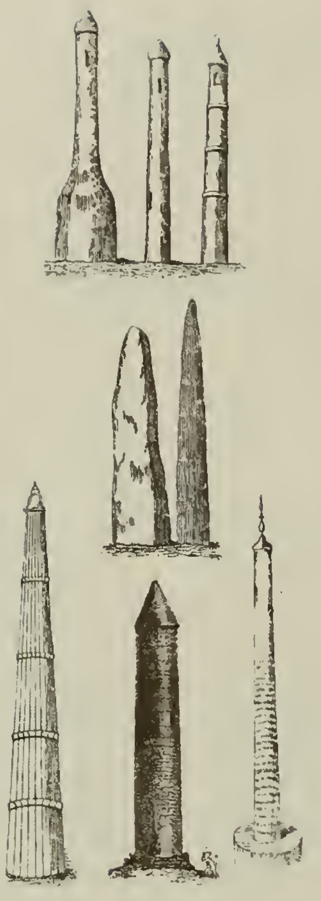
ory I explicitly ordered Bishop Miletus to build churches on pagan shrines.

In the Middle Ages in Ireland, Catholic monks still used tall conical towers with carefully oriented openings at the top to observe the skies and record the passage of the days, months and years by shadows on the walls and floors.

These "Round Towers," as they were called, were fitted for Polaris observations at the north window, for transit observations at the south window, and for noting the moment of the rising and setting of heavenly bodies at the east and west windows. H. G. Wood in his *Ideal Metrology* says that by threads drawn across the openings, like the spider lines in a telescope, the exact position of a star could be noted. The walls being two or three feet thick, the solar shadows of the jamb and lintel cast upon the floor within would show the hour of day and the time of the year. Every month could have its transit floor-mark.

Similar structures have been found in France. In a booklet oddly entitled *Falicon,* privately printed in 1970, the author Maurice Guignaud, a French artist and ceramist, describes a small pyramid in the south of France built in the thirteenth century by Knights Templar on their return from the Middle East.

Guignaud observed that at solar noon of the autumn equinox of September 21, 1969 (which in that region occurs at 12:53 P.M.) the pyramid projected no shadow on the ground around it. Guignaud also noted that a raised area in the doorway caused the sun to cast a shadow that precisely split the end of the entranceway.



Examples of Irish and other round towers.

There are remains of some 120 observation towers in Ireland, twenty of them still in good condition, ranging in height from 60 to 132 feet. The tower at Killcullen is the highest.

Built near churches between the eighth and thirteenth centuries, the towers have door and window jambs that are narrow like the doors of ancient Egyptian temples, which served to measure the shadow of the sun in its daily and seasonal movements.

At the equinox Guignaud measured the shadow of a meter stick held vertical at noon and found it to be exactly one meter long, whereas on June 21 it cast a shadow of .80 meter and on December 22 a shadow of 2.52 meters.

Guignaud found that this exotic truncated pyramid, which is known by the weird name of *Ratapignata* or "The Bat," was also built directly over two subterranean pits, one almost above the other, and that carved signs on its walls indicated it had been used for astronomical and astrological observation.

According to Cotsworth, the value of ancient astronomical observatories cannot be overestimated. The importance of establishing the exact length of the year so as to know when to plant and when to harvest crops could mean the difference between famine and plenty.

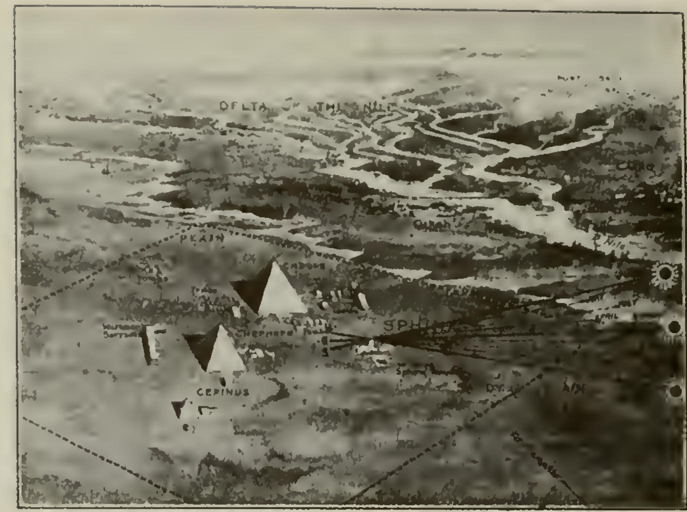
Far from being Professor Barnard's "stupendous monument of folly," the colossal effort employed by the ancients in building the Great Pyramid (or the million-ton mounds of the Britons) would have had a vital effect on the citizenry, redounding to the benefit not only of the builders, but of countless generations to come.

Cotsworth took several more photographs at the Great Pyramid to illustrate his thesis, but most of these were stolen from his carriage and irretrievably lost. This particular photograph, taken in 1900 by a third party, shows Cotsworth seated on a camel with the Sphinx and the Great Pyramid as a background. The white-whiskered Arab at the extreme right is none other than the indefatigable Ali Gabri, now over seventy, who added Cotsworth to the list of Great Pyramid explorers he guided round Giza since the time of Caviglia and Howard-Vyse in the 1830s.

Archeologists give varying opinions as to the age of the Sphinx. Petrie considered it possibly prehistoric. Budge refutes its being prehistoric. Most Egyptologists assign it to Kephren's reign in the Fourth Dynasty.

The Sphinx faces due east, which indicated to Cotsworth that it was used as a sighting device by priests who could stand on the flat platform of its rump and sight the rising sun in a direct line to the horizon marked by the point of the asp on the crown on the Sphinx. Cotsworth also found a series of ancient lines fanning out from the neck of the Sphinx which could have served to indicate the point of sunrise at different dates from solstice to equinox.

It has repeatedly taken several hundred men several years to clear the sand from its base and reveal a six-tiered obelisk against its chest (now missing), which Cotsworth believes was used for sighting the midday sun. Each time the base was cleared, windstorms filled it again with sand, indicating that when the Sphinx was originally built the Sahara was almost certainly not a desert.



Lancelot Hogben in *Science for the Citizen* says that "the continuity of careful observations which preceded, and the precision involved in settling the exact length of the year, entitle this achievement to be regarded as one of the half-dozen great cultural feats in the history of mankind."

With the present availability of cheap watches, radio signals and published almanacs, one is likely to underestimate the value to ancient people of a reliable system for telling the day, the season, the year, and, most important in Egypt, where the entire system of agriculture depended on the swamping of the arable land, the forthcoming flooding of the Nile.

For three-quarters of the year the Egyptian peasants would leave their protected villages on the hillsides and move into the flatland with their families, livestock and most of their belongings, to plow, seed and harvest the fields.

When the time came to move their families and belongings back to the hills, they required at least a fortnight's warning lest they linger too long and be cut off and drowned by the yearly rising of the waters.

According to Cotsworth, all efforts at tracing the number of days in the year by purely seasonal signs would have given imperfect and variable results.

In the early dynasties the flooding of the Nile was said to have been heralded by the annual heliacal rising of Sirius, known to us as the Dog Star. Once a year, with the first glimmer of dawn, Sirius, a bright star of the first magnitude, would appear in the eastern sky and dominate the heavens till its sparkle was eclipsed by the splendor of the risen sun. This stunning phenomenon was taken by the Egyptians as a sign that the Nile would be flooding in about twenty days.

But the flooding of the Nile is governed not by the stars but by the sun melting the snows and the rain falling in the Ethiopian highland sources of the Blue Nile. To have continued to date the flooding by the rising of Sirius would have gradually brought the phenomenon out of phase.

O. Muck, in his *Cheops and the Great Pyramid,* postulates that as a result of a series of disastrous inundations during the reign of Cheops, the Egyptians were obliged to change from a stellar calendar of 365.2563 days to a solar calendar of 365.2422 days, and that the historic Cheops introduced a new calendar by which an extra day was added every four years of 1460 days to account for the differing fraction.*

* According to Muck the new calendar was designed for Cheops not by an Egyptian but by a light-skinned European who brought to Egypt an older, more accurate calendar such as that of Dardanie. Muck says there is archeological evidence that Cheops married a light-eyed, white-skinned European with reddish-blond hair who bore him a blond, blue-eyed daughter whom Cheops gave in marriage to a European known as Didoufri who reformed the calendar and redesigned his pyramid. Other Egyptologists suggest that Cheops' wife, who is represented as a blonde in the Giza tomb of her daughter Meresank III, may be merely wearing a wig. Such divergencies give a slight idea of the general lack of concurrence among historians of Egypt. But there is no doubt that the Egyptians developed two basic calendars, a civil calendar of 365 days, and a sothic calendar one-quarter day longer. The extra quarter day caused the sothic New Year to fall back one full day every four years so that each and every day of the civil calendar coincided with the New Year over a period of 365×4, or 1460 years, until the New Year once more fell on its original July 19. Hence was generated what was known as the sothic cycle of 1460 years.

The double dating of sothic and civil years appears in many Egyptian documents, so that it has been possible to reconstruct the years in which the sothic new year coincided with the original new year and establish that sothic cycles began in A.D. 140, 1320 B.C., 2780 B.C., and 4240 B.C.

Muck and others believe the foundation of the sothic calendar occurred in the 2780 cycle, but Schwaller de Lubicz is convinced from his study of ancient texts and hieroglyphs that the year was 4240. He says that tradition always placed the heliacal rising of Sirius in the constellation of the Lion, and that this was so from 4240 on. The main objection to such an early date is the conviction of Egyptologists that the ancient Egyptians were not yet equipped for such careful astronomical observation.

That the Egyptians handled astronomical cycles of even greater duration is indicated by inscriptions recently found by Soviet archeologists in newly opened graves during the period of their work on the Aswan Dam. Here the cycles appear to cover periods of 35,525 years, which would be the equivalent of 25 cycles of 1461 years. The apparent discrepancy of one year in this recording of cycles is due to the sothic cycle of 1460 years being the equivalent of a civil cycle of 1461 years. According to Muck there were three main cycles: one of $365 \times 4 = 1460$; another of $1460 \times 25 = 36{,}500$; and a third of $36{,}500 \times 5 = 182{,}500$ years.

Dürer's woodcut of the zodiac. In the course of a year the earth makes a 360° circle round the sun. Seen from the earth, the sun appears to move through a circular belt of constellations. These are the stars of the zodiac. For convenience, the zodiac is divided into twelve constellations, so that every month at sunrise a new one appears to the earth viewer in the eastern sky; and every year the sequence is repeated, with a slight precession owing to the earth's wobble on its axis.

Schwaller de Lubicz in his *Le Temple de l'Homme* maintains the pharaonic Egyptians adopted neither the sidereal nor the solar tropical year, but a Sothic year based on the cycle of the fixed star Sirius, which is exactly 365.25 days. According to this archeologist and philosopher, who spent twelve years at Luxor measuring and studying its temples, tombs and hieroglyphs, the mere fact that the Egyptians were able to note that Sirius is the *only* fixed star with an unvaried cycle of 365.25 days denotes an extremely long period of previous careful observation.

From the texts it is clear, says Schwaller de Lubicz, that long after the heliacal rising of Sirius was no longer a visible phenomenon, it continued to be accurately computed by the priests of Heliopolis, who then broadcast their observations to the other temples of Egypt, there being a difference of as much as 4 days between the heliacal rising as noted at Thebes and at Memphis.

Muck suggests that to dramatize the importance of the 1460 cycle the figure was built into the pavement around the Pyramid of Cheops in such a way that a cortege of priests dressed in white could liturgically march round the pyramid rythmically counting out 1460 paces—which were subdivided into 25 inches, and again subdivided by 5.

By coincidence, Muck's pace of 25 inches is the same length as Newton's and Piazzi Smyth's sacred cubit, one hundred of which form the side of an English acre.

One incontestable deduction was drawn by Schwaller de Lubicz from the existence of the sothic calendar and the shifting of the annual festivals of the civil calendar: the ancient Egyptians must have been cognizant of and able to measure the phenomenon known as the precession of the equinoxes.

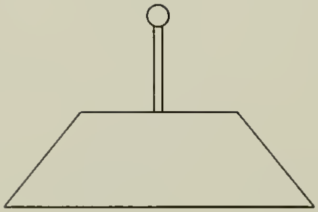
To obtain a simple picture of the precession, an earth observer in the northern hemisphere should be looking due east just before sunrise at the spring equinox. As the dawn tints the sky the observer will see a constellation on the eastern horizon: nowadays it is Pisces. In 2000 B.C. it was Aries. In 4000 B.C. it was Taurus. In A.D. 2300 it will be Aquarius.

The entire circle of the zodiac appears to be slipping back in relation to the sunrise at the equinox, at the slow rate of about 1 degree in 72 years; 30°, or one constellation, in 2160 years; and 360° in 25,920 years.

This *pre*cession of the equinox is said to have been discovered by Hipparchus in the second century. But a number of ancient representations of the zodiac bear the note: "The Bull marks the beginning of spring." This has been interpreted to indicate that astronomical observations of the constellations at the equinox were being made at least as early as 4000 B.C.

The phenomenon of the precession was not explained till Newton postulated that the earth's tilted axis was wobbling as it spun, causing the celestial pole of the earth's axis to draw a slow circle in the heavens around the fixed pole of the solar system, the pole of the ecliptic. To an observer on earth watching the sunrise at the equinox, this slow circling has the effect of making the equinoxes occur about 20 minutes earlier each year in relation to the zodiacal constellations then visible in the sky.

To have figured out the slow rate of the precession of the equinoxes, the ancient Egyptians must have had an appropriate system and equipment. According to Cotsworth, to devise an accurate *star* calendar to record the apparent movement of the stars around the heavens, someone first had to devise a structure that would provide a perfectly oriented meridian for the observation of stars in relation to a fixed point on earth.



According to Muck, to have an accurate *sun* calendar, with which to establish the solstices and equinoxes, someone would have had to build an enormously high obelisk.

Sir Gaston Maspero, director of the Department of Antiquities of the Cairo Museum, found a curious hieroglyph in inscriptions around Saqqara for which he could find no explanation: an obelisk atop a truncated pyramid, with a solar disk balanced on top of it. For Cotsworth he kindly made a drawing of it.

To Cotsworth the similarity of Maes-Howe, the Silbury Hill Maypoles and the obelisks atop a mastaba or unfinished pyramid was inescapable. Only, how did this fit with the Pyramid of Cheops?

XII. ASTRONOMICAL OBSERVATORY

That the Great Pyramid had originally been designed as an astronomical observatory and that it had contained reproductions of the celestial spheres was repeatedly reported by Arab historians; yet none could put forward a sensible solution as to how its steep polished sides could be climbed as an observatory, or its interior passages employed for observations; that is, until the appearance of a book shortly before the turn of the century by the British astronomer Richard A. Proctor, called *The Great Pyramid, Observatory, Tomb, and Temple*. Proctor found a reference in the works of the Roman neo-Platonic philosopher Proclus to the effect that the Pyramid had been used as an observatory *before* its completion. Analyzing the report, which appears in Proclus's commentary on Plato's *Timeaus*, Proctor theorized that the Pyramid might have made an excellent observatory at the time it had reached the summit of the Grand Gallery, which would have given onto a large square platform where the priests could observe and record the movements of the heavenly bodies.

Richard Anthony Proctor.

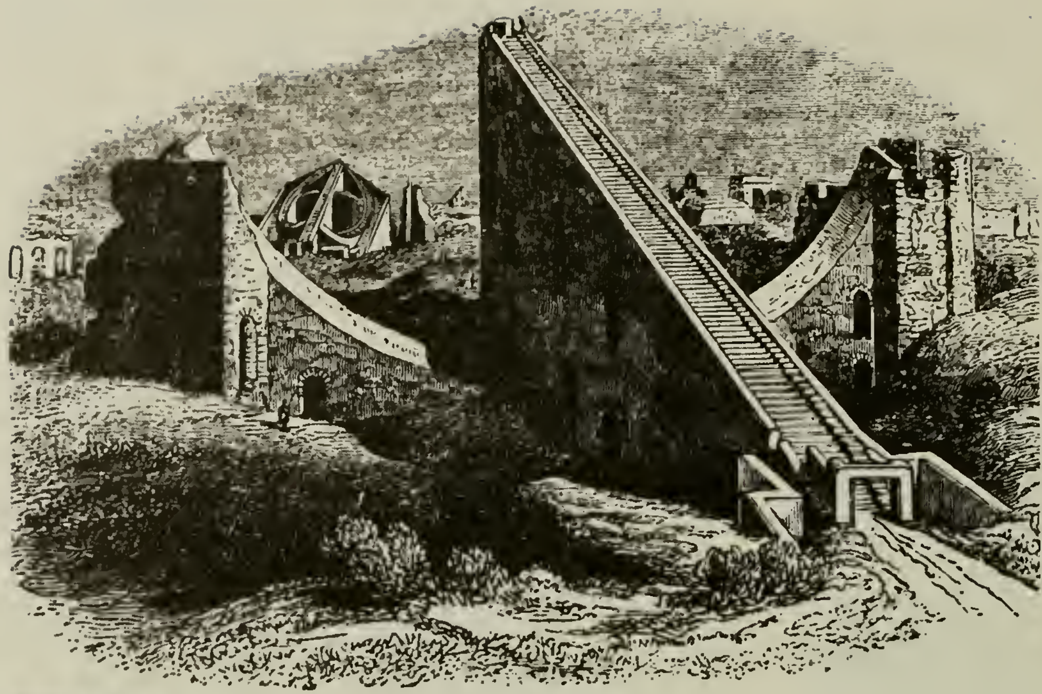
Proctor's theory was so shockingly simple that it was quickly ignored by academic Egyptologists, who were as skeptical of its astronomical value as they were of the value of Stonehenge or the other megalithic observatories scattered about Europe.

In order to create a firm body of astronomical data, the ancients needed a true meridian on the solid earth from which to extrapolate a meridian across the heavenly vault, so as to detect the precise moment when stars, sun, planets and moon transited this meridian in their apparent rotation through the heavens.

In Proctor's analysis the builders of the Great Pyramid had accomplished such a feat by building what he, as a modern astronomer, considered the only sensible instrument short of a great modern telescope.

On the Giza plateau, in the heart of the Great Pyramid, they first built a huge graduated slot, perfectly aligned on the meridian. Through this slot they could observe the apparent movement of the panoply of stars, accurately noting their several transits.

Proctor describes in detail how the ancient architects would have gone about building such an observatory. To



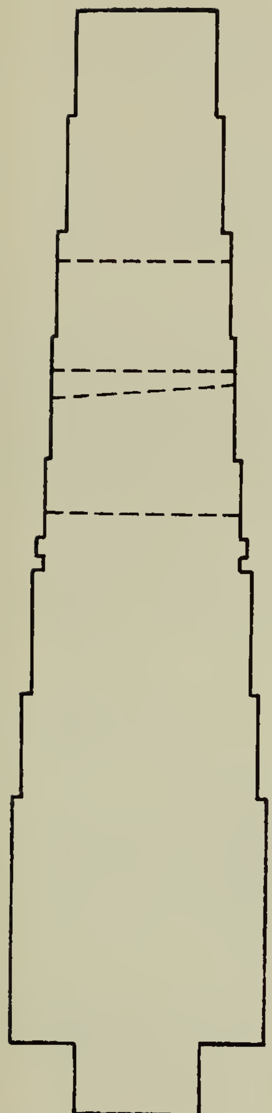
Indian astronomical observatory erected at Delhi by the Maharajah of Jaipur consists of a 56-foot triangular structure which casts a shadow onto an arc of masonry calibrated in hours, minutes and seconds (top).

Another Indian observatory at Benares, known as Yantra, provided fixed angles to check the position of the stars.

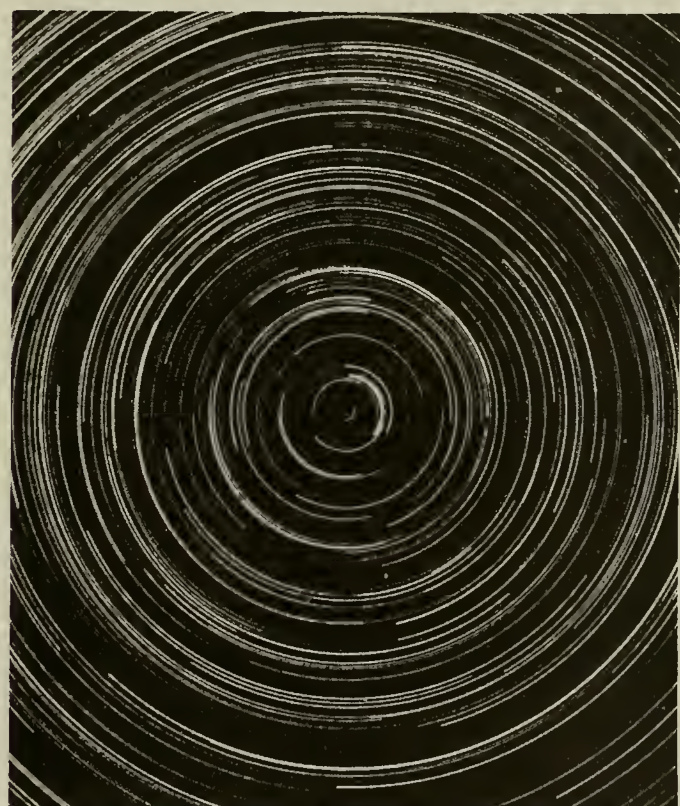
obtain a true north-south line for their terrestrial meridian, they would have observed across the tops of a couple of upright pillars whatever star was closest to the celestial north pole (the point around which the stars appear to wheel in their daily motion), then found the star's culmination, or the top and bottom of its circular path. A line through these two points, which could be measured with an ordinary plumb line, would be true north; and any such northern star would do, as all move in a small circle round the celestial pole.

Following the suggestion of Sir John Herschel, Proctor concluded that it might have been alpha Draconis, which was 3° 43′ from the pole in 2160 B.C. and again in 3440 B.C. The French astronomer A. Poge suggests that the ancients could have used Xi Mizar of the Great Bear any time before 1500; but alpha Draconis fits the rest of Proctor's theory quite adroitly.

The question of the method of orienting the pyramids has been the object of a detailed study by the Egyptologist Zbynek Zaba in a recent monograph for the Czechoslovakian Academy of Sciences entitled *L'orientation astronomique dans l'ancienne Egypte et la précision de l'axe du monde*. Far from considering the pyramids monuments to the



Meridian slot for observing the transit of the stars.



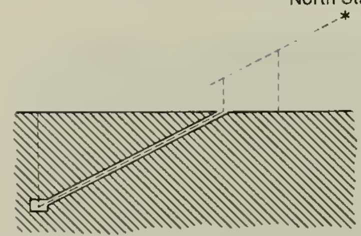
The stars appear to be carried around the pole of the heavens as if they were fixed points in the interior of a hollow revolving sphere. It is therefore possible to determine the position of the pole, even though no bright star actually occupies that point. Any bright star close to the pole revolves in a small circle whose center is the pole.

megalomaniac pride of some theocratic despot, Zaba considers them monuments incorporating the culture, science and technology of the times in which they were built.

The documents adduced by Zaba prove beyond question that the initial operation in erecting an important structure in Egypt was the ceremony of the "stretching of the cord," by which, through the observation of the culmination of some circumpolar star, the north-south direction was determined and marked out on the ground.

An inscription, translated by Johannes Dümichen, describes this royal ceremony: "Looking up at the sky at the course of the rising stars, recognizing the *āk* of the Bull's Thigh Constellation (our Great Bear), I establish the corners of the temple. . . ." "Dümichen says the word *āk* represents the star's culmination as it passes the meridian.*

Having transferred a true meridian from the sky to the ground, the ancient architects, says Proctor, could have begun to consolidate this line by digging it into a descending passage through the live rock, using their polar or circumpolar star to guide the tunnel downward at precisely the angle of its rays.



Proctor's design of how the North Star was sighted along the Descending Passage.

Such a cream-white tube, says Proctor, would have given perfect stability to this fundamental directional line, and the longer the passage the truer its orientation.†

For alpha Draconis, at 3° 43′ from the pole, to have shone directly down a passage at the thirtieth parallel, the passage would have had to be inclined at an angle of 26° 17′—just the angle of the Descending Passage beneath the base of the Great Pyramid.

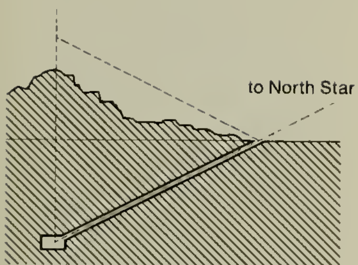
Proctor points out that there would have been no question about the advantage of taking the lower culmination of such a star in preference to its upper one; using the bottom of its circular path as a fixed point would have required far less depth of boring to reach a point directly beneath the center

* The meridian, or great circle through the earth's celestial poles, is the plane in which all the heavenly bodies culminate, or obtain the highest point in their passage midway from the eastern to the western horizon as seen from the earth. Circumpolar stars have a high and a low culminating point on the meridian above and below the celestial pole.

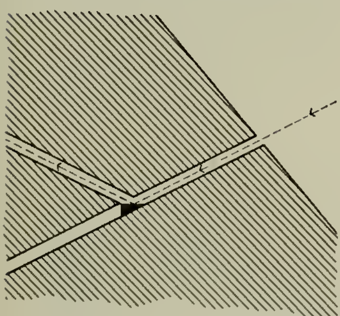
† The advantage of digging such a tunnel is obvious when compared with what would have been needed to achieve the same result aboveground. Someone would have had to hold a plumb line 100 yards high standing at a distance of 200 yards from the observer, who in turn would have had to line up the top of the plumb line with the polar star by night at a slant distance of 260 yards—without benefit of a telescope.

of the proposed building, which was the next object of the operation.

The theory provides an explanation for the quite extraordinary straightness of the walls of the Descending Passage, as measured by Petrie, who was astounded to find a mean variation from a central axis along the entire length of 350 feet of less than 1/4 inch in azimuth—from side to side—and only .1 inch in altitude—up and down. In the part nearest the aperture, which was to be the most important, the exactness is even greater, the mean error amounting to less than 1/50 inch!



How the central point of the Pyramid base could be located by knowing the angle of the Descending Passage.



Reflecting pool at the juncture of the Descending and Ascending Passages.

Once the ancients had measured the length of the Descending Passage and its angle of descent, it would have been simple, by elementary trigonometry, to locate a central spot immediately above the end of the Descending Passage as a center for the proposed pyramid—even if this were on roughly elevated ground.

With a central spot and a true meridian, the architects could set about laying the socket holes for a square base and begin to lay courses on a leveled platform. To obtain true levels, Proctor surmises that the ancient builders used water troughs in conjunction with the light rays from the star.

By continuing the tunneling up through the lower tiers of the growing pyramid, they could maintain a precise orientation for at least the first ten courses, or until the tunnel debouched from the narrowing side of the growing pyramid.

Thereafter their polar star would no longer serve directly, and a new system would be needed to continue the meridian alignment upward in the Pyramid. For this, says Proctor, the builders hit upon the idea of creating an Ascending Passage at precisely the reflecting angle of another 26° 17′. By plugging the Descending Passage and filling it with water, they could reflect the polar star back up an Ascending Passage and continue to keep the passage truly aligned and the building level as it rose another score or more of courses.

For the Descending Passage to have held water, says Proctor, its masonry at the point of juncture would have had to be of hard rock, carefully joined. For no other apparent reason, the stones at this particular point are quite different from the rest of the passage, much harder and smoother and more finely jointed. In fact, the feature escaped observation till 1865.

As Proctor expressed it in his Victorian style: "By using the known properties of liquids combined with the known property of light rays, the ancient builders were able to orient and level a building to a very great height."

But to what purpose? Of a sudden the constricted Ascending Passage changes to an overlapping gallery 28 feet high, in no way essential, or even desirable, to increase or maintain accuracy in orientation for the mounting courses. Yet so extraordinary an architectural design, so carefully executed, must, says Proctor, have served some definite purpose.

Analyzing the problem from the point of view of the astronomer rather than the architect, Proctor came up with an answer. Had an ancient astronomer wished for a large observation slot precisely bisected by a meridian through the north pole, so as to observe the transit of the heavenly bodies, what would he have requested of an architect? A very high slit with vertical walls, says Proctor, preferably narrower at the top, a gallery whose aperture, thanks to the reflected light of the polar star, could be designed so as to be exactly bisected by a true meridian.

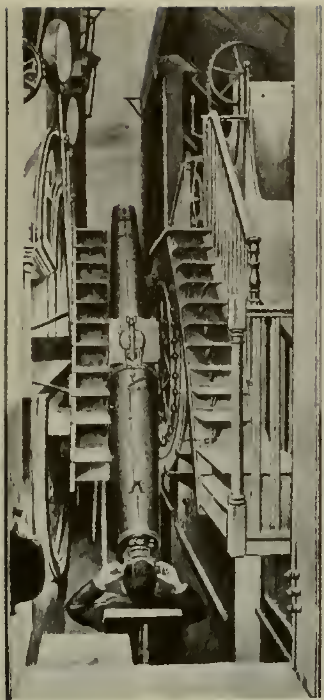
Interior of the Grand Gallery (about one-quarter of its length) showing how it could have been used to observe the stars circling in the southern sky.

Looking up through such a slot, an observer could watch the passage of the entire panoply of the zodiac, easily noting the transit of each star across a perfect meridian—precisely what is done today by the modern astronomer when he sets his transit circle to the vertical meridians. As Proctor points out, such a Grand Gallery might well be described as the *only* very accurate method available for preparing an accurate map of the sky and of the zodiacal cyclorama—before the invention of the telescope in the seventeenth century of our era.

With various observers in the Grand Gallery, placed one above the other on the slanted incline, the southing—or transit across the meridian—of every key star in an arc of about 80° could be observed with remarkable accuracy. As Proctor points out, the most important object of transit observation is to determine the exact moment at which the observed object crosses the meridian. This might have been best accomplished by noting the moment when the star was first seen on the eastern edge of the vertical sky space, and then when it disappeared past the western edge; the instant midway between these two would be the true time of transit.

Proctor surmises that someone in either the Queen's Chamber or on the flat platform of the truncated pyramid above the Grand Gallery could keep time by hourglass or water clock in coordination with the observers in the Gallery, who would signal the beginning or end of transit across the Gallery's field of view.*

* A container with a small hole which drips one drop at regular intervals makes a satisfactory timer. Ancient Chinese astronomers had a system of three such containers in a series to minimize the effect of resistance.



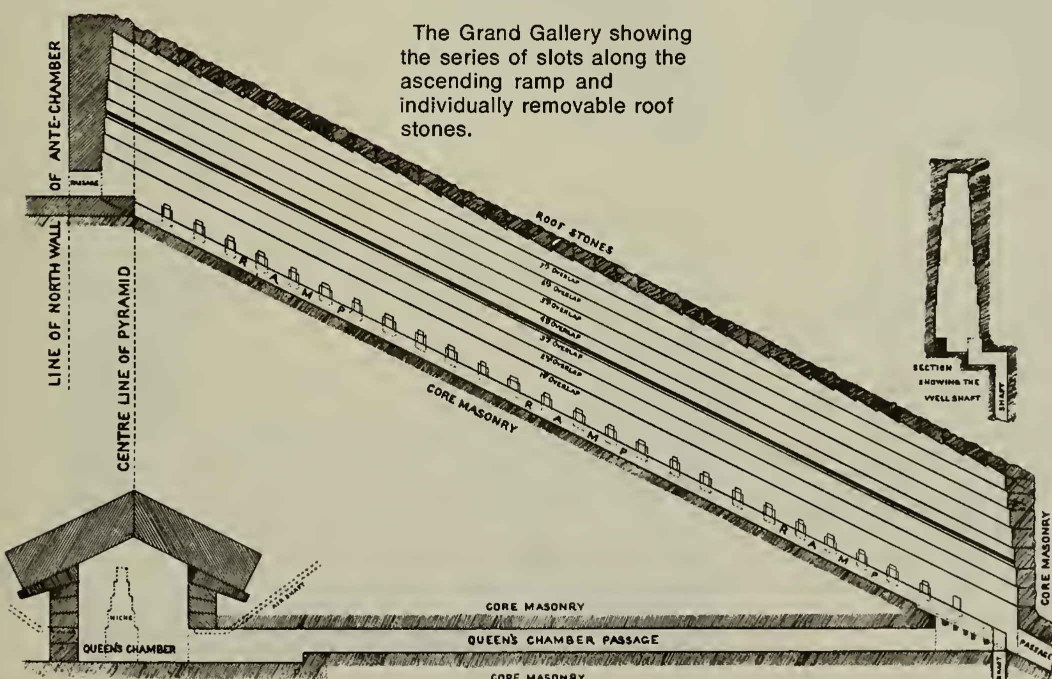
The Transit Circle, Royal Observatory, Greenwich.

By looking down the Descending Passage into a reflecting pool, an ancient astronomer could have noted the exact second of a star's transit, because only at that moment will its rays be reflected. The very same system is used today at the U.S. Naval Observatory in Washington, D.C., where the daily transit of stars is noted to a split second by their reflection in a pool of mercury.

The slope of the Gallery and the corbeling of its walls would also have made it remarkably easy to note the declination of a star—its distance above or below the celestial equator. By combining the observations made by several of what Proctor calls "watchmen of the night," stationed at different levels of the Grand Gallery, a very close approximation of true sidereal time could have been obtained. For such observers to function effectively, cross ramps or reclining benches of some sort would have had to be positioned at different levels of the Gallery.

In support of this theory, there is the series of 27 oblong holes cut vertically along the walls and into the ramps to a depth of 8 or 11 inches. They served to hold some sort of scaffolding across the Gallery. Proctor postulates that there were benches for observers at regular intervals up the Gallery.

The fact that the walls of the Gallery are corbeled like those of the earlier mastabas and of the megalithic observatories, whose top stones could be readily removed, and that each of the roofing stones of the Grand Gallery



The Grand Gallery showing the series of slots along the ascending ramp and individually removable roof stones.

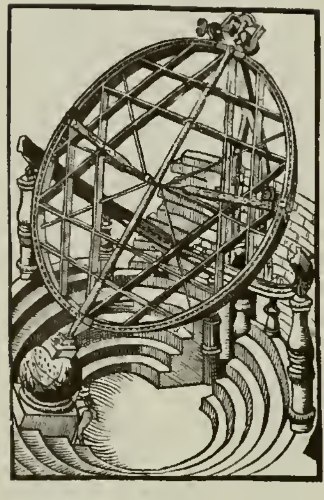
was independently removable (none presses down on its neighbor) may indicate that by the removal of these stones almost as much again of the northern arc of sky could be observed as was visible of the southern sky through the upper end of the Gallery. The movement of particular stars could be pinpointed by the removal of single stones.

Proctor surmises that the method used to determine the declination of a star involved a very practical use of the odd grooves that appear along the walls of the Gallery. At approximately half the height of the Gallery, just above the third overlap on each wall, a narrow groove runs the whole length of the gallery, 6 inches wide and 3/4 inch deep.

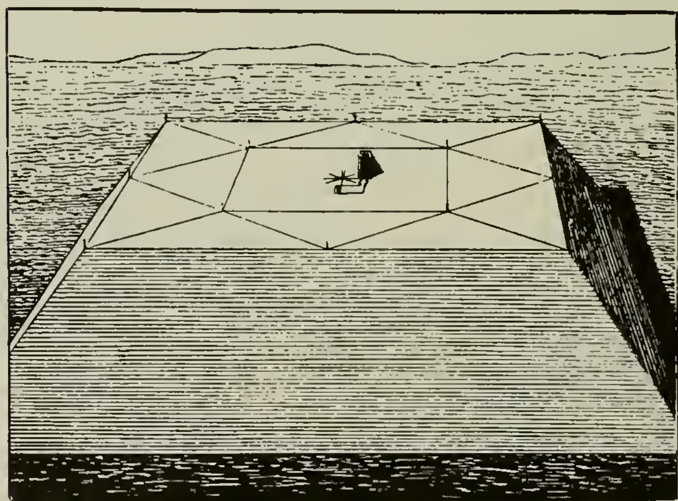
Proctor suggests that horizontal bars carrying vertical rods at suitable distances, perhaps with horizontal lines on them, were held between these grooves, and could be slid to any convenient position. The vertical rods could also have been adjustable.

To locate a star correctly, the transit observers would also have to determine what is called its "right ascension," or distance measured parallel to the equator from a certain assigned starting point on that circle. Knowing the time of transit, it is simple to position the celestial object in its "right ascension."

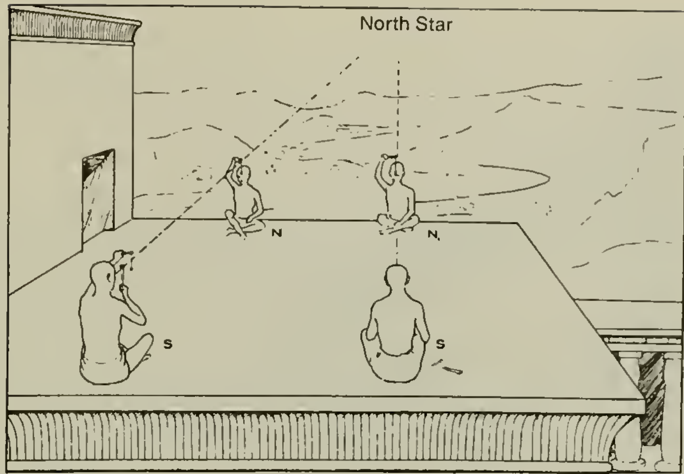
By placing observers not only in the Gallery but outside at the cardinal points of the great truncated pyramid, Proctor says that the entire visible sky could be accurately plotted. The ancient astronomers, says Proctor, would doubtless have made even more observations *off* the meridian, once they had established the meridian observations as their guide marks. They would certainly have made multitudinous observations of the risings and settings of stars at the



Ancient polar astrolabe.



The truncated pyramid, as depicted by Proctor, would have made an observation platform 142 feet high and 175 feet square.
The cardinal points, or compass rose, could have been marked by upright posts on the periphery of the platform. To locate the rising and setting of stars east and west, azimuth observers could occupy the center of the square from which they could command the entire compass.



Ancient method of observing stars with rings and rods.

Equinoctial armillary disk.

horizon, and especially their heliacal risings and settings just before dawn and just after sunset.

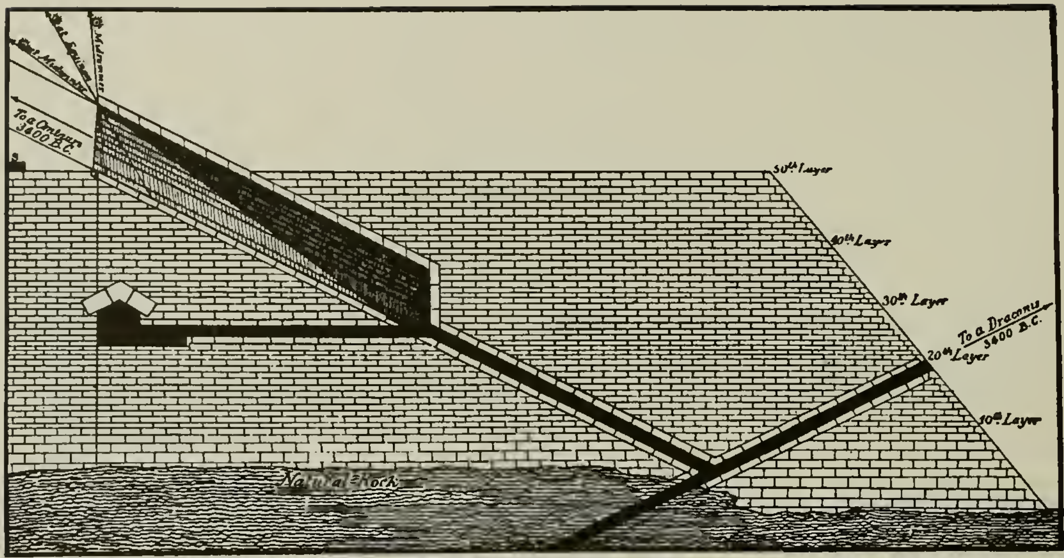
Proctor suggests that there were at least thirteen observers for azimuthal directions around the horizon, whose work could be combined with that of at least seven transit observers at different levels of the Grand Gallery.

The azimuthal observers would be supplied with astrolabes, armillary spheres of reference, direction tubes, or ring-carrying rods. Together with the transit watchers they would be able to make observations which, in Proctor's opinion, would be inferior only to those made in our own time with telescopic adjuncts.

George Sarton, professor of the history of science at Harvard, says the astronomical ability of the early Egyptians "is proved not only by their calendars, tables of star culminations, and tables of star risings, but also by some of their instruments such as ingenious sundials or the combination of a plumb line with a forked rod that enabled them to determine the azimuth of a star."

Proctor adds that for a greater knowledge of the sun's motion, the Grand Gallery slot could have been used to better effect than an obelisk or a sundial by noting the sun's shadow cast by the edges of the upper opening against the walls, sides and floor of the long Gallery. To make observations of the sun more exact, Proctor envisaged the use of screens: by placing an opaque screen at the upper end of the Gallery with a small aperture to receive the sun's light upon a smooth, white surface at right angles to the sun's direction, a much magnified image of the sun would be formed on which any sunspot could hardly have failed to appear. The movement of the spots would have indicated the sun's rotation on its axis.

The moon's monthly path and all its changes could have



Proctor's direction lines show the midday sun at midsummer, midwinter, and the equinoxes as they would strike the Grand Gallery of the Great Pyramid, forming light and shadow marks even more effective than those of obelisks.

He also shows the alignment of alpha Draconis with the Descending Passage, as it was in 3400 B.C. and a line to alpha Centauri, which was then on the meridian, from the Grand Gallery. Proctor believes that through such a sighting tube as the Grand Gallery, alpha Centauri could have been seen transiting in broad daylight.

It is noteworthy that the Grand Gallery debouches at precisely the fiftieth course of masonry, and that at that level the square platform is exactly half the area of the base of the Pyramid.

been dealt with in the same effective way, as indeed the geocentric paths of the planets or their true orbits around the sun: these could have been determined very accurately by combining the use of tubes or ring-carrying rods with the direction lines determined from the Gallery's sides, floor, etc.

Once the diurnal pattern of the stars' apparent rotation past a fixed meridian had become clear to the observers, they could more easily plot the irregular and sometimes apparently retrogressive path of the planets and the moon in relation to the "fixed" stars. The heliocentric pattern of our solar system could well have been extrapolated from a study of the relative motions of these planetary satellites, anticipating Copernicus by several thousand years.

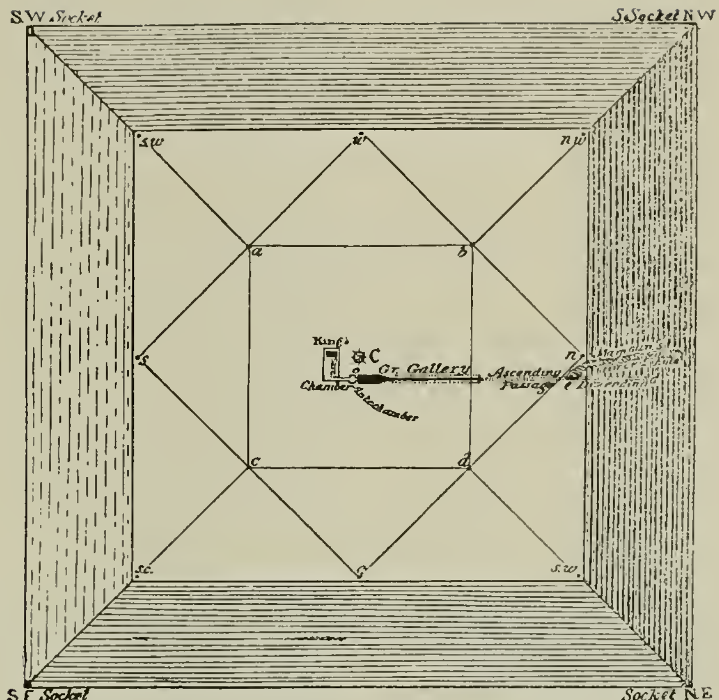
To Proctor, the Great Pyramid thus constructed would have been the greatest observatory and the most perfect till the art of the telescope could reveal a way to more exact observation without the need for such a massive structure.

That the flat top of the truncated pyramid served as the plan for mapping the zodiac is supported by the zodiacal maps of the early astrologers. Even Kepler and Galileo, when making a chart for someone's horoscope, used square charts for their zodiacs, which are the shape of the truncated pyramid.

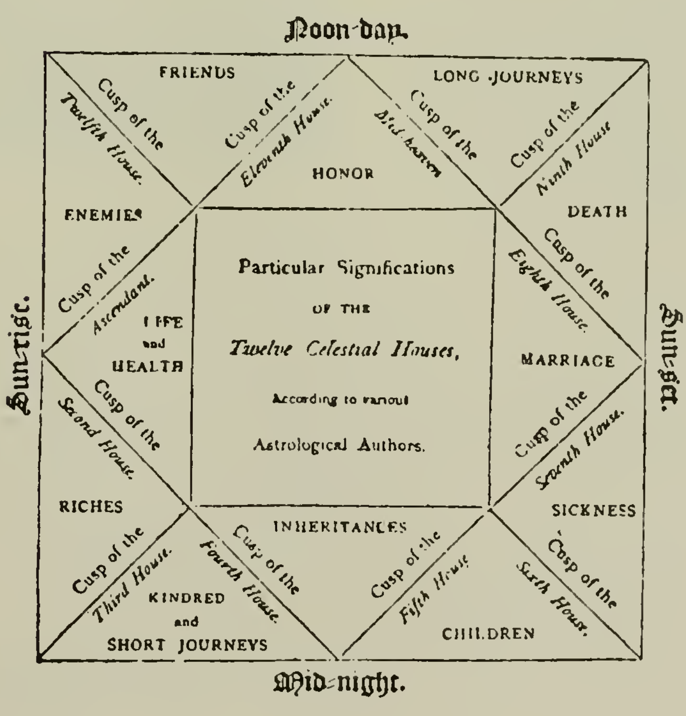
The French mathematician Funk-Hellet even suggests that the 24 holes in the sides of the Grand Gallery once supported, two by two, movable panels with symbolic figurations of the zodiac.

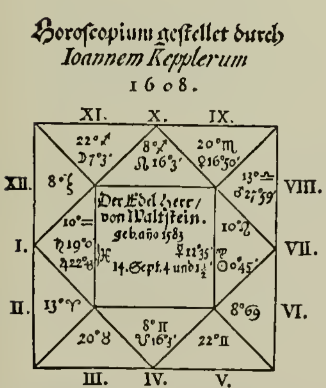
At the end of a few years' observation it would have been obvious to the ancient astronomers at the moment of the

By placing the gallery slightly to the east of the north-south axis of the Pyramid, the ancient astronomers could make their observations from the center of the truncated square, and a gnomon, or shadow pole, could be raised in dead center. That such a square was the prototype for astrological as well as astronomical computations is strikingly illustrated by the format for horoscopes which persisted into the seventeenth century.



The twelve celestial houses of the zodiac according to astrological authors.





Horoscope prepared by Kepler.

equinox that the whole stellar caravan was returning to its original position just a fraction later—hence each year the equinox itself appeared to move forward. By fine observation of the circumpolar stars, the ancient astronomers could have measured the angle of this precession and deduced its rate to be about 1° in 72 years, making a grand cycle of 25,920 years to cover a full circle of 360°.

Proctor's astronomical analysis of the Grand Gallery was discounted by Egyptologists on the grounds that they had no evidence the ancient Egyptians were capable of making accurate astronomical observations. But in 1934 Proctor received strong support from another professional astronomer, Eugene Michel Antoniadi, who was also an Egyptologist, attached to the Egyptian Observatory of Medûm, in a serious work dealing with the various branches of ancient Egyptian astronomy.* Antoniadi agreed that the Great Pyramid had been used as an observatory before the closing of its inner corridors. He also agreed with Proctor's theory of the alignment and use of the Grand Gallery.

Astronomer E. M. Antoniadi added a refinement to Proctor's theory, showing that the ancients might have used a temporary trestle to help start the alignment of the Descending Passage. However, such a trestle would have had to be 300 feet high and 600 feet long, with a slant height of 780 feet, merely to serve a function that could be better performed by digging the Descending Passage directly. It is more likely the builders avoided the scaffold.

Antoniadi figured that the Grand Gallery would have permitted priests to observe 80° of the sky. He says they should have been able to note the declination of all visible stars from —50° below the celestial equator to +30° above it, and that with the use of clepsydras (water clocks) they should have been able to measure hour angles and deduct the right ascension of stars and planets.

These two data are all that is required for constructing a star map or planisphere. "From a star map," says Lancelot Hogben, "it was a very short step to the recognition that the Earth itself could be divided into similar zones with simple relations to the fixed stars—hence the first world maps with latitude and longitude."

* *L'Astronomie égyptienne depuis les temps les plus reculés, jusqu'à la fin de l'époque alexandrine* (Paris, Gauthier-Villars, 1934).

XIII. ASTRONOMICAL TEMPLES OF EGYPT

In his avant-garde book *The Dawn of Astronomy,* written at the turn of the century, Sir Norman Lockyer minutely demonstrated how the Egyptians built and used their temples for astronomical observations from the very remotest antiquity. Lockyer showed how Egyptian solar temples were so arranged that at sunrise or sunset on the longest day of the year, a ray from the sun shot through a skillfully contrived passage into the dark interior of the inner sanctum of the temple. The illumination from the sun was cut off by means of pylon screens so that a concentrated shaft of light cut through the gloom.

Lockyer was the first English astronomer to conclude that Stonehenge had been accurately aligned in about 1680 B.C. to catch the first gleam of the midsummer sun at its solstice, a fact which was recently corroborated on the basis of computerized data by the astronomer Gerald S. Hawkins in *Stonehenge Decoded.*

Both of Lockyer's conclusions were ignored.

The difference between the megalithic and the Egyptian systems lies in the fact that anyone who can set up a circle of well-placed stones with a sighting avenue can note the farthest points north and south on the horizon where the sun rises at the summer and winter solstices; by taking the halfway mark along the semicircle of stones, the day of the equinox, when the sun is due east at the equator, can be geometrically fixed. To obtain a more precise length of the year—to within a matter of hours and minutes—requires a more sophisticated system.

Lockyer—whom Hawkins describes as "an extraordinary man whose true worth as an astronomer and theorizer concerning the history of astronomy has not yet been adequately appraised"—shows how the esthetically incomparable Egyptian temples scattered along the Nile were astronomical instruments designed like a modern telescope aimed at a specific point on the horizon.

Within the Egyptian temples the light of the sun, or other heavenly body, was funneled between two rows of delicately carved columns which ran through a chain of variously dimensioned halls, like the light of a heavenly body being funneled through the gradually narrowing diaphraqms of a telescope.

Temple at Luxor (above) drawn by a member of Napoleon's expedition, showing a row of columns oriented as an astronomical observatory. Temples usually contained a pylon, forecourt, hypostyle hall, and sanctuary.

Astronomical temple at Edfu, later known as Appolonopolis Magna, half buried in the sand as it was found and drawn by Dominique Vivant, one of Napoleon's savants.

Sir Norman Lockyer.

The longer the temple's axis, the longer and narrower the beam, and the greater the accuracy in measuring it. The darker the sanctuary, the more obvious the path of light on the end wall.

The purpose, says Lockyer, was to narrow the beam of light to the point where it could indicate the precise moment of the solstice.

According to Lockyer, a beam of light coming through a narrow passage some 500 yards all the way to a properly oriented sanctuary would remain there no more than a couple of minutes, then pass away. What's more, it would come in a crescendo and go in a diminuendo with an observable peak at the precise solstice.

This would enable the priests to determine the length of the year to within a minute, or four points of decimal—or 365.2422: an otherwise very difficult feat because the sun appears to linger several days around the point of solstice, and its movement of a mere 50″ a day is almost imperceptible without some refined instrumental aid.

Lockyer, who went to Egypt regularly in the summer holidays, found that the sun temple of Amen-Ra at Karnak was built in such a way that at sunset at the summer solstice —the longest day in the year—the sunlight entered the temple and penetrated along the axis to the sanctuary. In Lockyer's words it was "a scientific instrument of very high precision, as by it the length of the year could be determined with the greatest possible accuracy."

Extrapolating backward from the present orientation of the building, and taking into account the small but gradual shift in the tilt of the axis of the earth, Lockyer applied the

(*Overleaf*)

Colonnade to the temple of Amon-Ra at Karnak as it was discovered by members of Napoleon's expedition. Lockyer found that the temple's axis was accurately oriented to the summer solstice and considered it "beyond all question the most majestic ruin in the world."

Reconstruction of the temple of Amon-Ra at Karnak showing how the colonnade was aimed like a telescope toward the sunset of the summer solstice. This romanticized etching was produced by the French savants for the *Description de l'Egypte*.

system he had used for Stonehenge and estimated the temple to have been originally laid out about 3700 B.C.

Lockyer found sun temples oriented to catch the sun at the solstice or equinox, and star temples oriented to frame a star rising on the horizon just before sunrise at the solstice or equinox, so as to give warning of the imminent solar event.

Herodotus describes two pillars of gold and green stone in the temple of Tyre which shone at midnight. According to Lockyer, "there can be little doubt that in the darkened sanctuary of an Egyptian temple the light of Alpha Lyrae, one of the brightest stars in the northern heavens, rising in the clear air of Egypt, would be quite strong enough to throw into an apparent glow such highly reflecting surfaces as those to which Herodotus refers."

Maspero suggests that the priests were not above "pious frauds" accomplished by means of statues which were animated, spoke, moved and acted. For those not in on the secret, the priests may have achieved quite stunning effects by having a large jewel in the breastplate of a statue suddenly and mysteriously sparkle with light.

Lockyer realized that temples oriented to the sun could provide a useful calendar for thousands of years because the tilt of the earth's axis shifts no more than a degree in six or seven thousand years. But temples oriented to stars could function only for a limited 200 or 300 years because each year the rising or setting of stars just before sunrise or after sunset at the solstice or equinox would occur a little later because of the precession of the equinoxes. The stars' lag behind the sun along the circle of the zodiac—a barely noticeable 1/72° each year—could become as much as 3° in 200 years, superannuating the usefulness of the temple. The temple would then need to have its axis reoriented, or another temple would have to be built. "This change of direction," says Lockyer, "is one of the most striking things which have been observed for years past in Egyptian temples."

Luxor, for instance, has four definite, well-marked changes in orientation. Lockyer measured temples at Karnak and found they were changed to match the precessional change of the stars' declination so that the priests could continue to observe it. Pylons were added, more courts were added, the sanctuary was moved eastward, the front of the temple westward.

As Maspero pointed out, "all the Ptolemaic temples and most of the Pharaonic temples have been reconstructed" during the period of their use.

Gunther Martiny, who tabulated the orientation of Assyrian temples for which the dates of foundation can be established

Small stones inserted in the regular masonry indicated a hidden line of orientation for the temple at Luxor.

(the oldest being about 1800 B.C.), found that the orientations also varied according to the angle of the precession of the equinoxes.

Nevertheless, says Lockyer, a temple once oriented to pick up the heliacal rising of a star could be *refitted* at a later time to mark the rising of some other heavenly body.

Lockyer drew up a stellar map with the positions of all the great stars along the sun's zodiacal path for the last 10,000 years, and he named a series of stars which could have been used to herald the solsticial dawn in different temples at different periods. In the course of centuries, according to

Reconstruction of the temple compound at Karnak showing the variation in axis of different buildings and colonnades.

Lockyer, the Egyptians oriented temples to alpha Ursa Major, Capella, Antares, Phact, and alpha Centauri. As early as 6000 B.C. they may have used Dubhe before it became a circumpolar star, and Canopus before 6400 B.C.

Professor Lockyer says that the earliest civilization in Egypt built temples at Annu or Heliopolis oriented to the heliacal rising of northern but noncircumpolar stars at the summer solstice. However, "the Great Pyramids were built by a new invading race representing an advance in astronomical thought" who used northern stars on the meridian and stars rising due east at the equinoxes.

The subsequent break in Egyptian history between the Sixth and the Eleventh Dynasties is associated by Lockyer with conflicts between these and two other races, which ended in a victory of the representatives of the old worship of Annu reinforced by supporters from the south, so that the north-star and south-star cults combined against the equinoctial cult.

Lockyer's deductions about the refurbishing of temples was to rekindle interest in the zodiac of Dendera found by Napoleon's General Desaix, and subsequently dynamited from the ceiling of the temple. It was purloined after a series of incredible adventures, to be sold to Louis XVIII for 150,000 francs and end up on display in the Louvre, where it resides today.

It was clear to Lockyer that there had been two temples of Dendera, one dedicated to Hathor and the other to Isis, both mythological personifications of heavenly bodies. Lockyer says the evidence is overwhelming that these two temples were also horizontal telescopes with the same number of pylons gradually getting narrower toward the holy of holies, so that a beam of horizontal light coming through the central door might pass uninterruptedly into the sanctuary to mark the rising of a celestial body. The columns, says Lockyer, shielded the eye from the sunrise light, so that the rising could be precisely indicated. According to Lockyer the present temples of Dendera were renovated in Ptolemaic times, but were built on much older sites.

The French astronomer Jean Baptiste Biot staked his academic reputation on his analysis of the circular zodiac. He said it represented the skies in Egypt in 700 B.C., and that it had probably been copied from older drawings made on papyrus or stone.

Lockyer confirmed that the Isis temple had been directed at Sirius in 700 B.C., when Sirius rose "cosmically," or in unison with the sun, at the Egyptian new year. But Lockyer quoted an old inscription which described a temple of Hathor at Dendera in the time of Khufu (Cheops) in the Fourth Dynasty (which he dated at 3733 B.C.) "when the star shone into the temple and mingled with the light of her father Ra."

Another inscription in a crypt of the temple indicated it had been built according to the plans of Imhotep, son of Ptah, who was the fabulous architect of the Third Dynasty King Zoser.

In Lockyer's opinion the temple of Dendera may have been rebuilt at least three times since then, once in the reign of King Pepi I (which Lockyer gives as 3233 B.C.), once again by Thothmes III in 1600 B.C., and finally by the Ptolemies about 100 B.C.

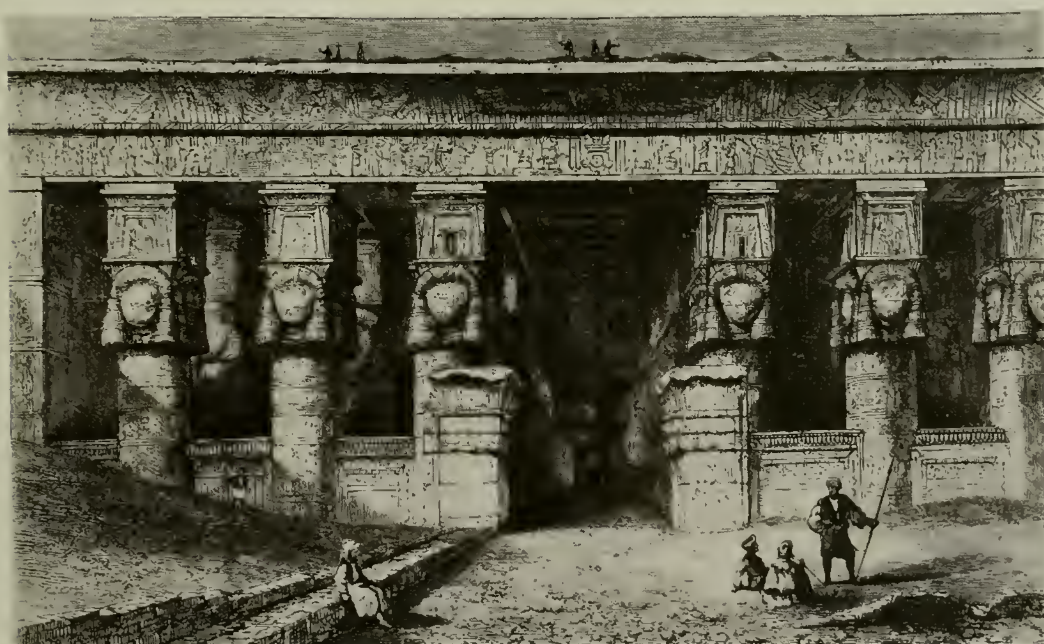
According to Lockyer the temple may previously have been directed at Dubhe, which ceased to be circumpolar about 4000 B.C., and before that at gamma Draconis, which ceased to be circumpolar in about 5000 B.C.

Egyptologists greeted Lockyer's astronomical theory about Egyptian temples with the same reserve they treated his theories about Stonehenge—which a computerized age has now shown to be correct. The Egyptologists objected to Lockyer's dragging in astronomy to straighten out the chronology of history, and dismissed his theory "with good-natured laughter, advising the cobbler to stick to his last"; so *The Dawn of Astronomy* dropped out of sight and became very hard to find, until reprinted in 1964 by Giorgio de Santillana at the Massachusetts Institute of Technology.

At the time of publication only Sir Gaston Maspero was impressed. He spent an Easter holiday at the sea studying Lockyer's theory, and he grudgingly agreed that "except for matters of detail I feel that on the whole your demonstration is conclusive, and in principle you must be correct."

Schwaller de Lubicz now supports Lockyer's conclusion, saying there can be no doubt about the orientation of temples or the fact that the ancient Egyptians understood the precession of the equinoxes, which brought a new constellation into position behind the rising sun at the vernal equinox every 2200 years. The mere fact that the cult of the Bull preceded the cult of the Ram in Egypt, and that the dates of these cults correspond with the equinoctial positions

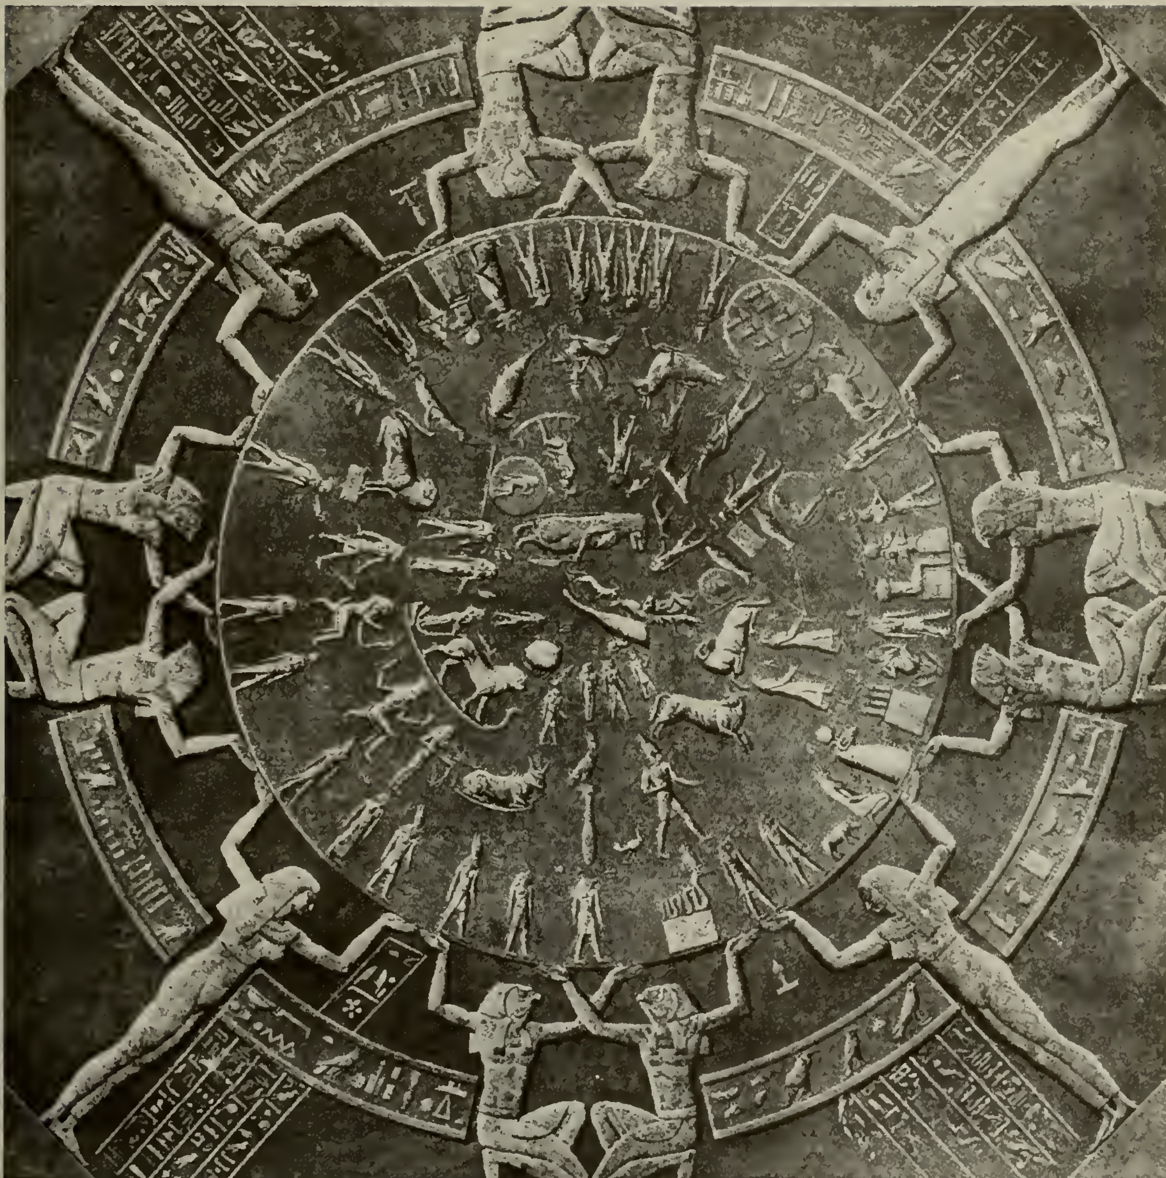
Temple of Hathor at Dendera, as drawn by Denon, showing main axis possibly oriented to gamma Draconis before 5000 B.C., according to Sir Norman Lockyer.



Interior of the temple of Hathor at Dendera as conceived by the French savants.

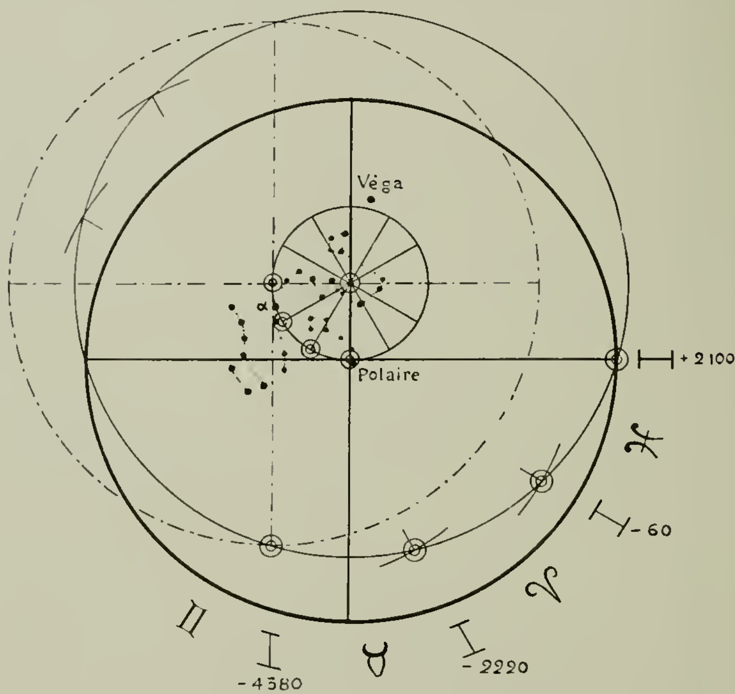
The circular zodiac of Dendera was on the ceiling of an upper room of the temple believed to have been used as an observatory.

The outer circle of figures, moving counterclockwise like the stars, represent the 36 *decans,* or 10-day weeks of the Egyptian year; the twelve arms of the supporting figures, the twelve months of the year.



of their constellations at the appropriate time—approximately 4000 and 2000 B.C.—is conclusive in his opinion. Furthermore, says Schwaller, an emphasis on duality in the Predynastic Period indicates a cult of Gemini coincident with the dominance of that constellation at the vernal equinox.

Schwaller also agrees with Lockyer that the temple of Hathor at Dendera is built on the remains of much older temples. To prove his point he produced a solution to the arrangement of the constellations in the circular zodiac which has been such a problem to archeologists for well over a hundred years. Schwaller shows that the zodiac discovered by General Desaix was indeed carved in Ptolemaic times, but incorporates a palpable demonstration



Zodiac showing the overlap of the circuit of the earth's celestial pole around the pole of the ecliptic, indicating different dates in the past.

of the precession of the equinoxes as well as three important historical dates.

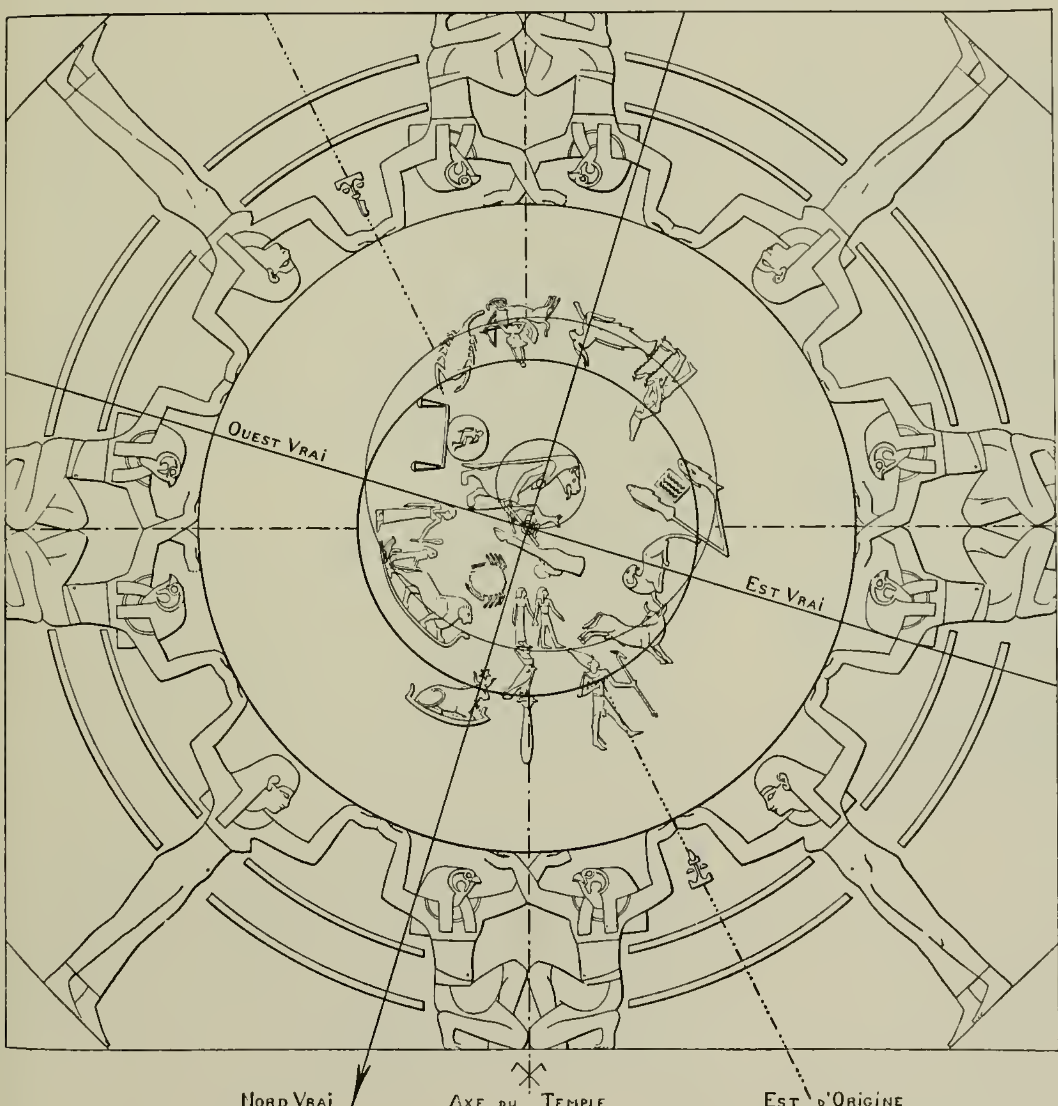
The zodiac is about 8 feet across, carved in relief on hard stone. The constellations are arranged in a spiral and the symbolic figures are marching counterclockwise in the diurnal direction of the stars as seen from the earth. Recognizable mythological figures for the constellations near the pole are a jackal for the Little Bear, an ox-leg for the Great Bear, and a hippopotamus for Drago. Sirius is depicted as a cow in a boat with a star between her horns.

The zodiac is in a circle at the center of which is our

The inner circle of spiraling figures shows the zodiacal constellations such as Gemini (the Twins hand in hand) and Taurus (the Bull) circling around our celestial north pole correctly situated in the Jackal (or Little Bear) which in turn circles around the celestial north pole of the ecliptic, situated in the breast of the Hippopotamus or Drago. Schwaller's lines show that the zodiac of Dendera correctly indicated earlier historical dates when different constellations appeared in the east at the equinox.

north pole. This circle is in a square oriented with the walls of the temple—or about 17° east of north. Our north pole is correctly located in the constellation of the jackal, or Little Bear, as it was at the time when the zodiac was carved, sometime about the first century B.C. But the zodiac also shows the pole of the ecliptic, located in the breast of the hippopotamus, or constellation of Drago.

To Schwaller this explains the spiral formation of the constellations. The mythological figures representing the constellations are entwined in two circles—one around the north pole and one around the pole of the ecliptic. Where these two circles intersect marks the point of the equinox, or due east. The zodiac thus becomes a calendar going back to remote antiquity.



A line due east, which runs between the end of the Ram and the beginning of Pisces, indicates the time when the temple was rebuilt, about 100 B.C. An earlier east line runs right through the Ram, indicating a date about 1600 B.C., at the height of the Amonian domination, during the Twelfth Dynasty.

A special hieroglyph on the ring of the zodiac indicates an equinoctial line running through the end of Gemini and the beginning of Taurus—the date of the founding of the empire of Menes and the beginning of the cult of the Bull and the adoption of the new calendar, sometime in the third or fourth millennium B.C.

In other Egyptian charts of the constellations there appears the figure of a hawk-headed man holding in his outstretched arms a line which ends against the figure of the ox-leg, representing the constellation of the Great Bear.

Hawk-headed man holding a spear (pointing at the Great Bear constellation) indicates the meridian through the pole of the ecliptic, according to Stecchini.

According to Zaba this line held by the hawk-headed man indicates the meridian through our north pole. But Professor Livio Stecchini points out that Zaba did not notice that this line always ends at a very specific position, at times with an arrow point, which divides the seven stars of the Great Bear into four and three. This line, says Stecchini, does not indicate the meridian passing through the north pole, but the meridian passing through the pole of the ecliptic. In Stecchini's opinion, the ancient Egyptians not only understood the precession of the axis of the earth but considered the true meridian the one passing through the pole of the ecliptic of the solar system. Lockyer added that the Babylonians had distinguished the pole of the equator from the pole of the ecliptic, naming the former Bil and the latter Anu.

The evidence leaves little doubt that the ancient Egyptians knew there were two poles in the sky, a north pole, which shifted round a fixed pole, or "open hole" in the heavens; they also knew that this slow circling brought about the precession of the equinoxes. That the phenomenon of the precession was the matrix from which a thousand myths were developed is abundantly illustrated by the work of Giorgio de Santillana and Hertha von Dechend in *Hamlet's Mill.**

There is no doubt in Santillana's mind that the ancient Egyptians were aware of the precession. In his preface to a recent reprint of *The Dawn of Astronomy,* Santillana, then professor of the history and philosophy of science at MIT, remarked that "when a stellar temple is oriented so accurately that it requires several reconstructions at intervals

* Published by Gambit Inc., Boston, 1969.

of a few centuries, which involve each time the rebuilding of its narrow alignment on a star," and "when zodiacs, like that of Dendera, are deliberately depicted in the appearance they would have had centuries before, as if to date the changes," it is not reasonable to suppose the Egyptians were unaware of the precession of the equinoxes.

Santillana was even more forceful in his condemnation of modern archeological scholars who refuse to accept the idea that the phenomenon of the precession was known in Egypt thousands of years before it was *re*discovered by Hipparchus. In *Hamlet's Mill,* Santillana accuses the scholars of having "cultivated a pristine ignorance of astronomical thought, some of them actually ignorant of the precession itself."

The precession was considered the basic mechanism of the universe by the Egyptians, controlling not only astronomical phenomena but all human and biological development.

Since the beginning of history, the spring equinox has moved through Taurus, Aries and Pisces, or almost one-quarter of a whole cycle. Santillana points out that the Copernican system, which for us explains the precession as the wobble of the earth's axis, has stripped the phenomenon of its awesomeness:

"But *if,* as it appeared once, it was the mysteriously ordained behavior of the heavenly sphere, or the cosmos as a whole, then who could escape astrological emotion? For the precession took on an overpowering significance. It became the vast impenetrable pattern of fate itself, with one world-age succeeding another, as the invisible pointer of the equinox slid along the signs, each age bringing with it the rise and downfall of astral configurations and rulerships, with their earthly consequences."

XIV. GEODETIC AND GEOGRAPHIC LANDMARK

The strongest evidence that the ancient Egyptians were capable of accurate astronomical observations comes from the fields of geodesy and geography, sciences whose object is to determine the size and shape of the earth, and to locate landmarks upon it. Until the development of radio and laser beams, coordinates of latitude and longitude with which to locate a spot on this planet could only be obtained by means of accurate astronomical sightings. When a temple or observatory or the remains of a city are found in a geographical location, either of latitude or longitude, or both, specifically related to other established locations, it is clear that its founders must have been able to make the required astronomical observations.

Professor Stecchini—who obtained his doctorate at Harvard in the science of classical mensuration—has now established that the ancient Egyptians not only developed an advanced system of astronomy and mathematics, but an equally advanced system of geography and geodesy.

From ancient hieroglyphs, hitherto neglected, Stecchini has been able to show that from the earliest dynasties in the third millennium B.C., the Egyptians could measure latitude to within a few hundred feet and do almost as well with longitude—a feat which was not repeated on this planet until the eighteenth century of our era.

The ancient texts and hieroglyphs vindicate Jomard in full, and show that at least as early as the unification of Egypt (ca. 2800 B.C.) the ancient Egyptians knew the length of the circumference of the earth very precisely, the length of their country almost to the cubit, and the geographical coordinates of all the main points in their realm from the equator to the Mediterranean. To do so the Egyptians must have been able to make astronomical observations with almost the exactness afforded by the modern telescope and chronometer.

From a twenty-year study of the mathematical and astronomical data contained in the cuneiform tablets of the ancient Sumerians and Babylonians, Stecchini has derived the evidence that astronomical observations of great

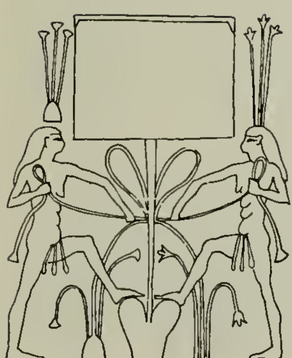
accuracy could be, and were, performed in Mesopotamia as well as Egypt in the third millennium B.C.

From his analysis of the pyramids and stepped ziggurats of the Middle East, Stecchini has demonstrated that they not only incorporate the basic techniques for projecting and mapping the hemisphere of the heavens but for mapping the terrestrial hemisphere; they also reveal a high level of mathematics, capable of resolving and simplifying the problems of trigonometry.

Stecchini points out that Herodotus, who has been ridiculed by scholars for his reported dimensions of Egypt, and accused of having lied about his travels there, turns out to have described ancient Egypt with great accuracy in terms of meridians and parallels carefully worked out by ancient Egyptian astronomers.

Stecchini found a glyph carved on the thrones of virtually all the Pharaohs since the Fourth Dynasty which contained geodetic data and hence astronomical data of extraordinary subtlety, enabling him to determine that the Egyptians used three figures for the tropic of Cancer: a simplified one of 24°, a precise one of 23° 51′, and one of 24° 06′ required for observing the sun's shadow at the summer solstice.

The sophistication of the ancients is demonstrated by the fact that they placed their observatory near Seyne on the island of Elephantine, 15′—or half a diameter of the sun—north of the actual tropic because they understood that it was not the center of the sun but its outer rim which had to be observed.



The most important Egyptian text deciphered by Stecchini was a set of three identical hieroglyphs on the back of standard Egyptian measuring rulers found at the temple of Amon at Thebes, the geodetic center of Egypt since the Middle Kingdom. These, says Stecchini, give the clue to the exact dimensions of ancient Egypt.

Ludwig Borchardt, an eminent German Egyptologist, who first published the texts in an article in *Janus* in Vienna in 1921, assumed *a priori* that the figures could not refer to actual latitudes computed astronomically, and did

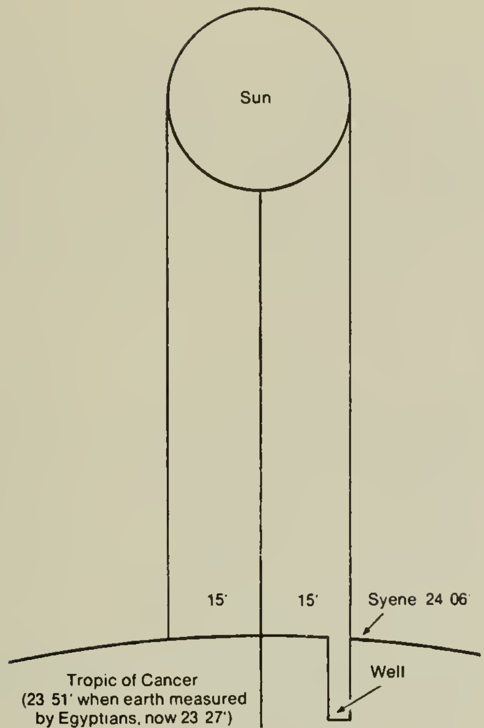
Knotted ropes beneath Pharaoh's throne are used to symbolize the union of Lower and Upper Egypt at the thirtieth parallel, where the apex of the Delta crosses the prime meridian of Egypt, just north of the Great Pyramid.

Three pairs of short horizontal lines at the bottom of the picture are symbols of three distinct values given by the ancient Egyptians to the tropic of Cancer, basic to the geodetic mensuration of Egypt. The central one of these three lines represented the conventional latitude of the tropic at 24°; the lower line represented the actual latitude at 23° 51′; and the upper line a latitude of 24° 6′, which was 15′ north of the true tropic, at Syene, where astronomical observations were made.

not even bother to test them: "One must absolutely exclude the possibility that the ancients may have measured by degrees." Succeeding Egyptologists also failed to compare the texts with actual parallels and meridians. Stecchini found them to apply with astonishing precision.

The texts—which for stylistic reasons have been assigned to the Old Kingdom (third millennium B.C.)—state the length of Egypt to be 20 *atur* from Behdet on the Mediterranean to Pi-Hapy (the apex of the Delta just north of the Pyramid of Cheops) and another 86 *atur* south to the First Cataract of the Nile.

This means that 106 *atur* would span an arc of 7° 30′ from the Mediterranean to Syene. From a composite of texts and geographic evidence an *atur* is the equivalent of 15,000 royal cubits or 17,000 of Jomard's cubits of .4618 meter. This would make Egypt from Behdet at 31° 30′ to Syene at 24° 00′ a length of 1,800,000 of Jomard's cubits, or 831,240 meters. The *Smithsonian Geographical Tables* give the distance from 31° 30′, to 24° 00′ as 831,002 meters. Computing from the third millennium B.C. text, the mean length of a degree of latitude in Egypt would be 110.832 meters. The modern estimate is 110.800 meters.

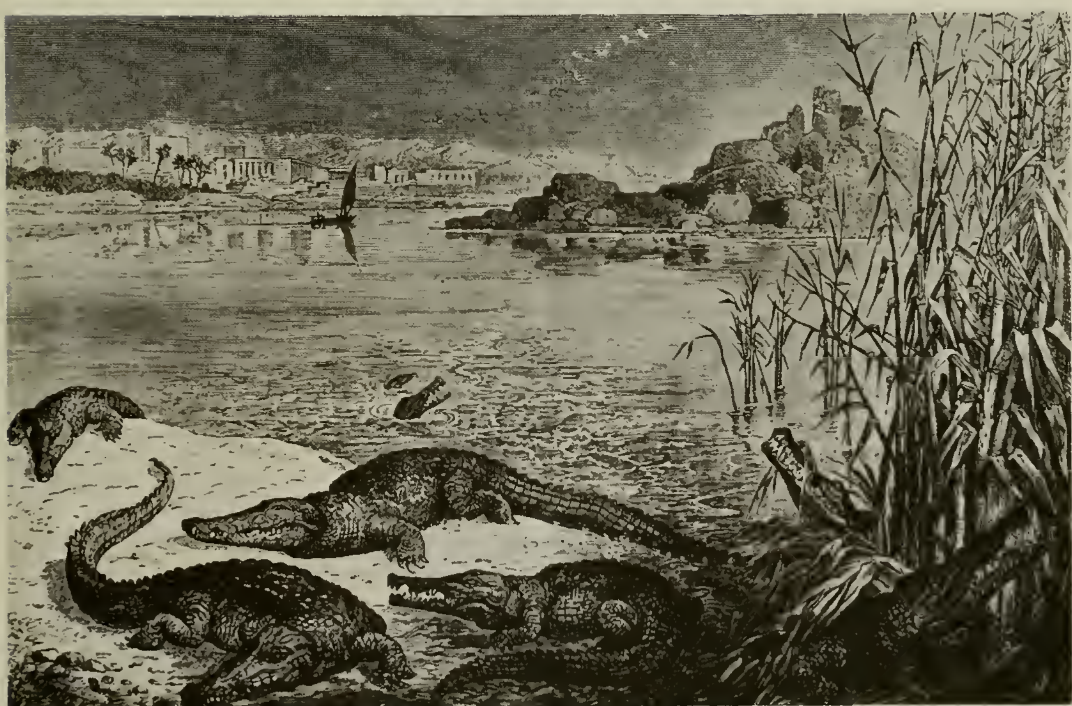


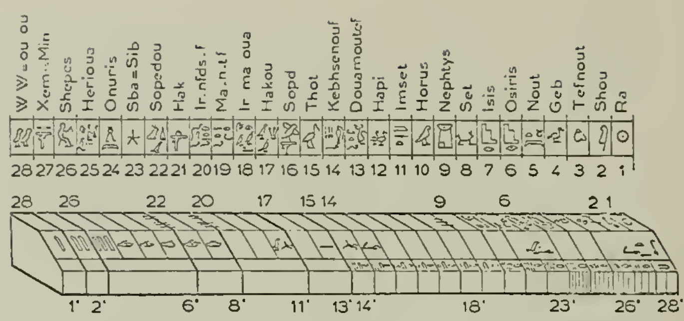
To observe the exact moment the sun fills a well without shadow as it reaches its farthest point north, at the summer solstice, the observation would have to be made under the northern rim of the sun, 15′ further north than the line of the tropic.

When the tropic was at 23° 51′, the ancient Egyptians observed it at Syene at 24° 06′.

Today the tropic is at 23° 27′. By establishing the moment of solstice at the tropic, the ancient astronomers were able correctly to compute the circumference of the earth by the use of deep wells and obelisks.

The island of Elephantine in the Nile near Syene, where the ancient Egyptians had an astronomical observatory and a nilometer to gauge the flood of the Nile.





Royal Egyptian cubit of Memphis. It was divided into 7 palms of 4 fingers each, for a total of 28. The basic unit from which this cubit is derived is the foot of 300 millimeters. One and a half of these feet made a cubit of 450 millimeters, divided into 6 palms of 4 fingers, for a total of 24 fingers. The royal cubit was obtained by the addition of one extra palm, for a total of 7, or 28 fingers, the equivalent of 525 millimeters.

Stecchini points out that a septenary unit was common to Mesopotamia, Egypt and Greece, because it allowed simple solutions to problems of practical measurement. With a π of 22/7, it was simpler to have a septenary cubit; a square of side 7 was considered to have a diagonal of 10, and a square of 10 as having a semi-diagonal of 7.

According to Stecchini, once the Egyptians were in possession of the true proportions of their country, they devised a means of simplifying their geodetic data into a geography that was easily committed to memory without recourse to portable maps, using such obvious natural landmarks as the cataracts on the Nile and the extremities of the Nile Delta as geodetic points for rectangles and triangles with easily remembered angles.

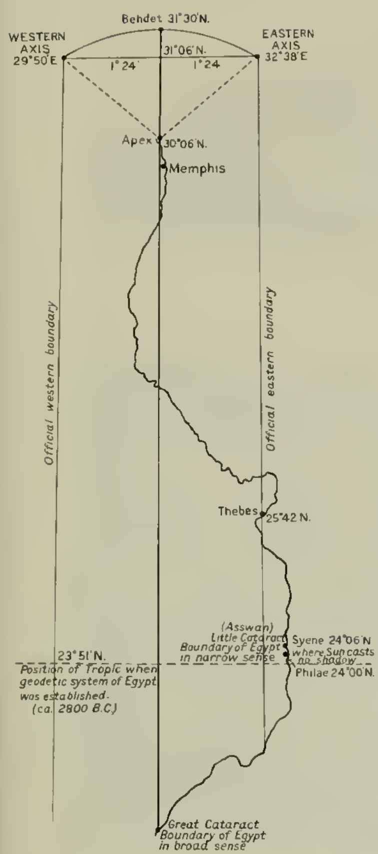
The prime meridian of Egypt was made to split the country longitudinally precisely in half, running from Behdet on the Mediterranean, right through an island in the Nile just northeast of the Great Pyramid, all the way to where it crossed the Nile again at the Second Cataract.*

To simplify the dimensions of Northern Egypt, the Egyptian geographers accurately marked it as a triangle exactly 1° deep, with its apex where the Nile splits (just north of the Pyramid of Cheops), fanning out 1° 24′ east and west to where its widest branches flow into the sea. This became an actual Δ-shaped delta, whose angles were designated by the shadows cast by the northeast and northwest corners of the Great Pyramid.

Southern Egypt was made to run precisely 6° to the First Cataract of Aswan on the tropic of Cancer. Two lines drawn parallel to the prime meridian, starting at the side mouths of the Nile in the Delta, running to the tropic, made a simple rectangle of Lower and Upper Egypt.

Stecchini says that when this particular geodetic system of ancient Egypt was established, the tropic of Cancer was at 23° 51′, which corresponds to a place on the Nile just south of the First Cataract called Parembole in Hellenistic times. On the island of Elephantine—15′ farther north—was the famous "well," whose bottom was said to be completely

* Close to the Mediterranean the meridian may have been marked by a northern pyramid. In 1800 the French Expedition saw the remains of a pyramid near Benha in the Delta, but its superstructure has since disappeared.



illumined once a year when the sun stood directly overhead at the solstice.

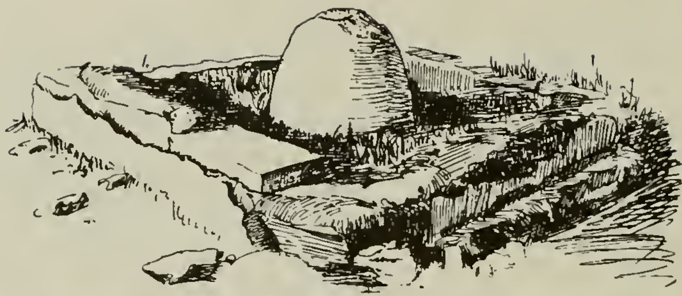
Were it possible to reconstruct exactly when the tropic was at 23° 51′ it would give a firm date for the establishment of the ancient system of geography; unfortunately no astronomer has yet been able to calculate mathematically the exact rate at which the tropic has moved since ancient times to its present 23° 27′. Schwaller de Lubicz figures it was at Elephantine between 2500 and 3000 B.C.

Cities and temples, says Stecchini, were deliberately built at distances in round figures and simple fractions from the tropic or the prime meridian. The predynastic capital of Egypt was set near the mouth of the Nile at Behdet, right on the prime meridian, at 31° 30′. This gave a length to Egypt of 1,800,000 geographic cubits. Memphis, the first capital of united Egypt, was again laid out on the prime meridian and at 29° 51′, precisely 6° north of the tropic. The northern limit of the Two Kingdoms was set at 31° 6′, and the country was measured by a newer unit, the royal cubit, of which there were 1,500,000 in the length of Egypt.

The geodetic point determining the location of Memphis was called Sokar after the god of orientation (whose name and location are preserved in the present village of Saqqara),

The first cataract, near Syene on the Upper Nile, was fabled to have been a land of the deaf because of the constant roaring of the waters over the outcroppings of granite.

This ancient boundary of Southern Egypt was the source of the hard pink granite from which the monolith beams of the King's Chamber were chiseled, as well as the many great obelisks, weighing as much as a thousand tons, which were set up in Egypt as sundials and geodetic markers.



Omphaloi, or "navels," used as geodetic markers.

Geodetic omphalos found by Reisner in the great temple of Amon.

which is exactly on the main axis of the meridian of Egypt, in the necropolis of Memphis.

As each of these geodetic centers was a political as well as a geographical "navel" of the world, an omphalos, or stone navel, was placed there to represent the northern hemisphere from equator to pole, marked out with meridians and parallels, showing the direction and distance of other such navels. In Thebes the stone omphalos was placed in the main room of the temple of Amon, where the meridian and parallel actually cross.

To obtain such precision in their geodesy, says Stecchini, the ancients must have made remarkable astronomical observations.

For the ancient Egyptians to have laid out an absolutely straight meridian of 30° of latitude from the Mediterranean to the equator, over 2000 miles, and drawn two more, equidistant, east and west, as boundaries of the country, must have required an enormous amount of personnel and careful astronomical sightings. Even more sophisticated was their method of establishing longitude, as reconstructed by Stecchini.

With the aid of an elementary system of telegraphy, consisting of a series of beacons, the Egyptians, says Stecchini, were able to note what star was at its zenith at a certain moment, and flash the data, via a string of flares, to other observers so many degrees to east and west.*

H. G. Wood, author of *Ideal Metrology,* assumes that if the Great Pyramid was originally an observatory, signal stations east and west of it once existed which are now in ruins or altogether lost. Wood quotes a Dr. Lieder's description of a little pyramid far to the west in the Libyan desert which could once be seen from the top of the Great Pyramid as the sun went down, but is now lost.

Traveling farther afield, the ancient geographer could establish his longitude with great precision on the basis of accurate tables of the nightly transit of celestial bodies as observed at the Pyramid.†

Fragmented data obtained from such accurate tables, says Stecchini, percolated to the Alexandrine Greeks such as Eratosthenes and Ptolemy, who mixed the accurate data with the inaccurately estimated coordinates of their own period, creating a hodgepodge of good and bad geography. It was not possible to disentangle and correct their work until the development of the chronometer in the eighteenth century of our era.

Because of the advanced geodetic and geographic science of the Egyptians, Egypt became the geodetic center of the known world. Other countries located their shrines and capital cities in terms of the Egyptian meridian "zero," including such capitals as Nimrod, Sardis, Susa, Persepolis, and, apparently, even the ancient Chinese capital of An-Yang.

All of these localities, says Stecchini, were set and oriented on the basis of the most exact sightings. The same applies to the centers of worship of the Jews, the Greeks, and the Arabs.

According to Hebrew historians the original Jewish center of worship was not Jerusalem, but Mount Gerizim, a strictly geodetic point 4° east of the main axis of Egypt. It was only moved to Jerusalem after 980 B.C.

The two great oracular centers of Greece—Delphi and Dodona—were also geodetic markers according to Stecchini.

* Fires such as were lighted by the Druids at the moment of the midsummer solstice may have been the origin of the "midsummer fires" and the Beltane fires of May Day, described in *The Golden Bough.*

† Because every observable star comes to the meridian of every place on the globe once in 24 hours, the interval which elapses between the same star coming upon the meridian of two different places is the difference in longitude of the two places.

Delphi is 7° and Dodona 8° north of Behdet, the northernmost part of Egypt, on the prime meridian of Egypt.

The Moselm shrine of Mecca is 10° east of the western meridian of Egypt and 10° south of Behdet. According to Stecchini the sacred black stone of the Kaaba was originally part of a set of four, placed in what he calls a pyramidical triangle from which the trigonometric functions of the shrine could be derived.

Islamic tradition stresses the point that the Kaaba was originally a geodetic center. The essential element of the Kaaba consisted of four stones marking a square with diagonals running north-south and east-west. The diagonal north-south with the northeast and southeast sides formed what the Egyptians called a pyramid. The angle formed by the diagonal with the southeast side was 36°, from which Stecchini concludes that the trigonometric functions of the shrine were measured along the northeast side.

The northwest side of the building of the Kaaba is completed by a semicircular wall: according to tradition this semicircular wall existed since the very beginning. Most likely, this was used, says Stecchini, as a sighting device.

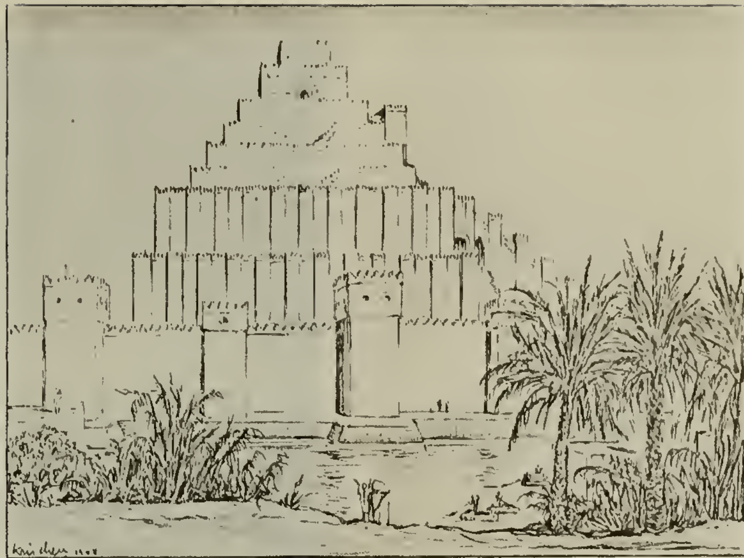
To make a map projection of the northern hemisphere, the ancient Egyptians found a simple mathematical and geometrical means of reducing the curved surface of the globe to a flat surface suitable for mapping, and with a minimum of distortion: they used the stepped pyramid, or ziggurat, each face of which could represent a 90° quadrant of the hemisphere, and each level of which could represent a mappable zone between two parallels of latitude.

Professor Maspero describes the ziggurats of Mesopotamia as "miniature reproductions of the arrangement of the universe." Professor C. P. S. Menon in his *Early Astronomy and Cosmology* says of the ziggurats: "We can deduce that the shape of the Earth, which appears to have served as a model for the temples, was a terraced pyramid with corners pointing to the South, West, North and East."

Ziggurats at Ur, Uruk, and Babylon reached a height of three hundred feet. The ziggurat of Nabu at Barsipki was called the "House of the Seven Bonds of Heaven and Earth" and was in seven stages said to have been painted in seven "Planetary colors."

The sophistication of the ancients, says Stecchini, is illustrated by the ziggurats of Babylon. These stepped "Towers of Babel," long a mystery to mankind, turn out to incorporate a series of Mercator projections, several thousand years before the advent of the Flemish cartographer.

For the purpose of mapping, the northern hemisphere was reduced to a series of flat surfaces represented by the



Reconstruction of Babylonian stepped pyramid or ziggurat. According to H. G. Wood, the ziggurat of Jupiter Belus at Babylon had an ideal basis in the number 360. In his *Ideal Metrology* it is described as a seven-staged pyramid in which each of the six upper stages is 360 inches shorter than the one next below it; the base side was 3,600 inches, and the total height of the structure was 3,600 inches. According to Wood, the entire system of ancient Babylonian metrology appears to have been derived from 360 × 360 × 100, or 12,960,000.

faces of the stepped ziggurat. The area between the equator and the pole was divided into seven bands or "zones" as the Greeks called them, each diminishing in width to correspond to the shrinking degree of longitude. The base line represented the equator, the first step the thirtieth parallel. Thus, each façade represented a 90° quadrant of hemisphere.

Stecchini says the limits of these four quadrants were established with great precision. Egyptian texts, Greek mythology (including the *Argonautica* and the *Odyssey*), and Greek and Roman writers from Herodotus onward unanimously agree in setting this western limit of the Mediterranean quadrant at 9° 54′ East. Another limit, says Stecchini, was known as the Golden Chersonnesos, that is to say, the peninsula of Malaya at meridian 99° 54′ East at a point where the equator cuts the western coast of the island of Sumatra.

Cuneiform tablets indicate that each level of the ziggurats had a specific area corresponding to standard units of land measure.

Nineteenth-century authors illustrated the ziggurats as astronomical observatories, with bearded Babylonians gazing from the battlements; but John Taylor maintained that such high terraces afforded no better vantage than the ground.

On the other hand, a square or tubular shaft of several hundred cubits, built into their interiors, would have made first-rate telescopes for observing the skies. In Mexico the Pyramid of Xochicalco near Cuernavaca contains a tubular well down which the sun shines perpendicularly without a shadow on a specific day of the year.

Nineteenth-century idea of Babylonian astronomers atop a ziggurat, published by the French astronomer Camille Flammarion.

Sir John Herschel pointed out that "from the bottom of deep narrow pits, such as a well, or the shaft of a mine, such bright stars as pass the zenith may even be discerned by the naked eye."

John Taylor indicated the reference in Ezekiel (XXIX: 10 and XXX: 6) to a "Tower of Syene," suggesting that perhaps the famous well at Syene was inside a sighting tower.

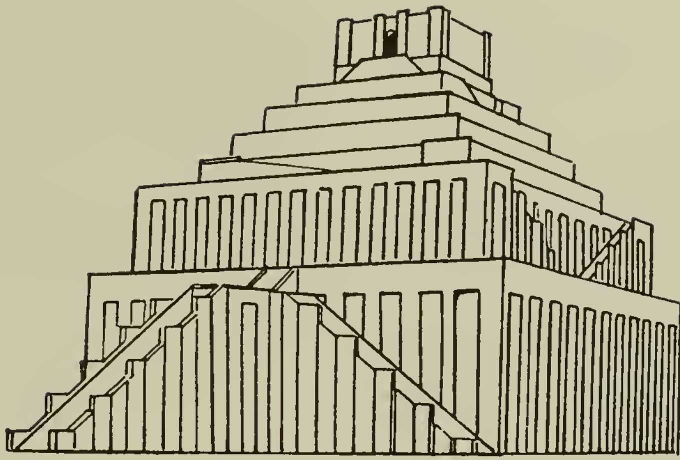
Reconstructing the ziggurat of Babylon on the basis of the cuneiform text known as the Smith tablet, Stecchini established that it rose in seven diminishing steps, each face of which was smaller than the one below it. For mapping, this allows meridians to cross the parallels at right angles, as in Mercator's projection, but avoids his distortion by shrinking each rectangular face in proportion to the shrinking degree of longitude as it approached the pole.

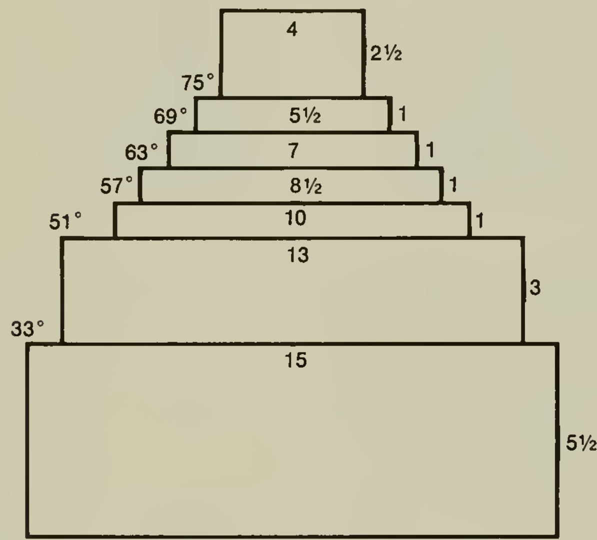
The ziggurat of Babylon, says Stecchini, would have been perfect trigonometrically if the height of the first three steps had been as originally conceived: 30, 48 and 55 1/2 degrees. But the Babylonians raised the first step to 33°, the approximate parallel of Babylon.

The cuneiform description of the ziggurat, known as the Smith tablet, specifically indicates that each level of the ziggurat has an area corresponding to standard units of land surface. Particularly important in Mesopotamian land surveying was the square with a side of 60 double cubits—the surface of the third step.

The slope angles at various heights also give important angles, such as $\sqrt{5} - 1$, which is also incorporated into the Great Pyramid. Such triangles, and the number $\sqrt{5} - 1$ (in common practice taken as the magic series 1–2–3) were fundamental in the operations of land surveying.

The third, fourth and fifth steps of the ziggurat make triangles with sides related as the Pythagorean 3–4–5 triangle.





In the original design, says Stecchini, the first step of the ziggurat was intended to represent the thirtieth parallel, but in Mesopotamia it was raised to 33°, the approximate latitude of Babylon. Thereafter the Babylonians made each step rise in units of 6° of latitude. This made it possible for them to obtain an easily remembered cosine value for each step by simply dividing its length by two thirds.

As the Babylonians liked to count by sixes, with a hexagesimal ana sexagesimal system, the steps of the ziggurat rose in multiples of 6°. Further to simplify their accounting, the degree of parallel represented by each step could be obtained by multiplying the height of each step by 6; e.g., $6 \times 5\ 1/2$ (first step) $= 33°$.

The system gave the Babylonians an extremely simple way of remembering the trigonometric value of each parallel.

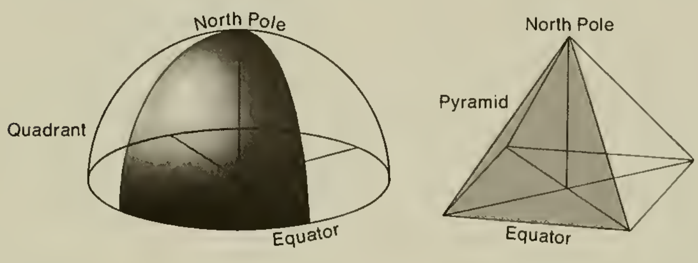
All they had to do was divide the length of each step by .666 (or 2/3). Thus, 2/3 of 15 (width of first step) is 10.000, which is the cosine value of the equator. Thereafter the operation produced a simple progression: 8.666, 6.666, 4.666, 3.666, 2.666 for the cosine value of the angles indicated by each step.

The top step, says Stecchini, was rectangular instead of square, because the average of its sides gives 2.5833, which is the cosine of 75° 01′.

XV. THE GOLDEN SECTION

In the Great Pyramid the Egyptians produced a system of map projection even more sophisticated than the one incorporated in the ziggurats.

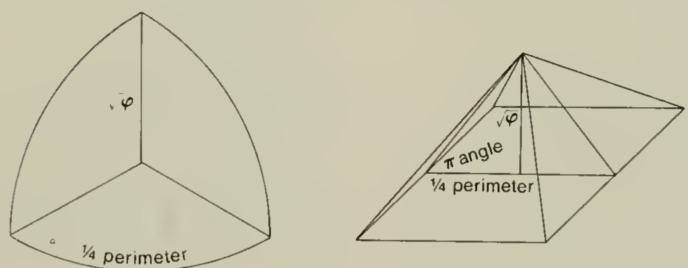
The apex of the Pyramid corresponds to the pole, the perimeter to the equator, both in proper scale. This fact was inherent in Jomard's conclusions, but got lost in the babble of cubits.



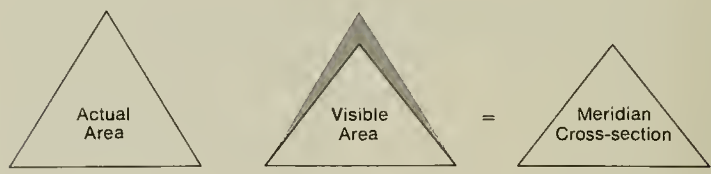
Each flat face of the Pyramid was designed to represent one curved quarter of the northern hemisphere, or spherical quadrant of 90°.

To project a spherical quadrant onto a flat triangle correctly, the arc, or base, of the quadrant must be the same length as the base of the triangle, and both must have the same height. This happens to be the case *only* with a cross section or meridian bisection of the Great Pyramid, whose slope angle gives the π relation between height and base.

John Taylor intuitively suspected something of the sort, but was unable fully to formulate it.

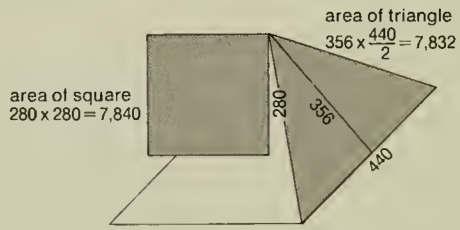


The subtlety of the Pyramid's projection lies in the fact that when viewed from the side, the laws of perspective reduce the actual area of a face (mathematically oversized) to the correct size for the projection, which is the Pyramid's *cross section.*



What the viewer saw, and sees, with the aid of perspective is the correct triangle.

The key to the geometrical and mathematical secret of the Pyramid, so long a puzzle to mankind, was actually handed to Herodotus by the temple priests when they informed him that the Pyramid was designed in such a way that the area of each of its faces was equal to the square of its height.



This interesting observation reveals that the Pyramid was designed to incorporate not only the π proportion but another and even more useful constant proportion, known in the Renaissance as the Golden Section, designated in modern times by the Greek letter φ (pronounced *phi*), or 1.618.*

φ, like π, cannot be worked out arithmetically; but it can easily be obtained with nothing more than a compass and a straightedge.

With the incorporation of the Golden Section, the Great Pyramid provides an effective system for translating spherical areas into flat ones.

Anyone who is not anxious to follow the simplified mathematics in this chapter may more simply skip to the following chapter—which contains the answer to the riddle. But he will miss some odd conceits about the relation of

* If the 356 cubits of the Pyramid's apothem are divided by half the base, or 220 cubits, the result is 89/55, or 1.618.

mathematics to the cosmos and to the creative function of life as embodied in the science of the builders of the Pyramid. The pharaonic Egyptians, says Schwaller de Lubicz, considered φ not as a number, but as a symbol of the creative function, or of reproduction in an endless series: to them it represented "the fire of life, the male action of sperm, the *logos* of the gospel of St. John."

The Golden Section, or φ, is obtained by dividing a line

at a point C

in such a way that the whole line

is longer than the first part

in the same proportion as the first part

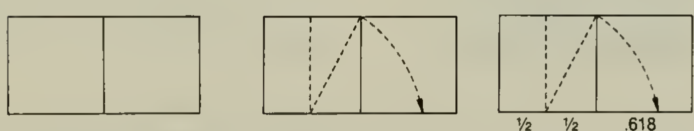
is longer than the remainder.

This will mean that $\frac{AB}{AC} = \frac{AC}{CB} = 1.618$.

This equation, which appears so simple, turns out to be loaded with meaning. Plato in his *Timaeus* went so far as to consider it, and the resulting Golden Section proportion, the most binding of all mathematical relations, and makes it the key to the physics of the cosmos.

In the Great Pyramid the rectangular floor of the King's Chamber (which consists of two equal squares, or a 1×2 rectangle) also serves to illustrate and to obtain the Golden Section.

If you split one of two squares in half and swing the diagonal down to the base, the point where the diagonal touches the base will be φ, or 1.618 in relation to the side of the square, which is 1.*

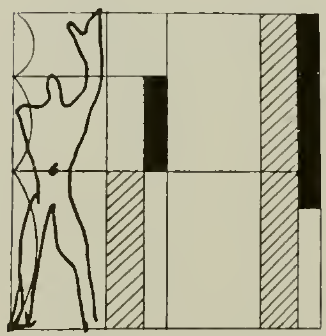


* Pythagoras' theorem will also show that the value of φ will be $1/2 + \sqrt{5/2}$, or 1.618, and that $\varphi - 1$ will be .618.

The odd, if not unique, mathematical fact that $\varphi + 1 = \varphi^2$ and that $1 + 1/\varphi = \varphi$ leads to an additive series, known as a Fibonacci series, in which each new number is the sum of the previous two: 1-2-3-5-8-13-21-34-55-89 . . . etc., and their ratio comes closer and closer to φ.*

In Egypt Fibonacci got wind of the additive series and popularized its mystical quality by bringing to Europe the story of the "rabbit problem," or how to find the number of rabbits born in one year, starting with an original pair. Assuming the rabbits to be enclosed by a wall and that every month they produce a pair of rabbits, and that each new pair in turn produce another pair each month, the answer could be obtained by the additive series 1-2-3-5-8-13-21. . . . In this case it is 377 pairs of rabbits.

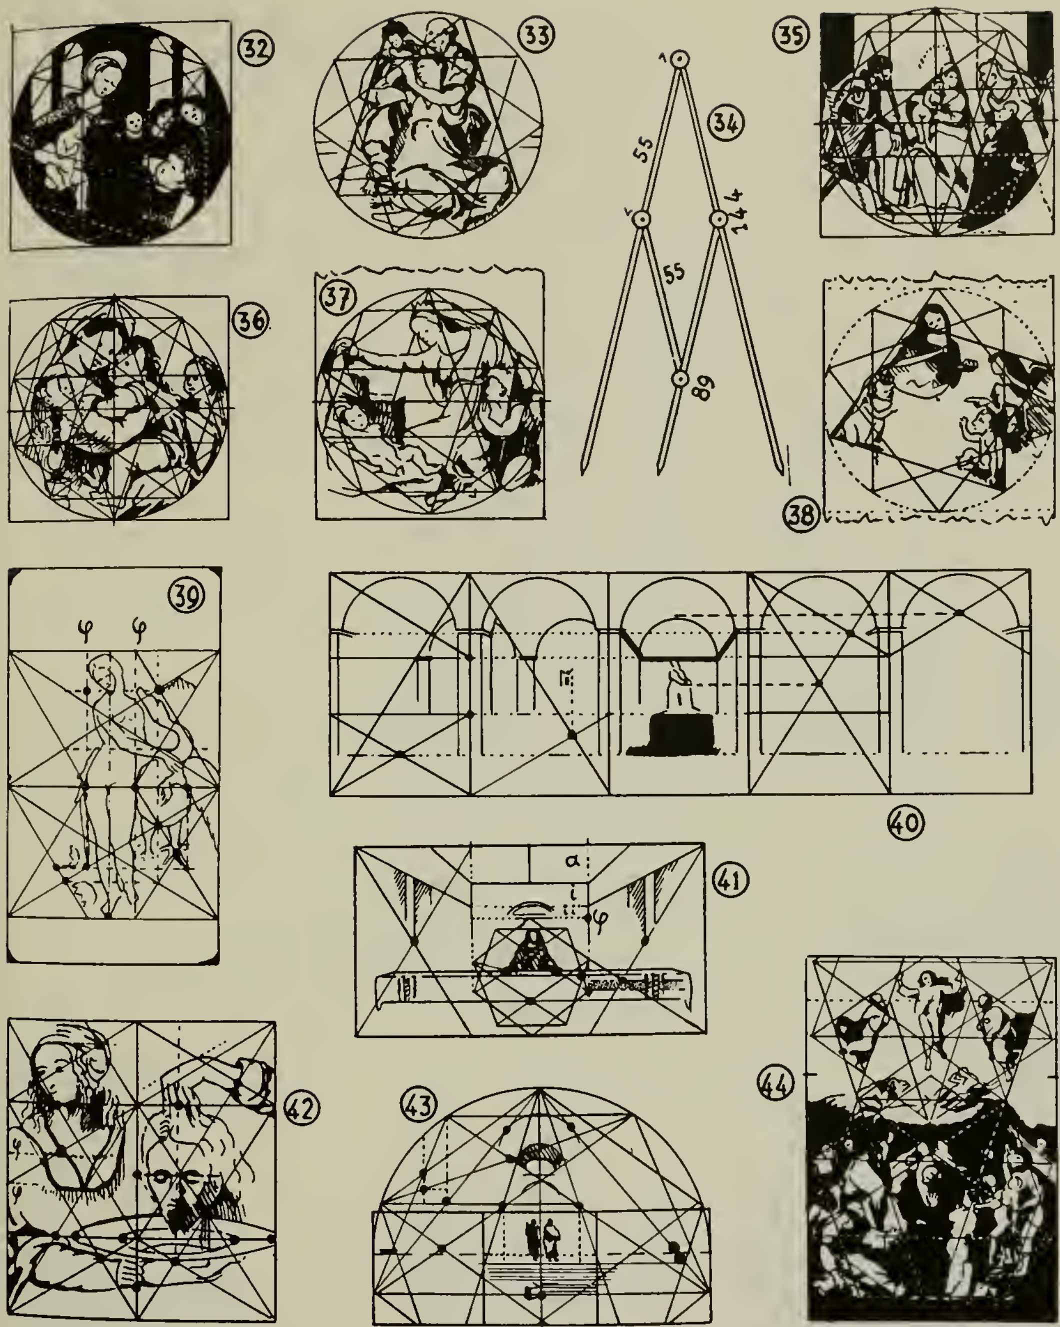
This mathematical grid, based on the Golden Section, was to become the backbone of the architectural system developed by the great French architect Le Corbusier for his construction of anything from the United Nations building in New York to the closets in a bathroom.



Le Corbusier's "modulor" based on the φ relation in the human body.

The Fibonacci series can be visualized geometrically as a mathematical grid growing larger (or smaller) in which each new unit always bears the relation of φ to its predecessors and successors.

* Leonardo Bigollo Fibonacci, known as Leonardo da Pisa, was perhaps the greatest mathematician of the Middle Ages. Born in 1179, he traveled to Algiers with his father, who acted as consul for the Pisan merchants. From the Arabs Fibonacci learnt the Hindu system of numerals from 1 to 9, which he is credited with having introduced to Europe, where calculations were still being made by the clumsy means of Roman numerals and Greek letters.



Funk-Hellet's analysis of (32) Mainardi, (33) Michelangelo, (34) Golden Section compass: note 55/89 relation, (35) Veronese, (37), (42), (43) Raphael, (38), (39), (41) Leonardo da Vinci, (40) Fra Lippo Lippi.

In the Renaissance the φ proportion, or Golden Section, as it was called by Leonardo da Vinci, served as the hermetic structure on which some of the great masterpieces were composed. Leonardo illustrated a book on the Golden Section for Luca Pacioli, known as "the monk drunk on beauty," which was published in Venice in 1509.

Funk-Hellet has analyzed the φ proportion in a score of masterpieces, including Titian's *Presentation of the Virgin,* Luini's *Sleep of the Infant Jesus,* and Veronese's *The Wedding at Cana.*

The conclusion that the Egyptians of the Old Kingdom were acquainted with both the Fibonacci series and the Golden Section, says Stecchini, is so startling in relation to current assumptions about the level of Egyptian mathematics that it could hardly have been accepted on the basis of Herodotus' statement alone, or on the fact that the φ proportion happens to be incorporated in the Great Pyramid. But the many measurements made by Professor Jean Philippe Lauer, says Stecchini, definitely prove the occurrence of the Golden Section throughout the architecture of the Old Kingdom.

Professor Lauer, for many years the architect for the Egyptian Department of Antiquities, has made thousands of measurements of ancient Egyptian buildings.

Schwaller de Lubicz also found graphic evidence that the pharaonic Egyptians had worked out a direct relation between π and φ in that $\pi = \varphi^2 \times 6/5$.*

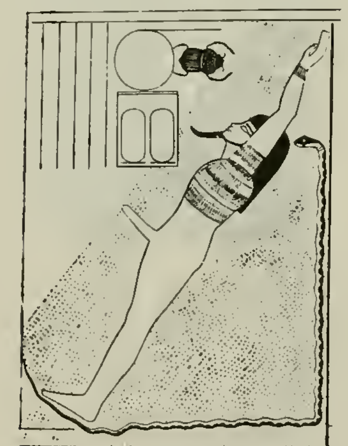
In the tomb of Rameses IX there is a strange figure of a royal mummy with one arm raised and an erect phallus. The mummy is lying at the hypotenuse of a sacred 3–4–5 right-angled triangle indicated by a snake.

The length of the body, says Schwaller, is clearly 5 cubits and that of the upright arm is one more cubit, for a total of 6. At the same time the body is divided by the phallus in the proportion of 1 and φ, for a total of φ^2.

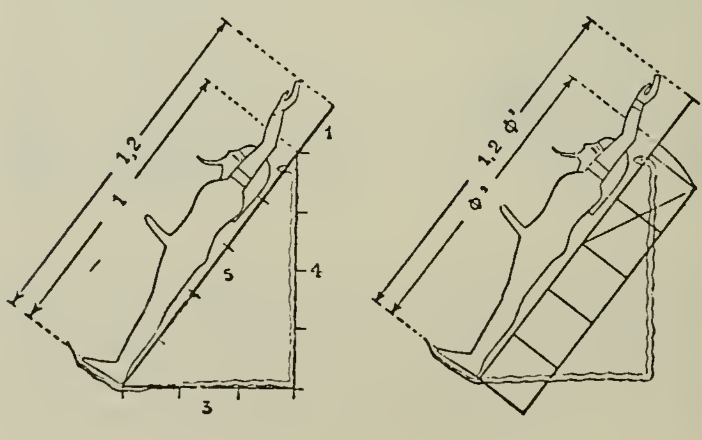
This, says Schwaller, makes the outstretched arm give a value for π of 6/5 of the body, or φ^2, which is 3.1416.

On the east side of the temple of Luxor, Schwaller also

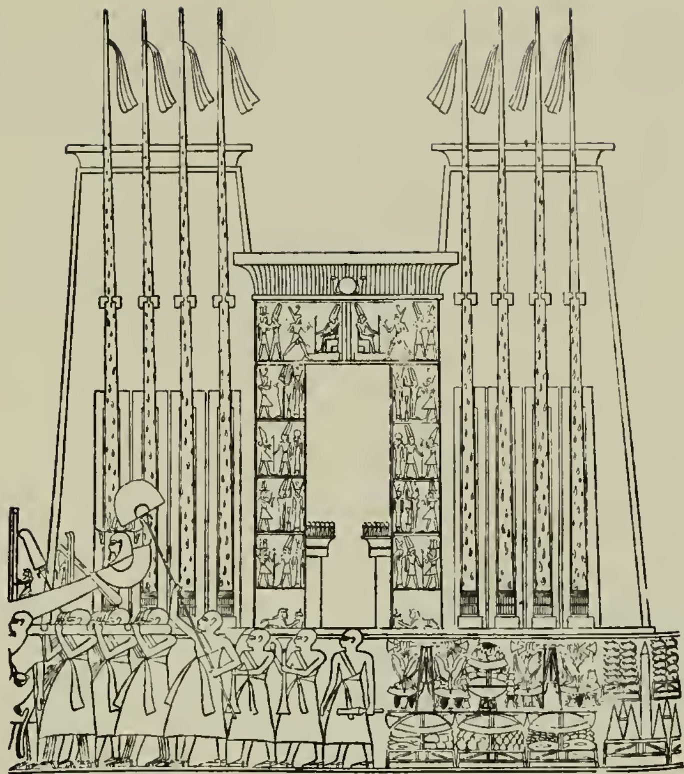
* $2.168 \times 6/5 = 3.1416$.



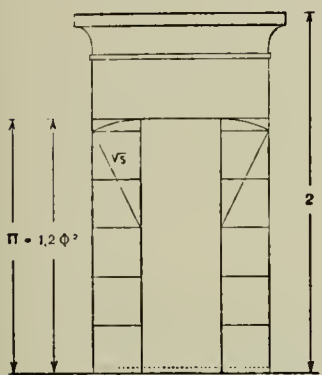
Egyptian king as the hypotenuse of a sacred 3–4–5 triangle formed by a snake.
Schwaller de Lubicz shows the king as φ^2, split into a $\varphi + 1$ proportion by the phallus. The king's raised arm gives a 6/5, or $1.2 \times \varphi^2$, proportion, which is exactly 3.1416, or π.



Priests exiting from third pylon of the Great Temple of Karnak bearing the king's barque.



Schwaller de Lubicz shows how the value of π correct to four decimals, or 3.1416, was incorporated into the great gate whose basic measurement was 1 × 2.



found a relief depicting a cortege of priests exiting from the great temple of Karnak, carrying the king's "solar barque." Schwaller points out that if the width of the gate of the temple, from outside wall to outside wall, is taken as 1, its full height will be 2, and the doorway $\varphi^2 \times 1.2$, or 3.1416; again the value of π, correct to four decimals.

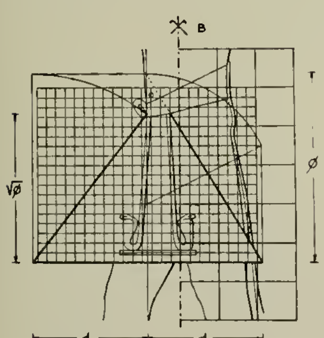
En passant, Schwaller notes the curious coincidence that the Greeks should have adopted for the relation of diameter to circumference the symbol of π, which looks just like the Egyptians' doorway.

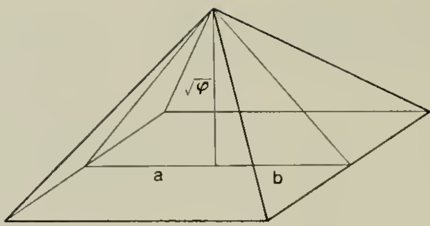
Even more extraordinary is Schwaller's resolution of the symbolic meaning of the triangular loincloth worn by the Pharaohs. Schwaller checked several score of these royal napkins for hermetic significance and found that they invariably gave two angles whose values were respectively φ and $\sqrt{\varphi}$.

Because of the location on the body of the royal napkin—similar to the Masonic apron of today—its phallic character, says Schwaller, was unmistakable.

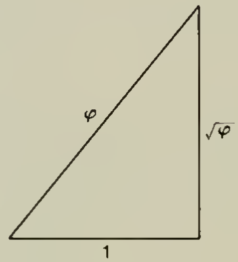
In the Great Pyramid the φ relation is found in the triangle formed by the height, the half base, and the apothem; that is to say, in the basic *cross section* of the structure.

Schwaller de Lubicz measured scores of triangular royal napkins and found that lower angles were invariably φ and $\sqrt{\varphi}$.

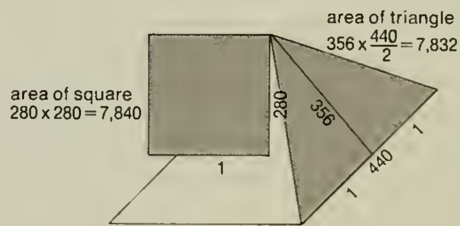




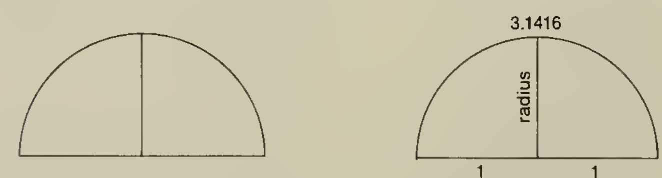
These proportions create a relation between the sides of the triangle such that if the half base is 1, the apothem is φ and the height is $\sqrt{\varphi}$.



This relation shows Herodotus' report to be indeed correct, in that the square on the height of the Pyramid is $\sqrt{\varphi} \times \sqrt{\varphi} = \varphi$, and the areas of the face $1 \times \varphi = \varphi$.



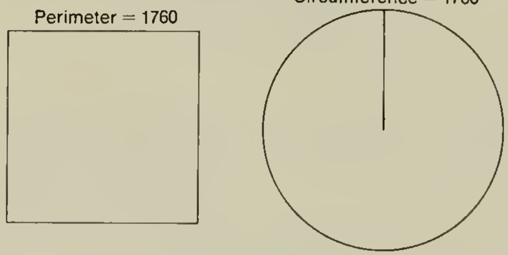
The simplicity of the system incorporated in the Pyramid makes child's play of the complexities of mathematical map projection. All one need understand is that π is the unchanging value which links a straight diameter to a curved circumference.*



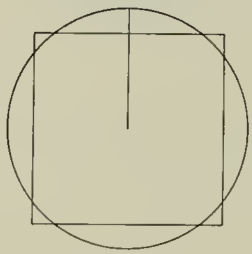
* π times the diameter of a circle will equal its circumference. π times one-half the diameter squared will equal the area of the circle.

Although the squaring of a circle is an insoluble problem if you use the irrational number of π, it is nevertheless practically resolvable as a function of the Golden Number φ. Because $\pi/2 = 2/\sqrt{\varphi}$ to within a thousandth part, π can usefully be taken as $4/\sqrt{\varphi}$.*

The Pyramid is so designed that for all practical purposes it accomplishes the squaring of the circle. The Pyramid's base is a square whose perimeter is equal to the circumference of a circle whose radius is the Pyramid's height.†



Superimpose the square on the circle and you get not only an interesting but an extremely useful diagram consisting of the perimeter of the Pyramid and the circumference of the circle it represents.



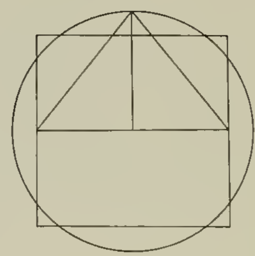
* The following examples are included for the sake of those who might doubt the mathematics; they are not essential to the narrative.

Because π also equals $\varphi^2 \times 6/5$, it is possible to use the Fibonacci series to obtain an accurate relation for the diameter of a circle to its circumference without recourse to π. In the Fibonacci series of 21–34–55, if 21 is taken as the diameter of a circle, its circumference will be $55 \times 6/5$, or 66, accurate to one-thousandth part, giving the Great Pyramid value for π of 22/7, or 3.14285.

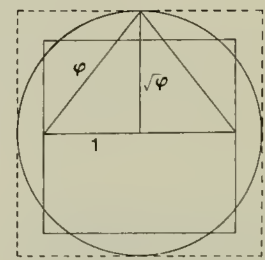
Higher numbers in the Fibonacci series provide increasingly finer values in whole numbers accurate to one ten-thousandth part. Prolonging the series, which goes . . . 89–144–233–377–610 . . . a diameter of 144 gives a circumference of $377 \times 6/5$, with a value for π of 3.1415; a diameter of 233 gives a circumference of $610 \times 6/5$, with a value for π of 3.1416; and so on.

† Four times the base of 440 cubits equals 1760 square cubits. The height of 280 cubits $\times\ 2\pi$, or twice 22/7, equals 1760 square cubits.

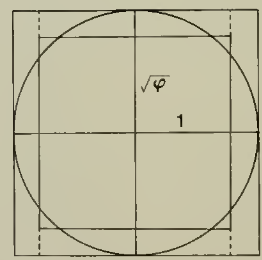
Three more lines will provide the mathematically correct cross section of the Pyramid of Cheops.



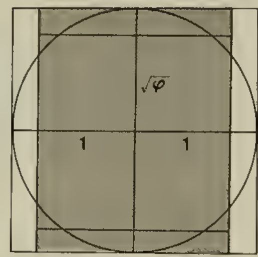
By simply enclosing the diagram in another square, and inserting the φ relationship as it exists in the Pyramid, a key is obtained for readily translating spherical surfaces into flat ones of equal area.



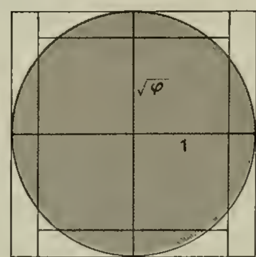
To obtain a rectangle equal in area to the basic circle, two sides of the smaller square need merely be prolonged till they touch the sides of the larger square.



The area of the rectangle is its length times its width, or $2\sqrt{\varphi} \times 2$, which is $4\sqrt{\varphi}$.

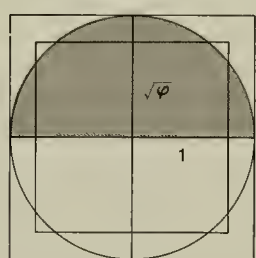


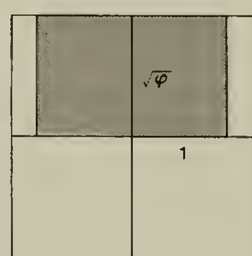
The area of the circle is πr^2, or $\pi\varphi$ in this case, the radius being $\sqrt{\varphi}$. But since $\pi = 4/\sqrt{\varphi}$, the area is also $4\sqrt{\varphi}$, the same as the rectangle.



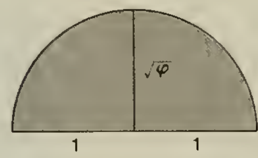
Thanks to the Pyramid's structure it is thus possible, with virtually no mathematics, to draw a rectangle (from the base of the Pyramid and twice its height) which will be equal in area to a circle on its height. This leads directly to being able to draw a rectangle or triangle equal to a spherical quadrant, resolving the main problem of the map maker with the same simplicity.

As the whole circle equals the whole rectangle, half the circle is equal to half the rectangle.

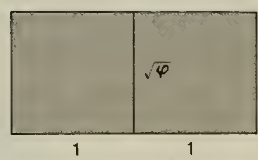




But half a flat circle is also mathematically rigorously equal in area to the spherical surface of a quadrant of 90°.



Thus a rectangle of height $\sqrt{\varphi}$ and a base of 2 is equal to a quadrant of height $\sqrt{\varphi}$ and an arc of 2.



Area = $2\sqrt{\varphi}$

Area = $2\sqrt{\varphi}$

It is thus possible to translate a spherical quadrant of 90° of longitude onto a flat Mercator surface of equal area or onto an undistorted triangle of exactly half that area.

With the Pyramid, the ancient Egyptians had not only squared the circle but effectively cubed the sphere.

XVI. SCIENTIFIC SURVEY GIVES GEOGRAPHICAL PROOF

That the Pyramid of Cheops was intended to represent a geographical rendition of the northern hemisphere was indicated repeatedly in the ancient texts, as Jomard had noted. From a careful analysis of classic Greek authors, Stecchini narrowed the sources of information on the Pyramid —other than Herodotus—down to a single Greek writer, Agatharchides of Cnidus, a peripatetic philosopher who was guardian to the king of Egypt at the end of the second century B.C.

Agatharchides reported that the length of one side of the base of the Pyramid corresponded to 1/8 minute of degree, and the apothem to 1/10 of a minute.

Jomard had hit upon this information and used it to find an almost exact solution: his apothem of 184.722 meters multiplied by 10 gave a minute of 1847.22 meters, which is almost precisely the length of a minute of latitude at the twenty-ninth parallel. This led Jomard to assume that the builders of the Pyramid had chosen to use the mean latitude value for all Egypt, which he figured to be 27° 40′.

What Jomard could not know was that the most ancient geodetic center of Egypt had been placed at 27°45′, precisely halfway between Syene on the Tropic, and Behdet on the coast of the Delta. He could not have known this because the site of the new capital of the young pharaoh Akhnaten called Akhtaten or "Resting point of Aten" had not yet been discovered near the modern Tell el-Amarna, nor had the young Champollion yet deciphered the hieroglyphs.

A stone text found in the ruins of Tell el-Amarna relates to the foundation of the capital. One of the surviving copies is about twenty-five feet high. It gives the length of the new capital as being limited by two boundary stones meticulously set "for eternity" at the extraordinary distance of 6 *atur*, 3/4 of a stadium and four geographic cubits. This indicates an intended accuracy of one in ten thousand. As Stecchini interprets the text, it not only specifically indicates 27° 45′ as the ancient geodetic center of Egypt, but gives the length of the *average* degree of latitude between the equator and the pole to be 240,715 cubits of 111,136.7 meters. The modern estimate is 111,134.1 meters.

As Stecchini points out, Akhnaten's geodetic reform was a return to the predynastic system of computing the length of Egypt in geographic cubits rather than royal cubits.

Had Jomard been able to measure all four sides of the base of the Pyramid with the precision of modern surveyors, he would have realized that the ancient Egyptians intended—quite logically—for the *base* of the Pyramid to indicate the value of a degree at the equator (where they apparently considered the earth to be a true circle and a degree of latitude to be equal to a degree of longitude).

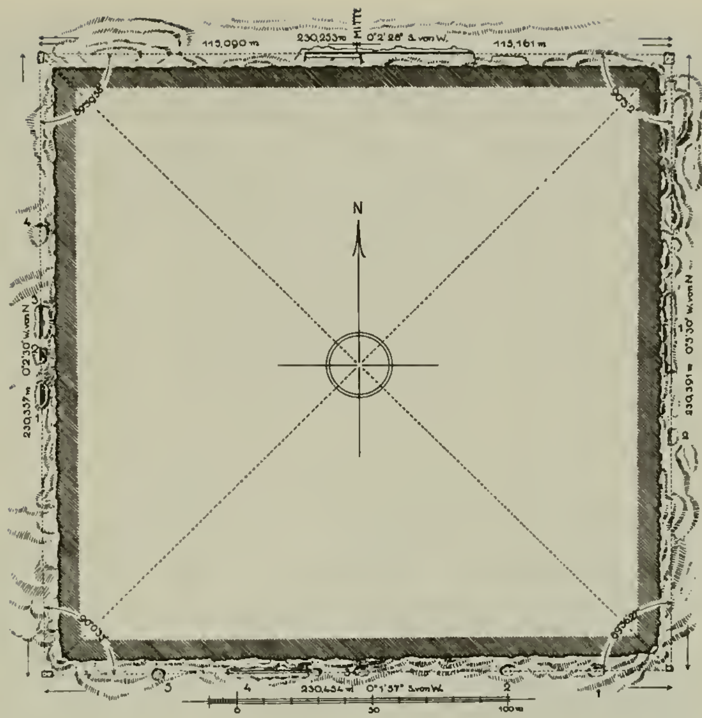
Up until the time of World War I there still remained considerable doubt as to the actual lengths of the four sides of the base of the Pyramid. Petrie had encountered great difficulty in delimiting the exact position of the corners, from which several blocks had been removed. But in 1925, Ludwig Borchardt, then director of the German Institute of Archeology in Cairo, asked to borrow the instruments of the Government of Egypt in order to make a new survey of the Great Pyramid. Borchardt hoped that a really accurate set of measurements might at last separate the strands of fact from fiction in the matter of the geometry of the Great Pyramid.

The Egyptian government agreed to make the survey on condition that Borchardt first clear all the remaining debris from around the base. When this was accomplished, an engineer named J. H. Cole was employed to make a thoroughly scientific survey. Cole used an extensive sounding of the foundations, and was finally able to ascertain to within millimeters the original position of each of the four corners.*

* These were published in *Determination of the Exact Size and Orientation of the Great Pyramid of Giza* (Survey of Egypt, paper 58). Cole gives 230.215 meters (± 6 millimeters) for the south side; 230.454 meters (± 10 millimeters at the west end and ± 30 millimeters at the east end) for the north side; 230.391 for the east side; and 230.253 for the west side.

Stecchini surmises that the apparent discrepancies of a few inches in the lengths of the four base lines might not have been errors on the part of builders who could set casing stones with the precision of a modern optician and dig a descending passage of over 350 feet with a mere 1/4 inch error in azimuth, but *intentional variants* for a definite purpose.

Were the difference in length of the sides to be explained not as the result of imprecision, but as intended skill, it would be possible to explain the lack of squareness in the angles of the base of the Pyramid. In Stecchini's opinion, the Pyramid's sides may have been deliberately planned with angles differing from a right angle in multiples of 15″ in order to correspond to a second time in the apparent motion of the stars.



Ludwig Borchardt's measurements of the angles of the base of the Great Pyramid.

If the base of the perimeter is intended to be 1/8 minute of degree, twice the perimeter will equal one minute.

Cole's mean figure for twice the perimeter is 1,842.91 meters. The modern figure for a minute of latitude at the equator is 1,842.9 meters.

From the figures it is evident that the ancient Egyptians knew that a degree of latitude is shortest at the equator and lengthens as it approaches the pole.

Schwaller de Lubicz arrived at the same conclusion by noting that the Egyptians counted a minute of arc as being 1000 brasses, or 1000 fathoms of 6 feet. According to Schwaller the brasse was a strictly geodetic measure that varied between 1.843 meters and 1.862 meters, depending upon the degree of latitude at which it was figured. The concordance is remarkable in that a minute of latitude is 1,842.9 meters at the equator, and 1,861.65 at the pole.

Stecchini's analysis of the ancient texts also helps resolve the problem of the apothem of the Pyramid which was said to be 1/10 of a minute, or 600 feet.

Pyramidion, or capstone, from the pyramid of Amenemhet III (1849–1801 B.C.) at Dashur. It is of polished black granite with winged sun disk of gold and carved hieroglyphs.

Agatharchides of Cnidus reported that the Pyramid of Cheops was topped by a pyramidion, or capstone, of four cubits which could be included in a calculation or excluded depending on the problem to be resolved. Like the obelisks, most pyramids were capped by a pyramidion of precious metal that would sparkle in the first rays of sunlight.

Discounting 4 royal cubits for the pyramidion leaves an apothem of 352 cubits of .525 meter each, and solves the whole riddle of the cubits in the Pyramid.

It gives an apothem of 600 geographic feet of .308 meter, or 400 cubits of .462 meter. It also gives an apothem of 500 remen, 220 megalithic yards, 320 *pyk belady* cubits, 100 brasses, 60 decapodes, 40 cannes, 10 short schoenia, 6 plethra, or 1 stadium. It is one tenth of a minute of latitude measured at the parallel of the Great Pyramid.

Jomard had been lucky when he found 600 feet to the apothem of the Pyramid. He had measured short, not knowing about the pyramidion, and come up with a very close 184.72 —which was derided by his colleagues.

Six hundred feet of .308 meter is 184.8 meters. The modern estimate of 1/10 minute of latitude at the parallel of the Great Pyramid is 184.75.

But Jomard had been absolutely right when he said he found 500 old Egyptian cubits of .4618 meter in the base of the Pyramid, and 400 larger *pyk belady* cubits of .5773 meter. These cubits are based on what Stecchini found to be the oldest foot in antiquity, the geographic foot which was still used in classical Greece and which survived in Europe down to our Middle Ages: in Egypt it was still common when Jomard arrived. Stecchini found evidence of this foot in temples in Mesopotamia in the preliterate era as early as 3500 B.C. The same geographic foot forms the edge of a cube or *artaba* which was the standard unit of grain measure in the Near East down to the Persian Empire.

It is now clear that the minute differences that appear in this foot in Persia, Greece, Mesopotamia and Egypt are due to the fact it was computed astronomically, varying a mere fraction of a millimeter depending on the latitude at which it was measured.

The façade of the Parthenon is 100 geographic feet of .3082765 meter, or 1 second of arc at the latitude of Athens, which is 37° 58′. At the equator a foot is a millimeter less, or only .30715 meter; at the mean latitude of Egypt, at 27° 45′, it is .307795. At the latitude of the Great Pyramid it is what Jomard found it to be: .3079. One and one-half of these feet made a geographic cubit of .4618, the same cubit Jomard found in current use when he arrived in Egypt, and which had been current since the time of Al Mamun (by means of which the Arabs could have correctly computed the circumference of the earth).

If you divide the earth into 360 degrees, and again into 60 minutes of 60 seconds, the result is one second of arc, or 100 geographical feet. Translated into meters by multiplying by .308 the result is 39,916.8 kilometers, which is within one quarter of one percent of our modern earth circumference of 40,000 km. By Akhnaten's average degree it was an even closer 40,009.32 kilometers.

Taylor had come within a hair of resolving the problem when he correctly postulated that the builders of the Pyramid had taken a great circle of 360 degrees and divided it first into 60 minutes and then into 60 seconds for a total of 1,296,000 seconds of arc.

Searching for a unit among the ancient measures that would fit this total, Taylor came up with what he called the short Greek foot, or Ptolemaic foot, which was 1.0101 of an English foot. One hundred of the Ptolemaic feet to a second of arc gave an earth circumference of 129,600,000 Ptolemaic feet, or 130,908,960 English feet, which was a bare one thousandth short of the estimate of the earth's circumference in Taylor's day.

Taylor's Ptolemaic foot was, of course, none other than Jomard's foot of .3079, from which was derived the cubit of .4618 meter, 500 of which fit the base of the Pyramid.

But Taylor couldn't make the sums come out because he was using the base computed by Le Père and Coutelle, which was about six feet too long, and into which neither the Ptolemaic foot nor the cubit would fit.

For lack of Cole's precise survey, poor Taylor, who was hot on the scent, was obliged to discard Jomard's thesis that 500 cubits of .4618 fit the base of the Pyramid along with the idea that it was intended to represent 1/8 minute, or 1/480 of a geographical degree. That Taylor was loath to do so is clear from his comment that he was sure that "it is in this direction, if any, that we may hope to find a satisfactory answer to the question: why was the Great Pyramid built?"

Instead, Taylor pursued the confusing idea that the Pyramid had been intended to indicate a polar axis for the earth of 500,000,000 Pyramid inches, and that the Egyptians had measured the base of the Pyramid in units to fit a solar year of 365.2322 days.

Piazzi Smyth, who also sensed there was truth in Taylor's probings, followed him into this apparent cul-de-sac.*

* Even so Taylor and Smyth may have been on the track of a solution. Taylor suggested that the circumference of the earth had been measured in Ptolemaic feet and common cubits, whereas the *polar* axis had been measured in inches and sacred cubits. In his recent *Historical Metrology*, Algernon Berriman supports Taylor's hypothesis by showing that whereas a "sacred" cubit of 25.064 inches is the ten millionth part of the earth's polar radius, a "royal" cubit of 20.6265 inches is a fraction of the circumference of the earth in that it is 206,265 sexigesimal seconds of arc: in other words the radius laid along a circumference of 1,296,000 seconds becomes a radian of 206,265 seconds.

Why Taylor, Smyth, Petrie and Davidson could not, or would not, avail themselves of Jomard's figures is a mystery. The twenty-one volumes of the *Description de l'Egypte* are bulky, hard to come by, and harder to handle (they are in leatherbound folio and double [Atlantic] folio, weighing as much as fifty pounds), and the information is scattered, without an index, through hundreds of pages of text, mixed with thousands of incongruous or irrelevant facts and figures; but the hard facts and figures are there; and Jomard's handling of them is lucid.

More surprising is the dogged determination of Egyptologists and writers on the Pyramid to continue to overlook or deny these facts. Even so eminent an Egyptologist as Jean Philippe Lauer, architect for the Egyptian Department of Antiquities, who certainly had ready access to *Description de l'Egypte* (his father was a curator of the Biblioteque Nationale) continued to dispute Jomard's conclusions even as late as after World War II.

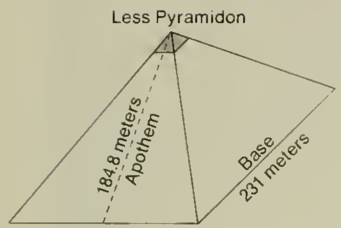
In his book *Le Problème des pyramides,* Lauer writes: "We must recognize that all this pretty hypothesis rests on inexact data. The cubit of .462 meters derived by Jomard from the base and the apothem of the Pyramid appears to be as hypothetical as that of Piazzi Smyth."

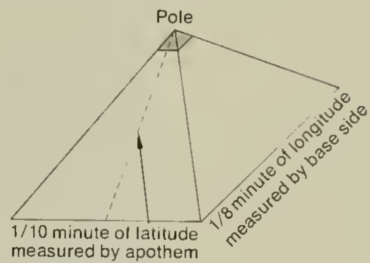
Ironically, the Director of the Department of Egyptian Antiquities, M. Etienne Drioton, who wrote the preface to Lauer's book, complained that it is because of their opposition to such theories as Jomard's that Egyptologists are being treated like "naif, blind, refractory dabblers in science whose quiet routines have been disturbed!"

That Jomard's cubit of .4618 or .462 meter is incorporated 500 times in the base of the Great Pyramid and 400 times in the apothem is no longer a matter of debate. Thanks to Cole it is a simple matter of multiplication. Even the confusing report of the Roman historian Pliny that the base of the Pyramid measured 833 1/3 feet and its apothem 666 2/3 feet becomes easily resolvable. The incongruity is rational when it is realized that Pliny's foot was simply 9/10 of a geographic foot. In other words, 833 1/3 of Pliny's feet turn out to be 750 geographic feet, or 500 geographic cubits.

The 500 cubits base is equal to 230.3625 meters (almost exactly Cole's figure) if measured by a geographic cubit computed at the equator, and 230.925 (almost exactly Jomard's figure) if measured by a cubit computed at the parallel of the Great Pyramid. The difference in cubits—which amounts to a fraction of a millimeter—makes no difference whatsoever to the relative values of the other units. For the sake of clarity the accompanying chart uses a cubit of .462 and a foot of .308.

Ancient Units of Measure Contained in the Great Pyramid in Round Numbers or Exact Fractions





The units of measure, from the short foot of .300 meter, through the various cubits, brasses, megalithic yards, parasangs, and miles, all fit perfectly in either round numbers or exact fractions into the base and apothem of the Great Pyramid because they are *all* fractions of a correct geographical degree of latitude or longitude at the equator. The Great Pyramid is thus a true standard of measure and a scale model of the northern hemisphere.

Apothem	Base
616 Egyptian feet of .300 meter	770 Egyptian feet
600 Greek or geographic feet of .308 meter	750 Greek feet
500 remen of .3696 meter	625 remen
400 geographic cubits of .462 meter	500 geographic cubits
352 royal cubits of .525 meter	440 royal cubits
320 *pyk belady* of .5775 meter	400 *pyk belady*
275 megalithic yards of .84 meter	220 megalithic yards
100 brasses or fathoms of 1.848 meters	125 brasses or fathoms
60 decapodes or rods of 10 feet	75 decapodes
40 rods of 15 feet	50 rods of 15 feet
6 plethra	7.5 plethra
1 stadium of 600 feet (.308)	1 1/4 stadium
1/10 of a mile, or angular minute	1/8 mile or minute
1/600 of a geographic degree	1/480 of a degree

Agatharchides was quite right when he quoted ancient Egyptian sources as saying that the base of the Pyramid was intended to be 1/8 minute of degree at the equator. 500 of Jomard's cubits multiplied by 8 for a minute, by 60 for a degree and 360 for a circumference, equal 86,400,000 cubits.

Relation of the Ancient Egyptian Foot (of .308 meter) and Multiples Thereof to the Circumference of the Earth

In the circumference there are			129,600,000 feet
There are 360	degrees	of	360,000 ft.
3,600	great Egyptian schoene	of	36,000 ft.
21,600	miles	of	6,000 ft.
216,000	stadia	of	600 ft.
1,296,000	plethra	of	100 ft.
2,160,000	schoenia	of	60 ft.
8,640,000	cannes	of	15 ft. (1) cubit
12,960,000	decapodes	of	10 ft.
21,600,000	brasses or ogyie	of	6 ft.
86,400,000	cubits	of	1 1/2 ft.
129,600,000	feet	of	1 ft.
518,400,000	palms	of	1/4 ft.
2,073,600,000	fingers	of	1/16 ft.

Obelisks outside the temple of Amon-Ra at Karnak which was oriented to the solstice. By measuring their shadow at the solstice it was possible to extrapolate the meridian circumference of the planet.

This reveals the source of the Egyptian cubit and foot. There are 86,400 seconds in a day of twenty-four hours, or the time it takes the earth to revolve on its axis. So the distance traveled by the earth at the equator in one second is exacly 1000 of Jomard's cubits.

The builders of the Great Pyramid gave its base a length corresponding to the distance the earth rotates in 1/2 a second. This makes the cubit and the foot doubly earth commensurate: the cubit was equal to 1/1000 of a second of time, the foot to 1/100 second of arc.

How could the ancient observers have established this fact? To compute the polar circumference of the earth the ancients used the sun and the shadows cast by obelisks. To compute the equatorial circumference they observed the passage of stars across fixed points such as obelisks. For the polar circumference they needed merely to measure the distance between two obelisks a few miles apart and the difference in the length of the shadows of the obelisks.

There was no need to measure such a vast distance as separated Alexandria from Syene. The difference in latitude, and hence the fraction of arc separating any two meridian obelisks, can be obtained by the relation of the obelisk's shadow to its height *when measured at the moment of the solstice or equinox.*

To obtain the equatorial circumference, an observer at the base of an obelisk at the thirtieth parallel could signal the appearance on the eastern horizon of a zenith star to an observer at a measured distance in the western desert where the tip of the obelisk would be on the horizon. Noting the interval of time between the signal from the first observer and the moment the star appeared on *his* horizon (and knowing the earth moves through 1,296,000 seconds of arc in 86,400 seconds of time), the observer could figure the equatorial circumference of the earth. At the thirtieth parallel it would vary from the equator by the cosine value of 30° or $\sqrt{3/2}$.

It was thus simply a matter of deciding what *unit of measure* to use in computing these lengths. An observer looking up at the Grand Gallery from a point far enough back to subtend an angle of 2° at the opening, could then note the time it took a star on the celestial equator to cross the opening. He would then possess the necessary data to relate the width of the Grand Gallery to the circumference of the earth.

From the figures it is evident that the ancient astronomers took the earth's daily rotation on its axis as a unit of time and made 1000 cubits the distance traveled by the earth in a second of time.

With a series of obelisks they could physically measure minutes and seconds of meridian arc, along a meridian and extrapolate the distorted distance to the pole.

From many scattered texts Stecchini has deduced that the Egyptians had worked out a simplified method of computing the change in each degree from equator to pole by means of an additive and subtractive series. The geographic cubit was also ideal in that it gave an admirable length for Egypt of 1,800,000 cubits. From Behdet to Syene is 7 1/2 degrees, or 1/48th of the earth's circumference of 86,400,000 cubits.

These cold facts should settle one whole facet of the mystery of the Great Pyramid. Clearly the ancient Egyptians knew the shape of the earth to a degree not confirmed till the eighteenth century when it was established that Newton was correct in his theory that the planet was somewhat flattened at the poles, and they knew the size of the earth to a degree not matched till the middle of the nineteenth century when it was first remeasured with comparable accuracy by the German geodesist Friedrich Wilhelm Bessel. It is equally evident that they could divide a day into 24 hours of 60 minutes and 60 seconds, and produce a unit of measure that was earth commensurate—just as Taylor, Smyth and Jomard had surmised.

So now that Cinderella's foot has been found to fit her lost slipper without pinching or effort, to go on lengthening and shortening the carbuncled feet of her ugly sisters would indeed be like M. Drioton's naif, blind and refractory dabblers in science. On the other hand, a little cooperative effort by experts on ancient Egypt and Sumeria might help bring to light many more fascinating details of the early history of science.

Sexagesimal, Decimal and Quaternary Relations of Ancient Egyptian Units of Measure

60 palms	= 1 canne
60 feet	= 1 short schoenion
60 decapodes	= 1 stadium
60 short schoenia	= 1 Hebraic mile
60 plethra	= 1 Egyptian mile or minute of degree
60 stadia	= 1 grand schoenion
60 Egyptian miles	= 1 degree or moira
60 grand schoenia	= 1 sexagesime
60 sexagesimes	= 1 circumference of the globe
10 Egyptian feet	= 1 decapode
10 Egyptian cubits	= 1 canne or Egyptian pole
10 orgyie or brasses	= 1 short schoenion
10 decapodes	= 1 plethron
10 cannes	= 1 side of land unit of 100 cubits (aroura?)
10 short schoenia	= 1 stadium
10 stadia	= 1 Egyptian mile
10 grand schoenia	= 1 degree of longitude
4 fingers	= 1 palm
4 palms	= 1 foot
4 cubits	= 1 orgyie or brasse
4 cannes	= 1 short schoenion
4 sides of 100 cubits (aroura?)	= 1 stadium

Number of Greek or geographic feet of .308 meters.

In circumference of world	360,000 × 360
In a geographical degree	360,000
In a long schoene	36,000
In a geographical minute (or mile)	6,000
In a stadium	600
In a brasse	6
In a cubit (geographical)	1 1/2

Geodetic Values Incorporated in the Dimensions of the Great Pyramid

	Base	Perimeter	Apothem
Egyptian foot of .300 meter	770	3080	616
Greek or geographic foot of .308 meter	750	3000	600
Greek or geographic cubit of .462 meter	500	2000	400
Royal Egyptian cubit of .525 meter	440	1760	352
Pyk belady cubit of .5775 meter	400	1600	320
Megalithic yards of .84 meter	275	1100	220
Brasse of 6 geographic feet (1.848 meters)	125	500	100
Decapodes of 10 geographic feet	75	300	60
Plethra	7.5	30	6
Stadium of 600 geographic feet	1 1/4	5	1
Miles or minute of degree	1/8	1/2	1/10
Parasangs	1/24	1/6	1/30
Long schoene	1/48	1/12	1/60
Geographical degree	1/480	1/120	1/600

XVII. DECLINE OF ANCIENT KNOWLEDGE

What remains a mystery is how all the advanced science of the ancient Egyptians could have been lost for so many centuries.

In his reconstruction of preclassic geographical data, Stecchini has traced an advanced science of geography based on accurate astronomical tables which were kept up to date all the way down to the beginning of the first millennium B.C. He has established that the later Babylonians still had excellent maps for their area of the world between the thirtieth and thirty-sixth parallels, made in segments of 6° of latitude by 7° 12′ of longitude, which gave them perfect squares because of the diminished length of a degree of longitude between those parallels.

This same system, says Stecchini, was in use as late as the reign of Darius the Great of Persia, whose empire, centered on the arbitrary geodetic point of Persepolis, ran precisely 3 units of 7° 12′ east of the Egyptian meridian and three units of 7° 12′ west of the Indian border.

But errors were already creeping into the geography because of a lack of direct observation of celestial phenomena and because of the reliance by geographers on ancient astronomical data that were no longer up to date.

As an explanation for this regression of geographic science, especially during the Hellenistic period, and thereafter almost to modern times, Stecchini suggests that when Alexander the Great destroyed Persepolis in the fourth century B.C. he may have exterminated the Egyptian geographers imported by the Persians to do their figuring, and that when he dismantled the center of Egyptian science at Heliopolis in order to build his own capital at Alexandria, he may have compounded the damage.* The destructions of Persepolis and Heliopolis were considered by Alexander

* Heliopolis, the On of the Bible, was considered the greatest university in the world. It had existed since much earlier times under the domination of the priests, of whom there were said to be 13,000 in the time of Rameses III, 1225 B.C. More than 200 years earlier, Moses was instructed at Heliopolis "in all the wisdom of the Egyptians," which included physics, arithmetic, geometry, astronomy, medicine, chemistry, geology, meteorology and music.

Romantic nineteenth-century depiction of Moses being found in the bullrushes.

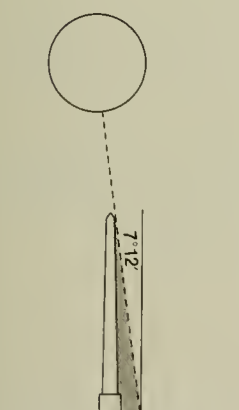
essential in order to destroy the geographic, and therefore the political, basis of the older empires.

Stecchini's evidence shows that far from being the great innovators of geographical knowledge, the Alexandrine geographers of the next half millennium, such as Eratosthenes, Hipparchus and Ptolemy were mainly handling and mishandling traditional data of an advanced science that preceded them, and which they only understood in part.

Current scholarship keeps repeating that the circumference of the earth was first measured by Eratosthenes, the Greek who was put in charge of the library of Alexandria, but it is clear that Eratosthenes merely cited old Egyptian information about the circumference of the earth without really understanding it.

Eratosthenes claimed to have found that a degree of latitude was 700 stadia. This, says Stecchini, was nothing but the traditional Egyptian datum of 14 *atur* to 50 stadia.

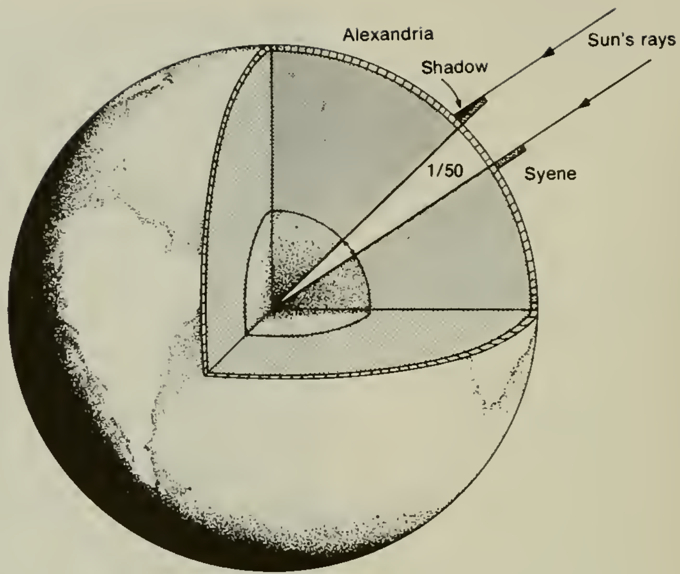
Eratosthenes also claimed to have found by observation that when the sun does not cast a shadow at the southern limit of Egypt, it casts a shadow of 7° 12′ at Alexandria.



Gnomon at Alexandria at summer solstice.

Eratosthenes is said to have measured the circumference of the earth by noting the angle of the sun's rays at Alexandria at the summer solstice, the day he knew the sun would be directly overhead at Syene on the tropic of Cancer.

Finding a shadow angle of 7° 12′ at Alexandria, he deduced the distance from Alexandria to Syene to be 7° 12′ of the 360° circumference of the globe. As 360/7° 12′ = 50, Eratosthenes multiplied the 5000 stadia he believed to separate Alexandria from Syene by 50 and got a figure of 250,000 stadia for the circumference of the earth. Because his various errors canceled out, he was credited with a scientific answer.



In reality Eratosthenes had read the old Egyptian data (then more than 2000 years old) to the effect that the tropic was at latitude 23° 51′ and that the sun did not cast any shadow at Elephantine. What he did not know, and could not measure, was that by his time the tropic had shifted to 23° 45′. Nor did Eratosthenes understand the necessity of adjusting his figures according to the apparent semi diameter of the sun; he believed Alexandria to be 7° 12′ north of 23° 51′; he even claimed that Alexandria was on the same meridian as Elephantine, whereas they are apart by about 3°, or 200 miles of longitude.

Furthermore, Eratosthenes used the "great cubit" of Babylon (532.702 millimeters) to obtain his stadium, instead of the more ancient royal cubit of the Egyptians of 525 millimeters, unaware that the first step taken by the Assyrians when they conquered Egypt in the seventh century B.C. was to substitute their own Mesopotamian cubit for the Egyptian one in order to manifest their own dominion.

On the basis of his research into ancient geography, Stecchini is now convinced that there existed on this planet a people with an advanced mathematical and astronomical science several millennia before classic Greece.

XVIII. WHO BUILT THE PYRAMID? WHEN? AND HOW?

It would be satisfactory to be able to describe the method by which the Great Pyramid was put together, by whom, and when.

But the builders, whoever they may have been, left no description of their method. No one has even found a *later* Egyptian report of how the first pyramids were built. It is only on the basis of shrewd guessing that Egyptologists estimate the stepped pyramid of Saqqara to be the oldest of the Egyptian pyramids and attribute its construction to the legendary architect Imhotep in the reign of King Zoser of the Third Dynasty.

The stepped pyramid of Medûm, which was the first stepped structure to be converted to a true pyramid, is attributed to Cheops' father Sneferu on similarly sketchy evidence; the same goes for the bent pyramid of Dashur.

Lacking solid history, the Arabs (and the Jews) of the Middle East proliferated legend. The most ancient tradition about the Great Pyramid is that it was erected to memorialize a tremendous cataclysm in the planetary system which affected the globe with fire and flooding.

Arab authors recount that the pyramids were built before the deluge by a king who had a vision that the world would be turned upside down, and that the stars would fall from the sky. According to these Arab sources, the king placed in the pyramids accounts of all he had learnt from the wisest men of the times, including the secrets of astronomy, complete with tables of the stars, geometry, and physics, treatises on precious stones, and certain machines, including celestial spheres and terrestrial globes. They also speak of "malleable glass."

The earliest Jewish reports—other than the vague reference in the Bible to "pillars of stone"—is in Josephus, who says the Sethites were inventors of a wisdom which dealt with celestial bodies and their order in the heavens, and that to preserve their wisdom for all mankind they built two monuments—one brick, the other stone—the stone one being still extănt in Egypt in Josephus' time, during the first century after Christ.

The Arab legends maintain that the Great Pyramid not only contained representations of the position of the stars and their cycles, but also a history and chronicle of the times past and future.

As to *who* built the Great Pyramid, Arab historians such as Ibrahim ben Ebn Wasuff Shah say that the Giza pyramids were built by an antediluvian king called Surid or Saurid, who saw in a dream a huge planet falling to earth at the time when "the Heart of the Lion would reach the first minute of the head of Cancer."

Abu Zeyd el Balkhy quotes an ancient inscription to the effect that the Great Pyramid was built at a time when the Lyre was in the Constellation of Cancer, which has been interpreted as meaning "twice 36 thousand solar years before the Hegira," or about 73,000 years ago.

The famous traveler ibn-Batuta, writing 730 years after the Hegira, says that Hermes Trismegistos (the Hebrew Enoch), "having ascertained from the appearance of the stars that the deluge would take place, built the pyramids to contain books of science and knowledge and other matters worth preserving from oblivion and ruin."

According to Basil Steward, a theosophist, author of *The Mystery of the Great Pyramid,* there is no more reason to believe that because the Pyramid stands in Egypt it was built by Egyptians than that the modern Egyptians built the Aswan Dam. Steward says that when all the evidence—archeological and traditional—is coordinated and examined collectively, it leads to but one conclusion: ". . . The seeds of Egypt's greatness were sown by a few colonists who entered the country peaceably and organized the carrying out of great constructional works."

Sir George Cornewall Lewis, in *An Historical Survey of the Astronomy of the Ancients,* complained of the arbitrary dating used by Egyptologists which he compared to "the manipulation of the balance-sheet of an insolvent company by a dexterous accountant (who, by transfers of capital to income, by suppression or transposition of items, and by the alteration of bad into good debts, can convert a deficiecy into a surplus)." Lewis pointed out that Baron Bunsen and Dr. Lepsius, both eminent Egyptologists, separated the dates of the figure Sesostris by no less than 3793 years, and asked: "What would we think if a new school of writers on the history of France, entitling themselves Francologists, were to arise in which one of the leading critics were to deny that Louis XIV lived in the seventeenth century, and were to identify him with Hercules, or Romulus . . . or Charlemagne."

The only major historian of ancient Egypt was Manetho, a priest, who wrote a history of Egypt for Ptolemy II, but it was lost. Only scraps of it, translated by authors who lived about six hundred years after his death, have survived. His list of dynasties, checked and modified, forms the framework on which the history of Egypt has been reconstructed. But very little detail is known concerning the political history of the first two dynasties, other than the nearly twenty names of Pharaohs listed by Manetho.

Most Egyptologists consider the First Dynasty to have started with Menes about 2900 B.C., and the Fourth, consisting of Sneferu, Cheops, Didoufri, Kephren, and Mykerinos, to have lasted about 120 years from 2680 to 2560 B.C., as the Old Kingdom.

There followed a first intermediate period, a Middle Kingdom from 2052 to 1785 B.C., a second intermediate period, and a New Kingdom from 1580 to 1085 B.C. Post Empire Dynasties XXI to XXVI follow down to 525 B.C.

According to Steward the colonists were probably a band of Asiatic or Euphratean travelers with a very advanced scientific and mathematical knowledge, who entered Egypt and organized the erection of the Great Pyramid, on completion of which they left the country, taking their knowledge with them.

As Steward puts it, the plans for the Great Pyramid were in existence a long time before the actual construction commenced, and were the design of a single individual "who belonged to the Adamic White civilization endowed with moral, scientific and cultural attainments far in advance of all other contemporary civilizations."

Petrie substantiates this theory to the extent that he believes: "the exquisite workmanship often found in the early period (of Egyptian architecture) did not so much depend upon a large school of widespread ability, as on a few men far above their fellows." Referring to the phenomenal accuracy of the work embodied in the Great Pyramid, Petrie says, "It was limited to the skill of one man."

Recent Soviet authors postulate that the Egyptians may have come from Indonesia when their civilization was devastated some ten to twelve thousand years ago as a result of some cosmic catastrophe such as the falling of an asteroid.

According to Peter Kolosimo in *Terra Senza Tempo,* published in Milan in 1969, the Russians have recently brought to light some fascinating secrets of Egyptian archeology.

The Russians are said to have found astrònomical maps of surprising correctness, with the position of the stars as they were many thousands of years ago. The Russians are also reported to have dug up several objects, many not yet identified, including crystal lenses, perfectly spherical, of great precision, possibly used as telescopes. Kolosimo says similar lenses have been found in Iraq and central Australia, but that they can only be ground today with a special abrasive made of oxide of cerium which can only be produced electrically.*

As to the actual dates of construction of the Great Pyramid, apart from the statement that it was built 300 years before the Flood, the legends add little. Egyptologists who worked out that the Fourth Dynasty must have reigned between 2720 and 2560 B.C. believe the Great Pyramid was commenced in 2644; others believe that its construction was begun in 2200 and that 30 to 56 years were required to

* Several attempts to check these data with Soviet academicians have so far been without result.

complete it. Still others place the building of the Pyramid a thousand years earlier.

As for the method employed by the builders, the record is equally bleak. I. E. S. Edwards of the Egyptian Department of the British Museum, who spent a lifetime going over the available evidence, points out in his scholarly treatise on the pyramids written in the 1930s that little or no light is thrown on the subject by extant Egyptian records, either written or pictorial.

The result is a congeries of conflicting theories not only about when but about how the Great Pyramid was built.

Nevertheless Egyptologists are in general agreement that the first step required on the Giza plateau was to clear the sand and gravel down to bedrock, then produce a leveled base by removing protuberances and filling in depressions.

R. L. Engelbach, a pupil of Petrie, and for many years Keeper of the Cairo Museum, believes that to obtain a true level the Egyptians surrounded the four sides of the area with low banks of mud from the Nile which they filled with water and through which they cut a network of trenches. The degree of their success is attested by Cole's survey, which found the base rock of the thirteen acre perimeter to be less than 1 inch out of level.

Into the base rock a row of fine rectangular, white limestone slabs were carefully fitted as a pavement on which to lay the first row of casing stones.

When it came to drawing the first straight side, Borchardt and Lauer agree, the correct orientation must have been obtained by means of repeated observations of the rising and setting of circumpolar stars, of which the most likely was alpha Draconis.

The next step would have been to fix the large limestone corner blocks into the rock base so as to form the square corners for the laying of the first rows of casing stones.

Archeologists have had little trouble establishing that most of the limestone blocks for the construction of the Pyramid must have been obtained from the deep Mokattam quarries a few miles across the Nile on the Arabian side of the river, though many of the blocks may have been obtained directly from the Giza hills.

On some of the blocks the names of the quarry gangs were daubed in red ochre, such as "Boat Gang" or "Vigorous Gang."

The nearest source for the 70-ton granite monoliths used to protect the King's Chamber is the Aswan quarry, near Syene about 500 miles up the Nile; from there they were presumably floated downstream on a series of reed barges.

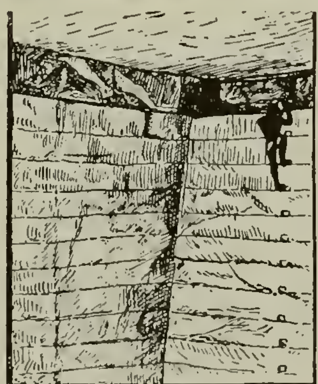
W. Emery has shown that as early as the First Dynasty

To Egyptologists Imhotep (above) was a national hero in the reign of King Zoser (below). Imhotep as designer of the stepped pyramid of Saqqara was considered not ony the world's greatest architect but a sage, magician, high priest, medical doctor, diplomat, economist, and poet.

The limestone blocks with which the Pyramid is built appear to have been mostly quarried on the spot, or across the Nile in the Mokattam hills about 20 miles away, or from the Turah and Maura quarries opposite Memphis. The 22 acres of casing stones are from the same quarries.

The granite blocks for the Pyramid are believed to have come from Aswan, near the First Cataract, where they were quarried from the face of the rock about a mile from the right bank of the Nile.

Hillsides were hollowed out to provide uniform limestone blocks for the outer casing of the Pyramid.



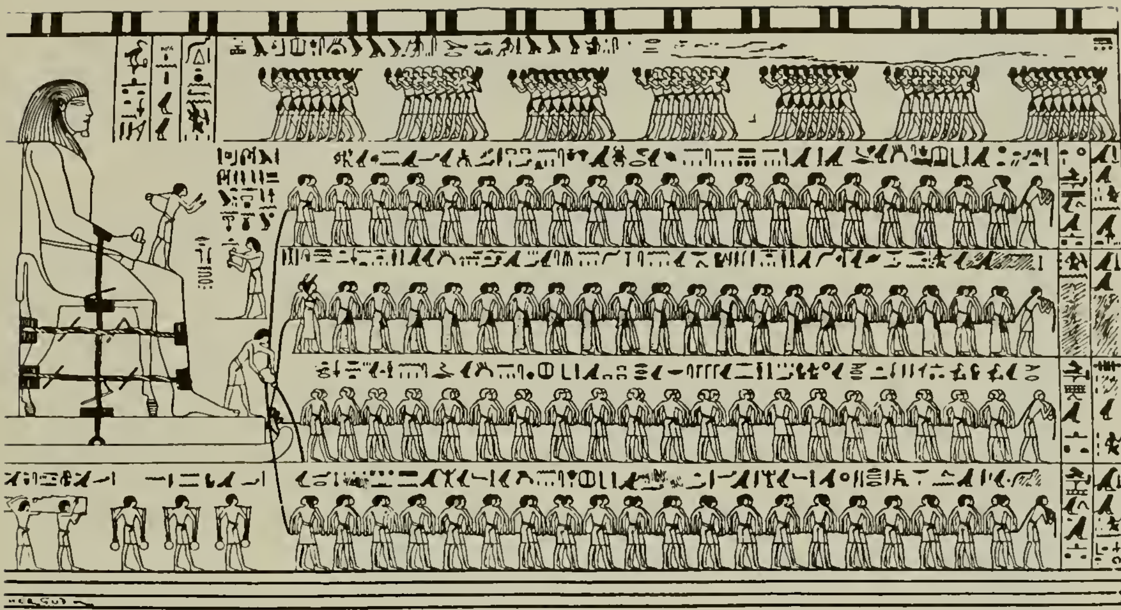
Limestone was quarried in layers from the top down.

The Aswan granite quarries were 500 miles south of the Great Pyramid.
Egyptologists conjecture that in order to cut the stone blocks, the ancient Egyptians must have had some method of tempering bronze unknown in modern times. To cut and finish hieroglyphs and other ornaments would require a tool with an extremely hard-tempered edge.
Few iron tools have been found, probably because of the rapid oxidation of iron in Egypt, where the soil is especially nitrous.

the Egyptians possessed excellent copper tools, including saws and chisels, with which to cut any kind of limestone, and that their technique of working and polishing granite was developed to a truly remarkable art. As an abrasive material in their sawing operations they are believed to have used moistened quartz sand.

To quarry the rock from the hillside, the Egyptians developed a variety of systems, traces of which can still be found on the Mokattam range. Tunnels were dug several hundred feet into the rock, shelves were cut out between the roof and the block to be detached, then a line was chipped away vertically with a wooden mallet and a copper chisel, which must have been highly tempered by some method unknown today. Wedges were inserted which were moistened till they expanded to crack the rock. Sometimes fires were built along the grooved lines, and water poured on the heated stone to obtain a clear fracture.

The only historical description of the manner in which the limestone blocks were taken to the Pyramid is by Herodotus, who claims that he was informed in Egypt that it took twenty years to build the Pyramid and that levies numbering a hundred thousand men were employed for periods of three months to transport stone from the quarries. Herodotus says that to transport the rough blocks from the edge of the Nile up to the top of the Giza plateau, a great causeway was built, which required ten years to complete. The causeway was said to be 3000 feet long and 60 feet wide, of polished stone, over which sleds could pull the heavy stones.



Several score Egyptians transporting a colossal statue with men harnessed in double rank. Note the timekeeper standing on the statue's knee, and a man pouring liquid on runners to decrease friction.

Commander F. M. Barber, an American naval attaché who was stationed in Egypt at the end of the last century and wrote an informed booklet entitled *Mechanical Triumphs of the Ancient Egyptians,* figured that if the causeway had to rise to a height of 120 feet above the Nile, it would have had an incline of 1 foot in 25, which he considered a very easy grade for a greased stoneway.

Barber estimated that it would take a force of 900 men harnessed in double rank on four draft ropes to drag a 60-ton monolith up such an incline. On the causeway the men would cover a space 225 feet long by 16 feet wide, which Barber considered a sufficiently compact and manageable force.

Barber says that such a force would have no trouble dragging the stone, especially if they were drilled to pull together; he concludes that for this reason men and not animals are pictured hauling wrought stones: men could be drilled to march in absolute cadence to a song or time-keeping instrument. A "one-two-three, surge," says Barber, produces a momentary force represented by nearly the weight of the whole mass of men, or several times their ordinary pulling force. Also, vacancies in the ranks caused by sickness could be filled without materially affecting the drill of the remainder. Cattle could never be so well organized.

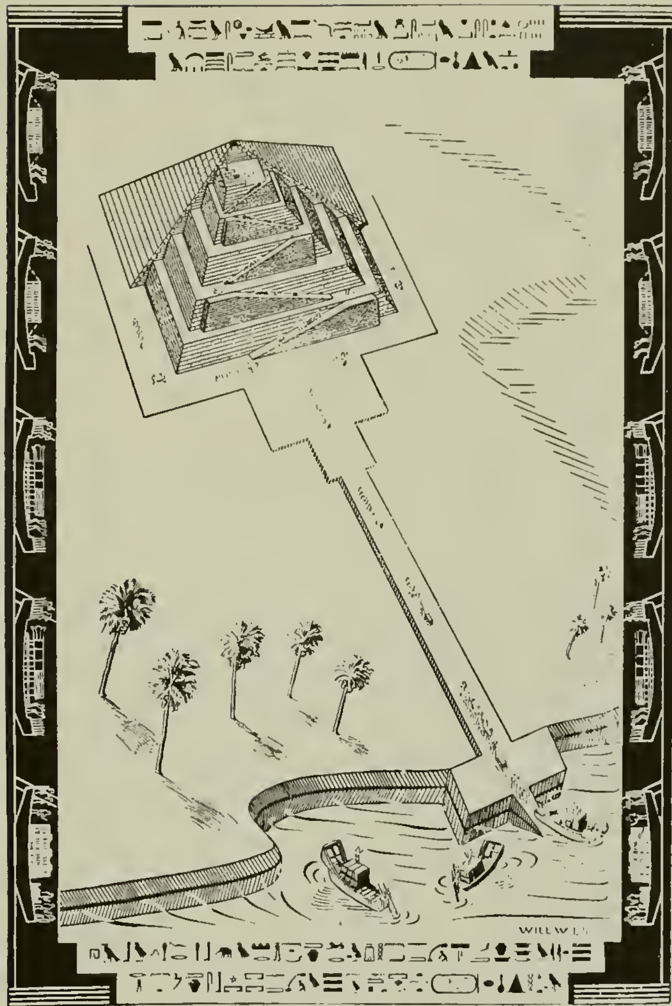
Pictures show Egyptians hauling stone in the manner described by Barber and include a special artisan pouring some sort of grease on the sled runners to reduce friction.

Other Egyptologists have suggested that owing to the great quantity of supplies necessary for building Cheops' pyramid, it was likely that several ramps led from the valley up to the Giza plateau, but very few remains of such possible causeways can now be observed because of modern excavations and the widespread tourist layout.

According to the French scholar E. Amélineau, considerable remains of an inclined plane leading to the pyramid of Kephren still existed at the end of the eighteenth century; and remains of a causeway leading to the pyramid of Mykerinos are still visible today.

The Egyptian archeologist Selim Hassan says that at the edge of the Giza plateau there is a considerable surface composed of large limestone blocks which run in a northeasterly direction and descend to a little less than half the height of the plateau. He believes they may have been part of a construction ramp which was demolished when the Great Pyramid was completed.

Causeway to the pyramid of Kephren.



W. W. Lucker's reconstruction of a pyramid and its causeway to the Nile.

Ahmed Fakhry, another Egyptian archeologist, says that remains of a southern supply ramp composed of rubble mixed with mud still exists a short distance from the south side of the main causeway.

As to how the Great Pyramid was actually constructed, there are differing opinions among Egyptologists. Herodotus reported that the upper portion of the Pyramid was finished first, then the middle, and finally the part nearest the ground. This has been interpreted as meaning that the finished outer casing stones were placed in position against the nucleus starting from the top, presumably by means of a ramp that was removed as the builders worked downward; this would have required four ramps, one against each face.

Herodotus maintains the casing blocks were lifted from the ground, step by step, on pieces of wood, with a machine

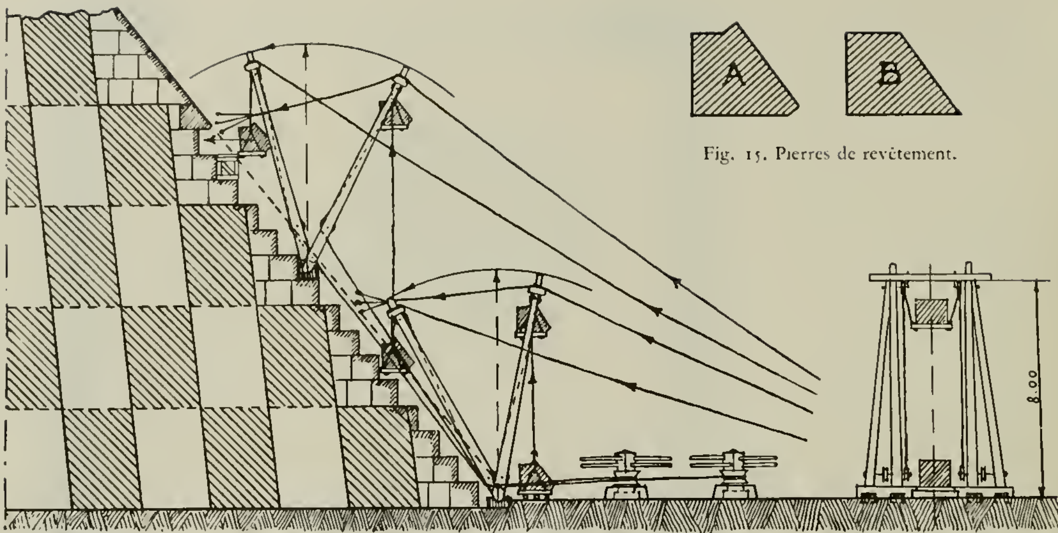


Fig. 15. Pierres de revêtement.

Machine for raising casing stones, as described by Herodotus and reconstructed by H. Straub-Roessler.
A and B are Lauer's indication of how casing stones may have been fitted.

which he does not adequately describe. Cotsworth figures that if the stones had had to be rocked to the top as reported by Herodotus, it would have taken about a month to get each of the final ones up to the summit.

Barber maintains that steel cranes or derricks would have been required to swing such great stones as are found ir, the Pyramid, and that for lack of such equipment the Egyptians would have had to construct a ramp in order to raise the heavy stones to the required level. Remains of such ramps have been found at the pyramid of Amenemhet at Lisht and also at Medûm. Aerial photographs indicate substantial remains of ramps under the sand at Dashur.

Petrie thinks the casing stones were placed in position at the same time as the core, starting from the bottom and going up course by course. He estimates that about 500 blocks were brought over from the quarries each day and laid in place. As the lower courses contain as many as 50,000 blocks, it would have taken over three months to lay each of these courses.

Petrie says the transporting was done during the three months of inundation, when a vast labor force was available and when advantage could be taken of the flood waters to float the blocks from the quarries downstream and across five miles of swollen Nile. Petrie suggests that even if no more than eight men could work together on an average block of 40 cubic feet weighing about 2 1/2 tons, they could have transported ten such blocks to the Pyramid in three months, taking two weeks to bring the blocks down the causeway from the quarry, a day or two with good wind to ferry the blocks down the Nile, and six weeks to raise them to the required position on the Pyramid. By November the men would be at liberty to return to their usual occupations when the land was again accessible.

Petrie estimated the Great Pyramid to contain about 2,300,000 stones weighing 2 1/2 tons apiece and averaging $50 \times 50 \times 28$ inches. If eight men could bring ten stones in three months, 100,000 men could bring 125,000 stones each season, or the required total in the twenty years reported by Herodotus.

Edwards says there can be little doubt that in addition to the 100,000 men levied for the purpose of transporting the blocks to the Pyramid, many others were engaged in building the Pyramid. These men, says Edwards, consisted of skilled masons and an attendant body of laborers, continually employed throughout the year preparing and laying the blocks and erecting or dismantling the ramps. Presumably these workers could have been housed in the buildings found

Aerial photograph showing ramp under the sand leading to the pyramid of Dashur.

Romanticized modern drawing of barges being rowed down the Nile toward the Giza pyramids.

by Petrie west of Kephren's pyramid, where about 4000 at a time could have lived in barracks.

Petrie figures that 40,000 skilled workers living permanently on the spot could easily cut and finish the 120,000 blocks needed each year; a party of four men would have a whole month to handle each block.

Petrie believes the masons finished and laid the casing and some of the core masonry, course by course, on the ground, before raising them. He found horizontal lines carved on the casing stones and on the core stones showing just how they were to be fitted. He believes that skilled masons planned all the work throughout the year and that at flood time gangs of unskilled workmen raised the finished stones to their indicated positions.

Petrie says the casing stones were dressed by very fine picking or adzing and were moved into position from the *inside,* whereas the core was filled in afterward.

Maragioglio and Rinaldi, two Italian scholars who recently made extensive measurements of the pyramids of Giza which they incorporated into four carefully illustrated quarto volumes entitled *L'Architettura delle Piramidi Menefite,* agree that the casing and the nucleus were built up at the same time; they think the casing blocks were slid into place by means of a thin layer of very liquid mortar that served as a lubricant as well as a filler and binder; they also think the casing blocks were levered into position from the back and sides so as not to show marks or chips on the front.

Ballard believes it would have been impossible to place the finished blocks without damaging their fine edges; he thinks the roughly scabbed blocks were put in place and finished off with the aid of templates.

In support of Petrie, I. E. S. Edwards points out that because the lowest course of casing stones lies on the smooth pavement of Turah limestone which projects a couple of feet beyond the Pyramid base, it would have been impossible to lay the casing stones from the *outer* side without damaging the fringe of the pavement which was to remain exposed; nor could they have been dressed *after* being put in position without damaging the pavement.

The fact that some of the limestone slabs of the foundation pavement are seen to be laid *beneath* the nucleus blocks also indicates the nucleus was filled in after the casing blocks had been placed in position.

Petrie believes the casing blocks were placed side by side on the ground and worked so that the back, sides and bottom would fit perfectly when put in place. The only thing left to do on the spot would have been the leveling of the upper faces.

According to the architect Rex Engelbach and the engineer Somers Clarke, authors of *Ancient Egyptian Masonry,* in order to render the sides of the casing blocks perfectly equal they were placed side by side in the yard and a saw was passed between them. However, Maragioglio and Rinaldi could find no trace of saw marks on the vertical sides of any of the remaining blocks.

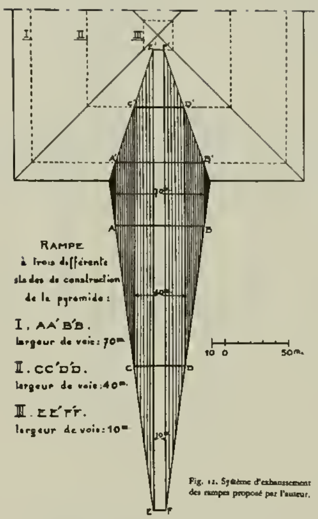
Petrie claimed to have found traces of red ochre on some of the stone faces which had not been perfectly dressed. From this he deduced that the dressing was done by degrees —as a dentist shapes a tooth—the control being made with facing plates covered with ochre.

In any case, the arrangement of casing blocks must have been worked out in detail well in advance of placement so as to assure a variance in the width and height of the backing stones from level to level, so as to prevent the vertical joints from coinciding.

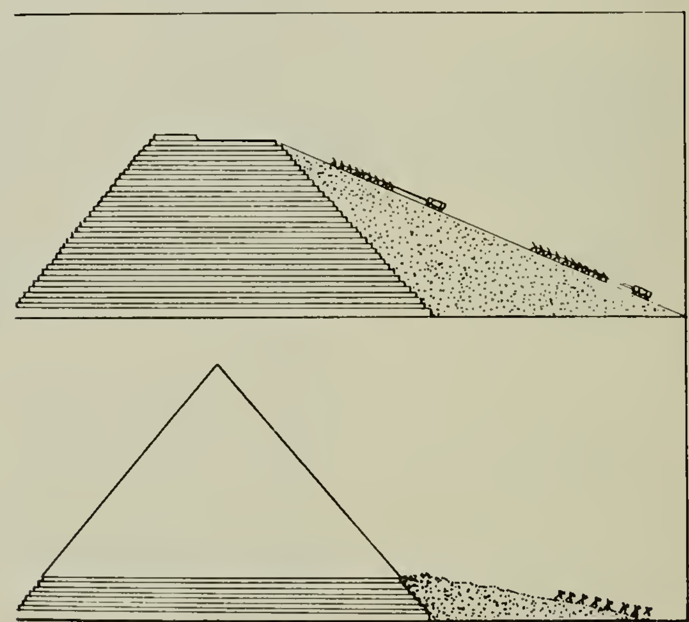
All the stones presently visible in the Pyramid are backing stones specially cut to dovetail and fit behind the outer casing. They are well dressed and squared, but made with fossilized limestone instead of the pure white.

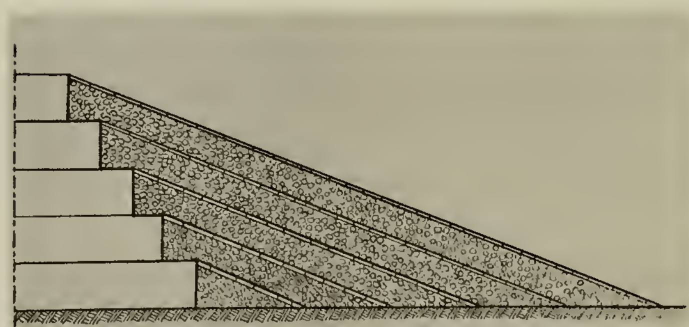
Behind them the nucleus consists of less well-dressed and roughly faced blocks of greatly varying sizes, for easier construction, and to insure that break joints did not coincide in either sense. They are held together by a mortar composed of sand, lime and crushed red pottery, which gives it a slightly pinkish color.

Maragioglio and Rinaldi attribute the concavity of the sides of the visible backing blocks to a means of preventing the facing courses from sliding, especially in the middle, by wedging the backing stones together at the center. On the north side the concavity has been measured as .94 meter. Maragioglio and Rinaldi believe the casing faces may also have been slightly concave, if only for esthetic reasons, as the optic aberration would thus be corrected, the Pyramid edges would appear sharper, the faces flatter; also,



Lauer's idea of how the ramp would grow wider and narrower.





Various methods of building ramps.

any errors in dressing the faces could be more easily distinguished.

Slight variations in the angle of the outer faces of casing fragments found in the rubble at the Pyramid's base may be explained by such a surface concavity.

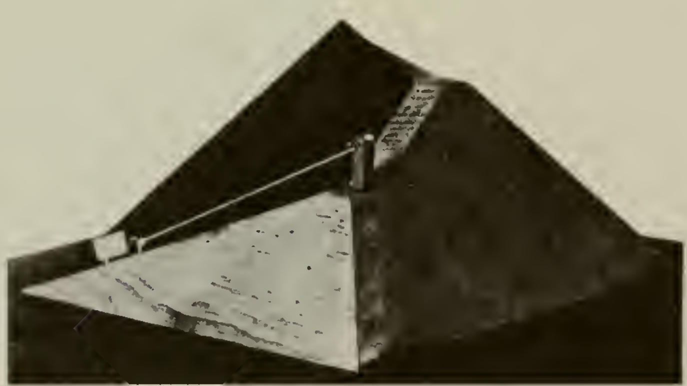
To raise each course of casing stones and nucleus all the way up the Pyramid, Petrie believes a ramp was constructed against one face, and he estimates that its volume would have had to be at least equivalent to that of the Pyramid itself.

Barber points out that to carry an inclined plane to the top of the Pyramid at a grade of one in ten, it would have been necessary to start the ramp 6000 feet away in the Nile valley at a point over 1600 feet before the commencement of Herodotus' causeway. Furthermore, says Barber, there would always have been four times as much work to do on the inclined plane as on the Pyramid.

In order to carry the ramp to the top of the Pyramid, Barber estimates that some 75,000,000 cubic feet of Nile bricks would have been necessary, or four times the number of cubic feet of stone still required to finish the Pyramid. With each additional course of masonry the ramp would grow higher and longer, but it would also grow narrower as the Pyramid narrowed at the top. According to Pliny such ramps were composed of niter and salt which could later be dissolved with water, but the idea seems fanciful as it would have required an ocean.

In *Natural History* of November, 1970, Olaf Tellefsen, an engineer, suggests that the Great Pyramid could have been erected with only a few thousand men using a simple piece of machinery consisting of a sturdy wooden arm balanced with counterweights on a fulcrum fixed to wooden skids—much like the machine drawn by the German engineer L. Croon.

This, says Tellefsen, would have done away with the need



for huge ramps postulated by Egyptologists on the basis of archaeological remains. According to Tellefsen, there was not enough manpower in ancient Egypt to build such ramps beyond the halfway mark of the Pyramid. Egyptologists countered, a little acidly, that from that point on the ramps narrowed rapidly, and that there appeared to be little evidence for Tellefsen's contention.

Cotsworth believes the Egyptians used a more ingenious system for raising the stones by taking advantage of the building itself as a ramp, dragging the stones up the Pyramid's own spiraling outer wall. This would enable the builders to fill in the core as they went up and finish the casing as they came down. Cotsworth says he watched a modern Egyptian peasant build a pigeon house by just this method.

The system has the added advantage that if the south wall of the Pyramid were completed first, the rest of the work could have been carried out in its shade rather than in the broiling sun.

But with or without the broiling sun, if one takes into account the problems of quarrying, roughing out, transporting over two million core stones, and finishing some 115,000 enormous casing stones to a precision of 1/100 inch, then raising, manipulating and mortaring them into their correct

place in a unified polished structure, one must agree with Antoniadi that the mind boggles at the enormity of the effort.

According to Barber's well-trained naval mind, it must have required the organizing capacity of a genius to plan all the work, to lay it out, to provide for emergencies and accidents, to see that the men in the quarries, on the boats and sleds, and in the masons' and smithies' shops were all continuously and usefully employed, that the means of transportation was ample, that the commissariat did not fail, that the water supply was ample and conveniently disposed, and that the sick reliefs were on hand.

Barber points out that public works were essential to keep this population employed and fed during the floods. August Mencken presumes that no less than 150,000 women and children also had to be housed, fed, and policed in nearby settlements. Judging from the texts and the paintings dealing with the subject of forced labor, Barber figures a large portion of the duty of the standing army of 400,000 men must have been that of guards.

Cotsworth says that in the rainless climate of Egypt no housing was needed for the natives who were accustomed to surviving on grain and water, and that the desert provides better sanitation than was available in Victorian England.

The waste chips of the masons were thrown over the

In 1950 the Museum of Science in Boston built a model to the scale of 1:120 showing how they believed the pyramids of Giza to have been constructed with slanting side ramps, three up and one down.

Dows Durham, curator of Egyptian art at the Museum of Fine Arts in Boston, responsible for the technical details, disagreed with the theory of long ramps because every time the building rose a few feet the ramp would become unusable until it was raised and extended.

Durham conceived the side ramps as being about 10 feet wide, or sufficient to handle a sledge with a double row of men to drag the stones over wet timbers for reducing friction. However, turning the corners would not have been easy.

cliffs of the Giza hill on both the north and the south sides, where they formed banks stretching out a hundred yards, occupying a space almost half the bulk of the Pyramid. The slopes formed an angle of rest of about 40°, showing the different qualities of refuse thrown away on different days, varying from large chips to mere sweepings.

In pits which had recently been made in part of the heap close to the edge of the cliff, Petrie noted layers of desert flint and sand showing when a piece of desert ground had been cleared to get more space for working. Among the rubbish he found pieces of workmen's water jars and food vessels, chips of wood and charcoal, and even a piece of ancient string.*

The only report on the daily cost of building the Pyramid is given by Herodotus, who says that an interpreter told him the daily sum spent on radishes, onions and garlic for the workmen was inscribed in Egyptian characters on the base of the Pyramid. But the report sounds apocryphal, as does the one passed on by Herodotus to the effect that Cheops became so broke during the operation that he prostituted his daughter by placing her in a chamber and charging each visitor the equivalent of a finished limestone block for her favors.

Kingsland figured that to position an estimated 2,300,000 blocks in a period of 20 years, or 7300 workdays, would have meant placing 315 stones each day, or 26 stones an hour working 12 hours a day.

Mencken, who has such disdain for the mathematical and astronomical knowledge of the ancient Egyptians, considers it remarkable that they were able to solve some of their problems of construction unless they had "more knowledge, better instruments, and far more ingenuity than is generally believed."

Kingsland wonders what means of illumination the Egyptians used while digging down to the subterranean pit and what method they used for getting air to the diggers. He finds it difficult to resist the conclusion that the Egyptians must have had tools and appliances of which we are totally ignorant, and must have employed methods which today would be termed occult.

Some of their solutions may have been no more arcane than Lockyer's suggestion that with one movable mirror and several fixed ones, sunlight could have been reflected to any part of the interior of the Pyramid.

Though legend attributes to the priests of Heliopolis the

* It would be helpful if more fragments could be excavated and carbon-tested.

knack of being able to cause tempests and levitate rocks that a thousand men could not move, most Egyptologists argue strenuously against the possibility of sophisticated instruments such as laser beams for cutting surfaces, or ground-effect or antigravity machines for raising weights, insisting that the job was accomplished with nothing but primitive appliances and unlimited manpower. Nevertheless the conscientiously academic Edwards fudges the issue by saying: "Cheops, who may have been a megalomaniac, could never, during a reign of about twenty-three years, have erected a building of the size and durability of the Great Pyramid if technical advances had not enabled his masons to handle stones of very considerable weight and dimensions."

Petrie is more specific and gives substance to the hypothesis of unknown methods, pointing out that in the pyramid of Kephren there is a granite portcullis weighing about 2 tons which is in such a position in a narrow passage that only 6 or 8 men could work on it at once. As it would take a force of 40 to 60 men to manipulate such as a mass, Petrie concludes that the Egyptians must have had some more efficient means which remains unknown to us.

Although the Danish engineer Tons Brunés has demonstrated how a block as large as the beams of the King's Chamber could be comfortably raised by a single man with the dexterous use of balancing and wedges, Petrie is convinced that ancient builders possessed some more efficient means of raising and setting stones than mere rollers, levers, ramps and manual hauling.

But perhaps the most puzzling riddle of the Pyramid, requiring an intellectual game of detection, is the one constituted by the three granite plugs wedged into the end of the Ascending Passage.

XIX. WHY WERE THE PYRAMID PASSAGES PLUGGED? WHEN? AND HOW?

Most Egyptologists conclude that the Pyramid was built as a tomb for some Pharaoh, presumably Cheops. Any mathematical, religious or prophetic theories about the structure they consider to be fanciful, or, at best, coincidental. To Egyptologists the corridors of the Great Pyramid were designed solely as a means of transporting the coffin of the dead Pharaoh to his sarcophagus in the burial chamber, as a means of exiting after the entombment, or as blinds to lead grave robbers away from a hidden chamber.

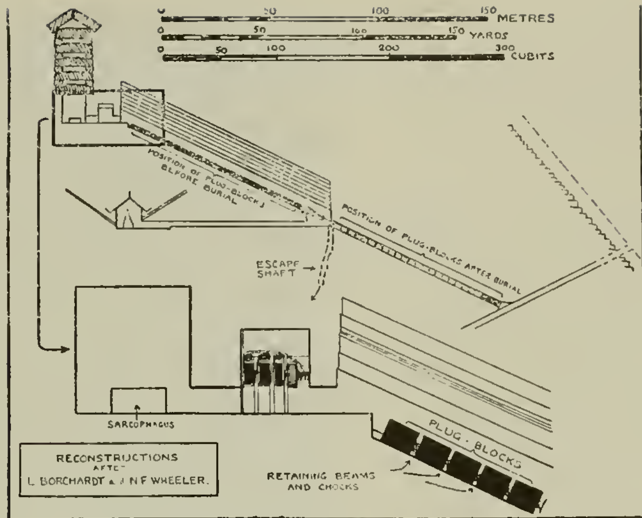
No other reason is offered for piling up so massive a mound of masonry than to protect the dead Pharaoh from the attention of grave robbers. Oddly, this is the single function which neither the Great Pyramid, nor any of the others, managed to fulfill, there being no reliable report of any body having been found in any of the pyramids, only some fragments of bones whose dates are uncertain.

Even the "unplundered" tomb of Cheops' mother, Hetepheres, found in 1925 by the Harvard-Boston Expedition at the bottom of an 85-foot-deep shaft filled with rubble, appeared untouched in 5000 years: yet the sarcophagus was empty and is presumed to have been so placed within the "burial" chamber.

According to the Egyptologists, who include such eminent figures as Petrie and Borchardt, once the body of a Pharaoh had been laid to rest in the Great Pyramid and the burial party had made its exit, the three huge granite blocks, plus several limestone ones, were allowed to slide down the incline between the ramps of the Grand Gallery till they had completely plugged the Ascending Passage.

Whether the tripping mechanism could have been operated by remote control from a safe distance below the plugged entrance, or whether the technicians responsible for the tripping device were immured for life, or whether they managed to make their escape down what is known as the "well" are theories supported in different degrees by different Egyptologists.

Method of plugging the Ascending Passage as visualized by Cottrell from the ideas of Borchardt and Wheeler.



Ideas of various Egyptologists of the methods of plugging passages, lowering portcullises and sealing sarcophagi.

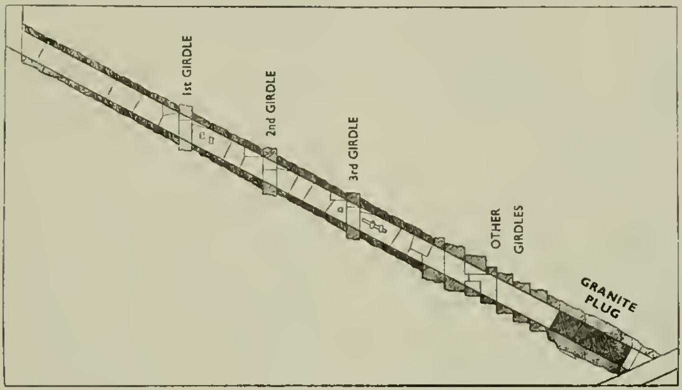
Modern illustration of the granite plugs in the Grand Gallery.

To account for the three granite plugs and the peculiar arrangement of the Pyramid's passages and chambers, Borchardt put forward the theory that the builders started with one plan, but kept changing it as they went along.

Borchardt believes the "original" intention was to bury the dead Pharaoh in the pit carved out of natural rock at the bottom of the Descending Passage, but that this plan was changed. For some unspecified reason, says Borchardt, it was decided to bury the king higher in the body of the Pyramid, which was already several courses high. The pit was therefore left unfinished. An Ascending Passage was carved up through the already laid courses of masonry, and continued as a new passage up to the level of the Queen's Chamber.

While making a careful study of the walls of the Ascending Passage, Borchardt observed that the stones at the lower end were laid approximately parallel with the ground, whereas nearly all those at the upper end were parallel to the gradient of the corridor. From this he deduced that the Pyramid must have already reached a level corresponding to halfway up the as yet nonexistent Ascending Passage before it was decided to use an upper chamber; at that point the Ascending Passage was dug up through the existing level courses; thereafter it was built with blocks parallel to its slope.



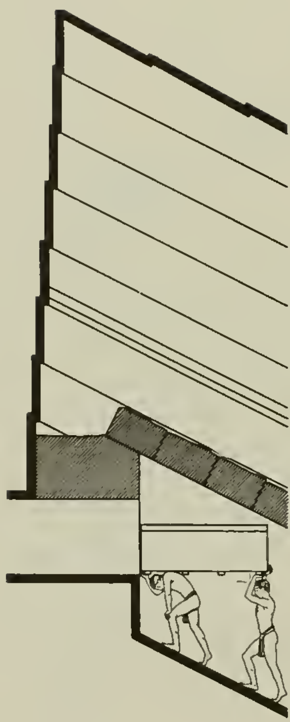
Arrangement of girdle stones 10 cubits apart, to tie the Ascending Passage to body of Pyramid, as drawn by Adam Rutherford, director of the Institute of Pyramidology in Great Britain.

Borchardt's theory is supported by Leonard Cottrell, author of a popular book on the pyramids, *Mountains of Pharaoh,* who suggests that when the builders switched plan they got as far as the Queen's Chamber complete with its air channels before they again changed their minds.

Cottrell says a third scheme brought with it the decision to heighten the Ascending Passage into "the magnificently corbeled Grand Gallery," extending it another 160 feet so as to build yet a third chamber, the King's, as the final resting place for the Pharaoh's body.

According to Cottrell, the change came about as a sort of afterthought, while the great mass of builders was already in the midst of constructing a building whose base and slopes appeared to have been worked out with such extraordinary precision.

Why the Grand Gallery should have been raised to 28 feet, when less than half that height would have been ample for the bearers and for the storage of the plugs, was not explained by Cottrell.



Borchardt's fanciful idea of pallbearers reaching the Great Step at the top of the Grand Gallery, with plug stones supported on a platform above them.

Borchardt and Cottrell's theory was disputed by Maragioglio and Rinaldi, who point out that the bottom of the Ascending Passage was *intentionally* cut through the lower courses simply as a means of anchoring it to the body of the Pyramid. The Italians say the lower part of the Passage was not dug out of normal masonry or with normal methods, but in masonry especially erected to anchor the end of the Passage, many of the blocks being exceptionally large, laid flat, vertical and edgewise, and of a different quality from the rest of the nucleus, with joints very thin and finely finished; whereas in other areas where the regular nucleus masonry is visible, the joints are wide and coarse.

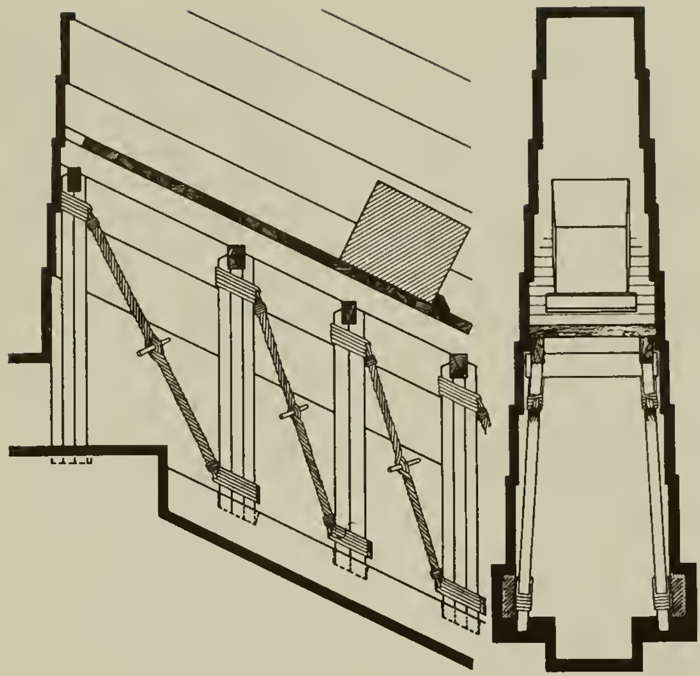
The object, say Maragioglio and Rinaldi, was to create a bulwark at the juncture of the Ascending and Descending Passages so that the ceiling and floor of the Ascending Passage would not thrust down on the empty space of the Descending Passage. The Italians point out that several monolithic girdle stones are employed at 10-cubit intervals all the way up the Ascending Passage to reinforce its bond with the nucleus of the Pyramid, and prevent its slipping, but that no such girdle stones appear in the Descending Passage, where they are not needed because the whole passage rests against the solid rock of the Giza hill.

Borchardt produced a further refinement to his theory, which not only found few supporters, even among his fellow Egyptologists, but tended to discredit his whole approach to the problem: namely, that the granite and limestone plugs which filled the Ascending Passage could not have been stored on the Grand Gallery floor between the ramps, because they would have provided an "undignified obstacle" for the funeral train to clamber over. As the plugs were too large to be brought in or out of either the Queen's Chamber or the King's, Borchardt theorized that the blocks were raised onto a wooden platform which was fitted into the grooves which appear halfway up the walls of the Gallery.

This would have allowed the funeral cortege to move beneath them; though how this would have been any less undignified than having to crawl up the low and narrow Ascending Passage is not explained, nor is it explained how the heavy blocks were brought down from the level of the wooden planking to the level of the pavement on which they were to slide.

That Borchardt's hypothesis is unreasonable, say Maragioglio and Rinaldi, is evident from the fact that few archeologists have paid much attention to it.

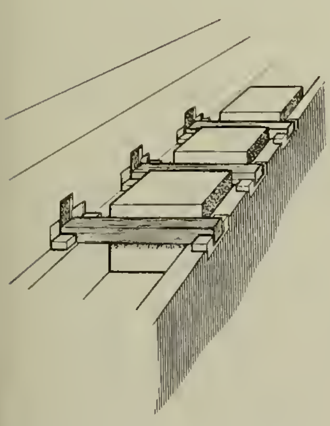
As for the method of triggering the plugs down the Ascending Passage, Cottrell believes the notches in the



Trestle believed by Borchardt to have raised plug stones to a level half the height of the Grand Gallery.

ramp of the Grand Gallery were cut to hold cross beams of wood or limestone to keep each of the massive plugs from prematurely sliding. According to Cottrell, once the funeral cortege had passed, operators standing on the ramps could have released each plug, starting with the bottom one, and allowed them to slide into the Ascending Passage, on the theory that had they all been released simultaneously the momentum and the total weight might have caused damage at the lower end.

The theory raises the question as to what became of the wooden or limestone crosspieces. Had they been made of wood they might conceivably have pulverized and completely disintegrated in the thousands of intervening years. They might also have been carried down the well by the escaping operators, though this would have been something of an ordeal, if indeed possible. The material might also have long since been disposed of by grave robbers. Still, the question is puzzling. Also, why go to all the trouble of plugging the Ascending Passage, only to leave the well shaft as a perfectly simple way for thieves to climb back up to the Grand Gallery? The lower end of the well shaft could have been cleverly concealed; but its whole length could hardly have been plugged or made impassable with fill *after* it had been used as a means of escape.



Goyon's idea of how granite and limestone plugs were held in place by crossbeams fitted into the ramps.

Part or all of the *Descending* Passage could have been plugged and the Pyramid sealed. This would have been the simplest way conclusively to close up *all* the chambers in the Pyramid, making it an almost superhuman job to chisel out 350 feet of solid limestone.

Petrie disputes the notion that the long Descending Passage could have been filled with blocks; and Maragioglio and Rinaldi suggest that traces of the dismantling of such plugs would have been left on the walls of the Descending Passage, which is not the case, with the exception of a few feet beyond the entrance.

The most sophisticated refutation of the theory holds that the Descending Passage may have been purposely left empty and the pit unfinished as a blind to lead any robber who entered by the trap door to believe that no king had been buried in the Pyramid!

As for the well shaft, Maragioglio and Rinaldi have a completely different theory about its function. They do not think it was ever designed as an escape route; they think it was built in from the early stages as a service shaft and to bring air to the lower end of the Descending Passage.

The Italians say the need which led to the building of such a shaft may have arisen shortly after the beginning of the Ascending Passage, most likely as a means of ventilating the lower shaft. They believe the diggers at the bottom of the Descending Passage had difficulty breathing. Plausible at first sight, the theory is open to two objections: as the building went up course by course, above the level of the rock base, there would have been all the air in the world; whereas digging the well shaft *below* rock level, the diggers would have been as cramped and airless digging the well shaft as digging the Descending Passage, at least until the two met at the bottom—by which time the well would no longer have served its ventilating purpose, the digging having been completed.

Such an air vent might conceivably have been useful to bring air to the pit, had the pit been used for any continuing purpose, such as observing the stars.

The Italians also believe that long before any funeral party entered the Grand Gallery, the entire well shaft was filled from the top with debris and loose material. The bottom entrance was then carefully camouflaged, and a stone was mortared into the upper end in the west ramp of the Grand Gallery to seal and hide the shaft from the top. They cite the fact that from classic times till the nineteenth century no one appears to have spotted the bottom entrance to the well shaft.

Maragioglio and Rinaldi agree with Petrie that the Pyramid was violated by thieves or grave robbers soon after it was finished, during the civil wars, which they date between 2270 and 2100 B.C. At this point the theory of the Italians becomes radical. They maintain it was these early despoilers of the Pyramid and not Al Mamun who cut a hole around the granite plugs at the end of the Ascending Passage. These thieves then worked their way up the Ascending Passage, broke through the lowered portcullis, and entered the "crypt." According to the Italians it was these or successive thieves who found the well shaft by noting a difference in the stones at the bottom of the ramp in the Grand Gallery, which they forced in order to clear out the well shaft in search of treasure. The Italians maintain that the marks in the west ramp around the missing stone appear to have been made with a chisel struck from above. They say it would also have been extremely difficult to remove the stone from below in the very restricted passage which leads to the head of the well shaft.

To explain the way the Ascending Passage was plugged, the Italians maintain the tripping mechanism could have been operated by remote control. They point out that it has recently been discovered that in the bent pyramid of Sneferu, the blocks of granite which plug the Descending Passage could *only* have been moved by gravity and not directly levered by workmen, because there *is* no escape route.

The Italians believe the plugs in the Great Pyramid were slid on liquid mortar and that its forced accumulation accounts for the 10 centimeters of empty space between the first and the second granite plug; though they offer no explanation as to what may have become of the mortar, which could hardly have volatilized in the meantime, unless it was some sort of oil and not mortar.

It is also hard to imagine how the antique grave robbers could have immediately found the exact spot halfway down the Descending Passage from which to dig up past the granite plugs if there is any truth in the story of the plug being covered by a prismatic block.

Maragioglio and Rinaldi suggest there was no such block; paradoxically they give credence to the story that Al Mamun's workers heard a heavy block fall—simply because Al Mamun's passage takes a sudden turn to the east in order to break into the Descending Passage.

Another theory which attempts to account for what could have taken place in the plugging of the Pyramid was produced in 1963 by August Mencken, the engineer from Baltimore who has so little regard for the scientific knowledge of the ancient Egyptians. According to Mencken's somewhat farfetched reconstruction of events, when the Great Pyramid had been built up above the ridge of the roof of the King's Chamber, and work was still going on in the Grand Gallery and in the Antechamber, the structure was suddenly shaken by a severe earthquake. It was then, says Mencken, that the ceiling beams of the King's Chamber were cracked, the fissures opened, and, "to the terror of the builders, the triggering device which held the plugs on the floor of the Grand Gallery was sprung and the blocks slid down the Ascending Passage, blocking all exit from the Pyramid."

According to Mencken, the men inside were trapped, but their plight was not desperate. "As soon as the fright and confusion caused by the earthquake had subsided, the men on the outside discovered what had happened to the men on the inside and opened communication with them through the air ducts leading out from the King's Chamber. By the same ducts the trapped men were supplied with food and water."

Mencken figures that to have chipped out the three granite plugs in the restricted space of the Ascending Passage was out of the question, and that to have tunneled around them would have caused irreparable damage to the passageways. Rather than chip out the granite blocks, the Egyptians, says Mencken, decided to dig the well up from the bottom of the Descending Passage all the way to the end of the Grand Gallery.

The trapped men, says Mencken, were informed of what was being done, "and by the time the tunnel reached the opening in the Gallery they had removed the ramp stone." According to this theory an inspection crew was sent to ascertain the damage and examine the King's Chamber ceiling; for this purpose the small tunnel, later known as Davison's, was dug straight through the lowest of the cushioning chambers.

The plugging of the Ascending Passage, says Mencken, put an abrupt stop to all other interior work and made it impossible for the King's Chamber to be used for a burial, either real or token. "So everything above the plug blocks was abandoned and thus ended the first and only attempt of the ancient Egyptians to build elevated chambers."

In criticism of Mencken's theory it may be asked why, if the building had been constructed to just beyond the peak of the King's Chamber, would it not have been easier to remove several blocks from the upper tiers in order to reach the trapped men rather than go through the trouble of boring hundreds of feet up the whole length of the well? Also, if the builders had no further use for the interior of the building, why go to the effort of finishing off the Pyramid and casing it with 22 acres of finely polished limestone?

An entirely different solution to the problem is provided by David Davidson, the structural engineer from Leeds. According to Davidson, the depth and width of the granite plugs which seal the lower end of the Ascending Passage clearly indicate that the plugs must have been built into the passage *at the time the Pyramid masonry had reached the height of the plugs, or 17 courses.*

Davidson, who spent several months in Egypt studying the Pyramid closely, says the half-inch clearance at the sides of the top of the Ascending Passage would *not* be sufficient to insure the granite plugs being slid from the Grand Gallery without jamming.

This raises the question as to why the builders would have bothered to even build the Ascending Passage if they intended to plug it up immediately with three large granite plugs.

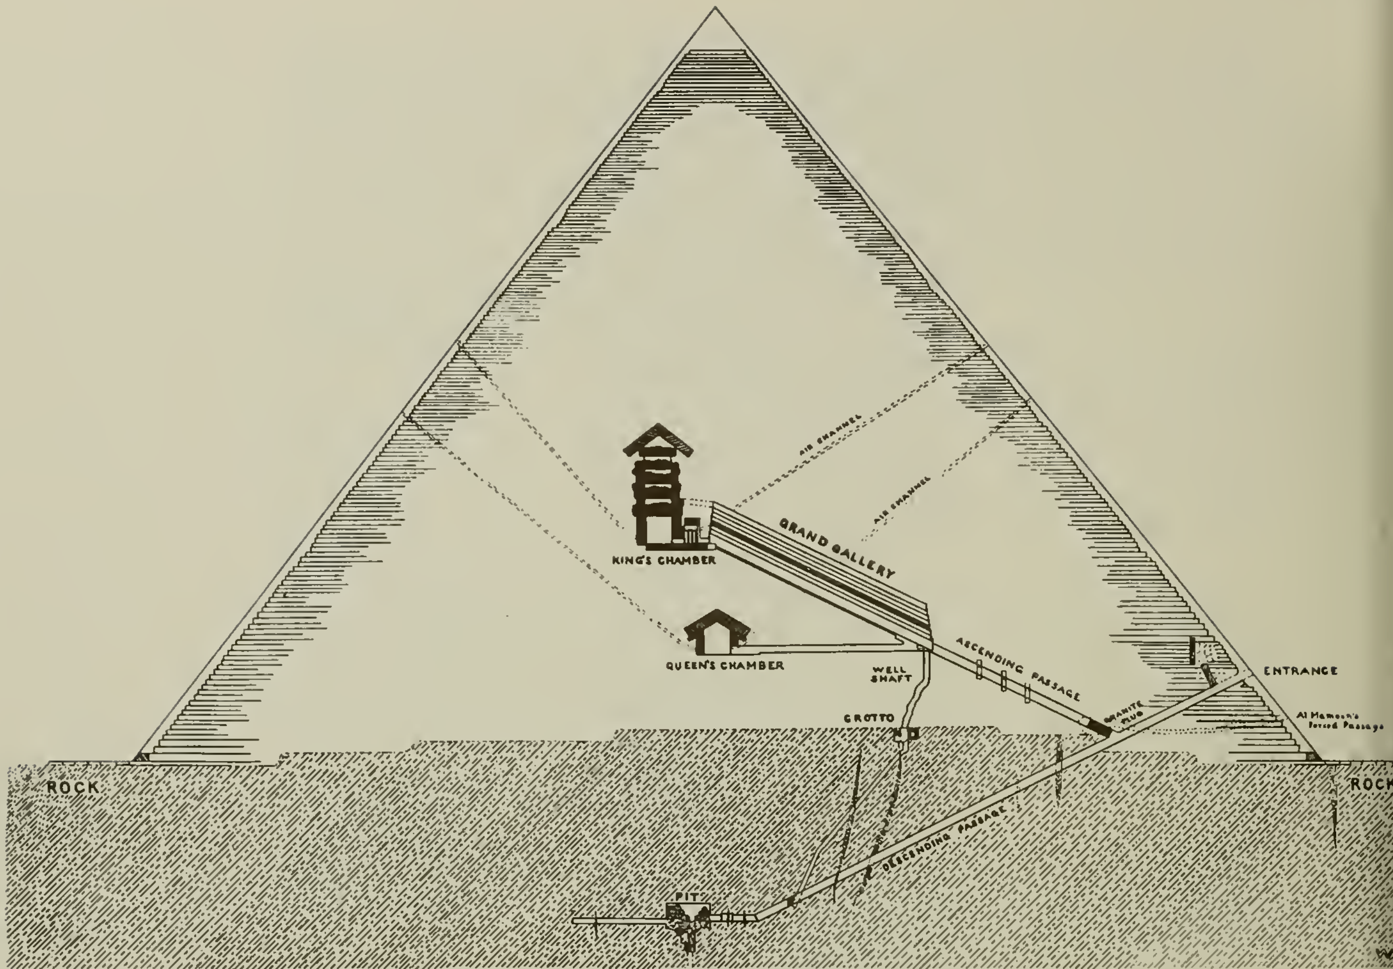
Davidson answers that the inside of the Pyramid was not designed for contemporary use, but was intended to be discovered by people of a much later civilization, rather like our modern time capsules, and that the discoverers would have to break their way in through the series of limestone plugs, much as Al Mamun is reputed to have done.

This raises the question of the presence of the well shaft, which could have led any intrepid explorer straight to the Grand Gallery, bypassing the Ascending Passage. Davidson answers that the well was an afterthought, not planned in the beginning as an escape route after a burial, if for no other reason than because the Pyramid was never intended as a tomb.

Davidson has an ingenious reconstruction of what may have occurred. He maintains that some time not long after the completion of the Pyramid, an earthquake or several disasters severely shook the building. After the disaster the priests or guardians of the Pyramid noted certain subsidence effects on the external surface of the structure, and they decided they must investigate the interior to see if the King's Chamber had collapsed or been badly damaged.

Davidson says this must have happened within a few generations of the completion of the construction, and before precise details and measurements of the internal construction had been lost.

The keepers, says Davidson, entered the Descending Passage and instead of trying to carve their way up through a score or more of limestone plugs in the Ascending Passage, as was later to be done by Al Mamun, they went nearly to the bottom of the Descending Passage and then began to bore a hole upward toward the beginning of the Grand Gallery.



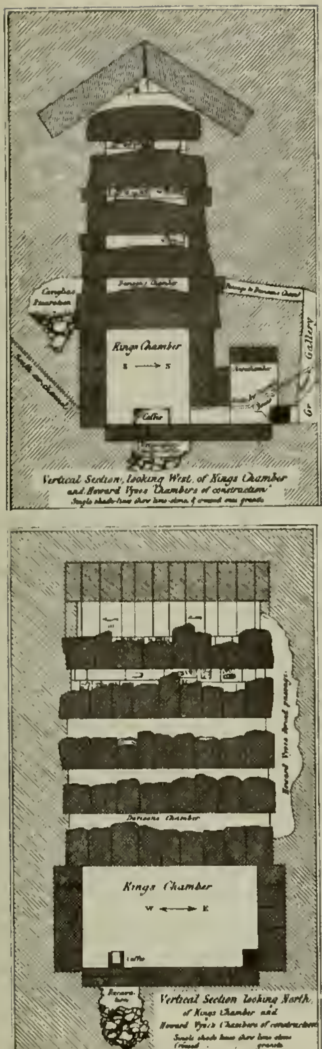
Davidson's rendition of the Great Pyramid passages, showing three large fissures in the natural rock.

Their reason for starting so far down, says Davidson, instead of taking a shorter route past the plugged Ascending Passage, was to cut their way through, and carefully observe, two large fissures that had appeared in the bedrock. A third fissure, present at the time of construction, had already been shored up by the builders.

The problem of the priests, says Davidson, was to determine if the fissuring was severe enough to cause further subsidence.

Digging in a gradual upward slope, says Davidson, the keepers worked their way through both fissures, finding them in not as bad condition as they had expected. At the level of the Grotto the keepers made a staging area for tools, for rest, and for the bypassing of workers and material.

From the Grotto they continued their shaft up toward the commencement of the Grand Gallery. Having somehow made an accurate survey of exactly where they were, they



Davidson's rendering of the way the chambers in the Pyramid are aligned just east of the main east-west axis.

then bored straight up and came out beneath the lowest ramp stone on the west side of the Gallery. To Davidson it is clear from the fractured appearance of the ramp around the well entrance that the stone was forced upward and outward.

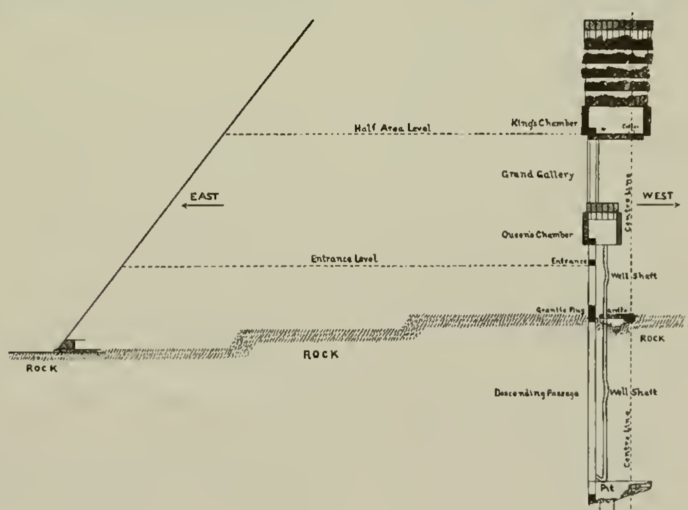
To accomplish such a feat of accurate digging would have meant knowing the precise internal arrangement and measurements of the Pyramid. Anyone boring blindly could have missed the few feet of Grand Gallery and been obliged to bore several hundred more feet through the limestone courses before coming out into daylight. This goes a long way toward discounting the possibility of the well shaft having been dug by either thieves or explorers.

Once they had reached the Grand Gallery, says Davidson, the keepers dismantled the lower section of the Gallery floor for a dozen or so feet and uncovered the passage to the Queen's Chamber. This they inspected carefully, but found little or no sign of failure.

Proceeding to the King's Chamber, the keepers found indications of possible instability due to the movement. Inside the chamber they found the ceiling beams uniformly cracked along the south ends.

According to Davidson, it was then that the keepers smeared the fractures and open joints with cement and plaster. Petrie was later to report that he had found cement daubed on with fingers for about 5 feet on each side of the joints.

When Petrie carefully examined the King's Chamber he discovered that it had been badly shaken, probably by an earthquake, which caused the whole room to expand



Cracks in granite beams at the south end of the King's Chamber.

an inch or so. Every single beam had been wrenched more or less loose from the south end, and cracked through; the whole ceiling, weighing some 4000 tons, was held up solely by "sticking and thrusting." As Petrie summed up the situation, the downfall of the King's Chamber "is a mere question of time and earthquakes." What has saved it so far was not being bonded to the main structure.

Davidson says the five construction chambers were especially designed to take a considerable impact. Instead of resting the uppermost beams on a hard granite wall, the builders rested them on limestone, which could more easily crush and flow in case of subsidence, taking the strain off the lower rows of rafters and keeping the walls of the King's Chamber intact. Davidson says that a more rigid design, uniform from the lowest to the highest chamber, would have been disastrous.

To permit this buffer effect being fully developed, the rafters of the chambers were not tied into the east and west walls. Instead, two immense limestone walls, wholly outside of, and independent of all the granite floors and supporting blocks, were built on the east and west sides. As Petrie put it: "Between these great walls all the chambers stand, unbonded and capable of yielding freely to settlement."

To gain access to these important construction chambers above the King's Chamber, the keepers, says Davidson, next drove an opening into the east wall of the Gallery, starting at its upper, or south, end.

In support of the theory that this hole was bored by keepers who were precisely acquainted with the layout of the Pyramid (rather than by later explorers or thieves), Davidson points out that the hole is bored in exactly the right place, and takes off at the precise angle and direction to reach the lowest of the upper chambers.

Once inside the first chambe; (later to become known as Davidson's), the Pyramid keepers, says Davidson, found that the indications of instability were not so serious as they had feared. The great granite beams were indeed cracked, but the damage did not seem to be enough to cause any further crumbling or subsidence, nor warrant their boring any higher into the overlaying chambers. Instead, the keepers again daubed the cracks with plaster so as to be able to return at a later date and observe if any further movement had taken place.

According to Davidson, the keepers then climbed back down the well, the bottom end of which they camouflaged, and left by the swivel-stone entrance on the north face.

There is nothing inherently illogical about this version of events. It would have been no easy job to tunnel upward through the solid rock and the various courses of masonry—altogether hundreds of tons of material would have had to be chipped away and taken out of the Pyramid up the Descending Passage—but it would not have been impossible.

It would also have been a problem to get light and air to the men doing the chiseling, and it would have been tricky to raise a platform or system of suspension while chiseling upward; also it would have been a nuisance to have the fragments fall constantly in the face of the chiselers and those below them; but all of this would not have been impossible.

What militates against this theory is the observation of Maragioglio and Rinaldi that the walls of the well shaft upward from the Grotto are built and lined with regular blocks of limestone, apparently as a feature of the original structure.

SINGLE SHADED LINES INDICATE NATURAL ROCK.

Grotto showing walls of the well shaft built out of masonry from the level of the Grotto to the first course of masonry of the Pyramid.

Conceivably these walls could have been lined by the keepers, operating from the Grotto, perhaps to insure a stable surface in this final section of the shaft.

Clear indications that it was *not* designed from the beginning were found by Petrie in the fact that the shaft is irregular and tortuous through the rest of the masonry, and that blocks with sharp corners were left in an irregularly curved shaft.

A French professor of architecture, J. Bruchet, who went to the spot to verify and measure, and who published an illustrated book on the subject in Aix-en-Provence in 1966, agrees with Davidson that the granite plugs could not have been slid down the Ascending Passage; he believes they were put in place at the moment of construction, when the Pyramid was still a truncated body. To have slid them down, with so little clearance, says Bruchet, would have required walls as smooth as glass, whereas he found the walls of the corridor roughly finished.

But Bruchet disagrees with Davidson that the well shaft could have been dug from the bottom up, giving as his reason the fact that the bottom of the well shaft goes slightly below the level of the Descending Passage. Bruchet believes that this would not be so if the shaft had been started from below.

For the well shaft to have been dug from above, the operation could only have been completed *before* the Ascending Passage was plugged, or *after* the opening of "Al

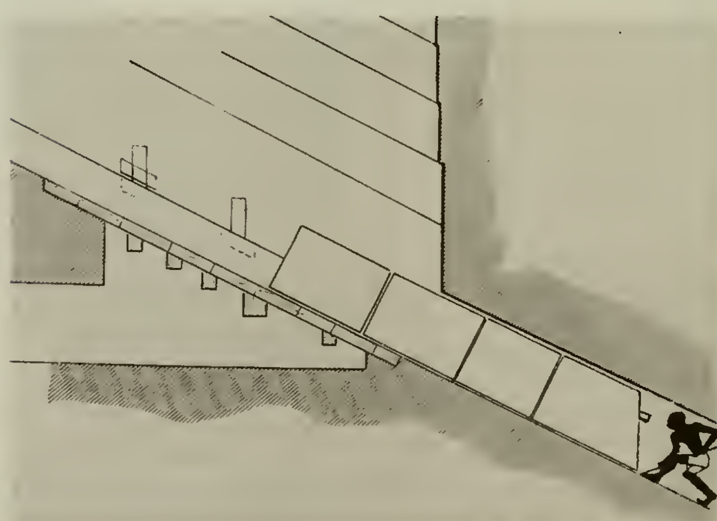
Mamun's hole." In a closed upper Pyramid there would have been no place to store the carloads of rubble from the digging of the well shaft: the King's and Queen's chambers would not have been sufficient, and storage in the sloping Grand Gallery would have required crosspieces and sacks.

Bruchet points out that the well shaft could not have been dug *after* Al Mamun, because the lower end of the Descending Passage was filled by him with the refuse of broken limestone plugs, which were not cleared out till 1817 by Caviglia. Also, says Bruchet, there are no graffiti to indicate the presence of visitors in the lower passage after the date of the Hegira.

Another Frenchman, Georges Goyon, who collected reproductions of all the graffiti on the Pyramid, which he put into a book dedicated to King Farouk, also does not accept the idea that the service shaft was used as an escape way. He too believes the Pyramid was violated a short time after it was built, and that "Al Mamun's hole" was made at this early period. He even goes so far as to suggest that the first violators entered by the tunnel now attributed to Al Mamun, and that Al Mamun's violation was made *after* the ablation of the Pyramid casing, which is in strict contradiction with the historical record.

Maragioglio and Rinaldi find some of Goyon's theories tenable, but are awaiting the publication of a booklet by Goyon in which he promises to add further material on the subject.

In a recent article in *Revue Archéologique,* entirely devoted to the mechanism of the closing of the Great Pyramid, Goyon suggests that one or two men alone could have manipulated the whole train of blocks down the Ascending



Goyon's view of how a single man could have eased a train of granite plugs down the Ascending Passage with the help of unguents and wooden wedges.

Passage by simply sliding them on clay mixed with cows' milk for greater viscosity, controlling the downward motion by means of wooden wedges on either side of the first block.

Goyon says there are indications on the lowest granite block of two slots 7 centimeters wide intended for wedges.

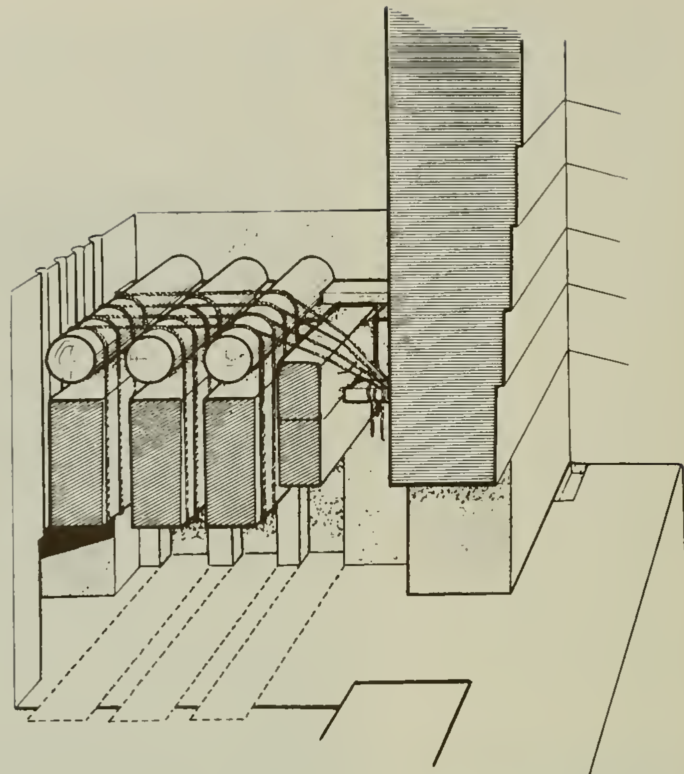
Goyon's arrows indicate slots in the granite plug for the insertion of wedges to control its downward movement.

Goyon disputes the point made much of by Davidson that the purely stylized portcullis outside the King's Chamber indicates it was never used to seal an actual tomb.

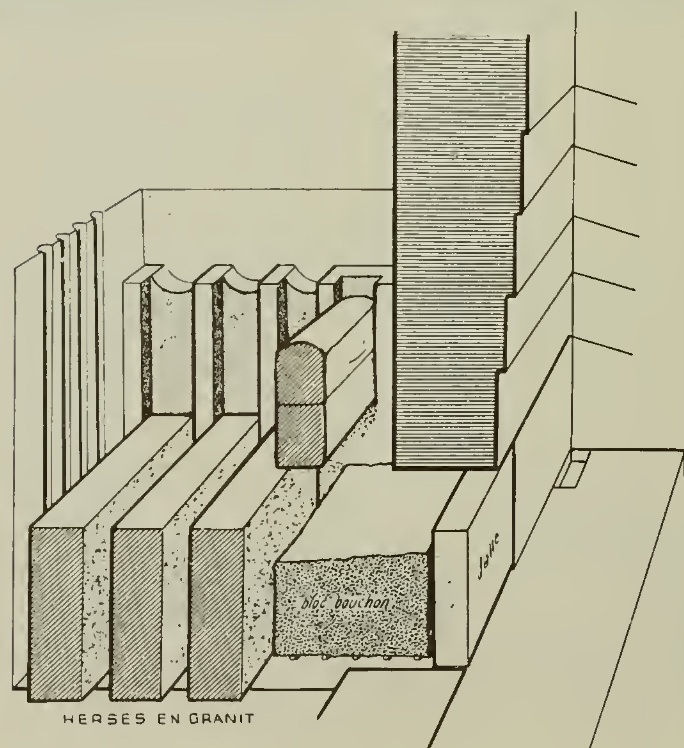
Goyon believes that the granite slabs—long since removed by grave robbers—could have been lowered in the appropriate side slots by ropes run on wooden rollers, and that the four vertical slots carved in the face of the portcullis were intended to allow free play for the ropes.

In the final analysis, the theory which stands up best, and is not in conflict with Davidson's findings, is that of the astronomers Proctor and Antoniadi, which is supported by Kingsland and John and Morton Edgar, that the truncated Pyramid served as a stellar observatory by means of which the ancient Egyptian priests were able to make accurate maps and tables of the visible stars from which to create their entire science of astronomy, geography and geodesy. Once they had obtained what they needed for their astronomical and astrological predictions (and for the secrets of surveying and map making), they may have decided to wall up their instrument so that no one else could know how their lore was obtained.

Borchardt's idea of how ropes around wooden rollers could have been used to lower the granite slabs of the portcullis.



Goyon's rendition of granite blocks plugging passage to the King's Chamber.



It would then have made sense to place the granite and limestone plugs in the Ascending Passage while the top of the Grand Gallery was still open to the level of the King's Chamber. To satisfy this theory, the well shaft could have been carved upward, as suggested by Davidson, or it could have been built in earlier to serve the builders for a variety of reasons, including to serve as a means of coming and going to the pit while the Descending Passage was blocked by a reflecting pool. In any case, the shaft could have been comfortably filled from the top before the builders finished off the building to its apex to serve as a sundial and almanac.

Donald Kingsbury, a professor of mathematics at McGill University, suggests that the well could have been used for observing the passage of stars at the zenith above the Pyramid. There are two vertical sections of the well which could have served this purpose admirably and at different moments in the construction. There is a short vertical passage dug into the plateau which is served by the Grotto and linked to the Descending Passage so that signals could have been freely passed between polar and zenith observers. Another vertical section leads from the bottom of the Grand Gallery and could have been used for zenith observation in conjunction with the Ascending Passage looking south and reflecting north. Kingsbury points out that with two such wells a short distance apart the circumference of the earth could have been computed by observing the passage of a zenith star.

Duncan Macnaughton in *A Scheme of Egyptian Chronology* subscribes to the slightly different theory that ancient scientists used the truncated Pyramid as an observatory, but that a later generation finished it off as a tomb for some Pharaoh.

The custom of burying distinguished citizens in national monuments that were not originally designed for that purpose is common to the world, as in Westminster Abbey, the Invalides, the Pantheon, and Maes-Howe.

Then there is the idea that the sarcophagus was never an actual tomb, but "an open tomb" symbolic of the resurrection, and of a reawakening of the dormant spirit of the great initiates.

XX. TEMPLE OF SECRET INITIATION

Several authors have expressed the opinion that there is a close connection between the Great Pyramid and what are known as the Egyptian mysteries, that is to say, the secret knowledge possessed by a hierarchy of initiates which was communicated to those who could prove their worthiness by passing a long period of probationary training and severe trials, the sort of system that was perpetuated or debased by such societies as the Templars, the Rosicrucians, and the Masons.

In due course the initiates are said to have been shown the great laws and principles of the cosmos and of man's relation thereto, which could not be explained to the more or less ignorant, "who could not rise above the level of a crude realism which takes things to be what they *seem.*"

The Egyptian temple order is described by modern Free Masons as a gradual process of initiation and admission, in which the Great Pyramid was probably used for the initiation of the highest degree, or the three highest degrees in the order.

Throughout the graduated admission, which is said by Masonic writers to have lasted twenty-two years, the prospective initiate was taught the various sciences, of which geometry and numbers were among the most important. "In this context," says Tons Brunés, author of *The Secrets of Ancient Geometry,* "it is not surprising that they should have worked this knowledge into the structure of the initiation temple."

Knowledge of the astronomical cycles and their application also formed part of the ancient initiatory teaching. In those days, says William Kingsland, astronomy was not the mere science of the mechanism of the heavens, but was intimately connected with astrology, "a profoundly esoteric science connected with the great cycles of man's evolution, understood only by the Adepts."

Kingsland adds that if the Great Pyramid was built by initiates for initiates, "What could be more likely than that some of the deeper forces of nature were used in its construction, and that these would—did we but know of them—solve the problems of construction which still remain an enigma to us."

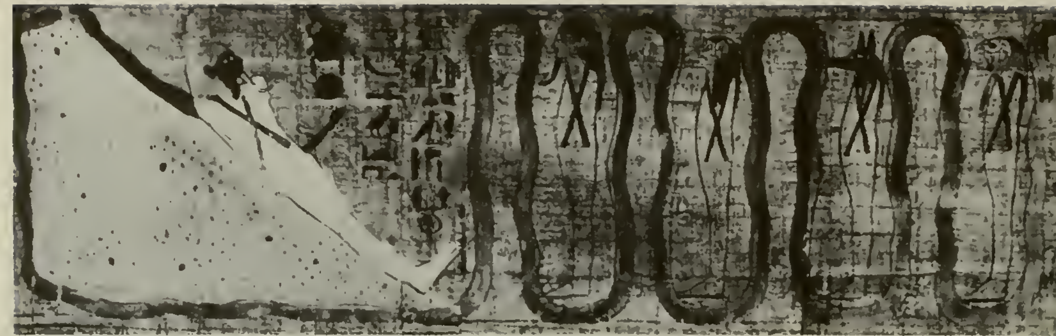
The theosophist H. P. Blavatsky in *The Secret Doctrine* says the Pyramid not only indicated the courses of the

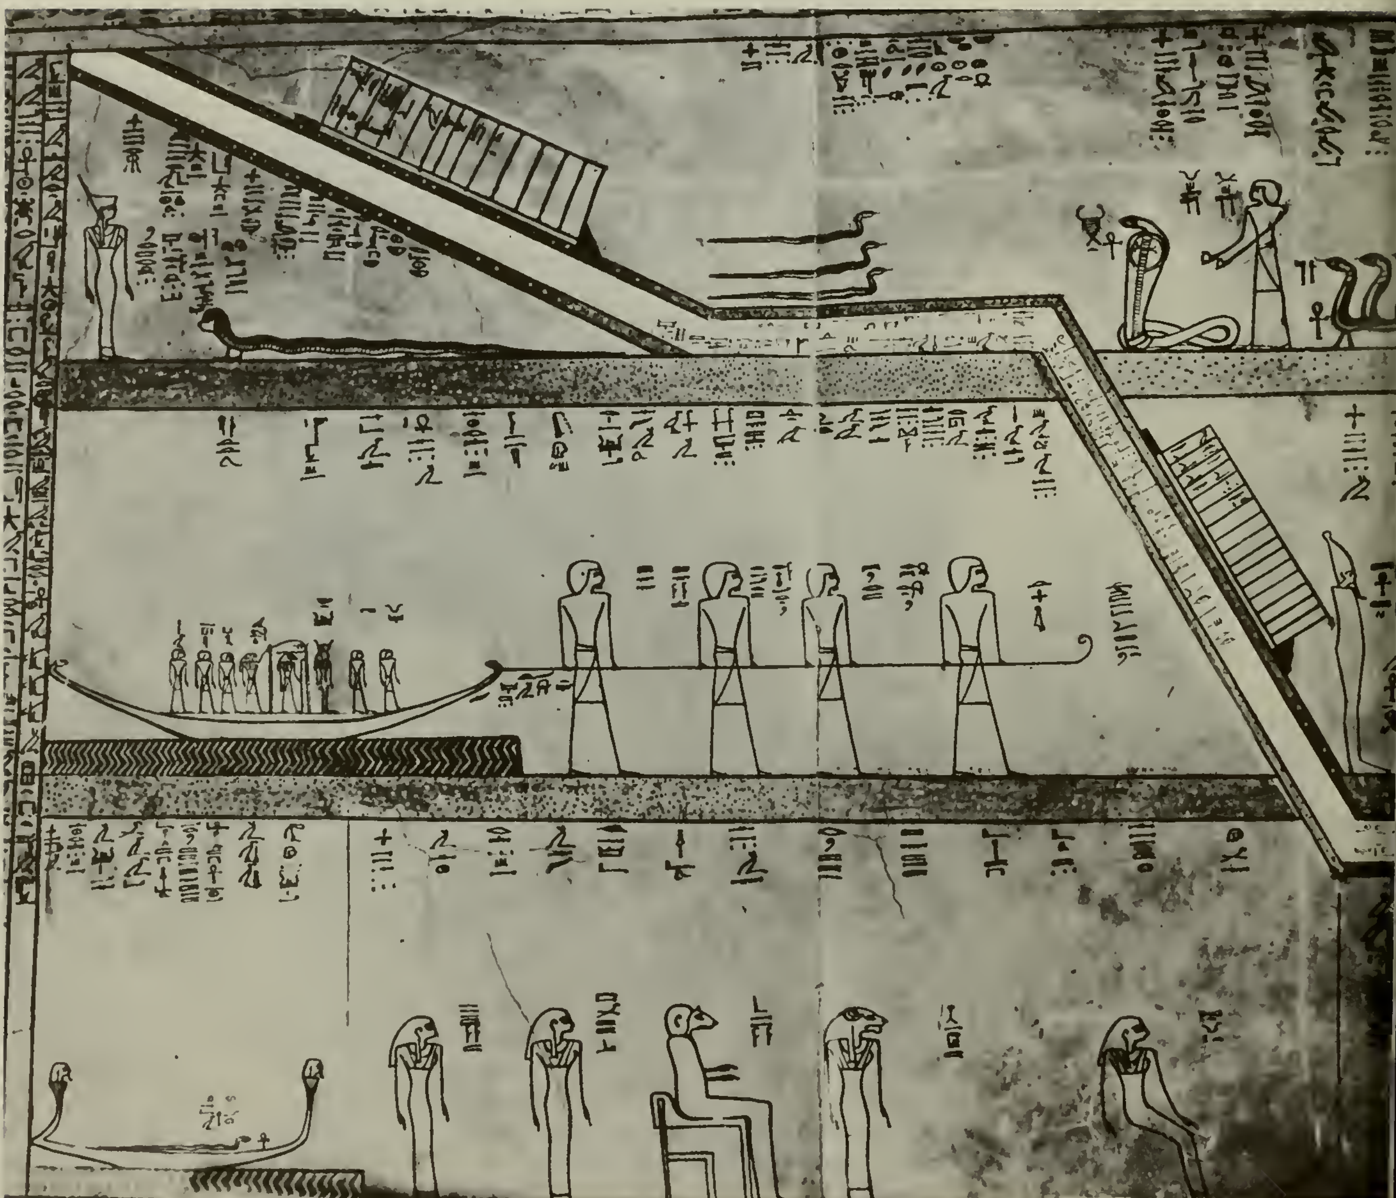
According to Manly P. Hall, the illumined of antiquity passed through the mystic passageways and chambers of the Great Pyramid, entering its portal as men and coming forth as gods.

"The candidate," says Hall, "was laid in the great stone coffin, and for three days his spirit—freed from its mortal coil—wandered at the gateways of eternity. His *Ka*, as a bird, flew through the spiritual spheres of space. He discovered that all the universe was life, all the universe was progress, all the universe was eternal growth. Realizing that his body was a house which he could slip out of and return to without death, he achieved actual immortality. At the end of three days he returned to himself again, and having thus personally and actually experienced the great mystery, he was indeed an Initiate—one who beheld and one to whom religion had fulfilled her duty bringing him to the light of God."

stars in heaven but was "the everlasting record and the indestructible symbol of the Mysteries and Initiations on Earth." In *Isis Unveiled* Madame Blavatsky elaborated, saying that whereas externally the Pyramid "symbolized the creative principle of Nature, and illustrated also the principles of geometry, mathematics, astronomy and astrology," within the building itself was the site of the mysteries of initiation—"a temple of initiation where men rose towards the Gods and the Gods descended towards men." To Blavatsky the coffer was "a baptismal font upon emerging from which the neophyte was born again and became an adept."

Brunés says that during the ceremony of initiation, the candidate was placed by the temple leader in a deathlike trance symbolizing death itself. On awakening from this condition, "having wandered in the world of the gods," he was regarded as having been reborn.





Blavatsky describes the ancient rite: "The initiated adept, who had successfully passed through all the trials, was attached, not nailed, but simply tied on a couch in the form of Tau . . . and plunged into a deep sleep (the 'Sleep of Siloam'). He was allowed to remain in this state for three days and three nights, during which time his Spiritual Ego was said to confabulate with the 'gods,' descend into Hades, Amenti, or Patala (according to the country) and do works of charity to the invisible beings, whether souls of men or Elemental Spirits; his body remaining all the time in a temple crypt or subterranean cave. In Egypt it was placed in the Sarcophagus in the King's Chamber of the Pyramid of Cheops, and carried during the night of the approaching third day to the entrance of a gallery where at a certain hour the beams of the rising Sun struck full on the face of the entranced candidate, who awoke to be initiated by Osiris, the Thoth and God of Wisdom."

For such a rite to have been possible, either the Pyramid must still have been truncated, or it contains secret passages at present undiscovered.

Most of the ancient philosophers and great religious teachers, including Moses and St. Paul, acknowledged or are acknowledged to have derived their wisdom from the Egyptian initiates. Individuals who admitted or hinted they were initiates include Sophocles, Solon, Plato, Cicero, Heraclitus, Pindar and Pythagoras.

Some of the ceremonies of what are sometimes referred to as the lesser mysteries have survived in a more or less degraded and merely formal manner in the ritual of Masonry and of the Christian churches. Kingsland believes the secret of the Pyramid is even known to present-day initiates, but is probably "one of those matters which they do not see fit to disclose to the world at large."

According to Norman Frederick de Clifford, author of *Egypt, the Cradle of Ancient Masonry,* ancient Masonry had its origin long centuries before the dawn of authentic history; he claims the ancient brotherhood "possessed a far greater knowledge of mechanical arts and sciences than is known to architects of the present day."

Several authors, including W. Marshal Adams, believe the Pyramid represented in monumental form the doctrine which *The Book of the Dead* sets forth in script, containing in an allegorical and symbolic manner the secret wisdom of the initiates, or the laws which govern and direct the universe, enabling the initiate to know "how he came into being in the beginning."

The Book of the Dead is the title generally given to a collection of Egyptian inscriptions and papyri found in tombs

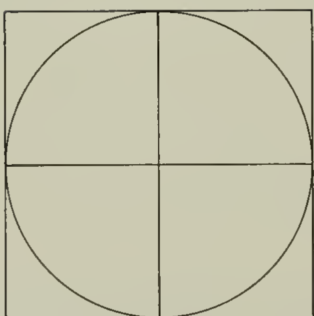
These illustrations from Albert Champdor's *The Book of the Dead* show a mummy with phallus erect sliding into the Seventh Region of the Lower World, described as being "filled with serpent's coils and the four sons of Horus who protect the viscera of the dead." This Twenty-first Dynasty drawing has lost the precise φ proportions of the earlier renditions of the same subject shown in earlier illustrations.

or in mummy wrappings. Sir E. A. Wallis Budge translated it as *The Book of the Mistress of the Hidden Temple*. One late text found with a mummy was on a papyrus roll 20 meters long divided into 165 chapters: It is now in the Turin Museum.

The ancient Egyptians attributed *The Book of the Dead* to Thoth, Lord of Wisdom, and recorder of the deeds of men, which were produced when the soul came to judgment.

Egyptologists in general label it a collection of funerary and ritual texts of different periods in different forms, used by ancient Egyptian priests in their burial ceremonies. But Henri Furville in his *La Science Secrète* claims that the texts of *The Book of the Dead* are incomprehensible to those who never made a careful study of them from the point of view of psychic science. The obscure texts, says Furville, "shine in the light of initiation, and the practices which seem extraordinary and even absurd to the profane, are, on the contrary, the result of the most profound science."

The problem of translating hermetic language from hieroglyphs is highlighted by Giorgio de Santillana when he points out that in the Erman-Grapow Egyptian dictionaries there are thirty-seven terms for "heaven." As a result, says Santillana, the elaborate instructions in *The Book of the Dead* referring to the soul's celestial voyage translate into "mystical" talk, and must be treated as holy mumbo-jumbo. Modern translators, says Santillana, believe so firmly in their own invention, according to which the underworld has to be looked for in the interior of our globe—instead of in the sky—that even 370 specific astronomical terms would not cause them to stumble. He gives as an example the goddess Hathor being described as "lady of every joy," when the literal translation is "the lady of every heart circuit." The determinative sign for "heart," explains Santillana, often figures as the plumb line coming from the astronomical or surveying device, the *merkhet*. "Evidently," says Santillana, "the heart is something very specific, as it were, the center of gravity."



J. Ralston Skinner in *The Source of Measure* was convinced that the Pyramid was not a tomb, but a temple of initiation. He went further and linked the Pyramid to the Jewish cabala, a system of allegorical symbolism among the initiated which sets forth the secret teachings of the Bible, concealing the great cosmic principles of man's origin.

According to Skinner the key to the cabala was said to be the geometrical relation of the area of the circle inscribed in the square, or the sphere in the cube. This gave rise to the relation of the diameter to the circumference of a circle, with the numerical value of the relation expressed in integrals, such as 22/7.

The relation of diameter to circumference, says Skinner, was considered a supreme one, connected with the god names Elohim and Jehovah, the first being the circumference, the second the diameter, which were numerical expressions of these relations.

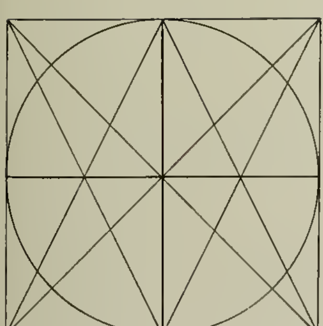
Tons Brunés, who dedicated his *The Secrets of Ancient Geometry* to the Fraternity of Free Masons, shows that the Great Pyramid, like most of the great temples of antiquity, was designed on the basis of an advanced but hermetic geometry known only to initiates, only fragments of which percolated to the classic and Alexandrine Greeks. According to Brunés, the secret of this ancient geometry was so well guarded that the whole of it was not revealed until the publication of his book in 1969.

Brunés shows how the ancient Egyptians used the basic design of a circle inscribed in a square to divide both circle and square geometrically into equal parts from 2 to 10, and all their possible multiples, without recourse to measuring or arithmetical calculations, with the aid of nothing but a straightedge and a compass—common emblems, along with the Pyramid, of the Masonic orders of yesterday and today.

In Brunés' reconstruction of the secret geometry, the cross emerges as the first geometric addition to the circle and square, and is the key not only to the solution of geometric problems but to the development of numerals and the alphabet.

By including the diagonals, every number both Latin and Arabic and all the letters of several alphabets may be obtained.

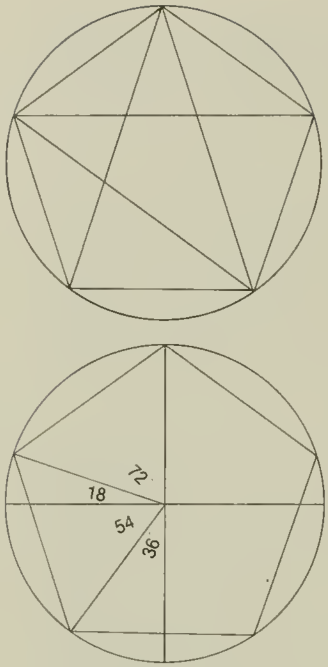
According to Brunés, both mathematics and the alphabet sprang from geometry, not the reverse. He says that nowadays we use numbers as the primary factor in our calculations, and geometry only as a subsidiary, whereas he believes the Egyptians reversed the order. He uses a detailed analysis of the Rhind Mathematical Papyrus to demonstrate that the ancient Egyptian system of counting was directly governed by geometric factors and that their ideas and theories were bound in geometric rules.



Brunés found that the circle was indeed considered sacred by the Egyptians, as were the square and the cross and the triangle, all of which are intimately incorporated into the Great Pyramid with its square base and triangular faces designed to represent the "sacred" circle.

Brunés demonstrates how the circle inscribed in a square and quartered by a cross enabled the ancient Egyptian geometer to inscribe in a circle the basic figures of pentagon, hexagon, octagon and decagon.

Of these the pentagon with its five-pointed star is perhaps



$\text{Sin } 18 = \tfrac{1}{2}\varphi$
$\text{Sec } 36 = 2/\varphi$
$\text{Sin } 54 = \varphi/2$
$\text{Sec } 72 = 2\varphi$

The circle in a square with a cross and diagonals, plus a pentagon or decagon, enabled ancient mathematicians to measure lengths of $\sqrt{2}$, $\sqrt{3}$, $\sqrt{5}$, as well as multiples and fractions thereof without arithmetical computation.

the most important: it automatically produces the Golden Section and the φ proportion in the simplest geometric manner.

Each line of the five-pointed star—the symbolic sign of recognition of the initiated Pythagorean, whose hermetic meaning it meant death to reveal—cuts the other in the proportion of major to minor: the Golden Section.

Furthermore, the side of a pentagon inscribed in a circle whose circumference is equal to the perimeter of the Pyramid will be equal to the apothem, or slant height, of the Pyramid, which will be the value of φ.

A pentagon divides a circle in 72° segments. With the main cross, the pentagon radii form angles of 18°, 36°, 54° and 72°.

Though Greece has been looked upon as the birthplace of mathematics—largely because of surviving written material on the subject of mathematics and geometry—Brunés points out that Pythagoras, the founder of Greek mathematics, spent 22 years in Egypt as a priest of the temple, and only returned to Greece after Cyrus the Great, king of Persia, burnt the temples at Memphis and Thebes in 527 B.C. and dragged him off as a prisoner to Babylon.

Back in Greece, Pythagoras taught mathematics on the basis of what he had learnt in Egypt; but after his death his followers were persecuted and had to take refuge abroad. Some eighty years later, Plato left Athens after the execution of Socrates and joined the Pythagorean societies. He traveled to Egypt, where he too was initiated into the lower degrees of learning in the temple, which were slowly recovering from being disbanded by the Babylonian-Persian conquerors.

Plato collected documents and writings connected with Pythagoras. In the end he produced the concept that the cosmos was represented by the five regular solids that can be inscribed in a sphere.

Brunés maintains that Plato incorporated into the body of his writings, and especially in the *Timaeus,* the secret teachings of the Egyptians, which he had sworn not to divulge directly, but which he handled in a hermetic language for which Brunés provides a solution.

Brunés says that Moses, who was also an Egyptian priest, had knowledge of the ancient geometry, which he passed hermetically in his instructions for building the Tabernacle, data which eventually reached Jerusalem and were incorporated into holy teaching.

The French archeologist and mathematician Charles Funk-Hellet, in his *La Bible et la Grande Pyramide d'Egypte,* agrees that the cubit of the Bible can only be the Egyptian royal cubit, which he makes a hair, or 1/2 millimeter, shorter than Stecchini's. According to Funk-Hellet the cubit was incorporated into the Temple at Jerusalem as $\pi/6$, or 523.6 millimeters, instead of Stecchini's 524.1.

Funk-Hellet points out that Solomon had Hiram Abiff build a temple whose columns were 18 cubits high and 12 cubits around. In other words, one cubit equaled the twelfth part of the circumference of the arc of 30°, or $\pi/6$.

By subtracting the circumference from the height, they obtained 6 cubits in a straight line, which was equal to half the circumference, or the exact value of π; so that a thousand years before Christ the Hebrews knew that a cubit was a mathematical entity dependent on the circumference, and were able to resolve π to four points of decimal.

Using *one unit* of measure as the radius of a circle, the ancients found the trigonometric value of 30° to be $\pi/6$, which was the value of the royal cubit, or .5236 of the unit used.

$$\frac{3.1416}{6} = .5236$$

Funk-Hellet found another additive series made by adding 5 to 1, and so on; 1, 5, 6, 11, 17, 28. . . . He developed the series in 18 columns and 36 lines horizontally, with some extraordinary results, including values for π, φ, and the royal cubit; this led him to conjecture that the royal cubit might have had a theoretical value before it had a practical one.

The first line gives the numbers 11, 17 and 28, which are divisions of both the royal cubit and the Chaldean cubit; furthermore, 11 × 17 × 28 equals 5236, which is Funk-Hellet's figure for the royal cubit in millimeters, or $\pi/6$.

The fourteenth column of the series gives the φ^2 value of 2.618, the royal cubit value of 5236, and the π value of 3.1416.

The second row produces the φ, or Fibonacci-type, series of $1/\varphi$, 1, φ, φ^2 with 618, 1000, 1618 and 2618.

The seventh column gives the divisions of a 360-degree circle in halves, quarters, eighths, etc.

Funk-Hellet maintains that as early as the fourth millennium B.C. the Chaldeans had a mathematical series which gave the exact values of the cubit, the meter and π. What's more, he insists that the present *meter,* as developed by the French in the nineteenth century, was already a hermetic measure known in antiquity, and was linked trigonometrically with the cubit.

To Funk-Hellet the Great Pyramid is a geodetic gnomon, or pillar, incorporating values for both the meter and the cubit. He says the finger, palm and cubit are built into the apothem. In the King's Chamber, he says, the double square of the floor is 5.236 meters by 10.472 meters—which varies from Petrie's and Davidson's measurements by a few millimeters.

Funk-Hellet says the basic meter unit from which the cubit was derived had to be kept a deep secret, presumably so that all the calculations, including the means for obtaining the exact length of the year, would remain the sole property of the officiating priests.

Schwaller de Lubicz in *Le Temple de l'Homme* corroborated the evidence that the Egyptians knew the meter, pointing out that on the whole length of a surrounding wall of the Third Dynasty (3000 to 2000 B.C.), "one finds three lines painted at the time, of which the distance between two lines is exactly one meter," adding that this is not an isolated case, "but one of thousands." In ancient constructions of Troy, Heinrich Schliemann found a unit of measure which was exactly half a meter, or 50 centimeters.

Funk-Hellet says the meter and the cubit depended from each other and were both defined by geodetic measurements. He suggests the way the meter was derived by the ancients was by watching from a measured height the moment a light disappeared on the horizon.

At the beginning of the nineteenth century, Sir John Herschel tried to calculate the radius of the earth with two observers placed 10 feet above the sea who ceased to see each other at 12,873 meters. This gave Herschel an earth radius of 6797 kilometers instead of the correct 6378, or an error of 419 kilometers.

Funk-Hellet believes the ancient Egyptians did better. He points out that the full apothem of the Pyramid including the pyramidion is 10,000 fingers long, or 187 meters. He then computes that if 1870 meters is taken as an arc of 30°, the resulting radius will be 3570 meters. Modern experiments indicate that a light disappears on the horizon at 3570 meters when the eye of the observer is exactly 1 meter above the ground.

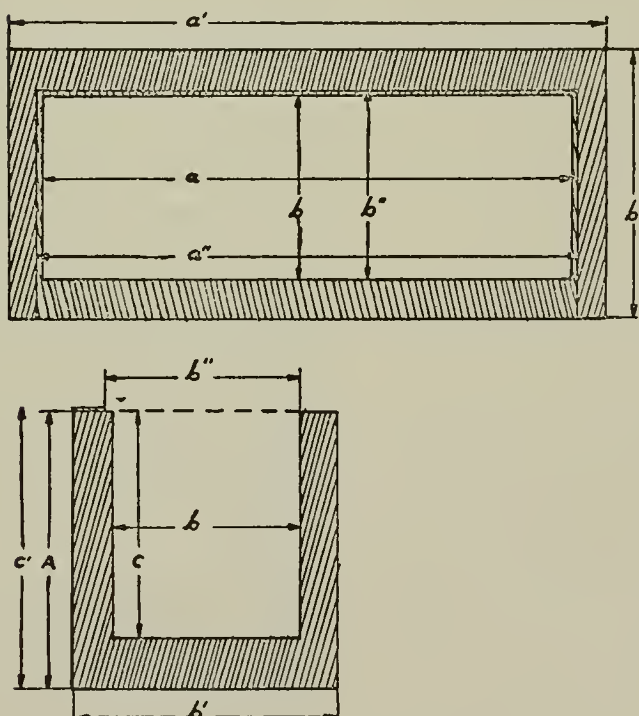
José Alvarez Lopez of Argentina, in his work *Fisica y*

Creacionismo, says that a cubit of 523 millimeters—about half a millimeter shorter than Funk-Hellet's and 1 millimeter shorter than Stecchini's—is exactly half of what he calls an *absolute meter*, which he says occurs as a natural unit in the solar system.

According to Alvarez Lopez the planets of our system orbit in harmonic distances from the sun which are multiples of a single unit of length—his *absolute meter*—in an arrangement which is naturally decimal.

Alvarez Lopez says that beginning with Mars, the planets are disposed in the order of the colors in the solar spectrum —with Mars as red, Jupiter yellow, Saturn yellowish-green, Uranus green, Neptune blue, and Pluto violet. According to Alvarez Lopez the Pyramid may once have been painted with the colors of the spectrum starting with red for Mars, just below the gilded pyramidion representative of the sun, and diminishing through yellow and blue to violet at the base, symbolizing the construction of the solar system both geometrically and with color.

The only evidence that the Pyramid may have once been painted, apart from the legends of the Arab storytellers, are some fragments of casing stone found in the early nineteenth century which were covered with what appeared to be red paint. Subjected to careful chemical and spectrographic



Alvarez Lopez's rendition of the dimensions of the coffer used by the Egyptians for basic astronomical ratios.

analysis at the Sorbonne, it was determined that the casing stones had once been covered with a layer of paint with a red ochre base, and that the paint could not have been caused by any chemical recomposition of the stone itself.

The Great Pyramid, says Alvarez Lopez, represents a decimal schema of the solar system. He figures the height of the Pyramid to be a millionth part of the distance to the sun, measured from the limit of the earth's atmosphere, and its base to be the ten-thousandth part of the surface of the earth.

The dimensions of the granite coffer in the King's Chamber, as worked out by the Argentine professor, are arranged to form a perfect "astronomical atlas": he says the inner measure gives an *absolute cubic meter,* but that the coffer was not designed as a cube so that its various inner and outer measures could also represent the various astronomical constants of the solar system.

He says there was just one way to build a coffer so that it would include not only the distance from the earth to the sun (a basic astronomical unit), but the weight of the earth, the weight of the earth and the moon, the weight of the sun in relation to the earth, the weight of the sun in relation to the earth and the moon, the weight of the earth in relation to the moon, the value of the absolute cubic meter, and the polar radius (one-half the diameter from pole to pole) of the earth in terms of an absolute meter.

Alvarez Lopez considers the original discovery of these figures to have been perhaps the hardest job yet mastered by man, and says this explains the care and trouble taken by the builders of the Pyramid to secrete the information in the heart of the building. Were the coffer not so badly chipped and worn, says Alvarez Lopez, it might give us more exact astronomical figures than we now possess.

All these astronomical constants, says the professor, depend on a precise knowledge of the solar parallax; he is amazed that the builders of the Pyramid could have known the parallax and the earth's polar radius so exactly without the help of telescopes and cameras. It will be interesting, he says, to compare our new figure for the sun's parallax with that of the granite coffer, as determined by the near passage of the small planet Eros, which occurs every 37 years and is due in 1975.

Stecchini is more *terre-a-terre.* He can show that the half meter found by Schliemann is really a Babylonian cubit of .49907 meter and that the meter of Funk-Hellet and de Lubicz is in fact three feet of .3329 meter, both derived from the geographic foot and cubit.

When I reminded Stecchini that Petrie had found the coffer in the King's Chamber to be designed in even numbers of fifths of a cubic cubit, Stecchini resolved the millennial riddle of the coffer by showing that it contains exactly 40 *artaba,* or 40 cubes whose sides are one geographic foot, and that its outside volume is twice this amount, or 80 cubes of one geographic foot.

Would it not be worthwhile, nonetheless, for academic institutions, so admirably equipped with computers and talent, carefully to analyze such conceits as those of Alvarez Lopez and Funk-Hellet and either refute them or support them with reliable data? Some of their ideas may turn out to be no wilder than those for which Jomard, Taylor, Smyth and maybe even Davidson were unjustly lampooned.

Napoleon's French Institute in Cairo.

XXI. MORE SECRET PASSAGES AND CHAMBERS

Many Egyptologists and explorers were convinced—and many still are—that the Pyramid conceals one or more secret and yet undiscovered chambers. It is also believed that the Pyramid is connected by subterranean passageways to other pyramids, to the Sphinx, and to long-demolished reception halls, small temples and other enclosures.

The engineer of the Australian railways, Robert Ballard, believed the Giza pyramids may also have been built above a vast series of catacombs, with chambers and galleries, like the pyramids of Lake Moeris, which are said to have vast subterranean residences for its priests and keepers.

Ballard suggests that much of the limestone for the structure of the pyramids of Giza may have been quarried from such catacombs. He suggests that a good diamond drill with two or three hundred feet of rods be used to make tests on the Giza plateau. Ballard believes that when this subterranean city is discovered, it will be found that it had access passages for the priests and the surveyors linking it to every pyramid.

While the pyramids appeared to the outside world to have been sealed up as mausoleums for the dead, says Ballard, the sealing may simply have rendered more mysterious and private the recesses and abodes of the priests who entered from below, and who were possibly enabled to ascend by private passages to their very summits.

When Perring and Howard-Vyse were exploring the bent pyramid at Dashur in 1839, they noticed an extraordinary phenomenon. The workmen clearing the passages were suffering from intense heat and lack of oxygen when suddenly a strong cold wind began to whistle through the passages. It blew so fiercely for two days that the men had trouble keeping their lamps lit. Mysteriously it stopped and no one has yet figured out the mystery.

Ahmed Fakhry, working in the same pyramid in the 1950s, heard weird noises which led him to conclude that there must be undiscovered passages within or under the bent pyramid.

Edgerton Sykes, an archeologist and author, who is perhaps the best living authority on ancient Atlantis, also

Herodotus speaks of a palace complex of 3500 chambers half above and half below ground at Moeris. The Egyptians called it "the temple at the entrance to the lake." Herodotus called it a "labyrinth," and considered that it outranked the pyramids as a wonder.

believes there is a whole maze of corridors and passages dug into the Giza hill. Sykes quotes an ancient Arab source to the effect that the designers of the Pyramid made "several doors, built over underground vaults of stone, each with a secret stone door revolving upon a hinge."

Peter Kolosimo believes there are more tombs and caves beneath Saqqara, Abydos, and Heluan, of very ancient dynasties, and reports the legends of hidden doors "that could be opened by a mysterious force" such as a supersonic wave length, or specially resonant voice.

According to the Baron de Cologne, as quoted by Robert Charroux in *Le Livre des Secrets Trahis* (Paris, Laffont, 1965), there is an underground kingdom under the Egyptian desert similar to the "Agartha" of Tibet.

Commander Barber, the American attaché who gave such attention to the construction of the Pyramid, wrote that "when one considers the inexplicable and yet exact arrangement of the various chambers and galleries, and that there is room for 3700 more such chambers, provided we could find them, we can almost be tempted to believe that we have not yet discovered all the chambers or even the true chamber of Cheops."

Piazzi Smyth was equally convinced that there was an undiscovered chamber in the Great Pyramid "which will prove to be the very muniment room of the whole monument."

Bent pyramid at Dashur. Arrow points to a secondary entrance to pyramid high on the north side.

When a multitude of chips of black diorite rock were discovered on the Pyramid hill, Smyth surmised that the undiscovered chamber might be lined with black diorite.

Thomas Holland, a Thirty-third Degree Free Mason, believed that if the granite leaf were removed from the portcullis it would disclose the way to "magnificent passages and chambers hitherto undiscovered."

Louis P. McCarty, in a privately printed booklet, *The Great Pyramid of Jeezeh,* published in San Francisco in 1907, says he believes the Pyramid contains at least three more chambers located between the King's Chamber and the apex, and at least one with double the capacity of the King's Chamber. McCarty believes the next largest chamber will be found at the 75th course, and the largest at the 100th course, and that the largest should be of an equal capacity to the three below it. He believes there is a fifth and final chamber on the 120th course of masonry, and that this one should be just half the capacity of the King's Chamber. McCarty also subscribes to the theory that there is a passage somewhere beneath the northeast corner of the Pyramid which leads to the Sphinx.

Funk-Hellet suspects there might have been a room on top of the present platform, now destroyed.

William Kingsland, in his two-volume work on the Pyramid, suggested generating radio waves of 5 meters length in the King's Chamber, and by noting the strength of reception at measured intervals all round the outside of the Pyramid, determine if some hidden chamber might exist.

In the late 1960s Dr. Luis Alvarez, the 1968 Nobel Prize winner for physics, developed a machine for recording the passage of cosmic rays through the pyramid of Kephren, by means of which he hoped to discover any secret chambers or passages within its body.

The operation, which required a team of scientists, turned into an expensive venture in which twelve United States and United Arab Republic agencies became involved, including the U.S. Atomic Energy Commission, the U.A.R. Department of Antiquities, the Smithsonian Institution and the Faculty of Science of the Ein Shams University in Cairo.

Alvarez's project was based on the fact that cosmic rays, which bombard the planet day and night, lose part of their energy as they pass through an object, in proportion to the density and thickness of the object.

By placing a "spark chamber" in the subterranean vault of the pyramid the scientists planned to monitor the number of cosmic rays which made their way through the pyramid walls. Those rays which passed through a void in the body of the pyramid would reach the chamber more frequently than those traversing solid rock, and the variance would indicate the presence of a secret chamber or passage in the pyramid.

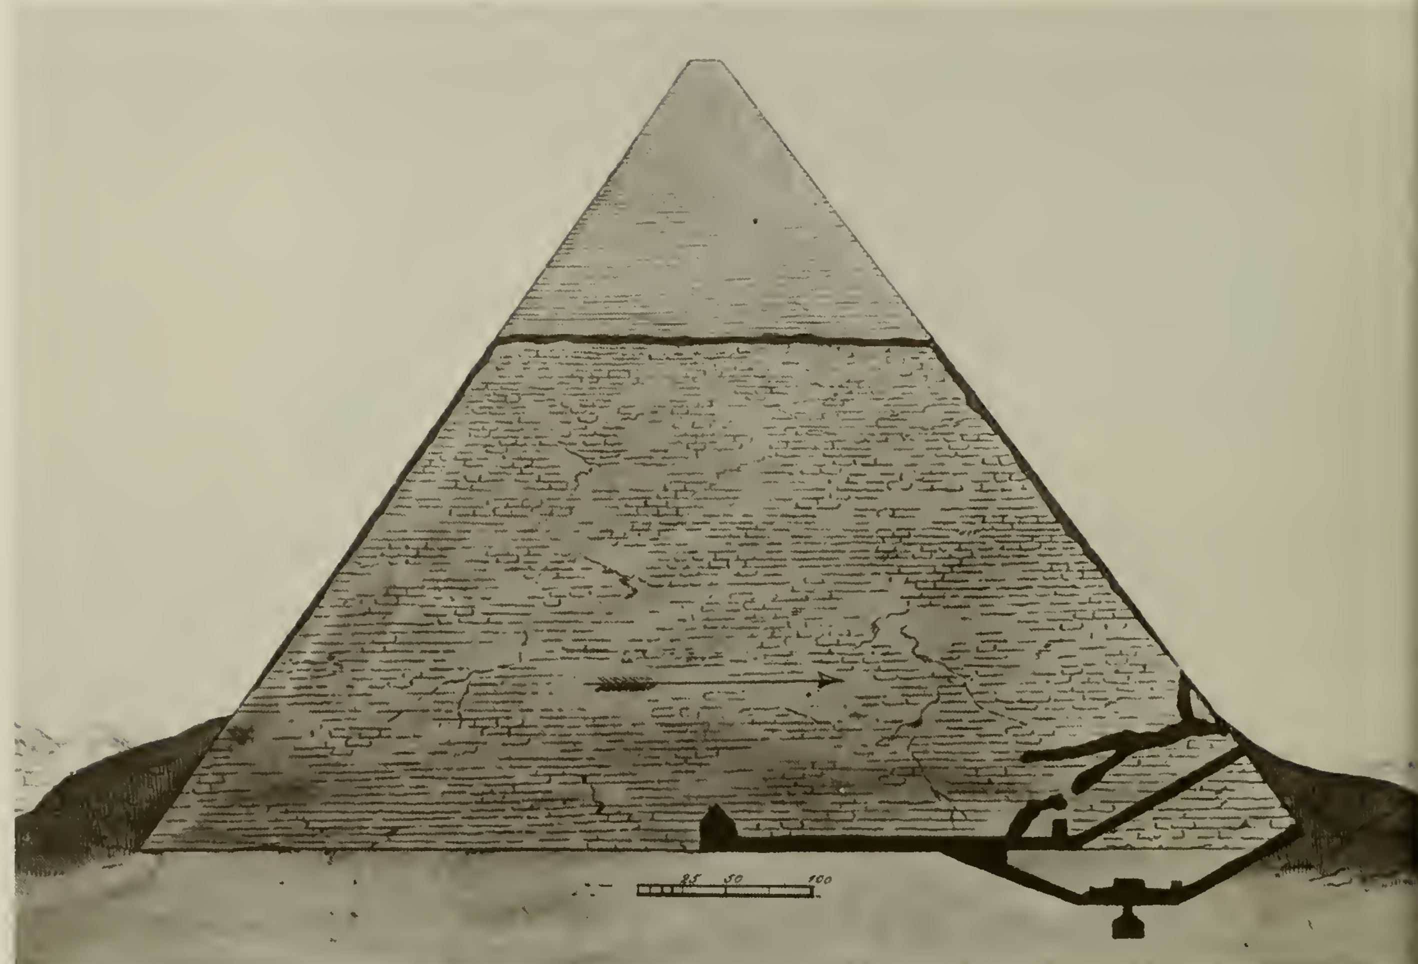
The path of each ray is recorded electronically and stored on a magnetic tape. The tapes are then fed into a computer to calculate and memorize the point at which each recorded ray penetrated the surface of the pyramid.

To pinpoint the location of any cavities which showed up, the scientists planned to shift the "spark chamber" and obtain a sort of stereo picture.

Were any hidden chamber located, it would then be possible to dig directly to it without risking great damage to the rest of the pyramid. The operation would consist of drilling a small hole upward in the indicated direction of any cavity that appeared on their "X-ray plate." Modern optical tools would allow archeologists to look into the chamber through a long hole, perhaps 100 feet long and only 3/4 inch in diameter.

Dr. Alvarez chose the pyramid of Kephren because he considered it unlikely that Kephren, as the son of Cheops, would have had such an imposing pyramid erected without incorporating some secret system of passages and chambers such as have been discovered in the Great Pyramid.

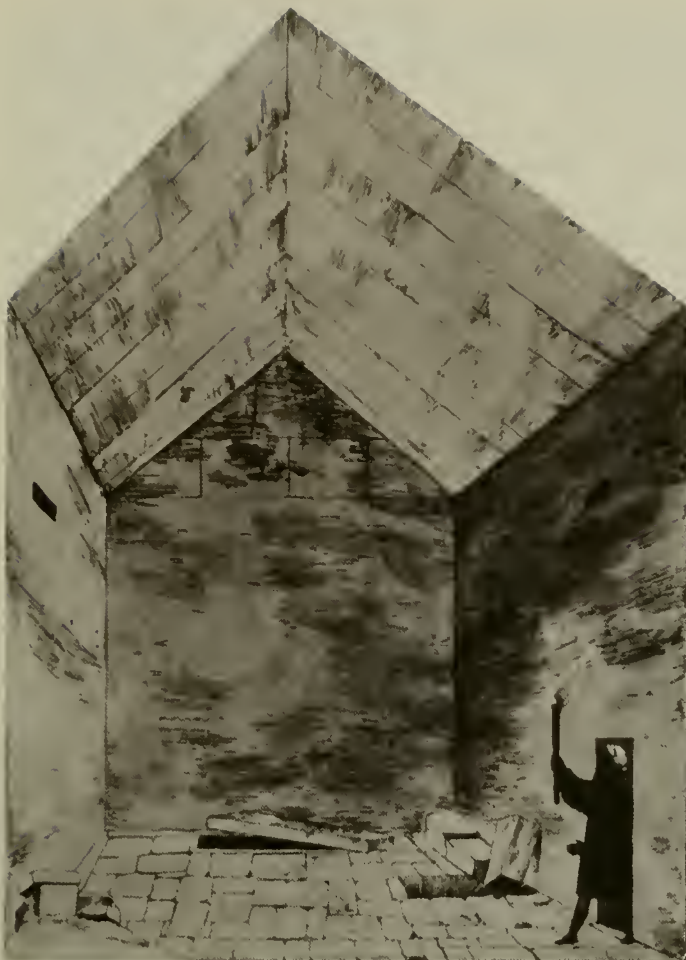
Alvarez assumed that Cheops' architects must have had a choice of clever ideas for secreting chambers, some of which had to be left out of his pyramid, but could have been applied to Kephren's. "My hunch," says Alvarez, "was that younger architects working on Cheops' pyramid would have had their ideas rejected. Later, in Chephren's time, they could have persuaded Chephren to use them, or some other improved plans."



On this tenuous assumption Alvarez hoped to find a secret chamber in Kephren, and perhaps even the sarcophagus of the dead Pharaoh: an Egyptologist's dream.

Alvarez also chose Kephren's pyramid because its central chamber was more convenient for setting up his complex electronic equipment. The subterranean vault discovered in 1818 by the Italian explorer Giovanni Belzoni had recently been cleared of rubble, and other chambers and passages in the pyramid had been lit with electricity by cable from the nearby Mena House.

By September of 1968 two million cosmic-ray trajectories had been measured: these were considered ample for finding any hidden vault within the field of view of the upward-looking equipment. When the tapes were run through the local computer in Cairo for the first analysis, the results looked wonderful. They clearly



In 1818 the Italian adventurer Giovanni Belzoni tried to find an entrance to the second pyramid of Kephren.
He found what appeared to be the original entrance close to the ground plugged by three granite blocks. The passage was cleared all the way down to a funerary chamber containing only a granite sarcophagus. On the west wall of the chamber an inscription in Arabic indicated the chamber had been penetrated some time after the Hegira.

Portrait of Giovanni Belzoni used as a frontispiece for a book edited by his wife commenting on his exploits in Egypt.

showed up the corners and the faces of the pyramid as outlined by the passing cosmic rays, recorded in the central chamber. The equipment appeared to be functioning excellently. But there were some mysterious developments.

As Dr. Lauren Yazolino, Alvarez's assistant, returned to the United States to analyze the tapes on the most up-to-date computer at Berkeley, a correspondent from the London *Times* visited Cairo to check on the results locally. At Ein Shams University, John Tunstall found an up-to-date 1130 IBM computer surrounded by hundreds of tins of recordings.

"It defies all known laws of physics," Tunstall quoted Dr. Amr Goneid, who had been left in charge of the pyramid project since the return to America of Dr. Yazolino.

According to Tunstall's report, each time Dr. Goneid ran the tapes through the computer a different pattern would appear, and the salient points which should have

been repeated on each tape were absent. "This is scientifically impossible," Tunstall quoted Goneid, explaining that earlier recordings which had raised the hopes of a great discovery were now found to be a jumbled mass of meaningless symbols with no guiding pattern whatever.

Tunstall asked Goneid: "Has all this scientific know-how been rendered useless by some force beyond man's comprehension?" To which Goneid is reported to have answered: "Either the geometry of the pyramid is in substantial error, which would affect our readings, or there is a mystery which is beyond explanation—call it what you will, occultism, the curse of the pharaohs, sorcery, or magic; there is some force that defies the laws of science at work in the pyramid."

At Berkeley, Alvarez refuted Tunstall's account, insisting that the equipment was functioning admirably. In the 35° cone scanned by the spark chamber there was no sign of any hidden passageway or chamber. This was the area believed by the scientists to be the most likely to contain them, though there was still hope of finding something in the remaining sections.

As soon as further funds were available the team of scientists planned to resume their scanning of Kephren. Dr. Yazolino added that if sufficient funds were available they might even move their equipment to the Queen's Chamber in Cheops to see if they could find any unknown passages or chambers in the Great Pyramid.

Yazolino explained that the only trouble they had encountered had been poor readings when the spark chamber ran out of neon and produced some mysterious dark spots which looked like a possible chamber till they were carefully analyzed and found to be caused by the gap between two spark chambers.

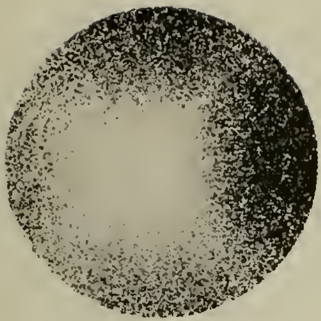
Alvarez stressed his confidence in Dr. Goneid as a very able physicist, saying that he thought so much of him he had invited him to spend a year at his lab at Berkeley. "If I thought for a moment that he had said any of the nonsense attributed to him, you can be sure I wouldn't want him as a member of my research group."

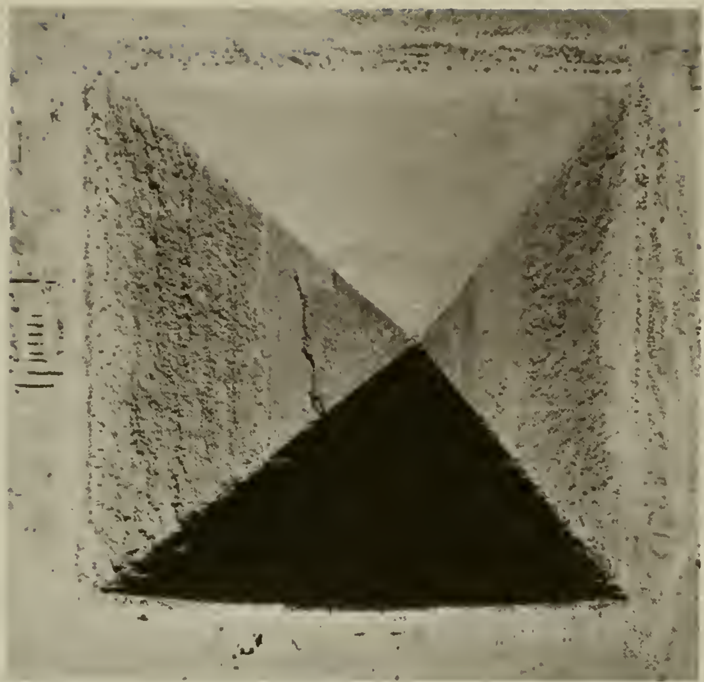
Yet there remains something mysterious about the pyramid which needs to be explained.

When a Frenchman, M. Bovis, visited the Great Pyramid he noticed that some garbage cans in the King's Chamber contained dead cats and other small animals that had apparently wandered into the Pyramid and died.

There was something odd about these corpses: there was no smell or decay to them. Curious as to the cause

Diorite statue of Kephren dating from the Sixth Dynasty found by Marietta Bey in the so-called Temple of the Sphinx, now in the Cairo Museum.





of this phenomenon, Bovis examined the animals and found them dehydrated and mummified, despite the humidity in the chamber.

Bovis wondered if the mere shape of the Pyramid could have been responsible for this natural process of embalming: so he made a wooden model of Cheops with a base three feet long, and oriented it due north. Inside the model, a third of the way up, he placed a freshly dead cat. After a few days it mummified. Bovis then placed other organic materials in the model, especially matter that normally decays very quickly, such as calf's brains, and when these failed to putrefy, he concluded there must be something about the shape of the Pyramid which prevents decay and causes dehydration.

A Czechoslovakian radio engineer named Karel Drbal read Bovis's reports and made some further experiments with pyramid models, concluding that there is "a definite relation between the shape of the space inside the pyramid, and the physical, chemical and biological processes going on inside that space."

The same phenomenon has been noted in Italy and Yugoslavia where milk packaged in pyramidal cartons keeps fresh indefinitely without refrigeration. A French firm has also patented a pyramidal container for yogurt.

Drbal wondered if the shape might be responsible for an accumulation of electromagnetic waves or cosmic rays, or of some unknown energy. Placing a used razor blade within a six-inch-high cardboard model of Cheops' pyramid, oriented to true north, Drbal found that the edges of the blade automatically recovered their sharpness after use, that he could shave with one Gilette blue blade as many as 200 times. He concluded that the environment inside the pyramid somehow made the crystals in the blade return to their original form. Drbal was issued patent no. 91304 by the Czechoslovak patent office and began manufacturing "Cheops Pyramid Razorblade Sharpeners" out of cardboard. Today they are being made of styrofoam.

An engineer and former professor of radio, L. Turenne, maintains that all sorts of different forms—being combinations of different frequencies—act as different types of resonators for energy in the cosmos. This has led to speculation that the Pyramid might be some sort of gigantic lens which is able to focus an unknown energy simply by means of its shape.

Even the coffer in the King's Chamber has been considered such a device by Worth Smith, who points out that the cubic capacity of the coffer is *exactly* the same as that of the biblical Arc of the Covenant.

According to Maurice Denis-Papin, descendant of the famous inventor, the Arc of the Covenant was a sort of electric capacitor capable of producing an electrical charge of 500 to 700 volts. The Arc is said to have been made of acacia wood, lined inside and out with gold: that is to say, two conductors separated by an insulator. On either side were garlands which may have served as condensors. Denis-Papin says the Arc was placed in a dry spot where the magnetic field reached a normal 500 to 600 volts per vertical meter.

Insulated from the ground, the Arc is said to have given off fiery rays, acting like a Leyden jar. According to Denis-Papin the capacitor was discharged to earth by means of the garlands. To move the Arc, two golden rods were slid through rings attached to the exterior.

The similarity of such an "energy accumulator" to the orgone box developed by Wilhelm Reich, which was such a puzzle to Albert Einstein, is also striking.

Sir W. Siemens, the British inventor, related that one day while he was standing on the summit of Cheops' pyramid an Arab guide called his attention to the fact that whenever he raised his hand with his fingers outspread an acute ringing noise was heard.

Raising just his index, Siemens felt a distinct prickling in it. When he tried to drink from a wine bottle he had brought along he noted a slight electric shock. So

Siemens moistened a newspaper and wrapped it around the bottle to convert it into a Leyden jar. It became increasingly charged with electricity simply by being held above his head.

When sparks began to issue from the wine bottle, Siemens's Arab guides became distrustful and accused him of practicing witchcraft. One of the guides tried to seize Siemens's companion, but Siemens lowered the bottle towards him and gave the Arab such a jolt that he was knocked senseless to the ground. Recovering, the guide scrambled to his feet and took off down the Pyramid, crying loudly.

Such weird but soberly recounted tales about the Pyramid are tame compared to the wilder conceits that have been propounded by pseudoscientific, science-fiction and sensational authors. According to one science-fiction theory, the Pyramid was used as a huge protecting baffle for ancient scientists who had found a way to tap the energy of the Van Allen belts by letting it flow on an ionized path through the atmosphere to the peak of the Pyramid, possibly on a laser beam. The authors of this science fiction recount how an error was committed in the length of time the energy was allowed to flow, causing an avalanche of power which knocked the planet off its axis.

Another popular idea is that the truncated Pyramid served not merely as an observatory but as a landing pad for extraterrestrial space ships. The polished sides of the Pyramid would have made such a platform inaccessible to the hoi polloi, so that godlike visiting astronauts could have confabulated in security with the high priests who had access to the platform from interior passages. Herodotus lends romance to the idea that ziggurats and pyramids were steppingstones for the gods from heaven and that the King's Chamber—which Petrie found to be built quite separately from the surrounding Pyramid—could have served as a reception room on the truncated platform.

Herodotus describes a reconstructed ziggurat which he visited in Babylon. "On the topmost tower there is a spacious temple, and inside the temple stands a great bed covered with fine bed-clothes, with a golden table by its side. There is no statue of any kind set up in the place, nor is the chamber occupied at night by any but a single native woman who—say the Chaldean priests—is chosen by the deity out of all the women of the land. The priests also declare—but I for one do not credit it—that the god comes down in person into this chamber, and sleeps upon the couch."

In the light of recent scientific discoveries, one more theory must be added to this world of fable: that the Great Pyramid was built not only as an astronomical observatory but as an astrological one in order to make accurate large-scale horoscopes for the reigning monarch.

XXII. ASTROLOGICAL OBSERVATORY

Though many of the doctrines of astrology appear to be preposterous, modern science is beginning to indicate that in its original form astrology may have been based on some reasonable theories.

Proctor points out that the ancient Egyptians viewed the king as the representative of all the people in their relations with the forces of the cosmos, and the world of spiritual powers.

On the theory that what was good for the king was good for the country, Proctor suggested that the Egyptians made no move in either domestic or foreign policy without the recommendation of their astrologer priests, whose opinions were based on the movement of heavenly bodies as scanned from a pyramidal observatory.

Once the king was dead, Proctor believes, his body may have been buried within the pyramid and the platform finished off to a point.

The idea that the shifting of heavenly bodies bears some relation to man's fate is so ingrained that people are still called martial, jovial, saturnine or lunatic; the days of the week are still named for sun, moon and planets; and our religious festivals are still based on the astrological system of ancient Egypt, with Christmas tied to the winter solstice and Easter to the spring equinox.

In his *The Scientific Basis of Astrology,* published in 1969, Michel Gauquelin describes some of the effects of the motions of the sun and moon upon terrestrial phenomena. Apart from such obvious effects as the seasons, the growth of vegetation and the tides, he deals with the less apparent but equally powerful effects of the eleven-year cycle of sunspots on our flora, fauna and inhabitants.

Sunspots, which appear like dark flowers on the surface of the sun, spring up, develop and disappear. As they do so, the sun spews up fantastic incandescent clouds of gas, and whips up huge magnetic whirlwinds.

Rotating on its axis in a twenty-seven-day cycle, the sun periodically aims these spots and eruptions directly at the earth. The result is an increased projection of waves and particles towards the earth. In the words of Gauguelin, "we terrestrians can regard ourselves as living in the interior of the sun."

The position of the earth in its orbit also affects the sunspots: when Venus and Earth are on the same side of the sun, their effect on the sunspots is combined. The sun's vagaries induce earthquakes and even alter the duration of the day; the earth's magnetic fields are disturbed; there are radio interferences and other such mysterious phenomena. At the same time the earth is subject to bombardment by galactic particles such as Alvarez's cosmic rays, which also have their effect.

Sunspot activity has been related to such different phenomena as the number of icebergs in the North Atlantic, the level of water in lakes, the concentric rings in the growth of trees and the number of rabbit skins taken by the Hudson's Bay Company. Even the quality of wines in Burgundy is affected, excellent vintages corresponding to periods of maximum solar activity.

Sunspots have been proved to affect the smallest cells, and the world of microbes is disturbed to the point that waves of epidemics can be generated. Gauguelin quotes a Doctor Fauré to the effect that the frequency of diphtheria cases in Central Europe and of smallpox victims in Chicago follow the eleven-year cycle of sunspots, as did the recurrent great plagues of typhus and cholera in Europe.

Indirectly, most of the phenomena of weather, such as barometric pressure and the rate of winds, depend on the eruptions of sunspots. Gauquelin wonders if there may not be more subtle effects on the air we breathe, on our physical and mental states, and even on the way we think.

Recent experiments indicate that subjects breathing air charged with positive ions are likely to feel discomfort, headaches and giddiness; whereas when the atmosphere is full of negative ions the same subjects feel cheerful, relaxed and in top form.

The concentration of positive and negative ions in the air we breathe depends in the final analysis on solar activity. The ionosphere is filled with positive and negative ions. Particles which induce a very high ionization in the upper atmosphere are directed toward the earth by the sun. Unfortunately, negative ions have a tendency to attach themselves to clouds, whereas positive ions tend to accumulate on the ground.

Such data tie in with the theories of Wilhelm Reich about the healthful effects of what he calls "orgone energy" and the toxic effects of its counterpart "deadly orgone," which was reputed to turn rocks brown, make strong men giddy and bring on women's menses out of season.

Current research and experiments behind the Iron Curtain as reported by Ostrander and Schroeder in their *Psychic Discoveries Behind the Iron Curtain** have added even more fantastic details to the use of astrology as a science.

These authors describe a Czechoslovak Ministry of Health center, complete with modern computers, run by gynecologists and psychiatrists. It is called Astra Research Center for Planned Parenthood and uses astrological data, or the position of sun, moon and planets in relation to the birth of an individual, in order to assure a safe and reliable means of birth control without pills, contraception or operations. The same system is being used to help seemingly sterile women become fertile, help women who have had nothing but miscarriages deliver full-term babies, and even allow them to choose whether they will have a boy or a girl child.

In a book called *Predetermining the Sex of a Child,* Eugen Jonas, a Czech medical doctor who developed the Astra clinic, maintains that women's cycles are affected not only by the phases of the moon, but that each individual at birth is affected by the basic pattern of sun, moon and planets. From this basic pattern Dr. Jonas claims to be able to figure out the exact days in a woman's entire lifetime when she can conceive, as well as the ones which are the best or worst for a forthcoming child. The woman may then take advantage of such days, or avoid them.

Jonas found that dead, deformed and retarded children were produced when women conceived during certain oppositions of the sun, moon and major planets.

The system is now being tested in Hungary as well as Czechoslovakia, where Dr. Kurt Rechnitz, former director of the Budapest Obstetric Clinic prescribed astrological birth control for one hundred twenty women. None was reported pregnant.

It has been too short a period to establish the validity of such data, but the endeavor could prove more rewarding than voyaging to the moon. It would certainly be simpler for a lady in New York to step into the booth of an astrological computer in Grand Central Station in order to arrange her calendar of engagements for the year. And it might do wonders for an overpopulated planet.

Jonas' good-humored complaint is that most gynecologists know as little about astronomy as astronomers know about obstetrics, and that both believe

* Prentice-Hall, Englewood Cliffs, New Jersey, 1970.

astrology to be superstitious nonsense. If the disciplines were combined, the results, says Jonas, might be great for mankind. Had the designers of the Great Pyramid been able to monitor the sunspots with a screen across the Grand Gallery, as suggested by Proctor, and had they been aware of such phenomena as has been described by Dr. Jonas, they may well have been able to use the Great Pyramid as a means of providing accurate astrological data on which to formulate the charts for individual behavior, if not for the thronging masses, at least for the pharaohs, priests or nobles.

In his book on the Great Pyramid William Kingsland declares flatly that the ancient Egyptians used "their profound knowledge of what we call the outer facts of astronomy" to connect them astrologically with the principles of man's relation to the cosmos, and that this formed part of the concealed knowledge contained in the mysteries.

Kingsland notes that from the very remotest antiquity the Egyptians believed firmly in an afterlife and were not afraid to think cosmically in terms of millions of years. He quotes an introductory hymn to *Ra* in *The Book of the Dead* as saying: "millions of years have gone over the world; I cannot tell the number of those through which thou hast passed. . . ."

To Kingsland *The Book of the Dead,* though it appears to be a ritual for funerary rites of a deceased king or high official, was actually a description of the trials, temptations and difficulties which the adept had to meet and overcome as he progressed from knowledge to knowledge and from power to power, as he penetrated the superphysical regions from plane to plane. The ultimate goal of initiation, says Kingsland, was "the full realization of the essential *divine nature of man,* the recovery by the individual of the full knowledge and powers of his divine spiritual nature, of that which was his source and origin, but to the *consciousness* of which he is *now* dead through the 'Fall of Man' into matter and physical life."

The old Greeks, says Kingsland, learning from the Egyptians, embodied these trials and difficulties of the great initiates into the legends of their heroes and demigods.

Manly P. Hall, a lifelong researcher into the mysteries of ancient initiation, says the Great Pyramid was dedicated to the god Hermes, the personification of Universal Wisdom; it was not only a temple of initiation but a repository for the secret truths which he calls the foundation of all the arts and sciences. The time will come, says Hall, when the secret wisdom shall again be the dominating religious and philosophical urge of the world: "Out of the cold ashes of lifeless creeds, shall rise phoenix-like the ancient Mysteries . . . . The unfolding of man's spiritual nature is as much an exact science as astronomy, medicine and jurisprudence."

Whatever mystical, occult or science-fiction tales may be associated with the Great Pyramid, it is still an extraordinary piece of masonry, and its designers must have been extraordinary beings. Who they were and when they built their Pyramid remains a mystery. So the quest continues.

But certain facts must be confronted, and the textbooks amended to conform with them. Eratosthenes was obviously not the first to measure the circumference of the earth. Hipparchus was not the inventor of trigonometry. Pythagoras did not originate his famous theorem. Mercator did not invent his projection—though he did visit the Great Pyramid and leave his graffito to prove it.

Whoever built the Great Pyramid knew the dimensions of this planet as they were not to be known again till the seventeenth century of our era. They could measure the day, the year and the Great Year of the Precession. They knew how to compute latitude and longitude very accurately by means of obelisks and the transit of stars. They knew the varying lengths of a degree of latitude and longitude at different locations on the planet and could make excellent maps, projecting them with a minimum of distortion. They worked out a sophisticated system of measures based on the earth's rotation on its axis which produced the admirably earth-commensurate foot and cubit which they incorporated in the Pyramid.

In mathematics they were advanced enough to have discovered the Fibonacci series, and the function of π and φ. What more they knew remains to be seen. But as more is discovered it may open the door to a whole new civilization of the past, and a much longer history of man than has heretofore been credited.

APPENDIX

NOTES ON THE RELATION OF ANCIENT MEASURES TO THE GREAT PYRAMID

by LIVIO CATULLO STECCHINI

The following pages constitute an abstract from a lifelong research into the history of measures. I became interested in this subject toward the end of my secondary education, when I was trying to put to some use my eight years of Latin and Greek grammar. It was then that I became an acolyte of Angelo Segré, whom I knew as a fellow law professor with my father at the University of Catania. Segré was a scholar of Roman law, but, coming from a family of distinguished scientists and mathematicians, had specialized in the study of ancient measures.

Upon completing my secondary education, I ended my study with Segré to register as a student at the University of Freiburg, Germany. Since at that age one believes that a thinking person must have a philosophical foundation, I chose Freiburg because it was the university where Husserl taught, whose philosophy appealed to me because of its mathematical rigor. But at Freiburg at the moment the focus of attention was the philosopher Heidegger, who had just announced to the world the discovery of something called existentialism. I did not share the excitement of my fellow students for the new dispensation (although I liked the lectures on existentialist mathematics by Oskar Becker), but there were a couple of things that I learned from Heidegger. One was that the idea of the progress of human civilization, on which practically all historians operate, is a theological doctrine developed by the Church Fathers. The other, more specific, was that scholars of Greek culture have murdered the texts of early Greek philosophers, on the assumption that since they were early philosophers they must have had infantile conceptions. In the area of my vocational studies, I identified myself with a group of professors, led by Fritz Pringsheim, who had dedicated themselves to one topic, the contract of sale in ancient times. Since seminar work consisted in interpreting contracts from several areas of the eastern Mediterranean, I focused my attention on the clauses relating to measures, which these contracts contain in abundance. My teachers were tolerant of my passion; for instance, Otto Lenel in his *privatissimum,* dedicated to the development of postclassical Roman law, allowed me to read a paper on the length of the miles in the Syro-Roman Law Book.

After the Freiburg group was disbanded by Hitler, I returned to Italy, where I received a doctorate in the field of Roman law. On that basis I became assistant to the chair of history of Roman law at the University of Rome and a member of the Institute of Roman and Oriental Law of that University. During my Roman years, I learned the most from Edoardo Volterra, later holder of the chair of Oriental law at the University of Rome; he was sympathetic to my interests, since he was the son of the famous mathematician Vito Volterra.

When World War II brought me to the United States, since my interests were historical rather than legal, I registered as a candidate for a doctorate in ancient history at Harvard University. There I discovered that those who come to ancient history from literature have a completely different view of the ancient world from the practical, realistic, and utilitarian view which prevails in legal studies: in substance they see the ancient world as the realm of poetic fantasy. My Harvard teachers used to admonish me to understand "the spirit of the ancients," but the only image that their perorations could stir in my mind was the image of the ancients in a constant state of alcoholic stupor. As to my special field of research, my teachers thought that my notion that the Greeks were concerned with precision in measurement was intellectually preposterous and historically impossible.

The terms of the controversy were clarified for me by Werner Jaeger, who tried to support me by suggesting that I write under him a thesis on the concept of *akribeia,* "precision," in Greek thought. In outlining the proposed thesis, Jaeger explained that with Isocrates there was developed in Greece a new conception of humanism opposed to *akribeia.* Jaeger was impliying that my critics were followers of Isocratean humanism. Because of youthful stubbornness, I declined the flattering offer of Jaeger, being convinced that what counts is to put precision into practice, rather than to talk about it. I tried to prove my point by submitting a thesis on "The Origin of Money in Greece." It was accepted as containing much that was valuable, but I received the advice that before publishing it I should cut down on "all those numbers."

After this, I thought that I could still achieve a result by expanding my documentation. From the study of Greek monetary weights and the operation of Greek mints, I passed to the topic of the dimensions of Greek temples. The study of Greek temples much later led me to the study of ancient geography and geodesy. But I was gradually forced to accept the fact that scholars of ancient history do not read numbers, neither in ancient texts nor in research papers. I noticed a number of times, when I submitted a paper for judgment to a specialist of a particular area, that he would quickly turn a page if he saw numbers on it. In many different guises I was told that "numbers do not constitute evidence in ancient studies." Finally, I learned that I had no choice but to pursue my interests in splendid isolation.

About ten years ago I exchanged manuscripts with Hertha von Dechend, who was then beginning to write her book *Hamlet's Mill.* As an expert of ancient cosmology, she raised a strong objection to the fact that I would discuss length, volume, and weight for hundreds of typewritten pages, without ever mentioning time, whereas the ancients were dominated by the preoccupation with cosmic time, with the movement of the vault of heaven. I answered that she was right, but that I had not yet found in the texts anything that would establish a connection between time and other measures. Giorgio de Santillana, who was writing *Hamlet's Mill* together with Dechend, teased me in a friendly way by saying that I had become so stuck in the mire of economic documents that I could not lift myself out of it; I replied in the same half-serious tone that I was willing to lift my eyes to heaven only on condition of being sure that my feet remained firmly planted on the ground.

Although I recognize that astronomical measurements are extremely important, I have always been wary of dealing with them, because studies of ancient astronomy have become cluttered with metaphysical and theological doctrines. My opposition to the view that the ancients lived in a world of fantasies or even of outright hallucinations (as it is specifically claimed by scholars of ancient astronomy) is such that, after years of dealing with all sorts of measurements, I still feel most at ease with agrarian measures in cuneiform tablets, rates of money exchange in Greek inscriptions, or the volume of jars in papyri from Egypt. Yet the techniques of land surveying used in Meso-

potamia are a key to the understanding of how the ancients mapped the sky.

Because of my horror of metaphysical or pseudo-metaphysical intrusions, I had several times picked up and then dropped the problem of the dimensions of the Great Pyramid of Giza. It was only after Peter Tompkins took upon himself the task of organizing the literature in the field, separating sense from nonsense, that I gained the courage to deal with the problem to the point of some conclusion. In the course of discussing with me the geometry of the Great Pyramid, Tompkins explained how the Great Pyramid with its galleries could have been used to measure the movements of the vault of heaven. In describing the possible procedures, he pointed out how a second of time in the motion of the vault of heaven corresponds to a definite length on earth. For me this was a Galilean revolution in that it permitted me to see ancient astronomy in terms of observational techniques based on measurements, rather than systems based on the theological persuasions or the psychological projections of the modern investigators. Once I was able to link time together with length, volume, and weight, a number of scattered researches suddenly became related to each other. Up to that moment I had had the uncanny feeling that somewhere there was a piece missing, and I knew that a missing piece, even a little one, is vital when one deals with measurements.

Since Tompkins has asked me to write a summary of my findings that relate to the problem of the Great Pyramid, I have tried to comply with his request.

I. EGYPTIAN GEODETIC SYSTEM

1. The present Arabic name of Egypt is *al Miṣri,* which is the equivalent of the biblical *Miṣraîm.* This name is derived from the Semitic root which in Akkadian gives the verb *aṣaru,* "to cut, to delimit, to delineate," and hence "to draw a picture, a plan," and the noun *eṣertu,* "drawing plan, representation," applied in particular to the specifications for the construction of a building. In Semitic language an "m" before the root of a verb forms what we would call a past participle: Egypt is the country built according to a geometric plan.

The Egyptians expressed this idea by calling their land *To-Mera,* "the land of the *mr.*" The word *mr* is used to refer to the pyramids, but more specifically it refers to the meridian triangle of a pyramid, whose hypotenuse is the apothem. The *mr* essentially is a right triangle with an angle of 36° and another angle which of necessity is 54°.

Since the Egyptians did not have trigonometric tables, they used this triangle to obtain the value of trigonometric functions. They conceived of this triangle as the basic building block of the cosmos. They used this triangle or modifications of it by a few degrees in geometric constructions, in the planning of buildings, in surveying, and in geography.

In the last century the Egyptologist Karl H. Brugsch noticed that the hieroglyphic sign for *mr* when used in the name *To-Mera* is accompanied by a determinative in the form of a fret or Greek key. In hieroglyphic writing a determinative is an extra sign which helps in understanding the meaning of a word by indicating the class of concepts to which the word belongs. Brugsch observed that this fret is "a peculiarly shaped geometric figure which in principle could represent the entire land *Mera* and must have a meaning pertaining to a specific peculiarity of Egypt." But, although he was much more sympathetic to science than Egyptologists usually are, he did not pursue this line of reasoning. He resisted accepting the notion that the Egyptians conceived of their country as having an exact geometric shape.

The Egyptians were proud that their country had some unique geographic features which could be expressed in rigorous geometric terms and had a shape which related to the order of the cosmos as they saw it. They believed that when the gods created the cosmos they began by building Egypt and, having created it perfect, modeled the rest around it.

2. Everybody knows that Egypt is a most peculiar, almost unique, country. Since it seldom rains there, the entire life of humans, animals, and plants depends on the water of the Nile. It is also known that the Egyptians linked the regular flood of the Nile with the movement of the sun and other heavenly bodies, such as the star Sirius. But the Egyptians put great stress also on the geographic peculiarities of the course of the Nile.

The Nile originates at the equator from lakes so immense that their water could be identified with the primeval water of the ocean. From the equator it moves north following substantially the meridian of its source at Lake Albert. It follows this line up to latitude 30°, one-third of the distance from the equator to the pole.

The key geographic position in Egyptian geography was the southern tip of the island today called al-Warraq, at the northern limit of the city of Cairo, where the Nile begins to divide into branches to form the estuary which the Greeks called Delta, after the triangular shape of the fourth letter of their alphabet. The apex of the Delta, the tip of the island al-Warraq, is cut by meridian 31° 14′ east. This meridian indicates the main line of the course of the Nile from the equator to the apex of the Delta and divides the Delta into two equal parts. It was considered the main axis of Egypt.

But in terms of latitude the apex appeared at first not as perfect as it should have been, since it was at latitude 30° 06′ north and not at the perfect latitude 30° 00′ north, which is the latitude of the Great Pyramid of Giza. But the Egyptians reassured themselves by observing that the southern limit of Egypt is indicated by the First Cataract. The upper edge of this cataract is at the perfect latitude 24° 00′ north, whereas its lower edge is at 24° 06′ north. Hence, they could say that Southern Egypt has an extension of 6° 00′, which may be counted either from 24° 00′ to 30° 00′ north or from 24° 06′ to 30° 06′ north. They adopted as a principle that geographic distances are measured by units of 6 minutes (1/10 degree). They assumed that the interval between the equator and the pole was divided into belts (in pictures they portrayed actual belts with clasps) of 6′; on the basis of this the Greeks introduced into our geography the term *zone*, which in Greek means "belt."

For the benefit of those who understand mathematics, I may add that the Egyptians analyzed curves by dividing the area under a curve into a series of rectangles, which is the basic principle of integral calculus. It seems that in analyzing the curvature of the earth, they used rectangles 6′ wide.

Geographically Egypt is divided into two different parts. Southern (or Upper) Egypt is essentially a canyon cut into the desert plateau by the Nile; it is long and narrow. Northern (or Lower) Egypt is a typical estuary, swampy and wide. In spite of the efforts of the rulers to stress the unity of the country, the two parts continued to be conceived as different even in political and administrative terms. This is the reason why the Hebrew word for Egypt, *Miṣraîm,* has the grammatical form of the dual. The Pharaoh wore two crowns on his head: a red straw hat for Northern Egypt and a white wool cap for Southern Egypt.

Although not much is known about the history of predynastic Egypt, it seems rather well established that in this period the two Egypts were unified for a time, with a capital at Behdet at the extreme north of the curved coastline of the estuary, as far north as one could go in Egypt. Although archeologists have not yet identified the location of Behdet, the data of geography indicate that Behdet, either as a geodetic point or as an actual city, was at 31° 30′ north 31° 14′ east. It was on the main axis of Egypt and of the

Nile, on the meridian of the apex of the Delta, at a distance of 7° 30′ (1/12 of arc of meridian) from the southern boundary of 24° 00′ north and at a distance of 1° 24′ = 1.4° from the apex. The distance from latitude 30° 00′ north is 1° 30′, so that it could be assumed that Southern Egypt relates to Northern Egypt as 4:1. Southern Egypt is 1/15 of arc of meridian and Northern Egypt is 1/60. We shall see that the total length of Egypt from 24° 00′ north to Behdet was calculated as 1,800,000 geographic cubits. Since 400 cubits is a stadium and 600 stadia is a degree, it is a length of 4500 stadia (3600 stadia for Southern Egypt and 900 stadia for Northern Egypt).

This is the way in which the dimensions of Egypt were rationalized in the predynastic period.

3. The dynastic period begins with the final unification of the two Egypts. At this moment Egypt emerged from prehistory, because writing was invented in the form of hieroglyphs. At the same time the geodetic system of Egypt was revised, stressing the importance of the number 7 and linking the geography of Egypt with the geography of the heavens.

The main feature of the map of the sky is that the sun follows a course which is at an angle with the equator. The circle marked by the sun is called the ecliptic and the angle of this circle with the circle of the equator is the angle of the ecliptic (roughly 24°). The ecliptic cuts the plane of the equator at two points and reaches its highest and lowest points in relation to the equator at celestial latitudes which are marked on the surface of the earth by the tropics.

The moon and the planets in their movements around the earth follow substantially the line of the ecliptic, being at times north and at times south of the course of the sun. (The body which deviates most sharply from the ecliptic is Mercury. Mercury can be as much as 7° 00′ north or south of the ecliptic.) For this reason it was conceived that there was marked in the heavens a great "highway" (*hodos* in Greek) in which there moved the sun, the moon, and the planets. This path is 14° wide and is the origin of the concept of the zodiacal band. Since Mercury determines its dimensions and determines them by a perfect figure, in ancient religions this planet was associated with the god of measurement. It was conceived that the sun, the moon, and the planets were engaged in competing with each other running in the racing course of the zodiacal band. Another conception was that there were two walls, running parallel 14° apart, within which there was going on a ball game. The notion of a wall accounted for the fact that the heavenly bodies could not go beyond a given distance from the ecliptic; they appeared to run away from the ecliptic, hit a wall, and bounce back past the ecliptic to hit the wall on the other side. This is the ritual origin of racing competitions (such as the Olympic races, on foot or in chariots) and of ball games. The most vivid expression of the second conception is the famous ball court in the Mayan city of Chichen Itzá; the structure of this ball court can be understood when one realizes that its two parallel side walls are unfolded cylindrical projections of the sky.

The zodiacal band was conceived to be the inhabited part of the sky; the rest of the sky was still and lifeless (*erēmos,* "desert, desolate," in Greek), because nothing moved in it, except for the rotation of the vault of heaven in a solid block. Hence, in order to make a map of the sky for the study of the moving heavenly bodies, it was enough to draw a map that reaches latitude 31° (24° + 7°). Such a map could be drawn in the form of a cylindrical projection without substantial deformation; this cylindrical projection was unfolded to form a rectangle.

On the basis of this conception, stress was put on the fact that Egypt begins at the line of the tropic of Cancer (the upper edge of the First Cataract is at 24° 00′ north) and extends north for 7°, so that Egypt could be considered as the equivalent on earth of the northern half of the zodiacal band. For the sake of mapping the earth from the equator to the northern limit of Egypt, one could use a cylindrical projection. The maximum deformation in such a type of projection could be determined; it was established that a degree of longitude at parallel 31° 06′ north is exactly 6/7 of a degree of longitude at the equator. According to the Clarke Spheroid a degree of equator is 111,321 meters, of which 6/7 is 95,418 meters; according to the same Spheroid a degree of longitude at 31° 06′ is 95,407 meters. To the north of latitude 31° 06′ north there was the expanse of the Mediterranean, the "Great Green" for the Egyptians, which could be compared with the expanse of the empty sky, north of the same celestial latitude.

The angle of the ecliptic has decreased slowly (today it is 23° 27′; it was about at 23° 45′ in the age of Ptolemy), and accordingly the tropic of Cancer has moved south. This movement is due to the gravitational pull of the planets, particularly Jupiter and Venus. Nobody as yet has succeeded in constructing a valid formula for calculating the angle of the ecliptic in ancient times. But, it is a fact that when the second geodetic system of Egypt was established it was assumed that the tropic of Cancer was at 23° 51′ north. Greek scholars living under the rule of the last Egyptian dynasty, the Ptolemies, continued to quote this figure, although it was not correct at their time.

If the tropic is at 23° 51′ north, it would follow that the southern border of Egypt is out of place. But the discrepancy was rationalized by considering the fact that when one follows the movement of the sun along the ecliptic by observing the shadow cast by a pointer, there must be introduced a correction of about 15′. The position of the shadow is not determined by the center of the sun, but by the upper limb of the disk. The apparent diameter of the sun is about half a degree; calculating exactly, it varies between 32′ 30″ and 31′ 28″, according to the seasons, but, considering the corrections that have to be made for the phenomenon of irradiation, the figure of 15′ for the half diameter of the disk of the sun is satisfactory.

If the tropic of Cancer is at 23° 51′ north, the point at which the sun is at the zenith at noon of the day of the summer solstice is at 24° 06′ north, that is, at the latitude of the lower edge of the First Cataract. Hence, the Egyptians conceived that the line of the tropic of Cancer was marked by three parallels: 23° 51′, 24° 00′, and 24° 06′ north.

For this reason the hieroglyphic symbol for Southern Egypt consists essentially of three parallel lines with a vertical line rising at the middle. Since hieroglyphic writing aims at being colorful and pictorially decorative, this symbol was stylized in the shape of a trunk of a tree from which there sprout three parallel tiers of branches. Egyptologists who do not want to recognize the existence of scientific thought in Egypt have stressed the incidental vegetal appearance of this symbol. They have understood that the name for Southern Egypt, which is *To-Shemau*, "the land of the heat, of the sun, of the summer solstice," means "the land of the plant *sh-m-a*." But if there was such a plant associated with Southern Egypt (which as yet has not been identified), it is possibly the same plant which is called *šamšu*, "sunflower" in Akkadian; the word *šamšu* means "sun" in Akkadian (Hebrew: *šemeš*). In a text of the Old Kingdom in which the hieroglyphs are drawn with particular care, in the symbol for *shemau* there is only one tier of branches, but the trunk starts from a little arc, a semicircle, which obviously symbolizes a parallel. But what probably is most revealing is that in most hieroglyphic texts the tiers of branches sprout from the bottom of the trunk and not from its top.

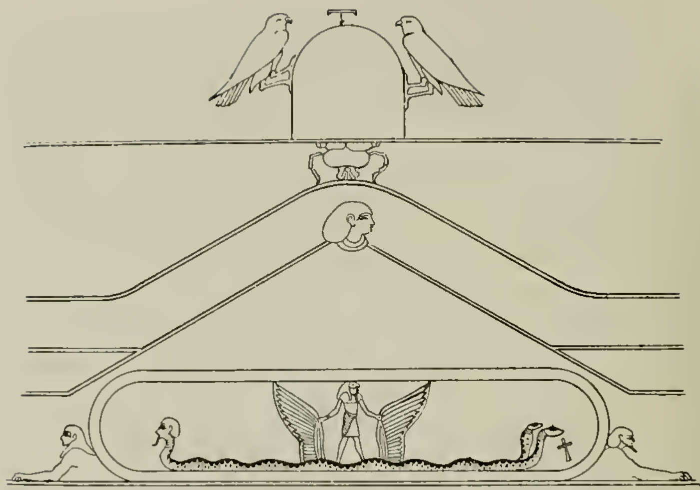
4. Once the latitudes of the southern limit of Egypt were rationalized by identifying the line of the tropic with three parallels (the first of which cuts the lower edge of the First Cataract at 24° 06′, the second cuts the upper

edge of it at the perfect latitude 24° 00′, and the other cuts the Nile at 23° 51′ north, at a place which the Greeks called Parembole, "supplement, addition"), it became possible to rationalize the boundary between Southern Egypt and Northern Egypt. This boundary was understood as marked by three parallels, the first at 30° 06′, the latitude of the apex of the Delta, the second at the perfect latitude 30° 00′, and the third at latitude 29° 51′.

In the administration of Egypt, the area between 29° 51′ and 30° 06′ north was organized as a special district which did not belong either to the list of nomes (provinces) of Southern Egypt nor to that of nomes of Northern Egypt. The hieroglyph for this district is a rectangle which is either empty or filled with water or fish. A distinguished Egyptologist, being at a loss for a better explanation, has read this hieroglyph as "fishpond." He did not realize that a rectangle, either empty or filled with water or fish, is the symbol of the Square of Pegasus. In *Hamlet's Mill,* de Santillana and Dechend have presented illustrations of this symbolism occurring all over the globe (between pages 434 and 435). There are in the sky four stars which are at a distance of about 15° from each other and mark a square with sides that run according to the celestial meridians or parallels; these four stars form the Square of Pegasus. In iconography this square was at times portrayed as filled with water or fish, because it was in the constellation of Pisces. The Square of Pegasus was considered the starting point in the mapping of the sky. The ancients, from the Sumerians to the Romans, in surveying land began by marking a square of a standard dimension and then proceeded to measure out of it in a checkerboard pattern. In cuneiform texts the name *ikū* is given to the basic surveying square, to a unit of land surface, and to the Square of Pegasus. The hieroglyph used to refer to the district extending for 15′ from Memphis-Sokar to the apex of the Delta indicates that this district was considered the basic reference unit from which there started the mapping of Northern and Southern Egypt.

The capital of united Egypt was established at Memphis, at latitude 29° 51′ north. But, since the capital city of necessity had to be on the bank of the Nile, which here runs slightly east of the apex, the geodetic point was set to the west of the city in the funerary area (the city of the dead is always to the west of the city of the living), on the basic meridian 31° 14′ east. This was the point called Sokar, the name of which is preserved by the present village of Saqqara (29° 51′ north, 31° 14′ east). In the religion of the Old Kingdom, Sokar is an important god of orientation

Egyptian papyrus depicting Sokar, the god of orientation. The gadget on top of the *omphalos* is a standard Egyptian measuring ruler (and also the symbol for the sky). The two pigeons facing each other are the standard glyph for the laying out of parallels and meridians.



and of cemeteries. The god and the geodetic point were represented by the stone object which the Greeks called *omphalos,* "navel"; it is a hemisphere (the northern hemisphere) resting on a cylinder (the foundations of the cosmos). Usually on top of Sokar, as on top of any *omphalos,* there are portrayed two birds facing each other; in ancient iconography these two birds, usually doves, are a standard symbol for the stretching of meridians and parallels.

The practice of placing the geodetic center in the city of the dead was followed by King Darius the Great, when he established a new capital for the Persian Empire, Persepolis. Historians have wondered why Darius should have chosen for Persepolis a most inconvenient location; actually the capital of Persepolis was seldom used except for ritualistic purposes. Persepolis is at latitude 30° 00′ north and three units of 7° 12′ east of the main axis of Egypt (31° 14′ east). The reason for choosing units of 7° 12′ is that the Persian Empire was mapped by drawing a series of geodetic squares, east and west of Persepolis, which extend 6° in latitude from 30° 00′ to 36° 00′ north and have a width of 7° 12′ of longitude, since 7° 12′ of longitude is equivalent in actual length to 6° of latitude at the middle point between 30° 00′ and 36° 00′ north. Hence, these geodetic squares are true squares. The geodetic point of Persepolis, 30° 00′ north, 52° 50′ east, is north and west of the wide expanse of the royal buildings and is identified by the tomb of King Darius, around which there were built the tombs of his successors. At the geodetic point 30° 00′ north, 52° 50′ east, there could be erected tombs, but there was not the kind of ground on which there could be stretched a capital city.

The location of Memphis-Sokar had the advantage of being exactly 8° north of the point where meridian 31° 14′ east cuts again the course of the Nile at the Second Cataract. In a new imperialistic spirit, Egypt in a wide sense was understood to end at the Second Cataract.

5. According to the new conception which links Egypt with the sky, if Southern Egypt extends 6° from the tropic, Northern Egypt must extend only 1° to the north of the apex, in order to be in agreement with the order of the cosmos. Hence, the northern limit of Egypt was set at parallel 31° 06′ north.

This was achieved by identifying the northern limit of Egypt with the line that joins the two outer ends of the estuary of the Nile. This line extended 1° 24′ = 1.4° east and west of the axis 31° 14′ east. Hence, there was marked a triangle, which the Greeks called the Delta, with a base line extending from 31° 38′ to 29° 50′ east along parallel 31° 06′ north and a vertex at the long-established point of the apex of the Delta. This isosceles triangle is divided by meridian 31° 14′ into two right triangles of the type *mr*. In calculating the proportions of this triangle, one must keep in mind that at latitude 31° 06′ north, 1.4° of longitude corresponds to 1.2° in actual length, since the degree of longitude is shrunk by 1/7 at this latitude.

The base line of the mathematical triangle of the Delta fell perfectly at the eastern end. Here the corner of the Delta coincides with the well-defined natural boundary point Pelusium, along the shore. On the western side the corner of the Delta did not fall right on the shore, but at the middle of a coastal lagoon; even today the eastern boundary of the Western Desert province of Egypt passes through it.

The old geodetic center of Behdet was not completely ignored, since it could be fitted into the system by considering that it is 1.4° north of the apex of the Delta.

I have stated earlier that it was assumed that at latitude 31° 06′, the degree of longitude is 6/7 of the degree of equator. This calculation permitted the rationalization of the shift of the key positions of Egypt by 6′ to the north of the perfect latitudes 24° 00′ and 30° 00′ north. The shift was related to the polar flattening of the earth, which, according to the septenary order of the cosmos, was assumed to be 1/280. If the earth were a perfect sphere, the degree of longitude which is 6/7 of degree of equator would be at latitude 31° 00′ (cosine 31° 00′ = 0.85717; 6/7 = 0.85714).

Anticipating what I will explain in greater detail later, I must mention here that the dimensions of Egypt were recalculated in terms of a new unit of length, the royal cubit, which is obtained by adding a seventh hand to the usual six which compose a cubit. In terms of this longer cubit, the length of Egypt from 31° 06′ to 24° 00′ north was set at 1,500,000 cubits. The royal cubit summed the septenary spirit of the new geodetic system.

In hieroglyphic writing the name for Northern Egypt is *To-Meḥu*. Most Egyptologists, following the line of reasoning which I have mentioned in relation to Southern Egypt, have understood that *To-Meḥu* means "the land of the papyrus," but the name of the papyrus is *ḥly*, and the symbol for Northern Egypt cannot be compared with a papyrus plant by any stretch of the imagination. The name of Northern Egypt can be explained when we consider that it is similar to the name of the cubit (*maḥe* in Coptic), which comes from a root which means "to fill up." Hence, *To-Meḥu* may mean "the land which fills up the dimensions of Egypt." Northern Egypt corresponds to the seventh hand added to the cubit.

From what we have of early writing attempts from predynastic Egypt, it is absolutely clear that the symbol for Northern Egypt used to be the red straw hat. With the beginning of the dynastic period, the creation of hieroglyphic writing, and the new geodetic system, the symbol of Northern Egypt becomes a plant with three stems springing from one root. In some cases the reference to the triangularity of the Delta is emphasized by putting at the end of each stem a flower with a triangular calyx. In carefully drawn representations the plant springs from a rectangle either empty or filled with the wavy line for water, which is the symbol for the intermediary district, extending from 29° 51′ to 30° 06′ north.

At times the stems in the symbol for Northern Egypt are broken and bent at the top. This may be a reference to the fact that in the new geodetic system the northern limit was lowered from 31° 30′ to 31° 06′ north.

On the two sides of the throne of the Pharaoh there was a design which Egyptologists call "Unity of Egypt." We know it well because it appears in all statues of Pharaohs sitting on the throne; the series of such statues starts with the Fourth Dynasty, but occasional drawings indicate that the design "Unity of Egypt" is older. In the course of centuries the design varied somewhat and the artists who carved the throne stylized it according to different tastes; but on the basis of what I have explained above, one can always recognize that it represents the geodetic system of Egypt.

The center of the design is the hieroglyphic sign for the verb "to unite," which is a windpipe with two lungs.

However, in the design "Unity of Egypt" the windpipe is stretched, so that it looks like a long trunk of a tree, in order to indicate the main axis of Egypt; the lungs are reduced to a diminutive size. On one side of the windpipe there is the symbol for Northern Egypt and on the other side the symbol for Southern Egypt. But what is most significant is that the entire drawing is tied together by a system of ropes and knots, which indicate the geodetic lines and points of Egypt.

The design called "Unity of Egypt" is the standard decoration of the royal throne, because it symbolizes all that the Egyptians held fundamental in their political, ethical, religious, and cosmological conceptions, a cluster of ideas which they summarized by the word *maet,* a word with which I will deal in a following chapter. Nevertheless, this design has received only casual attention. The best way in which I can convey in brief how this design is pregnant with meaning is by referring to Hebrew Cabalistic literature. The Cabala is a Hebrew underground religion or philosophy. The starting point of Cabalistic doctrine is that God in creating the world began by creating the ten numbers and arranged them according to a diagram of points and connecting lines, which proves to be modeled on the design "Unity of Egypt." Actually, what gave me the first insights into the Egyptian geodetic system was the reading of the Italian Renaissance scientists who were influenced by Hebrew Cabalists.

The state of Israel has adopted as its national emblem the Cabalistic symbol of two overlapping triangles. These two triangles should be seen as inscribed in a circle: they represent the poles, the tropics, and the ecliptic, besides having the added meaning of the male and female elements coming together to generate the cosmos. The Founding Fathers adopted as the seal of the United States a pyramid; they wanted to convey the notion that a perfect society had been organized, and in order to convey it they adopted a symbol which, through the tradition transmitted by masonic societies, goes back to the Egyptian idea of *maet.*

6. The geodetic system established at the beginning of the Old Kingdom was modified in part with the advent of the Twelfth Dynasty, the most dynamic of the Egyptian dynasties as far as we know. The advent of this dynasty marks the beginning of what scholars call the Middle Kingdom period. But probably more significant in Egyptian terms was that the advent of this dynasty coincided with the beginning of the age of Aries. It became necessary to revise the system of cosmology, since the sun had moved out of the constellation of Taurus to enter into that of

Aries. The kings of this dynasty identified themselves with the god Amon, symbolized by the ram. The first king of the dynasty called himself Amenemhet, introducing the custom of theophoric names, that is, of personal names composed with the name of a god. The god Amon was made to spring from relative obscurity into the position of the main official divinity of Egypt. It seems that up to that time Amon was a local god of the desert area west of Thebes or that Amon was identified with a local god of that area.

The Twelfth Dynasty moved the capital and the geodetic center of Egypt to a more central position, Thebes. The longitude of the new capital was determined by the point where the eastern axis of Egypt (32° 38′ east) cuts the course of the Nile. The latitude was 2/7 of the distance from the equator to the pole (25° 42′ 51″ north). This latitude was marked by the central room of the temple of Amon, in which the god and the geodetic point most probably was indicated by the same object, the *omphalos,* "navel," which used to represent the god Sokar. What is certain is that when centuries later in the capital of Nubia, Napata, there was built a second temple of Amon in order to link Nubia with Egypt politically, in the center of this temple there was placed such an object.

Egyptologists have tried to torture Egyptian linguistics in order to explain why the Greeks should have given the name Thebes to a city which the Egyptians called Wast. The likely explanation is that the Greeks learned the name of the city from the Phoenicians, who in their own language called it *thibbûn,* "navel." There is textual evidence that in Hebrew, which is practically the same language as Phoenician, the word *thibbûn* is used to refer to a geodetic navel.

The choice of the latitude emphasized the septenary system of Egyptian geography. The ancients divided the space between the pole and the equator into seven zones. This is indicated not only by Greek writers of geography, but also by the ziggurats of Mesopotamia and the earliest pyramids of Egypt, which are step pyramids.

7. It was possibly on the occasion of the transfer of the capital and geodetic center to Thebes, which stresses the importance of the eastern meridian of Egypt (32° 38′ east), that something was done to rationalize the longitude of the First Cataract. The First Cataract happened not to be included in the rectangle of Egypt, being somewhat to the east of meridian 32° 38′, at 32° 53′ east. The lower edge of the cataract, at 24° 06′ north, 32° 53′ east, is 15′ north of the right position and 15′ west of it. It must have been

disturbing that the southern boundary of Egypt should not fit with the system of three meridians passing through the three angles of the Delta triangle. Hence, the area of the First Cataract was extended southward along the course of the Nile up to the point where meridian 32° 38′ east cuts the course of the Nile. This point happens to be at 23° 00′ north. The new point 23° 00′ north, 32° 38′ east was called Sacred Sycamore and was set as the legal boundary of Egypt. The stretch of the Nile from the Sacred Sycamore to the First Cataract was attached to the district of the First Cataract. In Hellenistic times this attached district was called Dodekaschoinos, which in Egyptian would be "twelve *atur.*" The *atur,* as I will explain later, was a unit of length such that slightly more than 14 (14 in practical computations) went into a degree. If the distance of 51′ between 23° 00′ and 23° 51′ north, the correct line of the tropic, is calculated as 12 *atur,* it means that counting exactly a degree would be 14.11765 *atur.* The Egyptians used two types of *atur:* an *atur* of 17,000 geographic cubits (7848.8 meters) and an *atur* of 15,000 royal cubits (7862.2 meters). Now, 51′ at latitude 23° to 24° is about 94,135 meters, whereas 12 *atur* of the first kind is 94,186 meters and 12 *atur* of the second kind is 94,346 meters.

Even though the district Dodekaschoinos was attached to Egypt purely for mathematical reasons, it continued to be included in Egypt into the Roman period.

I suggest that the establishment of the supplementary district Dodekaschoinos with a new southern boundary of Egypt at 23° 00′ north was linked with the transfer of the capital to Thebes, because there is a text which gives the dimensions of Egypt from the sea at Pelusium (eastern corner of the triangle of the Delta) to the end of the district Dodekaschoinos, that is, all along meridian 32° 38′ east. The distance is divided into two-thirds from Pelusium to Thebes and one-third from Thebes to the Sacred Sycamore. If we round the latitude of Thebes from 25° 42′ 51″ north to 25° 42′ north, the calculation is perfect:

31° 06′ to 25° 42′ north = 5° 24′
25° 42′ to 23° 00′ north = 2° 42′

When the southern boundary of Egypt is moved to the Sacred Sycamore by adding the district Dodekaschoinos, the Temple of Amon in Thebes is in a rational position not only in relation to arc of meridian, but also in relation to the extension of Egypt.

The text that gives the information just mentioned indicates also that the latitude of Thebes has a further peculiarity: at this latitude the degree of longitude is 9/10 of degree of equator.

II. EGYPTIAN UNITS OF LENGTH

1. All the measures of length, volume, and weight of the ancient world, including those of China and India, constituted a rational and organic system, which can be reconstructed starting from a fundamental unit of length. I have not yet completed the gathering of data concerning the units of pre-Columbian America, because these are difficult to obtain, since the metrology of the American continent has received meager attention; but the figures that I have succeeded in establishing so far suggest that the American units agree with those of the Old World. The units used in Europe up to the adoption of the French metric system were the ancient ones or modifications of them introduced for specific reasons. The ancient system of measures continues to be used today in the form of English measures; we find the basic units of the English system, such as the pound of 453.8 grams, used in Mesopotamia in the third millennium B.C.

The effort to reconstruct the original and unitary system of measures was started by scholars of the Renaissance as a result of the beginning of the age of geographical discoveries. Their investigations, although they took the form of antiquarian research, had two practical purposes: to interpret correctly the data provided by ancient geographers and to establish an absolutely reliable and fixed standard of length. Although the major concern of Renaissance investigators of measures was to establish the exact value of the ancient Roman foot, they were also concerned with a tradition to the effect that all measures were derived from the Egyptian ones. This is the reason why John Greaves went to measure the Great Pyramid of Giza, in order to complete his researches on the length of the ancient Roman foot. In Egypt Greaves met with Burattini, who had gone to measure the monuments of Egypt, in order to establish the linear starting point (for which he coined the name *meter*) in his proposal for a new metric system which would be strictly decimal, like the one later adopted as the French metric system. Greaves had the advantage of having spent a long time in Rome measuring buildings, vessels, and weights and of being provided with accurate measuring tools, based on English units; Burattini had the advantage of having already measured a number of Egyptian buildings. Greaves and Burattini joined forces in measuring the Great Pyramid of Giza, which they hoped would provide a solution to their problems. After this survey Greaves returned to England, leaving his measuring tools with Burattini, who continued the study of Egyptian monuments. On his return Greaves published the results obtained at Giza, results which were later interpreted by Newton. But Burattini had the ill luck to be robbed of his notes by Hungarian brigands while on his way to Poland. As a result, when he published his proposal for a decimal metric system, for lack of a better alternative, he advocated that one should start with the English foot and divide the cube of this foot decimally in order to obtain the units of volume and weight.

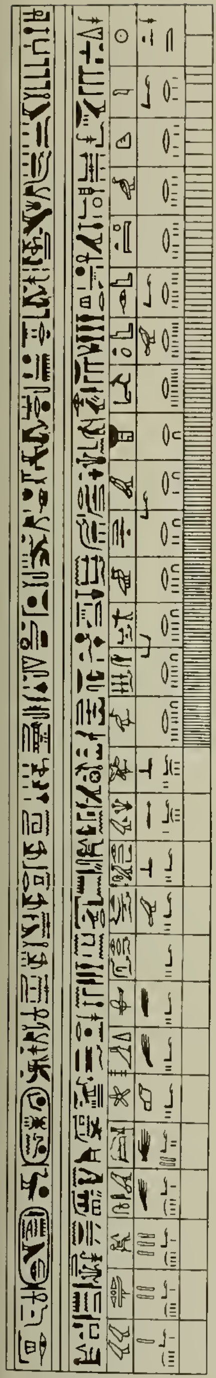
The study of Egyptian measures received a new impulsion with the Napoleonic expedition to Egypt and the consequent decipherment of Egyptian hieroglyphs by Champollion. This decipherment had been unsuccessfully attempted by Father Athanasius Kircher, who had sponsored Burattini's expedition to Egypt. In the first half of the nineteenth century, it was established that the Egyptians had a septenary system of linear units.

In the ancient world one measured by feet and cubits. The cubit is equal to 1 1/2 feet. The cubit is divided into 6 hands of 4 fingers each (24 fingers) and the foot is divided into 4 hands (16 fingers). The division of the foot into 12 inches, with which we are familiar, became common only with the Romans. According to the Roman reckoning the cubit is 16 inches. The inch was considered to be the thickness of the thumb; generally in the ancient world one preferred to reckon by fingers, assumed to be the thickness of the other four fingers. It must be kept in mind, however, that terms like foot, cubit, finger, and inch were introduced in order to give a name to units obtained scientifically, units which correspond only vaguely to the natural units of the same name.

Scholars of Egyptology concluded that the Egyptians had started with a foot of 300 millimeters and a corresponding cubit of 450 millimeters, divided into 16 and 24 fingers as in the rest of the ancient world, but then had adopted as their linear basic unit a cubit, called a royal cubit, of 525 millimeters. The royal cubit is composed of 7 hands, or 28 fingers: it is an ordinary cubit with a seventh hand added.

2. One can find examples of septenary units also outside Egypt. The use of measuring rods of seven feet is common in medieval and early modern Europe. A typical example of septenary units is the Russian *sajen'*, which is composed of 7 English feet and is divided into 3 *arshin* of 28 inches. The *sajen'* was the basis of the Russian system of measures until the Soviet government adopted the French metric system in 1918.

The reason for the occurrence of septenary units is that they were convenient in practical reckonings. Agrarian units of surface were arranged in a series in which each was double of the preceding one. It was assumed in practical



Egyptian measuring rule carved out of wood showing various fingers, palms, and cubits (at present in the Turin Musem).

reckonings that a square with a side of 100 was the double of a square with a side of 70 and the half of a square with a side of 140. This implies that $\sqrt{2} = 1.414214$, taken as equal to 1.4. A typical example of this reckoning is the area of 5000 square cubits, within which a Jew can move on the Sabbath, which is described by the Talmud as "the square of seventy cubits." When greater precision was desired in practical reckonings, one averaged the results of considering the diagonal of a square as 10/7 of the side and as 14/10 of the side ($1.42857 + 1.4/2 = 1.41428$).

Septenary units were used also in order to facilitate other practical reckonings. The height of an equilateral triangle being equal to $\sqrt{3}/2$ of the side, the relation can be taken as 7:6, since $12/7 = 1.71428$ and $\sqrt{3} = 1.73205$.

According to the septenary system of reckoning, the circumference was considered 22/7 of the diameter; the approximation $\pi = 3\ 1/7 = 3.142857$ is still used today as an adequate approximation in many problems of engineering.

The figure 22/7 used to obtain the value of π in practical reckonings is related to the fact that the ancients used both septenary and undecimal (i.e., eleven-based) units in order to achieve easy computations in practical reckonings. Undecimal linear units were common in the ancient and early modern world; an example of them is the English chain of 66 feet. An acre, originally a square with sides of 70 yards, is now 10 square chains (4840 sq. yards).

An important practical problem involving the number π was solved by the use of undecimal units. Units of volume were legally defined as cubes, but measuring vessels were built as cylinders. All that an ordinary potter, who could be an illiterate person, had to know was that, in order to construct a cylinder equal in volume to a given cube, he had to take the height and width of the cube and use them as the height and diameter of the cylinder, provided he measured the cylinder by a ruler based on a unit of length increased by 1/10. The procedure results in a cylinder of slightly excessive volume. If we assume a cube with a side of 10 fingers, its volume is 1000 cubic fingers. A cylinder with a diameter of 11 fingers and height of 11 has a volume of 1045.4 cubic fingers. But this small excess was automatically corrected in practice, since a measuring vase must have a rim and cannot be filled to the brim. A filling line marked on the measuring vase slightly below the brim took care of the difference. I first became aware of this procedure in interpreting cuneiform mathematical texts, but later I found it referred to in Athenian inscriptions and applied concretely in Athenian measuring vessels.

By combining calculations by the factor 7 and calculations by the factor 11, one could solve practically a number of geometric problems involving irrational numbers. This practice is one of the reasons why the builders of the Great Pyramid began their plan with a height of 280 royal cubits and a side of 440.

A simple example of the combination of reckoning by septenary and undecimal units is the following. As I have said, in agrarian units it was assumed that a square with the side of 100 is the double of a square with a side of 70 and half of a square with a side of 140. This procedure would result in units of the following surface:

49,000
100,000
196,000

In order to make the series more regular, the middle unit was often taken as a square with a side of 99, so that the series became:

49,000
98,010
196,000

When Herodotus reports the surface of the sides of the Great Pyramid, he reckons by units of surface calculating by the second pattern.

Although the use of septenary units had been common in ancient times and later, in Egypt the septenary cubit became a national symbol related to the essential structure of Egypt and of the cosmic order.

3. In the second half of the nineteenth century, some scholars of ancient measures tried to derive them from the Egyptian units of length. Although in the last fifty years it has become fashionable among scholars of ancient cultures to deny that they had any knowledge of a scientific system of measures, all serious scholars of ancient and medieval measures have always known that all measures of volume and weight are derived from the units of length. Units of volume were obtained by cubing the units of length. Units of weight were obtained by filling the units of volume with rain water at ordinary temperature; this water has the same density as distilled water at 4° Centigrade adopted by the French metric system, since in the earlier procedure the impurities of the rain water compensated for the higher temperature.

Friedrich Hultsch, who was the most authoritative investigator of ancient measures in the later part of the last century, concluded his lifelong research by announcing just before his death that all ancient measures could be derived from the Egyptian foot of 300 millimeters and from the corresponding ordinary (not septenary) cubit of 450 millimeters. He also supported the view expressed by others that the Egyptian unit of weight called *qedet,* of 9 grams, is the basic unit of weight of the ancient world.

But Hultsch left a difficulty unsolved. If we cube an Egyptian foot of 300 millimeters, we obtain a cube of 27,000 cubic centimeters or grams, which is divided into 3000 *qedet* of 9 grams. If we cube an Egyptian ordinary cubit of 450 millimeters, we obtain a cube of 91,125 cubic centimeters or grams, which is divided into 10,000 *qedet* of 9.1125 grams. Sample weights indicate that both *qedet* were used in Egypt. A *qedet* of 9 grams relates to a *qedet* of 9.1125 grams as 80:81.

The same discrepancy occurs all over the ancient world. Prince Mihail Sutzu, Director of the National Bank of Rumania, having dedicated his life to the study of ancient weights, in 1930 concluded that the *qedet* of 9 grams is the *bazele fundamentale ale metrologiei ponderale din antichitate,* but, in order to explain the mentioned discrepancy in weights, supposed that there had been a gradual decrease from a unit of 9.20 grams established in the neolithic period.

But in presenting this explanation Sutzu contradicted one of his basic assumptions, which is the amazing stability of measures throughout history. From the very beginning of literate cultures, documents indicate an extreme concern with the preservation of exact metric standards. The concern with precision seems to have lessened in the course of history. Early modern Europe was less careful than medieval Europe. The Greeks of the Hellenistic age were less careful than those of the classical age. Even though the Greeks of the classical age seem to have been obsessed with the problem of correct standards, they did not reach the subtlety of Egypt and Mesopotamia. One of the reasons why the study of the history of measures was actively pursued in the late Renaissance was that by that time standards had started to waver.

There were two factors which determined extreme concern with absolutely exact standards: units of length were used to measure geographic distances, and units of weight were used to measure gold and silver used as means of exchange.

The amazing stability of measures is indicated by the circumstance that the kilogram was established by relating it to the Paris livre which was directly related to the Roman *libra*. The official definition of the kilogram is such that the livre equals 489.5058466 grams. Since the livre was divided into 9216 grains (16 ounces of 24 scruples of 24 grains), the Paris grain according to this definition is 0.05311478 gram. Historically the Paris livre was established by fixing the Paris grains as 1/6100 of the ancient Roman *libra*, the Roman *libra* being 324 grams (5000 English grains) or 36 Egyptian *qedet*. If the original standard had been preserved, the grain of Paris would have been found at the moment of adoption of the French metric system to be 0.05311475 gram and the livre to be 489.5055737 grams. In substance the standard of the Paris livre and hence of the Roman *libra* appear to have been well preserved, even though those who established the French metric system did not consider the theoretical foundations of the livre, but simply averaged several sample weights which were available. However, scholars of the seventeenth century complained that Paris measures were not very clearly defined and had concluded that English units of weight were more exactly defined.

The English grain has remained stable as 1/5000 of a Roman *libra*. English weight units have not changed at all since Sumerian times. The oldest weights of which I have found mention in an archeological report are those excavated at Tepe Gawra in Iraq, near the present oil center of Mosul. The lowest strata of Tepe Gawra embody the very first steps of the transition from village life to urban life. The earliest weights of Tepe Gawra precede by about a millennium the invention of writing. According to my interpretation these weights are fractions of the present English ounce avoirdupois of 28.350 grams (1/16 pound, which is 7/5 of a Roman *libra*).

4. Before explaining why there was a *qedet* of 9 grams and a *qedet* of 9.1125 grams, I must deal with a much more serious difficulty met by Hultsch.

He assumed that all measures of the ancient world can be derived from the Egyptian foot, but could not solve the absolutely essential problem of explaining how the Roman foot of roughly 296 millimeters could be derived from the Egyptian foot of 300 millimeters.

The key to the solution of this problem was provided to me when in 1942 the archeologist August Oxé, at the end of lifelong research, published a monograph explaining that almost all units of volume and weight of the ancient world exist in two varieties, related as:

12.5	25	50	62.5	75	100	125	150
12	24	48	60	72	96	120	144

He called the first series units *brutto*, and the second series units *netto*. The reason for the existence of the second series is that it is impossible from the practical point of view to divide decimally a cube into smaller cubes.

Developing the discovery of Oxé, I arrived at the logical consequence that units of length must usually occur in two varieties, one which is the edge of a cube containing a unit *brutto* and one which is the edge of a cube containing a unit *netto*. The two varieties of units of length are related as $\sqrt[3]{25}:\sqrt[3]{24}$. I call the first group of units of length by the name of *natural* units and the second group by the name of *trimmed* units.

From an Egyptian cubit of 300 millimeters we derive:

Basic talent *brutto* of 27,000 cubic centimeters or grams
1000 Roman ounces of 27 cubic centimeters or grams
3000 Egyptian *qedet* of 9 grams

It follows that the cube of the Roman foot (which the Romans called *quadrantal*, or *pes quadratus*) must be 24/25 of the preceding unit:

Basic talent *netto* of 25,920 cubic centimeters or grams
960 Roman ounces of 27 cubic centimeters or grams
2880 Egyptian *qedet* of 9 grams

The Roman quadrantal or basic talent *netto* is divided into 80 librae of 324 grams (12 ounces or 36 *qedet*). The libra is equal to 5000 English grains.

Accordingly I could establish that the Roman foot relates as $\sqrt[3]{24}:\sqrt[3]{25}$ to the Egyptian foot of 300 millimeters, and hence is a unit of 295.9454 millimeters, which is a figure in agreement with the empirical evidence.

Having established the theoretical basis of the Roman foot and of the Roman quadrantal, I could dispose of a difficulty which had bedeviled scholars since the Renaissance. By examining the empirical evidence it had been established that the Roman foot existed in two varieties, one shorter (called *pes Statilianus* by Renaissance scholars) and one longer (called *pes Aebutianus*). Correspondingly, there were two varieties of Roman libra.

The explanation for this difference is that units of volume and weight may occur in two varieties related as 80:81, with a difference which I call discrepancy komma. In 1909 Jean Adolphe Decourdemanche, at the end of his book on Arabic measures, added a proviso explaining that all Arabic units of weight and volume occur in two varieties related as 80:81. My teacher Angelo Segré, in studying the measures of Hellenistic Egypt, found that, although the cube of the cubit is 3 3/8 of the cube of the foot, given that $(1\ 1/2)^3:1^3 = 3\ 3/8:1$, often this relation between the cube of the cubit and the cube of the foot is taken as a relation 3 1/3:1 for the sake of easy reckoning, with the result that there is a discrepancy of 1/80, since 3 1/3:3 3/8 = 80:81.

The most striking example of the discrepancy komma (1/80) is that next to the quadrantal (cubed Roman foot) of 80 librae there is a quadrantal of 81 librae. This larger quadrantal has an edge which constitutes a special Roman foot of 297.1734 millimeters (instead of 295.9454 millimeters), which was called geometric foot in the Middle Ages. The Roman foot of the geometric variety was the scientific foot of early modern science. Scientists began to calculate by the French *pied de roi* (which originally was the undecimal version, 11/10, of the Roman foot) after Picard used it in his famous calculation of the circumference of the earth, and Newton quoted Picard's figures in presenting the empirical proofs for the theory of gravitation. The *pied de roi* was used in calculating the length of the Paris meter, theoretically defined as 1/10,000,000 of the arc of meridian: the meter is 1/10,000,000 of 30,784,440 *pieds de roi,* which was then the assumed length of the arc of meridian from the equator to the pole.

By dividing the quadrantal of 81 librae into 80 librae, the Romans obtained a libra of 328.050 grams, which was called the *geometric libra* in the Middle Ages. The edge of the larger quadrantal, the Roman *geometric foot,* was the standard unit in the planning of most monuments of classical Athens.

The larger Roman quadrantal (81 regular librae = 80 librae of the geometric variety), cube of a Roman geometric foot 297.1734 millimeters, contains 26,244 cubic centimeters or grams. It survived up to recently as the Russian *chetverik* (this Russian term has the same meaning as the Latin *quadrantal*). The law of 1918 that introduced the French metric system in the Soviet Union fixed the *chetverik* at 26,239 cubic centimeters.

The reason for the small difference is that Czar Peter the Great, according to his westernizing policy, had the length of the Russian *sajen'* readjusted to make it equal to 7 of the feet used in England. But the exact standard of the English foot had been lost in the Elizabethan age, and the length of the English foot has wavered until in England there was established the Imperial Yard of 1824, which makes the foot equal to 304.79974 millimeters, and in the United States the foot was defined by the Paris meter as 304.8 millimeters (act of Congress of 1928). The reform of Peter the Great caused uncertainties in the definition of Russian measures. The action of one autocrat extended the damage caused by another. As far as I can understand the record, the problem of the length of the English foot arose when Queen Elizabeth, following her policy which aimed at reducing the power of the municipal body of London, downgraded the authority of the standard of Guild Hall (*pes Curiae Londinensis*), which was considered by scholars the best standard of English foot. Incidentally, Piazzi Smyth suggested that a way to reconstruct the authentic value of the English foot is to compare the actual dimensions of the King's Chamber of the Great Pyramid with the report of the survey conducted by Greaves.

On the other side, I have examined the reports about the dimensions of the Church of St. Sophia in Novgorod, the oldest stone monument of Russia, in order to establish what was the original value of the Russian counterpart of the English foot. From the point of view of my investigations, it is lucky that an effort has been made to restore this church exactly as it was before it was destroyed by the German army in World War II.

5. Once I was able to establish the relationship between the Roman foot and the Egyptian foot (the former being the trimmed version of the latter) and succeeded in clarifying the history of the units called Roman by distinguishing two varieties of libra related as 80:81, I came to the conclusion that the root of the ancient system of measures is not the Egyptian foot of 300 millimeters, but another unit which is the geographic foot of 307.7957 millimeters.

If we take 9/8 of a Roman quadrantal of 80 regular librae or 10/9 of a Roman quadrantal of 81 such librae, we have a unit of 90 librae, which metrologists call the *artaba*. Artaba is the Persian name of this unit. Metrologists employ it because after this unit was adopted as the official standard by the Persian Empire, the use of its Persian name became general in the ancient world: we find it in Greek, Latin, Hebrew, Syriac, and Arabic texts. But the unit itself is as old as any other known unit of the ancient world.

The artaba has the following contents:

29,160	cubic centimeters or grams
90	Roman librae
1080	Roman ounces of 27 cubic centimeters or grams
3200	Egyptian *qedet* of 9.1125 grams
3240	Egyptian *qedet* of 9 grams
450,000	English grains

The artaba was a unit of paramount importance in Egypt and several other areas of the ancient world, because it was the standard ration of wheat for a month. This was the ration for an adult free male; women, slaves, and children were assigned fractions of it. The artaba was also the standard monthly ration of rice in China.

In cuneiform mathematical and economic texts the most common unit of volume is a pint (*sila* in Sumerian, *gā* in Akkadian) of 486 cubic centimeters, which is 1/60 artaba. The pint of cuneiform texts is divided into 60 sheqels of 8.10 grams (9/10 of an Egyptian *qedet*).

The paramount importance of the artaba continued up to modern times. I have established that the key to the metric systems of medieval Europe is an ounce of 29.160 grams, which is 1/1000 of an artaba of water. This ounce was made important in Europe by the monetary reforms enacted by the Frankish Kings Pepin and Charlemagne. The artabic ounce was known in Europe as the Cologne ounce, because Cologne was the seat of one of the important mints of the Carolingian Empire. In England the artabic ounce was called ounce Tower, after the mint of the Tower of London.

In England the ounce Tower remained stable at 450 English grains (29.160 grams) or 16/15 of ounce Troy. The ounce Tower is no longer used today because it was used only to weigh coins. On the European continent the Cologne ounce remained less stable, because often it was computed as 451 grains (to my knowledge this figure is first mentioned in a document A.D. 1275). The reason for this shift was an effort to adjust the Cologne ounce to a shift in the Paris livre. The Paris livre was divided into 9216 grains (16 ounces of 24 scruples of 24 grains). For technical reasons of monetary economics, the Paris ounce had to be 22/21 of an artabic ounce. Hence, in the early Middle Ages the Paris ounce was 30.54857 grams and the Paris livre 488.77714 grams, with a grain of 0.0530357 gram. Since there were 6109.1 of these grains in the Roman libra of 324 grams, in the later part of the Middle Ages, in order to relate easily the Paris units to a well-established standard, the Paris grain was recalculated as 1/6100 of a Roman libra and the Paris ounce and livre were increased accordingly (livre of 489.50557 grams). The Paris grain (0.05311475 gram) came to be 50/61 of the English grain. This small and apparently reasonable readjustment of the Paris units was enough to create a spreading wave of uncertainty in the value of European weight units which did not come to rest for centuries. For instance, one can trace its consequences in metric and economic documents of the Low Countries, Scandinavia, and Russia.

Because of the increase in the Paris units, the Cologne ounce came to be often calculated as 451 English grains instead of 450. At the beginning of the nineteenth century, when the German states were taking steps toward national unity, it was thought expedient to try to unify the German coinage in terms of the Cologne ounce. A survey conducted in 1829 established that in Cologne itself the Cologne mark (8 ounces) was 233.8123 grams; 8 artabic ounces would be 233.280 grams and 8 ounces of 451 English grains would be 233.79840 grams. The standards of other German cities were found to be slightly different from that of Cologne, reaching a minimum with the mark of the mint of Bonn, which was

233.612 grams. On July 30, 1838, the German states signed a convention to establish a uniform monetary mark defined in terms of the French metric units as 233.855 grams; but the mine administration of Saxony continued to consider as correct the mark of Dresden, which had been set at 233.5804 grams in an assembly for the testing of monetary weights (*Münzprobationstag*) held at Regensburg in 1737. Apparently the assembly of Regensburg had followed the pattern of the medieval Assizes of Weights and Measures, who when called to resolve discrepancies between different standards of the same measure usually settled the matter by selecting an intermediary value. I may finally mention that when the French metric system was adopted in Spain, it was decreed that the pound of Aragon, composed of 12 ounces, would be thereforth considered equal to 350 grams; 12 artabic ounces is 348.720 grams.

6. The edge of the cube containing an artaba is a foot of 307.7957 millimeters (cubit of 461.6935 millimeters), which I call geographic foot, because it was the unit most commonly used in geographic measurements in all areas of the ancient world, Egypt being excepted for reasons that I will explain.

The multiple of the geographic foot is the stadium of 600 feet (400 cubits). The stadium is 1/600 degree, so that there are 360,000 geographic feet in a degree. It was assumed that a stadium (184.677 meters) corresponds to a double minute of march, implying that a man makes a step of 5 feet in a second. It was assumed that a man marching or a ship under oars covers 30 stadia (5540.3 meters) in an hour. Since it was assumed that a man can march or row for 10 hours a day, 300 stadia was considered the distance normally covered in a day. There are a great number of texts from Egypt and other areas of the ancient world which have not been understood, because they speak of 1,2,3,4, . . . days of march, when they mean a geographic distance of 30′, 1°, 1° 30′, 2°. . . . It was assumed that the speed of a ship under sail is 5/4 of that of a ship propelled by oars, so that a ship under sail covers 37.5 stadia in an hour and 900 stadia (1 1/2 degrees) in 24 hours.

In the ancient world the degree of latitude was usually reckoned as 360,000 feet (600 stadia). Sailors and travelers of the eastern Mediterranean and of the Middle East reckoned the degree of longitude as roughly 500 stadia, or 300,000 geographic feet (92,339 meters); this calculation is correct between parallels 34° and 35°.

The calculations of the degree of latitude as 360,000 geographic feet (240,000 geographic cubits) proves to be of Egyptian origin, since a degree of 110,806.5 meters proves to be correct at parallel 27° 45′ north, which is the middle latitude of Egypt according to the predynastic geodetic system, which counted 7° 30′ from Behdet to the southern limit of Egypt, latitude 24° 00′ north. According to the *Smithsonian Geographical Tables,* a degree at parallel 27° 45′ is 110,803.0 meters.

The Egyptians preferred to reckon by cubits (stadium of 400 cubits and degree of 240,000 cubits), because it is expedient to divide the circumference of the earth not only into 360 degrees but also into 24 hours. According to the second system a degree is equal to 4 minutes of time and a minute of degree is equal to 4 seconds of time. I shall deal with this matter more extensively later.

Two great scholars of this century who have dedicated their lives to the study of ancient measures concluded that these are so strictly defined and so rigorously organized that they must have a basis on some absolute natural standard. Since it is obvious from the reading of ancient texts that the ancients had a deep concern with cosmic time, with the movement of the vault of heaven, these two scholars concluded that the system of measures must have coordinated not only length, volume, and weight, but also time.

The first of these two scholars, Sir Flinders Petrie, whose major concern was Egyptian measures, thought that the starting point of ancient measures was the length of the pendulum. He advanced the theory that the Egyptians began with a pendulum that swings 100,000 times a day at the latitude of Memphis (29° 51′ north). Having established that this pendulum has a length of 740.57 millimeters, they would have taken as standard of length the side of a square the diagonal of which is the length of the pendulum. This would be the origin of the Egyptian royal cubit. Calculating by this procedure, the royal cubit would be 523.66 millimeters, but Petrie estimates it as about 524 millimeters.

Carl Friedrich Lehmann-Haupt, a scholar of ancient history who, after the death of Hultsch, took over the role of the great German specialist of ancient measures, making them his major concern up to his death in 1936, followed the same line of reasoning. Since he started his activities as one of the decipherers of the Sumerian language and was particularly competent in the reading of cuneiform mathematical texts, he argued that the ancient system of measures was organized in Mesopotamia from the pendulum that beats the second at latitude 30°. The early inhabitants of Mesopotamia would have taken the half of this length as their cubit (cubit of 491.16 millimeters according to Lehmann-Haupt).

The idea was not completely new: in the period of the adoption of the French metric system, there occurred to a scholar of ancient measures that the Roman foot might have been calculated as the length of the pendulum that beats the half-second.

Unfortunately, Petrie and Lehmann-Haupt were not so well informed about the history of measures as they should have been. Soon after Galileo discovered the law of isochronism of the pendulum, since scholars were debating among themselves the project for a new decimal system of measures, it was suggested by several of them that the new system should be based on the length of the pendulum, in order to link together time, length, volume, and weight. But in the course of the eighteenth century it was realized that the pendulum does not provide a reliable standard of length. First of all, it was established that the period of oscillation of the pendulum changes according to the latitude; this led to the discovery of the polar flattening of the earth. It was also successively established that the period of oscillation is influenced by the density of the earth and by any presence of large masses of matter, since the period depends on the gravitational pull. Hence, by the time of the adoption of the French metric system, it had been decided that the new decimal system should limit itself to coordinating length, volume, and weight.

When the Constitution of the United States was drafted, there was included a special clause to prepare the ground for the adoption of a new decimal system of measures, which was advocated by all enlightened people. When the French Revolution in one of its first steps put into law the decimal metric system, the Congress of the United States considered adopting the French system. But Thomas Jefferson, whom Congress respected as the authority on such matters, opposed the plan on the ground that the French system was inadequate, since it did not coordinate time with length, volume, and weight. This opposition from inside the camp of the progressive forces doomed the adoption of the decimal system in the United States.

Jefferson was correct in principle, and so were Petrie and Lehmann-Haupt. A truly desirable system of measures should coordinate time, length, volume, and weight, but what these people did not know is that the ancients had found an easy and reliable method to coordinate length with time. All that is needed is to relate the unit of length to the speed of the rotation of the vault of heaven, since this is the basis of our calculations of time. As I will explain later, today we calculate time by the length of the mean solar day, but since this is a highly artificial concept, astronomers set the length of the solar day by the apparent motion of the vault of heaven (sidereal time), which flows evenly.

The problem of coordinating time with the other measures is so important that after decades of research on ancient measures I was still fumbling for one element which would allow me to fit all my findings together, until Peter Tompkins ripped the veil from my eyes by pointing out to me that speed of rotation of the vault of heaven is 1000 geographic cubits a second.

The Egyptians set their standards of length in a manner that permits an easy correlation with time, but still the standard which was scientifically defined had to be the standard of length.

7. The tradition of what was the ancient procedure has been preserved by the scientist and mathematician Girolamo Cardano (1501–1576). Like other Renaissance scholars he was concerned with the establishment of an absolutely inalterable standard of length. In his book *De Subtilitate* (Chapter XVII, edition of Basel, 1553, p. 475) he discusses the length of the ancient Roman foot and passes from it to the problem of how to base length and weight on a *mensura perpetua*. He observes that such an absolute standard should be searched for in the heavens, but, since this is impossible for practical reasons, he declares that the standard is provided by the pyramids of Egypt, the Labyrinth of Thebes, cities like Cairo, and the river Nile. The meaning of this statement is perfectly clear, when we consider the geodetic system of Egypt, as I have reconstructed it; but its form is cryptic. This should not be surprising, since it is known that Cardano has been cryptic in announcing some of his major mathematical discoveries. It had been the practice of scientists and mathematicians up to the age of Newton to put into print the data which they considered of essential importance in a form such that the meaning would become obvious only after an explanation had been communicated orally, because this was the only method they had of protecting their copyright.

The Egyptians decided that the distance of 7° 30′ from Behdet to the southern boundary of Egypt should be reckoned as 1,800,000 geographic cubits. According to the *Smithsonian Geographical Tables* the interval from 31° 30′ to 24° 00′ is 831,091 meters. According to my findings 1,800,000 geographic cubits are 831,048 meters. The figures of the *Smithsonian Geographical Tables* are an estimate of the average length of the degree of latitude, based on the assumption that the earth is a regular geometric body. It would be necessary to consider what is the actual length of the degree in Egypt. Up to now I have deliberately avoided obtaining this information, because I did not want my interpretation of the texts to be influenced by the knowledge of the possible results.

In order to appreciate the nicety of the Egyptian figure, we must keep in mind that in the first French legislation the length of the meter was established by assuming that the arc of meridian is 30,794,580 *pieds de roi,* on the basis of the survey conducted in 1740. Later the length of the meter was revised to the present one, because according to the survey conducted in 1792–98 the arc of meridian is 30,784,440 *pieds de roi*. After this survey the meter was no longer revised, although it has been ascertained that the arc of meridian is about 2000 meters more than 10,000,000 meters.

8. From the geographic cubit, defined as 1/1,800,000 of the length of Egypt, there was derived the geographic foot of 307.7957 millimeters. By cubing this there was fixed the volume of the artaba as 29,160 cubic centimeters.

The artaba was divided into 64 pints of 455.6250 cubic centimeters, that is, into 64 cubes with a side of a hand (4 fingers = 1/4 foot). This unit is the standard pint of Egypt. The pint was divided into 50 *qedet* of 9.1125 grams, employed to weigh gold and silver used as a means of exchange. Sutzu is correct in concluding that, although the *qedet* of 9 grams is the more current unit of weight in advanced civilizations, the heavier *qedet* appears common in prehistoric or early times.

From the artaba there was derived a unit of 3 artabas, which is the cube of the Roman cubit. This is the origin of the Roman foot. There was also derived a unit which is the *brutto* version of the preceding one; since in the cube of the Roman cubit there are 9600 *qedet,* this second unit contains 10,000 *qedet* of 9.1125 grams. The edge of the cube which corresponds to this second unit is the ordinary Egyptian cubit of 450 millimeters. This cubit implies a foot of 300 millimeters. The cube of this foot is the talent of 27,000 cubic centimeters or grams, which was divided into 3000 *qedet* of 9 grams or 1000 Roman ounces of 27 cubic centimeters or grams. The *netto* version of this unit is the cube of the Roman foot (25,920 cubic centimeters or grams). Since the cube of the Roman foot is 8/9 artaba, this cube was divided into 80 librae of 36 *qedet* of 9 grams, whereas the artaba is composed of 90 librae. Three *qedet* of 9 grams makes the Roman ounce of which 1000 makes the cube of the Egyptian foot of 300 millimeters (27,000 cubic centimeters or grams). However, following the reckoning of a *qedet* of 9.1125 grams there continued to be in common use a larger quadrantal (Russian *chetverik*), the edge of which is the Roman geometric foot, and which contains 80 geometric librae

(81/80 of regular libra of 324 grams). This larger quadrantal is 9/10 of artaba.

The organization of the units according to this pattern had a practical purpose. The unit of 3 artabas was the cube of the cubit (443.9181 millimeter) called Roman, a unit of 87,470 cubic centimeters or grams. This was considered a unit *netto*, to which there corresponded a unit *brutto* (25/24) of 91,125 cubic centimeters or grams, which is the cube of the common Egyptian cubit of 450 millimeters. The units of 87,470 grams and of 91,125 grams, that is, the weight of the cubes of the Roman and of the common Egyptian cubits filled with water, are called by me basic load *netto* and basic load *brutto*. I have given them these names because they were considered the standard amount that could be carried by a pack ass. In Akkadian these units are called *imēru*, which means "ass." The Masoretic text of the Old Testament uses a different punctuation of vowels under the consonants to distinguish between the term *ḥmr* as referring to an ass and the same term as referring to the unit of measure, but there are puns in the Old Testament which indicate that one could confuse one meaning with the other. Since the language of measures is very international, there is a transfer of terms among Semitic, Indo-European, and Fenno-Ugrian languages, in which the same terms are applied at times to the measure and at times to the animal. Some easy examples are the following. In Hellenistic Egypt the ass was called *gomarion*, from *gomos*, "load"; the ass is called *gomari* in modern Greek. In Italian the ass is called *somaro*, from the Greek *sagma*, "pack saddle." The corresponding English word is *sumpter*, which corresponds to a German *Saumtier*, a term in turn corresponding to the Italian *bestia da soma*, "pack animal." In German *Saum* means "burden" and also refers to a large unit of measure. In Italian *salma* is both a large unit of weight or volume and a corpse carried on a stretcher, which has on the average the weight of what I call a basic load.

The cube of the foot was called talent in Greek or by equivalent terms in other languages of the ancient world. There was a basic talent *netto* of 25,920 grams and basic talent *brutto* of 27,000 grams, which were respectively the cube of the Roman foot of 295.9454 millimeters and the cube of the Egyptian foot of 300 millimeters. Names such as talent refer to the fact that these weights were considered half of the amount that could be transported by a man. It was assumed that a man transports burdens by suspending them at the two ends of a carrying yoke. At each end of the yoke there were weights, which ideally had to be identical; each of these weights was called a talent. It is evident that this is the origin of the idea of equilibrium and of the measuring scale. Incidentally, I may also mention that it was assumed that the carrying yoke has a length of 2 cubits or three feet.

9. Since the development of units from the artaba had started with the cube of the Roman cubit, which is equal to 3 artabas, there was developed a unit equal to 5 artabas. The edge of the cube containing 5 artabas is the origin of the Egyptian royal cubit. Five artabas were the volume of a basic load of barley (barley was assumed to have a specific gravity between 0.6 and 0.666).

The edge of the cube which contains 5 artabas was interpreted as the septenary version of the Egyptian cubit of 450 millimeters, that is, as a cubit of 7 hands (28 fingers) instead of the normal 6 hands (24 fingers). But, if we reckon exactly, the cube of the cubit of 525 millimeters contains 144,703.125 cubic centimeters, which is something less than 5 artabas = 145,800 cubic centimeters. A unit of 5 artabas should contain 16,000 *qedet*. By dividing the cube with an edge of 525 millimeters by 16,000 there is obtained a *qedet* of 9.043945 grams, which is intermediary between the *qedet* of 9 grams and the *qedet* of 9.1125 grams. The analysis of the distribution of the weights of Egyptian sample weights indicates that there were in use three standards of *qedet:*

9.000000 grams
9.043945 grams
9.112500 grams

Correspondingly, the study of the monuments and of the measuring rods indicates that there were three values of the royal cubit:

524.1483 millimeters
525.0000 millimeters
526.3231 millimeters

The first royal cubit is the edge of the cube containing 16,000 *qedet* of 9 grams. It is the standard of the Great Pyramid and of the immense complex of buildings erected by the architect Imhotep around the pyramid of King Zoser of the Third Dynasty. This royal cubit was the scientific unit of Egypt, employed in the calculation of geographic distances.

The second royal cubit was exactly 7/6 of the Egyptian cubit of 450 millimeters. It was the one most commonly used in ordinary life. It is the standard of the Second Pyramid of Giza.

The third royal cubit had the virtue of being the edge of the cube containing exactly 5 artabas (16,000 *qedet* of 9.1125 grams). It is the standard of the coffers of the mentioned two pyramids of Giza.

The royal cubit had the advantage of being a septenary unit, a type of unit which had been found convenient in the practical solution of problems involving irrational roots such as $\sqrt{2}$, $\sqrt{3}$, and π. But, when the reorganization of the Egyptian geodetic system with the unification of Egypt stressed the number 7 as the link between the dimensions of Egypt and the order of the heavens, the septenary royal cubit was raised to the status of a national symbol and became the official standard of the Egyptian monarchy.

It may be worth pointing out, in order to indicate how the great majority of scholars deal with these problems, that Eduard Meyer, whose ideas and method dominate contemporary history of antiquity and of Egypt in particular, explained the origin of the royal cubit by asserting that the Pharaohs demanded contractors to build by the cubit of 7 hands, but exercised their royal prerogatives by paying them as if they had employed the regular cubit of 6 hands (a discount of 37 percent). Let us not forget that the current opinions about the Egyptian ability to measure time astronomically are based on the calculations of Eduard Meyer.

10. According to the second geodetic system of Egypt, the length of Egypt, from the base line of the Delta (31° 06′ north) to the usual southern boundary at 24° 00′ north, was recalculated as 1,500,000 royal cubits of 524.1483 millimeters. This is the reason why the cubit of 524.1483 millimeters became the one used in geographic measurements.

This second calculation of the length of Egypt is derivative and, hence, is not as precise as the one that made the geographic cubit equal to 1/1,800,000 of the length of Egypt. The length of Egypt according to the dynastic system is 7° 06′; 1,500,000 royal cubits equals 786,222 meters. According to the *Smithsonian Geographical Tables,* the interval from 31° 06′ to 24° 00′ is 786,741 meters. There is a difference of about 1000 royal cubits.

For the sake of geographical calculations the royal cubit was given as multiple the *atur* of 15,000 royal cubits, so as to make Egypt equal to the perfect figure of 100 *atur*. The term *atur* literally means "river"; it could be translated as "river measure." It was understood that an *atur* (7862.2 meters) corresponds to an hour of navigation along the Nile.

The *atur* fitted the septenary spirit of the system of measures, since it could be assumed that a degree of latitude is 14 *atur*. This was a practical approximation, which was corrected by adding decimal points to the figure of 14 *atur,* reaching a maximum of 14.1 *atur* at the north of Egypt.

A degree of 14.1 *atur* is 110,857.4 meters. According to the *Smithsonian Geographical Tables,* degree 30°–31° is 110,857.0 meters.

The length of Egypt was divided into 14 *atur* for Northern Egypt and 86 *atur* for Southern Egypt. If we divide 100 *atur* by 7° 06′, we have a degree of 14.084507 *atur* = 110,735.6 meters, which is the length of the degree at parallel 23° 00′ (110,736 meters according to Helmert). A reason why the length of Egypt was extended south to the Sacred Sycamore, at 23° 00′ north, appears to have been that of giving a more exact scientific basis to the calculation of the royal cubit as being such that 211,267.605 royal cubits (14.0845 *atur*) makes a degree.

We shall see that the Pharaoh Akhenaten attacked the authority of the Temple of Amon at Thebes by questioning the scientific exactitude of the second geodetic system of Egypt and of the calculations by royal cubits. There is a possibility that the extension of the boundaries of Egypt from latitude 24° 00′ to latitude 23° 00′ north was part of the counterattack against the reforms of Akhenaten. The purpose may have been that of calculating the value of the royal cubit independently of the value of the geographic cubit.

III. COFFER OF THE GREAT PYRAMID

1. On the basis of my reconstruction of the Egyptian system of measures, it is possible to solve the riddle of the coffer placed inside the King's Chamber of the Great Pyramid.

Many investigators have tried to explain the dimensions of this coffer, but none has reached a positive conclusion. However, the majority of the investigators agree on two basic assumptions: the coffer embodies some numerical conundrum and the contents of the coffer corresponds to some standard of volume. According to my interpretation both of these assumptions are correct: the contents of the coffer is 8 cubic royal cubits = 40 artabas (1166.40 liters), and the walls were given a thickness such that the outside volume of the coffer is twice that of the contents, that is, 16 cubic royal cubits = 80 artabas (2332.800 liters).

The investigators who have preceded me have been hampered by not knowing that there were three possible values of the royal cubit. For this reason they could not realize that the standard of measure of the coffer is a royal cubit different from that employed in planning the King's chamber and the rest of the Pyramid. The King's Chamber was planned by the royal cubit of 524.1483 millimeters, because this is the standard of the Pyramid, chosen because this was the royal cubit usually employed by the Egyptians in calculating geographic distances. The coffer, on the other hand, was planned by the royal cubit of 526.3231 millimeters, because this was the unit employed in calculating the fundamental units of volume and weight.

Before the Cole survey of the dimensions of the Great Pyramid, the only datum available to scholars to determine the exact value of the cubit of the Pyramid was the dimensions of the King's Chamber. It was Newton who, on the basis of the survey conducted by Greaves, realized that the King's Chamber measures 10 by 20 cubits. Having established this fact, he calculated that the cubit of the Pyramid is 1732.5/1000 of an English foot and rounded the figure to 1732/1000. Calculating by the British Imperial standard foot established in 1824, the figures of Newton indicate a cubit of 528.0655 or 527.9131 millimeters. Newton was interested in the length of the Egyptian royal cubit, because he wanted to interpret the statement of Eratosthenes that a degree of latitude is 210,000 cubits.

Petrie proceeded to an extremely accurate survey of the dimensions of the King's Chamber, taking into account the fact that the blocks have been spread apart by the action of earthquakes. By deducting from the length of the sides the spaces which today separate the blocks, he concluded that the cubit of the King's Chamber is 20.632 ± 0.004 English inches $= 524.0523 \pm 0.1016$ millimeters. This empirical datum agrees with the figure of 524.1483 millimeters which I have obtained by considering the mathematical structure of the Egyptian system of measures and all the empirical evidence available.

The coffer is not calculated by the cubit of the King's Chamber, but the cubit of 526.3231 millimeters, because this cubit when cubed contains 145.800 liters = 5 artabas = 16,000 *qedet* of 9.1125 grams.

The reports about the dimensions of the coffer show some discrepancies, because the coffer was cut rather roughly. Petrie relates that an entire side was cut by the strokes of a huge saw, which at times was backed up after it had dented the stone as much as one inch out of plumb. However, by comparing the reports of Greaves, Piazzi Smyth, Petrie, and others, I have identified the intended dimensions of the coffer, since I have the advantage of knowing the exact value of the unit of measurement.

The coffer was computed in hands of 1/7 of the cubit of 526.3231 millimeters. Its inner dimensions are:

Width:	9 hands =	676.70 mm
Length:	26.3 hands =	1977.47 mm
Height:	11.6 hands =	872.19 mm

The corresponding figures in the reports of Greaves and Petrie are:

26.616 English inches = 676.15 mm	26.81 inches = 680.97 mm
77.856 English inches = 1,977.54 mm	78.06 inches = 1982.72 mm
34.32 English inches = 871.73 mm	34.42 inches = 874.27 mm

The report of Smyth agrees substantially with that of Greaves. Petrie's figures are slightly excessive, because he computed the inner dimensions by deducting the thickness of the walls from the outer dimensions, and he thought that it would be proper to measure the walls at the point of their minimum thickness.

The lateral walls were intended to be 2 hands thick, so that the outside dimentions are:

Width: 13 hands = 977.46 mm
Length: 30.3 hands = 2278.23 mm

Petrie's figures for these two dimensions are:

38.50 English inches = 977.90 mm
89.62 English inches = 2276.35 mm

The height of the outside was intended to be 2 cubits = 14 hands, but in order to establish a link between the coffer and the rest of the Pyramid these two cubits were calculated by the cubit of the Pyramid and the King's Chamber. Two cubits of 524.1483 millimeters is 1,048.29 millimeters. In terms of the cubit of 526.3231 millimeters, this means 13.9422 hands; possibly the figure was rounded to 13.9333 hands = 1,047.63 millimeters. I assume that the bottom of the coffer was given a thickness of 2.333 hands = 175.44 millimeters (Petrie reports 6.89 inches = 175.01 millimeters). I assume that the height was 13.9333 hands = 1,047.63 millimeters (Petrie reports 41.31 inches = 1049.27 millimeters).

According to Greaves's figures the contents of the coffer is 71,118 cubic inches = 1,165.428 liters. According to Petrie's figures the contents is 72,033 cubic inches = 1,180.405 liters; I have explained why Petrie overestimated the inner dimensions. According to my interpretation the contents is 2745.72 cubic hands. Now, 2744 cubic hands is 1,166.400 liters = 8 cubic cubits = 40 artabas.

If the outside of the coffer is 13 by 30.3 by 13.933 hands, its volume is 5488.3 cubic hands. Now, 5488 cubic hands is 16 cubic cubits = 80 artabas.

Since the two volumes of the coffer are 8 and 16 cubic cubits, it is not possible to be certain that a measurement by artabas was in the mind of the builders, although I cannot think of any other reason why the builders should have chosen the cubit of 526.3231 millimeters, unless they intended to choose the cubit which when cubed has a contents of exactly 5 artabas. A clearer proof that the calculation was intended to be by artabas is provided by the similar coffer of the Second Pyramid of Giza.

2. From the dimension of the sides of the Second Pyramid of Giza, it can be established that it was planned by the royal cubit of 525 millimeters. Nevertheless, as in the case of the Great Pyramid, the coffer was planned by the cubit of 526.3231 millimeters.

Petrie reports the following data about the coffer of the Second Pyramid, expressed in English inches:

	Length	Width	Height
Outside:	106.68 = 2,709.67 mm	41.97 = 1,066.04 mm	38.12 = 968.25 mm
Walls:	21.95 = 557.53 mm	15.28 = 388.11 mm	8.53 = 216.66 mm
Inside:	84.73 = 2,152.14 mm	26.69 = 677.93 mm	29.59 = 751.59 mm

As in the Great Pyramid, the coffer was planned in hands (1/7) of the cubit of 526.3231 millimeters. The dimensions are the following:

	Length	Width	Height
Outside:	36 = 2,706.80 mm	14.2 = 1,067.68 mm	12.88 = 968.43 mm
Walls:	7.4 = 566.40 mm	5.2 = 390.98 mm	2.88 = 216.54 mm
Inside:	28.6 = 2,150.41 mm	9 = 676.70 mm	10 = 751.89 mm

Petrie's figures imply an inside volume of 1,096.554 liters. According to my interpretation the volume is 2574 cubic hands = 1094.137 liters. If we assume that the volume was intended to be 2572.5 cubic hands = 1093.500 liters, the contents of the coffer corresponds to:

7.5	cubic royal cubits
37.5	artabas
12	basic loads *brutto*
120,000	*qedet* of 9.1125 grams
121,500	*qedet* of 9 grams

The contents of this coffer is 15/16 of the contents of the coffer of the Great Pyramid.

Because the Second Pyramid had been planned by the royal cubit of 525 millimeters, the coffer, although measured by the cubit of 526.3231 millimeters, indicates a volume expressed best of all in basic loads *brutto;* the basic load *brutto* is the cube of the cubit of 450 millimeters, which is the common cubit coresponding to the royal cubit of 525 millimeters.

Petrie's figures imply an outside volume of 2796.883 liters. According to my interpretation the volume is 6584.25 cubic hands = 2798.786 liters. If we assume that the outside volume was intended to be 6585.4 cubic hands = 2799.360 liters, the volume corresponds to:

19.2	cubic royal cubits
96	artabas
32	basic loads *netto*
307,200	*qedet* of 9.1125 grams
311,400	*qedet* of 9 grams

The outside volume of this coffer is 6/5 that of the coffer of the Great Pyramid.

The coffer of the Second Pyramid was planned so as to embody the key units of the Egyptian system of volumes:

Artaba of 29,160 cubic centimeters (cube of the geographic foot)
Basic load *netto* of 87,480 cubic centimeters (cube of the Roman cubit)
Basic load *brutto* of 91,125 cubic centimeters (cube of the Egyptian common cubit)

IV. DEGREES OF LATITUDE

1. The calculation of the dimensions of Egypt by royal cubits was less precise than that by geographic cubits, but it had the advantage of stressing the number 7 as the key to the dimensions of Egypt and as the link between the structure of Egypt and the order of the cosmos.

Following the septenary system of measurement, the stadium, a tenth of minute of degree, was reckoned as 350 royal cubits (183.45 meters). This stadium is somewhat shorter than the stadium of 400 geographic cubits (600 geographic feet = 184.68 meters). It implies a degree (600 stadia to the degree) of 210,000 royal cubits = 110,071.1 meters. But the calculation of the stadium as 350 royal cubits was considered a first approximation which could be employed in practical computations. Just as in the calculation by *atur*, a degree of latitude was considered basically equal to 14 *atur*, but in exact calculations a decimal point was added to the figure of 14, so in exact calculations a few cubits were added to the figure of 350 royal cubits to a stadium.

In round figuring the Egyptians calculated the stadium at the equator as 354 stadia; but more accurate figures were known. By this round figure they obtained an equatorial minute of degree (10 stadia) of 1855.485 meters, which is 88 millimeters more than the figure of the International Spheroid (1855.398 meters). A stadium of 354 cubits implies an equatorial circle of 76,464,000 cubits = 40,078,491 meters, whereas according to the International Spheroid the equatorial radius is 6,378,388 meters ± 18 meters, so that the equator would be 40,076,594 meters ± 113 meters. Since the Egyptians preferred to count by 90 degrees of equator, the figure of 354 cubit for a stadium of equator contains a numerical game, such as frequently occurs in ancient computations for mnemonic reasons. Ninety degrees of equator is 54,000 stadia of 354 cubits.

Assuming a stadium of 354 royal cubits, a degree of equator is 212,400 cubits, which is a good round figure. We shall see that the Egyptians estimated the exact figure as between 212,380 and 212,392 cubits.

An absolutely exact calculation of the length of the equator was a matter of scientific interest, whereas the Egyptians put much greater stress on the exact calculation of the length of the degrees of latitude, since the anchor of their geodetic conceptions was the course of the Nile.

For the stadium of latitude of the equator they used the figure of 351.6 cubits = 184.2905 meters, which is as exact as any modern calculation can be. According to the Clarke Spheroid a minute of latitude at the equator is 1842.787 meters; according to the International Spheroid it is 1842.925 meters. We shall see that the base of the Great Pyramid is calculated by a stadium of 351.6 cubits.

To those who may not be conversant with these matters, I must explain that, since the shape of the earth is irregular, modern scholars have tried to construct a regular geometric figure, called the spheroid, the dimensions of which fit as closely as possible the actual dimensions of the earth. Different scholars have constructed different spheroids, in part because they have based their work on surveys conducted in different areas of our planet. For instance, in the United States many agencies and institutions continue to use the spheroid calculated by the English geodesist Clarke in 1866, because its data fit rather well with the shape of the earth in North America. Many scholars prefer the computation published by the German Helmert in 1907. But the calculation most usually considered authoritative by scholars is that completed by the American Hayford in 1910, known as the International Spheroid. This calculation is based on a gigantic survey conducted under the auspices of the British Empire from the tip of South Africa to the Equator and then up to the Mediterranean along the Nile. This survey happens to overlap the Egyptian calculations along the course of the Nile.

The stadium of latitude increases as one moves to the north from the equator, reaching the value of 354 cubits, equal to the length of the stadium of equator, between parallel 55° and parallel 56°. It reaches a maximum estimated as 355 cubits at the pole. This figure of 355 cubits for the stadium of latitude at the pole, which indicates a minute of 1860.726 meters, was a convenient round figure which was refined in exact reckonings. A stadium of 355 cubits implies a polar degree of 213,000 cubits = 111,643.6 meters; if 1/2000 was the amount added to the latter figure we would have 213.106.5 cubits = 111,699.4 meters. According to the *Smithsonian Geographical Tables,* degree 89°–90° is 111,699.3 meters.

For navigation along the Nile, there was used the following formula for the length of the degrees of latitude:

211,500 cubits = 110,857 meters at latitude 31° 06′
211,300 cubits = 110,753 meters at latitude 24° 06′
211,100 cubits = 110,648 meters at latitude 15° 36′

Latitude 15° 36′ north is the latitude of the confluence of the White Nile with the Blue Nile.

2. One of the major difficulties of ancient mathematical science was that it could not rely on printed tables, although some numerical tables, such as exponents, roots, and logarithms, are occasionally found in cuneiform tablets. Even maps were so drawn that the key positions could be memorized. The lack of the printing press is the reason why in ancient mathematics we find a variety of formulas and mnemonic devices for obtaining trigonometric functions. In the same spirit the Egyptians had developed a simple formula for calculating the length of the degree of latitude at all parallels between the equator and the pole.

The scheme was based on the circumstances that the Egyptians used three values for the length of the degree of latitude at the equator—an exact value based on a stadium of 351.6 cubits and two rounded values:

A. Exact value. Stadium of 351.6 cubits, degree of 210,960 cubits = 110,574 meters.

B. Value rounded to degree of 211,000 cubits = 110,595 meters.

C. Value rounded to arc of meridian of 19,000,000 cubits, degree of 211,111 = 110.654 meters.

Value *B* was considered exact for a degree at 9° and value *C* for a degree at 16°.

The length of the degree was calculated by taking the second value, 211,000 cubits, and assuming that each degree is longer than the preceding degree by a number of cubits equal to the number of the degree.

Degree	Cubits added to degree	Cubits added to length of degree at 0°
1°	1	1
2°	2	3
3°	3	6
4°	4	10
5°	5	15
6°	6	21

This pattern was followed up to degree 36°, which is 36 cubits longer than the degree at 35° and 666 cubits longer than the degree at 0°. For six degrees, from 37 to 42°, the amount added to each degree is 37 cubits. For the following six degrees, from 43 to 48°, the amount added to each degree is 38 cubits. Then for six degrees, from 49 to 54°, the amount added is again 37 cubits. For the remaining 36 degrees, from 55 to 90°, the amount added is the same as that applied to the first 32 degrees but in the inverse order.

The scheme gives immediately the length of the degrees from 24 to 58°, that is, for 35 degrees. For the first 23 degrees and for the last 32 there are introduced simple corrections:

(1) For the first eight degrees, from 1 to 8°, the amount is added to the exact value of the degree (value *A*, 210,960 cubits to degree). From a degree at 9° one begins to count by value *B* (211,000 cubits), but 45 cubits is deducted from the amount added to this degree; this deduction is reduced by 3 cubits for each of the following 13 degrees, until 3 cubits is deducted from 23°.

3. At 90° the amount added according to the scheme is added to a basic degree calculated by value *C* (211,111 cubits). For the 32 degrees from 59 to 90°, an adjustment is

90°	1	2004	+111.11	111,704	111,697

made for a transition from value *B* to value *C*. Thus, to a degree at 59° there is added 111.11/32 cubits, or practically 3.5 cubits ($32 \times 3.5 = 112$); to a degree at 60° twice as much is added; to a degree at 61° there is added three times as much.

This scheme gives values of the degree of latitude which differ most from the one we use today in the area near the pole. This could be connected with the fraction that the Egyptians used in calculating the polar flattening of the earth. I shall deal with this fraction in a following chapter. According to the scheme, the degree between parallel 89° and the pole is 213,115.11 cubits = 11,703.9 meters. According to the Clarke Spheroid the minute of degree of latitude at the pole is such that the corresponding degree is 111,699.36 meters; but in 1880 Clarke revised the figure to 111,702,06 meters. According to the International Spheroid the figure is 111,700 meters.

4. The scheme which I have presented provides excellent values for the length of the degree of latitude, but probably was intended to be only a practical device, not the most exact calculation. There is evidence which suggests that efforts were made to calculate the lengths of the degrees with greater mathematical refinement.

The Egyptians invented the column as an architectural element. If one observes the decoration of Egyptian columns with a scientific attitude, he will recognize that the column represents the map of Egypt: the capital is Northern Egypt and the shaft is Southern Egypt. This explains why among the Greeks, who learned the use of the column from the Egyptians, for the Doric order, the most conservative of the Greek orders, there was the rule that the shaft should be six units high and the capital one unit high. In the Greek orders the base of the column preserves the arrangement on three horizontal lines, which are the symbol of the tropic of Cancer (parallels 24° 06′, 24° 00′, and 23° 51′ north). The column basically represents the three meridians of Egypt and through its curvature suggests the extension of the system of meridians to the east and west of Egypt. But, since the column is circular, the structure of the column was related to the problem of presenting the map of Egypt as part of a cylindrical projection of the surface of the earth from the equator to latitude 31° 06′ or latitude 31° 30′ north. The elaborate numerical rules for the proportions of Greek columns, which archeologists treat as numerological superstitions, can be explained when one considers the two interrelated problems of describing mathematically the curvature of the earth and of projecting a curved surface on a flat map. The theory of conic sections, which is considered the highest achievement of Greek mathematics, may have been developed in order to solve these problems. Greek columns taper from the bottom to the top, but to the rectilinear line of the shrinking there is applied a curved line, so that the column seems to swell slightly toward the middle. If we consider the scheme I have presented for the calculation of the lengths of the degrees, a scheme in which a basic simple progression was modified by the addition of another progression, we can understand why Greek columns diminished in diameter from bottom to top according to a combination of two lines. In the case of the columns of the Parthenon, the added curvature, called *entasis* by the Greeks, is a hyperbolic curve, but in other temples we meet with more complex mathematical curves. It may be enough to say this much here: if one assumes that the bottom of the colonnade of the Parthenon represents the equator and its top the latitude of Athens, the proportions of the entire colonnade can be readily explained.

V. TEXTUAL EVIDENCE

For lack of space, it is impossible for me to present here the evidence for what I have stated to be the Egyptian estimates of the length of the degrees of latitude, since this evidence was obtained by gathering scores of scattered pieces of information, the interpretation of which often involves delicate issues of textual interpretation. But the preoccupation with geographical distances was so dominant in Egyptian civilization that one can find many documents the meaning of which is obvious; several of these documents are well-known texts. It has taken me a great deal of painstaking research to fit these documents together, in order to arrive at a unified view of what was the Egyptian system of geography; but the interpretation of single documents *per se* in many cases did not present difficulty. What is difficult to explain is why Egyptologists have stubbornly refused to accept these documents at their face value. In order to illustrate how Egyptologists operate in order to slough off the evidence, I shall present two examples of such nature that the issues involved can be understood by the non-specialist.

Inscribed Cubit Rules

1. In 1921 the famous Egyptologist Ludwig Borchardt wrote a report on three Egyptian measuring rules found at the Temple of Amon in Thebes. These three royal cubit rules

bear an identical inscription. The inscription appears to be a traditional one; for reasons of style the text of the inscription has been ascribed to the Old Kingdom, although the rules themselves belong to a later period. It is known that at times measuring rules were given a sacred meaning, although nobody has ever asked why; it should be evident to the reader of these pages why a measuring rule could be a sacred object for the Egyptians. The cubit rules studied by Borchardt, according to his report, seem to be of the type used as sacred objects rather than as instruments of actual measurement.

Borchardt did not test the length of these rules, but concentrated his attention on the inscription. The essential meaning of the inscription is open and clear, even though a professional Egyptologist may find difficulty with some of the hieroglyphs, as it often happens when archaic hieroglyphic texts were copied centuries later when the language and the writing style had changed. The inscription states that the distance between Behdet and Syene, the area of the First Cataract, is 106 *atur*, and divides this distance into 20 *atur* from Behdet to a place called Pi-Hapy, and 86 *atur* between Pi-Hapy and Syene.

Borchardt considered the evident possibility that the distances should be understood as differences of latitude, but dismisses it outright: "one must absolutely exclude the possibility that the ancients may have measured by degrees." No further words are added to justify this drastic pronouncement. Then he states that it must be a matter of measurements taken along the actual course of the Nile, the only measurements of which the Egyptians were capable. By referring to modern data about the length of the line of navigation along the Nile, he concludes that the inscription expresses a rough estimate.

He proceeds by remarking that the inscription provides an excellent opportunity to establish the value of the important Egyptian linear unit *atur*. He observes that by reading documents that contain calculations in *atur* one gathers that the value of the *atur* in royal cubits must be expressed by numbers such as 5000 or 10,000. Finally, he concludes that, given the length of the course of the Nile from one end to the other of the country of Egypt, the *atur* must be 20,000 royal cubits.

I have concluded that the *atur* is 15,000 royal cubits (7862.225 meters), and this inscription bears me out. The difference of latitude between Behdet and the southern limit of the First Cataract is 7° 30′. Now, 106 *atur* is 1,590,000 royal cubits = 833,395.8 meters. The distance between 24° 00′ and 31° 30′ is 831,091.6 meters according to the

Smithsonian Geographical Tables. The Egyptian figure is in excess by 2300 meters, or 2/7 *atur*. The excess is not surprising, since the calculation of the length of Egypt as ending at Behdet was originally related to the geographic cubit and not the royal cubit. I have explained that the geographic cubit was defined as 1/1,800,000 of the length of Egypt to Behdet. In *atur* of 17,000 geographic cubits, this length could be expressed as 106 *atur* (1,802,000 geographic cubits) = 831,971.7 meters, with only a small excess over the initial figure of 1,800,000 geographic cubits = 831,048.4 meters.

The calculation of the length of Egypt to Behdet as 106 *atur* of 15,000 royal cubits has the virtue of indicating the length of the arc of meridian from the equator to the pole; since the length of Egypt to Behdet is 7° 30′, it is 1/12 of this arc. Multiplying 106 *atur* by 48, we have a great circle of 5088 *atur* = 40,002,998 meters, which is an excellent figure (212,000 cubits to a degree); Helmert's figure of 40,008,268 meters differs by less than an *atur*.

The purpose of the inscription on the rules which were found at the Temple of Amon in Thebes is to stress the scientific value of the calculations by the septenary royal cubit, which was a matter of essential political interest to this temple, as I will explain in the second part of this chapter.

The calculation of the length of Egypt as 106 *atur* had also the purpose of indicating by one of the usual numerological games that the average degree of latitude is 212,000 royal cubits = 111,119.4 meters; 212,000 was the Egyptian round figure for the average length of the degree of latitude (stadium of 353,333 royal cubits). If the average degree is identified with the middle degree, the degree at parallel 45°, this figure is only 2 cubits short of the Egyptian estimate of 212,002 cubits = 111,120.5 meters for this degree. The estimate of the *Smithsonian Geographical Tables* is 111,121.0 meters.

2. The inscription on the rules divides the interval of 106 *atur* into 86 *atur* from Syene to Pi-Hapy and 20 *atur* from Pi-Hapy to Behdet. It occurs immediately that the two figures must refer to Northern and Southern Egypt. But the figure of 20 *atur* is slightly too much for Northern Egypt and that of 86 *atur* is slightly too little for Southern Egypt.

If the degree is calculated as 212,000 royal cubits, 20 *atur* = 300,000 cubits is too much for the interval between Behdet and the apex of the Delta, since 1.4° × 212,000 = 296,800 cubits. Conversely, 86 *atur* would be 1,290,000 cubits, whereas the distance from 24° 00′ north to the apex is 6.1°, and 6.1° × 212,000 = 1,293,200 cubits. In either case there is a difference of 3200 cubits. Hence, the breaking point in the calculations must be somewhat south of the apex of the Delta.

Even though Egyptologists ignore scientific geography, there are specialists of Egyptian toponymy, that is, the study of local names. These have wondered about the identification of the locality of Pi-Hapy, "House of the Nile," mentioned in the inscription we are discussing. They have observed that in Egyptian texts Pi-Hapy is usually mentioned together with Kher-aha, although Pi-Hapy is a different place. They have concluded that Pi-Hapy was on the right bank of the Nile about 2 kilometers south of Kher-aha. But specialists of Egyptian toponymy have failed to identify Kher-aha, which was a fundamental point of Egyptian geography; Kher-aha, called Kerkasoros by the Greeks, was the apex of the Delta, the point 30° 06′ north, 31° 14′ east, at the southern tip of the island al-Warraq. Pi-Hapy, called Nilopolis by the Greeks, was on the right bank of the Nile, facing the southern tip of the island al-Warraq. Since the Nile in its course comes to the island al-Warraq from the west, the point Pi-Hapy was on meridian 31° 14′ east and could be considered to be on the right bank of the Nile directly opposite the apex of the Delta, or point Kher-aha. The width of the Nile between Kher-aha and Pi-Hapy, measured along meridian 31° 14′ east, fits well with what I have calculated to be the distance between the apex and Pi-Hapy (3200 royal cubits = 1,677 meters).

The breaking of the distance of 106 *atur* into a segment of 20 *atur* by establishing a new reference point called Pi-Hapy may have been influenced by the calculation of the length of Egypt up to the base line of the Delta as 100 *atur* (1,500,000 royal cubits).

In the inscribed royal cubit rules, the original estimate of 106 *atur* of 17,000 geographic cubits was interpreted in terms of 106 *atur* of 15,000 royal cubits, in order to link more closely the dimensions of Egypt (1/12 of arc of meridian counting to Behdet) to the measurements of the arc of meridian. As I have stated, 12 × 106 *atur* = 1272 *atur* = 19,080,000 royal cubits = 10,000,749.6 meters is an excellent estimate of the length of the arc of meridian, obtained with an extreme economy of reckoning. Let us not forget that the French metric system was established on the assumption that the arc of meridian is 10,000,000 meters. Even today in practical reckoning we take 111,111.1 meters as the round figure for the average degree of latitude, whereas the figure of 106 *atur* for the length of Egypt indicates a round figure of 212,000 cubits = 111,119.4 meters, which is more precise, and is almost perfect if we take 212,000 cubits to mean the length of the degree at the middle parallel.

1. Because Egyptologists have ignored the issue of geodetic points and of the linear units, the figure of the revolutionary Pharaoh Akhenaten has turned out to be the most mysterious and controversial in the long history of the Egyptian monarchy, although this Pharaoh was unusually articulate and self-expressive in his utterances. The archeologist Cyril Aldred, who is the author of the most recent study of the reign of Akhenaten, begins his book (page 11) with this observation.

> With the possible exception of Cleopatra, no ruler of Ancient Egypt has provoked a greater flow of ink from the pens of historians, archaeologists, moralists, novelists and plain cranks than the Pharaoh Akhenaten who governed almost half the civilized world for a brief span during the fourteenth century B.C.

The Pharaoh Akhenaten.

The reason why even "plain cranks" write interpretations of the historical role of Akhenaten is that professional scholars have given the example. Because they have resisted accepting the solidly documented facts, established scholars have devoted their energies to debating theories such as that Akhenaten was impotent, was a practicing homosexual, or a woman masquerading as a man; there are historians who profess to be informed about the intimate relations between him and his wife, the beautiful Nefertiti. Since the picture of Akhenaten has remained indefinite and blurred, scholars have used it to project their own emotions. Those who do not like Akhenaten present him as a psychopath and dispute about the clinical definition of his illness. In the middle are those who describe him as a playboy Pharaoh. Those who admire him have chosen to portray him either as some sort of Christian evangelist, an Anabaptist preacher thrown into the midst of the history of Egypt, or, at the opposite end of the psychological personality scale, as an *artiste* type, bent on freeing Egyptian culture from its formalistic tradition in order to release untrammeled individualistic self-expression. If one were to look for a common denominator among all the conflicting interpretations, one fact could be considered as universally accepted, in spite of the heated controversies, namely, that Akhenaten was as far as possible from being a rational scientific thinker. Nevertheless, the documentary evidence suggests a style of thought that today we would call scientific naturalism.

There is a phrase which occurs again and again in the pronouncements of Akhenaten and represents his effort to summarize his program by a slogan: "Living in *maet.*" This is so obvious that Aldred declares (page 67):

> There is in Akhenaten's teaching a constant emphasis upon *maet*, "truth," as is not found before or afterwards.

It is agreed that *maet* was the central concept of Egyptian civilization and that the role of a Pharaoh was to be the defender and the living embodiment of *maet*. This concept was so basic in Egyptian culture that Aldred has no difficulty in explaining it in a few words (page 25):

> The king was the personification of *maet*, a word which we translate as "truth" or "justice," but has the extended meaning of the proper cosmic order at the time of its establishment by the Creator. For it was believed that the gods had first ruled Egypt after creating it perfect.

Akhenaten, his wife Nefertiti, and two daughters (Berlin Museum).

The reader can easily grasp what was meant by *maet* by referring to what I have said about the geodetic system of Egypt. But, having admitted what is indisputable, that Akhenaten saw himself as the Pharaoh who would truly uphold *maet*, Aldred stops cold and does not draw the implications. Like other interpreters, he wanders afar and regales us with a chapter entitled "The Pathology of Akhenaten."

2. If instead of trying to imagine what were the hieroglyphic notes of the psychoanalyst of the royal family, we consider the documented facts, the most important action in the revolutionary reign of Akhenaten proves to be the establishment of a new capital for Egypt, the city of Akhet-Aten, "Resting-point of Aten." The miles-long remains of the buildings of this city have been found and excavated in the locality today known as Tell el-Amarna. During the reign of Akhenaten a substantial percentage of the national resources was dedicated to the construction of this city.

Scholars of the last century, who had not yet adopted the psychologizing fashion, at least recognized the political meaning of the shift in the location of the capital of Egypt. Akhenaten intended to cut at the root the power of the priests of the Temple of Amon in Thebes, who through their control of the national oracle, identified with the god of this temple, had usurped the royal functions. But what these scholars did not know is that the Temple of Amon was the geodetic center of Egypt, the "navel" of Egypt, being located where the eastern axis (32° 38′ east) crosses the Nile, at the parallel which is at 2/7 of the distance from the equator to the pole (25° 42′ 51″ north), and that the god Amon was identified with the hemispheric stone which marked this point.

The new city which was intended to replace Thebes as the capital and geodetic center of Egypt was planted in a position which seems most undesirable in terms of what we would consider the function of a capital city. Some scholars have interpreted this fact as further evidence of the mental derangement of its founder. It was in an area of difficult access, where there had never been any known significant center; some scholars have doubted whether even villages had existed there. It did not provide large flat areas for a major urban development. When maintenance was suspended after the fall of Akhenaten, large sections of the new buildings were washed away by the rainwater rushing down torrentially from the surrounding cliffs. Even the climate was inferior to that of many other areas along the course of the Nile. Unless one assumes that there was a compelling mathematical reason for choosing this location, one must agree that there is justification in claiming that what is often called the "Tell el-Amarna Revolution" was the product of a playful young man, or a religious fanatic, or a degenerate obsessed with his sex problems. Akhenaten himself relates that his courtiers raised objections to the selection of the new site, although he states that it was pointed out to him directly by his father, the god Aten.

The new capital for the god Aten, who was raised to the status of the one true god, was set at latitude 27° 45′ north, at the middle point between the northernmost point Behdet and the southern limit of Egypt at latitude 24° 00′ north. The longitude could not be equally as significant, since the capital had to be on the banks of the Nile. It was one degree east of the western axis of Egypt, that is, 30° 50′ east.

The longitude, although it was not as crucial as the latitude, was significant according to the system that the Egyptians used to describe the east coast of Africa. In order to describe this coast, down to the equator, the

Aerial view of the Tell el-Amarna (RAF photo).

Egyptians used a system of right triangles, in which one side was one of the three axes of Egypt and the other a perpendicular to it; the hypotenuse usually indicated the course of a segment of the east coast of Africa. The most important of these triangles was one obtained counting from Behdet 19° 30′ south along the central axis of Egypt and then 19° 30′ to the east, to reach a point 12° 00′ north, 50° 44′ east, near Ras Alula (11° 59′ north, 50° 46′ east), a point which was considered the extreme limit of the Arabian Gulf. The ancients took the Gulf of Suez, the Red Sea, and the Gulf of Aden as a single entity, the Arabian Gulf, which at times they described as a river similar to the Nile. The geographical point in question is called Notou Keras, "horn of the East," by Strabo; it had a counterpart in the "horn of the West," the innermost point of the Gulf of Guinea on the west coast of Africa. The segment of parallel reaching the "horn of the East" from the meridian of Behdet marks the basic latitude 12° 00′ north, halfway between the equator and the basic latitude 24° 00′ north, and bisects Lake Tana, the source of the Blue Nile. The Nile was considered to have two sources, one at the equator (White Nile) and one at latitude 12° 00′ north (Blue Nile). This system of calculations for the geography of the area east of the course of the Nile has an importance which carries beyond ancient history, since the establishment of a geodetic point 10° south of Behdet and 10° east of the western axis of Egypt explains the origin of the religious importance of Mecca. The essence of this system of calculations was that points to the east of Egypt were identified by drawing perpendiculars to the course of the Nile. Considering this system in relation to the position of Akhet-Aten, if one counts east from it as much as it was south of Behdet, that is 3° 45′, one reaches the sea at a point presently called island Ghānim (off Cape Az Zaytīyah, called Drepanon Promontory by Ptolemy, which is at 27° 47′ north, 33° 35′ east); Cape Az Zaytīyah together with the island south of it was considered the southernmost limit of the Gulf of Suez on the Egyptian side; it was assumed that the line drawn from Behdet to this point gave the course of the coast of Egypt on the Gulf of Suez.

3. The most revealing pieces of evidence uncovered in the area of the new capital established by Akhenaten are the so-called "Boundary Stelae." Along the outskirts of the new city there have been found huge inscriptions, either cut on pillars or cut on the cliffs, which contain a text substantially identical in the fourteen samples which have been uncovered so far. These inscriptions proclaim what was for Akhenaten the leading idea behind the establishment of the new capital.

The inscribed text relates in detail the rituals performed in the establishment of Akhet-Aten, "Resting-point of Aten"; but the greatest emphasis is placed on the setting of two boundary pillars, one at the extreme north and one at the extreme south of the sacred territory of the city, at a distance of 6 *atur*, 3/4 *khe*, and 4 cubits from each other. After setting these pillars the King took a solemn oath, to be repeated at regular intervals, never to remove or displace them and to restore them in the same identical place in case they were moved or damaged.

It should be obvious that the figure of 6 *atur*, 3/4 *khe*, and 4 cubits, given with numerical precision, is the key to the reason for the establishment of the new capital. Nevertheless, only one Egyptologist has made an effort to interpret these figures. This effort was a half-hearted one; it ignored Egyptian geographical texts and parallel occurrences of the terms *atur* and *khe* in Egyptian writings. Nevertheless, ever since, scholars quote this interpretation if they bother to mention the dimensions of Akhet-Aten in dealing with its establishment. The interpretation took as a starting point the distance between the relatively northernmost and the relatively southernmost of the fourteen inscriptions which have been found, and divided this distance by 6 to conclude that an *atur* must be 4000 royal cubits. It can be objected

Boundary stelae at Tell el-Amarna.

that the pillars which in some cases were erected to carry the text of the inscription cannot be the boundary pillars of which the inscription is speaking, since the latter must be of such a nature and form that their position could be established to the inch. It stands to reason that when, after the collapse of the revolution, masons were sent to demolish or deface the monuments of the accursed Akhenaten, not sparing even the tombs of the members of his family, the work of destruction must have started with the boundary pillars; we are not likely to find them, unless broken pieces were scattered around. In any case, the Egyptian texts which mention distances measured in *atur* positively exclude that an *atur* can be as short as 4000 royal cubits (2097 meters).

As to the *khe*, the interpretation stated in a hit-or-miss manner that it is equal to 100 royal cubits. Nobody asked why Akhenaten should have selected a figure refined not only to 3/4 of *khe*, but also to 4 cubits. It was a matter of such precision that the inscribed text indicates that even knocking the limit markers or hitting them with stones would interfere with their function.

According to Egyptian practice, geographic distances could be measured either in geographic cubits or in royal cubits. The natural multiple of the geographic cubit was the stadium, called *khe* in Egyptian, of 400 geographic cubits (600 geographic feet), whereas the natural multiple of the royal cubit was the *atur* of 15,000 royal cubits. But the two systems were merged by using an *atur* of 15,000 royal cubits (7862.2 meters) and an *atur* of 17,000 geographic cubits (7848.8 meters), and a *khe* of 350 royal cubits (183.45 meters) and a *khe* of 400 geographic cubits (184.68 meters). In the case of the inscriptions of Akhet-Aten, the occurrence of the figure of 3/4 of *khe* suggests that a calculation by geographic cubits is involved, since 3/4 of a stadium of 350 royal cubits would be an odd figure. It is my understanding that the dimensions of the district of Akhet-Aten were:

	6 *atur* of 17,000 geographic cubits
	3/4 of a stadium of 400 geographic cubits
	4 geographic cubits
Total:	102,304 geographic cubits = 47,233.1 meters

4. Even without considering the exact value of the units mentioned by Akhenaten, the figure of 6 *atur* should have rung a bell in the mind of Egyptologists, calling to their attention the traditional figure of 106 *atur* for the length of Egypt. Akhenaten wanted to emphasize that the "Resting-point of Aten" was at the middle point of Egypt. By giving to the new geodetic center a dimension of 6 *atur*, he left 50 *atur* from it to Behdet and 50 *atur* from it to parallel 24° 00′ north. This was particularly significant since there was another basic estimate of the length of Egypt as 100 *atur*, from the base line of the Delta (31° 06′ north) to parallel 24° 00′ north.

Before proceeding any further I must remind the reader that the traditional figure setting the length of Egypt at 106 *atur* did not intend to convey information only about Egypt itself, but also to indicate the length of the arc of meridian, 12 × 106 *atur*.

Since the length of the geographic cubit was defined by considering the distance from Behdet to parallel 24° 00′ north equal to 1,800,000 cubits, if the district of Akhet-Aten had had an extension of 0° 25′ 30″, it would have had a length of 6 *atur* = 102,000 cubits. This length was increased to 6 *atur*, 3/4 stadium, 4 cubits = 102,304 cubits, in order to indicate that the average degree of latitude on earth is 240,715 cubits.

The figure of Akhenaten indicates that the average degree of latitude was estimated as 240,715 cubits, since 0° 25′ 30″ of a degree of 240,715 is 102,303.875 cubits. A degree of 240,715 cubits is 111,136.6 meters; the corresponding arc of meridian is 21,664,375 geographic cubits = 10,002,301 meters. Hayford's figure is 10,002,286 meters.

Akhenaten wanted to prove that Thebes could not properly claim to be the geodetic center of Egypt and that he had chosen the geodetic center conforming to an absolutely rigorous interpretation of *maet*, the cosmic order of which the dimensions of Egypt were an embodiment. In order to follow absolutely exact standards of measurement, he reverted to the predynastic geodetic system which counted in geographic cubits starting from Behdet. This system was more precise than the system which counted in royal cubits (septenary units) starting from the base line of the Delta, making Egypt equal to 100 *atur* of 15,000 royal cubits. Thebes could claim to be a geodetic center only in terms of the second system, which is septenary and makes the meridian of Thebes coincide with the eastern corner of the Delta. In terms of the system based on the predynastic capital of Behdet, there could be no question that Akhet-Aten is the "true and just" navel of Egypt.

This conclusion implies that one should reevaluate the entire historical role of Akhenaten, taking as the starting point what he himself considered the initial step in his program to establish true and just conformity with *maet*. There is a possibility that his revolutionary reforms, which extended from religion to art and family relations, were understood as a general return to predynastic ideas and practices.

5. Since the Egyptian monarchy set the style for the trappings of royal power thorughout the world, the prescriptions of Akhenaten about the dimensions of the territory of his capital did not remain without parallel in history. A striking parallel can be found in what may appear a most unlikely time and place, Saxon England.

Scholars are so bent on principle to interpret the history of measures and measurement in terms of the most crude primitivism, that in most works of history that deal with English measures one reads that the English foot was originally set by the length of the foot of an English king. The name of the king whose lower extremities were so decisive varies from scholar to scholar, although, when one thinks about it (which is not done in matters of measurement) kings of average human size should be excluded. There is agreement among scholars that the king in question reigned in the centuries following the Norman conquest, since it is assumed and often stated that before this time England did not have set units of measure. A variant of the fairy tale about the English foot is provided by the historians who tell us that it was not a matter of the foot but of the arm of a king which decided the length of the yard (three feet). Usually the length of the arm of King Henry I (1068–1135) is mentioned in this connection.

Such statements are made in spite of the fact that it is not necessary to be a specialist in the history of measures to find out that a foot equal to the English foot was the basic standard of Russia, from the time of the first available historical records to the Soviet revolution. I grant that it takes a specialized historical training to trace the linear standard of England and Russia to the ancient Orient, but I may also observe that there are well known Greek temples which have been planned in English feet, and that archeologists of English and American nationality have studied them without realizing what they had before their eyes.

Historians could have developed less benighted notions about the origin of English measures, even without extending their horizon beyond the British isles, because there is a law of King Athelstan (924–940) which defines the length of the English foot. The text of this law is included in the standard collections of medieval English laws. The words of law of Athelstan were repeated exactly in the legislation about measures issued by King Henry I. The law of Athelstan provides the most fundamental text for the study of English measures, but it has been ignored.

Athelstan prescribed that the king's girth shall extend from the royal residence for a distance of 3 miles, 3 furlongs, 9 acres, 9 feet, 9 palms, and 9 barleycorns. The King's girth was the area considered a direct extension of the King's place of residence and as such the area in which the King's peace was in force. This was the area in which attacks on private persons were crimes against the Crown.

The picturesque language of the law means that the King's girth extends for a radius of 18,250 feet, since it is a matter of the following units:

mile	5280 feet
furlong	600 feet
acre	66 feet
palm	3/4 foot
barleycorn	1/3 inch

The law employed a form of expression which had a particular numerological rhythm and at the same time defined the value of the multiples and submultiples of the foot.

My understanding of the law of King Athelstan is that the radius of the King's girth was defined as 3 minutes of latitude. The King's girth extended 6 minutes or 1/10 of degree from north to south. This implies that a degree was understood to be 365,000 English feet, which is the length of the degree at the latitude of towns like Winchester.

A more detailed analysis of the law of Athelstan belongs to a study of English measures. What is important to stress here is that the English foot was defined by length of a stretch of 1/10 latitude around the king's place of residence. The political conditions of the feudal society of Saxon England were very different from those of Pharaonic Egypt, but the method used by King Athelstan in order to relate his power to the system of measures and to the cosmic order bears a remarkable similarity to that adopted by the Pharaoh Akhenaten.

VI. DEGREES OF LONGITUDE

1. When the Egyptians fixed the value of their fundamental unit of length, the geographic cubit, they chose as standard degree the degree of latitude at 27° 45′ north, taken as the middle latitude of Egypt. When they recalculated the dimensions of Egypt in terms of royal cubits, they chose as the middle latitude 27° 33′ north. These latitudes were chosen taking into account the length of a degree of longitude at the equator. Latitude 27° 45′ is the half of latitude 55° 30′ and latitude 27° 33′ is the half of latitude 55° 06′. The Egyptians assumed that at the two higher latitudes a degree of latitude is equal in length to a degree of equator.

According to the *Smithsonian Geographical Tables,* a degree of latitude at parallel 55° 30′ is 111,324.7 meters, but probably the Egyptians calculated it as 361,680 geographic feet = 111,323.5 meters: this degree is equal to the fundamental degree of 360,000 geographic feet (600 stadia) plus 2.8 stadia or plus 1/214.28. According to the *Smithsonian Geographical Tables* a degree at parallel 55° 06′ is 111,317.3 meters. According to the Egyptian table of the lengths of the degrees of latitude which I have reconstructed, it is 212,378.5 royal cubits = 111,317.3 meters. This length could be expressed also as 361,660 geographic feet = 111,317.4 meters, that is, as 600 stadia plus 2.7666 stadia. This implies that the Egyptians estimated the equatorial circle either as 130,204,800 geographic feet = 40,076,478 meters or as

130,197,600 geographic feet = 40,074,261 meters. I suspect that they began with an estimate of 130,200,000 geographic feet (degree of 361,666 feet = 360,000 feet plus 1/216) = 40,075,000 meters, and then modified the figure in order to establish a relationship between the equatorial degree and the degree of the middle latitude of Egypt. The Egyptian estimate agrees with our current ones: the equator is 40,075,452 meters, according to the Clarke Spheroid and 40,076,596 meters according to the International Spheroid.

Very revealing is that a base line was marked along parallel 45° 12′ north on the north side of the Black Sea. This base line started from the mouth of the Danube, cut across the Crimea, and ended at the foot of the Caucasus. Beginning from this base, Russia was surveyed for a length of 10 degrees, along the three meridians which formed the three axes of Egypt, up to latitude 55° 12′ north. The river Dnieper was understood to be a symmetric counterpart of the Nile, running between the same meridians. Key positions along the course of the Dnieper were identified with corresponding key positions along the course of the Nile, up to the point of transferring Egyptian place names to Russia. The information about the existence of this geodetic system is provided by the description of a map of Russia which is based on it. The description of the map indicates that it was used at the end of the sixth century B.C., but the map may be older; in any case there are other sources of information about the base line which indicate that it was marked in very early times.

The figures of the geodetic system on which the map of Russia was based are most intriguing. The base line at parallel 45° 12′ north suggests that it was decided that it is at this latitude that the degree of latitude has a length equal to the average length of the degree of latitude. The fact that the meridians of Egypt were followed for 10° up to parallel 55° 12′ north suggests that it was decided that a degree of latitude at this parallel is equal to the length of a degree of equator.

The designation of 45° 12′ north for the location of the average degree indicates what the Egyptians assumed to be the degree of ellipticity of the earth. According to the *Smithsonian Geographical Tables,* the length of the degree of latitude at the point 45° 12′ north is 111,134.9 meters; from this figure we would get an arc of meridian of 10,002,141 meters. According to the Egyptian table of the length of the degrees of latitude that I have reconstructed, the degree at the point 45° 12′ north is 212,028.6 royal cubits = 111,134.4 meters; this length implies an arc of meridian of 10,002,099 meters. According to the *Smithsonian Geographical Tables* the degree ending at parallel 55° 12′ is 111,319.3 meters; if this is taken as the length of the degree of equator, the equatorial circle is 40,074,948 meters. According to the Egyptian table of the length of the degrees of latitude, the degree at 55° 12′ north is 212,381 royal cubits = 111,319.1 meters; this would indicate an equatorial circle of 76,457,160 royal cubits = 40,074,890 meters (stadium of equator = 353.96833 cubits).

2. In performing astronomical observations it is necessary to express differences of longitude in terms of units of time. The equator and all parallels are divided into 360 degrees, but considering the rotation of the earth it is expedient to divide the equator and all parallels into 24 hours. Given 360/24 = 15, a minute or a second of time is equal to 15 minutes or 15 seconds of degree.

In astronomical calculations, there are employed two different kinds of time, solar time and sidereal time. Solar time is our ordinary time. Solar time assumes that the day is the interval between two successive passages of the sun at the meridian. The length of the day so defined varies greatly according to the seasons of the year; it varies by more than 1/90. The reason for this variation is that the speed of the earth along its orbit around the sun is not constant and that the apparent motion of the sun around the earth does not follow the line of the equator, but of that of the ecliptic. Hence, in ordinary life we reckon by mean solar time, which is obtained by assuming that a fictitious sun moves along the celestial equator at a speed equal to the average speed of the sun along the ecliptic.

Mean solar time is a highly artificial concept and we can use it because we have mechanical clocks. The ancients calculated by sidereal time, which they could measure by observing the apparent movement of the vault of heaven. Sidereal time has the advantage of flowing evenly. There are small variations due to the nutation of the earth under the influence of the gravitational pull of the moon and the planets; but these variations are too small to be relevant to the calculations we are considering.

A sidereal day is the interval between two passages of a star at the meridian. A sidereal day is shorter than a solar day. If one observes a star at the meridian today, that star will be again at the meridian in less than a solar day. In other words, if one counts by solar time, the vault of heaven rotates about one degree more than a full circle in a day. The difference between mean solar time and sidereal time can be easily computed, because in a year the vault of heaven makes exactly one more circle around the earth than the number of circles made by the sun.

Hence the ancients could reckon:

$$\frac{\text{Solar time}}{\text{Sidereal time}} = \frac{366}{365} = 1.00273972$$

or more precisely:

$$\frac{\text{Solar time}}{\text{Sidereal time}} = \frac{366.25}{365.25} = 1.00273785$$

They did not need a formula more precise than the second one; today we reckon by the ratio 1.00273791.

The ancients simplified this complex matter by counting by the speed of movement of a point at the equator. That speed was taken by them as constant; the infinitesimal variations in speed of the rotation of the earth on its axis are relevant only to some calculations of modern astronomy.

The speed of a point at the equator in terms of mean solar time was obtained by dividing the length of the equator into 24 hours = 1440 minutes = 86,400 seconds. But the ancients were concerned particularly with the speed of a point at the equator in terms of sidereal time. A minute of time (solar time) corresponds to the length of 15 minutes of degree of equator. A minute of time (sidereal time) is equal to the same length multiplied by 365.25/366.25, that is, it is shorter.

3. When the Egyptians standardized their system of measures by establishing that the degree at the middle latitude of Egypt is 240,000 geographic cubits (360,000 geographic feet = 600 stadia) or that 1/48 of great circle measured from 24° 00′ north to 31° 30′ north is 1,800,000 geographic cubits, they must have had in mind the following equivalence:

1 second (sidereal time) = 1000 cubits
1 minute (sidereal time) = 60,000 cubits =
1/4 length of degree of latitude in Egypt

This calculation was convenient, but implied an equatorial degree (degree of latitude in Egypt × 1.00273785) of 111,109.8 meters, which is slightly too short; it is the length of a degree of longitude at about 3° 30′ from the equator.

In order to obtain the right length of the second and minute of sidereal time, one must take as reference a degree of latitude further north than Egypt. The degrees at the latitudes of Dodona and Delphi provided the correct values.

Classical Greece was not a unified country, being divided into cities proudly clinging to their absolute political independence; but, most incongruously, it had a national oracular center, just as Egypt, a strongly unified country, had a national oracular center at the Temple of Amon in Thebes. In Greece there were two centers which competed

Another Greek conception of an *omphalos* as derived from the Egyptians.

Omphalos of Delphi depicted with two pigeons (usually facing each other), evidently carrier pigeons used for establishing geographic distances. According to Greek legends, a central geodetic point was obtained by loosing two birds of equal strength and using the mean of the time employed in flight. This would allow for differences in wind current and other variables. By repeated flights even more accurate measurements could be obtained.

for the role of national oracle, Dodona and Delphi. The oracle of Dodona was considered more ancient and many Greeks considered it more authoritative, but it was at a practical disadvantage because it was located beyond the limits of solidly Greek territory in an area of most difficult access. In modern Greece, which extends more widely than ancient Greece, Dodona is near the Albanian frontier. The position of the oracle of Delphi, even though not as surprising as that of the oracle of Dodona, was peculiar; it was located in the mountains, north of all major centers of Greece.

The Greeks narrated that two doves flew from the temple of Amon in Egypt in order to establish the oracles of Dodona and Delphi. In ancient literature and iconography the flight of two doves is the standard symbol for the stretching of meridians and parallels.

Because the oracle of Delphi was less isolated, it received more attention and consequently we are better informed about it. Delphi was considered the geodetic center of Greece. The god of Delphi, Apollo, whose name means "the stone," was identified with an object, the *omphalos*, "navel," which has been found. It consisted of an ovoidal stone (the ovoidal shape indicated the lengthening of the degrees of latitude as one moves north) covered by a net. The net was the symbol of what even today we call the net of meridians and parallels. The *omphalos* of Delphi was similar to the object which represented the god Amon in Thebes, the "navel" of Egypt. In 1966 I presented to the annual meeting of the Archeological Institute of America a paper in which I maintained that historical accounts, myths, and legends, and some monuments of Delphi, indicate that the oracle was established there by the Pharaohs of the Ethiopian Dynasty. This is the reason why the Greek portrayed Delphos, the eponymous hero of Delphi, as a Negro.

The relevance of the latitude in the location of Delphi is indicated by a number of Greek accounts which associate Delphi with Sardis, the capital of the kingdom of Lydia in Asia Minor, which is on the same parallel (38° 28′ north).

The role of geography in the oracular importance of Delphi is indicated also by the method employed in obtaining oracular responses. Modern scholars who have been impervious to the rational elements of ancient thought and prefer to ignore that Apollo, the god of Delphi, was a god of reason and scientific thought, are generally inclined to think that the oracular responses were given by a priestess who, put in a trance by drug fumes, uttered gibberish. But there is abundant pictorial evidence which shows vividly how the oracle was consulted. An object which resembles a roulette

Egyptian *omphali* with twin birds. Carrier pigeons are depicted in Egypt as early as the Fourth Dynasty, and were evidently used to establish parallels and meridians from prehistoric times. Homing pigeons, which fly in a straight line (as the crow flies!), could cover the more than five hundred miles from one end of Egypt to the other in a single day.

wheel, and actually is its historical antecedent, was centered on top of the *omphalos*. The spinning of a ball gave the answers; each of the 36 spokes of the wheel corresponded to a letter symbol.

In studying ancient computing devices, I have discovered that they were used also to obtain oracular answers. This is the origin of many of the oracular instruments we still use today, such as cards and ouija boards. The psychological foundation of this phenomenon is simple. If I have a problem in interpreting an ancient text or an archeological report, I "consult" my calculating machine which "gives me the answer." By stretching this imagery further, one could assume that the calculating machine is an oracle. The roulette wheel of Delphi originally was a special kind of abacus for calculating in terms of angles.

The latitudes of Dodona and Delphi are significant. The length of the degree of latitude at the parallels of these two oracular centers gave the length of the minute or second of sidereal time, that is, the distance covered by a point at the equator in a sidereal minute or second of rotation of the earth.

Dodona is at 39° 32′ north. According to the *Smithsonian Geographical Tables* a degree at this parallel is 111,014.0 meters. This means that the degree must have been calculated as 360,673 geographic feet (360,000 plus 1/535) = 111,013.6 meters. If we multiply this length by 1.00273785, we obtain 361,660 geographic feet, the length of the degree of latitude at parallel 55° 06′, which is equal to the length of a degree of longitude at the equator.

If the figures employed in the reckoning of Dodona are rounded to a degree of 360,600 geographic feet and to a second of sidereal time of 1001.666 geographic cubits (that is, 1000 plus 1/600), we obtain the length of the degree of latitude at the parallel of Delphi, which is 38° 28′ north. A degree of 360,600 geographic feet is 110,991.1 meters; a degree at parallel 38° 28′ is 110,993.5 meters according to the *Smithsonian Geographical Tables* and 110,992.1 meters according to the Egyptian table of the length of degrees of latitude. Latitude 38° 28′ north may also have been chosen because it is at the standard distance of 6′ from latitude 38° 34′ north, which is at 3/7 of the distance from the equator to the pole, whereas the Temple of Amon in Thebes was set at 2/7 of this distance.

4. Metrologists of the past have wavered in establishing the value of the geographic foot (and hence of the artaba), because they confused this unit with a similar one, the Greek foot, which is about half a millimeter longer.

Roman writers mention a Greek foot which is 25/24 of the Roman foot and a Greek stadium which is equal to 600 Greek feet or 625 Roman feet. The Romans used the two units in conjunction. Roman roads were divided into miles of 5000 Roman feet, but at times between the milestones there were smaller markers which divided the road into 8 Greek stadia ($8 \times 625 = 5000$). In giving itinerary distances, writers of the Roman period usually reckon by Roman miles on land and by Greek stadia at sea.

Because Roman authors indicate that the degree is 75 Roman miles or 600 Greek stadia, since the Renaissance metrologists have been concerned with establishing the exact value of the Greek foot; but in examining the empirical evidence they met with data that appear conflicting, for the reason that they did not separate sources of information which apply to the geographic foot. Travelers and sailors of the eastern Mediterranean and the Middle East used to assume that a degree of latitude is 600 geographic stadia (110,806 meters) and a degree of longitude is 500 geographic stadia (92,339 meters); Greek and Roman travelers and sailors used to assume that a degree of latitude is 600 Greek stadia = 75 Roman miles (110,980 meters) and a degree of longitude is 500 Greek stadia = 60 Roman miles (92,483 meters). As a result scholars have confused information concerning two different types of units. The confusion occurs easily, unless one assumes high standards of precision and accuracy in ancient measurements, since we have:

Geographic foot	= 307.7957 millimeters
Geographic cubit	= 461.6935 millimeters
Greek foot	= 308.2764 millimeters
Greek cubit	= 462.4147 millimeters

A degree of latitude of 600 Greek stadia = 75 Roman miles is correct at parallel 37° 42′, which is the latitude of Mycenae. The system of calculation used by the Greeks and Romans goes back to the Mycenean ancestors of the Greeks.

Archeologists assume that, if the Greeks of the classical period measured badly, the Greeks of the Mycenean age did not measure at all. It is assumed that when the Myceneans erected their buildings they placed one stone on top of another without much of a plan. However, we know that the Myceneans were engaged in extensive long-distance trade and through it they accumulated huge quantities of gold of African origin; long-distance navigation and exchange of precious metals were the two activities which created for the ancients the most compelling need for exact standards.

By examining the dimensions of Mycenean citadels, I have established that they were planned by a foot which is 15/16 of the Roman foot, a foot of 277.4488 millimeters. This foot has been called Oscan or Italic by metrologists of the last century, who noticed its occurrence in pre-Roman Italy and in the earliest remains of Rome. I call this foot Mycenean.

The Mycenean foot not only is 15/16 of the Roman foot of 295.9454 millimeters, but also is 9/10 of the Greek foot of 308.2764 millimeters. The Greek foot is 25/24 of the Roman foot and $25/24 \times 16/15 = 400/360 = 10/9$.

A degree of 360,000 Greek feet (75 Roman miles), a degree of latitude at the parallel of Mycenae, is equal to 400,000 Mycenean feet. The occurrence of the factor 4 indicates that a calculation by time units is involved, since there are 4 minutes of time in a degree. A minute of time is equal to 100,000 Mycenean feet. Hence, by using the Greek cubit and the Mycenean foot, one could obtain the following easy formula:

Second of time = 1000 Greek cubits
Minute of time = 100,000 Mycenean feet

These units are slightly too short for a second and a minute of sidereal time. If we take the degree of 360,000 Greek feet = 400,000 Mycenean feet = 110,979.5 meters and multiply it by 1.00273785, we obtain a degree of 360,986 Greek feet = 110,283.4 meters, which is the length of a parallel circle at about 1° 30′ from the equator.

But the numerical structure of the units indicates how the exact length of the degree of equator was obtained by introducing an easy correction. One starts with these data:

1000 Greek cubits = 1 second of time
Day of 86,400 seconds = 86,400,000 Greek cubits
100,000 Mycenean feet = 1 minute of time
Day of 1440 minutes = 144,000,000 Mycenean feet

These figures can be modified as follows:

Equator = 86,666,666 Greek cubits = 40,075,939 meters
Equator = 144,444,444 Mycenean feet = 40,075,939 meters

Similarily, one may start with the Greek foot and obtain

100 Greek feet = 1 second of degree
Circle of 1,296,000 seconds = 129,600,000 Greek feet

The last figure can be modified to

Equator = 130,000,000 Greek feet = 40,075,939 meters

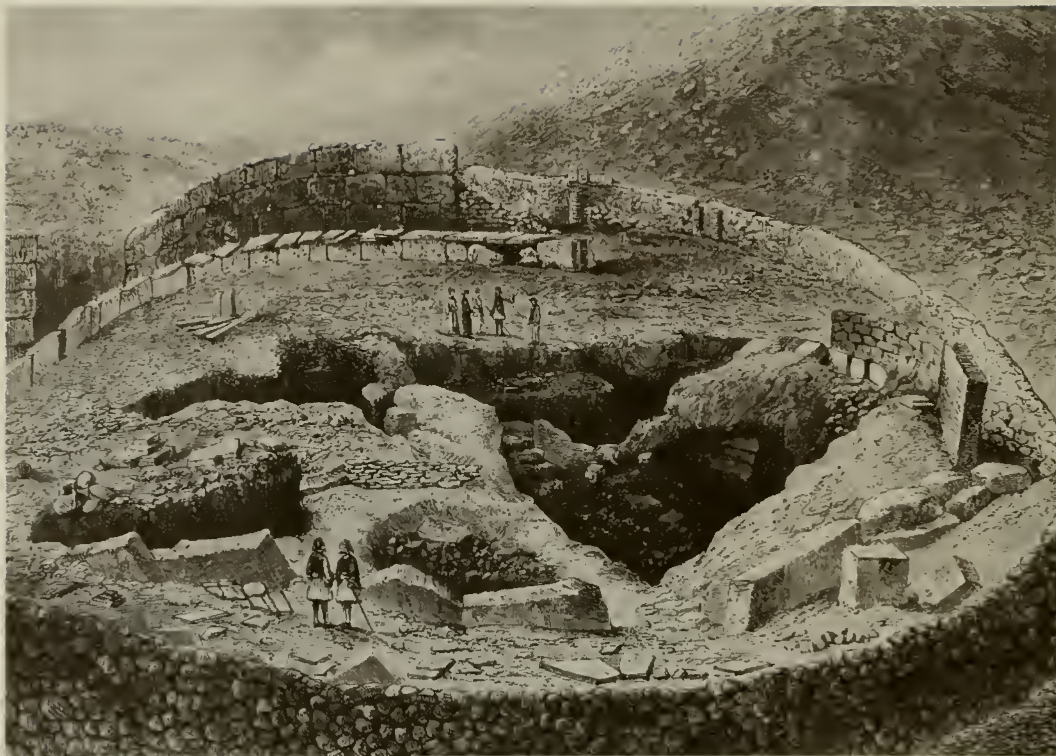
All that was needed in order to obtain the exact length of the equator was to assume that a circle is equal to 1,300,000 seconds of degree, instead of 1,296,000.

It is possible that this formula was used to calculate the actual length of the solar day in the different seasons of the year. Today almanacs assign the value of 1200 to the length of the mean solar day and list a figure greater or smaller than 1200 in order to indicate the actual length of the solar day for each day of the year. Possibly the ancients proceeded in a similar way, assigning the value of 1300 to the mean solar day.

Archeologists and historians assume that the Myceneans had no concern with science, but the most famous remains of Mycenean civilization proclaim otherwise.

Lion Gate at Mycenae.

The best known monument of Mycenae is the entrance gate which today is called the Lion Gate, because he who approaches the city is overpowered by a huge relief sculpture on the triangular capstone of the entrance; the relief consists of a column between two facing lions. The column is sandwiched between two sets of parallel horizontal lines. At the bottom the column rests on a support on which three parallel lines are strongly marked. These three lines are the same three lines which occur in the hieroglyphic symbol for Southern Egypt; they represent the tropic of Cancer, which was identified with parallels 24° 06′, 24° 00′, and 23° 51′ north. The column represents the three basic meridians of Egypt; the curvature of the column suggests the development of the system of meridians to the east and the west of Egypt. On top of the capital of the column (symbol for Northern Egypt) there rests what appears to be a segment of a floor. This segment of floor is on three levels. The bottom and the top levels are two horizontal lines, whereas the middle level consists of four circles. I have explained the significance of the factor 4 in the Mycenean system of linear units. The top part of the relief represents the parallel of Mycenae.



The grave circle at Mycenae excavated by Schliemann. A geodetic point for astronomical observation similar to the circular henges and mounds of the second millennium B.C. elsewhere in Europe.

The two lions which face each other on the sides of the column represent a circle closing on itself. The easiest way to convey the meaning of this symbol is to refer to pieces of ancient jewelry which consist of a bracelet open at one side with a head of a lion on each open end. The lions represent the summer solstice. The stance of the lions, with the front paws on the line of the tropic and their hind paws extending below it (this stance will later become the heraldic symbol of the lion rampant), indicates the spread of the zodiacal band north and south of the ecliptic. The ancients established their astronomical system when the spring equinox was in Taurus, which ceased to be true at the beginning of the second millennium B.C.; for them the point zero of the sky was between the two horns of Taurus. Today we count from the constellation of Aries, although the spring equinox has not been in Aries since the time when the Roman Emperor Antoninus Pius (A.D. 138–161) celebrated the end of the age of Aries and introduced new cults and religious beliefs in accordance with the beginning of a new cosmic age. When the spring equinox was in Taurus, the summer solstice was in Leo.

The cosmological meaning of the Lion Gate of Mycenae should not have been lost to archeologists, since next to this gate there is the second most impressive relic of ancient Mycenae, the so-called Grave Circle. It consists of a circular arrangement of stone blocks. If excavators had not been completely blinded by their belief in the primitiveness of the Myceneans, they would have immediately assumed that this circle must have some cosmological meaning. Instead the Smithsonian Institution spent time and energy to proceed to measurements of the skeletons found buried within the circle, arriving at the conclusion that they were bones of ordinary size men and not of giants. But the dimensions of the stone circle have not received attention; it may be enough to report here that the inner diameter of the circle is 100 Mycenean feet.

When the first circuit of walls of Mycenae was erected, the Circle was outside the walls directly in front of the Gate; the middle of the Gate is on the line of the north-south diameter of the Circle. Later the circuit of the walls was extended so as to include the Circle within the citadel.

5. A splendid illustration of the Mycenean system of linear units is provided by the Parthenon of Athens.

The Parthenon of Athens is the only Greek temple which has been surveyed with an adequate level of accuracy. But unfortunately for my investigation of the dimensions of Greek temples, the system of proportions of the Parthenon is an aberrant one. I have established the mathematical formula that determined the dimensions of Greek temples and the mathematical formula that determined the dimensions of Mycenean throne rooms; the Parthenon conforms to the latter and not to the former. The reason is that the Parthenon was built as a replacement on a larger scale of the Temple of Athena destroyed by the Persians, when they sacked Athens in 480 B.C. The old Temple of Athena in turn was built on top of a Mycenean throne room, some remains of which have been found by deep excavations. For this reason the Parthenon was planned in Mycenean feet, whereas most of the other monuments of the Acropolis of Athens were planned in Roman feet. However, the major dimensions of the outer colonnade of the Parthenon were so chosen that they could be expressed also in Greek feet, which was easy since Mycenean foot and Greek foot relate as 9:10.

For the study of the Parthenon we can rely on data that are satisfactory for some of the major dimensions, because at the middle of the last century an English architect and scholar of the history of architecture, Francis Cranmer Penrose, who was also an outstanding dilettante astronomer, on the basis of reports on the mathematical curvatures of the lines of the temple became convinced that the Parthenon

The so-called Treasury of Atreus at Mycenae built into a mound with corbeled roofing similar to the Maes-Howe mound.

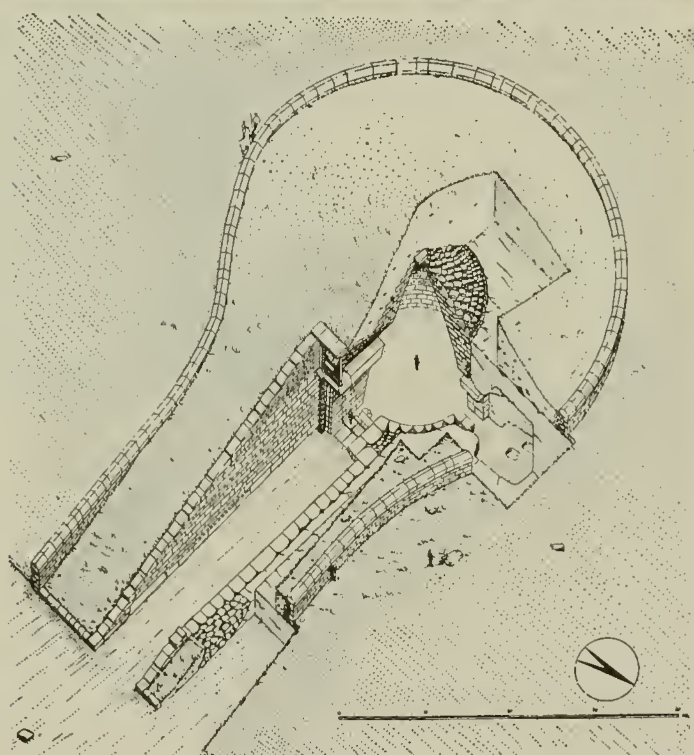
had been planned and executed with high standards of mathematical skill. In order to prove his point he measured it accurately with the precision of one-thousandth of an English foot.

Penrose, however, was ridiculed by archeologists, and no other Greek temple has been surveyed with comparable care ever since. The Archeological Institute of America does not support any survey or publication which does not assume that the maximum precision achieved in construction of reference foot rules by the ancient Greeks was a fifth or at the very best a tenth of centimeter. Naturally, the precision achieved in the construction of buildings was much less than the precision of the official reference rules.

Penrose was not able to convince scholars of his major contention, because he was obsessed as an architect with the notion that buildings should have perfectly square corners. He put this notion into practice when he planned the building of the British School of Archeology in Athens, of which he was director for two short periods, after its foundation in 1882. Because of this obsession, when Penrose found that the western front of the Parthenon is longer than the eastern front and that the south flank is longer than the north flank, he concluded that this was the result of mistakes in construction. His opponents were quick to point out that, if it is so, his major contention is disproved.

Penrose believed that the difference in the lengths of the sides of the Parthenon results from mistakes in the marking of the four corners which were intended to be perfectly square. In reality, the four corners of the Parthenon

Nineteenth-century view of the Parthenon.



The Treasury of Atreus at Mycenae (isometric view, after Hood), which has a striking resemblance to the Maes-Howe burrow and appears to have been designed for azimuth and zenith observation, like the subterranean chambers of the pyramids.

were not intended to be exactly square, but to deviate by set small amounts from a right angle, as is the case with the four corners of the Great Pyramid. I have established that the west front of the Parthenon was intended to be 1/48 of a Mycenean foot longer than the east front, and that the south flank was intended to be longer than the north flank by the same amount. The two longer sides join at the southwest corner, which is also higher in level over the other three corners. Taking these intended deviations into account, the actual findings of Penrose about the length of the sides agree almost perfectly with the theoretical dimensions obtained by mathematical principles.

Even with the intended lengthening of the west and south sides, the northeast corner, which joins the two most important sides, could have been a right angle, but instead it was acute by a figure close to a minute of degree. Unfortunately, Penrose measured the angle of this corner rather casually, because he thought that the lack of exact squareness was the result of a mistake in construction, and nobody else has tested the angle of this corner again in more than 120 years.

East end of the Parthenon.

There are many problems in the architecture of the Parthenon that cannot be solved, because archeologists prefer to go on building fanciful theories rather than establish the facts by an accurate survey. It is a basic principle of epistemology that our ability to reject erroneous theories increases in proportion with the precision and accuracy of the measurements; the converse is true, and this is what archeologists like, because, as they put it, it permits the spirit to soar. For instance, if one were to accept the loose standards of measurement dogmatically adopted by the Archaeological Institute of America, it would not be too difficult to present an argument to the effect the the surface of the earth is concave.

In the specific case of the Parthenon, I can point out that Penrose tested the orientation of the north flank, and that on the basis of his finding I could establish that the Parthenon is correctly oriented according to the latitude and longitude of Athens. But details of construction have led me to realize that the orientation of the inner part of the temple, the cella, was a trifle different. Since the difference of azimuth between the two longitudinal axes of the Parthenon has never been tested, I am left in the dark about the fine points in the orientation of the Parthenon.

An essential datum is that there are similarities between the mathematical structure of the Parthenon and that of the Great Pyramid. In both constructions the corners deviate deliberately from a right angle. I have established that the elevation of the fronts of the Parthenon was calculated by the factor φ and that the elevation of the flanks was calculated by the factor π. According to the data available, I have interpreted the elevation of the Great Pyramid to be such that the north side was calculated by the factor φ and that the west side was calculated by the factor π.

Here, I will deal only with the horizontal dimension, width, of the two fronts of the Parthenon, because it is directly connected with the Mycenean system of measures.

Before Penrose proceeded to a careful measurement of the sides of the Parthenon in the winter 1846–47 (the season of winter was deliberately chosen in order to reduce the effects of changes in temperature which may be macroscopic under the sun of Greece), an attempt at careful measurement was conducted in 1753, under unfavorable political and physical circumstances, by the painter James Stuart and the architect Nicholas Revett, who had become interested in the measurements of ancient buildings while studying in Rome. The expedition of these two English antiquarians had been carefully planned and created great stir in Europe at the time. One of their specific aims, indicated in the campaign for the raising of the necessary funds, was to ascertain the exact length of the Greek foot and by inference of the Roman foot, which is 24/25 of Greek foot. The Parthenon is called *Hekatompedon,* "one hundred foot temple," in Greek texts and these texts indicate also that its width was 100 feet. Earlier visitors to the Parthenon had concluded that the two fronts of the temple measured 100 Greek feet. For this reason Stuart and Revett provided themselves with highly reliable instruments of measurement and paid the greatest attention to the measurement of the two fronts.

They were so concerned with the length of the Greek foot that they reported the dimensions of the temple in such a way as to arrive at the results that were expected. Their figures for the length of the fronts are scanty. But they arrived at the conclusion that the value of the Greek foot is 12.137 English inches = 308.2795 millimeters, which agreed well with what scholars had estimated to be the length of the Roman foot (24/25 of Greek foot). According to my reckonings the Greek foot is 308.2765 millimeters.

Stuart and Revett used a yard rule prepared by the famous instrument-maker John Bird of London. A few years later (1762) Bird prepared a yard rule on behalf of the Parliamentary Committee appointed in 1758 "to inquire into the original standards of weight and measure of this kingdom." Although Bird had to follow the instructions of the committee, it can be presumed that the rule he built in 1762 did not differ in a manner significant for the present research from those he had built earlier. The Bird rule of 1762 was the main basis in the calculation of the Imperial Standard Yard made legal by Parliament in 1824.

What Stuart and Revett did not know is that the fronts of the Parthenon were intended to be slightly more than 100 Greek feet.

If the fronts had had a length of 100 Greek feet = 111.111 Mycenean feet = 111 1/9 Mycenean feet, they would have had a length equal to a second of degree of latitude at the parallel of Mycenae (37° 42′ north), whereas the latitude of Athens is 37° 58′ north.

The fronts of the Parthenon were planned to have a length of 100 1/5 Greek feet = 111 1/3 Mycenean feet. This length was increased by 1/48 of a Mycenean foot on the west front. Hence, the lengths of the fronts, according to my interpretation, was:

Eastern front = 30,889.3 millimeters
Western front = 30,895.1 millimeters

Penrose reported the following findings:

Eastern front = 101.341 English feet = 30,888.7 millimeters
Western front = 101.361 English feet = 30,894.8 millimeters

The western front is better preserved.

These figures prove how accurate was the planning of the Parthenon and how justified was Penrose in testing the dimensions of this temple with the greatest care of which he was capable.

But all the horizontal lines of the Parthenon have a parabolic curvature. The sides of the temple have a double parabolic curvature: they are curved upward and inward. The spacing of the columns proves that dimensions that were relevant were those measured along the parabolic line.

The two parabolic curvatures increased the length of the sides. What I have been able to establish with certainty is the effect of the combined double parabolic curvature on the edge of the sides, because of necessity the spacing of the columns which were placed all along the sides had to be based on the actual length of the edge of the sides. The two curvatures added 8/48 = 1/6 of foot to the length of the fronts, so that the eastern front measured 111 1/2 Mycenean feet = 100.35 Greek feet = 30,935.5 millimeters, when measured along the edge of the blocks. But in calculating the width of the temple one should consider only one parabolic curvature, the curvature upward, that is, in substance, the curvature of the floor. Before expressing exact conclusions I would like to see the results of a new survey of the curvatures of the Parthenon, but I can definitely state that the width of the temple measured along the curvature of the floor was halfway between 111 1/3 and 111 1/2 Mycenean feet, that is, close to 111 5/12 feet = 30,912.4 millimeters.

If we add to this amount the 1/48 foot added to the western front, we have a length of 111 7/16 feet = 30,918.2 millimeters. This length would indicate an equatorial degree of 111,305.5 meters and an equatorial circle of 40,069,988 meters.

It can be concluded that the width of the fronts of the Parthenon was intended to indicate the length of a second of degree of longitude at the equator. But further testing of the dimensions of the Parthenon is necessary in order to establish what was exactly the length of the second of degree that the builders had in mind.

As I have indicated, the Mycenean system of measures, which was followed by the Greeks of the classical age, assumed an equatorial circle of 144,444,444 Mycenean feet and hence a second of degree of equator of 111.45404 feet. This would imply a width of the Parthenon of 30,922.8 millimeters.

VII. DIMENSIONS OF THE GREAT PYRAMID

1. Since the dimensions of the Great Pyramid have been endlessly debated, and studies of them have often degenerated into mysticism, it is proper that in approaching the subject I clarify my method. The essence of my method is to be absolutely pedestrian. I have spent years of my life in trying to ascertain the exact length of the Roman foot, eliciting from the academy the reaction that it is a disgrace for a classical scholar to waste energy on such mechanical trivialities. Similarly, after reading scores of studies on the architecture of the Parthenon, I set myself two tasks: to determine the length of the foot employed in the construction, and to compare item by item all available modern

reports on the actual dimensions of this temple. I followed this line of research although I was warned by the learned that a person guilty of such *banausia,* which in Greek means behavior worthy of a manual wageearner, would always remain blind to the lofty mind of the ancient Greeks. In dealing with the geometry of the Pyramid, I have taken as starting points my conclusions about the length of the Egyptian royal cubit and the survey of the dimensions of the Pyramid conducted by Cole, who was not an Egyptologist but a professional surveyor.

Up to now the Cole survey has been neglected. Trust has been put on the survey conducted by Petrie, but, although Petrie considered himself an expert of measurements (he started his career as an Egyptologist under the guidance of his father, who was an engineer) and used all the diligence of which he was capable, his survey proves to have arrived at misleading results when compared to that of Cole.

In order to justify my method, I shall refer to another great scientific issue which, as we shall see, happens to be related to the problem of the dimensions of the Pyramid. In the *Principia* Newton argued that because of the centrifugal force generated by its rotation, the earth must be flattened at the poles. Reasoning purely on mechanical grounds, he concluded that the polar flattening is 1/230, which means that the polar radius is shorter than the equatorial radius by 1/230 of the latter. The calculation was based on the assumption, which is not true, that the earth is a homogeneous fluid body. Following the survey of Picard, for which Newton waited before publishing his *Principia* in 1686, other scholars of the French Académie des Sciences applied themselves assidiously to the problem of determining by geodetic surveys what was the actual shape of the earth. Their results were contradictory, but they were such that for seventy years after the publication of the *Principia* the empirical evidence could be understood to indicate that the earth, far from being flattened at the poles, was elongated. This caused most serious controversies in the field of physical theory. I have reexamined the records of this gerat debate to find that the French scholars were successful in advancing mathematical theory, in developing correct methods of triangulation, and in refining the techniques of astronomical observation, but had neglected the need of setting a reliable unit of linear measurement. The several surveys of the length of the degree of latitude, up to and including the famous survey conducted by Father Ruggiero Boscovich in Italy in 1751–53 (a survey which took as a starting point the Roman milestones of the Appian Way), kept using standards of the *pied de roi* which were different from each other.

The history of these surveys is a comedy of errors. This was sensed by the keen mind of Voltaire who, when Maupertuis announced triumphantly that his survey of the degree conducted in Lapland had proved that the earth is flattened at the poles, called him *le grand aplatisseur*, "the great flattener," building a pun on the extracurricular activities of Maupertuis with a Lappish maid.

The difficulties of scientists arose from the circumstance that the original standard of the *pied de roi* had been lost. The *pied de roi* used to be a fraction of the ancient Roman foot, and good reference standards of the Roman foot and of the *pied de roi* were kept by French trade guilds. But, the French absolute monarchy followed a policy of eliminating the public functions of the guilds. Finally the minister Colbert issued an ordinance prescribing that the only reference rule that could be used should be that kept at the Châtelet, the seat of royal administration and justice in Paris. But the standard of the Châtelet was poorly defined and badly protected from accidental damage. This is the reason why many scholars could arrive at the startling scientific conclusion that the earth is elongated at the poles. The intellectual confusion came to a rest because the engraver Langlois built his own private standard of the *pied de roi*, by assuming that the *pied de roi* is the edge of a cube that contains 70 Paris livres of water. Langlois's standard was used in establishing the Paris meter of the French metric system.

2. Although Petrie's survey of the length and orientation of the sides of the Great Pyramid proves to be unreliable, his survey of the dimensions of the King's Chamber proves to be superior to the several ones conducted since the seventeenth century. Since Petrie's survey of the King's Chamber has established that the royal cubit of the Pyramid measured 524.05235 $\pm$ 0.1016 millimeters, it permits the conclusion that the royal cubit employed in the construction was 524.1483 millimeters.

Cole began his survey of the length and orientation of the sides of the Pyramid by trying to establish the exact location of the corner points. By an extensive sounding of the foundations, he located the corner points with a possible margin of error which he estimated as follows:

West side:	30 millimeters at either end
North side:	6 millimeters at either end
East side:	6 millimeters at either end
South side:	10 millimeters at the west end
	30 millimeters at the east end

Next, Cole examined the alignment of the four sides and concluded that they meet to form angles which deviate as follows from a right angle:

Northwest corner:	−0° 00′ 02″
Northeast corner:	+0° 03′ 02″
Southeast corner:	−0° 03′ 33″
Southwest corner:	+0° 00′ 33″

I interpret these data to mean that the west side was drawn first and that the north side was intended to be perfectly perpendicular to it. The east side was intended to be at an angle of 3′ with the perpendicular to the north side, and the south side was intended to be at angle of 30″ with the perpendicular to the west side. In other words, the four corners were intended to deviate from a right angle according to the following pattern:

Northwest corner:	0
Northeast corner:	+3 minutes
Southeast corner:	−3 1/2 minutes
Southwest corner:	+ 1/2 minute

Having established the alignment of the sides according to the figures mentioned above, Cole calculated the length of the sides to be the following:

West :	230,357 millimeters
North:	230,253 millimeters
East :	230,391 millimeters
South:	230,454 millimeters

There is a contradiction in Cole's report about the length of the north side. In the summary of the lengths of the sides, Cole states that this side is 230,253 millimeters; but in an earlier part of his report he states that the north side is divided into a segment of 115,090 millimeters and a segment of 115,161 millimeters (total of 230,251 millimeters) and confirms these figures by explaining that the difference between the two segments is 71 millimeters. This contradiction is most unfortunate, because it is a conclusion of mine that the lengths of the two segments of the north side provide a key to the determination of the vertical dimensions of the Pyramid. I am inclined to infer that Cole found the north side to have a length of 230,251 millimeters.

I interpret Cole's figures to mean that the basic length of the side was 439 1/2 cubits = 230,363.18 millimeters. According to Cole the average length of the sides is 230,363.25 millimeters. Each side was intended to have a length of 1 1/4 stadia according to the stadium of 351.6 cubits; for the Egyptian this was the stadium (1/10 minute) of the degree of latitude at the equator. The perimeter of the Pyramid was intended to be 1758 cubits = 921,452.71 millimeters; Cole reports a perimeter of 921,453 millimeters. The perimeter was intended to be equal to 1/2 minute of latitude at the equator. The length of the minute of degree of latitude at the equator was calculated 3516 cubits = 1842.905 meters; it is 1842.925 meters according to the International Spheroid.

In the calculation of the Pyramid the royal cubit was divided into 24 fingers, each finger being 21.8395 millimeters. Egyptian measuring rods indicate that the royal cubit, which in principle is composed of 28 fingers (fingers such that 24 make an Egyptian common cubit), at times was divided into 24 fingers according to the ordinary division of the cubit. There are Egyptian measuring rods in which the royal cubit is divided into 28 fingers on one face and 24 fingers on the other face.

The west side was drawn first and then the north side was drawn perpendicular to it. The south and the east sides were at an angle different from a right angle with the two neighboring sides. This caused variations in the length of the sides, but steps were taken in order to assure that the average length of the sides remained 439 1/2 cubits.

The south side was intended to be at an angle 90° 00′ 30″ with the west side. Reckoning by tangent 0° 00′ 30″, this would cause a lengthening of the east side of 33.494 millimeters. Apparently this lengthening of the east side was computed as 1 1/2 fingers = 32.758 millimeters. The lengthening of the east side was compensated in part by shortening the west side by 1/4 of finger. In other words, the south side was moved backward by 1/4 of finger. The west side came to be 439 1/2 — 1/96 cubits = 230,363.1778 — 5.4597 millimeters = 230,357.72 millimeters. The east side was lengthened by 1 1/4 fingers, so that it came to be 439 1/2 + 5/96 = 230,363.1778 + 27.2994 = 230,390.48 millimeters.

The western side was rotated at the middle point by 3 minutes, so as to shorten the north side and to lengthen the south side. Multiplying the length of half of a side by tangent 0° 03′ 00″, there would be a shortening and a lengthening of 100.519 millimeters, which could be understood as 4 5/8 fingers = 101.008 millimeters. Since the east side had been lengthened by 1 1/4 fingers and the west side had been shortened by 1/4 finger, there remained an increase of a finger to be compensated. Hence, the north and south sides were shortened by 1/2 finger each. In other words, the east side was moved backward by 1/2 finger.

The length of the north side came to be 439 1/2 cubits — 4 5/8 fingers — 1/2 finger = 439 55/192 cubits = 230,251.250

millimeters. The length of the south side came to be 439 1/2 cubits + 4 5/8 fingers − 1/2 finger = 439 129/192 cubits = 230,453.266 millimeters. The difference between the two sides is 74/192 cubits = 202.016 millimeters.

This analysis of the method followed in planning the base of the Pyramid arrives at the striking conclusion that my estimates of the lengths of the sides, based on theoretical principles, do not differ by a millimeter from those obtained empirically by Cole (length of sides expressed in millimeters).

	My estimate	Cole's report
West side:	230,357.72	230,357
North side:	230,251.25	230,251
East side:	230,390.48	230,391
South side:	230,453.27	230,454
	921,452.72	921,453

3. In his survey Cole paid attention to a detail which in my opinion provides the key to the entire geometrical structure of the Pyramid. The Egyptologist Borchardt had noticed that, at about the middle of the north side, a small line is marked on the pavement which extends outward from the bottom of the Pyramid. Cole measured the position of this line and found it to be at a distance of 115,090 millimeters from the northwest corner and 115,161 millimeters from the northeast corner, with a difference of 71 millimeters between the two distances. He stated that this line is "probably the original line of the axis." Cole apparently did not pay much attention to this detail, since he reported also that the north side has a length of 230,253 millimeters. Reginald Engelbach, in presenting Cole's findings to the academic world, failed to notice the discrepancy in Cole's figures. I suspect that the figure of 230,253 millimeters for the length of the north side crept into the Cole report as a result of a mistake of 2 millimeters in placing the end of the tape against the pin that marked the position of the line of the axis.

If the north-south axis of the Pyramid is off center, it follows that the apex was off center. Petrie, when he surveyed the slope of the Pyramid, on the basis of preliminary tests suspected that each face of the Pyramid had a different slope, but did not try to establish whether this suspicion was justified. Instead he concentrated his efforts on establishing the slope of the north face, which is the best preserved one. As far as I know, none of those who tried to interpret the geometry of the Pyramid on the basis of Petrie's report considered the possibility that the four faces of the Pyramid had different slopes. Nobody has ever utilized Cole's survey in order to interpret the geometry of the Pyramid. If the four faces have different slopes, it follows that the apex is off center.

I have concluded that the north side had a length of 439 55/192 cubits = 230,251.250 millimeters. Hence, I understand Cole's figure to mean that the line which divided the north side into two parts is at a distance of 219 137/192 cubits = 115,162.479 millimeters from the northeast corner, and a distance of 219 55/96 cubits = 115,088.771 millimeters from the northwest corner. The difference between the two segments is 27/192 cubits = 73.708 millimeters. I suspect that there was a mistake of 2 millimeters in setting the end of the tape against a pin at the middle of the north face; this is the reason why Cole reports that the north side has a length of 230,253 millimeters with an excess of 2 millimeters. This type of mistake is common in surveying.

A great number of those who have tried to explain the geometry of the Pyramid can be placed into one of these two categories: those who conclude that the Pyramid was calculated by the factor π, and those who believe that the Pyramid was calculated by the factor φ. In my opinion both explanations are correct, in the sense that the slope of the west face was calculated by the factor π and the slope of the north face was calculated by the factor φ. The inclination of the other two faces was affected by the fact that the angles at the northeast and the southwest were more than right angles.

For reasons that I shall explain below, I have concluded that the height of the Pyramid was either 279.53 cubits = 146,515.174 millimeters or a figure very close to 279.53 cubits.

According to what I have said above, the distance of the apex from the west side was 115,088.771 millimeters. If the west face was calculated by the factor π, the height of the Pyramid had to be $\pi/4$ of the base of the meridian triangle of the west side. Now, 146,515.174 millimeters relates to 115,088.771 millimeters as 0.78550752, which would imply $\pi = 3.142030$. If π was reckoned as 3.1420, the height would have been 146,516.522 millimeters. By the exact value of π, the height would have been 146,535.569 millimeters.

Because of Cole's report we know the distance of the apex from the west side, but we do not have direct information on the distance of the apex from the north side. However, it can be presumed that the west-east axis was not displaced from the middle position. It can also be presumed that the line of the west-east axis was set according to the basic length of sides, before the length of the sides was altered by the widening of the southwest and northeast corners. Since the basic length of the sides is 439 1/2 cubits = 230,363.178 millimeters, it can be presumed that the apex was at a distance of 219 3/4 cubits = 115,181.589 millimeters from the north side. If this is the length of the base of the meridian triangle of the north face, and the height of the Pyramid is 279.53 cubits = 146,515.174 millimeters, the base of the meridian triangle of the north face is 0.78614103 of the height. If the north face was calculated by the factor φ, the height should have been equal to $\sqrt{1/\varphi}$ of the base of the meridian triangle. If one had recokoned by the exact value of φ, the height would have been 146,513.250 millimeters. If the height was 146,515.174 millimeters, as I tentatively assume, and the northern half of the north-south axis was 115,181.589 millimeters, $\sqrt{1/\varphi}$ was reckoned as 0.786141 (the exact value is 0.7861514) and hence $1/\varphi$ was reckoned as 0.61801767.

If $1/\varphi$ was reckoned as 0.6180, the height would be 146,517.274 millimeters, which would imply $\pi = 3.141985$. Therefore, I would conclude that the height possibly was reckoned as 279 15/28 cubits = 279.53714 cubits = 146,518.169 millimeters. According to Petrie the slope of the north face is 51° 50′ 40″ ± 1′ 05″. If the north face had been calculated by the exact value of φ, the slope would have been 51° 49′ 38″. This angle can be easily calculated, because if the meridian triangle of the north side is calculated by φ, the secant and the tangent of the angle of the slope must be equal to each other, that is, must be equal to $\sqrt{\varphi}$. If the west side had been calculated by the exact value of π, it would have had a slope 51° 51′ 14″.

4. Most interpreters agree that the Pyramid had a height of 280 cubits. Even Borchardt, who is so opposed to the idea that Egyptians had any knowledge of mathematics that he calls Herodotus an "idiot" for having said that the Pyramid was calculated by φ, agrees that the Pyramid had a height of 280 cubits.

In general one could establish a consensus of the responsible interpreters to the effect that the meridian triangle of the Pyramid was the following:

Height:	280 cubits
Base:	220 cubits
Apothem:	356 cubits

In my opinion, this triangle was purely the starting point of the calculations. It was chosen in order to indicate the relation π and the relation φ, since 22/28 is the value of $\pi/4$ used in practical reckonings ($\pi = 3\ 1/7$), and

356/220 = 89/55 = 1.6181818 is an approximation to the value of φ according to the initial terms of the Fibonacci series. But the initial meridian triangle was modified for several reasons, the first one being that it is impossible to construct a right triangle with sides 280, 220, and 356, since we have:

$$\begin{aligned} 280^2 &= 78{,}400 \\ 220^2 &= 48{,}400 \\ 356^2 &= 126{,}736 \end{aligned}$$

We have seen that the basic length of the sides was reduced to 439 1/2 cubits (semiside of 219 3/4).

In my opinion, the height of 280 cubits was chosen in order to indicate the polar flattening of the earth. The Egyptians calculated the polar flattening as 1/280, but this was a round figure adopted on the assumption that the order of the cosmos must be septenary.

Information about the Egyptian estimate of the size and shape of the earth is provided by Chapter LXIV of the *Book of the Dead*. This chapter was the most important one: reciting it was considered almost as effective as reciting the entire book. In one of the papyri of the *Book of the Dead* there is an annotation to the effect that this chapter was found in the shrine of the solar boat during the reign of Udimu, the fourth or fifth Pharaoh of the First Dynasty. Chapter LXIV states that the spirits of the Nether World (that is, all that is below the surface of the earth) are 4,601,200 and that each is 12 cubits high. The occurrence of the factor 12 indicates that it is a matter of geographic cubits. Now, 12 × 4,601,200 cubits = 55,214,000 cubits = 138,036 geographic stadia, is equal to two diameters of the earth. In order to explain the figure of 138,036 stadia, one must assume that the Egyptians reckoned as if the polar flattening occurs only in the northern hemisphere. On the basis of this assumption the figure of 138,036 stadia can be decomposed into the following four earth radii:

34,538 stadia	= 6,378,388 meters = equatorial radius
34,538 stadia	
34,538 stadia	
34,422 stadia	= 6,356,966 meters = polar radius
138,036 stadia	

These figures imply that the flattening of the North Pole is 116/34,538 = 1/297.74.

With extreme economy of numerical expression the Egyptians had arrived at values which are as good as the best modern ones. The figure for the equatorial radius happens to coincide to the meter with that calculated by Hayford. But Hayford calculated the polar flattening as 1/297. Helmert, however, set the polar flattening at 1/298.3, a figure which has been adopted in several of the recent surveys and calculations of the size of the earth which aim at achieving the maximum possible exactness.

At the beginning of the dynastic period the above mentioned figures were revised in order to make them fit into the septenary system of measures and cosmic order. The polar flattening was set at 1/280. This was achieved by decreasing slightly the polar radius and increasing slightly the equatorial radius. The equator which used to be reckoned as 217,000 geographic stadia = 40,074,999 meters, was calculated by a stadium (1/10 of minute) of 354 royal cubits, which made it 40,078,476 meters. It is conceivable that the data mentioned in the *Book of the Dead* was reinterpreted as follows:

34,540 geographic stadia = 6,378,758 meters = equatorial radius
34,540 geographic stadia
34,540 geographic stadia
34,416 geographic stadia = 6,355,858 meters = polar radius
138,036 geographic stadia

The figure of 1/280 for the polar flattening was adopted because it fits into septenary reckoning also in a second and more subtle way. If the polar flattening is 1/280, the arc of meridian is 0.7840 of equatorial diameter. Now, 0.784 = $280^2/100,000$ = 78,400/100,000. This is the reason why Herodotus put emphasis on the fact that the surface of each face of the Pyramid is 78,400 square cubits, being equal to the square of the height, which is 280 cubits. However, the figures reported by Herodotus apply only to the initial plan of the Pyramid. When the figures were further refined the height was calculated as 279.53 cubits. If the polar flattening is 1/297.74, the arc of meridian is 0.7408 of equatorial diameter. This means that an arc of meridian is $0.78408/\frac{1}{4}\pi = 279.53/280$ of a fourth of equator. Hence, the height of the Pyramid in the final plan indicated the correct figure for the polar flattening.

VIII. ADDITIONAL REMARKS ON THE DIMENSIONS OF THE GREAT PYRAMID

1. Herodotus provides only two pieces of information about the dimensions of the Great Pyramid. He states that the surface of each face is equal to the square of the height, which means that the Pyramid was calculated by the Golden Section (by the factor φ). He states also that this surface of each face is equal to 8 Egyptian acres. The Egyptian acre is a square with a side of 1000 royal cubits (2747 square meters). The Egyptian acre, the amount plowed in a day, is similar to the Roman acre (*jugerum*), which is 2524 square meters. Herodotus's figure indicates that he had in mind a

height of 280 royal cubits. He reckoned by half acres, which, as I have explained earlier, were taken to have sides of 70 cubits. If the Pyramid has a height of 280 cubits, the square of the height is 16 half acres (78,400 square cubits). If Herodotus assumed a side of 440 cubits, in order to have this surface the faces should have had an apothem of 356.4 cubits; but if he assumed a side of 439 1/2 cubits the apothem should have been 356.8 cubits. But Herodotus's figure for the surface of the faces was not intended to be exact.

The Roman geographer Pomponius Mela (I,9) paraphrases Herodotus in these terms: *quatuor fere soli jugera sua sede occupat, totidem in altitudinem erigitur,* "it occupies almost four acres with its base, and it rises as much in height." Mela expresses himself awkwardly, but the main point is clear. In order to make the reckoning more easily comprehensible he counts by double acres which have sides of 140 cubits. If the Pyramid had a height of 280 cubits, it would be immediately clear that the square of the height is 4 (double) acres. But Mela states that the surface of the faces and the square of the height is *almost* 4 acres. It was a current practice in all ancient cultures to double units of measure, while continuing to refer to them by the name of the simple unit. Mela erroneously speaks of the surface of the base, whereas it is a matter of the surface of the faces. The error probably originated through an inept translation from a Greek author who used the technical term *epipolēs,* which means "in elevation, by the lateral surface," but may also mean "in surface." The same error occurs in Pliny. It is likely that the error in translation originated with Varro, who almost certainly was the common source of Mela and Pliny. The polymath Varro, who lived in the first century B.C., proves inept in mathematical matters, and Mela and Pliny were certainly no more adept in these matters. But, the text of Mela, in spite of its shortcomings, supports my contention that the height of 280 was merely an initial figure in the calculation of the Pyramid, a figure which was reduced in the course of the development of the calculation.

I have analyzed all other ancient authors who provide information about the dimensions of the Pyramid. By a careful collation of their words and phrases, I have established that they all draw, directly or indirectly, on a single source. These authors wrote in Greek or in Latin during the first century of the Roman Empire. They are the historian Diodorus of Sicily (I, 63), the geographer Strabo (XVII, 1, 33), the encyclopedist Pliny the Elder (XXVI, 12, 78–80), and the engineer Philon of Byzantium (*Wonders of* *the World,* II). Their common source is the Greek grammarian Agatharchides of Cnidus, who toward the end of the second century B.C. was guardian to one of the Ptolemy kings of Egypt. Quotations from Agatharchides' lost works indicate that he wrote extensively on the geography of Egypt, with particular emphasis on natural science.

The interesting feature of Agatharchides' report about the dimensions of the Pyramid is that he excludes the pyramidion from the reckoning. We know from the descriptions of other pyramids that the very top of the structure was a small pyramid of metal, usually a precious metal such as gold or silver, which shined in the sun. From Agatharchides' account one gathers that the Great Pyramid of Giza was topped by such a pyramidion, "small pyramid," as the Greeks called it. In the case of this Pyramid, at least, the pyramidion was used to achieve a mathematical result.

In ancient mathematics extensive recourse was made to a mathematical procedure which we no longer use, but which was extremely convenient. If the square root of a number cannot be expressed by an integer, the number is conceived as the product of two integers of which the second is the same as the first, but increased or decreased by a small quantity, usually the unit. Similarly, if the cubic root of a number cannot be expressed by an integer, the number is conceived as a cube in which one side is longer or shorter than the others. For instance, the number 8400 is conceived as a cube with sides 20, 20, and 21. This procedure is called *basi* in Sumerian. I have established that the calculation by what I call near-squares and near-cubes was common not only in theoretical mathematics but also in architecture, land surveying, and the construction of measuring vessels.

The procedure just described was applied in geometry by removing a small part of a figure. For instance, a problem of geometry could be solved by cutting off a slice from a side of a parallelogram. Most commonly the procedure was applied by cutting off a corner of a triangle; this is the reason why the part cut off is called *gnōmōn* in Greek. Most usually *gnōmōn* means "pointer of a dial" in Greek; hence, the term applies perfectly in our case in which the top of the Pyramid was conceived as cut off in the computation presented by Agatharchides.

An essential point of Agatharchides' account is that he describes the Pyramid as having an apothem which measures a stadium up to the pyramidion and having a side which measures 1 1/4 stadia. The term stadium has a double meaning: it refers to 1/10 minute of degree and it refers to a specific unit of measurement. Agatharchides uses the term in both senses.

I have already indicated that the base of the Pyramid has a length of 1 1/4 times 351.6 royal cubits, which for the Egyptians was the length of the stadium (1/10 minute) of the degree of latitude at the equator. From the authors who drew on Agatharchides we gather that he said that the perimeter is 5 stadia, that is, 1/2 minute of degree.

One would have expected the perimeter of the Pyramid to have been calculated by the length of the degree of longitude at the equator, but the builders instead calculated by the degree of latitude, because their concern was the length of the arc of meridian. From Agatharchides we learn that the apothem up to the pyramidion had a length of a stadium, that is, 1/10 of a minute of degree. This permits us to understand what was the specific function of the pyramidion. Since the degrees of latitude increase in length from the equator to the pole, the apothem of the Pyramid up to the pyramidion gave the length of the shortest degree of latitude, the degree at the equator. The pyramidion may have been graduated, giving the length of all the degrees from the equator to the pole. According to Egyptian reckonings, the stadium of the degree of latitude at the equator is 351.6 royal cubits and increases to a length which at the pole the Egyptians assumed to be 355 cubits in practical reckonings and slightly more than 355 cubits in exact reckoning. The apothem of the full Pyramid came to be something less than 356 cubits.

Agatharchides interprets the dimensions of the Pyramid also by taking the word stadium as referring to the stadium of 600 geographic feet. The geographic stadium was the unit most commonly used by the ancients in calculating geographic distances. A stadium was 600 geographic feet, and 600 stadia made a degree. This calculation was correct for the degree of latitude at the middle latitude of Egypt, for the latitude of the capital built by the Pharaoh Akhenaten. According to Agatharchides the side of the Pyramid is 1 1/4 stadia or 750 feet (230,847 millimeters), and the apothem is a stadium or 600 feet. The side of the base of the pyramidion is 9 feet. The figures indicate that Agatharchides was not concerned with presenting the actual dimensions of the Pyramid, but in illustrating the mathematical principles according to which the Pyramid had been conceived.

The figures quoted from the text of Agatharchides by later authors suggest that he began his analysis of the meridian triangle of the Pyramid by presenting a triangle with the following dimensions:

Height:	480 feet
Base:	377 feet
Apothem:	610 feet

This approach gives excellent values of φ and π.

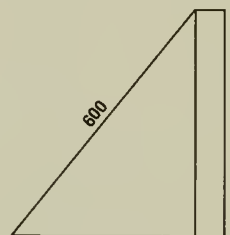
$$\varphi = 610/377 = 1.6180371 \text{ (exactly } \varphi = 1.6180339887)$$
$$1/\varphi = 377/610 = 0.6180328 \text{ (exactly } 1/\varphi = 0.6180339887)$$
$$\pi/4 = 377/480 = 0.785\,41666$$
$$\pi = 3.14166$$

It is impossible to construct a right triangle with sides 480, 377, and 610, since we have:

$$480^2 = 230{,}400$$
$$377^2 = 142{,}129$$
$$610^2 = 372{,}100$$

But the calculation I mention is less off the mark than the calculation by the triangle 280, 220, and 356, which was the one with which the builders of the Pyramid actually began.

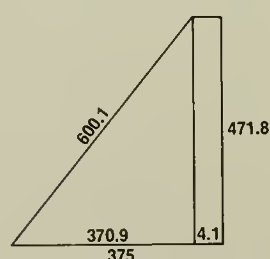
Having started with the mentioned meridian triangle, Agatharchides cut off the side so as to reduce the apothem to 600 feet and the base to 371 feet, excluding the part of the base below the half of the pyramidion.



Since Pliny in quoting Agatharchides does not give the length of a side of the pyramidion (which another author describes as being 9 feet), but the combined length of two sides, I have concluded that the pyramidion had an average side of 9 feet, but had different lengths of different faces.

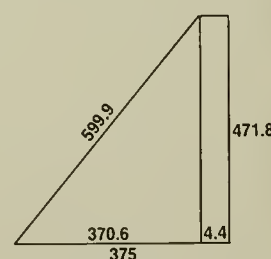
I presume that Agatharchides presented two different meridian sections of the Pyramid, one calculated by the factor φ and one calculated by the factor π.

By φ:



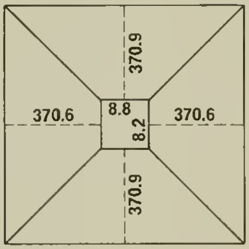
$1/\varphi = 0.61806368$

By π:



$\pi = 3.1420090$

The two possible meridian sections were combined so as to obtain two faces calculated by π and two faces calculated by φ. The Pyramid seen from above would have had the following dimensions:



Like Herodotus, Agatharchides was not concerned with reporting the exact dimensions of the Pyramid, but with presenting the general principles of the mathematics of the Pyramid. This was the point which was of the greatest interest to a Greek audience.

I do not pretend to have reconstructed the authentic reckoning of Agatharchides, but I feel confident that I have understood the general drift of his interpretation. It seems to me that he intended to improve on the presentation of Herodotus, who had only mentioned the factor φ, by stressing the roles both of the factor φ and of the factor π. Agatharchides wanted also to emphasize that the dimensions of the Pyramid were related to the length of the degree of latitude. This was a point of essential importance which had not been mentioned at all by Herodotus.

2. The Egyptians ascribed the invention of the art of building with stone to Imhotep, vizier and architect of King Zoser, who reigned about fifty years before the building of the Great Pyramid. And in fact there has not been found any important building made only of stone blocks which dates before the reign of Zoser. The Egyptians described Imhotep as a sort of Leonardo da Vinci of Egypt, mathematician, scientist, engineer, and architect. Not many years after his death he was made into a demigod, son of Ptah, the god of craftsmen and technicians. Up to recently there were Egyptologists who insisted that Imhotep was a legendary figure. One argument was that there is no other instance in Egyptian history of an ordinary person having bene divinized. But more basic was the argument that a person with all the gifts ascribed to Imhotep could not have existed in the Old Kingdom. It is only in the last few years that it has been definitely accepted that Imhotep was a real person, since it has been possible to gather some specific details of information even about his physical appearance. His genius was recognized even during his life, since King Zoser

covered him with all sorts of honors, although he was a man of humble origin.

But, even though it is now granted that the Egyptians were not living in dreams when they idolized the genius of Imhotep, Egyptologists have failed to investigate what were the scientific achievements of Imhotep other than that he was the first one to have designed a pyramid, the step pyramid of Saqqara. This pyramid is just one element in an enormous group of buildings which is known as Zoser's Complex. This group of buildings is not only so extensive but also so elaborate that nothing of the sort was produced again in the long history of Egypt. In spite of this, not one Egyptologist has tried to investigate this monument and other constructions directed by Imhotep in terms of what the Egyptians said were his talents. Scholars are willing to grant that a man with the name of Imhotep walked on the land in Egypt, but they are not yet willing to grant that Egypt could have produced a mind like his.

The French archeologist Jean Philippe Lauer has dedicated many years to the study of Zoser's Complex. He is a highly competent archeologist and essentially factual and realistic. Actually he has been criticized for insisting too much on technical problems of architecture. For instance, the German Egyptologist Herbert Ricke has disputed point by point Lauer's interpretation of the monuments of Zoser's Complex, claiming that the architecture must be understood in terms of the conflict between the psychological attitudes of nomadic hunters and that of sedentary agriculturists. But Lauer has learned how far the academic community is willing to go in tolerating rational thought in the area of ancient studies. In 1944 he published a short paper in which he tried to deal with the geometry of the pyramids and enlisted the cooperation of a professional mathematician, Paul Montel. But, four years later, when he published the book, *Le Problème des pyramides,* he backtracked and dismissed any mathematical interpretations.

In reporting about Zoser's Complex, Lauer keeps stumbling into mathematical problems, but ignores them. For instance, he found that the wall that surrounds the entire Complex forms a rectangle 544.90 by 277.60 meters. He concludes that it is a matter of a dimension of 1040 by 530 cubits. I would understand that the intended dimensions were 545,114 by 277,799 millimeters, according to the cubit of 524.1483 millimeters. Lauer is surprised at meeting with the figure of 1040 cubits, whereas he would expect 1000 cubits, and explains it away by assigning arbitrarily 40 cubits to the thickness of the walls. But in another part of his work he points out that the same proportions occur in some First Dynasty royal tombs which have dimensions of 54 by 27 meters. It may be enough to point out here that the dimensions of the enclosure of Zoser's Complex are based on the near-square with sides 52 and 53, a mathematical entity of which I have spoken earlier. It is a matter of two near-squares with sides of 520 and 530 royal cubits. It is relevant to what follows that such a near-square has a diagonal of 742.49579, which is 6 times 123.749.

Lauer notices in Zoser's Complex four instances of the occurrence in important positions of the anomalous dimensions of 123 cubits, whereas in the Complex dimensions are generally decimal multiples of the cubit. One of the most impressive remains of the Complex, the monumental entrance gallery, has a length of 123 cubits. Lauer suggests that the Egyptians may have been fascinated by a magic number composed by the first three integers. This is a way of shunting off a problem by appealing to that undefinable entity called magic and by implying, at the same time, that the Egyptians, and their hero Imhotep in particular, were frivolous in matters of mathematics.

Lauer did not realize that the number 123 is an expression in terms of integers of the number $2/\varphi = \sqrt{5} - 1 = 1.236068$. In his book on the pyramids Lauer had denied the occurrence of the factor φ in their architecture.

It is a matter of the right triangle with an angle of 36° which the Egyptians called *mr*. I have suggested that the name *To-Mera,* which the Egyptians gave to their country, was a reference to this triangle. If a right triangle has an angle of 36° and the longer side is 100, the hypotenuse is $2/\varphi\ 100 = 123.6068$, the other side being 72.6542.

Since I have argued that the Great Pyramid was calculated both by the factor φ and by the factor π, I might point out here that there is a close relation between these two numbers, which goes beyond the fact that there is a numerical similarity between $\pi/4 = 0.7853981$ and $\sqrt{1/\varphi} = 0.7861514$. The number φ was used to obtain the value of circular functions, since we have

$$
\begin{aligned}
\sin 18^\circ &= \cos 72^\circ = 1/2\varphi \\
\sin 54^\circ &= \cos 36^\circ = \varphi/2 \\
\sec 36^\circ &= \operatorname{cosec} 54^\circ = 2/\varphi \\
\sec 72^\circ &= \operatorname{cosec} 18^\circ = 2\varphi
\end{aligned}
$$

In practical reckonings the right triangle with an angle of 36° was taken as a triangle with a side of 100 and a hypotenuse of 123. The side opposite the angle of 36° was taken as being 72; this permits us to calculate in terms of half degrees all the trigonometric functions of the angles between 0° and 36°. Since the angle of 36° is 2/5 of a right angle and 1/10 of a full circle, one can calculate from the mentioned triangle the trigonometric functions for all angles.

This is the reason why the triangle *mr* was considered the basic constituent of the cosmic order.

In order to recognize the importance of the right triangle with an angle of 36°, one may start by considering how much attention it received in Euclid's *Elements*. It plays an even greater role in early Greek mathematics. The symbol of the Pythagorean sect, the five-pointed star, was a combination of such triangles.

I have explained that the right triangle with a hypotenuse of 123 was a practical simplification of the triangle of 36° built according to the Golden Section. A further simplification was the right triangle with sides related as 3:4:5. If this triangle is enlarged to the scale of the one with hypotenuse of 123, it has sides 120, 100, and 75, instead of 123, 100, and 72.

I need to point out that the Great Pyramid incorporates the relation 4:5 in the proportion between the length of the apothem up to the pyramidion and the length of the side. This provides a point of transition to an analysis of the dimensions of the Second Pyramid.

The Great Pyramid tried to compress a great number of mathematical relations, whereas the Second Pyramid limited itself to embodying the triangle *mr*.

The basic idea of the Great Pyramid was that it should be a representation of the northern hemisphere, a hemisphere projected on flat surfaces, as is done in mapmaking. This was the principle according to which was built the ziggurat of Babylon, the biblical Tower of Babel, and according to which were built the earlier pyramids. The Great Pyramid was a projection on four triangular surfaces. The apex represented the pole and the perimeter represented the equator. This is the reason why the perimeter is in relation 2π with the height. The Great Pyramid represents the northern hemisphere in a scale 1:43,200; this scale was chosen because there are 86,400 seconds in 24 hours. But then the builders became concerned with the problem of indicating the ratio of polar flattening of the earth and the length of the degrees of latitude which depends on the ratio of this flattening. Next, they incorporated into the Pyramid the factor φ as the key to the structure of the cosmos. The Second Pyramid, on the contrary, limits itself to embodying the trangle *mr*, which is based on the number φ, at least as far as I have been able to establish up to the present moment.

According to Petrie's survey the sides of the Second Pyramid have the following lengths:

West: 215,278 millimeters
North: 215,186 millimeters
East: 215,269 millimeters
South: 215,313 millimeters

The royal cubit of this pyramid is that of 525 millimeters. The basic length of the sides is 410 cubits = 215,250 millimeters.

The meridian triangle of the pyramid is a triangle with proportions 3:4:5. The base is 205 cubits, the height is $4/3 \times 205 = 273.33$ cubits, and the apothem is $5/3 \times 205$ cubits = 341.66 cubits.

Reckoning by third of cubits, we have:

Base: 123×5
Height: 164×5
Apothem: 205×5

Possibly the pyramid was calculated by a rod of 5/3 of a cubit, which is called *nbyw* (*nebiu* in Coptic).

It is clear that this pyramid was intended to incorporate the number 123 as a round figure for $2/\varphi$.

The slope of the pyramid is the same as the angle of problems 67–69 of the Rhind Papyrus. The tangent $164/123 = 1.3333$ corresponds to a slope 53° 07′ 48″. The angle of the apothem with the height is 36° 52′ 12″. This angle was intended to be an approximation to the perfect angle 36°.

The geometry of the Second Pyramid could be considered crude in relation to the sophisticated one of the Great Pyramid, but it emphasizes the importance that the Egyptians attached to the triangle *mr*.

3. Petrie's survey of the Second Pyramid helps in clarifying the problem of the orientation of the sides of the Great Pyramid.

Petrie reported that the four sides of the Second Pyramid are oriented as follows:

West	side:	0° 04′ 21″	west of true north
North	side:	0° 05′ 31″	north of true east
East	side:	0° 06′ 13″	west of true north
South	side:	0° 05′ 40″	north of true east

Petrie warns that the triangulation of Egypt existing at his time did not permit him to establish the direction of north with absolute certainty. Hence, his figures can be taken only as an indication of the angle of the sides in relation to each other.

Petrie's figures prove that the deviation from the right angle in three of the four angles of the Great Pyramid was intentional and not the result of mistakes in construction, as claimed by professional archeologists. The north side of the Second Pyramid is shortened in relation to the south side, as it occurs also in the Great Pyramid. But in the Second Pyramid the shortening of the north side and the lengthening of the south side was achieved by constructing a more regular figure. The base of the Second Pyramid has the shape of a trapeze or a trapezoid. The north and south sides were drawn parallel to each other. Possibly the west side was intended to be at an angle of one minute with the north-south axis, and the west side was intended to be at an angle of half a minute with the north-south axis.

In any case the approximate findings of Petrie indicate that, if one proceeded to a new survey of the Second Pyramid and then surveyed the orientation of the sides of other pyramids and possibly of other major constructions of the Old Kingdom, one could recognize a pattern on the basis of which it could be established what was the purpose in making the angles of pyramids and possibly of other major constructions different from a right angle. It is impossible to formulate a reliable explanation for the differences among the angles of the base of the Great Pyramid without establishing what was the general practice in establishing the angles of the base of pyramids.

I have come across the same difficulty in dealing with the dimensions of Greek temples. I have ascertained that the four angles of the Parthenon were intended to deviate slightly from a right angle. Further, in the case of the Parthenon the north side is shorter than the south side, as in the case of the two major pyramids of Giza. But it is impossible to advance hypotheses in order to explain the differences among the angles of the Parthenon, as long as the angles of other temples are not surveyed so as to make possible the identification of a regular pattern.

There is one further problem to be considered in relation to the orientation of the faces of the Great Pyramid. The west face, which in my opinion was drawn first and is the basic face, is not oriented to the north, but is oriented 2′ 30″ west of true north.

This deviation from orientation to the north is the result of the precession of the equinoxes.

From cuneiform texts one gathers that in Mesopotamia there was a distinction of roles between the mathematician who formulated the general plan of a building and the architect who executed the plan. Whether this distinction existed in Egypt or not, it can be assumed that in the construction of a pyramid the first step was the drawing of a mathematical plan. This plan would include the alignment of the stars to be observed in establishing the direction of the north. If my interpretation of Egyptian sky charts is correct, the line that indicates the north used to be marked so as to pass through the celestial pole and through the pole of the ecliptic.

In any case, it appears that there was drawn a plan of the Great Pyramid which included the calculation of the stars to be observed in order to obtain the direction of the north. After this plan was drawn, the ground of the Pyramid had to be cleared in order to proceed to the ceremony called "stretching of the cord," which for the Egyptians was the equivalent of our laying of the first stone. This ceremony had the purpose of establishing the direction of true north and, as the Egyptians saw it, suspending the building from the sky by tying the building with an imaginary string to the axis of rotation of the vault of heaven.

If there had passed exactly three years from the drawing of the plan to the ceremony of the "stretching of the cord," the clustering of stars, which gave the exact north of the moment of the drawing of the plan, would give an orientation 2′ 30″ west of north, because of the precession of the equinoxes, which displaces the star taken as the polar star in practical calculations to the west at a rate of about 50″ a year.

The Second Pyramid too is oriented west of true north, but unfortunately Petrie's figures for the orientation of this pyramid are not exact, as he himself warns.

The question to be asked is whether the incorporation of the rate of the precession of the equinoxes into the dimensions of the Great Pyramid and of the Second Pyramid was accidental or intended. I am inclined in favor of the second alternative, since in the case of the Great Pyramid the angle corresponds exactly to three years in the precession of the equinoxes. In their book *Hamlet's Mill* de Santillana and Dechend have used mythological and iconographic evidence in order to prove that all ancient cultures of the world were deeply preoccupied with the phenomenon of the precession of the equinoxes. They intended to prove that the movement by which the celestial pole in about 25,920 years (Platonic year) makes a full circle around a point called the pole of the ecliptic was conceived as the basic movement in the life of the universe. This cycle determined all other movements, including biological developments, and determined the length of human life (taken as equal to 72 years, or the time that it takes the celestial pole to move a degree) as well as historical events. The authors of *Hamlet's Mill* have kept their conclusions vague, probably in the hope that thereby their findings would be less readily attacked by the academy. They open their book with the statement: "This is meant to be only an essay. It is a first reconnaissance of a realm well-nigh unexplored and uncharted." This is a most gentle way for a professor of the history of science at the zenith of his career to present a thesis which, if accepted, should have the impact of a Copernican revolution on current conceptions of the development of human culture. Since the essence of my method is quantitative, I cannot indulge in the luxury of such linguistic niceties. I have collected a mass of numerical evidence which shows that the inhabitants of the ancient world were acquainted with the rate of the precession of the equinoxes and attached a major significance to it. But in order to deal with this evidence, I would have to open an entirely new topic. I beg the indulgence of the reader in asking him to remain satisfied for the moment with the mere hint that there is yet another lesson about the level of Egyptian science to be drawn from the stark nakedness of the Great Pyramid.

GLOSSARY OF NAMES AND TERMS

Abd-al-Latif (1179–1231)	Arab historian who taught medicine in Baghdad. Author of one of the early Arab histories of Egypt: *Relation de l'Égypte*. In 1220 he explored the Great Pyramid, reporting that he came out of it "more dead than alive."
Abdullah Al Mamun (d.833)	Caliph of Baghdad, son of Harun al-Rashid. Patronized literature and science; built an astronomical observatory outside Baghdad; ordered a degree of latitude to be measured across the plain of Palmyra. Is reputed to have broken into the Great Pyramid in 820 in search of treasures, but to have come away empty-handed after opening the way to the King's Chamber.
Agatharchides of Cnidus	Greek historian and geographer who lived in the time of Ptolemy Philometor (181–146 B.C.) and dealt with the geography of the Near East.
Akhnaten (1388–1358 B.C.)	Revolutionary pharaoh of the Eighteenth Dynasty who changed his name from Amenophis IV, and broke with the priests of Amon at Thebes. He built a new capital, Akhtaten, between Thebes and Memphis near the site of Tell el-Amarna. Of his religious reform, which was monotheistic and recognized the sun as the symbol of living energy, Petrie remarked: "no such grand theology had ever appeared in the world before."
Akhtaten (Resting point of Aten)	Capital built by the young pharaoh Akhnaten at the predynastic geodetic center of Egypt, halfway between the Tropic and the Mediterranean coast, near the site called Tell el-Amarna. The city, which was decorated with splendid temples and palaces, was destroyed after Akhnaten's death.
Ali Gabri (1830–19?)	Arab guide, sometimes referred to as Alee Dobree, who was an assistant to Howard-Vyse, Piazzi Smyth, Sir Flinders Petrie, and Moses B. Cotsworth over a period of nearly seventy years, helping them explore and measure the Great Pyramid.
Alvarez, Luis Walter (1911–)	Nuclear physicist. Professor of physics at Lawrence Radiation Laboratory, Berkeley, California. Nobel Prize winner for physics in 1968. Developer of radar. Helped develop A-bomb and flew in B-29 observer following the plane that bombed Hiroshima. One of the youngest members to be elected to the National Academy of Science. Author of several scientific articles. Adapted spark chamber to X-ray the pyramids with cosmic rays.
Amèlineau, Emile (1850–1915)	Studied Egyptian and Coptic under Maspero. Did much excavating but was criticized by Petrie and Maspero for unscientific methods. Professor of history of religions in École des Hautes Études in Paris, where he died in 1915. Author of several volumes on ancient Egyptian history and science.
Amenemhet	Four Pharaohs of the Twelfth Dynasty, the first of which reigned from ca. 1991 to 1962 B.C.

Amon	A god who was related to the wind, promoted to an imperial divinity at the beginning of the Twelfth Dynasty as Amon-Ra. Amon was considered the creator of other gods, and to have had no beginning and no end.
Ancient Empire	From the Third to Sixth dynasties, variously estimated, but approximately 2780 to 2280 B.C. There is little historical data on this period, most of the relevant papyri having disappeared. Under the influence of King Zoser and his architect Imhotep, brick structures gave way to stone. The political center was at Memphis.
anomalistic year	365 days, 6 hours, 13 minutes, 48 seconds. The time it takes the earth to return in its elliptical orbit to the point nearest the sun —about 4¾ minutes longer than the sidereal year.
apothem (of a pyramid)	The distance from the apex down one face to the center of a base side.
Arya-Bhata (b. 476–?)	Hindu astronomer and mathematician, author of Aryabhatiya which gave the rules of mathematics as known in his time. Most of his work deals with astronomy and spherical trigonometry. Gave a value for π of 3 177/1250, or 3.1416. Taught that the daily rotation of the heavens was an appearance due to the earth's rotation on its axis.
Aten	God of the solar orb, raised to a prime position by Akhnaten. Represented by a golden disc radiating rays that end in hands. Was considered a universal deity who could have held sway over a universal empire.
azimuth	Angle of arc around the horizon, or angular distance of an observed point from geographic north (or other fixed point).
Ballard, Robert T.	Australian engineer who made a study of the pyramids in 1882 which he wrote up in "The Solution of the Pyramid Problem; or, Pyramid Discoveries with a New Theory as to Their Ancient Use."
Barnard, Professor F. A. P. (1809–1889)	President of Columbia University (1864) and president of the American Association for the Advancement of Science. An authority on weights and measures, he took issue with the conclusions about the Pyramid drawn by Piazzi Smyth and other pyramidologists.
Behdet	Town in lower Egypt which was the capital of Egypt in predynastic times. In Ptolemaic times it was the capital of a nome and was known to the Romans as Hermopolis Parva. In Stecchini's reconstruction of the ancient geography, Behdet was the northern limit of Egypt, 7 1/2° north of the Tropic.
Belzoni, Giovanni Battista (1778–1823)	Italian explorer and adventurer. A large and powerful man, six feet seven inches, who exhibited himself in feats of strength. He came to Egypt to demonstrate a hydraulic machine he had invented, but when the machine proved unsuccessful he turned to archeology and discovered several tombs as well as the entrance to Kephren's pyramid. A narrative of his exploits was published in 1820.
Biot, Jean Baptiste (1774–1862)	French physicist, professor of mathematics at Beauvois and professor of physics at the Collège de France. A prolific writer, he covered a wide field of physical science, becoming a member of the Academy of Sciences and a commander of the *Légion d'Honneur*. He was especially interested in the astronomy of the ancient Egyptians.

The Book of the Dead	An Egyptian collection of hermetic inscriptions and papyri purportedly providing funerary and ritual texts.
Borchardt, Ludwig (1863–1938)	German Egyptologist. Studied Egyptology at Berlin University under Professor Johan Erman. Worked at Philae in Egypt in 1895, and conducted many excavations in subsequent years. Inaugurated the great Catalogue of Cairo Museum with Professor Gaston Maspero. Founded German Institute of Archeology in Cairo. A bibliography of his many writings was issued in 1933.
Bouchard, Pierre-François-Xavier, Captain (1772–1832)	Engineer working on Fort Julien near Rosetta, 70 kilometers east of Alexandria, in 1799 found the Rosetta Stone as part of an old wall.
Brugsch, (Pasha) Karl H. (1827–1894)	German Egyptologist sent to Egypt by the Prussian government in 1853. Consul general in Cairo, 1864, then professor of Egyptology at Göttingen, 1868. Director of School of Egyptology in Cairo. Published a demotic grammar, a hieroglyphic dictionary, and a history of Egypt.
Brunés, Tons	Danish consulting engineer and Freemason who devoted a score of years to resolving the problems of ancient geometry. In 1967 he published a six-hundred-page two-volume book, *The Secrets of Ancient Geometry,* in which he attempted to substitute a "Sacred Cut" for the Golden Section or phi relation.
Budge, Sir Ernest Alfred Wallis (1857–1934)	Orientalist. Keeper of Egyptian and Assyrian Antiquities at the British Museum. Large published output including popular and semipopular works. Compiled an Egyptian dictionary, and a full edition of *The Book of the Dead.*
Burattini, Tito Livio (16?–1682)	Italian follower of Father Athanasius Kircher. Made several trips to the Great Pyramid and took measurements with Greaves which were used by Newton in his first calculations for the theory of gravitation. A Venetian by birth, Burattini spent the better part of his maturity in Poland. Author of works on standards of measure and the use of pendulums.
Cabala	A system of mystical interpretation of Scriptures practiced by certain medieval Jewish rabbis and certain Christian sects, on the assumption that Scriptures have an occult meaning.
Campbell, Patrick, Colonel (1779–1857)	Army officer and diplomat. British consul general in Egypt, 1833 to 1840. Associate of Colonel Howard-Vyse in exploration of pyramids, who named for him one of the construction chambers above the King's Chamber in the Great Pyramid.
Cardano, Girolamo (1501–1576)	Milanese doctor, mathematician, and astronomer, author of several books. His works in mathematics include treatises on arithmetic and algebra. He referred to ancient traditions as indicating the Great Pyramid incorporated an earth commensurate unit of measure of great exactness.
cardinal points of the compass	North, east, south, west.
cartouche	An oblong figure containing a Pharaoh's name.
Cayce, Edgar (1877–1945)	American clairvoyant whose thousands of readings while in trance are filed in a foundation created in his memory at Virginia Beach, Virginia. Had many memories as a being at the time of Atlantis and the construction of the Pyramid, but readings lack solid data.
Cassini, Gian Domenico (1625–1712)	French astronomer and geodesist of Italian origin, founder of a family of geodesists. He measured meridian arc through Paris.

	Was assisted by his son Giacomo (1677–1756), who was assisted by his grandson Cesare Francesco (1714–1784). His great-grandson, Giacomo Domenico, also a geodesist and astronomer, was born in Paris in 1747 and died 1845.
Caviglia, Giovanni Battista (1770–1845)	Genoese mariner, owner and master of a trading vessel in the Mediterranean based on Malta. Regarded himself as a British subject. Explored the pyramids and the Great Sphinx, from whose base he had great quantities of sand removed. An ingenious excavator, he discovered the outlet to the well in the Great Pyramid and was in charge of several hundred men excavating for Colonel Howard-Vyse until they quarreled. Caviglia was given to occultism and mysticism, and spent his final years in Paris as a protégé of Lord Elgin.
celestial equator	A great circle produced by projecting the earth's equator outward to the celestial sphere.
Champollion, Jean-François (1790–1832)	At 16 at the Academy of Grenoble, Champollion presented a thesis in support of Father Athanasius Kircher's idea that Coptic was a degeneration of ancient Egyptian. The discovery of the Rosetta Stone by Napoleon's troops helped Champollion to decipher the system of ancient Egyptian hieroglyphs.
clinkstone	Compact grayish rock which clinks like metal when struck.
clinometer	A device to measure angle of slope.
Cole, J. H.	British surveyor who carried out the official survey of the Great Pyramid for the Egyptian government in 1925. His measurements made it possible to know the dimensions of the base of the Pyramid to within a few millimeters, and put an end to years of controversy.
corbeled masonry	An arrangement of stones in which successive courses project beyond those below.
Cotsworth, Moses B. (1859–1943)	British legislative enthusiast who wrote a series of pamphlets and books advocating a more rational almanac and demonstrating how the pyramids, obelisks, Druid circles, and mounds were erected as yearly almanacs. Expatriated to Canada, where he died during World War II.
Cottrell, Leonard (1913–)	British author of several books on Egyptian history and the pyramids. Writer and producer for radio and television.
Davison, Nathaniel (?–1783)	Accompanied Edward Wortley Montagu on his travels in the East. Arrived at the Great Pyramid in July of 1765, where he discovered the first construction chamber over the King's Chamber, which has since been named for him. Was later British consul general at Algiers until his death in 1783.
decans	Ten-day periods marked by the passage of constellations by which the Egyptians divided the year into thirty-six units.
declination	Angular distance of a heavenly body north or south of the celestial equator; analogous to latitude on the stellar vault.
Dendera	Ancient site of a Ptolemic temple compound about 60 kilometers north of Luxor on the east bank of the Nile dedicated to Hathor and Isis. Several temples are believed to have been constructed on the site, attributed to Cheops, Pepi I, and earlier monarchs. A zodiac on the ceiling of an upper room was removed and is now on display at the Louvre where it has been the object of heated controversy as to its age and significance.

Denon, Baron Dominique Vivant (1747–1825)	French antiquary and man of letters. Joined Napoleon's expedition and made many remarkable drawings. Published *Voyage dans la basse et la haute Egypte,* 1802, which was an instant success; translated into German and English. Appointed director-general of French Museums.
Didoufri	Fourth Dynasty king who succeeded Cheops and preceded Kephren.
Diodorus Siculus	Greek historian of the first century B.C. Published a history, or *Bibliotheca historica*, the first surviving book of which deals with Egypt, to which he traveled about 60 B.C. In his geography he quotes various lost sources.
diurnal pattern	The apparent movement of the stars in each rotation of the earth.
Dümichen, Johnnes (1833–1894)	German Egyptologist. Professor of Egyptology, Strassbourg, 1872–1894. Several publications. Traveled frequently to Egypt.
dynasties	Thirty dynasties of Egyptian kings were listed by the priest Manetho, from Menes to Ptolemy II Philadelphus. Though erratic, the list has formed the basis of Egyptian history for succeeding Egyptologists.
Edfu	Ancient temple said to have been built during the Third Dynasty. Capital city of second nome of Upper Egypt on the west bank of the Nile, 100 miles downstream from Thebes. Site of huge sandstone temple dedicated to Horus, constructed in Ptolemaic times, and found half buried in the sand by Napoleon's forces during their campaign in Upper Egypt.
Edwards, I. E. S. (1909–)	British author and Egyptologist. Keeper of Egyptian Antiquities British Museum since 1955. Visiting professor at Brown University, 1953–1954.
Egyptian mysteries	Secret knowledge of the cosmos possessed by initiates.
Elephantine	Island in the Nile just north of the first cataract, which was used as a geodetic point. Known as the city of the elephants, capital of the first nome in Upper Egypt on the border of Nubia. Opposite Syene, the modern Aswan.
Engelbach, Reginald (1880–1946)	British engineer and Egyptologist. Assisted Petrie in several digs. Appointed Chief Inspector in Upper Egypt for the Services des Antiquités. Keeper of Cairo Museum 1931. Published work on obelisks and Egyptian masonry.
equinox	Time at which the sun crosses the equator in March and September (vernal and autumnal) when day and night are of equal length all over the earth.
Fibonacci, Leonardo Bigollo (1179–1250)	Italian mathematician, known as Leonardo da Pisa. His *Liber Abaci* (1202) was for years a standard work on algebra and arithmetic. In *Practica Geometriae* (1220) he organized and extended material in geometry and trigonometry. The Fibonacci series, which he popularized in Europe in the thirteenth century, appears in the construction of the Great Pyramid several millennia earlier.
Fibonacci series	A sequence of numbers in which each is the sum of the two previous numbers—1, 2, 3, 5, 8, 13 . . . The limit of this series gives the exact value of φ.
Firth, Cecil Mallaby (1878–1931)	British Egyptologist. Served thirty years in Service des Antiquités.
geodetic gnomon	A vertical pillar whose shadow can be used to determine time, distance, and latitude.

Golden Section (ϕ proportion) — Division of a line (or geometric figure) so that the proportion of the smaller section to the larger is the same as that of the larger to the whole. For example, in the line below, the Golden Section is such that AB:AC = AC:CB.

A ——————— C ———— B

Greaves, John (1602–1652) — Mathematician and antiquarian. Son of Rector of Colemore in Hampshire. Educated at Baliol College, Oxford. Professor of geometry at Gresham College, London. Traveled to the East to collect Arabic and Persian manuscripts. Made the first accurate survey of the Great Pyramid during a trip to Egypt in 1639. Author of *Pyramidographia*. Appointed Savilian professor of Astronomy in reign of Charles I; dismissed by Roundheads.

Hapy — The animating spirit of the Nile, self-engendered; lord of the fish represented by an androgynous divinity crowned by a papyrus reed.

Hathor — Egyptian goddess, originally a personification of the sky. In the Dendera cult, Hathor was considered the wife of Horus. The Greeks identified Hathor with Aphrodite.

heliacal rising (or setting) — Observation of a star as close as possible to the rising or setting of the sun.

heliocentric pattern — The arrangement of the planets in orbits around the sun.

Heliopolis (or On or Annu) — Northeast of Cairo on the edge of the desert; believed to be the capital of a prehistoric state. City of the Sun, embellished by a series of kings from the Third Dynasty on, it was the seat of temple of priests who numbered as many as twelve thousand. Ancient center of theological learning. It was reduced by Alexander the Great in the fourth century B.C. One of the earliest obelisks was found still standing at Heliopolis.

Herodotus (484–425 B.C.) — Greek historian born in Asia Minor. Visited Egypt towards the end of the first Persian domination. In his *History* he devoted a book (called Euterpe, after the muse of lyric song) to Egypt, giving many interesting and accurate details of geography.

Herschel, Sir John (1792–1871) — Astronomer, only son of astronomer Sir William Herschel. Made a fellow of the Royal Society at twenty-one for a brilliant mathematical investigation. Author of books on mathematics and astronomy considered among the elevating influences of the century.

Horus — Prehistoric Egyptian sky god in the form of a falcon whose eyes were the sun and moon; also called the "Behdetite" in the form of a winged sun-disk. Later incorporated in the Osiris cycle. Identified by the Greeks with Apollo.

Howard-Vyse, Colonel (later Major General) Richard William (1784–1853) — Son of General Richard Vyse and grandson of Field Marshal Sir George Howard. Retired as Colonel of Second Life Guards, 1826. Equerry to the king of Hanover. Member of Parliament. Traveled to the Middle East in 1835, where he organized excavation of the pyramids in 1837, employing Caviglia and hundreds of other workers. Discovered original casing stones and found chambers above Davison's. Author of *Operations Carried on at the Pyramids of Gizeh in 1837.*

Hyksos — Asiatic kings who invaded Egypt and formed the Fifteenth and Sixteenth dynasties. They were chased out of Egypt by Ahmosis I who founded the Eighteenth Dynasty.

ibn-Batuta (ca. 1352)	Mohammedan traveler. Said the pyramids were built by Hermes, who is the same person as the biblical Enoch, to preserve the arts and sciences, and other scientific acquirements, during the flood. Said dream occurred to King Surid that the Pyramid would be opened on the north side, so he deposited a sum of money equal to the expense of excavation.
Imhotep (ca. 2800 B.C.)	King Zoser's architect, who is accredited with the building of the stepped pyramid of Saqqara, of limestone. He is reputed to have been an author, diplomat, architect, and physician.
Ka	Metaphysical part of human being. Lived only on the essence of foods and was satisfied with facsimiles of food and mock buildings which had only façades.
Lepsius, Karl Richard (1810–1884)	German Egyptologist. Led Prussian expedition to Egypt and Nubia. Published seventeen folio volumes of *Denkmäler,* mostly epigraphic material. Keeper of Egyptian collections of Berlin from 1873.
Lieder, Rudolph Theophilus (1797–1865)	German missionary. Member of the Egyptian Society of Cairo, 1836. Collected antiquities.
Lindsay, (Lord) Alexander William Crawford (afterwards 25th Earl of Crawford and 8th Earl of Balcarres) (1812–1880)	Traveler and writer on art. His *Letters from Egypt,* etc., contain particulars on Caviglia.
Lockyer, Sir Joseph Norman (1836–1920)	English astronomer, educated on the continent of Europe; knighted for his work in spectroscopy and for identifying helium in the sun. The author of several books on the astronomy of ancient peoples, he was the first to demonstrate convincingly how ancient Egyptian temples were used as solar and stellar observatories and almanacs.
Luxor	Part of the ancient site of Thebes. A huge temple dedicated to the god Amon was built in the reign of Amenhotep III, and altered by succeeding Pharaohs, especially by Rameses II, who had many colossal statues of himself erected on the grounds.
Mandeville, Sir John (fl. 1356)	Fabulous writer of traveler's guidebooks. Most of his data were available in contemporary travel books and encyclopedias. His "voyages" are believed to be the work of a notary in Belgium who never traveled abroad.
Manetho	Egyptian priest and annalist in the reign of Ptolemy I who wrote a history of Egypt in Greek, only fragments of which remain. His division of the kings of Egypt into thirty dynasties is still the basic structure underlying Egyptian history.
Mariette, (Pasha) Auguste (1821–1881)	French Egyptologist. Traveled to Egypt to collect Coptic manuscripts and engaged in excavations. Appointed Conservator of Egyptian Monuments by the Khedive and settled in Egypt, where he made numerous finds which became the nucleus of the Cairo Museum.
Maspero, Sir Gaston Camille Charles (1846–1916)	French Egyptologist of Italian origin. Professor of Egyptology at Collège de France. Succeeded Mariette as director of the Services des Antiquités. Wrote many scientific memoirs and a large number of popular books and reviews.
mastaba	An oblong masonry structure with sloping sides and a flat top, usually above a deep pit.

Menes (fl. 3400 B.C. [3500?])	First historic ruler of the First Dynasty of ancient Egypt, who is reputed to have united the southern and northern kingdoms and settled on a new capital on the Nile at the point of juncture at Memphis.
mensuration	The science of measurement.
meridian	A great circle passing through the poles of the celestial sphere and the zenith of a fixed point on earth.
Meroe	Village in the Sudan on the Nile north of Khartoum which still has ruins of temples and pyramids.
Middle Kingdom	Twelfth to Fourteenth dynasties, from 2000 to 1600 B.C. Follows first intermediate period of chaotic conditions. The capital was at Thebes.
Minutoli, Johann Heinrich Carl, Freiherr von (1772–1846)	Prussian officer of Italian origin. Collected large quantities of antiquities. Published *Mes souvenirs en Egypte.*
New Kingdom	Covers Eighteenth and Nineteenth dynasties, 1580–1350 and 1350–1200 B.C. The Hyksos invaders were crushed and a military state embarked on wide conquest from as far as Cush to the Euphrates.
nilometer	An instrument for measuring the height of the Nile.
Nubia	Ancient region, originally called Cush, extending from the Nile Valley near Aswan southward to the modern Khartoum, east to the Red Sea and west to the Libyan desert.
obelisk	A tapered four-sided pillar used for measuring shadow length, usually inscribed with hieroglyphs proclaiming the achievements of a Pharaoh.
omphalos	Navel, or a central point on the surface of the earth.
Pepi	Two pharaohs of the Sixth Dynasty.
Perring, John Shae (1813–1869)	British civil engineer. Assistant to manager of public works for Khedive Mohammed Ali. Assisted Colonel Howard-Vyse in survey and exploration of the pyramids. In 1839 wrote and drew pictures for a large folio, *The Pyramids of Gizeh from Actual Survey and Measurement on the Spot.*
Petrie, Sir (William Matthew) Flinders (1853–1942)	Egyptologist, son of William Petrie, a civil engineer, and Anne, daughter of Matthew Flinders, the explorer of Australia. Surveyed ancient British sites such as Stonehenge before making first scientific survey of Giza hill. Founded the British School of Archaeology in Egypt. Responsible for many excavations and numerous books. He is considered the father of modern scientific archeology.
ϕ (phi) proportion	See Golden Section.
π (pi)	The constant by which the diameter of any circle may be multiplied to give its circumference.
Picard, Jean (1620–1682)	French astronomer, noted for having made the first accurate modern measurement of a degree of the earth's meridian. His figures enabled Newton to calculate the force of gravitation. Occupied the chair of astronomy in the Collège de France in 1655. Largely responsible for the establishment of the Paris Observatory and the appearance of *Connaissance des temps,* the first two volumes of which he authored.
Pococke, Richard (1704–1765)	Traveler and divine, bishop of Ossory (1756–1765). Ascended the Nile as far as Philae. The manuscript journal of his travels is in the British Museum.

precession of the equinoxes	Each year at the spring equinox the constellation in the sky where the sun rises due east appears to have fallen back about twenty minutes. This phenomenon, or precession, is caused by a slow toplike wobble of the earth on its axis which takes about 26,000 years to cycle.
Proctor, Richard Anthony (1837–1888)	English astronomer and popular writer on scientific subjects. Founded the popular scientific magazine *Knowledge*. Lectured in the United States and Australia. Author of many books on science and astronomy. Developed the theory that the Great Pyramid had been designed and used as a great astronomical observatory while still a truncated body at the level of the King's Chamber.
Ptah	Called Hephaistos by the Greeks. Egyptian god of the city of Memphis, portrayed as a human figure in a tight mummy wrapping. Considered the creator of the world who produced visible phenomena through thought and the word. The protector of artisans. His high priest was the doyen of master craftsmen.
Pylon	A double tower with rectangular base pierced by central door to a temple. The temple of Karnak had ten pylons.
Pythagoras' theorem	The square of the hypotenuse of a right triangle is equal to the sum of the squares of the other two sides.
Ra	The sun, later deified. Creator of the world, was said to be swallowed at night by Nut and recreated fresh each day.
Reisner, George Andrew (1867–1942)	American Egyptologist (Ph.D., Harvard University, 1893). Director of the Hearst expedition to Egypt 1905–1907. Excavated for Harvard University for many years in Egypt, particularly at Giza. Professor of Egyptology at Harvard (1914–1942). Curator of Egyptian Department, Boston Museum of Fine Arts (1910–1942). Author of several books on archeological excavations.
Rhind, Henry Alexander (1833–1863)	Scottish lawyer and traveler. Owing to ill health was obliged to winter in Egypt. Excavated at Thebes and bequeathed collection to National Museum of Antiquities, Edinburgh. Noted for the Mathematical Papyrus (BM10057–8), which was sold to the British Museum, and is considered the oldest manuscript dealing with Egyptian mathematics.
right ascension	The arc along the celestial equator which separates a star from an arbitrary zero point; analogous to longitude around the stellar vault.
sacred triangles	Right triangles with sides in such proportions as 3–4–5 or $2–\sqrt{5}–3$, which were credited with magic or esthetic properties.
Saqqara	Situated 28 kilometers south of modern Cairo, just west of Memphis and south of Giza. Ancient burial site named after Sokar, the god of measure. Graves date from the First Dynasty. Pyramids attributed to the Fifth and Sixth dynasties. Site of the stepped pyramid built for King Zoser of the Third Dynasty by the architect Imhotep.
Schwaller de Lubicz, R. A. (?–1961)	Philosopher, archeologist, and author who spent twelve years at Luxor reconstructing the philosophical and theological system of the ancient Egyptians. Born in Alsace, he was granted the title Chevalier de Lubicz by O. W. de Lubicz Milosz for his help after World War I in obtaining independence for the Baltic States.
sextant	An instrument for precise measurement of angular distances to determine latitude and longitude.

sidereal year	The time it takes the earth to revolve around the sun so that an observer will see a given star reappear in the same position—about 20 minutes longer than the solar year.
Sneferu (ca. 2700 B.C.)	First king of the Fourth Dynasty. Father of Cheops. Built bent pyramid at Medûm.
solar parallax	The angle formed by the semidiameter of the earth as regarded from the sun, or 8.80″.
solar year	The time between two successive equinoxes 365 days, 5 hours, 8 minutes, 49.7 seconds 365 days, 5 hours, 48 minutes, 46 seconds
solstice	The two points—in summer and winter—when the sun is at its greatest declination north or south of the equator.
Sothic year	365 days, 6 hours—introduced in ancient Egypt to correct the civil calendar year of 365 days. A "Sothic cycle" began when civil and Sothic new year coincided.
Syene	Site of the modern Aswan. The southern limit of Egypt at the First Cataract of the Nile, close to the Tropic of Cancer. Nearby quarries supplied the hard granite monoliths for the King's Chamber in the Great Pyramid and for the tall Egyptian obelisks used for measuring shadows.
Taylor, John (1781–1864)	Devoted his early years to publishing in London, becoming editor of the *London* Magazine. An amateur astronomer and mathematician, he was also a student of Scripture and devoted much time to mastering Old English, Welsh, French, and Italian. His *The Great Pyramid: Why Was It Built & Who Built It?,* published in 1854, established the π proportion in the pyramid, but his theory, that the Great Pyramid had been built under divine guidance, caused his work to be disputed and he was given little recognition.
Thebes	Ancient city in upper Egypt renowned in antiquity for its hundred gates. Became prominent with the Eleventh Dynasty (c. 2160 B.C.) for the worship of Amon. Went into decline when the locus of power shifted to the Nile Delta. There is a nearby large necropolis where kings and nobles were entombed. It was sacked by the Assyrians in 661 B.C. The remains of the temples of Luxor and Karnak are still among the most impressive in the world.
theodolite	A telescopic instrument for precise measurement of horizontal angles, used in land surveying.
Thoth	Lunar god in form of Ibis, patron of scribes and calendars. The Hermes of the Greeks.
triangulation	By carefully measuring a base line and the angles formed by either end of it with a distant point, the distance of the point may be calculated by trigonometry.
vernier	A small moveable scale attached to a large scale for obtaining finer fractions of measurements.
ziggurat	The stepped-pyramid temples of Mesopotamia.

ACKNOWLEDGMENTS

My first debt is to the courteous and efficient staff of the Library of Congress, whose institution—along with those of other helpful librarians round the world—made the research for this book a delight instead of an ordeal; they are a better and cheaper investment for our future than more weapons of destruction.

To Geraldine Dent, of Hopewell, New Jersey, and to Edward O. Mitchell, of McLean, Virginia, I wish to express my gratitude for painstaking help in reproducing the pictures which adorn this volume; to Diagram Ltd. of London for the streamlined drawings which illustrate the text.

Father Francis J. Heyden, S.J., Director of Georgetown College Observatory, I wish to thank for his cheerful encouragement in the face of monumental problems: and Monsignor Patrick W. Skehan for his kind assistance with the weighty tomes of the Semitics Library of Catholic University.

For a careful checking of the mathematical properties incorporated in the Great Pyramid I am indebted to Philippe Dennery, author of *Mathematics for Physicists.* His mathematical analysis of the secret geometric structure of the Great Pyramid as discovered by the Danish engineer Tons Brunés, made it possible to resolve the problem of the geodetic and geographic functions of the pyramid.

Most grateful I am to Livio Catullo Stecchini, Professor of the History of Science (characterized by Professor Giorgio de Santillana of MIT as "a Copernicus of the twentieth century"), for permission to quote from numerous unpublished monographs, the fruit of thirty years research into the advanced science of geography, geodesy and astronomy developed by the ancient Egyptians and Sumerians, several of which appear for the first time in the appendix to this volume.

This is indeed a cumulative effort, and I hope that my successors in pyramidal quests will be as lively and entertaining as have been my predecessors.

I have taken the book's 350 illustrations from the most disparate Medieval, Renaissance, Romantic, and Modern sources, from the 400 engravers of Napoleon's 20-volume *Description de l'Egypte* to the most recent archeological journals.

I am indebted to the Royal Society of Edinburgh for the original plates of the first photographs ever taken inside the Great Pyramid, by Professor Piazzi Smyth in 1865.

In particular I wish to thank Manly P. Hall for permission to reproduce the illustrations on pages 4 and 257 from his *Encyclopedic Outline of Masonic, Hermetic, Qabalistic and Rosicrucian Symbolical Philosophy;* Mlle. Lucy Lamy for permission to reproduce from the works of R. A. Schwaller de Lubicz, published in Paris by Flammarion and Caractères; Charles E. Jeanneret-Gris, better known as Le Corbusier, for the illustrations on page 192, from his *The Modulor,* published by Harvard University Press; Albert Champdor for the illustration on page 259, from his *Le Livre des Morts,* published by Albin Michel; C. Funk-Hellet for illustrations from his *La Bible et la Grande Pyramide,* published by Vincent Fréal; David Davidson for several plates from his *The Great Pyramid: Its Divine Message,* published by Williams & Norgate; Morton Edgar for plates from his *The Great Pyramid, Its Scientific Features,* published by Bone & Hulley; Howard B. Rand for the intricate interior of the Pyramid on page 28, from his *The Challenge of the Great Pyramid,* published by Destiny Publishers; Ludwig Borchardt for line drawings from his various works listed in the bibliography; Georges Goyon for the illustrations on pages 252 and 254 from *Revue Archéologique;* Adam Rutherford for the photographs and diagrams appearing on pages 7, 66, 69, 104, 110, 116, and 248 derived from the third volume of his five volume *Pyramidology* published in Harpenden, Hertfordshire, by the Institute of Pyramidology; Leonard Cottrell for the portrait of Flinders Petrie from his book *The Mountains of Pharaoh,* published by J. Hale; and Sir Flinders Petrie for the illustrations on pages 98 and 99 from his *70 Years in Archeology,* published by S. Low, Marston in London. The cover and the extraordinary interiors of the Grand Gallery and the King's Chamber on pages 14 and 16 are from Ludwig Mayer's *Views of Egypt from the Original Drawings in the Possession of Sir Robert Ainsley During his Embassy in Constantinople,* published in London in 1804.

INTRODUCTION TO THE PAPERBACK EDITION

The astronomical, mathematical, and geodetic science of the ancient inhabitants of Egypt, their cosmology and theology, are only beginning to be appreciated.

The degree of prejudice that for the past few thousand years has obscured the physical and metaphysical wisdom of the ancients is beginning to dissolve, and their perennial wisdom may still be in time to save a planet rushing headlong to self-destruction.

When I began to write this book some twenty years ago, I suspected that the Great Pyramid might incorporate a secret or secrets, the revelation of which could lead to a better understanding of the cosmos and man's place in it.

I did not realize by half the depth of knowledge it incorporates. The veil is only parted, not removed. Dangerous as it is to venture into areas peripheral to accepted dogma, it is fortunate that even eight years after the original publication of this book, no one in or out of the academic world has faulted the basic premises; further scholarship has merely reinforced them.

In my narrative reconstruction of the discoveries made in and about the Great Pyramid I may have underplayed my own notions about the earth commensurate relation of ancient feet and cubits the base and apothem of the structure. Yet now that our figures for the dimensions of this planet have been refined by orbiting satellites, the results are that much closer to the figures mysteriously built into the so-called Pyramid of Cheops. And the Egyptian units are not only earth commensurate but cosmic—which makes it clearer why the Meso-American contemporaries of the Egyptians named their prime deity Hunab-Ku, sole dispenser of a movement and measure. It is measure which informs this universe: the same measure upon which all of modern science is dependent.

Wherefore I commend the appendix written by Livio Stecchini, one of the world's leading authorities on ancient mensuration.

Plato was not idle when he placed the apparently senseless dictum 'Αγεωμετρητος μηοεις εισιτω ("Those who don't know geometry stay away") over the doorway to his academy. As one reader of this volume, William Kelley, was quick to demonstrate, the hermetic meaning cryptically encoded in the dictum is that without geometry no one may enter into the secret of universal measure. The key to that geometry is encoded in the Pyramid.

INTRODUCTION

Does the Great Pyramid of Cheops enshrine a lost science? Was this last remaining of the Seven Wonders of the World, often described as the most sublime landmark in history, designed by mysterious architects who had a deeper knowledge of the secrets of this universe than those who followed them?

For centuries a debate has been waged between supporters of such a theory and its opponents, with eminent scientists and academicians lining up on either side. Though all agree that the Great Pyramid is at least four thousand years old, none can say for certain just when it was built, by whom, or why.

Till recently there was no proof that the inhabitants of Egypt of five thousand years ago were capable of the precise astronomical calculations and mathematical solutions required to locate, orient and build the pyramid where it stands.

It was attributed to chance that the foundations were almost perfectly oriented to true north, that its structure incorporated a value for π (the constant by which the diameter of a circle may be multiplied to give its true circumference) accurate to several decimals and in several distinct and unmistakable ways; that its main chamber incorporated the "sacred" 3–4–5 and 2–$\sqrt{5}$–3 triangles ($a^2 + b^2 = c^2$) which were to make Pythagoras famous, and which Plato in his *Timaeus* claimed as the building blocks of the cosmos. Chance was said to be responsible for the fact that the Pyramid's angles and slopes display an advanced understanding of trigonometric values, that its shape quite precisely incorporates the fundamental proportions of the "Golden Section," known today by the Greek letter φ (pronounced *phi*), revered equally by masters of the *cinquecento* and luminaries of modern architecture.

According to modern academicians the first rough use of π in Egypt was not till about 1700 B.C.—at least a millennium after the Pyramid; Pythagoras' theorem is attributed to the fifth century B.C.; and the development of trigonometry to Hipparchus in the second century before Christ. That is what the Egyptologists say, and that is what they put in their textbooks.

Now the whole subject has had to be reviewed.

Recent studies of ancient Egyptian hieroglyphs and the cuneiform mathematical tablets of the Babylonians and Sumerians have established that an advanced science did flourish in the Middle East at least three thousand years before Christ, and that Pythagoras, Eratosthenes, Hipparchus and other Greeks reputed to have originated mathematics on this planet merely picked up fragments of an ancient science evolved by remote and unknown predecessors.

The Great Pyramid, like most of the great temples of antiquity, was designed on the basis of a hermetic geometry known only to a restricted group of initiates, mere traces of which percolated to the Classical and Alexandrian Greeks.

These and other recent discoveries have made it possible to reanalyze the entire history of the Great Pyramid with a whole new set of references: the results are explosive. The common—and indeed authoritative—assumption that the Pyramid was just another tomb built to memorialize some vainglorious Pharaoh is proved to be false.

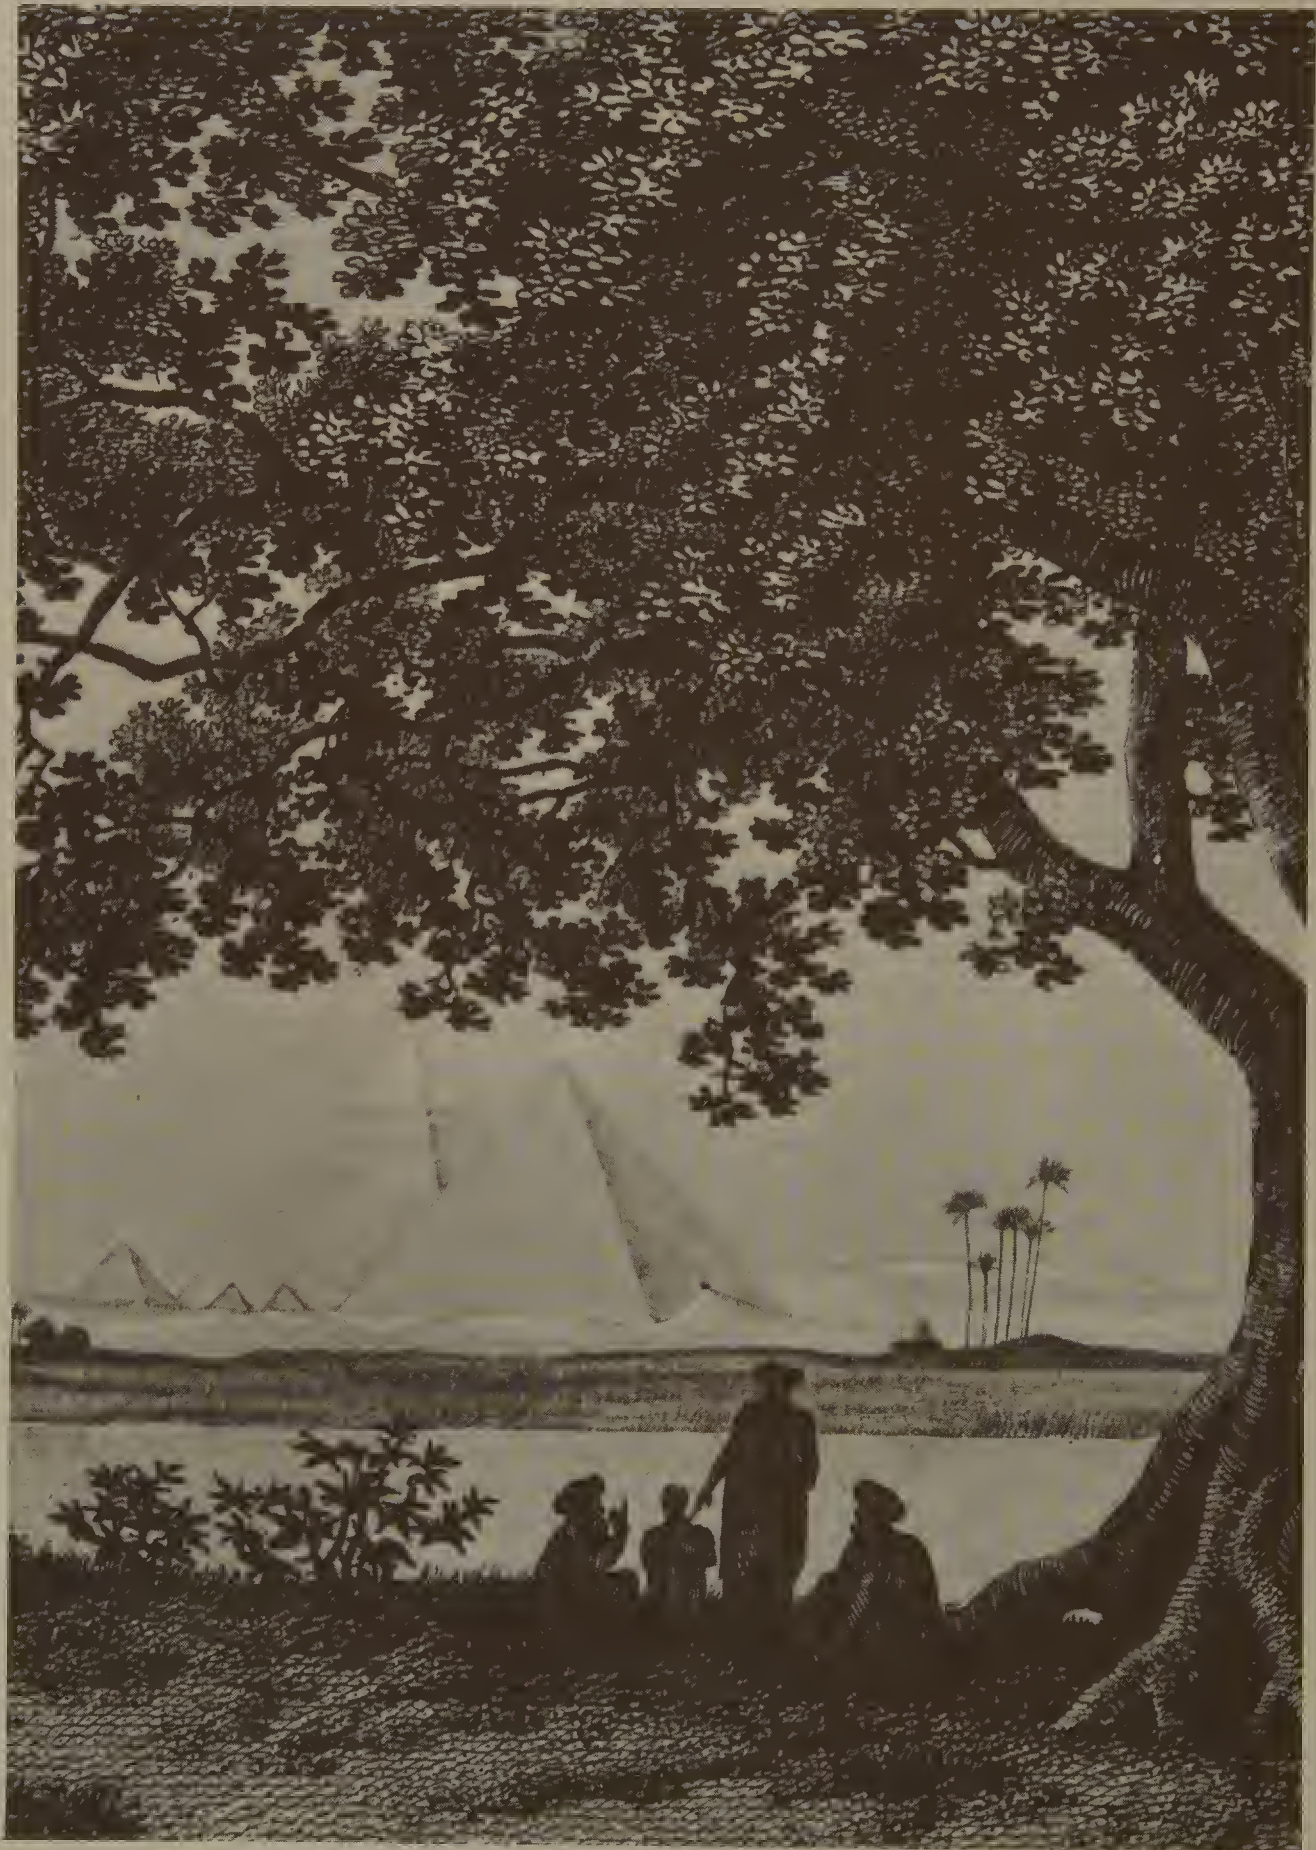
For a thousand years men from many occupations and many stations have labored to establish the true purpose of the Pyramid. Each in his own way has discovered some facet, each in its own way valid. Like Stonehenge and other megalithic calendars, the Pyramid has been shown to be an almanac by means of which the length of the year including its awkward .2422 fraction of a day could be measured as accurately as with a modern telescope. It has been shown to be a theodolite, or instrument for the surveyor, of great precision and simplicity, virtually indestructible. It is still a compass so finely oriented that modern compasses are adjusted to it, not vice versa.

It has also been established that the Great Pyramid is a carefully located geodetic marker, or fixed landmark, on which the geography of the ancient world was brilliantly constructed; that it served as a celestial observatory from which maps and tables of the stellar hemisphere could be accurately drawn; and that it incorporates in its sides and angles the means for creating a highly sophisticated map projection of the northern hemisphere. It is, in fact, a scale model of the hemisphere, correctly incorporating the geographical degrees of latitude and longitude.

The Pyramid may well be the repository of an ancient and possibly universal system of weights and measures, the model for the most sensible system of linear and temporal measurements available on earth, based on the polar axis of rotation, a system first postulated in modern times a century ago by the British astronomer Sir John Herschel, whose accuracy is now confirmed by the mensuration of orbiting satellites.

Whoever built the Great Pyramid, it is now quite clear, knew the precise circumference of the planet, and the length of the year to several decimals—data which were not rediscovered till the seventeenth century. Its architects may well have known the mean length of the earth's orbit round the sun, the specific density of the planet, the 26,000-year cycle of the equinoxes, the acceleration of gravity and the speed of light.

But to disentangle the authentic from the phony in what has been attributed to the builders of the Great Pyramid has required the technique of a Sherlock Holmes. To climax the story there is a mystery of detection to match the classic style of Sax Rohmer's Abu Hassan, complete with radiography by cosmic rays.



I. ANCIENT BACKGROUND

Ten miles west of the modern city of Cairo at the end of an acacia, tamarind and eucalyptus avenue stands a rocky plateau. A mile square, it dominates the luxuriant palm groves of the Nile Valley from a height of 130 feet. On this man-leveled plateau, called Giza* by the Arabs, stands the Great Pyramid of Cheops. To the west stretch the vast wastes of the Libyan desert.

The Pyramid's base covers 13 acres, or 7 midtown blocks of the city of New York. From this broad area, leveled to within a fraction of an inch, more than two-and-a-half *million* blocks of limestone and granite—weighing from 2 to 70 tons apiece—rise in 201 stepped tiers to the height of a modern forty-story building, etched against the cloudless blue of the Egyptian skies.

In terms of solid masonry, the structure contains more stone than all the cathedrals, churches and chapels built in England since the time of Christ; as a feat in masonry it was not to be matched till the construction of Boulder Dam. Modern engineers are astounded by both the enormity of the problems involved in the construction of the Pyramid and the optician's precision with which these problems were resolved. As originally designed, with its full mantle of polished limestone, the Pyramid must have been a dazzling sight. Unlike marble, which tends to become eroded with time and the weather, limestone becomes harder and more polished.

Near the Pyramid of Cheops stand two more pyramids, one, slightly smaller, attributed to Cheops' successor, Kephren, and another, smaller still, partly sheathed in red granite, attributed to Kephren's successor, Mykerinos. Together with six diminutive pyramids, supposedly built for Cheops' wives and daughters, they form what is known as the Giza complex. About a hundred more pyramidal structures of various sizes and in various stages of dilapidation follow the western bank of the Nile southward toward the Sudan, mostly within one degree of latitude, or 70 miles; but it is the Great Pyramid, unique in size and proportion, which is of paramount interest in this story.

The three large pyramids on the Giza plateau seen from across the Nile. The nearest of the three large pyramids is that of Cheops. Kephren's appears to be higher because it stands on higher ground. The third is that of Mykerinos. The two smallest pyramids are attributed to Cheops' wife and daughter.

* Most often spelt Giza, but transliterated by various authors as Djiseh or Jeeseh, the G is pronounced hard by the Egyptians and soft by other Arabs—as in *J* or *Dj*.

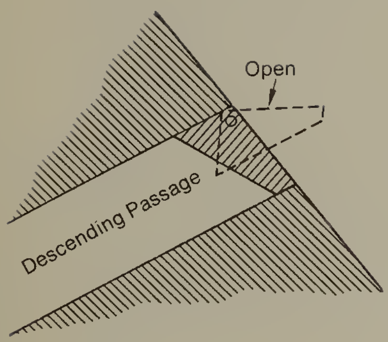
Reconstruction of a pyramid, showing the original polished limestone mantle which covered the entire structure.

What the Great Pyramid looked like when it was completed, or even for the first one or two millennia thereafter, is not recorded in history. No description of the Pyramid has survived in the Egyptian texts. Legends have it painted in various colors, marked with designs and inscribed with symbols. The thirteenth-century Arab historian, Abd-al-Latif, says the Pyramid was once inscribed with unintelligible characters in inscriptions so numerous they would fill ten thousand pages: his colleagues assumed them to be the graffiti of myriads of ancient tourists.

The first eyewitness descriptions from classical authors are pitifully sparse. Thales, the father of Greek geometry, who visited the Pyramid sometime in the sixth century B.C., is reputed to have astounded its Egyptian guardians with a correct computation of its height by measuring its shadow at the time of day when his own shadow was equal to his height. Unfortunately he left no detailed description of his visit.

The works of other classical authors known to have written about the Pyramid, such as Euhemerus, Duris of Samoa, Aristagoras, Antisthenes, Demetrius of Phaleron, Demoteles, Artemidorus of Ephesus, Dionysius of Halicarnassus, Alexander Polyhistor, Butoridas, and Apion are all lost, and survive only in fragmented quotation.

Herodotus, who saw the Pyramid about 440 B.C.—by which time it was as ancient to him as his period is to us—says that each of the structure's four perfectly triangular faces was still covered with a mantle of highly polished limestone, the joints so fine they could scarcely be seen. In his *History,* which contains the first comprehensive account of Egypt to have survived intact, Herodotus



Though no remains of a swivel door have been found at the Great Pyramid, Strabo's description fits the conditions; and a similar swivel door was found at the south pyramid of Dashur.

deals with other aspects of the Pyramid, but not all his information can be taken at face value.

Diodorus Siculus, the Greek historian who lived soon after the time of Christ, described the Great Pyramid's 22 acres of polished casing stones as being "complete and without the least decay." The Roman naturalist Pliny gives a report of natives gamboling up the polished sides to the delight of Roman tourists.

A man who may have had a lot to say about the Pyramids, in the forty-seven books of his *History,* was Strabo, the Pontine geographer who took a trip up the Nile in 24 B.C., but his history is lost: in the geographical appendix which survives he does little more than describe an entrance on the north face of the Great Pyramid made of a hinged stone which could be raised but which was indistinguishable from the surrounding masonry when it lay flush.

Strabo reports that this small opening gave onto a narrow and low passage, less than 4 feet by 4, which descended 374 feet into a damp, vermin-infested pit dug from the live bedrock 150 feet below the base of the Pyramid. That this pit was visited in Roman times was deduced from initials supposedly written with smoking torches on the rough ceilings by wealthy Greek and Roman tourists.

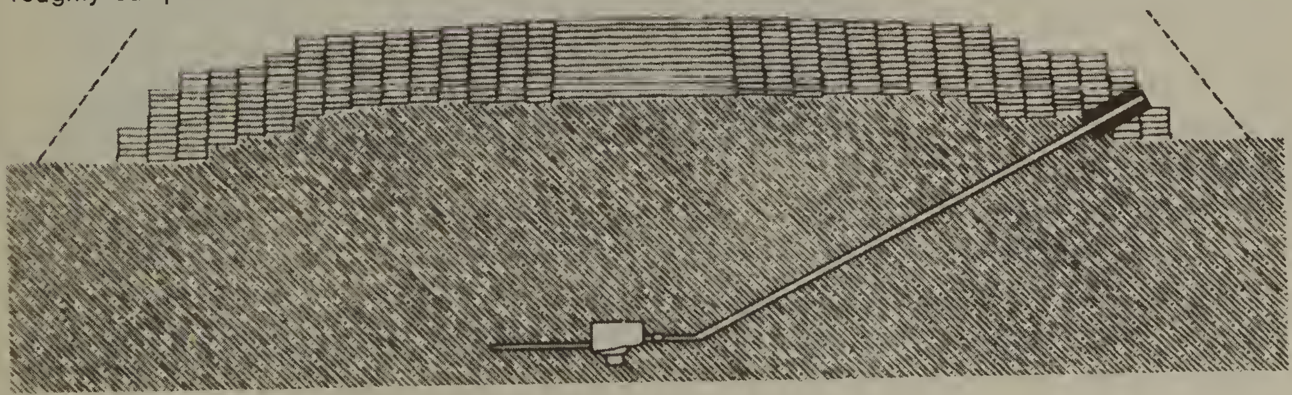
Sometime during the early centuries of the Christian era, the precise location of the movable door was lost. It was a period when information of all sorts began to grow scarce, when worldly learning came to be despised and denigrated. Christianized Egyptians were forbidden access to the ancient temples, which were either seized or razed by the Catholics; thousands of statues and inscriptions were disfigured; the hieroglyphs, whose meaning was already lost to most, became dead letters to the world to remain so for the next fifteen hundred years.

The great library of Alexandria, accidentally damaged by Julius Caesar and restored by Mark Anthony, was intentionally destroyed by a Christian mob on orders of the Christian emperor Theodosius in A.D. 389. All that was

From the original entrance a long passage descends Into the heart of the Great Pyramid at an angle of 26 1/2°, or a slope of about 1 in 2. The passage is 3 feet 5 inches wide and 3 feet 11 1/2 inches high.

For the first 130 feet down, the passage is built into the masonry with beautifully finished sides of white limestone, perfectly straight and smooth. Thereafter it is cut equally smoothly through the bedrock of limestone on which the Pyramid is founded.

At 345 feet from the entrance, the passage levels out for 25 feet, then enters a roughly cut pit.



ancient was pagan, and therefore sinful. Those interested in mathematics and astronomy were persecuted and put to death for their inquisitiveness. Even women weren't spared, as with the lovely Hypatia, who was seized by an angry mob (incited by the monks under the control of St. Cyril, then Bishop of Alexandria), dragged into a church, stripped naked, and scraped to death with oyster shells. Her crime was to have been the daughter of the celebrated Alexandrian mathematician Theon, to have edited her father's works, taught mathematics, and become a leading philosopher in her own right, renowned for her beauty, modesty and learning.*

As the Dark Ages continued, little or nothing more was heard of the Great Pyramid of Cheops.

* Though her writings perished with the burning of the library of Alexandria, Hypatia is known from contemporary writings to have produced a commentary on the *Arithmetic* of Diophantus, one on the *Astronomical Canon* of Ptolemy, and one on the *Comics* of Appolonius of Perga. Synesius, Bishop of Ptolemais requested her assistance in the construction of an astrolabe and a hydroscope.

II. MEDIEVAL EXPLORATION

The first dawn of a renaissance came with the Arabs. When the followers of Mohammed swept into power in the Near East in the seventh century and captured Alexandria in A.D. 640, they found no library of any importance, but a city of four thousand palaces, four thousand baths and four hundred theaters. Impressed by the opulence of the city and the size of the Christian fleet, they decided to emulate both.

The Mohammedans' delight in navigation engendered a need for geography, which required astronomy and mathematics. The search for such data was to lead them to the secrets of the Pyramid. To broaden their knowledge, the Arabs set about translating into Arabic all they could lay hands on of ancient Greek and Sanskrit material, ransacking monasteries for rare copies of Euclid, Galen, Plato, Aristotle, and the Hindu sages. In the midst of otherwise Dark Ages, Mohammed's religious successors, the caliphs of Baghdad, were soon the most enlightened as well as the most powerful potentates. Under caliph Harun Al-Rashid, whose feats were to be celebrated in the *Arabian Nights,* translators were paid in gold by the weight of each manuscript.

Harun's young son Abdullah Al Mamun, who came to the throne in A.D. 813, founded universities, patronized literature and science, and turned Baghdad—known as Dar-al-Salam, or City of Peace—into a seat of academic learning, with its own library and astronomical observatory.

Described by Gibbon as "a prince of rare learning who could assist with pleasure and modesty at the assemblies and disputations of the learned," young Al Mamun was responsible for the translation into Arabic of Ptolemy's great astronomical treatise, the *Almagest*. This work contained astronomical and geographical data, including the earliest star catalogue which has survived, all of which knowledge had been lost to the West for centuries but was of great value to the Arabs in their growing empire.

Claiming that Aristotle had appeared to him in a dream, Al Mamun commissioned seventy scholars to produce an "image of the earth" and the first "stellar map in the world of Islam." (Though they have since disappeared, these maps were consulted by the Arab historian Al Masudi in the first half of the tenth century.) To check Ptolemy's

In the *Arabian Nights* the Great Pyramid was reputed to have magical qualities and to contain extraordinary treasures. E. W. Lane's picture illustrates his nineteenth-century translation of *The Thousand and One Nights*.

statement that the circumference of the earth was 18,000 miles, Al Mamun ordered his astronomers to measure the actual overland length of a degree of latitude across the adjacent plain of Palmyra, north of the Euphrates. From a central point the observers moved north and south till they noted by astronomical observation that the latitude had changed 1°; with wooden rods they measured across the sandy plain and obtained a degree of 56 2/3 Arabic miles, the equivalent of 64.39 English statute miles. This figure, which gave a circumference of 23,180 miles, was more precise than Ptolemy's, but the Arabs had no way of checking it: no one had yet circumnavigated the globe; indeed, most still argued that the world was flat!

Al Mamun, who ran an up-to-date intelligence service under the direction of his postmaster-general employing as many as seventeen hundred old women as intelligence agents in Baghdad alone, was informed that the Great Pyramid was reputed to contain a secret chamber with maps and tables of the celestial and terrestrial spheres. Although they were said to have been made in the remote past, they were supposed to be of great accuracy. The chamber was also reported to contain vast treasures and such strange articles as "arms which would not rust" and "glass which might be bended and not break."

Arab historians, including one with the imposing name of Abu Abd Allah Mohammed ben Abdurakin Alkaisi, have recounted the tale of Al Mamun's attempts to enter the Pyramid. In 820 the young caliph collected a vast conglomeration of engineers, architects, builders and stonemasons to attack the Pyramid; for days they searched the steep polished surface of the northern slope for its secret entrance, but could find no trace of it.

Not to be thwarted, so the story goes, Al Mamun decided to burrow straight into the solid rock of the structure in the hope of running across some passage within the interior. Hammer and chisel would not dent the huge blocks of limestone, no matter how many blacksmiths stood ready to sharpen them; so a more primitive but effective system was used: fires were built close to the blocks of masonry, and when these became red hot they were doused with cold vinegar until they cracked. Battering rams knocked out the fragmented stone.

Al Mamun forced his way into the Pyramid to the west of the main axis of the northern face, at the level of the seventh course of masonry. He misjudged the level of the original entrance by starting ten courses too low, and too far to the west.

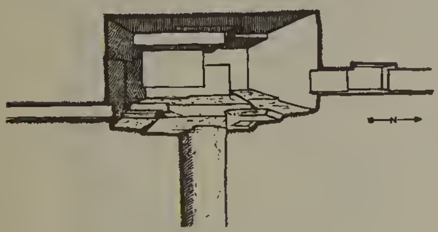
Entrance to Descending Passage.



The subterranean pit cut deep into the bedrock is almost 600 feet directly below the apex of the Pyramid. It is 31 feet in the east-west direction but only 27 feet north-south.

Though its ceiling is relatively smooth, its floor is cut in several rough levels, the lowest being 11 feet 6 inches from the ceiling.

In the south wall, opposite the entrance, is a low passage which runs another 53 feet southward before coming to a blind end.

In the center of the floor is a square hole, which was 12 feet deep in 1838, but was dug deeper by the English explorer Howard-Vyse in the vain hope of finding an outlet for a further hidden chamber.

For over 100 feet Al Mamun's men tunneled into the solid core of the Pyramid, excavating a narrow passage that became hotter, dustier and more constricted. Illumination by candle or flare consumed oxygen and poisoned the air.

Al Mamun was on the point of giving up when a workman heard a muffled sound of something heavy falling somewhere within the Pyramid, east of the tunnel. Renewing their efforts and altering the direction of the bore, the workers broke into a hollow way "exceeding dark, dreadful to look at, and difficult to pass." It was a passage 3 1/2 feet wide by 3 feet 11 inches high, which sloped at a steep angle of 26°. On the floor lay a large prismatic stone which had been dislodged from the ceiling of the passage.

Struggling up the passage on all fours, the Arabs discovered the original secret entrance about 90 feet to the north. It had been placed 49 feet above the base of the Pyramid, ten courses higher than Al Mamun had guessed, and 24 feet east of the main axis of the north face of the Pyramid.

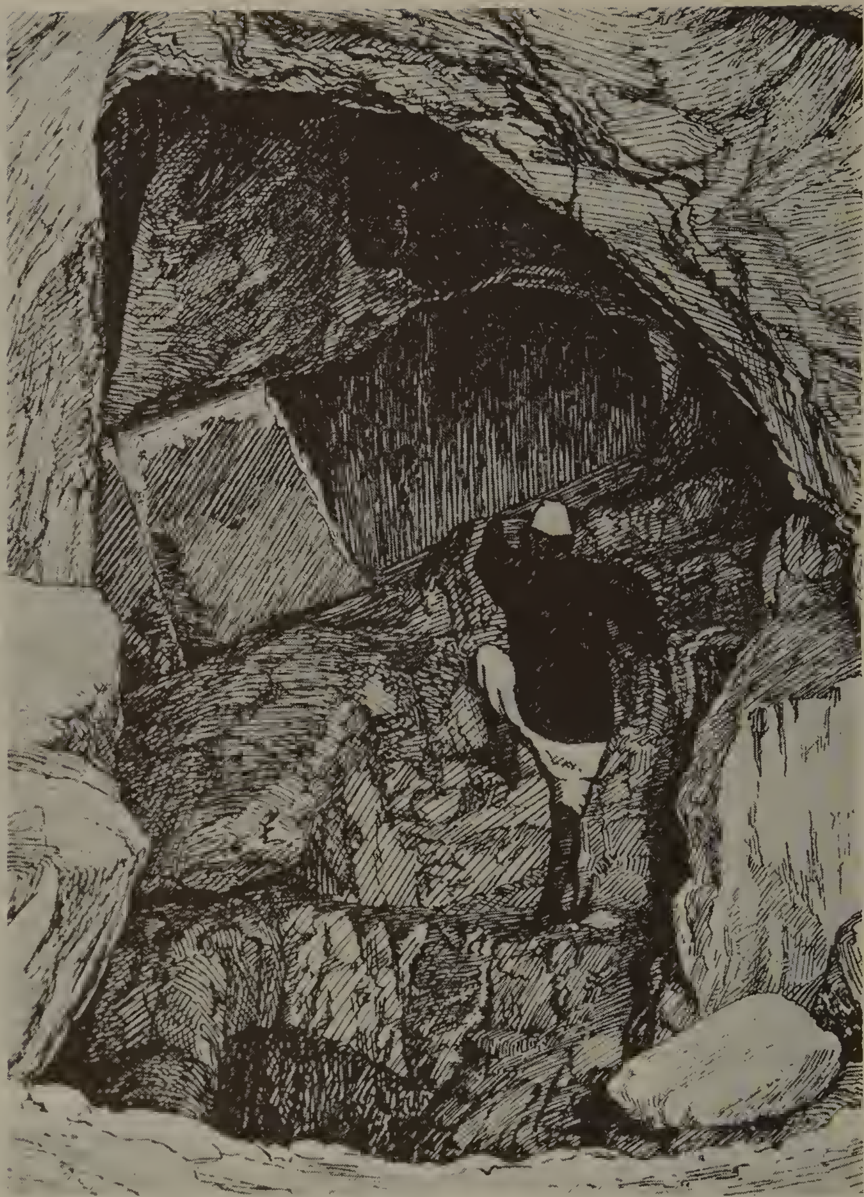
Retracing their steps, Al Mamun and his men groped down the low, slippery, Descending Passage, cut deep into the rock of the plateau. At the bottom they were disappointed to find nothing but the unfinished, roughly hewn chamber, or "pit," with an uneven floor, containing nothing but debris and dust. On the far side of it, an even narrower horizontal passage led 50 feet to a blank wall; in the floor a well shaft appeared to have been carved to a depth of 30 feet, leading nowhere.

From the torch marks on the ceiling, the Arabs deduced that the "pit" had been visited in classical times and that anything of interest it may have contained had long since been removed.

What now intrigued the Arabs was the large prismatic stone that had fallen from the ceiling of the Descending Passage. It had evidently covered the end of a large rectangular red-and-black granite plug which completely filled what looked like another passage sloping *up* into the body of the Pyramid. Of such a passage there had been no mention in the writings of Strabo or other classical authors; Al Mamun figured he might have stumbled onto a secret which had been kept since the original construction of the building.

The Arabs tried to chip or dislodge the granite plug, but it was tightly wedged, of indeterminate length, and it evidently weighed several tons. Spurred by the prospect of a new passage leading to some hidden treasure chamber, Al Mamun ordered his men to cut around the plug through

The granite plug in the ceiling, halfway down the descending passage, was of very hard quartz, mica and feldspar, which blunted the Arabs' chisels.



The Arabs dug a large cavity into the softer limestone blocks of the body of the Great Pyramid to the west of the Descending Passage. By means of this hole Al Mamun was able to circumvent the three impenetrable granite monoliths which barred his way to what appeared to be a passage leading upward into the Pyramid.

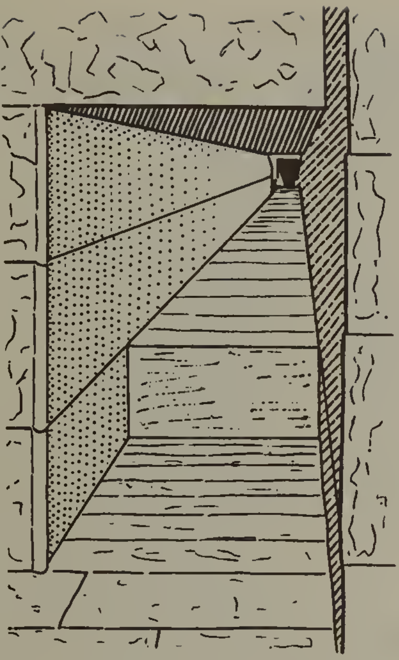
the softer limestone blocks of the surrounding walls. Even this turned out to be more of a job than expected. When the Arabs had bored beyond the first granite plug for over 6 feet, they encountered another granite plug, equally hard and equally tightly wedged. Beyond it lay yet a third. By now the Arabs had tunneled more than 16 feet. Beyond the third granite plug they came upon a passage filled with a limestone plug which could be cracked with chisels and removed piece by piece.

It is not recorded how many such plugs the Arabs encountered, but they may have had to clear a score or more before they could force their way into a narrow ascending passage, again less than 4 feet high and equally narrow. On their hands and knees, holding their torches low, Al Mamun and his men were obliged to scramble up 150 feet of dark, slippery passageway, at the same steep slope of 26°, before they could raise their heads and stand on a level spot.

In front of them stretched another low horizontal passage, no higher than the one they had painfully ascended.

Inching their way to the end of this passage, they found themselves in a rectangular limestone room with a rough floor and a gabled limestone roof. Because of the custom among the Arabs of placing their women in tombs with gabled ceilings (as opposed to flat ones for men), this room came to be known as the "Queen's Chamber."

The bare room, 18 feet long, and almost square, had an empty niche in the east wall large enough to have contained an overlifesize statue. Thinking the niche might conceal the entrance to a second chamber, the Arabs hacked their way into its solid masonry for another yard before giving up.



The first-level passage, at the top of the first long incline, is 127 feet long, 3 feet 9 inches high, and 3 feet 5 inches wide.
A sudden drop of 2 feet mysteriously appears in the passage.

Queen's Chamber, with niche, excavated by Arabs.

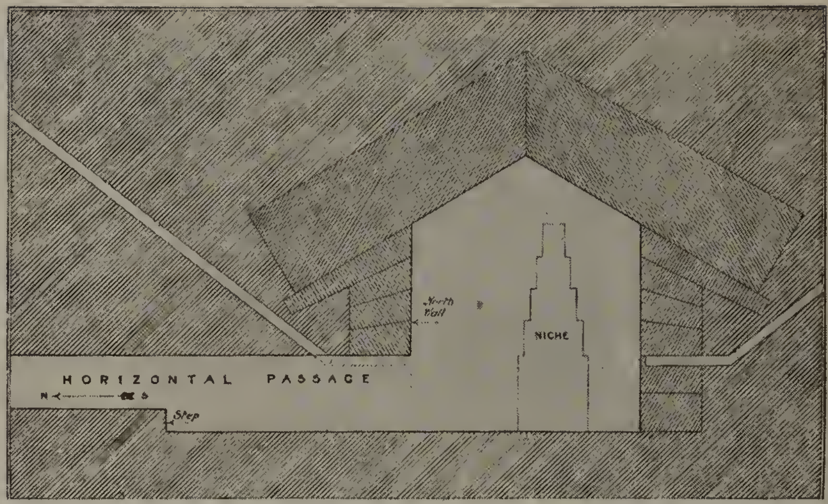
The name "Queen's Chamber" is considered a misnomer by Egyptologists, who claim that the Egyptians placed no queens in the pyramids of the Pharaohs.

The walls of the chamber are unblemished limestone blocks, beautifully finished, but early explorers found them mysteriously encrusted with salt as much as 1/2 inch thick.

Originally the niche was 3 feet 5 inches deep, but treasure seekers have hacked a passage through the back for several yards. The niche is just over 16 feet high. The sides have four corbeled courses, and are 61 3/4 inches (3 cubits) apart at the base and 20 1/4 inches (1 cubit) apart at the top.

The chamber, placed directly beneath the apex of the Pyramid, is almost square: 18 feet 10 inches from east to west and 17 feet 2 inches from north to south. It has a double-pitched ceiling, 20 feet 5 inches at its highest, formed by huge blocks of polished limestone at a slope of 30° 26′, which extend 10 feet beyond the supporting walls; there is no pressure, or arch thrust, at the apex, the center of gravity of each block being well behind the wall face.

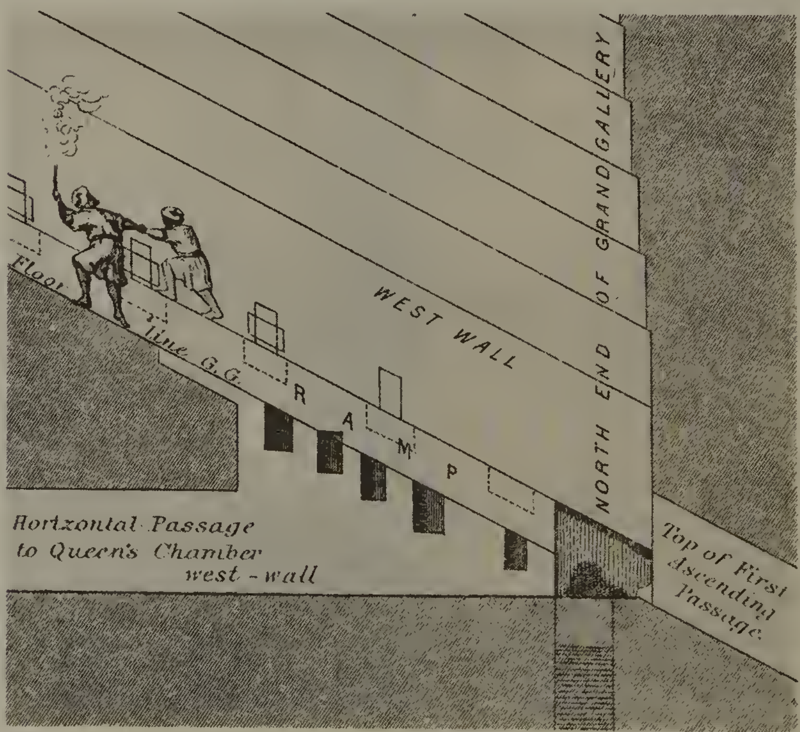
The floor of the chamber is of roughly dressed stones, and appears never to have been finished, as if another layer of polished stones were to be laid.



Retracing their steps to where they had left the low Ascending Passage, the Arabs raised their torches into an ominous void above them. In the side walls joist holes indicated that the floor of the Ascending Passage had once continued upwards, blocking and hiding the low passage to the Queen's Chamber.

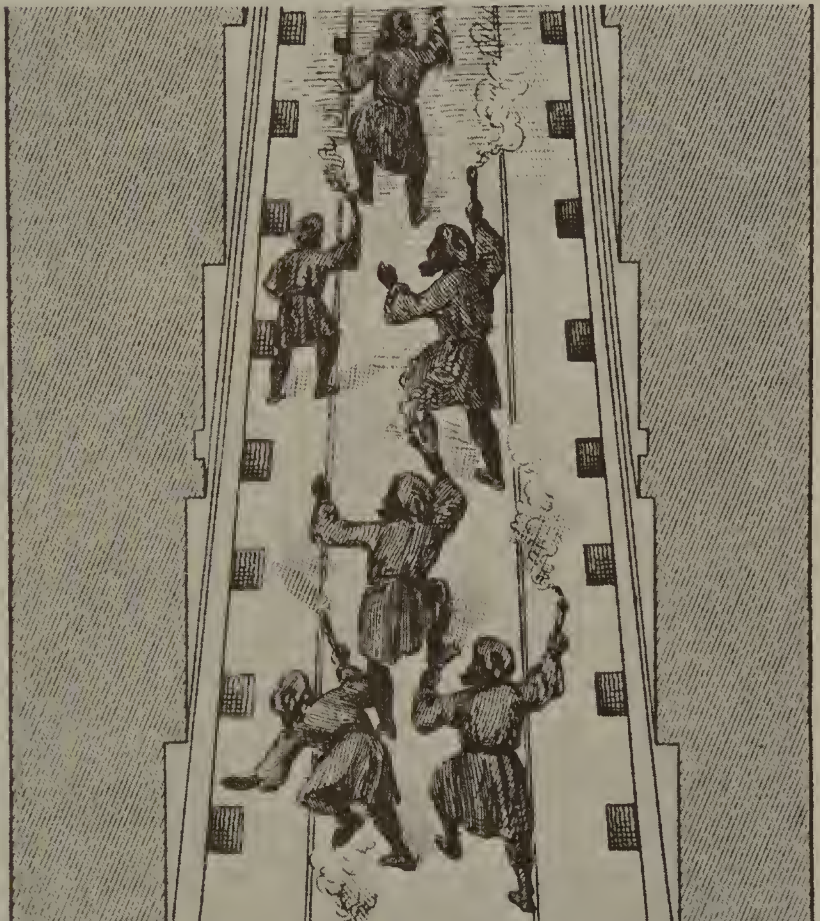
Climbing on each others' shoulders and raising their torches, the Arabs now saw that they were at the bottom of a narrow but grand gallery, about 28 feet high, which appeared to stretch upward at the same steep slope as the Ascending Passage into the black and mysterious heart of the Pyramid.

The center of this new passage was very slippery, but to either side of it were two narrow ramps slotted at regular intervals; they afforded a better foothold.



Holding their torches high, the Arabs proceeded to escalade these ramps. At the end of another 150-foot climb, they came upon a huge solid stone, raised 3 feet from the floor, which they had to clamber up in order to stand at the top of the gallery on a 6×8 foot platform.

Beyond this platform the floor continued level, but the

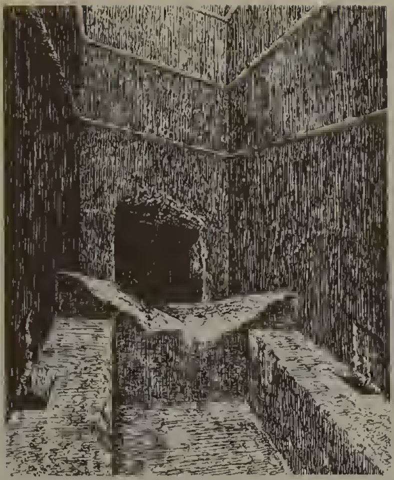


The overall length of the Grand Gallery, shown here, is 157 feet. It is inclined 26°, as is the Ascending Passage.

The walls are 28 feet high, rising vertically in seven courses of polished limestone, each corbeled 3 inches toward the center, making the gallery narrow from 62 inches at the base to 41 inches at the top. The first corbeling is 7 feet high.

On either side of the central 2-foot passage are two ramps 18 inches wide and 2 feet high; along the walls is a series of notches.

The gallery is considered an architectural masterpiece. Egyptologists have differed as to its function, and that of its ramps and notched holes.



At the top of the Grand Gallery lies a huge stone step, 6 feet wide, 3 feet high, which blocks the Ascending Passage and forms a platform 8 feet deep, now badly chipped and worn.

Beyond the Great Step there stretches another low, level passage 41 inches (or 2 cubits) square. A third of the way along this passage, it rises and widens into a sort of antechamber, the south, east and west walls of which are no longer of polished limestone but of polished red granite.

ceiling fell to a mere 41 inches, forming a sort of portcullis entrance to a small antechamber.

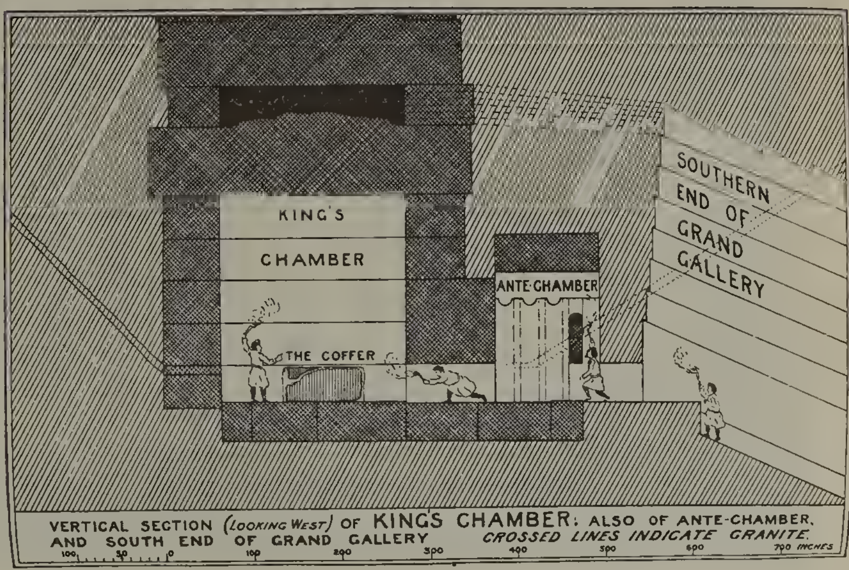
Past the portcullis, Al Mamun's men were again obliged to stoop along a short passage which led to yet another chamber.

Their torches revealed a great and well-proportioned room; the walls, floor and ceiling were all of beautifully wrought and polished red-granite blocks, squared and extremely finely jointed: "a right noble apartment, thirty-four feet long, seventeen broad, and nineteen high." Because of its flat ceiling, the Arabs named it the "King's Chamber."

Al Mamun's men frantically searched every cranny of the chamber but could find nothing of interest or value—there was no sign of any treasure, only a large lidless "sarcophagus" of highly polished, dark chocolate-colored granite.

Some Arabian authors have reported that Al Mamun found in the sarcophagus a stone statue in the shape of a man. They say that within the statue lay a body wearing a breastplate of gold set with precious stones, an invaluable sword on his chest, and a carbuncle ruby on his head the size of an egg, which shone as with the light of day. According to the storytellers the statue was inscribed with a mysterious writing that no one could decipher; but there is no historical evidence to support the tale.

To Al Mamun it appeared that either the vast mausoleum had been built about nothing but a single empty chest, or the whole place had previously been looted; though how and by whom it was hard to imagine, considering the enormous number of stone plugs the Arabs had been obliged to break up in order to make their entrance.



VERTICAL SECTION (LOOKING WEST) OF KINGS CHAMBER: ALSO OF ANTE-CHAMBER, AND SOUTH END OF GRAND GALLERY CROSSED LINES INDICATE GRANITE.

The sole item within the King's Chamber is a lidless coffer cut from a solid block of chocolate-colored granite, whose granules of feldspar, quartz and mica are even harder than those of the chamber walls. They were fabled to have come not from the Egyptian quarries up the Nile at Syene but from the mythical Atlantis or even from America.

Because the coffer is 6 feet 6 inches long, 2 feet 3 inches wide and 3 feet deep and could comfortably accommodate a human body, it has been called a sarcophagus and is believed by Egyptologists to have been the tomb of the Pharaoh Cheops.

A ridge along the top edge of the coffer indicates it may have once had a sliding lid, though no trace of the lid has been found.

As the Arabs removed 22 acres of 100-inch-thick pure-limestone covering from the Great Pyramid, vast mounds of chips and refuse built up as high as 50 feet around the base.

In a fury of disappointment, the Arabs ripped up part of the floor and hacked at the beautiful granite walls, even burrowing a short tunnel into a corner of the room, all to no avail.

Legend has it that to pacify his disappointed men Al Mamun had a treasure of gold secreted in the Pyramid at night, amounting to just the wages due his men, and palmed off the coincidence on the wisdom and prescience of Allah.

For another four centuries the great pile lay undisturbed on the desert's edge, its outer casing virtually intact, its geometric shadows lengthening and shortening with the revolutions of each year. An Arab historian who saw the Pyramid in the early thirteenth century compared it to a great female breast rising from the bosom of Egypt. He remarked that it was still perfect except for the entrance carved in it by Al Mamun.

Subsequently a series of earthquakes demolished large parts of northern Egypt, and the descendents of Al Mamun's workers wreaked their revenge on the treasureless Pyramid by stripping it of its precious limestone casing to rebuild their new capital city El Kaherah, "The Victorious." In the course of several generations they managed to remove the entire 22 acres of 100-inch-thick covering of the Pyramid, and even built two bridges especially to drag the heavier stones across the river on camel trains to Cairo for the construction of a series of mosques and palaces.

The Mosque of Sultun Hasan in Cairo, built in 1356 with limestone blocks removed from the covering of the Great Pyramid.

One of the more renowned of the several hundred minareted mosques in what came to be known as "Grand" Cairo was built in 1356 by Sultan Hasan almost entirely with stones removed from the Pyramid. Forty years later, in the reign of his successor Barluk, when the French Baron d'Anglure traveled to Egypt, he was able to see and report on the continued dismantling of casing stones by Arab stonemasons. D'Anglure was naïve enough to fall for the historical canard that the pyramids had been built as granaries by the biblical Joseph to store Pharaoh's grain in years of plenty; but his old French gives a vivid picture of the despoilers tumbling the massive blocks from the summit: ". . . *certain ouvriers massons qui à force desmuroient les grosses pierres taillés qui font la couverture de desdits greniers, et les laissoient devaller à val.*" ("Certain masons demolished the course of great casing stones which covered these granaries, and tumbled them into the valley.")

The stripping of the limestone left the core masonry exposed in a series of gradually ascending and receding steps to be weathered and worn by wind, sand and rain. Some of the underlying core blocks proved to be of pure limestone, others of nummulitic limestone containing large quantities of fossil shells resembling coins.

Around the stripped Pyramid, fragments of limestone and rubble were piled so high that they finally obliterated the entrance which Al Mamun had forced in the north face.

But the removal of the outer casing brought to light two huge transoms embedded in the masonry which formed a protective gable over the tiny gaping original entrance to the Descending Passage.

Only now, no one cared to reenter the Pyramid.

III. RENAISSANCE AND REVIVAL OF INTEREST

Superstition shrouded the ancient structure. It was said to be haunted by ghosts and to be alive with venomous vermin. According to the Arabs the Great Pyramid was haunted at noon and sunset by a naked woman with large teeth who seduced people into her power and then drove them insane.

When Rabbi Benjamin ben Jonah of Navarre, an adventurous twelfth-century traveler, reached the Giza plateau from Abyssinia he noted that "the Pyramids which are seen here are constructed by witchcraft."

Abd-al-Latif, who taught medicine as well as history in Baghdad, summoned the courage to enter the Great Pyramid shortly after Benjamin's visit but admitted that within its stifling interior he fainted from fear and came out more dead than alive.

The Pyramid's bad reputation spread so far afield that when the fabulous English explorer Sir John Mandeville is supposed to have visited Egypt in the fourteenth century, he is said to have complained he dared not enter the Pyramid because it was filled with serpents: but the serpents turned out to be as fabulous as his *Travels* which were produced by a notary in Liège who had never even left his native country.

Not till the Renaissance had swept away some of the cobwebs of medieval obscurantism, and revived man's interest in science, was there enough motive for Europeans to enter the Pyramid and rationally examine its interior.

In 1638 John Greaves, a 36-year-old mathematician and astronomer who had studied at Oxford and taught geometry in London, decided to set off for Egypt. His was no idle curiosity: like Al Mamun, he hoped to find in the Great Pyramid a datum that might help to establish the dimensions of the planet. Although the preceding century had spawned the great voyages of exploration, and Magellan's crew had circumnavigated the earth, the sciences of geography and astronomy were still so much in their infancy—to all appearances—that no one had improved on Ptolemy's or Al Mamun's geographical degree and hence no one knew the true circumference of the earth.

The Giza pyramids and Sphinx as depicted in 1610, showing European travelers.

A clue to a possible solution had been postulated by Girolamo Cardano, an astonishing Milanese physician and mathematician of the early sixteenth century and a close friend of Leonardo da Vinci's, who maintained that a body of exact science must have preexisted the Greeks. Cardano suspected that a degree of meridian (far more exact than that of Eratosthenes, Ptolemy or Al Mamum) must have been in existence hundreds if not thousands of years before the Alexandrians and that to find it one must search in Egypt. Pythagoras was said to have claimed that the measures of antiquity were derived from Egyptian standards, themselves copied from an invariable prototype taken from nature. It followed that the pyramids might have been built to record the dimensions of the earth and furnish an imperishable standard of linear measure.

Greaves had already traveled to Italy to measure its ancient buildings and statues in an attempt to establish the original standard of measure used by the Romans—which he concluded to be a foot somewhat shorter than a British foot by 28 thousandths.

John Greaves.

Statue of young Roman architect, Statilius Aper, in Vatican gardens, from which Greaves measured a Roman foot which was related to the circumference of the earth.

In the Vatican gardens Greaves found a statue commemorating a young architect of the first century A.D., T. Statilius Vol Aper, who had died in his twenty-third year. Portrayed in relief were Aper's architectural instruments, including a Roman foot. Greaves copied this foot and compared it to an English foot made of brass which he had divided in 2,000 parts. "I spent at least two hours," wrote

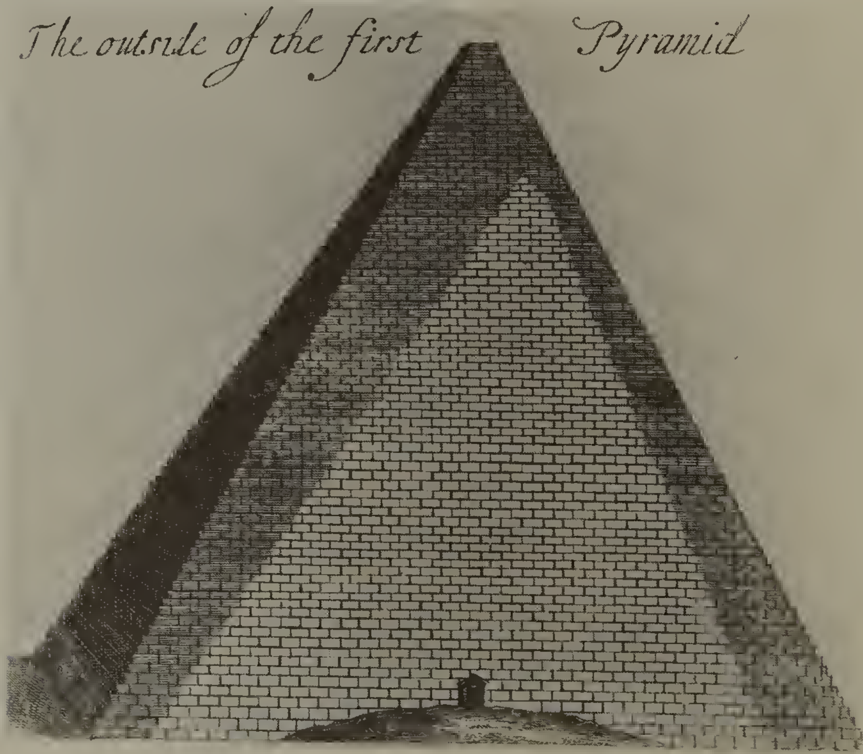
Greaves, explaining the diligence with which he performed the operation, "so often comparing the several divisions and digits of it respectively one with another, that I think more circumspection could not have been used."

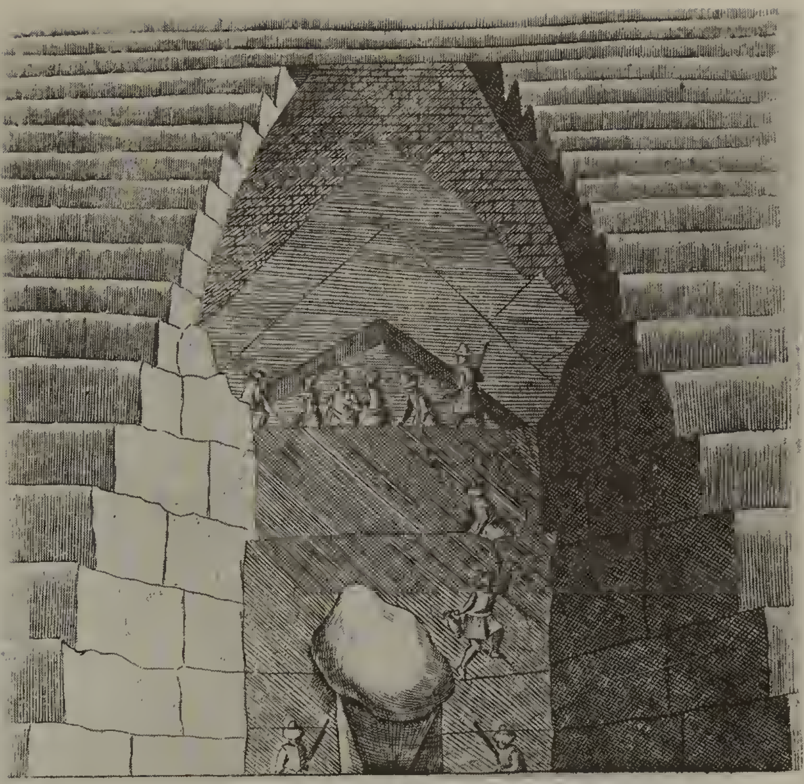
Greaves found that the Roman foot contained "1,944 such parts as the English foot contains 2,000." The interesting result of this measurement was the fact that it confirmed a Roman foot to be exactly 24/25ths of the Greek foot derived from the Parthenon—a foot of which there are 100 in the width and 225 in the length of the building.

Greaves's next problem was to establish the basic unit on which the Pyramid had been built—whether foot, pace, cubit (an arm's length), or palm.

To help defray his expenses, Greaves applied for the patronage and assistance of the magistrates of the City of London, but they turned him down. Luckily the Archbishop of Canterbury thought enough of Greaves, and was sufficiently interested in rare Arabic and Persian manuscripts which might be discovered in the East, to patronize him. Greaves was able to equip himself with instruments for measuring the inside and the outside of the Pyramid and for obtaining the declination and right ascension of the stars above it, and have enough money left over to spend a few weeks in Cairo.

Though a bookish mathematician and an ingrained antiquarian, Greaves was not without courage as an explorer. At the Pyramid he climbed onto the mound of rubbish 38 feet high which surrounded it and gingerly let himself into the Descending Passage, "creeping like a serpent," horrified to





Entrance to the Great Pyramid as depicted by John Greaves.

find himself in a storm of bats "so ugly and so large, exceeding a foot in length," such as he had never imagined.

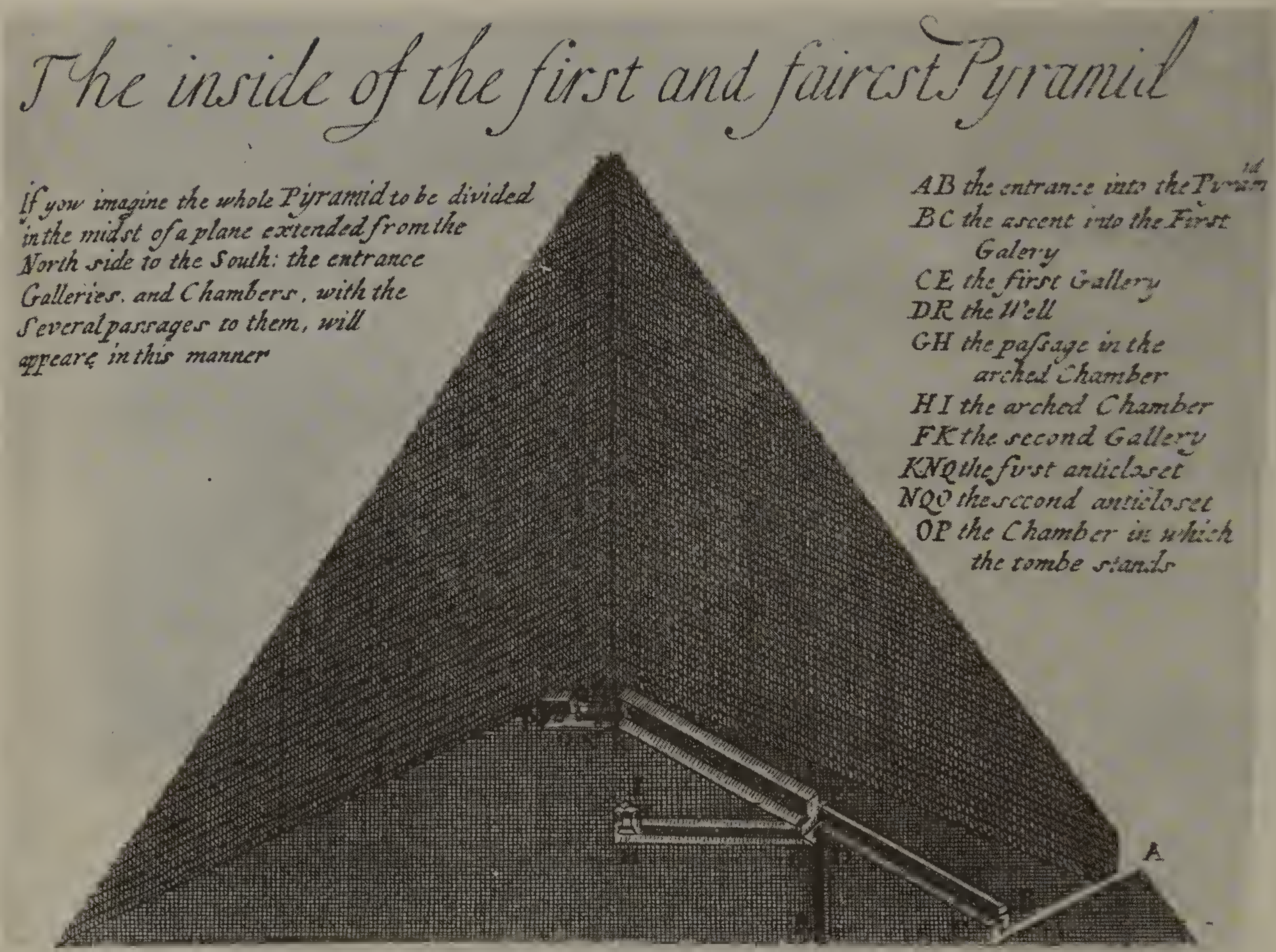
To scare off the bats and clear the air, Greaves resorted to firing his pistols; the explosions reverberated like cannon shots in the restricted passage of the Pyramid.

Working his way downward, Greaves reached the point where Al Mamun's original tunnel joined the Descending Passage, but was unable to proceed in a downward direction because of the debris left behind by Al Mamun's men when they had broken up the series of limestone plugs that had filled the upper passage.

Following in the Arabs' footsteps, Greaves climbed around the massive granite plugs and up into the low Ascending Passage. Having scrambled to the top, Greaves retraced Al Mamun's course along the short Horizontal Passage to the Queen's Chamber, where he found the stench of vermin so offensive he could not linger.

Everything Greaves came across was a puzzle to him. The steepness of the Grand Gallery seemed to preclude its having been designed as a chamber: the difficulty of scaling its polished slope made it impractical as a stairway. Also, it was accessible only through the preceding very low passage.

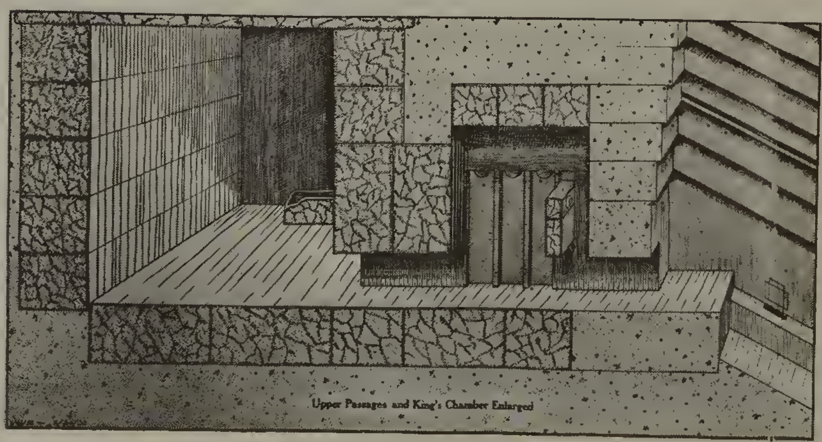
He admitted nevertheless that the Pyramid was "a very stately piece of work, and not inferior, either in respect of the curiosity of art or richness of materials, to the most sumptuous and magnificent buildings." He noted that it was built of polished limestone "very evenly cut in spacious



squares or tables"; and he found that the "coagmentation or knitting" of the joints was so close it was scarcely discernible with the naked eye.

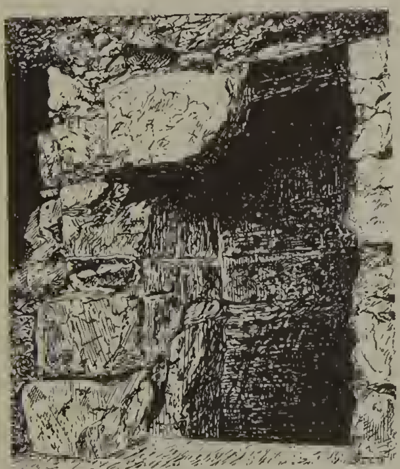
Making his way to the King's Chamber, Greaves was puzzled that so incredibly imposing a structure as the Pyramid should be built around a single chamber with a single empty coffer. He could see no apparent reason for its portcullis entrance or for the complexity of its antechamber where the walls changed mysteriously from limestone to granite. But being a scientist by nature, Greaves set to collecting and noting data about the building.

How the King's Chamber and its Antechamber with its portcullis are entirely cased by granite blocks within the limestone body of the Pyramid.



Entrance to the "well."

In the west wall of the Grand Gallery, not far from the north wall, a small part of the ramp is missing, allowing entry into a shallow pit. At the bottom of this pit a short passage leads westward to an opening in the floor which becomes a shaft.
This shaft descends through the nucleus masonry of the Pyramid and penetrates a rocky core which was left by the builders as an anchor for the Pyramid *above* the level of the foundation pavement.
A grotto opens off the shaft and the shaft passes through several natural fissures in the bedrock.
For many centuries the shaft's terminus was a mystery, as was its purpose.



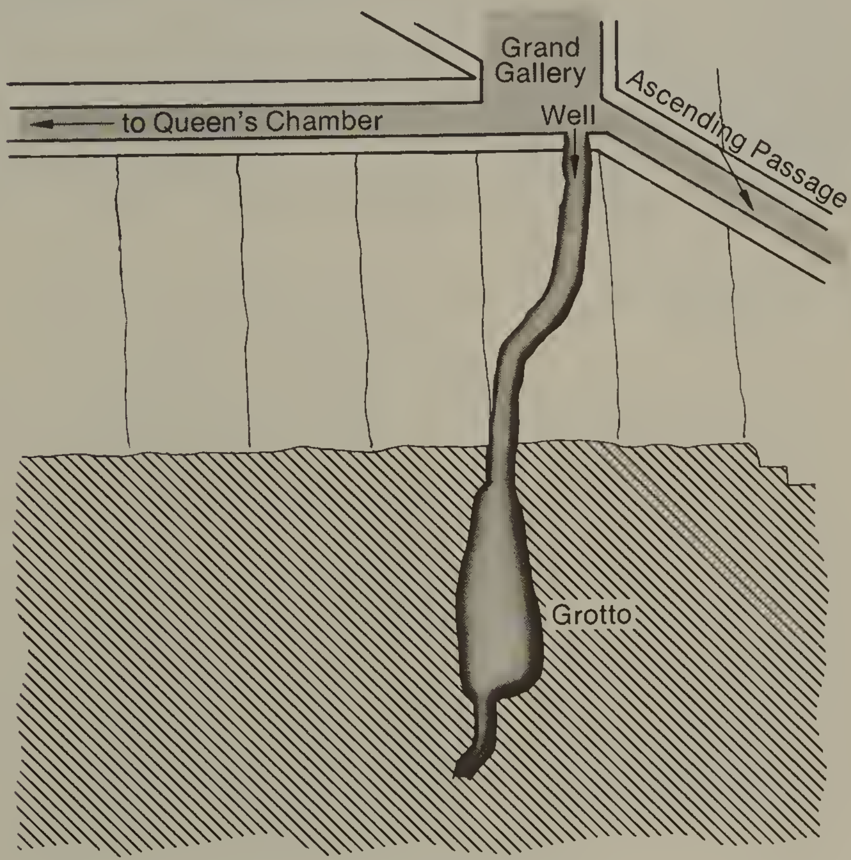
Shaft entrance to the grotto.

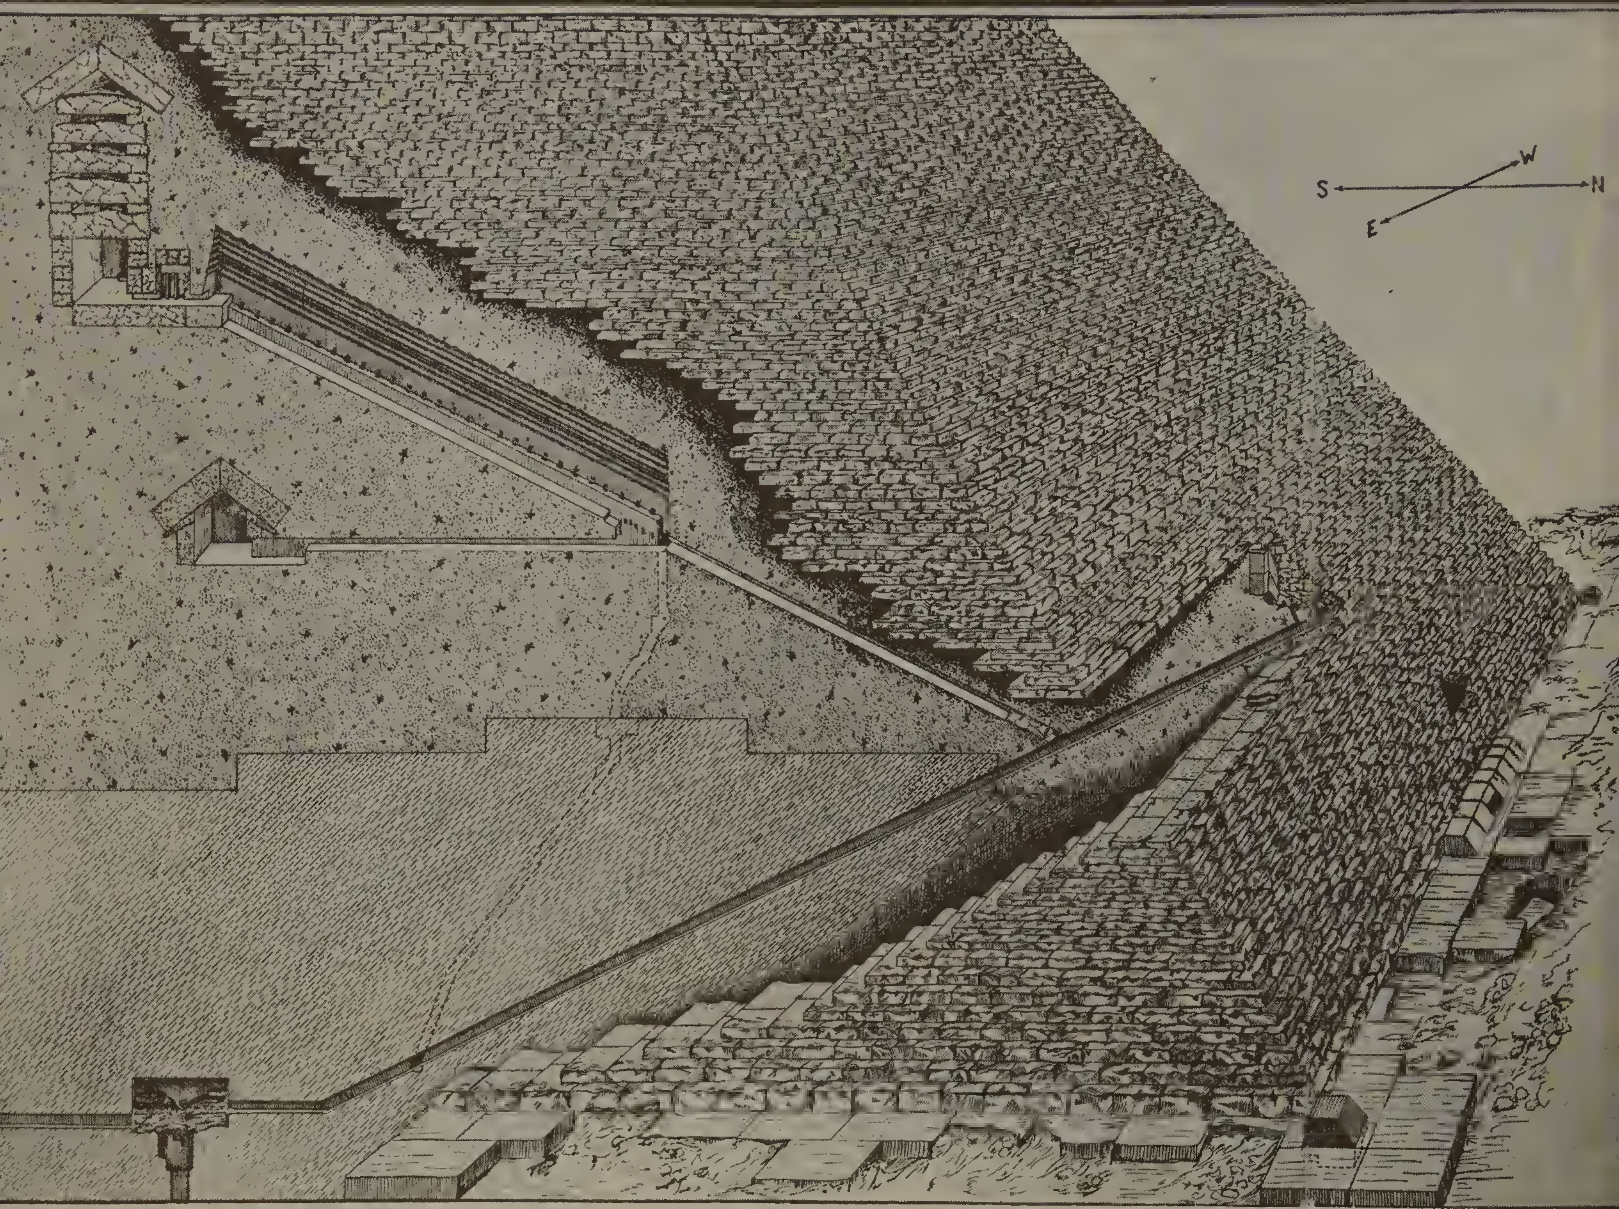
In London Greaves had furnished himself with a special 10-foot measuring rod based on a standard English foot deposited in Guild Hall, finely divided into 10,000 equal parts. With great care he measured the length, breadth and width of the King's Chamber, commenting that "the structure of it hath been the labour of an exquisite hand." He counted its tiers of granite, measured their length and breadth, and did likewise to the empty coffer, "even to the thousandth part of a foot," finding it to be 6.488 English feet.

Picking his way back to the foot of the Grand Gallery, Greaves made a new and startling discovery. From the ramp at one side, a stone block had been forcibly removed and a passage appeared to have been dug straight down into the bowels of the Pyramid.

The aperture was a little over 3 feet wide; but as notches had been carved opposite one another on the sides of this "well," Greaves lowered himself into it and descended about 60 feet, to where the shaft had been enlarged into a small chamber, or "grotto." Below him the shaft continued into the murky darkness, but the air was so foul, and the bats so thick, that Greaves decided to climb back up the way he had entered, puzzled by this strange feature of the Pyramid.

That the well shaft was not bottomless he established by dropping a lighted flare which continued to flicker from its depths.





Chambers and passages in the Great Pyramid.

Outside, Greaves climbed to the top of the Pyramid. From this high point he could admire the minarets of Cairo, the range of Mokattam hills across the Nile, and the silhouettes of the pyramids of Abusir, Saqqara and Dashur to the south.

On his way down Greaves was the first to make a reasonable count of the Pyramid's visible tiers of chiseled blocks, which he figured to be 207, estimating the total height of the structure to be 481 feet, or 499 with the missing capstone. This was within a dozen feet of being correct.

As a length for the base, Greaves estimated 693 feet, which was short of the mark by some 70 feet: but the base was so littered with rubbish that he had no way of telling where the first tier might rise from the hidden base.

Back in England Greaves was rewarded for his efforts at the Pyramid by being appointed Savilian Professor of

Pyramidographia:

OR, A

DESCRIPTION

OF THE

PYRAMIDS

IN

ÆGYPT.

By JOHN GREAVES, *Profeſſor of Aſtronomy in the Univerſity of* Oxford.

Romanorum Fabricæ & antiqua opera (cum veniâ id dictum ſit) nihil accedunt ad Pyramidum ſplendorem, & ſuperbiam.
Bellon. lib. II. Obſerv. cap. 42.

Astronomy at Oxford. All the facts and figures Greaves had accumulated he meticulously wrote up in a scholarly booklet entitled *Pyramidographia.*

His conclusions led to a very lively discussion—with as much con as pro—in which even the celebrated Dr. William Harvey, discoverer of the circulation of blood, took part. Harvey was surprised that Greaves had not described, or apparently even discovered, any conduits by means of which the central chambers in the Pyramid could be ventilated from the exterior. According to Harvey such conduits were bound to have existed, or the air in the King's Chamber would have become extremely foul—"Seeing we never breathe the same air twice, but still new air is required to a new inspiration (the succus alibilis of it being spent in every expiration)." Harvey's surmise turned out to be true, but was not established for another two generations.

Greaves had indeed noted "two inlets or spaces, in the south and north sides of the chamber, just opposite from one another," but attributed the blackness within them to their being receptacles for burning lamps.

Before returning to England, Greaves had left his instruments, including the special 10-foot rod, to a young Venetian whom he had met in Egypt and who had accompanied him to the Pyramid, Tito Livio Burattini, who who was as anxious as Greaves to find out not only the exact measurements of the Pyramid, but the unit—whether cubit, foot or palm—on which it had originally been designed.

Burattini's trip to Egypt had been subsidized by the Jesuit Father Athanasius Kircher of Cracow, Poland, who had moved to Rome and entered into correspondence with Galileo Galilei on the subject of a universal standard of measure.

At that time Galileo was living in seclusion near Florence, having been tried and imprisoned by the Inquisition for supporting the Copernican belief that the earth and the planets revolved round the sun, and the equally heretical conceit that the earth and the sun spun on their own axes.

As a young man Galileo had timed the oscillations of a lamp swinging in the Duomo of Pisa by means of his pulse beats and found the time for each swing to be the same, no matter what the amplitude of the oscillation, thus discovering what is known as the isochronism of the pendulum.

Developing Galileo's idea, Burattini had tried to obtain a universal standard of measure by using the length of a pendulum that would vibrate exactly 3600 times in one hour, or once every second, but the gold-ball pendulum he devised proved impractical because it was found that its swing varied with temperature, location, and altitude above sea level.

Burattini lingered four years in Egypt taking careful measurements with Greaves's instruments, and he sent reports of the results to Father Kircher by letter, which was lucky for the scientific world: on Burattini's journey through the Balkans back to his adopted Poland he was set upon by bandits and deprived of not only his cash but all his notes on the Pyramid which he intended to have printed as a book in Italy.

There remained the data which he had sent to Father Kircher; but it was from Greaves's data that Sir Isaac Newton deduced that the Great Pyramid had been built on the basis of two different cubits, one of which he called "profane" and the other which he called "sacred." From Greaves's and Burattini's measurements of the King's

Sir Isaac Newton is described by Giorgio de Santillana, of MIT, as "the last of the magicians, the last of the Babylonians and Sumerians, the last great mind which looked on the visible world with the same eyes as those who began to build our intellectual world rather less than 10,000 years ago."

Chamber, Newton computed that a cubit of 20.63 British inches produced a room with an even length of cubits: 20 × 10. This cubit Newton called the "profane," or Memphis, cubit; whereas a longer, more arcane cubit appeared to measure about 25 British inches.

This longer, or "sacred," cubit Newton derived from the Jewish historian Josephus's description of the circumference of the pillars of the Temple at Jerusalem. Newton estimated this cubit to be between 24.80 and 25.02 English inches, but believed the figure could be refined through further measurement of the Great Pyramid and other ancient buildings.

All of this Newton wrote up in a small and now hard-to-find paper called *A Dissertation upon the Sacred Cubit of the Jews and the Cubits of several Nations: in which, from the Dimensions of the Greatest Pyramid, as taken by Mr. John Greaves, the ancient Cubit of Memphis is determined.*

Newton's preoccupation with establishing the cubit of the ancient Egyptians was no idle curiosity, nor just a desire to find a universal standard of measure; his general theory of gravitation, which he had not yet announced, was dependent on an accurate knowledge of the circumference of the earth. All he had to go on were the old figures of Eratosthenes and his followers, and on their figures his theory did not work out accurately.

By establishing the cubit of the ancient Egyptians, Newton hoped to find the exact length of their stadium, reputed by classical authors to bear a relation to a geographical degree, and this he believed to be somehow enshrined in the proportions of the Great Pyramid.

Unfortunately Greaves's and Burattini's measurements of the *base* of the Pyramid were incorrect because of the accumulated debris, and though Newton's figure for the cubit was very close to perfect, the false measurements of the base failed to give him the answer he was searching.

To resolve Newton's problem, Burattini suggested taking the actual measure of two or three degrees of latitude across the flat countryside of Poland; but the operation proved too costly. Unfortunately, neither Newton nor Burattini knew that in 1635 Richard Norwood, author of *Sea-Man's Practice,* had made an observation of the sun at noon at York using a sextant more than 5 feet in radius, and a similar observation in London near the Tower; the distance between the two points was 9149 chains, and he thus obtained a figure of 69.5 English statute miles for 1° of latitude. This figure would have solved Newton's problem, but because of the political unrest in Cromwellian England he did not hear of it; so he put away his theory of gravitation for several more years, or until the French astronomer Jean Picard repeated Norwood's feat with rather more fanfare.

In 1671 Picard measured a degree of latitude between Amiens and Malvoisine. His method was to measure a base line at Amiens very meticulously with wooden rods, then measure the angles formed by this base line with a point on the horizon and deduce its distance by trigonometry. Selecting a series of points on hilltops easily distinguished with a telescope and measuring only the angles between their sides, he was able to string out a series of thirteen large triangles across the countryside and obtain a very accurate degree of 69.1 English statute miles.

On the basis of this computation Newton was able to announce his general theory of gravitation—that all bodies in the universe attract each other in proportion to the product of their mass and inversely as the square of their distance apart—and so launch a new era of physics.

As the English poet Alfred Noyes summed up the event:

> . . . Newton withheld his hope
> Until that day when light was brought from France,
> New light, new hope, in one small glistening fact . . .
> Picard in France—all glory to her name—
> Had measured earth's diameter once more
> With exquisite precision . . .

But all this Anglo-Gallic dalliance was short-lived because an argument developed between Newton and a French family of astronomers, map makers, and surveyors called Cassini. Newton figured that the centrifugal force of the globe spinning on its north-south axis would cause the earth to bulge at the equator and be slightly flattened at the poles.

In his *Principia* Newton estimated that this would have the effect of making a degree of latitude longer nearer the poles and shorter nearer the equator.

The theory was heatedly opposed by the Cassinis, who had extended Picard's triangulation survey north to Dunkirk and south to Perpignan on the Spanish border, and maintained that the earth was elongated like an egg, as depicted in Ptolemaic Egypt: that the degree of latitude was *shorter* north of Paris.

To settle the argument the French Academy of Sciences sent out two expeditions, one to Lapland to measure an actual degree near the Arctic Circle and another to Peru to measure a degree near the equator.

After 18 months of being frozen in winter and devoured by mosquitoes in summer, the expedition to Lapland returned with a figure that showed a degree of latitude was *longer* near the flattened Pole. The Peruvian expedition suffered

The Great Sphinx lies about twelve hundred feet southeast of the Pyramid of Cheops near the valley building of Kephren. Carved from a single sandstone knoll, the colossus is 240 feet long, 66 feet high, and 13 feet 8 inches at its widest.
The headdress and the cobra on the forehead are said to have been symbols of royalty; the features are thought to resemble those of Kephren.
At one time the Sphinx may have been coated with plaster and painted in various colors.
A rational explanation of the mystery of the Sphinx was produced by the British astronomer Sir Norman Lockyer, who said that its being half lion, half virgin symbolizes the junction of the constellations Leo and Virgo which occurred at a summer solstice in the fourth millennium B.C.

even worse conditions, measuring from mountaintop to mountaintop in the Andean highlands, but after ten years of misery, came back with a similar conclusion that the degree was shorter at the equator, vindicating Newton: the Peruvian degree measured 56,734 French *toises*, the Paris degree was 226 *toises* longer, and the Lapland degree 362 *toises* longer still.*

Cassini, who very sensibly proposed the adoption of a geodetic foot representing 1/6000th part of a terrestrial minute of arc, would have been astounded had he known that just such a foot had been in existence for several millennia and that the Sphinx, which could be used as a geodetic marker to indicate the equinox, also once had an obelisk between its paws whose shadow could be used to compute not only the correct circumference of the earth but the variance in the degree of latitude.

But in all this geodetic enterprise the Pyramid's geodetic values were forgotten; its secrets remained as enigmatic as those of its neighbor the Sphinx, which by this time was almost obliterated in the accumulation of wind-blown sand from the Libyan desert.

* The *toise*, or double arm's length, was the standard of measure used by the French before the development of the meter.

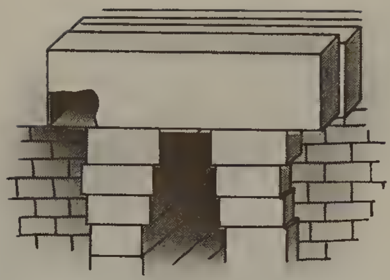
IV. THE AGE OF ENLIGHTENMENT

Travel to the Giza plateau became a dangerous undertaking in the eighteenth century. Though Egypt was still nominally under the suzerainty of the Ottoman Turks, the traveler was likely to be robbed or killed by gangs of bandit Arabs unless protected by a bodyguard of friendly Janissaries such as had accompanied Greaves.

Not until the time of the American Revolution was any further discovery of importance made at the Pyramid. In 1765, Nathaniel Davison, who was later British Consul General in Algeria, was able to spend a vacation in Egypt in the company of Edward Wortley Montagu, former British ambassador to the Sublime Porte, and carefully explore the Pyramid.

More intrepid than Greaves, Davison lowered a lamp into the "well," tied a rope round his waist, and had himself carefully lowered into its ominous darkness, about a hundred feet farther than Greaves, only to find the bottom blocked with sand and rubbish. To Davison it appeared strange that anyone should go to such an enormous amount of effort to dig a shaft almost 200 feet into the heart of the Pyramid and simply come to a dead end. But there was nothing more he could do. It was extremely close and filthy at the bottom of the "well," and his candle soon burnt up what little air was available. Also, an immense number of huge bats made it difficult for Davison to keep his candle alight; so he laboriously made his way back to the surface.

Abandoning this quest, Davison set about finding any other secret features within the interior of the Pyramid. At the top of the Grand Gallery he noted that his voice was answered in a curious way by repeated echoes which appeared to resonate from somewhere above him.



Davison's hole at the top of the Grand Gallery.

Placing a candle at the end of two long canes, Davison was able to spot a small rectangular hole about 2 feet wide at the very top of the Grand Gallery, where its wall joined the ceiling.

To reach this hole was a precarious ordeal: the walls of the gallery were polished and slippery; the perch upon which he had to place his ladder was extremely small and stood high above a yawning drop of 150 feet, all the way down the Grand Gallery. Nevertheless Davison managed to raise seven short ladders till the topmost reached the small rectangular hole.

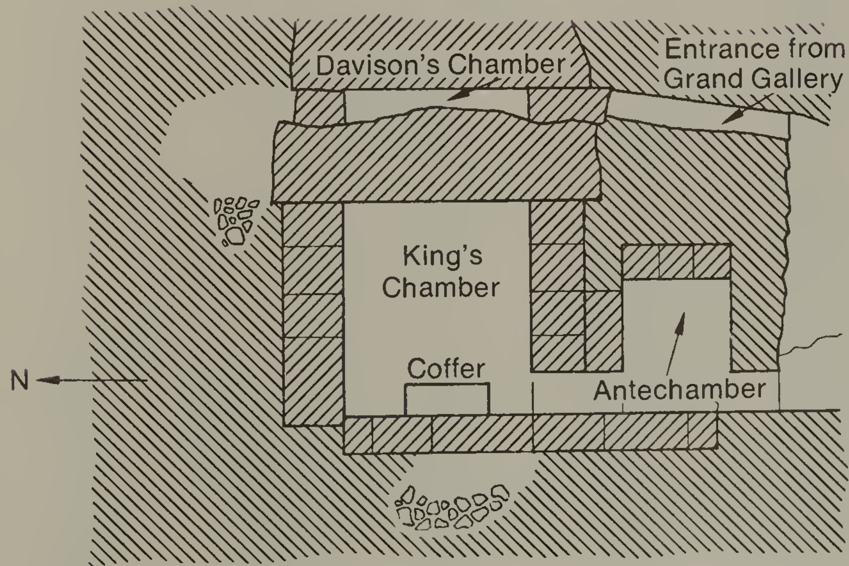
Davison climbed this rickety echeloning with difficulty. At the top he found that he was prevented from entering the 2-foot hole by some 16 inches of bat dung, which had accumulated through the centuries.

Masking his face with a kerchief, Davison managed to wedge himself into the stifling passage and crawl 25 feet to a chamber not high enough to stand in, but every bit as wide and as long as the King's Chamber below it.

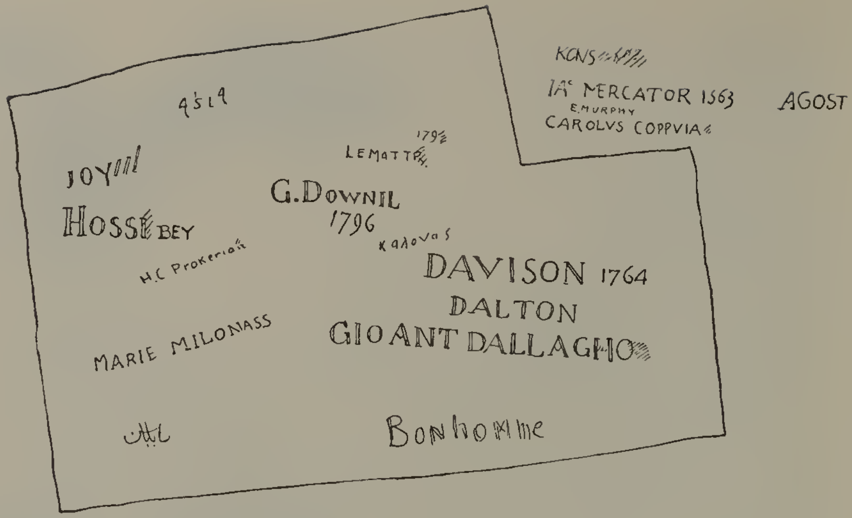
Beneath the bat dung Davison was able to make out a floor consisting of the tops of nine rough-hewn monolithic granite slabs, each weighing up to 70 tons, or as much as a modern railway engine. The under sides of these slabs formed the ceiling of the King's Chamber. To Davison's amazement, the low flat ceiling of the chamber was also constructed of another similar row of granite monoliths.

Otherwise, Davison could find nothing of either historical or architectural interest: no treasure, no inscription, no sign of any further passage. His sole reward was to carve his

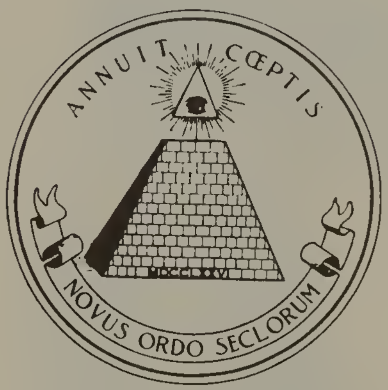
Three distinct types of Egyptian bats as depicted in the eighteenth century. The bats found by Greaves in the Great Pyramid were over a foot long, with an even greater wingspread. Of the more than a thousand known varieties of these curious nocturnal mammals the "flying foxes" of Australia have a wing-spread of up to 5 feet.



Davison's Chamber above the King's Chamber.



Davison's and other graffiti in the Great Pyramid, including that of Mercator, the Flemish cartographer.



Reverse of the seal of the United States of America. According to Manly P. Hall, an expert on Masonic lore, not only were many of the founders of the U.S. government Masons, but they received aid from a secret and august body existing in Europe, which helped them to establish the United States for "a peculiar and particular purpose known only to the initiated few." The Great Seal, says Hall, was the signature of this exalted body, and the unfinished pyramid on its reverse side "is a trestleboard setting forth symbolically the task to the accomplishment of which the U.S. Government was dedicated from the day of its inception." The eagle was apparently intended to represent a phoenix, or symbol of the immortality of the human soul. Great currency has been given to the pyramid and phoenix symbols by placing them upon a one dollar bill.

graffito on the wall and to have the newly discovered chamber named Davison's Chamber in his honor.

When the American Revolution was followed by the French, and Napoleon set out to spread his political doctrines of Free Masonry, interest was rekindled in the Pyramid.

The American revolutionaries had already gone so far as to adopt the ancient Masonic symbol of the Pyramid for the reverse of the Great Seal of the United States.

In their own revolutionary housecleaning, the French outlawed the biblical seven-day week and reverted to the decades of the ancient Egyptians. The *sans-culottes* replaced the old holidays with feast days celebrating Nature and the Supreme Being, the Human Race, the Martyrs of Liberty, Truth, Justice, Paternal Tenderness, Conjugal Faith and even Misfortune. To replace the archaic *toise* made up of six *pied de roi,* the new academicians remeasured the arc from Dunkirk to Perpignan and adopted as a decimal unit the meter, which they computed to be exactly one ten-millionth of the Paris meridian from pole to equator.

On the last day of the month of Floreal in the IXth year of the revolution—our May 19, 1798—General Bonaparte, a sallow little man of 29, set sail from Toulon with a force of 35,000 soldiers crammed into 328 vessels, to conquer Egypt as a steppingstone to India and world domination. Bored by the company of his fellow officers, Napoleon spent most of his time with an extraordinary collection of erudite French civilians classified as "savants." He had brought them along because they were reputed to have acquired a profound knowledge of Egyptian antiquities despite the fact that no one had yet deciphered Egyptian hieroglyphics, so that very little was known of Egypt's remote antiquity.

These savants, a hundred and seventy-five of whom were scattered throughout the fleet, were treated with something less than respect by Napoleon's lower ranks, who were convinced that the "graybeards" had been brought along solely to help locate and dig up hidden treasure. Once the learned gentlemen had landed in Egypt, where their function was to "civilize the natives," they were issued no rations or billets, and whenever the French came under attack from the Mameluke forces of Murad Bey, Napoleon's soldiers would form their famous squares and shout "savants and asses to the center."

Not that the savants ran any real risk. When the French reached the Great Pyramid and were attacked by 10,000 Mameluke horsemen armed with glittering yagatans under the command of Murad himself, in a brilliant green turban astride a snow-white charger, the slaughter consisted entirely of the intrepid Mamelukes. Renowned for having withstood the hordes of Genghis Khan, they were no match for the French sharpshooters and cannoneers.

In two hours two thousand Mamelukes were killed for two score Frenchmen.

Mameluke Beys and their horsemen were mostly converted Christian slaves like the Janissaries and Pages of the Sublime Porte, trained to police, tax, and control Egypt under the nominal suzerainty of the Ottoman Sultan.

In 1811 the Mamelukes were destroyed in one of the foulest but most successful ambushes in history. May 1 they were invited to a feast by Mohammed Ali, the Greek-born adventurer who governed Egypt for the Turks. Dressed in their finery, on richly caparisoned horses, 420 Mameluke Beys arrived at the citadel. Once they were crowded into the narrow street, Mohammed Ali's Albanian mercenaries opened fire from rooftops and windows with rifle and cannon. The Mamelukes screamed, their horses neighed, the street ran with blood. In half an hour all the Mamelukes were dead with the exception of Amir-bey whose horse is reputed to have leapt from the battlements and carried him safely to Syria.

Bonaparte's general staff arriving at the Great Pyramid.

Napoleon Bonaparte before the Battle of the Pyramids.

Murad Bey, whose Mameluke forces were defeated.

July 12, 1798, in the shadow of the pyramids of Giza, some 25,000 Frenchmen, demoralized, hungry, and sleepy from a ten-hour march, were ordered by Napoleon to face what he overestimated to be 78,000 Egyptians, including 12,000 mounted Mamelukes in multicolored turbans and gold-embroidered caftans that floated like gauze. The French formed into squares, ten soldiers deep, their cannons (and savants) in the center. With remarkable discipline the French held their fire till Murad Bey's cavalry were upon them. The Mamelukes outdid themselves in bravery, slashing through the barrels of the Frenchmen's rifles with their scimitars, but in vain. In two hours the squares were surrounded by corpses, the Battle of the Pyramids was over, and Napoleon was master of Egypt. As the flames from the Egyptian fleet illumined Cairo's minarets, Napoleon's men feasted on hoards of captured sweetmeats and looted the gold-laden bodies of the Mamelukes, dumping them into the Nile to float seaward the news of the Egyptian defeat.

The discoveries of the savants within the Pyramid were not sensational, mostly because of the hindrance of bats, which had greatly increased since the time of Davison.

Edmé-François Jomard, one of the younger but more astute of the savants, described the painful process of moving through the passages bent double, seared by the heat of the torches, stifled by lack of air, and sweating profusely from the effort.

Colonel Jean Marie Joseph Coutelle, a military member of the expedition, made another exploration of the well, but complained of being attacked by clouds of infuriated bats, "who scratched with their claws and stifled with the acrid stench of their bodies."

Discharging their pistols at the top of the Grand Gallery, the French were astonished at the repeated echo which sounded like thunder moving away into the distance.

In Davison's Chamber the accumulation of bat dung had risen to 28 centimeters. The savants retired without further contribution to the problem of the Pyramid's interior.

Outside, the savants were more successful. Jomard dogtrotted round the Pyramid, appalled by the amount of sand and debris which had accumulated on its flanks.

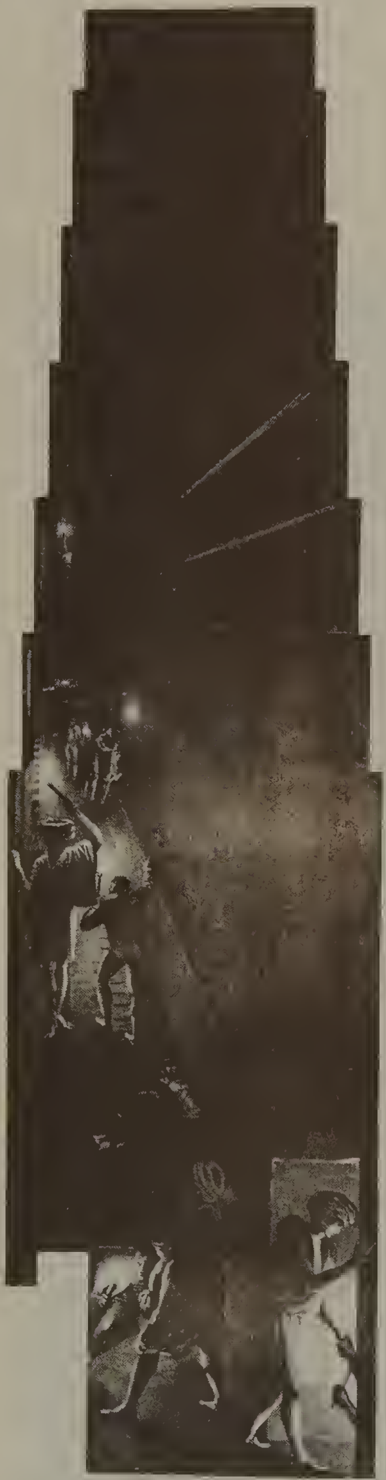
With the help of 150 Ottoman Turks, the French were able to clear the northeast and northwest corners of the building and make an important discovery.

They found the "esplanade" on which the Pyramid had originally been established, as well as two shallow rectangular "encastrements," or sockets, 10 feet by 12, hollowed some 20 inches into the base rock, quite level with each other, where the original cornerstones had once been laid.

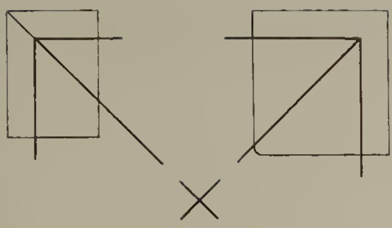
These gave the savants two firm points from which to measure the base of the Pyramid. Though the huge mounds of debris all along the north face of the structure still impeded their efforts, Jomard was able to make a series of measurements up and down and around. These gave a length for the base of 230.902 meters, or 757.5 English feet. The French now needed to know the height.

Jomard took almost an hour to climb the Pyramid, stopping on the way for breath. Once he reached the summit, his imagination was exalted by the view of the green Delta to the north, the black strip of fertile earth along the Nile, the wavelike dunes to the west. Arab villages looked like anthills on the horizon; men at the base of the Pyramid were barely distinguishable.

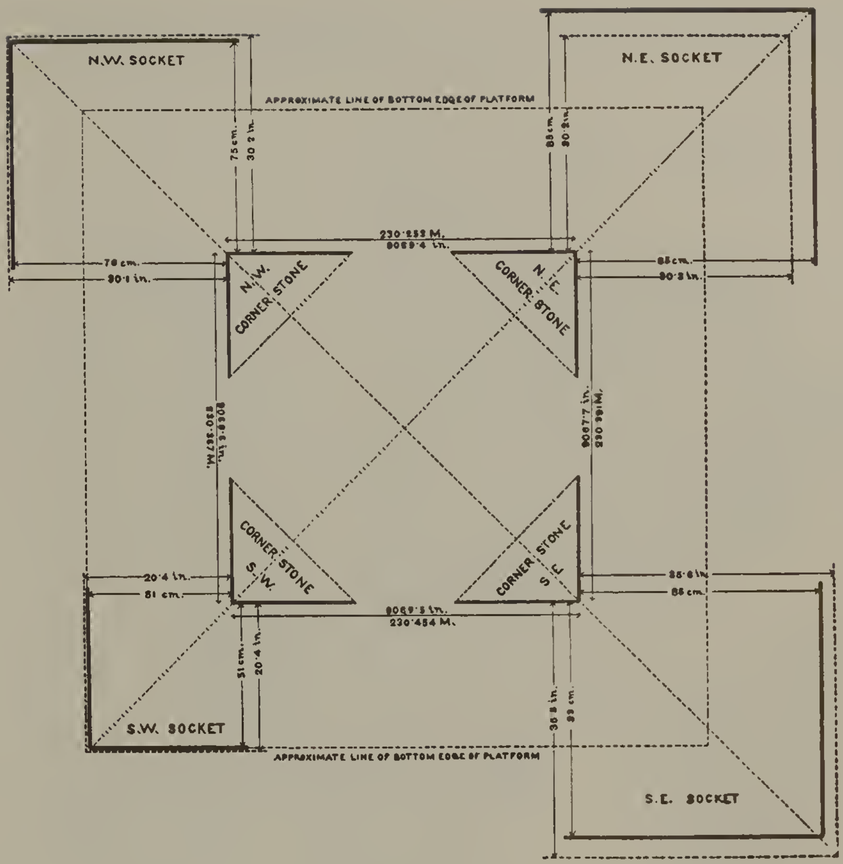
With a slingshot Jomard tried to hurl a stone far enough to clear the base, but in vain. Not even the Arabs had been able to shoot an arrow from the summit that would clear the footing.

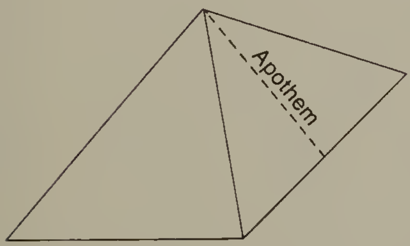


Jomard, Coutelle and Le Père exploring the Grand Gallery.



The positions of the sockets.





To obtain a height of the Pyramid, Jomard measured down each step, for a total of 144 meters, or 481 feet. By elemental trigonometry this gave him an angle for the slope of 51° 19′ 14″ and an apothem of 184.722 meters.

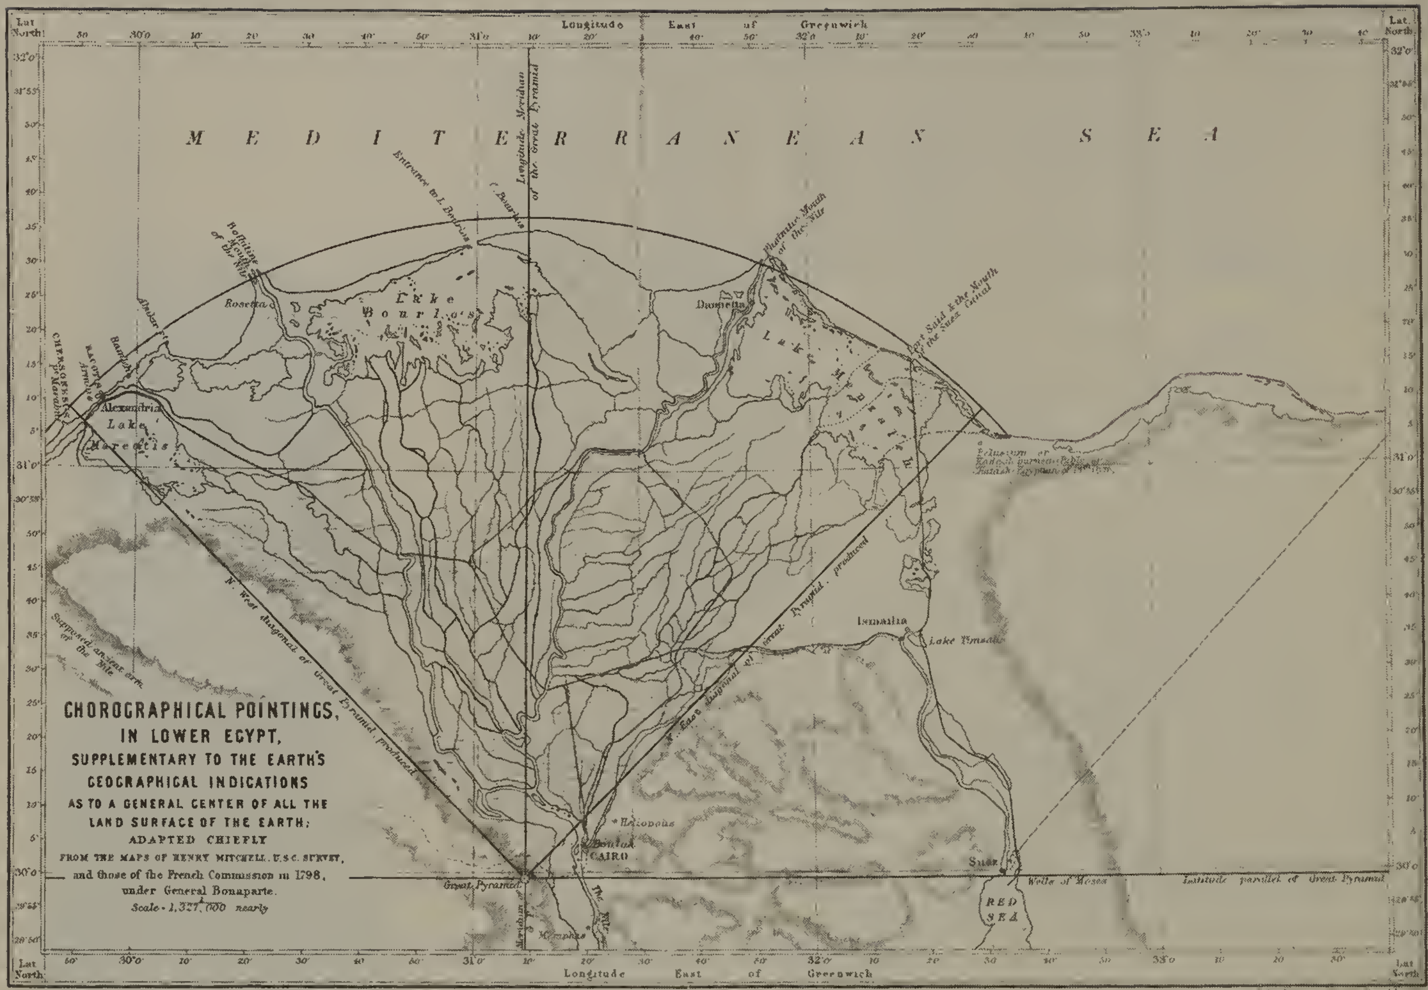
The apothem is the slant height of the Pyramid, or line from apex to center of each base, down which a raindrop would run as the shortest distance to the ground.

Because the outer casing was entirely missing there was no way to know just how thick it had been: so the measure for the apothem had to be an estimate; but the figure of 184.722 meters was to open up a whole new vista for Jomard, who was a very well-read young man.

Jomard remembered that according to Diodorus Siculus and Strabo, the apothem of the Pyramid was supposed to be one stadium long. He also knew that an Olympic stadium of 600 Greek feet—from which our modern stadium is derived—was a basic unit of land measure in the ancient world, one which was said to be related to the size of the earth.

Searching further through the trunks full of classics which the savants had brought to Egypt, Jomard found that the stadium of the Alexandrine Greeks (of Eratosthenes and Hipparchus) had been the equivalent of 185.5 meters—which was within a meter of what he had found for the apothem.

To reinforce the point, Jomard discovered that the



Bonaparte's surveyors found that the Pyramid was accurately oriented to the four cardinal points of the compass and therefore used the meridian running through its apex as the base line for their measurements.

Having mapped Lower Egypt, they were surprised to find that this meridian neatly cut the Delta region into two equal portions, and were even more surprised when they found that the diagonals drawn through the Pyramid, at right angles to each other, completely enclosed the entire Delta.

Evidently a structure which could serve as such a perfect geodetic benchmark could not have been located at random, and without considerable proficiency in astronomy, as well as a developed understanding of the configuration of the planet.

distance between the Egyptian localities as measured by Napoleon's surveyors also coincided with the classical distances between these localities computed in stadia, if the stadium was taken to be 185 meters.

Finally, Jomard learnt from his perusal of the classics that a stadium of 600 feet was considered to be 1/600 of a geographical degree.

Jomard calculated that a geographical degree at the mean latitude of Egypt was 110,827.68 meters. Dividing this figure by 600 resulted in a measure of 184.712 meters. This was within 10 centimeters of his value for the apothem.*

Could the Egyptians, Jomard wondered, have been capable of working out their basic units of measure—such as the stadium, the cubit, and the foot—from the size of the earth and then built this knowledge into the Pyramid?

To reinforce this exciting hypothesis Jomard found that several Greek authors reported that the perimeter of the base

* At Syene the degree of longitude is 110,791.11. At Alexandria it is 110,892.66. The mean for the whole planet is 111,111.9. Jomard took the mean for Egypt.

of the Pyramid was intended to measure half a minute of longitude. In other words, 480 times the base of the Pyramid was equal to a geographical degree.

Jomard took the 110,827-meter degree and divided it by 480. The result was 230.8 meters, or again within 10 centimeters of his measured length of the base.

To find the length of the cubit that would fit these measures, Jomard again consulted the classics. According to Herodotus 400 cubits made a stadium of 600 ft. Jomard divided the apothem of the Pyramid by 400 and obtained a cubit of .4618 meter. To his surprise this turned out to be the common cubit of the modern Egyptians.

According to other Greek sources the base of the Pyramid was said to be 500 cubits. Multiplying his .4618 meter cubit by 500, Jomard got 230.90 meters—which was just what he had measured for the base.

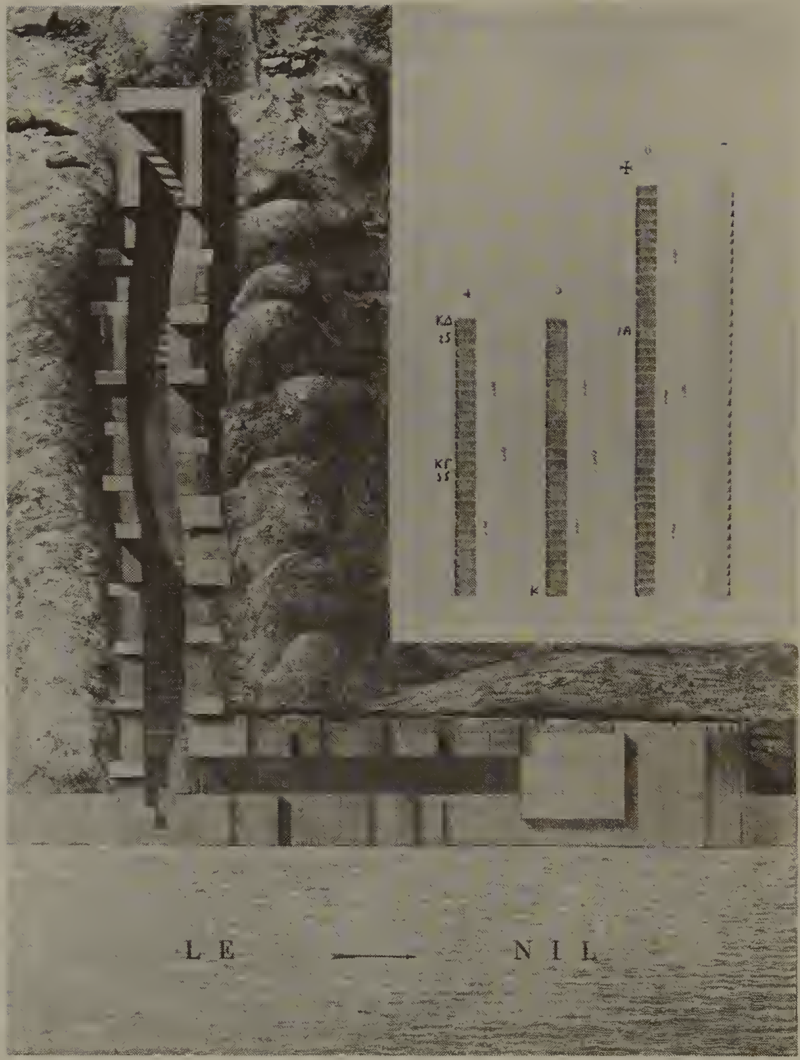
Jomard's theory was impressive to his colleagues; but when Gratien Le Père and Colonel Coutelle *re*-measured the base of the Pyramid, they found it to be 2 meters longer. They also *re*-measured the height with a specially designed instrument, step by step, and the results showed Jomard's angle of incline to have been too low, and his apothem consequently too short.

In vain Jomard argued that he had found an even more surprising coincidence in that the four-hundredth part of his base of the Pyramid gave a figure of .5773 meter, which was exactly the length of a longer modern Egyptian cubit called the *pyk belady*.

Jomard's colleagues insisted there was no evidence in any other ancient Egyptian building of the use of such odd cubits and that the only adequate cubit they had found was the one marked on the nilometer of Elephantine, which was nearly the same as the "royal" cubit of Memphis of .524 meter, or 20.63 inches, which Newton had derived from the dimensions of the King's Chamber.

Unperturbed, Jomard continued his observations. It seemed to him that from the bottom of the Descending Passage, the ancients might have been able to see the transit across the meridian of some circumpolar star, and thus have previously established true north and correctly oriented the building. Because of the length and narrowness of the passage, he said, they might even have been able to see such a star by daylight. His colleagues argued that the trap door would have prevented any such observation.

Jomard suggested that the King's Chamber, with its empty sarcophagus, might not necessarily have been a tomb but a metric monument, designed to embody, and perpetuate, a system of measures.



Nilometer discovered by the French at Elephantine, near Syene, used by the Egyptians for measuring the rise of the Nile at flood time, and marked in cubits very close to the royal cubit of Memphis.

To the end, Jomard remained convinced that the builders of the Pyramid had the necessary astronomical know-how to measure a geographical degree and thus the true circumference of the earth, and had developed an advanced science of geography and geodesy which they had immortalized in the geometry of the Great Pyramid.

Jomard pointed out that Herodotus, Plato, Diodorus and many others had all named Egypt as the birthplace of geometry, that Solon as well as Plato had come to Egypt to study geometry, and that Pythagoras had learnt from the Egyptians his theorems of geometry, his art of calculation, and his doctrine of metempsychosis.

Jomard's classically indoctrinated colleagues could not stomach the idea that their cherished Greeks might not be the founders of geometry; so the pursuit was dropped.

One last boost to Jomard's theory was given by one of Napoleon's favorite generals, Louis Charles Antoine Desaix: on his way up the Nile to conquer Upper Egypt, the 29-year-old general found a gorgeous temple near Thebes half

Edmé-François Jomard.

buried in the sand. On its ceiling was a circular zodiac. Because the zodiac clearly depicted the skies over Egypt and showed the recognizable constellations in quite different positions, the savants deduced that it must have represented the skies many centuries in the past and that the ancient Egyptians must have been acquainted with the zodiacal constellations in remote antiquity.

Unfortunately, an inscription also found in the temple appeared to date it from Ptolemaic times, shortly before our era; so another of Jomard's balloons was pricked.

Meanwhile Napoleon, whose logistical mind enabled him to figure that the Great Pyramid and its Giza neighbors contained enough stone to build a wall 3 meters high and one meter thick all around France, had become attracted by the arcane qualities of the King's Chamber.

On the twenty-fifth of Thermidor (the Revolutionaries' August 12, 1799) the General-in-Chief visited the Pyramid with the Imam Muhammed as his guide; at a certain point Bonaparte asked to be left alone in the King's Chamber,

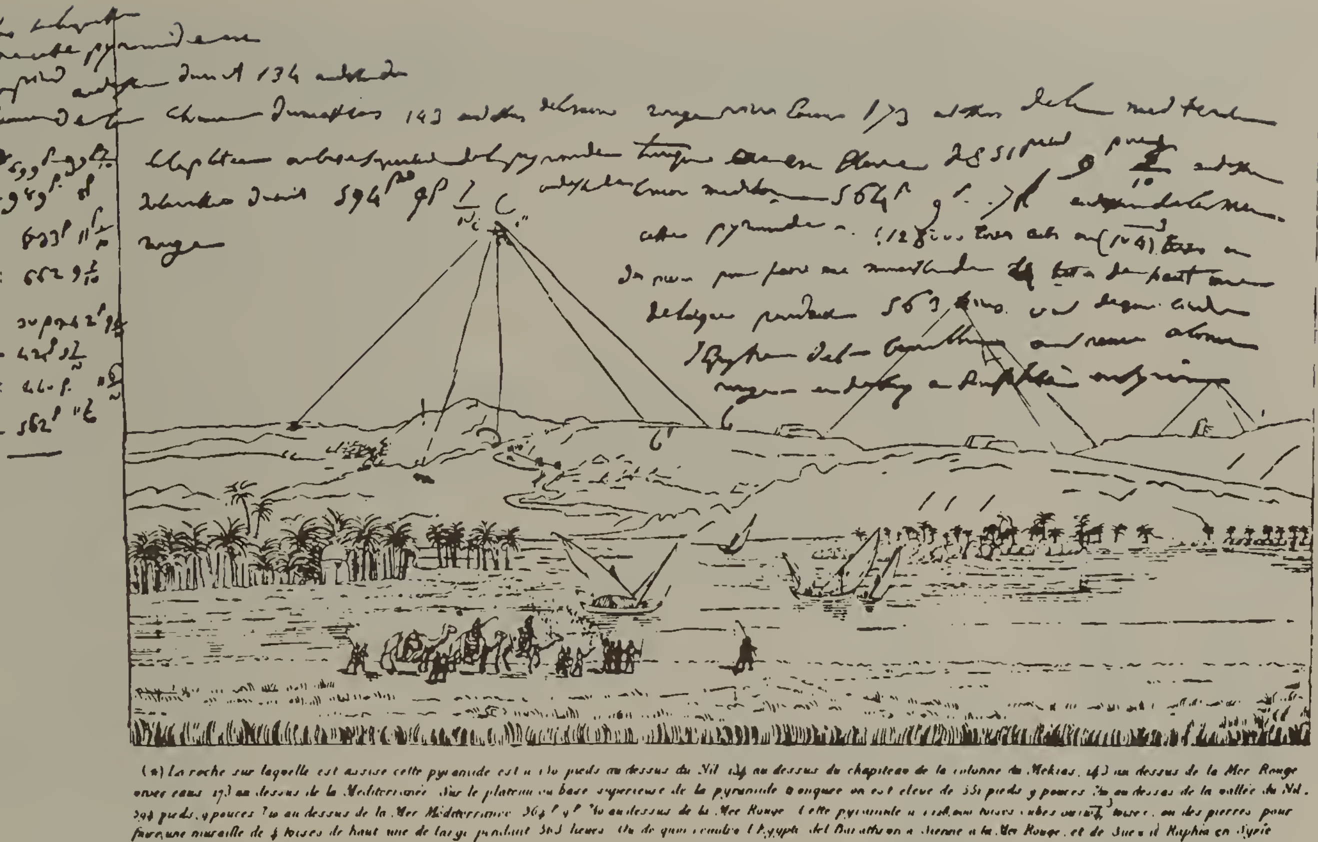
Napoleon in the King's Chamber.

as Alexander the Great was reported to have done before him.

Coming out, the general is said to have been very pale and impressed. When an aide asked him in a jocular tone if he had witnessed anything mysterious, Bonaparte replied abruptly that he had no comment, adding in a gentler voice that he never wanted the incident mentioned again.

Many years later, when he was emperor, Napoleon continued to refuse to speak of this strange occurrence in the Pyramid, merely hinting that he had received some presage of his destiny. At St. Helena, just before the end, he seems to have been on the point of confiding to Las Cases, but instead shook his head, saying, "No. What's the use. You'd never believe me."

When military and political priorities obliged Napoleon to pull out of Egypt, he abandoned his savants to be captured by the British. Chivalrously treated as civilians, they were allowed to return to France with their notes and drawings. By the time they got home Napoleon had gained sufficient power as First Consul to order them to produce a truly monumental work on all they had discovered about the sites, buildings, inscriptions, life, language and manners of the ancient and modern Egyptians. With the help of an army of painters, typographers and four hundred engravers, the study was completed and published over a period of 25 years



Napoleon's notes on his sketch of the Pyramid.

with the title, *Description de l'Egypte ou Recueil des observations et des recherches qui ont été faites en Egypte pendant l'expédition de l'armée française.*

The work ran to nine folio volumes of text and twelve of plates, and was described as "the most immortal conception and glorious performance of a book ever realized by man." Jomard contributed to it brilliantly, but his perspicacious thesis received little credit.

The savants were scooped by the wily Baron Vivant Denon, who brought out two volumes of the etchings he had made during the campaign in Egypt. His *Voyage dans la basse et la haute Egypte* became an instant best seller, stunning Europe with incredible sights of an unknown world of Egypt both ancient and modern, and launching a great vogue for the style known as *Empire.*

Denon's publication and the *Description de l'Egypte* which followed it piecemeal were to turn what had been a French military disaster into a cultural triumph. They also shattered once and for all the figment that before the Homeric Greeks there had been nothing but primitive barbarism.

Scientifically the most sensational discovery made by the French in Egypt proved to be a 3-foot diorite slab engraved with hieroglyphics found by a Captain Bouchard in a branch of the Delta near Rosetta. Hijacked by the British, the

Dominique Vivant Denon accompanied Napoleon on his expedition to Egypt and produced a series of drawings and etchings of the land of the Pharaohs which revealed a whole new world to an amazed Europe.

Born an aristocrat and renowned mostly for a series of pornographic etchings, Denon managed to ingratiate himself with the revolutionaries and escape execution. Hypnotically attractive to women, Denon was befriended by such notables as Madame de Pompadour and Catherine II of Russia. He was introduced to Napoleon by his wife Josephine.

In Egypt Denon would ride ahead of the French columns, sometimes under fire, to catch the vivid scenes of action. Sketching directly from the saddle, in which he had been for as many as sixteen hours, his eyelids ripped by the windblown sand, and seeing through a veil of blood, Denon managed to reproduce the most evocative scenes of Egypt, ancient and modern, full of verve and an exquisite sense of composition.

Brought up to think that Greek architecture of the best period was *the* standard of beauty, he was seized by the extraordinary beauty of the Egyptian works "with no extraneous ornaments or superfluity of lines." His two-volume illustrated description of Bonaparte's campaign in Egypt was an instant bestseller in Europe.

Denon was made a baron by his emperor and became superintendent of the Louvre and director of the Beaux Arts.

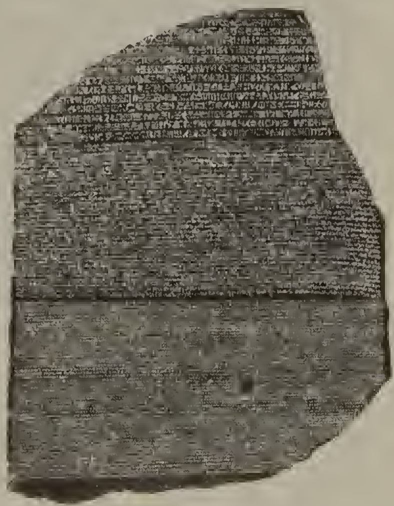
J. F. Champollion.



The Rosetta Stone, found in 1799, was ordered by Napoleon to be placed in the French Institute in Cairo. By an article of the treaty of capitulation it was surrendered to the British in 1801. Major General Turner sailed with it to Portsmouth in 1802 and deposited it with the Society of Antiquarians in London who turned it over to the British Museum.

A plaster of paris cast of its inscription in hieroglyphs, demotic Egyptian, and Greek, enabled Champollion to decipher the hieroglyphic language of the ancient Egyptians and formulate a system for their grammar; this made it possible for archeologists and Egyptologists to read the millennial inscriptions found throughout Egypt.

trophy ended up in the Egyptian Gallery of the British Museum. It lay there undeciphered for twenty years, until another young Frenchman, Jean-François Champollion, was to crack the mystery of its ancient hieroglyphs and throw the first real light on several millennia of Egypt's mysterious past.

As Napoleon had somewhat pompously remarked when elected a member of the National Institute, "the only true conquests are those gained by knowledge over ignorance."

V. EXPLORING WITH CHISEL AND GUNPOWDER

After Wellington's victory at Waterloo, the efforts of the French savants at the Pyramid were forgotten and the sockets they had cleaned were covered once more with the sands of the desert.

It remained for an obscure Italian to make the next impressive discovery within the Pyramid. While Napoleon was languishing on St. Helena, an exophthalmic Genoese merchant, Captain G. B. Caviglia, arrived in Egypt as the master of a Maltese vessel flying the British flag. Seized by the mystery of the Great Pyramid, he gave up the sea and settled down to exploring the Pyramid and its neighbors on the Giza plateau, financing himself by helping rich Europeans scavenge the surrounding tombs to assuage their taste for original Egyptian antiquities—a taste which ran to anything from scarab rings to thousand-ton obelisks.

Described by a contemporary as an "enthusiastic devotee at the shrine of antiquarian learning, who sacrificed country, home, friends and fortune for the indulgence of the refined though eccentric taste of exploring the hidden mysteries of the Pyramids and Tombs of Egypt," Caviglia cleared out the bat excrement from Davison's Chamber and set up housekeeping within it, turning "the gloomy recess into a residential apartment"—though how this was accomplished under a 3-foot ceiling is not explained.

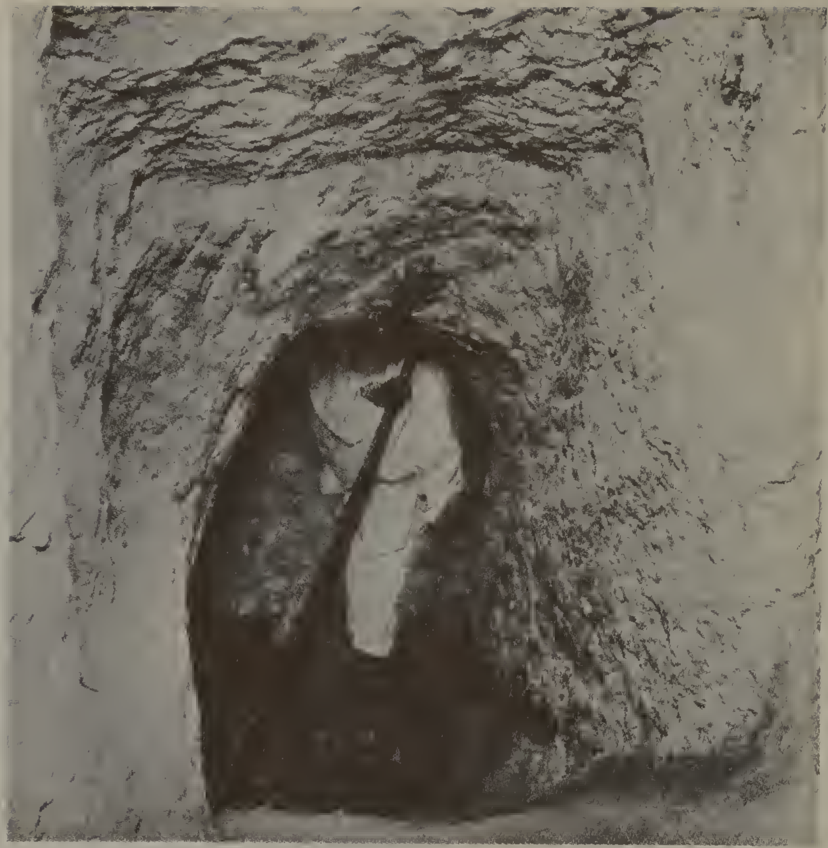
Alexander William Crawford (later Lord Lindsay), who encountered Caviglia in Cairo, found the Italian to be a deeply religious man, well versed in the Bible, which he constantly quoted, but also a man with some pretty strange ideas about what he would find in the Pyramid. To England Crawford wrote: "Caviglia told me that he had pushed his studies in magic, animal magnetism, etc., to an extent which nearly killed him . . . to the very verge, he said, of what is forbidden man to know, and it was only the purity of his intentions which saved him."

Caviglia was convinced that if he dug into the Pyramid he would eventually encounter a secret room. To find it he hired a gang of Arab workmen to dig a tunnel leading off from Davison's Chamber. But no matter how far they dug, they found nothing but solid masonry.

Caviglia cleared the sand from the base of the Sphinx and revealed the footing for a missing obelisk between its paws.

At last Caviglia was obliged to give up the job; to console himself he set about analyzing the mystery of the "well." Lowering himself down the shaft, Caviglia got as far as 125 feet below the grotto only to find, as Davison had before him, that the bottom was completely stopped, and that the air was so scarce his candle spluttered, making it difficult for him to breathe.

However, as the bottom appeared to be mostly sand and loose rocks, Caviglia was determined to unplug it and see where it led. For a while he managed to impress a gang of Arabs into raising basketfuls of the sand all the way up to the top of the well; but the shaft was so tight, the air so fetid with bat dung, and the dust so suffocating, that the Arabs began to faint and refused to work further. Caviglia attempted to clear the air at the bottom of the well by burning chunks of sulfur, but it was still impossible to breathe that far down for any length of time, and the Arabs would not resume their digging.

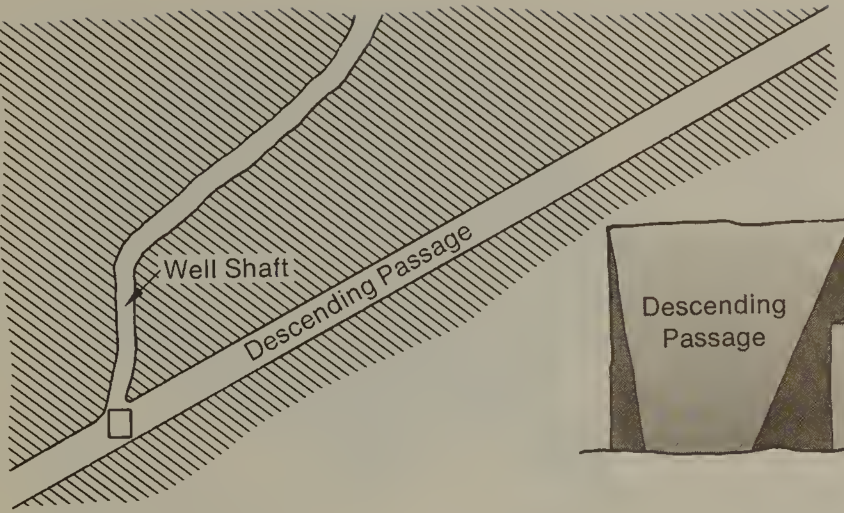


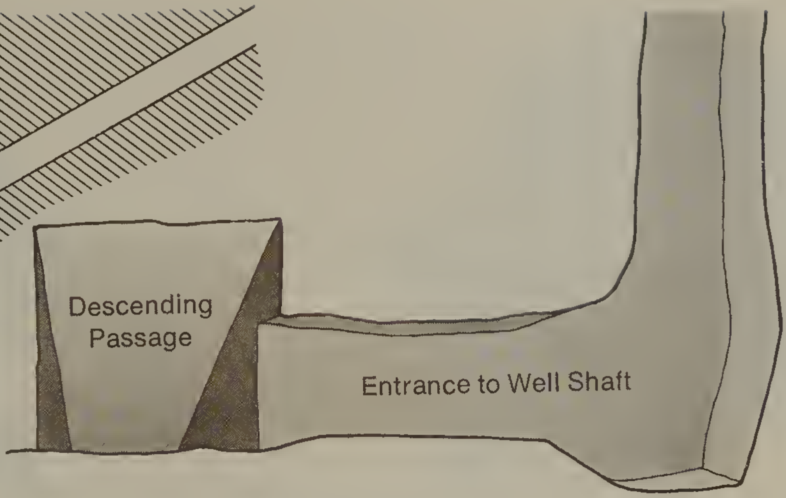
Lower end of the well shaft.

Caviglia decided to attack the problem from a different angle. He would attempt to clear the main Descending Passage to the subterranean pit which had been filled since Al Mamun's time with the refuse of the plugs they had broken out of the Ascending Passage. Caviglia had the refuse carried up and out of the Pyramid, and was able to push his way on hands and knees down the passage for 150 feet; then the air became so impure and the heat so great that he started to spit up blood. Still, he would not give up. At the end of another 50 feet he made a discovery which seemed to indicate he might be on the right track. On the west side of the passage he found a low doorway leading into a hole. As the Arabs began to dig upward into this hole, Caviglia noted a strong smell of sulfur. It occurred to him that he might have hit upon the solution to his previous problem: the smell of sulfur might be coming from the bottom of the well, which must therefore be very close.

Digging harder, the Arab workmen dislodged some loose earth. A pile of dust and rubbish fell onto them, including a basket and ropes which had been left at the bottom of the well. There was also a sudden gush of air up the tunnel, and those in the passage were able to breathe with ease. Caviglia had discovered the end of the well. But a greater mystery remained. Why had it been dug there, when, and by whom?

As Caviglia set about resolving this mystery, another





Where the well joins the Descending Passage.

strange figure joined in the Pyramid research, one quite the opposite of the romantic, uncommunicative Caviglia. Richard Howard-Vyse, a British Guards officer, at first collaborated heartily with Caviglia, but they soon grew angry at each other and came to a heated parting.

Colonel Howard-Vyse, son of General Richard Vyse and grandson of the Earl of Stafford, was a martinet with little humor who had been equerry to the Duke of Cumberland (later first king of Hanover) and had stood unsuccessfully for Parliament in the borough of Windsor. He has been described as thoroughgoing and as artless as Wellington, under whom he served.

Colonel (afterward General) Howard-Vyse in 1830.

A trial to his family, who were pleased to have him away from the county seat in Buckinghamshire, even if it cost them some of the family patrimony, Howard-Vyse was to spend over 10,000 pounds sterling on exploration of the Pyramid site.

Howard-Vyse first saw the pyramids on a moonlit ride from across the Nile at Turah in November of 1836, during a trip to Egypt as "a fashionable amusement seeker." In his own words he was attracted by "the remote antiquity and uncertainty of their origin, and . . . the peculiarity of their mysterious construction." He was curious about "the purpose for which the passages and chambers already discovered were originally intended, but in much greater degree respecting any other passage or apartments which might reasonably be supposed to exist in the enormous structures."

Impressed by Caviglia's theories about the mysterious and hermetic purposes for which the Great Pyramid had originally been constructed, Howard-Vyse hired the services of a professional civil engineer, John Shae Perring, who had been an assistant to Mohammed Ali, the khedive of Egypt. Perring was to take measurements of all the pyramids and tombs which had thus far been discovered on the Giza plateau, as well as many of those farther south.

In his *La Pyramide de Cheops ât-elle livré son secret* Fernand Ihek says that the shape of the Great Pyramid was such that it enabled bodies (either animal or vegetable) to become naturally mummified when placed within the King's Chamber. He says the end result was a desiccation or dehydration of the body with no sign of putrefaction. Experiments revealed that an uncleaned trout became mummified in thirteen days, a radish in fifteen days, and the heart of a sheep in forty days.

Ancient Egyptians removed the brain and entrails of a body to be mummified without scarring it by pulling the brain out through the nose and the viscera through the anal aperture.

The body was then soaked in brine for a month; aromatic plugs, often perfumed with onion, were placed in the nostrils and other orifices.

According to Manly P. Hall, there is every reason to suppose that originally only those who had received some grade of hermetic initiation were mummified; for "it is certain that, in the eyes of the Egyptians, mummification effectually prevented reincarnation."

Reincarnation was considered necessary to imperfect souls, or those who had failed to pass the tests of initiation. "The body of the Initiate," says Hall, "was preserved after death as a species of Talisman or material basis for the manifestation of the soul upon earth." When the body of a "god-like" Pharaoh was mummified it could serve as a medium through which survivors could communicate and plead their cause with "the beyond." At first only Pharaohs appear to have been mummified; later it was done to persons of royal rank, and to anyone who could afford it; eventually even animals were mummified.

Howard-Vyse set up his headquarters in an empty tomb near the Great Pyramid and was soon employing a larger number of workmen than anyone since the time of Al Mamun, often as many as seven hundred, using Captain Caviglia as superintendent of works.

All went well till the colonel chose to take an extended tour up the Nile to inspect a further series of pyramids. When he returned he was outraged to find that Captain Caviglia had almost entirely neglected the Great Pyramid and was using the men hired by Howard-Vyse to search for mummies and little green idols in the neighboring burial pits.*

Caviglia became equally outraged at the colonel's reprimands, and gesticulated abusively declaring that "he alone had the head to conduct excavations and to understand the value of 'curios' and *'anticos,'* the colonel having nothing but money."

When the colonel asked for the return of his money, Caviglia disdainfully appeared at breakfast in the colonel's tent and threw on the table the money wrapped in an old stocking.

It was the end of Caviglia's exploring in Egypt. He retired to Paris, where he was sporadically supported by another great scavenger of antiquities, the former British ambassador to the Sublime Porte, Lord Elgin.

Howard-Vyse took over Caviglia's duties. In the words of a Victorian lady admirer, the colonel "sat down before the Great Pyramid as a fortress to be besieged, and through winter and spring and the burning summer of Egypt, long after all travelers had left the country, became the sole director of operations, clerk of the works and paymaster of his hundreds of workmen, day after day, month after month, until they had wrought out his own ideas of pyramidical exploration to the full. For not only was he one of those men who was never known to turn back after having put his hand to the plow, but he was a religiously [*sic*] minded man, a devout Christian, who felt that he was in this case called to a certain work for the Master, and though in the first instance he had distrusted himself in a new field of labor

* Mummy flesh was in great demand in Europe during the sixteenth and seventeenth centuries as a medicinal; it was a common drug to be found in all apothecaries. Mistaken for Persian *moma,* or pitch, which was used to heal cuts and bruises, mummy flesh was believed to make fractures unite in a few minutes and to be good for all kinds of internal ailments. When mummies became scarce traders used the bodies of executed Christians, or the bodies removed from hospitals, many of which had died of loathsome diseases. The bodies were stuffed with bitumen, wrapped in bandages and baked.

so that he had thought it better to use the purchased help of the Italian professional, yet when that failed he became a most admirable example to all kinds of men, rich and poor alike, of giving himself to the work, putting his own shoulder to the wheel, and never quitting it until the end was gained, during all the time, too, preserving the utmost urbanity, but dealing out the strictest justice in a manner that made a most honorable and lasting impression on the tawny Arabs around him."

In the Queen's Chamber Colonel Howard-Vyse had relays of men work day and night digging up the floor in front of the niche, but all they found was an old basket: so they refilled the hole.

In Davison's Chamber they found a crack in the ceiling through which they could run a reed about 3 feet long. Believing this to be an indication of a similar chamber above, Howard-Vyse had the workmen chisel their way into the granite over their heads. But the stone was too hard, and again the Arabs could not stand the heat in the restricted space of Davison's low-ceilinged chamber.

Special quarrymen were imported from the Mokattam hills across the valley. When even they could not manage the job, the colonel resorted to gunpowder to blast his way upward. To handle the charges he found a workman called Daued who lived mostly on hashish and alcohol. Daued successfully set off the blasts—a job that was particularly dangerous as the splintered granite flew about like shrapnel.

When the dust subsided Howard-Vyse found that they had indeed broken through to another chamber, which he chauvinistically named after Wellington. Its floor was the top of the eight monolithic blocks of granite which formed the rough-hewn ceiling of Davison's Chamber, each block weighing over 50 tons. About a yard above them lay another flat ceiling made of eight blocks of granite.

The new chamber had a strange effect on those who entered; it turned them black. Instead of bat dung, the floor was covered with a thin black powder which when analyzed turned out to be exuviae, or the cast-off shells and skins of insects. Of living insects there were none to be found.

Convinced that the monoliths of the ceiling were in turn the floor of a third chamber, Howard-Vyse ordered the blasting resumed. The colonel's excavations above the King's Chamber became more and more difficult as they rose vertically to a height of 40 feet and took three and a half months to accomplish.

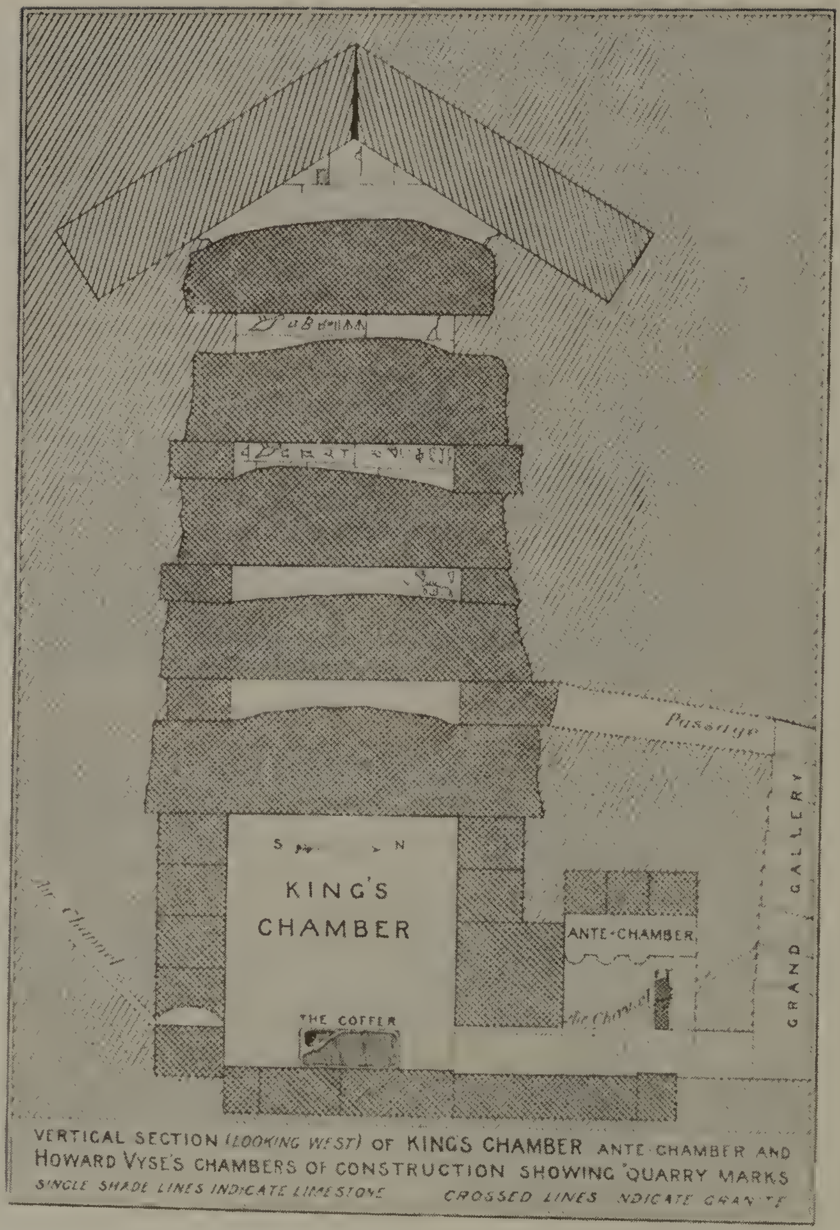
One by one, three more chambers were found above the two already discovered, the uppermost being gabled with huge blocks of sloping limestone. These chambers

Construction chambers above the King's Chamber.

As some of the quarry marks found in the chambers are hieroglyphs signifying "year 17," Egyptologists deduced that the building had reached that stage in the seventeenth year of the king's reign. Most of the marks were roughly daubed in red paint and appeared upside down, indicating they were quarry marks and not decorations.

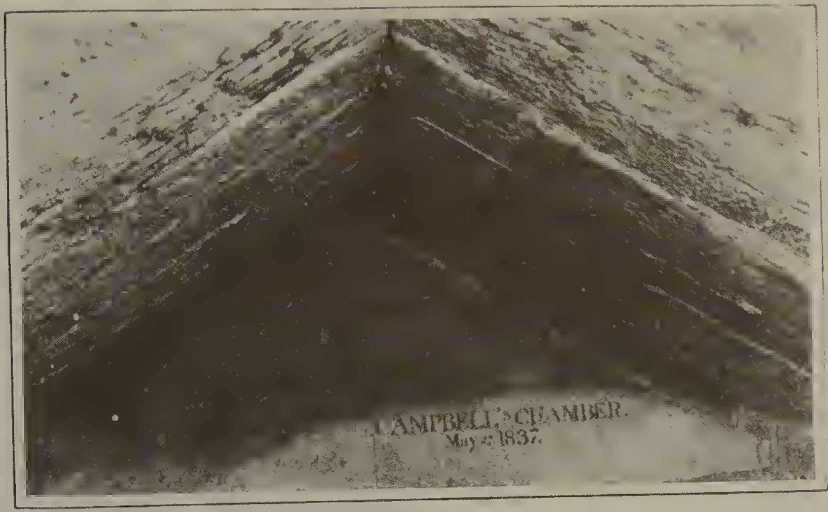
Similar marks, mostly red, but occasionally black, were also found on the first five or six courses of the Pyramid, behind the casing blocks.

Howard-Vyse sent copies of the crayon marks to Samuel Birch of the British Museum who identified one of the ovals as belonging to King Suphis, or Shofo, or Khufu.



Sectional drawing of the King's Chamber, looking west, showing all four chambers discovered by Howard-Vyse.

Lady Arbuthnot's Chamber, discovered by Howard-Vyse.



Ceiling construction above Campbell's Chamber.

Howard-Vyse named in turn for Admiral Nelson, for Lady Ann Arbuthnot, wife of Lt. General Sir Robert Arbuthnot, who happened to visit the Pyramid shortly after the room was discovered, and for Colonel Campbell, Her Brittanic Majesty's Consul in Cairo.

The most interesting discovery was not so much the chambers themselves but some red-paint cartouches daubed on the inner walls of the upper chambers. Thanks to the Rosetta Stone and Champollion's successors, one of these cartouches was recognized by Egyptologists as belonging to Khufu, believed to be the second Pharaoh of the Fourth Dynasty, called Cheops by the Greeks, whose reign was thought to have occurred in the third millennium before our era.

There was, of course, no way to prove that this Khufu was indeed the Cheops who had reigned in Egypt. But the fact that similar cartouches had been found in the quarries of the Wadi Magharah hills, from which much of the stone for the Pyramid was derived, added weight to the assumption.

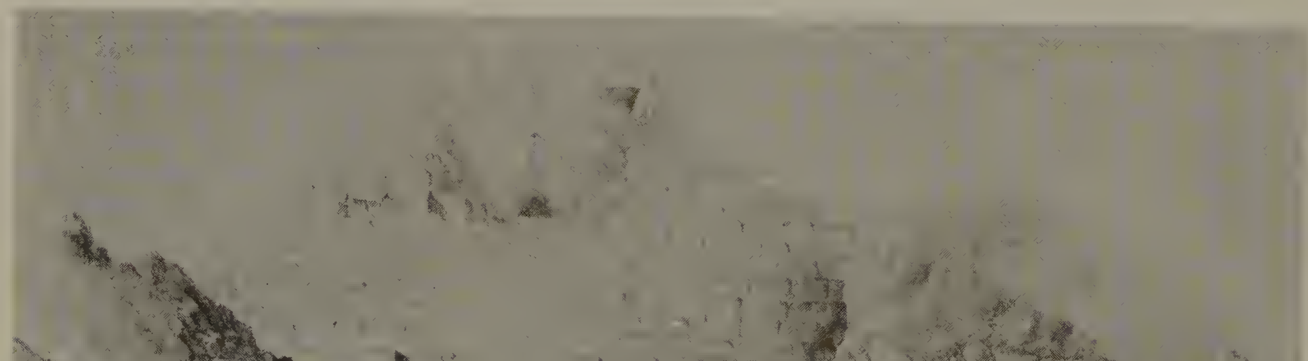
One thing seemed clear. Whoever had daubed the cartouches on the inner walls of the upper chambers must have done so *before* the chamber was sealed and the Pyramid completed; there appeared to be no entrance or exit other than the one blasted by the colonel.

Doubt still lingered that there might have been a far earlier king with a similar cartouche, quite unknown to Egyptologists; but until further evidence could be adduced, it seemed hard to go against the theory of the Pyramid having been built in the reign of the historic Cheops, as reported by Herodotus and other classic authors.

As for the reason for the five superimposed chambers, it was the conclusion of Howard-Vyse, and many who came after him, that they had been designed to relieve the flat

Air vent in the north wall of the King's Chamber.

Casing stones and pavement as exposed by Howard-Vyse. Both entrances can be seen, Al Mamun's on the sixth course, and the original entrance ten courses higher.



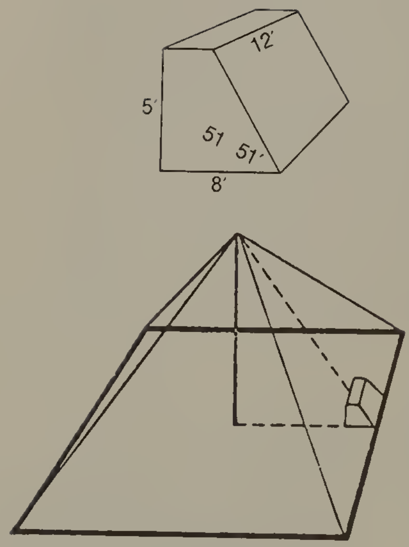
ceiling of the King's Chamber from the pressure of the 200 more feet of solid masonry piled above it.

Another remarkable discovery made by the colonel in the walls of the King's Chamber was to vindicate the hypothesis of Dr. Harvey. Greaves had found the two 9-inch-wide openings in the side walls of the King's Chamber, but it was not till Mr. Hill, one of Howard-Vyse's assistants, who ran a hotel in Cairo, climbed high up on the outer surface of the Pyramid and found two similar outlets that it was established they were connected for over 200 feet right through the solid masonry to the holes in the King's Chamber. The colonel's engineer, Perring, was nearly decapitated when a stone dislodged by Hill came crashing all the way down one of these conduits.

When the conduit was cleared, an immediate rush of cool air entered the King's Chamber. Thus ventilated, the temperature of this chamber in the center of the Pyramid was to remain at an even and pleasant 68 degrees, irrespective of the weather or season outside, a prehistoric system of air conditioning. This added substance to Jomard's theory that the chamber might have been the repository for weights and measures which require an even temperature and constant barometric pressure, such as the Paris observatory for measurements of standards 85 feet below ground.

Even more sensational for those who were bent on unraveling the secrets of the Pyramid was the next discovery of Howard-Vyse. Ever since the Middle Ages, when the Arabs had despoiled the outer casing, the whole perimeter of the base of the Pyramid had been heaped high with fragments of limestone, and sand and debris, often in piles as high as 50 feet. The two northern corners uncovered several years earlier by the French had already been buried again. This time Howard-Vyse decided to clear away a patch of debris in the center of the north façade to see if he could get down to the very base and bedrock of the Pyramid. In doing so, he was to make a great discovery: two of the original polished-limestone casing stones on the lowest level of the Pyramid were still in the spot where they had been originally placed.

This ended the argument about the casing; it silenced forever those who had continued to consider it a fiction that the whole of the Pyramid had once been covered with a fine mantle of limestone. The original limestone was there, and so finely carved that it was now possible to correctly measure the angle of the slope on which the Pyramid had originally been constructed. The blocks, 5 feet high, 12 feet long, and 8 wide, showed an angle of about 51° 51′, a little sharper than the one estimated by the French.



Relation of the casing stones to the slope of the Pyramid.

The base circuit of the Pyramid rests on a platform of finely finished limestone blocks which project beyond the end of the casing stones for an average of 2 feet on the south, east and west sides, and are still in place some 33 feet from the north edge.

This platform is so finely leveled that the official survey of the Egyptian government found it does not exceed 7/8 inch from dead level, and this variation may be due to subsidence.

At present it is not possible to say how far the platform extends under the building; but where the platform stones have been removed, the bed-rock is found to have been cut and leveled to receive each individual stone, sometimes as deep as 2 inches.

On the north side the platform stones have been deliberately laid at irregular angles, each corner being carefully cut out to receive the next irregularly angled stone.

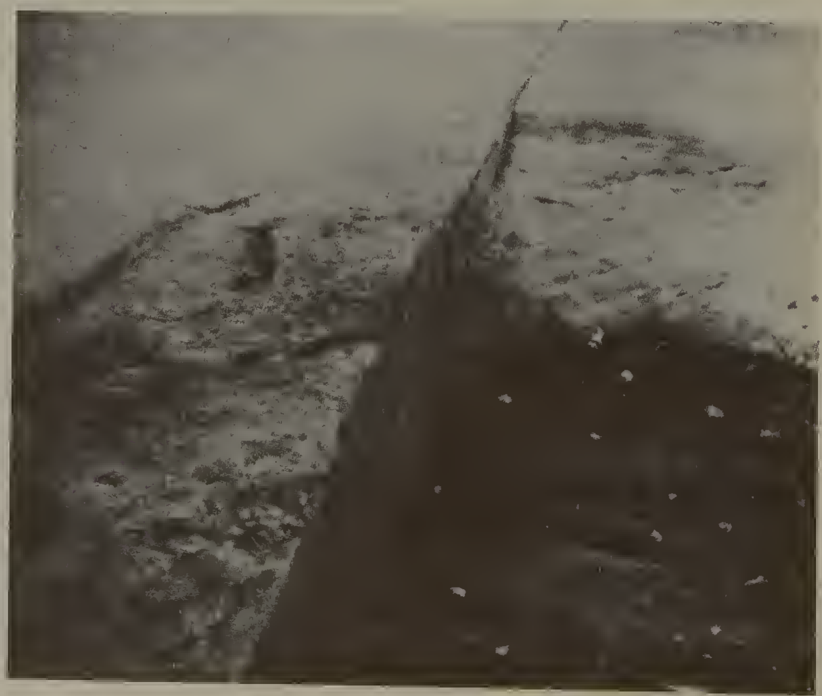
Hewn to the correct angle and polished to a uniform surface, they were quite perfect, in the words of Howard-Vyse, "in a sloping plane as correct and true almost as modern work by optical instrument makers. The joints were scarcely perceptible, not wider than the thickness of silver paper."

The colonel also managed to uncover part of the original pavement on which the building rested, and which appeared to stretch away to the north. "It was well laid and beautifully finished," noted Howard-Vyse, "but beneath the edifice it was worked with even greater exactness, and to the most perfect level."

Though the reason for this astounding accuracy on the northern side was not to become apparent for some years, Howard-Vyse summed up his discoveries thus: "I consider the workmanship displayed in the King's Chamber, in the pavement and the casing stones, is perfectly unrivaled."

The colonel had the casing stones quickly covered up pending permission to take them to the British Museum, but he was not able to prevent the infuriated local Moslems from uncovering them again and smashing the fine edges with hammers, jealous that Christians might obtain and dispose of something of value in their country.

With the angle of 51° 51′ of the casing stones and the base length of 763.62 feet measured by the Frenchmen Coutelle and Le Père, it was now possible to obtain by trigonometry a new dimension of the Pyramid. Its perpendicular height to where the missing capstone was presumed to have come to a point was figured to be 485.5 feet, or 147.9 meters, above the center of the base.



Stone sarcophagus found by Howard-Vyse in the pyramid of Mykerinos, which was lost at sea en route to the British Museum.

In 1840 Colonel Howard-Vyse sailed for England with his accumulated notes. Back home, at his own expense, or his family's, he produced two elegant volumes crammed with detailed but patronizingly Victorian descriptions of his exploits in Egypt, called *Operations Carried on at the Pyramids of Gizeh in 1837*. The book had the merit of including quotations from the works of 71 Europeans and 32 Asiatic authors who had written about the Pyramid from the fifth century B.C. to the nineteenth century.

The colonel's assistant John Perring also produced a handsome volume with some lovely copperplate etchings, *The Pyramids of Gizeh from Actual Survey and Measurement on the Spot*.

Unfortunately, Howard-Vyse was to lose his best trophy, the sarcophagus of Mykerinos, which he had found in the subterranean chamber of the Third Pyramid; the ship carrying it foundered in a storm off the coast of Spain and was sunk in deep water.

But the general measurements taken by Howard-Vyse and Perring were to open a whole new phase in the study of the Great Pyramid, now to be ennobled by the appellative "pyramidology."

VI. FIRST SCIENTIFIC THEORIES

A poet and essayist who had never set eyes on the Pyramid was to take the measurements of Howard-Vyse and those of the French savants and draw from them a set of conclusions, the most far-reaching thus far about the origin and purpose of the Pyramid.

John Taylor, the son of a London bookseller, whose regular job was editing the *London Observer,* already in his fifties when Howard-Vyse returned from Egypt, was to spend the next thirty years collecting and comparing accounts of travelers who had visited the Pyramid.

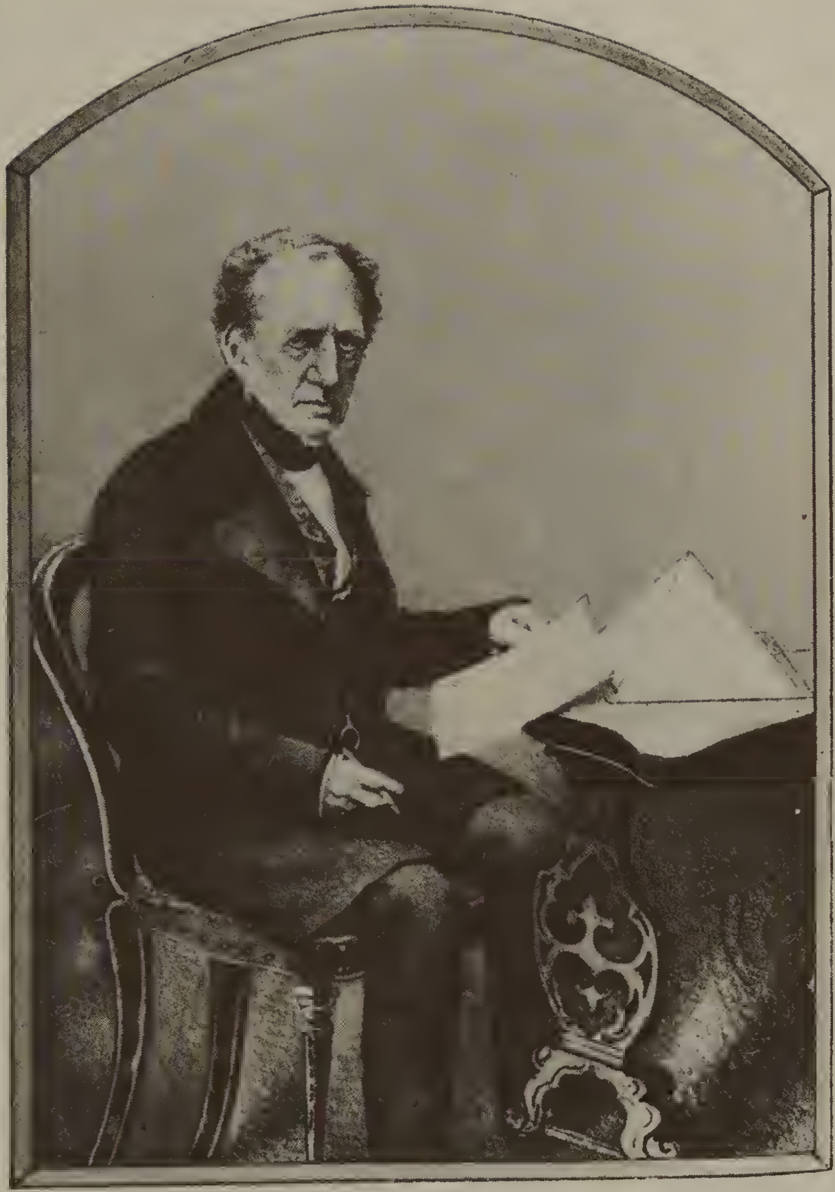
A gifted mathematician and amateur astronomer, Taylor made models to scale of the Pyramid and began to analyze the results from a mathematician's point of view. To account for the discrepancies in the length of the base reported by successive travelers—which increased progressively from the 693 feet of Greaves to the 763.62 feet of the French —it occurred to Taylor that as each measurer had arrived on the scene, more sand and rubble had been cleared from the base. Each had measured accurately, but at a constantly deeper layer of masonry.

Taylor set about drawing and redrawing every feature of the Pyramid on the basis of the measurements reported by Howard-Vyse, so as to see what geometrical or mathematical formulas might be derived from the structure.

Taylor was puzzled as to why the builders of the Pyramid should have chosen the particular angle of 51° 51′ for the Pyramid's faces instead of the regular equilateral triangle of 60°.

Analyzing Herodotus' report of what the Egyptian priests had told him about the surface of each face of the Pyramid, Taylor concluded they had been designed to be equal in area to the square of the Pyramid's height. If so, this meant the building was of a particular if not unique geometric construction; no other pyramid has these proportions.

Taylor then discovered that if he divided the perimeter of the Pyramid by twice its height, it gave him a quotient of 3.144, remarkably close to the value of π, which is computed as 3.14159+. In other words, the height of the Pyramid appeared to be in relation to the perimeter of its base as the radius of a circle is to its circumference.



John Taylor.

This seemed to Taylor far too extraordinary to attribute to chance, and he deduced that the Pyramid might have been specifically intended by its builders to incorporate the incommensurable value of π. If so, this was a demonstration of the advanced knowledge of the builders.* Still today the oldest known document which indicates that the Egyp-

* Not till the sixth century was π correctly worked out to the fourth decimal point by the Hindu sage Arya-Bhata. It took another thousand years before the Dutchman Pierre Metius calculated π to six decimals by means of the fraction 355/113. In 1593 François Viete carried the computation to eleven figures, and a generation later Rudolph Van Ceulin, just before he died, took π to 127 figures by postulating a circle with 36,893,488,147,419,103,232 sides. In 1813 the English mathematician William Shanks developed π to 707 decimals. Modern computers have carried the operation to 10,000 points of decimal, but with no solution to this apparently incommensurable number.

tians had a knowledge of the value of π is the Rhind Papyrus, dated about 1700 B.C., and therefore much later than the Pyramid. Found in the wrappings of a mummy in 1855 by a young Scottish archeologist, Henry Alexander Rhind, the rare papyrus is now in the British Museum. It gives a very rough value for π of 3.16.

Searching for a reason for such a π proportion in the Pyramid, Taylor concluded that the perimeter might have been intended to represent the circumference of the earth at the equator while the height represented the distance from the earth's center to the pole.

Perhaps Jomard had been right: perhaps the ancient designers *had* measured the length of a geographical degree, multiplied it by 360° for the circumference of the globe, and by the π relation had deduced the polar radius of the earth, immortalizing their knowledge by making the circumference to scale with the perimeter and the radius to scale with the height of the Pyramid.

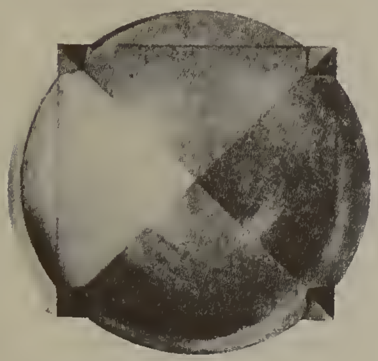
Taylor underlined his thesis: "It was *to make a record of the measure of the Earth* that it was built." He then elaborated: "They knew the Earth was a sphere; and by observing the motion of the heavenly bodies over the earth's surface, had ascertained its circumference, and were desirous of leaving behind them a record of the circumference as correct and imperishable as it was possible for them to construct."

But it was evident to Taylor that the builders of the Pyramid could not have used for their calculations such a unit as the British foot, which fitted neither the height nor the base exactly; he therefore looked for a unit that would retain the π proportion and fit the Pyramid in whole numbers.

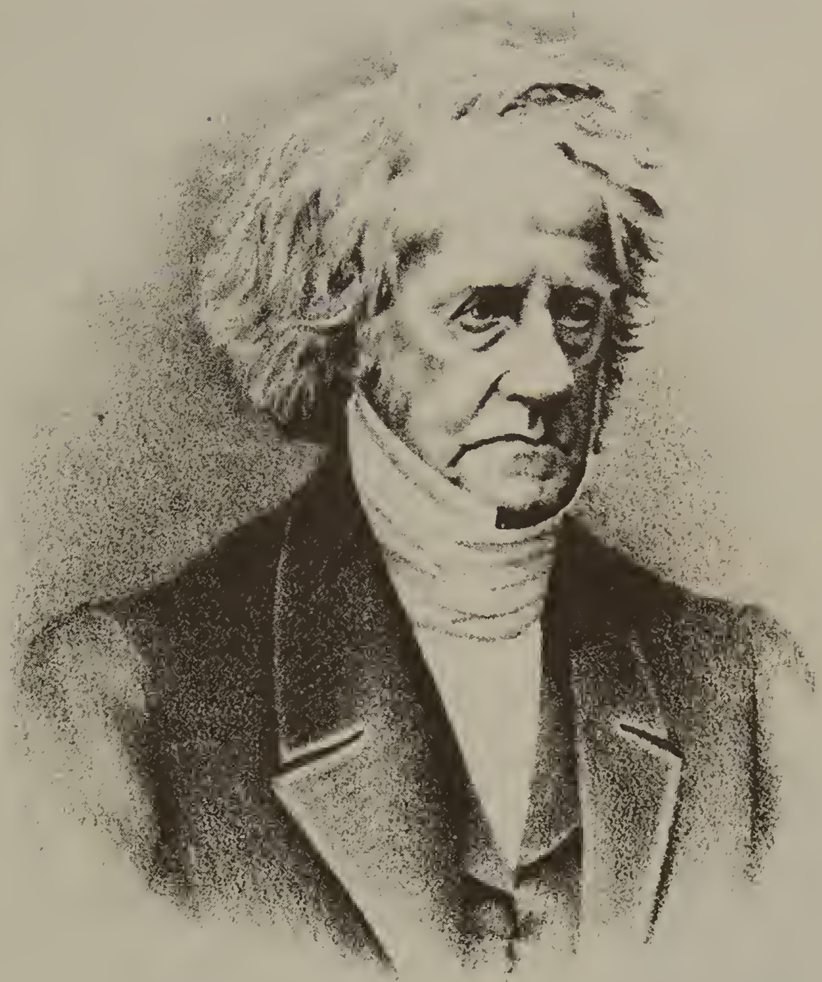
When he came to 366:116.5 he was struck by the similarity of 366 to the number of days in the year and wondered if the Egyptians might have intentionally divided the perimeter of the Pyramid into units of the solar year.

He then noticed that if he converted the perimeter into inches, it came to very nearly 100 times 366. Also he was surprised to see that if he divided the base by 25 inches, he obtained the same 366 result. Could the ancient Egyptians have used a unit so close to the British inch? And a cubit of 25 such inches?

By coincidence, Sir John Herschel, one of Britain's most eminent astronomers at the beginning of the nineteenth century, had just postulated a unit half a human hair's breadth longer than a British inch as the only sensible earth-commensurable unit, or unit based on the actual size of the earth.



Relation of a hemisphere to the Pyramid.



Sir John F. W. Herschel.

Herschel criticized the French meter derived from a curved meridian of the earth as being erratic and variable from country to country because the earth is not a true sphere, and each meridian of longitude would therefore be different. (What's more the French had erred, and produced a meter that was .0002 too short.)

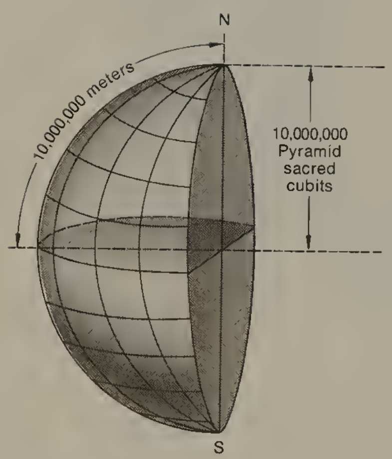
According to Herschel the only really reliable basis for a standard of measure was the polar axis of the earth—the straight line from pole to pole—which a recent British Ordnance Survey had fixed at 7898.78 miles (by taking the mean of all the available meridians measured). This translated into 500,500,000 British inches, or an even five hundred million inches if the British inch were half a human hair's breadth longer.

Herschel suggested that the regular British inch—which was officially computed as the length of three grains of barley taken from the middle ear and placed end to end—be arbitrarily lengthened by a mere one-thousandth part in order to obtain a truly scientific, earth-commensurable unit exactly one fifty-millionth part of the polar axis of the earth.

Fifty such inches, said Herschel, would make a yard that was exactly one ten-millionth of the polar axis, and half that measure, or 25 inches, would make a very useful cubit.

By coincidence these were the cubit and the inch which Taylor had found to fit the Great Pyramid in multiples of 366.*

Another unexpected piece of evidence astounded Taylor. He discovered that recent maps produced by the British Ordnance, the largest and most expensive yet undertaken, had been done on a scale of 1:2500. This scale turned out to bear no relation to the standard British mile of 5280 feet, which had varied through the ages, but almost miraculously fitted the "sacred" cubit as postulated by Newton, as well as the British acre, one side of which was equal to 100 cubits of 25 inches. It appeared that the British inch must have been an ancient unit of measure which had lost a thousandth part as it was handed down from generation to generation.†



To Taylor the inference was clear: the ancient Egyptians must have had a system of measurements based on the true spherical dimensions of the planet, which used a unit which was within a thousandth part of being equal to a British inch.

Fired by what he considered a stunning discovery, Taylor launched into a monumental study of the cubits, feet, spans, inches and stadia, not only of the ancient Egyptians, but of the Babylonians, Hebrews, Greeks and Romans. He found that all kinds of cubits had been used in the past, some of which appeared to have mathematical relations to each other. He also analyzed the ancient measures of cubic capacity along with the modern gallons, firkins, kilderkins,

* That this figuring was not arbitrary was confirmed by the International Geophysical Year 1957–58 geodetic research with orbiting vehicles, which obtained a figure of 3949.89 miles for the polar radius of the earth. Divided by 10,000,000 British inches, this gives 25.02614284, or the length of Taylor's and Newton's "sacred cubit" correct to the third point of decimal.

† Corroborative evidence for Taylor's conclusion was recently produced by Algernon E. Berriman in his *Historical Metrology,* published by E. P. Dutton in New York in 1953. "The English acre," writes Berriman, who is an engineer and an architect, "is the most intriguing of ancient measures because it is virtually equal to a hypothetical geodetic acre defined as one myriad-millionth of the square on the terrestrial radius." Berriman noted that the geodetic acre could also be defined as measuring one myriad square cubits of a hypothetical cubit equal to one ten-millionth of the terrestrial radius. Berriman gave a value to this cubit of 25.064 inches, saying "its former existence is as plausible (or as incredible) as a cubit derived from the sexagesimal division of the Earth's circumference." Berriman also noted that the slightly larger Scottish and Irish acres are related to each other and to the basic English acre as a square to an inscribed circle.

hogsheads, butts, barrels, gills, pecks, faggots, and chaldrons—all in the hope of finding an ancient unit of measure that could be used as a standard, and from which others could have been derived or corrupted.

Pursuing Jomard's theory that the King's Chamber and its sarcophagus might have been designed not so much as a tomb as to monumentalize a system of weights and measure, Taylor was amazed to find that the cubic capacity of the granite coffer was almost precisely four times what the British farmer still used as a standard measure for grain: the *quarter,* or eight bushels.

From all his studies, Taylor concluded that the proportions of the Pyramid had definitely been intended to incorporate geometric and astronomical laws simply and easily expressed, and that its purpose had been to preserve and pass on this knowledge to future generations.

However, as there was nothing in Taylor's philosophy to indicate the existence in such remote antiquity of any civilization which could have had a knowledge of the true shape of the planet, its actual size, and its motion in the solar system; and as the conceit was not then current that this planet might have been visited by superior beings from some other part of the universe, Taylor was hard put to explain the sources of science he found incorporated in the Pyramid. More than a scholar and a mathematician, Taylor was also a profoundly religious man, thoroughly steeped in the Old Testament which he believed to be literally true. To Taylor the creation of Adam had occurred in 4000 B.C. and the Flood in 2400 B.C. It seemed to him hard to believe that in a mere 300 years man could have redeveloped to the point of building so complex a structure as the Great Pyramid. Taylor could come to but one conclusion: whoever had built the Pyramid must have done so under the direct influence of Divine Revelation as Noah had built the Ark. In his own words: "It is probable that to some human beings in the earliest ages of society, a degree of intellectual power was given by the Creator, which raised them far above the level of those succeeding inhabitants of the earth."

Taylor even ventured the hypothesis that the builders of the Pyramid were of "the *chosen race* in the line of, though preceding Abraham; so early indeed as to be closer to Noah than to Abraham."

Because of the close similarity of the British inch to the "Pyramid inch," his idea was to give impetus to the theory that the British were related to the Lost Tribes of Israel, "which during their captivity and wanderings preserved a knowledge of the wisdom of the Egyptians."

As might have been expected, Taylor, who had been known as a benign and dignified old gentleman, had a hard time convincing his quiet Victorian contemporaries of such wild and revolutionary theories, especially as they were just then being rocked by Darwin's theory of the descent of man.

A paper on the Pyramid which he presented to the prestigious Royal Society was rejected with the suggestion that such a paper might be more appropriate for the Society of Antiquarians.

Growing older and more infirm, Taylor was afraid he would die without developing any audience for his theories which by 1859 he had formulated into a volume entitled *The Great Pyramid: Why Was It Built & Who Built It?*

Nearing his death, he had the luck to find the support of an eminent academician with the reputation of having an excellent and sober mathematical mind: Professor Charles Piazzi Smyth, the Astronomer Royal of Scotland.

VII. FIRST CONFIRMATION OF SCIENTIFIC THEORIES

Piazzi Smyth, who was born in Naples to Admiral William Henry Smyth (and named for his godfather, the renowned Sicilian astronomer, Father Giuseppe Piazzi, discoverer of the first known asteroid), was enough of a mathematician not to mock at Taylor's reasoning. Carefully studying Taylor's figures, Piazzi Smyth decided to support them with a paper which he presented to the Royal Society of Edinburgh, of which he had become a member because of his important contribution to the new science of spectroscopy.

It was Smyth's conclusion that the sacred cubit used by the builders of the Great Pyramid was the same length (25.025 British inches) as the one used by Moses to construct the tabernacle and by Noah when he built his Ark, and because the twenty-fifth part of this cubit was within a thousandth part of being the same as a British inch, Smyth also concluded that the British had inherited this "sacred" inch down through the ages.*

Smyth's fellow academicians treated him no better than they had treated Taylor.

During the last few weeks of Taylor's life, there was an animated correspondence between Smyth and Taylor. When Taylor died in 1864 Piazzi Smyth decided that the only way definitely to confirm or refute Taylor's theories about the π relation, and the Pyramid cubit, would be to go to Egypt and carefully measure the Pyramid.

In "utmost straits for funds," Smyth asked his fellows of the Royal Society in London for help; though the Society

* Attributing to Newton the original discovery of the presence of the sacred cubit in the Pyramid, Smyth wrote: "How thankful should we be that it pleased God to raise up the spirit of Newton amongst us; and enable him to make one of the most important discoveries of his riper years—though the opposition of the Church of England has caused it to remain unread almost to the present day—that while there undoubtedly was in ancient times a cubit of 20.7 inches nearly . . . and which Newton calls "the profane cubit" there was another which he equally unhesitatingly speaks of as the *sacred* cubit, decidedly longer."

C. Piazzi Smyth, Astronomer Royal for Scotland.

was "in receipt of a large annual grant from the government for the assistance of precisely such special efforts in science, it not only gave nothing to my semi-pauperized expedition, but actually sent back part of that year's grant to the government on the plea that there was nothing going on that needed it."

That same December, Piazzi Smyth and his wife—then in their early forties—set sail for Egypt with a vast number of boxes containing scientific instruments more accurate than any yet taken to the Pyramid, and with stores and equipment enough for several months.

Despite a series of mishaps, and the almost ruinous expense of everything in Egypt—which was in the midst of a cotton boom engendered by the American Civil War—the Smyths eventually arrived in Cairo, where they were obliged to hang around waiting for permits and local supplies. In his diary Smyth morosely entered exotic descriptions of "the abominations of the worst city in the world," where the food reeked of garlic, lard and African macaroni, the air was fetid from mounds of desiccated human excrement, where he was infested with flies by day and mosquitoes by night, and woken up by a predawn cacophany of howling cats and dogs which roused the pigs which roused the geese and turkeys "just before the disk of the sun comes up like a ball of liquid fire."

Poignantly he described little girls "diving between the hind feet of colossal camels to pick up its hideous droppings, pat them into nicely shaped cakes . . . to make high-scented ammonia-filled fuel for the cooks . . . of the resplendent city."

Smyth was so well received by Ismail Pasha (who a few years later was to commission Verdi's opera *Aïda* which opened in Cairo in 1871) that he tried to buttonhole the viceroy into providing men and funds to remove the great mounds of debris around the base of the Pyramid, to have a 3-inch hole carved through the center of the granite plugs in the Ascending Passage (so as to ascertain its true meridian), to have the ventilating ducts to the King's Chamber cleared, and to sink a shaft through the hole in the pit down to the level of the Nile.

The pasha shook his head, promising to provide twenty men for two weeks to clean and wash the main chambers of the Pyramid so that Piazzi Smyth might take some measurements. The pasha also kindly agreed to provide the Smyths with donkeys and a camel train to bear them and their luggage to the Great Pyramid.

Leaving "the purse-proud modern Muslim city with its tulip-clothed individuals struggling for wealth," the Piazzi

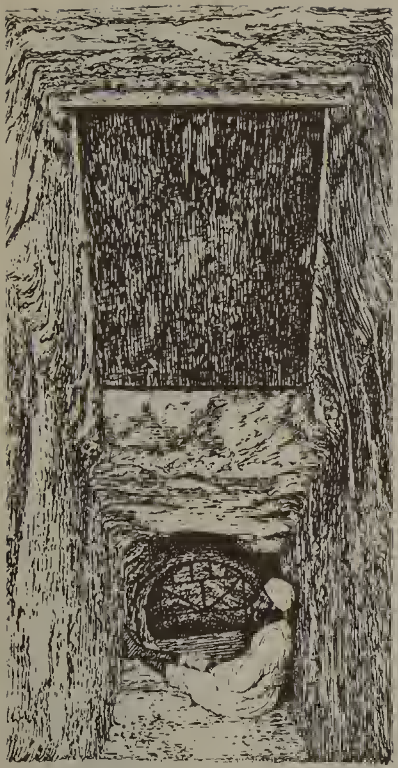
Traveling from Cairo to the Great Pyramid in the mid-nineteenth century.

Sandstorm in the desert.

Smyths set off for the Pyramid. On the way they stopped to eat buns "from Mrs. Smyth's commissary" and refresh themselves with Nile water "muddy and opaque as milk with suspended clay" but celebrated, says Smyth, for its health-giving qualities, the best cure for "the windy melancholy arising from the shorter ribs."

The pyramids, tinted by the golden rays of the setting sun "embalmed in the intense azure of the western heaven," appeared to grow no larger as the caravan approached. Only in the immediate vicinity did they suddenly tower so completely as "to take possession of the mind."

Looking up at the vast stepped sides toward the "dizzy apex 480 feet above in perpendicular height, the mind slowly and almost painfully began to realize the enormous size of the mountainous buildings."



Descending Passage blocked by Arab guides below the level of the granite plug.

As a place to live within reach of the Pyramid, the Smyths selected an abandoned tomb in the eastern cliff of the Giza hill which had previously been used as a storeroom by Howard-Vyse. It proved to be an agreeable residence: the solid rock was the best possible protection against the midday heat, and the orientation of the cave protected it from the sandstorms and the clouds of multicolored locusts that otherwise made life in the desert a misery.

To assist Smyth in his measurements, and to help with the general chores, he found a whiskered Arab called Ali Gabri who had carried baskets for Colonel Howard-Vyse a generation earlier.

At twilight Professor and Mrs. Smyth sat on campstools and watched with amazement as flock after flock of bats flew out of the Pyramid, "for almost twenty minutes without any cessation," to be pounced on by hawks or owls.

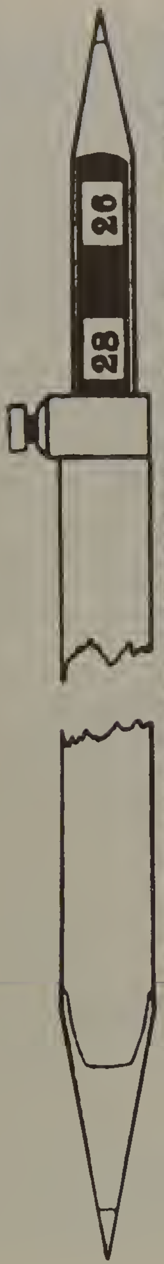
Several days were wasted while Ali Gabri impressed a gang of Arabs to clean the chambers of the Great Pyramid, but at last, in late January, the day came for Smyth to enter what he called "the largest building in the world by the smallest of all doorways."

As Smyth picked his way down the Descending Passage, partly on his seat and partly on hands and knees, he was relieved to find that shallow notches had been dug by Howard-Vyse every 2 or 3 feet so as to keep from slipping on the steep incline. However, each step raised a cloud of fine white dust that made it almost impossible to breathe. To his distress, Smyth also found that the passage leading down to the "pit," which had been cleared by Caviglia, was once more blocked with sand and stones, and barred by a grill just below Al Mamun's hole to the Ascending Passage.

It was explained to Smyth that it cost the Arab guides too much time and candle grease to accompany tourists all the way down to the "pit" before making the long climb back up to the King's Chamber, so they had blocked the passage and informed gullible tourists there was nothing but sand beyond the barrier.

Bent on finding proof that the Great Pyramid had been built on units of his "sacred cubit," Smyth had brought from England a 105-inch metal bar with built-in thermometers at either end to indicate the slightest variation in temperature with which to measure the available passages. A mere change of .01 degree Fahrenheit was enough to produce a sensible change in the length of the standard bars.

To obtain the exact angle of the Descending Passage, Smyth had a specially designed clinometer equipped with a gunmetal circle 8 inches in diameter, divided into units of



The Grand Gallery as Piazzi Smyth saw it in 1865.

Brass-tipped mahogany measuring rod.

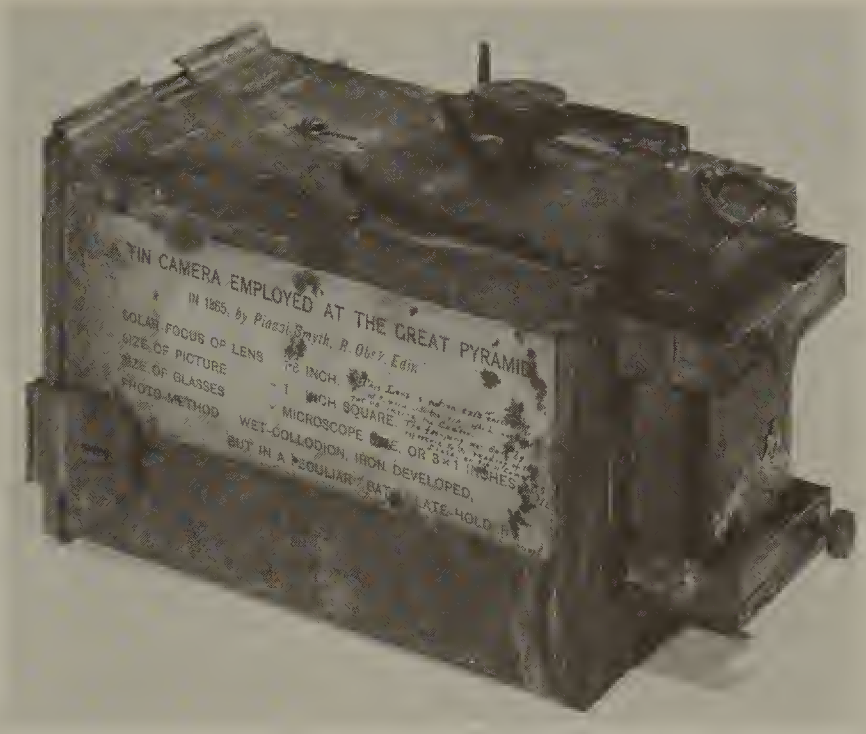
Special forms of apparatus, employed in measuring in the Grand Gallery.

10 seconds, and fitted with three pairs of verniers. The slope he calculated was the most precise to date: 26° 27′.

For measuring the individual stones of the floors, walls and ceilings, Smyth had mahogany and teak rods tipped with brass, carefully painted or waxed to prevent variation from humidity or temperature. One special ruler, remarkable for its straight, fine grain, had been obtained from an antique musical organ dating from the reign of Queen Anne. To fashion these measuring instruments, Smyth had obtained the services of an expert optician.

Each rod was checked daily for atmospheric shrinkage



"Miniature" camera, 8 inches long, used by Piazzi Smyth to photograph the interior and exterior of the Great Pyramid. On the right is a tiny container for the vulcanite nitrate bath which held the exposed wet-collodion plates which measured an inch square. Some two hundred microscope negatives, packed in a storage box, are still missing, but 48 lantern slides, 24 transparencies and 23 stereotypes are in the possession of the Royal Society of Edinburgh, examples of which are reproduced with their permission.

The camera is in the possession of the present Astronomer Royal for Scotland, Prof. H. A. Brück, and is here reproduced by kind permission.

or enlargement against a basic fine-grained clinkstone which could be measured with a magnifying glass to 1/100 inch.*

Thus began the first really systematic analysis of the Pyramid with modern measuring equipment. For weeks on end Smyth measured and remeasured whatever he could reach in the interior of the Pyramid, counting the stones in passages and chambers, computing angles and declinations.

Measuring the coffer in the King's Chamber, Smyth concluded that Taylor had been correct in recognizing it as a standard of linear and cubic measure. Unlike the European standards, such as the yardstick kept at Whitehall, which vary with temperature and barometric pressure, shrink, decompose, tarnish or oxidize with time, the coffer appeared to be designed to remain at a constant temperature and barometric pressure, its polished sides unaffected by decomposition over a period of thousands of years, subject only to the vandalism of man.†

* A clinkstone is a compact grayish-blue felspathic rock little subject to atmospheric changes which makes a clink sound when struck.

† Smyth echoed Herschel's complaint about the standard yard at Whitehall. Herschel had called it "a purely individual object, multiplied and perpetuated by careful copying, from which all reference to a natural origin is studiously excluded, as much as if it had dropped from the clouds."

Today our yard is related to the meter, which is determined by a finite number of wavelengths per second in vacuum of an atom of Krypton 86—measured by means of light waves. A second is no longer defined as the 3600th part of an hour but as the duration of cycles of radiation in a cesium atom.

Photograph of Mrs. Piazzi Smyth taken by her husband outside their tomb apartment in the Giza Hill, which Piazzi Smyth characterized as "a quiet nook, looking out over the green Egyptian plain."

For outside measurements Smyth used a 500-inch cord, and for elevations he had theodolites, sextants and telescopes, which were laboriously carted from spot to spot, up and around the Pyramid, to measure all that could be measured, despite the mounds of debris.

With his long and varied experience in observational astronomy, Smyth had brought the requisite apparatus for obtaining astronomical observations with a high degree of precision.

To obtain the correct latitude of the Great Pyramid without having his plumb line diverted from the perpendicular

Photograph of Ali Gabri (sometimes spelt Alee Dobree) seated outside the tomb in the east bank of Pyramid Hill where Piazzi Smyth, who is handling the camera, had his quarters.

by the attraction of the huge bulk of the Pyramid, Smyth made his observations from the very summit; there the Pyramid's pull of gravity would be directly downward.

Smyth and his wife spent several nights on the circumscribed platform, close to the stars, along with Ali Gabri, who complained he could not sleep because of indigestion. Smyth described the first night as eerie but wonderful, with the ghostlike summit of Kephren's pyramid lurking in the misty darkness. At daybreak he saw "a broad pinioned eagle floating serenely along looking downwards on other things, as we were looking down on him."

From the vantage of the summit Smyth figured the latitude of the Pyramid to be 29° 58′ 51″. From this he concluded that the designers might have purposely not placed the Pyramid directly on the thirtieth parallel because of the atmospheric refraction, which would have caused an error in their observations of about that much. Later he attributed the displacement to a gradual shifting of latitude, registered at Greenwich as 1.38″ per century.*

As for the extraordinarily precise orientation of the Pyramid—which Smyth found to be far superior to that of the world-renowned observatory of the sixteenth-century Danish astronomer Tycho Brahe—the Scottish astronomer concluded that for such refinement a meridian must have been obtained by observing a polar star along the Descending Passage.

When Caviglia had cleared this passage of the rubble left by Al Mamun, he noticed one night that the North Star was observable in the small patch of sky—about 1° square—of the opening. Intrigued by this phenomenon, Howard-Vyse had asked Sir John Herschel whether the direction of the passage could have been determined by the polestar. Herschel replied that 4000 years earlier Ursa Minor could *not* have been seen from the passage at any time throughout the twenty-four hours. He added, however, that alpha Draconis, the leading star in the constellation of Drago, would have been near the pole, and that though a comparatively insignificant star of less than the third magnitude, it could nevertheless have been clearly seen by an observer at the bottom of the passage at the moment of its inferior culmination, when its circumpolar orbit was at its lowest.

Smyth proceeded to subtract the 26° 17′ angle he had found for the Descending Passage from the Pyramid's latitude of 30° (or height of a true North Star above the horizon as seen from 30° of latitude) and obtained an angle of 3° 43′. Calculating that alpha Draconis would have been 3°43′ from the pole at its lower culmination in 2123 B.C. and again in 3440 B.C., Smyth concluded that either date might be taken as the one when the Great Pyramid had been laid out.

* Other pyramid experts have attributed the slight displacement to the fact that the Pyramid needed the solid basis of the Giza plateau for a foundation, and could not have been built any farther north, in the soft sand of the Nile valley. The astronomer Richard A. Proctor suggests that the emplacement was the result of the mean latitude obtained from observing sun shadows and star elevations, which are affected in opposite directions by the atmospheric refraction. An interesting explanation was produced by Dr. Everett W. Fish of Chicago who suggested at the turn of the century that the deviation of the Pyramid's latitude from 30° is neither an error in instrumentation, nor in polar axis, or latitude, but compensates for the spheroidal shape of the earth as postulated by Newton.

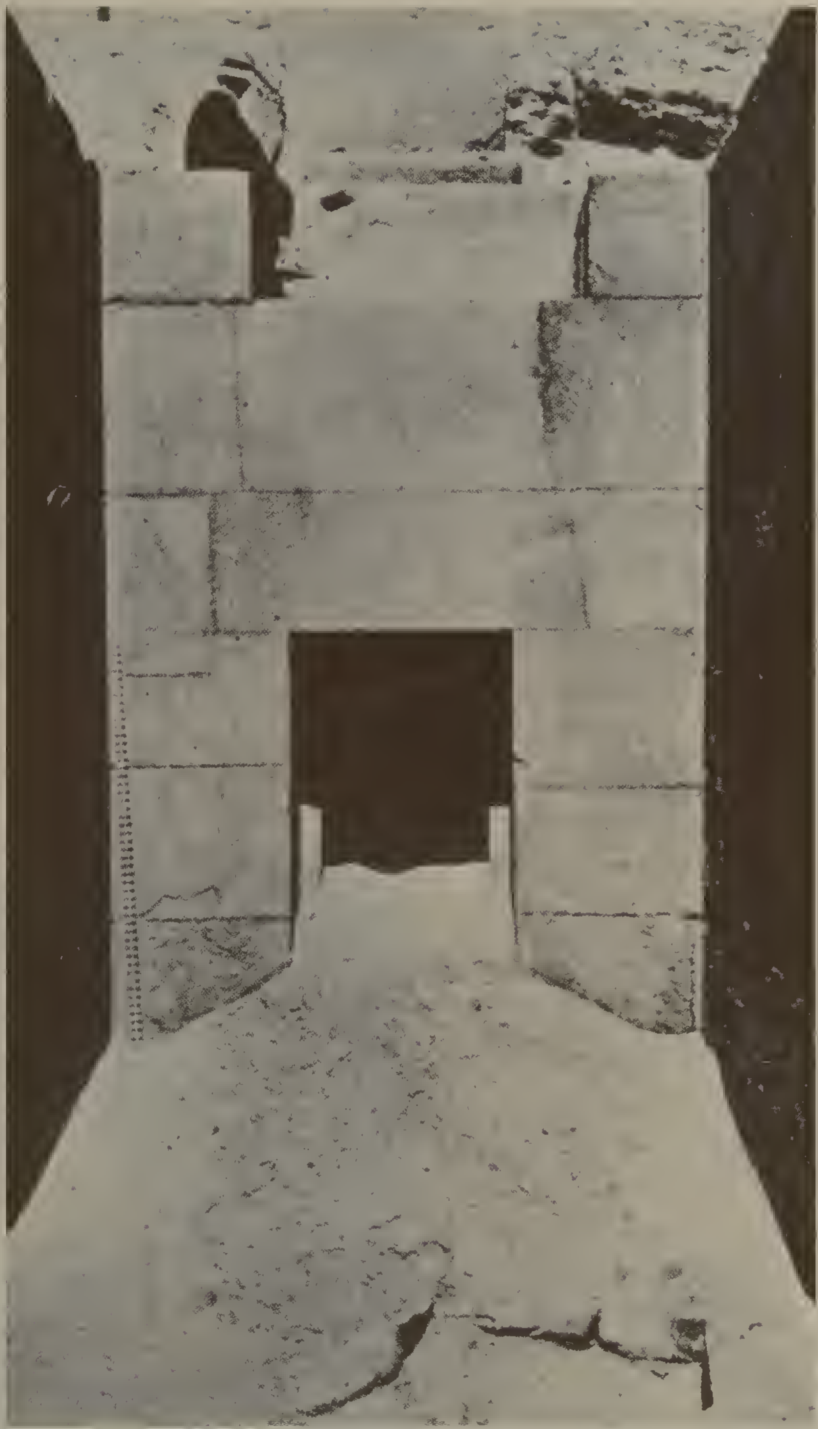
This photograph was taken by Piazzi Smyth and sold at auction after his death. It shows Mrs. Smyth sitting on the edge of what Smyth calls Shafre's burial chamber north of the Great Sphinx. It was taken at high noon to show that the tomb was correctly oriented along the meridian so that with the sun at its zenith, no light would fall on either the east or the west wall.

To ascertain the correct moment for noon Piazzi Smyth spent the previous night observing the stars with his telescope.

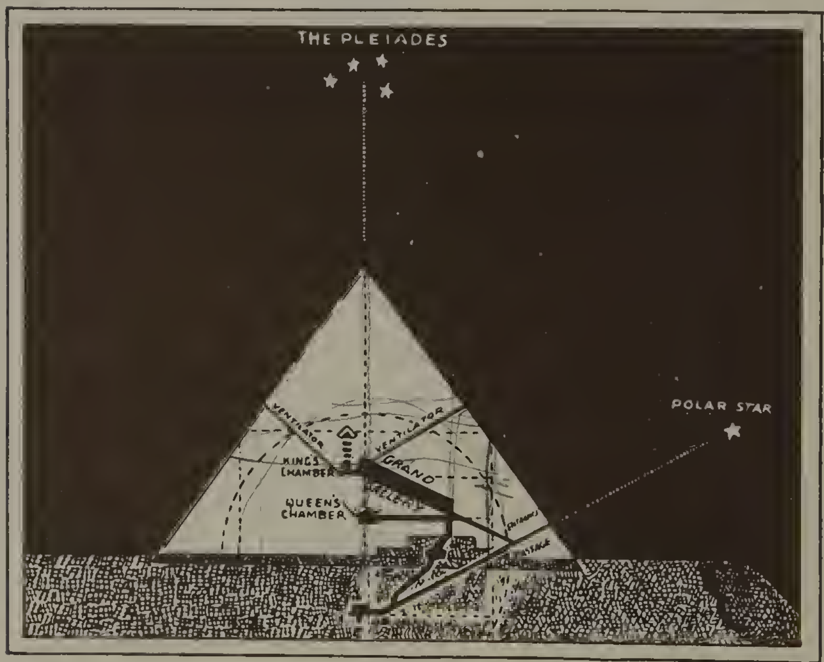
Piazzi Smyth photographed the Great Pyramid with the same scientific thoroughness with which he measured it, despite the difficulties of developing in the desert. He brought all his own chemicals, and used a special 1-inch plate "as small as an ordinary microscopic slide," which gave results that could be blown up with almost the detail of the larger photographic plate. To light the interiors of the Pyramid he used magnesium flares, experimenting with varying amounts so as to obtain the best exposure and the clearest detail. He had to wait hours between exposures in the King's Chamber, which filled up with smoke from each magnesium flare.

Smyth also achieved some remarkable stereoscopic effects by shooting with two cameras, and is responsible for the innovation of placing his cameras much farther apart than the standard 2 inches.

For lack of funds Smyth was unable to publish some fourscore photographs thus obtained at the Great Pyramid. The positive prints which he made were lent to scientific exhibitions or donated to friends interested in pyramidology, and gradually became lost, with the exception of this rather poor reproduction.



In support of the later date Smyth worked out that if the foundation of the Pyramid had occurred at midnight of the equinox in 2170 B.C., when alpha Draconis was at meridian below the pole, another very important star would have been crossing the meridian above the pole: *n*-Tauri, or Alcyone, of the Pleiades. In other words, when alpha Draconis was visible down the Descending Passage, the chief star of the Pleiades, *n*-Tauri, would have been crossing the meridian in the vertical plane of the Grand Gallery, at the moment of the autumn equinox.



Piazzi Smyth's ground plan of the circles of the heavens above the Great Pyramid, at the epoch when he believed it was founded: midnight of the autumnal equinox 2170 B.C. Smyth noted that *alpha* Draconis was on the meridian below the pole while the Pleiades were on the meridian above the pole, coincidentally with the vernal equinox.

Piazzi Smyth figured that the Great Pyramid might have been built so its Descending Passage was aligned with the polestar and at a time when the Pleiades were at the zenith at midnight.

Casing stones donated by Smyth to the Edinburgh Museum, showing the angle of the slope of the Great Pyramid.

Smyth considered this a very important date in history, as many ancient peoples dated the beginning of their year at Halloween, when the Pleiades and the equinoctial point were on the meridian together at midnight.

But Smyth's prime preoccupation was still with establishing whether Taylor's π proportion was really incorporated in the structure.

Along the face of the Pyramid, Smyth checked the angle of the casing stones discovered by Howard-Vyse. Unfortunately the sharp lines had already been almost obliterated by the Arabs and by the chipping away of souvenir hunters. But searching through the debris piled high round the base, Smyth was able to find fragments of casing stones with the angles still intact.

Invariably the angle checked out at about 52°, or its complement of 128°, confirming Taylor's theory that the height of the Pyramid was designed to be in relation to the perimeter of its base as the radius of a circle is to its circumference.

To see if he could refine this angle, Smyth observed the silhouette of all the backing stones against the sky by means of a very accurate altitude azimuth circle which had been donated to his friend and mentor Professor Lyon Playfair by his students in 1806 and in turn lent to Smyth.

By this method Smyth obtained an angle of 51° 49′. Meanwhile Sir John Herschel had obtained a figure of 51° 52′ 15.5″ from the dimensions of the casing stones as reported by Howard-Vyse. Smyth chose to take the mean of these available measures as 51° 51′ 14.3″—a difference of less than a minute from either figure. He also chose to take the mean of the 763.62-foot base line measured by the

Magnesium-light photography had been developed only a few months before Piazzi Smyth took this double exposure of the coffer in the King's Chamber. The apparent reflections are those of Ali Gabri and another Arab. Mrs. Smyth's head appears beyond the coffer. Smyth's method of burning magnesium powder in a spirit-lamp flame was an innovation in photography.

French and the 764 feet measured by Howard-Vyse, and got 763.81—a difference of barely 2 inches on a length of 763 feet.

This was an arbitrary act, but the result produced an astounding value for π in the Great Pyramid proportions of 3.14159+.

Searching for a reason for the incorporation in the Pyramid of this relation of the radius of a circle to its circumference, Smyth pursued Taylor's theory of the base being divided into 366 units to coincide with the number of days in the year.

To have been absolutely precise, the perimeter should have measured 365,24.2 Pyramid inches. This would require that each side be 9140.18 British inches. The measure obtained by Howard-Vyse and the French savants, though within 6 inches of each other, were both about 2 feet too long.

The only solution appeared to be to dig up the sockets and remeasure the base line more accurately; but time and money were running short. Fortunately two engineers from Glasgow, Messrs. Inglis and Aiton, happened to pass through Egypt on their way from a tour of the Holy Land. Cajoled by their fellow Scot, they agreed to help him uncover the sockets originally found by the French (which had once more become covered with debris in the intervening half century) and make a truly accurate survey.

Following Smyth's complex computations, the engineers were able to uncover not only the sockets but a perfectly leveled stretch of pavement at the perimeter of the base.

Stereographic photo taken by Piazzi Smyth of Mr. Inglis and Arab workers in the northeast socket cleared in April of 1865. The Royal Engineer surveyor went all over the floor of the socket with a spirit level and found it absolutely level.

To measure the distance between the sockets, up and around the debris, required a great deal of digging and moving of rocks. But Smyth could not tarry. His own instruments were already packed and his passage had been booked by the British consul. When the engineers promised to take great care in their measurements and forward the results to Scotland, Smyth disconsolately agreed to depart as scheduled.

All that remained to be done was to dispense the customary baksheesh to the neighboring Arabs who had helped during four months' stay. The Smyths gave each man a gold sovereign plus a present depending on the willingness with which he had served his Scottish employers: the best got globe lamps mounted in copper; the middling got frying pans; and the worst got mousetraps.

When the ancient Arab who guarded their cave by night appeared for his just reward, Piazzi Smyth puritanically noted that the old man "seized on the money with such an agony of clutch, and his eyes brightened with so strange a fire, that alas for perverted human nature! we feared we had done more harm to his soul than good to his body."

As the camel train was prepared for departure, the faithful Ali Gabri stood silent for a time, "then suddenly putting his fingers to his eyes" rushed into the desert to conceal his crying.

Back in Scotland, Piazzi Smyth received the results of the engineers' survey; these gave a much shorter length of 9110 inches for a side of the Pyramid. Smyth concluded that the true length must be the mean between this figure and the

longer one of 9168 inches obtained by Howard-Vyse, or 9140 inches, which was just 1 inch less than was required for Smyth's theory, resulting in a year of 365.2 days instead of the precise 365.24 required by theory.

A great deal now hung on the exactness of these figures. If Smyth's theory could be proved correct, it could mean that the ancient Egyptians had produced a structure whose basic unit, the Pyramid inch, incorporated not only a system for linear measurement—with the cubit and the inch—but also for temporal measurement, with a year of 365.24 days, both based on the most sensible foundation: the polar axis of the planet around which it rotates once in a day.

In Smyth's opinion "the linear measure of the base of this colossal monument, viewed in the light of the philosophical connexion between time and space, has yielded a standard measure of length which is more admirably and learnedly earth-commensurable than anything which has ever yet entered into the mind of man to conceive. . . ."

Smyth summed up his work: the Pyramid "revealed a most surprisingly accurate knowledge of high astronomical and geographical physics . . . nearly 1500 years earlier than the extremely infantine beginning of such things among the ancient Greeks."

From the Royal Society of Edinburgh, Smyth received a gold medal for the careful measurements he had taken in Egypt; these he published in monographs, and in a three-volume opus running to 1600 pages entitled *Life and Work at the Great Pyramid of Jeezeh during the Months of January, February, March and April, A.D. 1865.*

The work was not well received. As much of a religious zealot as had been his predecessor Taylor, Smyth was unable to account for the mathematics displayed by the ancient Egyptians. Like Taylor he was obliged to attribute this science to Divine Wisdom, somehow imparted to an earthly architect who had constructed the Pyramid under the direct influence of revelation. "The Bible," said Smyth, "tells us that in very early historic days, wisdom, and metrical instructions for buildings, were occasionally imparted perfect and complete, for some special and unknown purpose, to chosen men, by the Author of all wisdom."

The idea was received by some with derision, by others with acrimonious opposition. One reviewer remarked that Smyth's book contained "more extraordinary hallucinations than had appeared in any other three volumes published during the past or present century." A friendly reviewer summed up reaction to the book saying "it evoked numerous illustrations of envy, hatred, malice, and much uncharitableness from vain, flippant, and unqualified writers, the author being scoffed at, traduced, worried and all but *argued* with, by opponents who only succeeded in proving their egotistic inefficiency to apprehend the truth."

To make things worse another Scot, a religious enthusiast called Robert Menzies, advanced the theory that the passage system in the Great Pyramid was nothing less than a chronological representation of prophecy, corroborating the Bible, built on a scale of one pyramid inch to the solar year.*

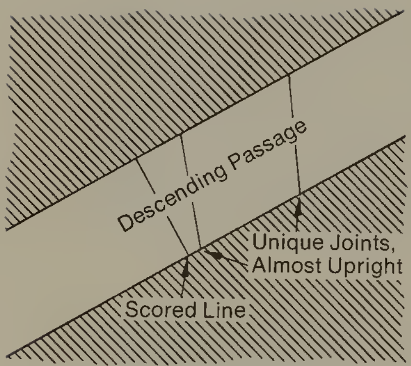
As Menzies' theory was formulated before anything was known of ancient Egyptian messianic prophecy, such as *The Book of the Dead,* the texts of which had not yet been deciphered, this new contribution merely added to Smyth's problems. Smyth was further derided and lampooned by his

* Menzies, knowing that Smyth had made an approximate calculation of the date at which alpha Draconis shone exactly down the Descending Passage, put forward the theory that the date of this important astronomical phenomenon should be clearly marked some way in the Descending Passage itself, at the place representing the said date on the chronological scale. To Menzies' delight, Smyth replied that he had discovered two scored lines on each side of the passage at the very spot indicated. Although the joints in the walls of the Descending Passage were perpendicular to the floor, said Smyth, there were two joints on each wall, immediately to the north of the scored lines, that were not so: these were peculiarly vertical joints, as if intended to draw attention to something of importance: in Smyth's and Menzies' opinion, evidently the scored lines.

fellow academicians. Sir James Y. Simpson, an eminent member of the Royal Society of Edinburgh, publicly ridiculed Smyth before his fellow members, saying, "the whole of Professor Smyth's theory about the Great Pyramid is a series of strange hallucinations, which only a few weak women believe, and perhaps a few womenly men, but no more." Simpson added that he had "talked about it to a great many engineers, mathematicians, and others, and found them scoffing at and despising it."

Smyth's mixing of religious and prophetic conclusions with sound scientific discoveries caused his entire theory to be discarded by skeptics. To this day, the lampooning persists. One modern writer on pyramidology still refers to Smyth as the world's "pyramidiot," and laments that "such a first-class mathematical brain should have wasted its energies in so unprofitable a field."

But Piazzi Smyth was far from being quashed. He continued to produce even more fantastic theories from the results of his measurements of the Pyramid. Recomputing the height of the Pyramid, Smyth found it to be about 6 inches longer than Taylor's figure of 5813 inches from base rock to apex. The new measurement revealed that the Pyramid rose from its base in a proportion of 10:9, that is, for every 10 units of height, the Pyramid extended 9 units in width. To Smyth this was an indication that the proportions were intended to symbolize in yet another way the earth's circuit round the sun. Multiplying the height by 10^9, he obtained an astonishing result. Reduced to British miles, the answer was 91,840.000—or a very good figure for the mean radius of the earth's orbit round the sun. The present figure varies between 91 and 92 million miles. Was this mere coincidence? The argument between the supporters of Smyth's theories and the entrenched academicians who opposed them became intensely heated.



Scored lines in Descending Passage.

Basic to the whole argument was the fact that no one had a series of absolutely reliable measurements for the *exterior* of the building, especially beneath its debris where the base line must actually be measured. Even a new survey by the Ordnance surveyors made in 1869, which gave a length of 9130 inches, was made on the basis of cumulative measurements up and down and around the piles of debris that still clogged part of the base of the Pyramid between the exposed sockets. Results which varied by even 3 or 4 inches could not be considered accurate enough to prove or disprove the theories of Taylor and Smyth. So long as the *actual* dimensions of the Pyramid, both interior and exterior, were not obtained, correct to a fraction of an inch, there would be no real way of *knowing* if Smyth had a point or not.

VIII. FIRST REFUTATION OF SCIENTIFIC THEORIES

To resolve the problem of the dimensions of the Pyramid once and for all, a mechanical engineer by the name of William Petrie, who had become fascinated by the theories of both Taylor and Smyth, set about designing and constructing even more specialized sextants, theodolites, and verniers with which to tackle the technical problems encountered by Smyth. It was no easy job. Smyth had gone a long way in perfecting his own equipment, and it was to take William Petrie all of twenty years to accomplish the task to his own satisfaction. Petrie stressed the importance of further exploration of the Pyramid because of its "paleologic, chronologic, metrologic, geodetic, geologic and astronomic interest to mankind," and above all "for its symbolic interest relating to the higher ideas intentionally embodied therein by its originator." Yet Petrie kept tinkering with the new instruments and postponing his departure for Egypt.

His young son, William Flinders Petrie, perhaps because of a spirit of adventure inherited from his maternal grandfather, the great explorer Matthew Flinders, became so impatient he finally decided to prime the pump by leaving ahead of his father, convinced that his father would quickly follow.

Fascinated by the varied standards of measure used in different parts of the world, young Petrie had read all he could on the subject; instead of going to school, he tramped around England, becoming proficient as a surveyor by measuring churches, buildings and ancient megalithic ruins such as Stonehenge, about which he was to write the first of his several score books.

At the age of thirteen, young Petrie had read Piazzi Smyth's *Our Inheritance in the Great Pyramid*. It had not only revived in him the ideas of Greaves and Burattini, but convinced him that a real history of measures might be deduced from a careful measurement of surviving monuments and objects. He was also determined to prove, one way or another, whether or not Taylor and Smyth had been correct in their theories regarding the Pyramid. To do so he would have to resurvey and measure the entire building.

William Flinders Petrie.

On a stormy day in November of 1880, Flinders Petrie, now a bearded professional surveyor of twenty-six, set off from Liverpool with a vast quantity of boxes containing the rare instruments designed by his father to eliminate the defects revealed by Smyth's experience. He also had with him the necessary supplies with which to survive for a long period in the inhospitable, bandit-infested desert. The gale blew so hard Petrie slept on the engine grating, too seasick to go below deck. Within a week of landing at Alexandria, Petrie had transported his equipment to Cairo, where he managed to get hold of Ali Gabri to help transport his food and instruments to the Giza plateau.

Ali Gabri was now a veteran of 40 years' service with Caviglia, Howard-Vyse and Piazzi Smyth. Reaching the Pyramid in December, Petrie followed the established practice of setting up house in an abandoned tomb.

Ali helped Petrie furnish his quarters with shelves and a hammock, helped him stock the larder with ship's biscuits,

Petrie standing before his living quarters in a tomb on the Giza plateau.

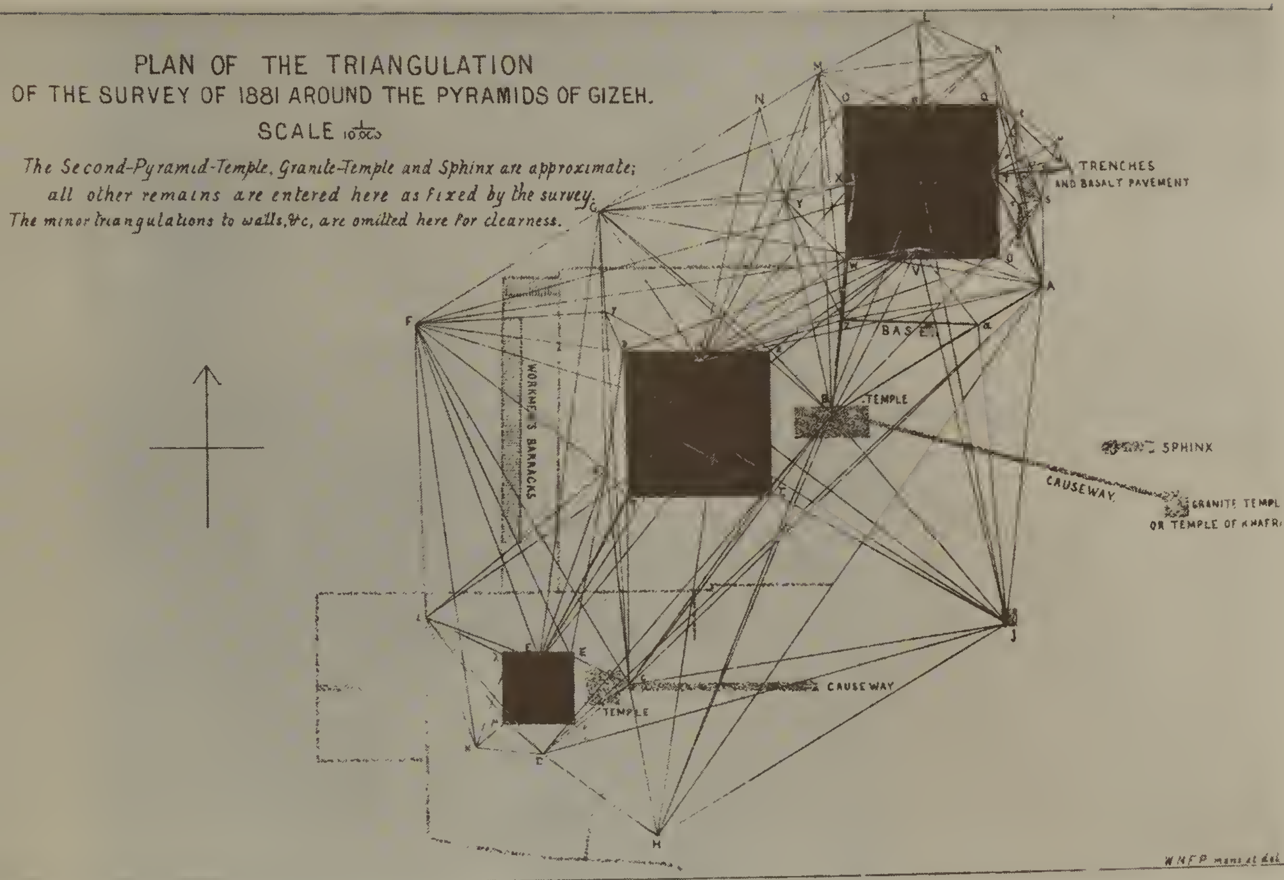
canned soups, tapioca and chocolate. To cook his evening meal Petrie had brought along a kerosene stove. Like his predecessors, Petrie found the solid rock of the tomb an extremely hospitable home, remarking that it seemed "as good as a fire in cold weather, and deliciously cool in the heat."

Petrie's day started with the lighting of his kerosene stove and the ritual boiling of tea water while he enjoyed a makeshift bath.

Breakfast was the time he accorded to reception. Men and women would look in at the door of his tomb, and if a special Arab friend paid a visit, Petrie would brew some coffee in his honor on the little stove by the door.

Petrie got along well with the Arabs, noting that "the smallest entering into their ways pleases them enormously; only sit squat, return the proper replies to salutations, catch their tricks of manner, and imitate their voice, and they will laugh heartily and treat you as a friend."

Petrie's first preoccupation was to accomplish what had been beyond the means of Smyth: a very precise triangulation all over the hill of Giza, including points around all three large pyramids, as well as the surrounding temples and walls which belonged to the complex. Though he couldn't remove the rubble, Petrie hoped to establish the dimensions of the pyramids by triangulation to within a fraction of an inch.



Petrie accomplished his triangulation of the Great Pyramid over a period of months, by means of a ten-inch French theodolite, "a splendid theodolite by Gambay" with a ×35 telescope. Some of the angles were read as many as 14 times from as many as 50 fixed stations. Petrie estimated the probable error in his base measurement of the Pyramid to be ±.03 inch, or 1/260.000 of the whole. But because of the debris and the fact that the cornerstones were missing, Petrie could not establish where the original corners had actually been placed.

Using a highly accurate theodolite by means of which single seconds of angle could be read, Petrie repeated his observations so many times that it would take him from dawn till sunset to accomplish the work at a single station. A second of arc is so fine that it is commonly referred to as the angle subtended by a dime at the distance of a mile.

All the while Ali Gabri held a huge parasol over the theodolite to keep the sun from shining on the metal circle and expanding it unevenly. Once the sun had gone down Petrie would have a solitary meal, washing his own dishes—because he distrusted the Arab's idea of cleanliness—and then sit down to meticulously write up his figures, laying the groundwork for that scientific archeology of which he was to become the prime promoter. His sole entertainment was the "indescribable" tunes played on a reed flute by Ali Gabri's nephew, whose job was to guard him from a neighboring tomb through the night.

Choosing good days, with cool air but no wind, and working for ten hours at a stretch without food, Petrie was able to get a figure to within a quarter of an inch, and usually to within a tenth of an inch, for the actual layout of the three large pyramids at Giza. He was amazed to find the layout of the Great Pyramid "a triumph of skill. Its errors, both in length and in angles, could be covered by placing one's thumb on them."

Victorian tourist and her escort being helped up the Pyramid courses by Arab guides.

The Great Pyramid was so precisely aligned with the cardinal points of the compass that it surpassed in accuracy any human construction to date.

As the weeks wore on, Petrie realized he would not complete the exteriors before springtime and the arrival of the tourist season; so he had the way prepared for his indoor measurements by having a gang of Arab workmen clear the Descending Passage down to the lower "pit" which Smyth had been unable to reach because of the rubble. Armed with baskets, a chain of workers were able to carry the debris up and out of the main entrance.

When the tourists did begin to trickle toward the Pyramid, Petrie devised a system to avoid being bothered by going about outside the Pyramid in nothing but his pink underwear. At the sight of him, the good Victorian ladies kept a safe distance.

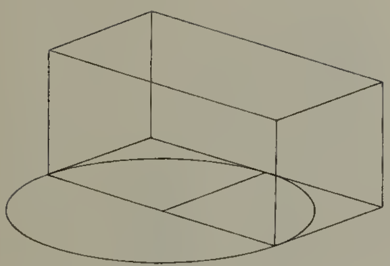
That the tourists were a formidable menace to the pursuit of science had been made clear by Piazzi Smyth, who described "many and multitudinous scenes of lurid-lighted revelry, indulged in by many smoking, tobacco-stinking gentlemen and a few ladies, from some vulgar steamer" who performed "whirling dances over King Cheops' tombstone with ignorant cursing of his ancient name . . . and the painful thunder of the coffer being banged, to close upon breaking, with a big stone swung by their Arab helps."

For lack of salacious statues or pictorial attractions at the Pyramid, the more boisterous tourists would amuse themselves by removing loose blocks from the summit which they would send crashing down to the already vast heaps of rubble accumulated round the base.

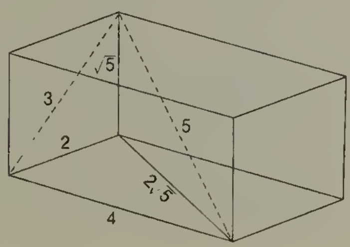
At the end of the day, once the tourists had left, Petrie would work in the intense accumulated heat of the Pyramid, often till midnight and sometimes right through till morning, like "the Japanese carpenter who had nothing on but a pair of spectacles, except that I do not need the spectacles." The ventilating shafts in the King's Chamber, which had been opened by Howard-Vyse, had once more been clogged by vandals, making the air unwholesome. After the first few hours the dust which was raised at every move caused Petrie feverish headaches; but he persevered in his task.

With steel tapes and special chains 1200 inches long, as well as self-compensating accessory appliances, Petrie set about measuring with a far finer accuracy than Smyth could obtain all that was worth noting. Most of Petrie's instruments allowed him to measure to within 1/100 inch, and some, for really careful work, enabled him to do so to within 1/1000 inch.

To measure upright surfaces he used plumb lines; for horizontal surfaces a leveling instrument. Thus he could find the dimensions of a room at any level, and establish where any faults might lie.



To measure the straightness of the sides of the Descending Passage Petrie used fine observations of Polaris at elongation—when it was farthest east and west from the pole. He was amazed to find that the average error in the part built of masonry was an infinitesimal 1/50 inch in 150 feet; and over the entire length of 350 feet the sides were within 1/4 inch of being absolutely straight.



In the King's Chamber, Petrie established to his satisfaction that the walls had been constructed on the basis of the same π proportion which ruled the exterior of the building. Its length was to the circuit of its side wall as 1 is to π.

This value was not immediately evident, because the floor of the chamber had been inserted between the walls so as to cut off a fraction at the bottom. But the cut was cunning in

President Ulysses S. Grant visited the Pyramid as part of a world tour.

In the archives of the Library of Congress lies a faded daguerreotype, with the unmistakable features of the general.

Piazzi Smyth describes the arrival of a party of enthusiastic Yankee tourists atop the Great Pyramid while Smyth was making early-morning observations. "In the short time they were there," writes Smyth, the Americans "arranged themselves into a meeting on constitutional principles of Anglo-Saxon derivation, with a chairman, secretary and audience; wherein a resolution was proposed, recorded and carried unanimously, to the effect—'that whereas this here pile whips everything in the way of building we've seen in all our grand tour through the used-up, worn-out world, yet we calculate King Cheops, its builder, must have been such a horrid old tyrant and cruel oppressor of the people, that it is hereby resolved by us free and independent citizens of the *Unyted* States that we *won't* give him a cheer.' "

After offering thanks to their "excellent chairman for his well-balanced conduct and impartial attitude on his very elevated seat," says Piazzi Smyth, "the gentlemen liquored up, the ladies, as they bashfully expressed it, consented to take a swallow, and the whole party disappeared down the steep slope of the pyramid . . . every man of them with little Confederate flags picked out on the soles of their boots, so that they might have pleasure in trampling on the hated ensign of the South wherever they went."

As an indication of how *tutto il mondo è paese*, Cheops is said (by Sir Gardiner Wilkinson) to have engraved the figures of the Gods of Egypt on the public roads "in order that they might be trodden under foot by man and beast."

that it thus incorporated in the chamber both the 2–$\sqrt{5}$–3 and the 3–4–5 Pythagorean triangles.

Checking to see if the π proportion could also apply to the coffer, Petrie found that its dimensions appeared to be all multiples of a square fifth of a cubit. The difference between the requirements of the theory and the actual squares being a mere 1/1500.*

All of this tended to corroborate Smyth's theory that the builders of the Pyramid had been possessed of an advanced science of mathematics. But Petrie also found in the Pyramid an extraordinary mixture of brilliant workmanship and astonishing clumsiness. He was amazed to find that the granite in the antechamber had never been dressed: many of the stones had been left unfinished and some were even defective. From such indications Petrie concluded that "the original architect, a true master of accuracy and fine methods, must have ceased to superintend the work when it was but half done."

From a careful scrutiny of the coffer in the King's Chamber, Petrie established that the ancients had used saws with 9-foot blades, their teeth made of hard jewels, to cut the sides of the coffer out of a single solid block. To hollow it out they had used drills with fixed cutting points also made of hard jewels, probably diamond or corundum.

Petrie estimated that in order to cut through the hard granite a pressure of 2 tons would have had to be placed on the drill. How this could be done was a mystery to Petrie, who concluded: "Truth to tell, modern drill cores cannot hold a candle to the Egyptians . . . their fine work shows the marks of such tools as we have only now reinvented."

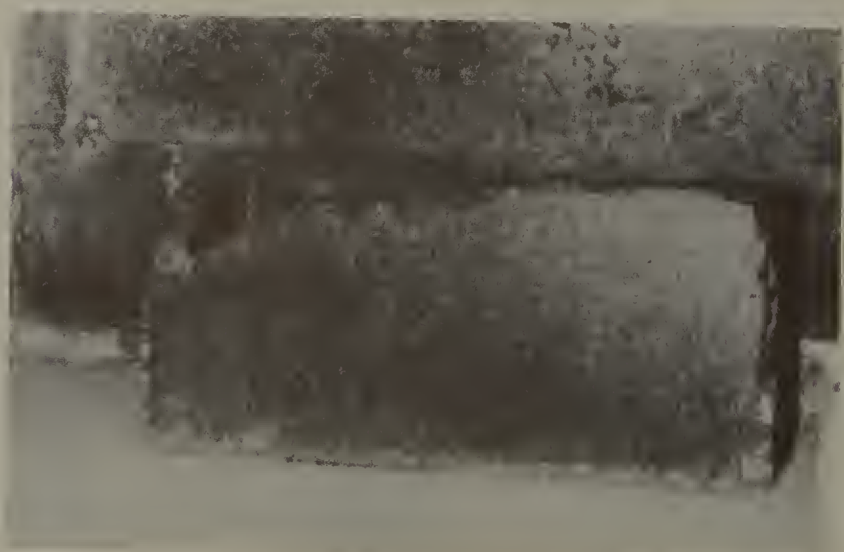
With such tools the ancient Egyptians were somehow able to cut sharp hieroglyphs into incredibly hard diorite, and also to turn stone bowls to paper-thin surfaces.

To measure the bottom of the coffer and to see if there were any secret opening beneath it, Petrie had its 3 tons raised about 8 inches, but found no sign of any opening. When raised and struck, the coffer produced a deep bell-like sound of extraordinary, eerie beauty.

Outside the building Petrie searched for more casing stones still in their original position such as had been

* Petrie also noted that the squares of the dimensions of the King's Chamber, Queen's Chamber, antechamber and subterranean chamber were all even numbers of cubits, nearly all multiples of ten. From this it followed that the squares of the diagonals were likewise multiples of 10 square cubits. And the King's and Queen's Chambers were so arranged that the cubic diagonals were in even hundreds of square cubits, or multiples of 10 square cubits.

Measuring the granite coffer before it was vandalized.



The coffer showing corner chipped away by tourists.

uncovered by Howard-Vyse at the base of the Pyramid. It was a painstaking and dangerous job to dig down through the accumulated debris. The rubble kept sliding back into the holes dug by the Arabs, and at one point Petrie nearly was killed.

Eventually he did manage to uncover more casing stones, as well as the base of the Pyramid. Petrie found the workmanship on the original casing stones, some of which weighed over 15 tons, quite as remarkable as Howard-Vyse had described it. The faces were so straight and so truly square that when the stones had been placed together the film of mortar left between them was on the average no thicker than a man's nail, or 1/50 inch over an area of 35 square feet.

Petrie found that the mean variation of the casings from a straight line and a true square was but 1/100 inch on a length of 75 inches. This staggering accuracy was equivalent to the most modern optician's straight edges.

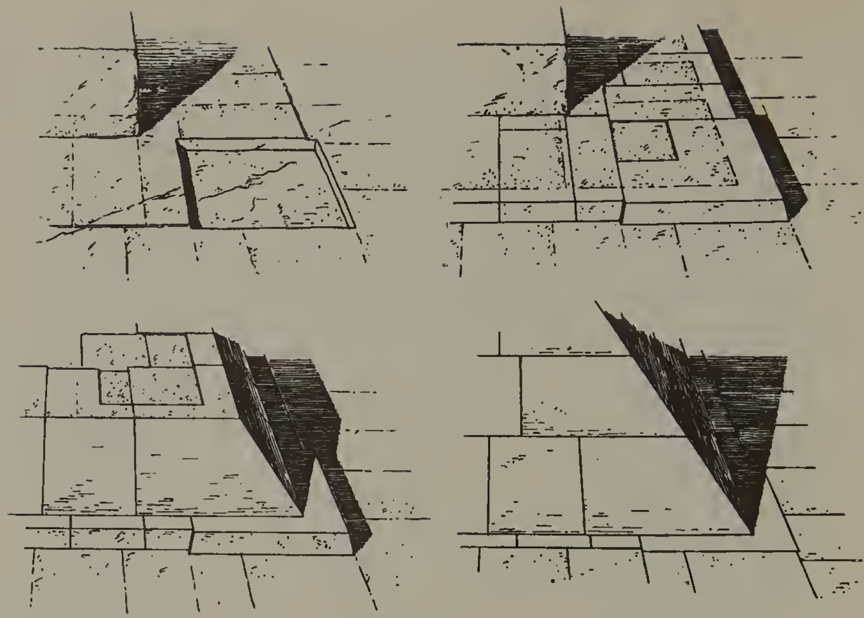
As Petrie remarked, "Merely to place such stones in exact contact would be careful work, but to do so with cement in the joint seems almost impossible: it is to be compared to the finest opticians' work on a scale of acres."

So fine was the texture of the cement that after millennia of exposure to the elements, the stones shattered before the cement would yield.

The casing stones of the Great Pyramid (looking east), showing the platform on which they rest, the pavement in front, and the leveled natural rock.

Shallow sockets dug into the rock at the corners of the Pyramid were designed to hold the four cornerstones for the base, and were apparently cut through the pavement at these points. This has engendered an argument among pyramidologists as to whether the base circuit should be measured from the edge of the pavement or the edge or bottom of the sockets.

It was at first assumed that the bottom of the Pyramid cornerstones had been fitted into these sockets so as to counterbalance any eventual thrust produced by sliding away from the center of the structure, but modern archeologists discount the assumption because at the northeast corner, the depth of the socket is virtually zero; and the outer edge of the southwest socket is merely an incised line In the rock, more for measurement than for structural support.



But the principal result of Petrie's survey was to prove a little abstruse. He considered the true base length of the Pyramid to be defined *not* by the limit of the sockets as measured by Smyth, but by the edge of the pavement 20 inches higher.

According to Petrie's measurements, the base of the Pyramid at the *pavement* was shorter than the distance between the outer corners of the sockets, as estimated by Smyth. Instead of measuring the 9140 British inches claimed by the Scottish astronomer, Petrie obtained a length of only 9069 inches for the base line.

Discarding Piazzi Smyth's theory that the Pyramid had been designed on an extra-long pyramidal cubit of 25.025 inches, Petrie showed by his own careful measurements that the builders of the Pyramid had used the royal cubit of 20.63 inches in order to produce a base line of 440 cubits and a height of 280 cubits. This confirmed Taylor's theory to the extent that the Pyramid was intended to symbolize the globe by giving a very effective π value of 22/7, or 3.14285, but apparently nullified Smyth's theories about the perimeter of the Pyramid giving the exact number of days in the year. The new product gave only 362.76 days.

Summing up the results of his measurements in a book entitled *The Pyramids and Temples of Gizeh* (which he was able to publish with a fortuitous grant of £100 from the Royal Society in London), Petrie remarked that he had never suspected, 15 years earlier, when he had first read Smyth's fascinating theory, that it would be he who "would reach the ugly little fact which killed the beautiful theory."

With success and recognition, Petrie turned from the romantic exploits of discovery to the prosaic minutiae of scientific archeology.

In the wake of Petrie's demolition of Smyth's basic contention about the length of the year being incorporated in the Pyramid's perimeter, soured academicians were happy to bury Smyth along with his theories. Foremost among such undertakers was Professor F. A. P. Barnard, president of Columbia College in New York, whose spadework in the 1890s consisted in arguing that the value of π was a modern discovery and therefore could *not* have been known to the ancients. In long-winded pieces for small periodicals, Barnard attacked Smyth for his "folly," and the builders of the Pyramid for the "stupidly idiotic task of heaping up a pile of massive rock a million-and-a-half cubic yards in volume."

In Barnard's opinion the Pyramids "originated before anything like intellectual culture existed; have been constructed without thought of scientific method, and have owed their earliest forms to accident and caprice."

Other academicians mocked the theory that the ancient Egyptians could have had an advanced knowledge of geometry, geodesy or astronomy. As recently as 1963 an eminent engineer in Baltimore, author of an expensive privately printed booklet, *Designing and Building the Great Pyramid,* was to write: "Because the sides of the Great Pyramid faced the four cardinal points almost precisely it is usually assumed that the designers intended they should, but it is unlikely that they had more than a vague idea, if any, of the four cardinal points. Like all peoples, the ancient Egyptians knew east and west from seeing the heavenly bodies rise in one and set in the other, but north and south were probably only known to them as general directions. There is no evidence in the Great Pyramid that they had any conception of true north or knew that a north-south line was perpendicular to an east-west line."

For years Smyth's painstaking measurements, carefully collected and illustrated in several large volumes (which went through several editions in his lifetime), were labeled by the academicians so much "trash and fancy."

In the conflict of opinions between biblical scholars and men of science, the true purpose of the Great Pyramid was buried in a rubble of verbiage.

Petrie had become Sir Flinders, and was on his way to becoming the dean of academic archeologists. Had it not been for the careful work of some conscientious scholars, Smyth and Taylor would have suffered the fate of Paracelsus and Mesmer, being relegated in the history books to the role of mountebanks.

IX. SCIENTIFIC THEORY DEVELOPED

Ironically, the next great investigator to throw light on the question of the Pyramid was a man whose object was to destroy and dispose of the theories of Robert Menzies, whose ideas about the prophetic revelations in the passage system had added to the difficulties of Piazzi Smyth.

An agnostic and a sober structural engineer from Leeds, in the north of England, David Davidson was determined to destroy Menzies' prophetic theory. But the more he attacked the data, the more he was obliged to assimilate it. In the end he was to produce an encyclopedic literature in support of Menzies' own idea, and to become convinced that the Pyramid was "an expression of the Truth in structural form" and that it "establishes the Bible as the inspired work of God."

From further analysis of the Pyramid, Davidson believed he could confirm Taylor's premise that the science of weights and measures of the ancients was founded upon two functions of the earth and its orbit, the standard time unit being the solar year, and the standard linear unit a decimal fraction of the polar axis about which the earth rotates.

On the question of the length of the Pyramid's base, Davidson was to vindicate Smyth, yet avoid harming Petrie. According to Davidson, not only was Petrie's survey correct, so was Smyth's theory that the Pyramid's base incorporated the length of the solar year.

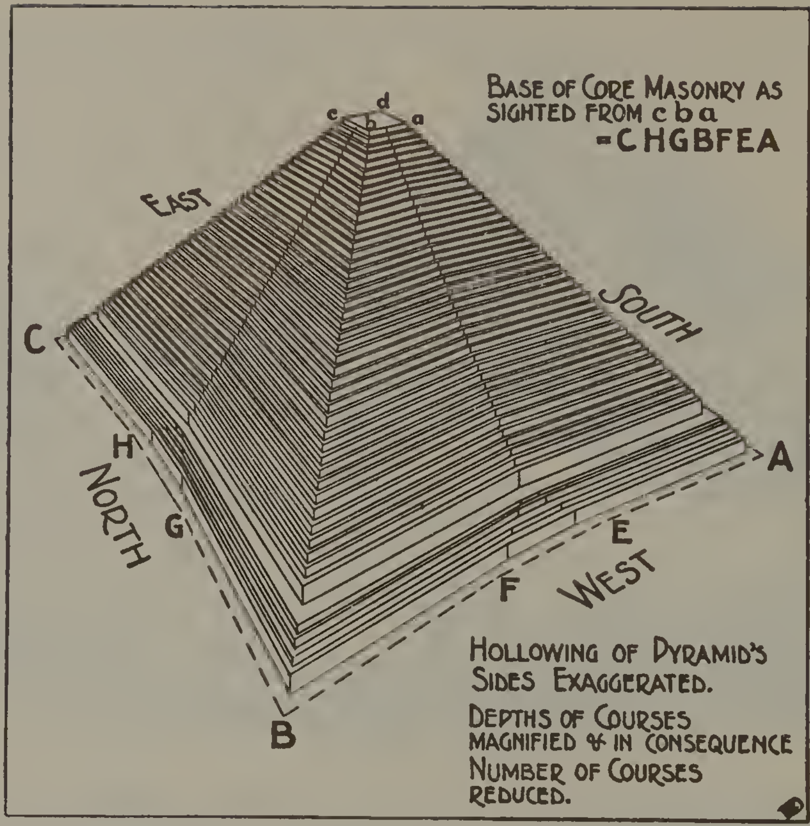
Petrie, with his meticulously careful measurements, had managed to observe a definite hollowing of the core masonry on each side of the Pyramid. The accuracy of this observation, normally invisible to the human eye, was revealed in Petrie's lifetime in a dramatic aerial photograph taken accidentally at a specific time and angle by Brigadier P. R. C. Groves, the British prophet of air power. A similar line along the apothem, visible in an etching made by Napoleon's savants, had been ignored for a century.

Davidson noted that Petrie had failed to extend this hollowing feature of the core material to his measurement of the outside casing. If this were done, a base length was obtained which fitted Smyth's theoretical length to account for the solar year, to four points of decimal.

Sir Flinders Petrie noted a distinct hollowing of the core masonry in the central portion of each face of the Pyramid. Though the hollowing amounts to as much as 37 inches on the north face, it is not directly observable unless special lines of sight are taken.

Petrie found no evidence of hollowing along the lower-level casing stones, running along the base of the Pyramid, which have now been completely uncovered.

A recent survey by two Italian scholars, Maragioglio and Rinaldi, indicates the casing stones *above* the base line may have been slightly sloped toward a central line.



Davidson's plan of the base of the Pyramid, showing three different ways of measuring the year's length.

SWXTYZUΠΔVQI—Base of core masonry.

As Davidson put it: "By reason of this unfortunate omission, scientists have been led to believe that the theory of the late Astronomer Royal of Scotland—Professor Piazzi Smyth—requiring a Great Pyramid base circuit of 36,524 inches, was nothing more than a delusion."

The ideal length postulated by Smyth for each side of the base in order to obtain the required length of 9131.5 Pyramid inches was 9141.1 British inches. Petrie's figure, revised by Davidson, came out to 9141.4, or about a third of an inch too long.

According to Davidson, the hollowing effect would give three basic lengths of the year as recorded in the base of the Pyramid: an outer or shortest length, from corner to corner, bypassing the hollowing, a second, slightly longer, which included part of the indentation of the four hollowed faces at the base; and a third, which included the entire angle within each hollowed face. These three measurements, which could have been performed by the ancients at their leisure, could have given the equivalents, according to Davidson, of the three lengths of the year as computed by modern science: the solar, the sidereal, and the anomalistic years, each of which is dependent on the system used for observation.*

The academicians rebutted that all this was purely attributable to chance. An American naval officer who dabbled in digging at Giza remarked that "if a suitable unit of measurement is found—say versts, hands or cables—an exact equivalent to the distance of Timbuctu is certain to be found in the roof girder work of the Crystal Palace, or in the number of street lamps in Bond Street, or the Specific Gravity of mud, or the mean weight of an adult goldfish."

But Davidson's conclusions were to reopen the entire subject of Pyramid measurements and breed a whole new school of pyramidologists.

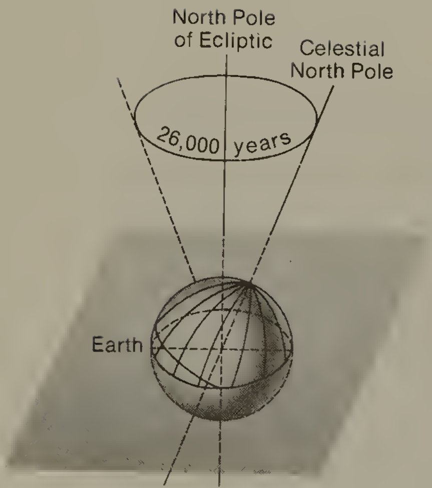
* The solar year is obtained by observing the exact time between two successive vernal or autumnal equinoxes, when the day is exactly as long as the night. It is now 365 days, 5 hours, 8 minutes and 49.7 seconds, or in decimals: 365.2242. The sidereal year (from the Latin *sidus,* for star) is the time it takes a star to reappear in the same spot in the sky, as seen by an earth observer. It is about 20 minutes longer than the solar year, or 365.25636 days. This 20-minute lag causes what is known as the precession of the equinoxes, which come 20 minutes earlier each year in relation to the stars behind the equinoctial point. The anomalistic, or orbital, year is the time it takes the earth to return to the point in its elliptical orbit nearest the sun, or perihelion. This is about 4 3/4 minutes longer than the sidereal year. According to Davidson, not only does the Pyramid give this value, but it gives the number of solar years it takes for the perihelion to complete a full circle of 360°.

The president of the French College of Astrologers, D. Neroman, a mining engineer by profession, showed in his *La Clé Secrète de la Pyramide,* published shortly after World War I, that Smyth's sacred cubit and Petrie's royal cubit were mathematically related. Neroman revived Newton's conclusion that the Pyramid had been built with both basic cubits, Petrie's shorter cubit for the common workmen, and Smyth's longer cubit for the hermetic science of the designers. Neroman showed that the Pyramid was the precise height and width to contain a round number of each unit. As 33 sacred cubits are equal to 40 profane, or royal, ones, the base measured 440 royal cubits or 363 sacred cubits; the height 280 or 221.*

It was suggested that the priests measured the year's length with a sacred cubit so that they alone could make use of the Pyramid's hermetic science. But why this yielded a base of 363 days was not satisfactorily explained.

Another necromantic solution was provided by John B. Schmaltz in a small book entitled *Nuggets from King Solomon's Mines.* Schmaltz demonstrated that the modern deck of cards could be taken as a symbol of the Egyptian year incorporated in the Great Pyramid. According to Schmaltz the 52 cards represent the weeks, the 12 face cards the months, the 13 cards in a suit the lunations, the suits the seasons, the total face value of the cards (counting jack as 11, queen as 12 and king as 13) 364 days, plus the joker as the magic 1.234, for a total of 365.234 days in the year.

A more solid boost to the memory of Piazzi Smyth—quickly made much of by the pyramidologists—was the refined figure for the polar axis of the earth obtained in 1910 by the American geodesist John Fillmore Hayford, who computed it at 6,356,910 meters, the ten-millionth part of which gives a cubit of 635.69 millimeters, or Piazzi Smyth's sacred cubit, correct to .03 millimeter.



The precession of the equinoxes.

Another extraordinary figure found by the pyramidologists in the base of the Pyramid was the sum of its diagonals, which they computed as 25,826.68 pyramid inches. This gave a very close approximation of the number of solar years in what is known as the great year, which is determined by the precession of the equinoxes. The great year is the time it takes the earth to make a complete gyration in the wobble of its axis in relation to the plane of its orbit; this with the solar year, are the two prime standards for astronomical time.

Actually, the rate of precession is far from uniform, and

* $33 \times 25.025 = 825.72$ and $40 \times 20.643 = 825.72$. It will be noticed from Neroman's figuring that to obtain this result he arbitrarily lengthened the royal cubit by about 1/100 of an inch.

is at present slowly increasing. According to Davidson, the Great Pyramid recognized this fact and provided a method of sums of diagonals at different levels of the monument to indicate the all-time mean, or average length of the precessional cycle.

To add to the coincidences, Morton Edgar, an ardent supporter of Davidson, who traveled to Egypt just prior to World War I and made extensive measurements and calculations, found that the perimeter of the thirty-fifth course, which is much thicker than any of the other courses, *also* gives a figure for the precession of the equinoxes.

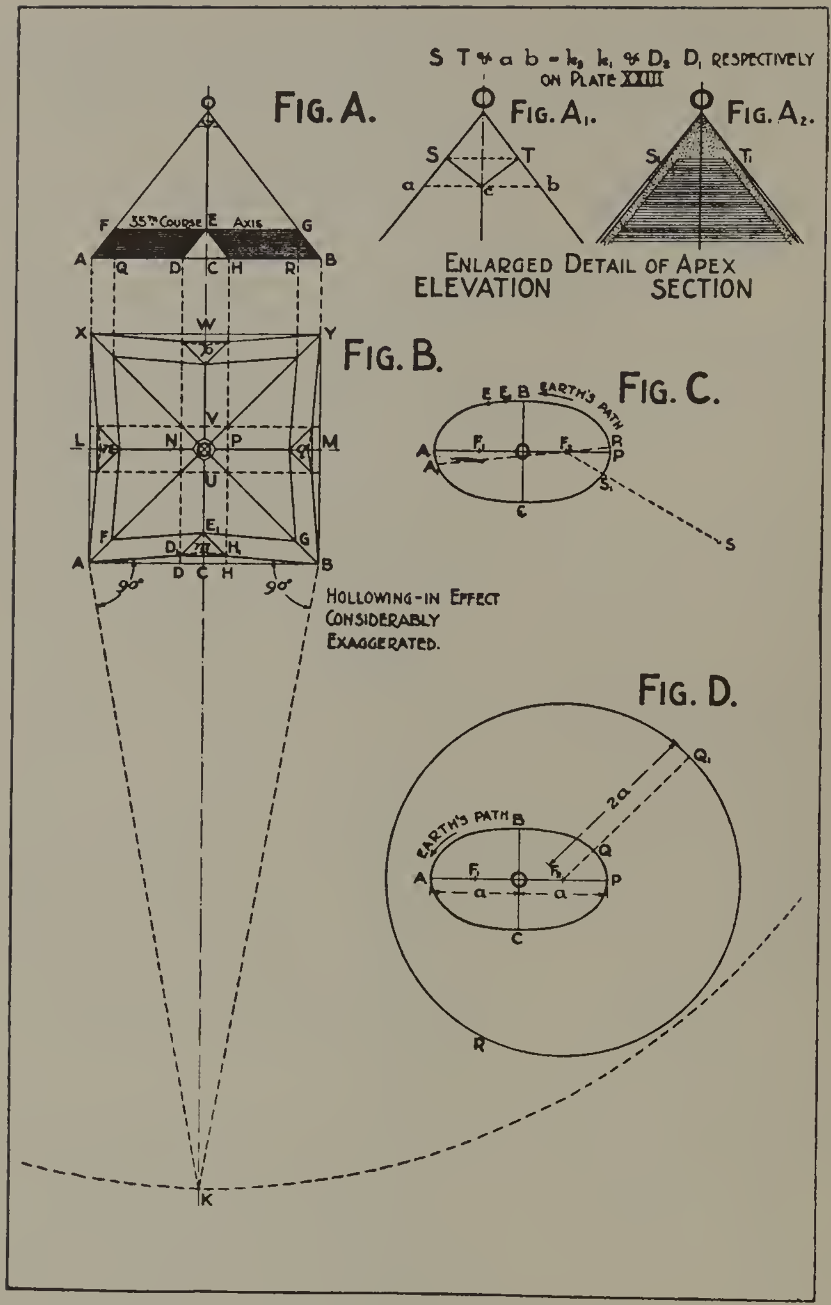
Egyptologists and astronomers argued that if the Pyramid had been designed to incorporate the π proportion, and its base had been designed to be 365.2422 cubits long, the chances of its diagonals being intentionally designed to mark the length of the precession would be simply astronomical.

Davidson replied that to build the Pyramid its designer must have been deeply acquainted with the workings of natural law: that before such a design could be put into effect, the astronomical properties of the solar year would have to be reduced to a simple pyramidical expression.

Davidson claimed that—without getting into higher mathematics—it was evident that if you know the earth's distance from the sun and the length of the sidereal year in seconds, you can compute the rate at which the earth is falling toward the sun. This in turn would lead to finding the specific gravity of the earth, of the sun, of the earth and moon combined, the solar parallax, and even the speed of light.

To Davidson the mathematics of the Pyramid indicate that the former civilization was more highly skilled in the science of gravitational astronomy—and therefore in the mathematical basis of the mechanical arts and sciences—than modern civilization. It was his conclusion "that it has taken man thousands of years to discover by experiment what he knew originally by a surer and simpler method." In Davidson's words: "It means that the whole empirical basis of modern civilization is a makeshift collection of hypotheses compared with the Natural Law basis of the civilization of the past."

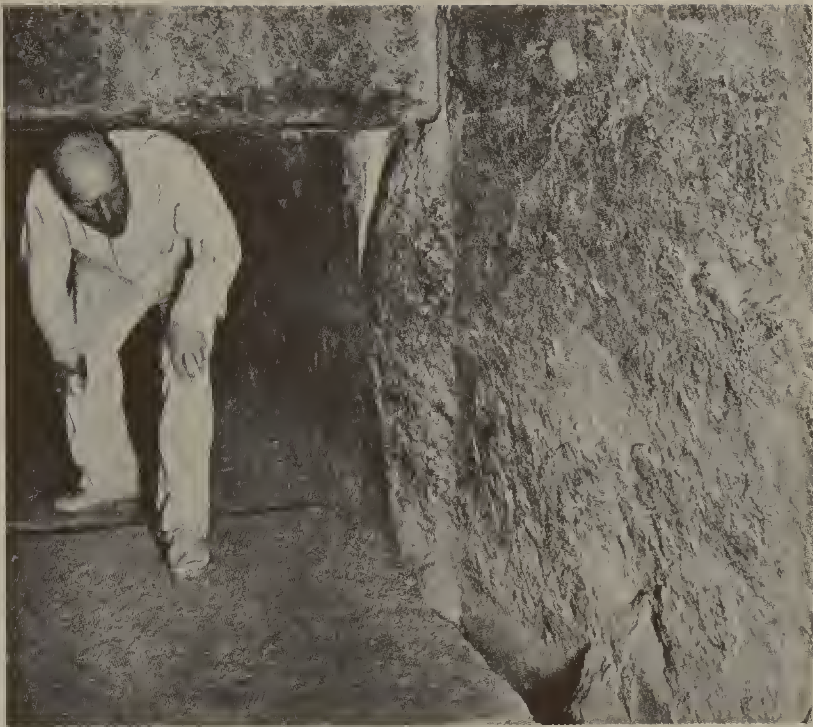
As to why the Pyramid was built and its passages carefully secreted, Davidson surmised that the builder intended to monumentalize the science of his time for another civilization far in the future, much as we go about burying time capsules. According to Davidson, the builder knew that the faculties by which he was able to handle the formulas of natural law could atrophy in man, and that by conveying his science to beings of a later civilization he might spur them to recover those powers.



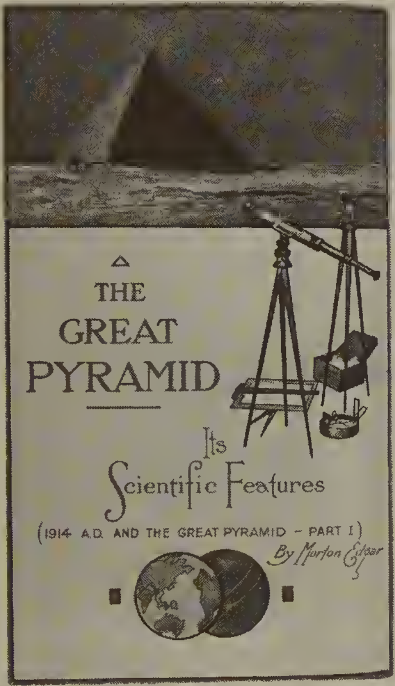
Davidson's computations to show that the Pyramid's base defines the earth and its orbit "in dimensions and motion."

Like Menzies and Smyth before him, all that Davidson managed to accomplish was to antagonize the scientific world with his insistence upon the record-preserving nature of the Pyramid while swamping the average pyramid enthusiast with the overwhelming bulk of his detailed mathematical analyses and computations.

Even worse were the efforts of a succession of pyramidologists who attempted to prove the Great Pyramid contained a six-thousand-year prophetic history of the world commencing in 4000 B.C. and going to A.D. 2045 which coincided with the prophecies of the Bible. They saw in the Pyramid an allegory in stone in which the Descending Passage represented humanity on its way down toward



Morton Edgar, supporter of the prophetic theories about the Pyramid, stooping to enter the King's Chamber. The picture shows how the floor was inserted between the walls so as to obtain both the π value and the 3–4–5 triangle.



ignorance and evil. At the juncture of the Ascending Passage, evil spirits were to continue toward the pit, whereas the rest of humanity, benefiting by the Christian Dispensation, moved upward along the Ascending Passage toward the Light of the Grand Gallery. Having passed the Great Step, humanity must continue bent in submission through the Antechamber of Chaos—representing the modern age—before it could come out into the King's Chamber and the glory of the Second Coming.

The prophetic chronology was supposed to be marked out along the passages and chambers, with one year corresponding to one pyramid inch, commencing with "Adam," or the "first created man," and ending with the "Day of Judgement."

According to Morton Edgar: "By the year 2914, the end of the 1000-year 'Day of Judgement,' mankind will have experienced the full benefit of the sacrificial work of Christ, and will regain that perfect human nature which father Adam lost in the beginning of his disobedience 7040 years previously."

By general agreement the commencement of the Low Passage into the Antechamber was said to mark the beginning of the Great War in 1914. The end of the King's Chamber was supposed to be indicated by the year 1953.

Considering the wide popular acceptance of such medieval prophets as Nostradamus, and such modern prophets as Edgar Cayce and Jeane Dixon, it should not have been harder to believe that some ancient prophet could

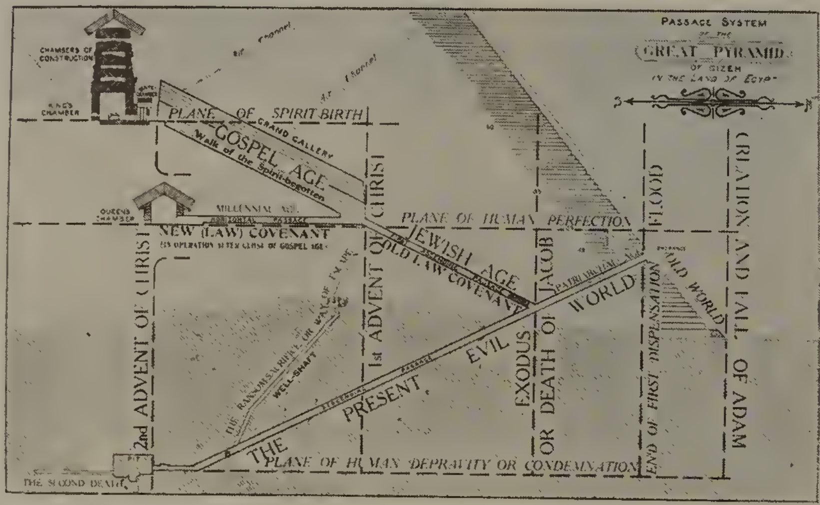
Chronology of the past 6000 years as indicated in the Great Pyramid passages according to Menzies and Piazzi Smyth.



have had prescience of the following 6000 years, and built his vision into the Pyramid passages; but as each prophetic date went by with no appearance of a Second Coming, the idea of the Pyramid as a prophetic calendar became largely discredited.

By 1920, when the waters of the Mediterranean failed to become thick and viscid, and the rivers and fountains of the world failed to turn into blood, as prophesied by Colonel J. Garnier on the basis of the Pyramid chronology, the whole subject became so unpleasant in the halls of academe that few professors dared mention the Pyramid as anything but the supposed resting place of the Pharaoh Cheops.

Nevertheless, a few intrepid investigators kept minds open enough to continue their research into the structure and purpose of the Pyramid, and to put forth some theories that in the end paved the way for a general vindication of much that Jomard, Taylor, Smyth, and even Davidson had propounded.

X. A THEODOLITE FOR SURVEYORS

One basic function of the pyramids on the Giza plateau was discovered by a chief engineer of the Australian railways, Robert T. Ballard, as he watched them from the window of a passing train in the 1880s.

From the constantly changing relative position of their clear-cut lines against the sky, Ballard realized that the pyramids could serve as excellent theodolites for a land surveyor, enabling him to triangulate the land anywhere within sight of the pyramids.

The land of ancient Egypt was parceled out in small lots to individual priests and soldiers, the boundaries of which would regularly vanish with the flooding of the Nile.*

By means of the pyramids, not only could the surrounding country be quickly resurveyed, but boundaries destroyed by the Nile could be readily restored.

From the silhouettes of the pyramids, the engineer realized that lines could be obtained as perfect as can be laid out nowadays with all of our modern instruments. With a string and a stone held in the hand and the clear-cut point of a pyramid 20 miles away against the ball of the sun 90 million miles away, the error in such a line would be trifling.

What's more, the same building could also be used with either moon or stars.

Knowing the latitude of the pyramids, survey lines could be shown all the way to the coast of the Delta—with nothing more than a string and a weight.

As the engineer's train steamed southward along the bank of the Nile, more pyramids appeared on the horizon, and the engineer realized that with a procession of such theodolites it would have been possible to adjust the boundaries of Egypt from one end of the country to the other.

Ballard figured that the simplest portable survey instrument would be a small scale model of the Pyramid of Cheops in the center of a circular graduated board marked like a compass. When the north end of the card was pointed toward the north, and the faces of the model turned to indicate the same light and shade displayed by the Great Pyramid, the

* Statisticians estimate that eight million people were crowded into a space of only 11,500 square miles, giving a density of 695 per square mile—which is more than modern Belgium, the most densely populated part of Europe.

The pattern of shadows cast by the three large pyramids of the Giza plateau can serve to orient the viewer as accurately as a compass or theodolite. Ballard suggests that the smaller pyramid of Mykerinos was intentionally sheathed in red granite, in bold contrast to the other two pyramids, so as to facilitate the work of the surveyor.

The Giza complex of pyramids, as depicted from the air, showing the north-south meridian through the center of the Great Pyramid.
According to Soviet space engineer Alexander Abramov the three large pyramids on the Giza plateau are arranged in a special geometric configuration known in ancient Egypt as an *abaka*. Ballard found that several Pythagorean triangles could be formed by the perimeters and centers of the pyramids.

surveyor could simply read off the angle of bearing. With a model of all three pyramids, the reading would be that much more exact. Furthermore, observation of the next pyramids farther to the south could be tied in with these readings.

The Australian engineer also worked out that the pyramids could be used for surveying by right-angled triangles with sides having whole numbers, such as the 3–4–5 triangle and the 2–$\sqrt{5}$–3 triangle Petrie had found in the King's Chamber, both of which were fundamental to land surveying. Similarly incorporated in the ziggurat of the Babylonians, the triangles were conceived by the ancients to explain the secret order of the cosmos, a conceit which percolated to Plato. In the *Timaeus* he explains the cosmos as being constructed by the triangle 3–4–5 and the number $\sqrt{5}$–1 or 1.236068 (which in common practice was taken as 1.2345).

For right-angled trigonometry, the Australian engineer realized, true straight lines could be extended from the pyramids in given directions by direct observation, without aid of other instruments, and that with the simplest of instruments, angles could be exactly observed from any point.

In a short time *anyone* might construct a table for himself answering to every degree or so in the circumference of a circle for which only forty or fifty triangles are required.

Such primary triangulation would be useful to men of almost every trade and profession in which tools or instruments were used.

Having come to these conclusions, Ballard incorporated them in a small illustrated volume with the rather grand title of *The Solution of the Pyramid Problem,* published in 1882.

XI. ALMANAC OF THE AGES

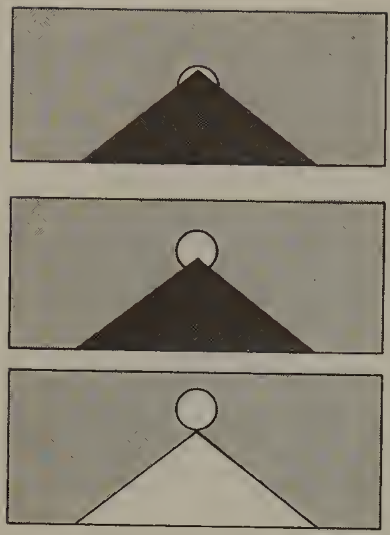
Ballard's little booklet and one of Smyth's discoveries at the Pyramid brought another strange investigator to the scene. Smyth had been astonished that with the advent of spring, when the sun rose high enough to shine down the northern slope of the Pyramid, the structure appeared to swallow its own shadow at noon. Smyth deduced that the Pyramid had been designed as a huge sundial whose shadows could indicate the seasons and the length of the year.

By Smyth's reckoning the Pyramid had been intentionally located, oriented, and sloped for the phenomenon to occur in that latitude at the spring equinox, when at noon the sun is directly over the equator, although for some reason the phenomenon no longer occurred precisely at that particular date.

Unbeknownst to Smyth, the French astronomer Jean Baptíste Biot had been to Egypt in 1853 and noted that "with or without intention by the Egyptians who built the Great Pyramid, it has, since it existed, functioned as an immense sundial which has marked annually the periods of the equinoxes with an error less than one day, and those of the solstices with an error less than a day and three quarters."

The phenomenon had a great impact on an obscure Yorkshireman, Moses B. Cotsworth, a legislative enthusiast whose life's ambition was to reform our present barbarous almanac.*

* The present calendar derives from the early Romans, who had a 10-month year of 334 days: hence our September, October, November, December. In the seventh century B.C. Numa Pompilius is credited with adding January and February for a lunar year of 354 days. The shortage of 11 1/4 days caused the seasons and the calendar to diverge to the point where Julius Caesar was obliged to add 91 days to 46 B.C. and succumb to the suggestion of Cleopatra that he adopt the Egyptian civil calendar of 365 1/4 days. Even so, the difference between the civil calendar and the actual solar year of 365.2422 days added up to an extra day every 128 years, which obliged Pope Gregory XIII to drop 10 days from 1582. When Protestant England refused to go along, Christendom celebrated different Christmases in England and France, till the British finally relented in 1752, though there were street riots in London with shouts of "give us back our ten days." By skipping leap days in centuries which are multiples of 400 and 4000, our calendar is now good for the next 20,000 years, but anyone who troubles to read Cotsworth's impassioned plea for a more rational system than our calendar of floating holidays will find it hard to dispute his logic.



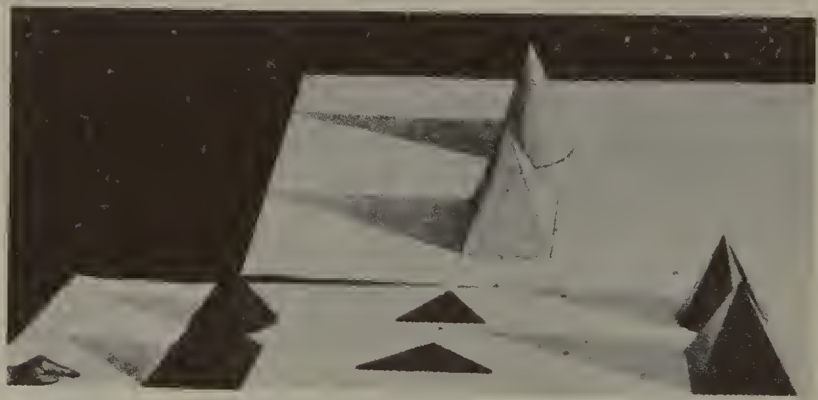
In early spring, when the sun rises just high enough above the apex of the Great Pyramid, the whole shadow on the north face vanishes at the stroke of noon.

Cotsworth was convinced that the designers of the Pyramid had intended their finished structure to serve as a perfect almanac for registering the seasons and the year. To prove his point Cotsworth went in search of further evidence.

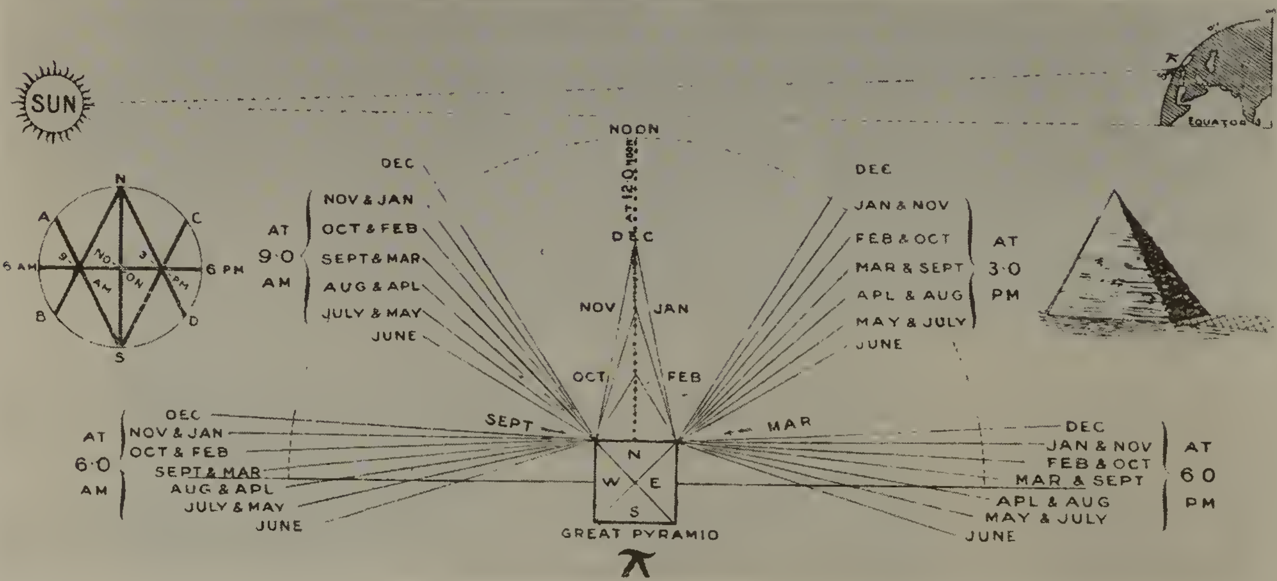
Just before Piazzi Smyth died in 1900, Cotsworth managed to have several conversations with him, and after his death was able to get hold of Smyth's books and papers when they were put up for auction. Though Cotsworth refused to accept Smyth's prophetic theories, he was determined to vindicate the astronomical theories of the ancient Egyptians, so he set about reconstructing with models the sundial system on which he believed the Pyramid had originally been designed.

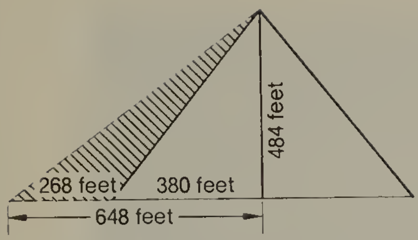
Cotsworth noted that at the latitude of the Pyramid, an ordinary obelisk would serve admirably for telling the time of day, or the general course of the seasons, but could not be built high enough to throw a shadow long enough to detect the length of a whole year of 365 days, let alone throw a shadow fine enough to distinguish the extra quarter of a day to four points of decimal. To obtain the difference in length of 1 foot per day would require an obelisk 450 feet tall, perfectly vertical and precisely oriented.

Cones and pyramids designed by Moses B. Cotsworth to demonstrate how shadow patterns could be used to measure the length of the year.

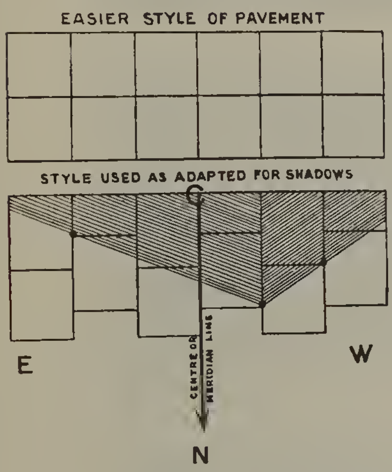


Cotsworth's models show how a square-based pyramid oriented to true north will cast a pointed shadow on the meridan line. A cone, showing no orientation, will not serve the purpose.





With the sun's winter solstice angle of 36° 45′, the Pyramid will throw a shadow of 648 feet. Deduct half the Pyramid's base length of 760 feet, or 380, and the maximum length of the Pyramid's winter shadow will be 268 feet.



Cotsworth found that part of the pavement north of the Pyramid was paved with blocks whose widths were close to the 4 1/2-foot gradation of the sun's shadows on successive days just before the Pyramid consumed its own shadow in the spring.

Cotsworth figured that the dimensions of the Pyramid would be ideal for measuring the six winter months, when the northern slope of the Pyramid is constantly shaded and when the shadow cast at noon onto the northern pavement grows longer up the meridian to a maximum at the winter solstice, gradually decreasing to the point of disappearance at noon on a certain day in March.

To test his theory, Cotsworth made several model pyramids and cones and laid them out on carefully diagrammed paper. On these sheets he marked the outline of the shadow cast by the sun each half hour during a period of several months.

To his satisfaction Cotsworth was able to prove that the pyramid was the best shape for the purpose. The pyramid was more easily oriented to a perfect north, its flat slope was easier to angle, and its sharp edges cast a better shadow. Also, the actual structure would be easier to build to the required height in the form of a pyramid than a cone.

To measure the Pyramid's lengthening and shortening shadows, Cotsworth realized that a wide and perfectly level pavement, or "shadow-floor," should have been constructed on the northern side of the Great Pyramid, presumably with a meridian line running due north, and a pavement laid in some geometric pattern to facilitate the measuring of the shadows.

Cotsworth worked out that a structure 484 feet high, such as the Pyramid of Cheops, would require a "shadow-floor" stretching 268 feet northward of the base in order to include the full length of its shadow at its longest point, at the winter solstice in December.

To verify his theory, Cotsworth sailed for Port Said in November of 1900 aboard the P. & O. liner S.S. *Osiris*. At the Giza plateau he found the north side of the Pyramid of Cheops reasonably clear of rubble and the rocky plateau leveled to the required distance. At the level of the main platform on which the Pyramid rests, he found a pavement, or "shadow-floor," which extended as far as the remains of an old wall which had once surrounded the pyramid complex.

Instead of being paved in adjacent squares, Cotsworth found it laid in alternate half squares, which provided twice the number of junction points by which to measure the daily shadow of the Pyramid along the meridian at noon.

To support his observations, Cotsworth made a series of photographs of these shadows as they grew shorter toward the vernal equinox. To his delight he found that the paving blocks had been cut in widths very close to the 4.45-foot gradation by which each noonday shadow succeeded the former as they approached the vanishing point in March.

Photograph taken by Cotsworth showing shadow cast by the sun close to the base of Pyramid at noon of the last day before the intended equinox. The negative was stolen and the print has suffered in reproduction; but the pattern of shadow can be measured on the northern pavement.

It was only thus, says Cotsworth, "that the ancient priests could have established by physical observation of the shadow on the flagstones, the precise length of a year to .24219 of a day."

William Kingsland, a professor of astronomy, commenting on Cotsworth's conclusions, pointed out that some of the paving stones are actually laid at all kinds of irregular angles and corners; but the corners of these stones are clearly cut out to fit into the adjoining stone—indicating, if anything, an even more sophisticated geometric pattern.*

To make up for the summer half of the year, when there

* According to Kingsland, Cotsworth's leveled rock area did not extend 268 feet north from the northern base of the Pyramid, but ended at a distance of only 33 1/2 feet, where there are the remains of a surrounding wall 9 1/2 feet thick; but there is no way of telling at what time this wall was built, or whether the pavement may not have once continued beyond it, and been dismantled by the Arabs for building blocks.

was no shadow on the northern slope of the Pyramid, Cotsworth figured that the priests could have subdivided and tabulated the intervening months.

In this he failed to realize that the southern face of the Pyramid, being highly polished, could throw a triangle, not of shadow, but of sunlight onto a southern pavement during the summer months, quite as definite as the winter shadows thrown on the northern side.

From May to August the south face would cast a triangular reflection of the sun onto the ground which would shorten as it approached the summer solstice, the shortest being at noon of the solstice, lengthening again till noon of the last day of summer.

Noon reflections would also be projected every day of the year from the east and west faces. But this was to remain for David Davidson to establish.

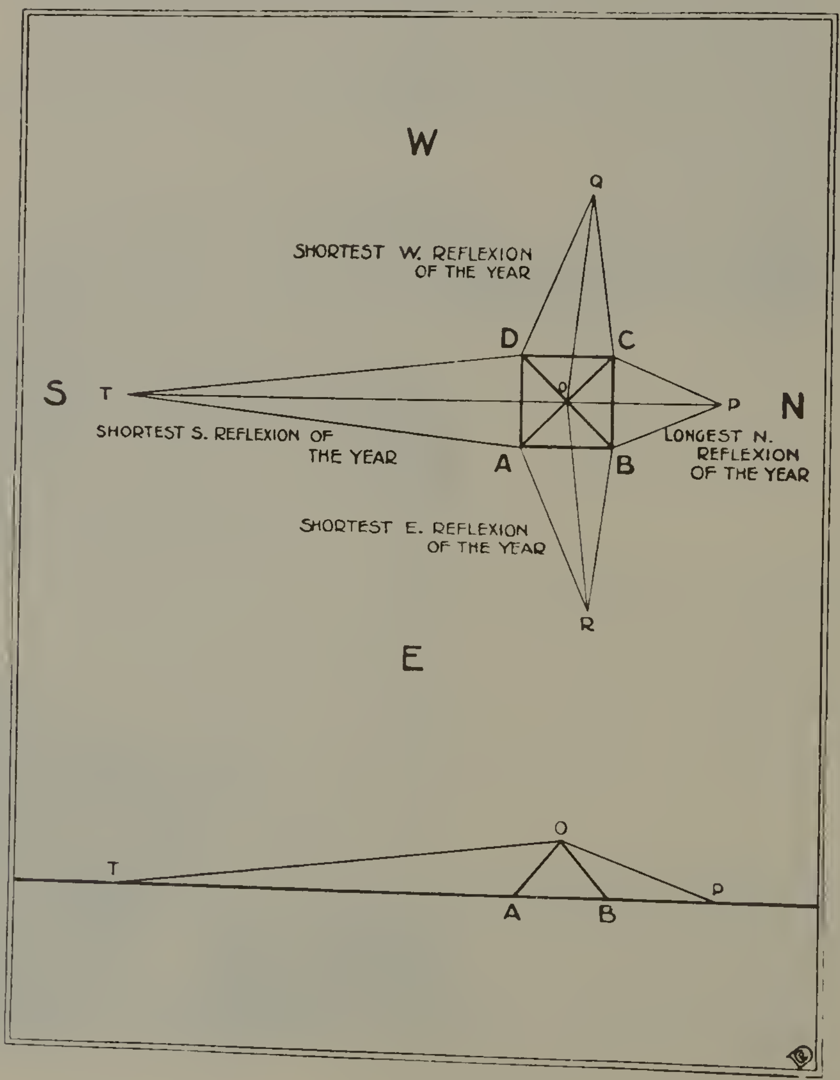
From a study of the sharper slopes of other pyramids, such as of Saqqara, Medûm and Dashur, Cotsworth deduced that their builders may have aimed these slopes not at the equinox, when the sun is midway, but at the summer solstice, when the sun is highest in the sky at noon. Sneferu's pyramid

Deliberately broken pattern of paving stones observed by William Kingsland on the north side of the Great Pyramid, apparently intended for finer mathematical measurement of the sun's shadow on successive days and years.

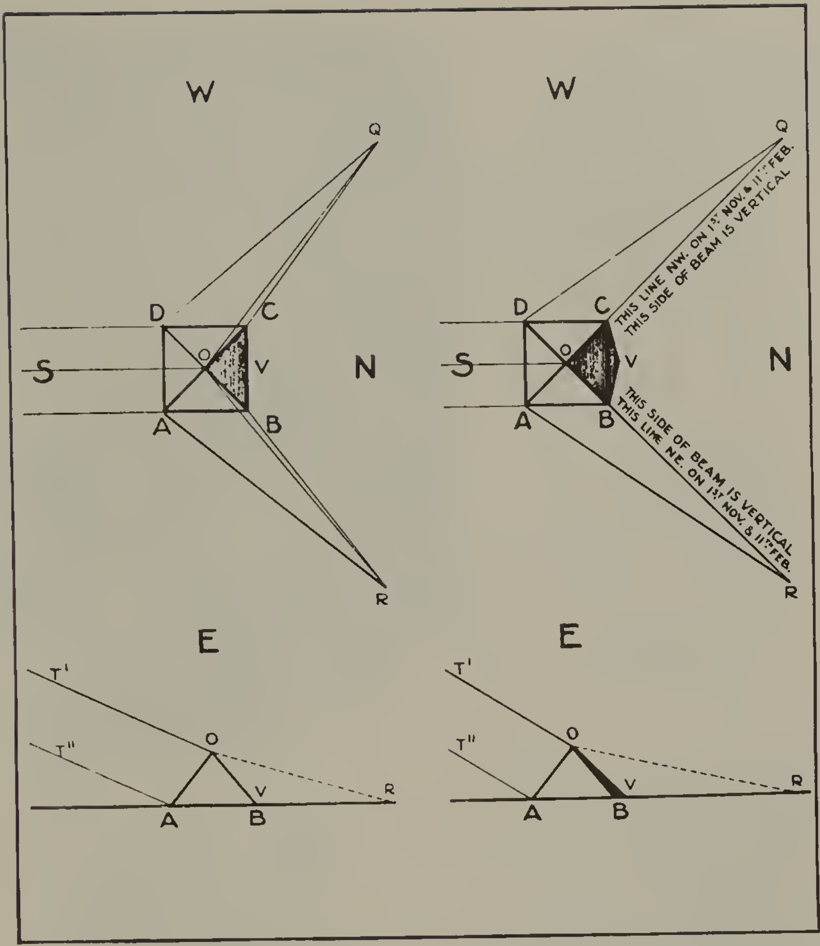
at Dashur, with its milder slope of 43°, may have been aimed at the winter solstice, when the sun is lowest at noon. From the gradually corrected slope of Saqqara and the change in angle in the bent pyramid at Dashur, Cotsworth concluded that the Egyptians may have progressed northward to the "truer" pyramid form, or π-shaped pyramid, at the thirtieth parallel, where morning and afternoon shadows form a series of perfectly straight lines.

In this, Cotsworth was supported by Joseph Norman Lockyer, the eminent British astronomer, who taught astronomical physics at the Royal College of Science. Lockyer noted that pyramids other than that of Cheops appeared to be oriented not to true north but to the rising sun at the solstice, which *changes with the latitude* of the place of construction.

According to Cotsworth the pyramids were originally developed from mastabas or raised terraces built to support an obelisk. To lengthen the shadow, the obelisk was successively raised on higher sloped platforms, which eventually turned into stepped pyramids.



Davidson's diagram of the reflections of sunlight cast by the Pyramid at noon of the summer solstice.



Davidson's diagram of winter shadows and reflections cast by the Great Pyramid. Left figure shows the noon shadow first appearing October 14–15. Other lines indicate reflected sunlight. Right figure shows the noon shadow first disappearing February 27–28. Other lines are pattern of reflected sunlight.

Cotsworth points out that the oldest true pyramid, that of Medûm, was constructed in several stages, as evidenced by the polished casings at each level.

The process, says Cotsworth, was developed to the point where the results no longer increased in proportion to the effort expended. A 60-foot platform which raised a 60-foot obelisk increased its shadow by 100 percent, but an added platform of 40 feet only increased the shadow by 19 percent; eventually the top platform became too small for raising an obelisk. According to Cotsworth, the optimum design turned out to be the solidified Pyramid of Cheops, with its slope set for a particular latitude to swallow the equinoctial shadow. Once this method of establishing the precise length of the year had been found, says Cotsworth, there was no further need for enormous pyramids.

Cotsworth obtained further confirmation of his theory from a comparison of the pyramids with the artificial hills built by ancient inhabitants of Britain who traced the year's end by the longest shadow of the year cast from vertical cones or artificial mounds such as Silbury Hill.

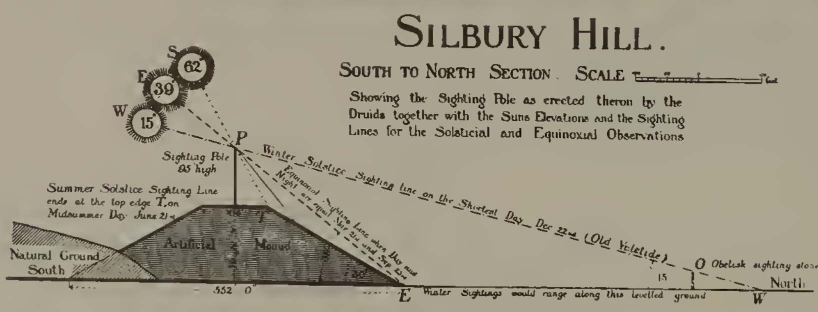
Later inhabitants of Britain, such as the Druids and Goths, continued to count the year's end from Yuletide, the December solstice.

Silbury Hill in Wiltshire, England, covers five acres and is built of over a million tons of hand-moved material. According to archeologists it is at least four thousand years old.

Cotsworth says that Silbury Hill was designed to have a Maypole on top to cast a shadow up and down the truncated hill and onto the level plain to the north, so as to mark the four seasons of the year.

The cone was truncated at a point where the shortest shadow thrown by the Maypole on the longest day of the year indicated the summer solstice. On the level plain north of the hill a stone was placed in the ground to mark the point of the longest shadow cast by the Maypole at the winter solstice, or shortest day of the year.

The juncture at the bottom of the hill, where it touched the plain, marked the spring and autumn equinoxes, when the day was exactly as long as the night.

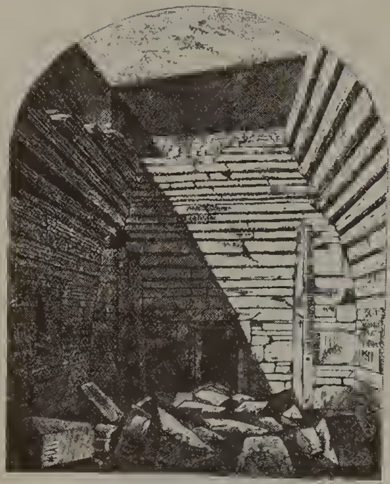


Aerial photograph of Silbury Hill, showing the footpath around the truncated top.

Druid in Old Irish meant "he who knows." Julius Caesar, our earliest source on the subject, considered the Druids highly educated and well organized. In *De Bello Gallico* he commented: "It is especially the object of the Druids to inculcate this—that souls do not perish, but after death pass into other bodies, and they consider that by this belief more than anything else men may be led to cast away the fear of death, and to become courageous. They discuss many points concerning the heavenly bodies and their motion, the extent of the universe and the world, the nature of things, the influence and ability of the immortal gods; and they instruct the youth in these things."

As Cotsworth reconstructed the system, the truncated cone of Silbury Hill enabled the ancient astronomers to measure the length of the seasons and the year by the length of shadow cast by a pine Maypole, which served as an obelisk, atop a hill intentionally truncated so that its edge would also mark the summer solstice, or the shortest shadow of the year.

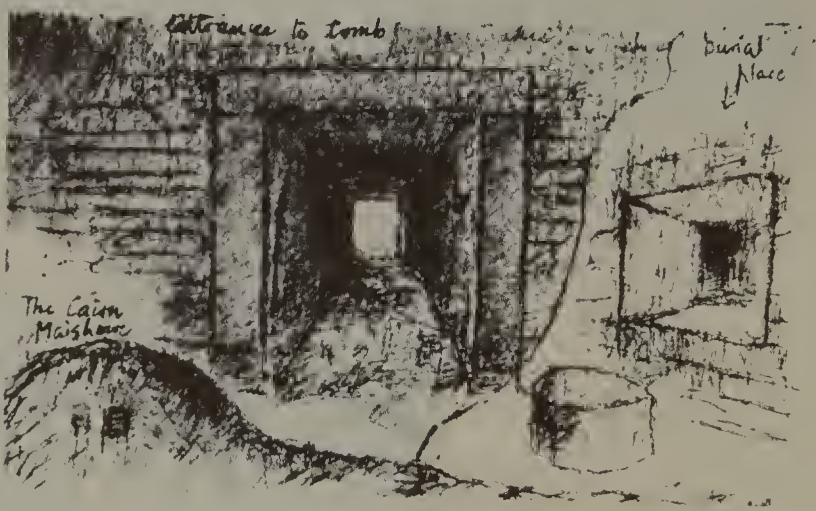
Had these astronomers simply required a great height, says Cotsworth, they would have used the adjacent Abury Hill, with its wide top which could easily have been raised. But this, says Cotsworth, would not do; they required an absolutely level piece of ground on which to mark the progress of the shadow. Hence they had no alternative but to pile up an artificial hill above the level plain. Fortunately, in latitudes of 50° or 60°, such as Brittany or Stonehenge, low mounds would give shadows long enough for detailed measurement. A height of 225 feet in Wiltshire gives a



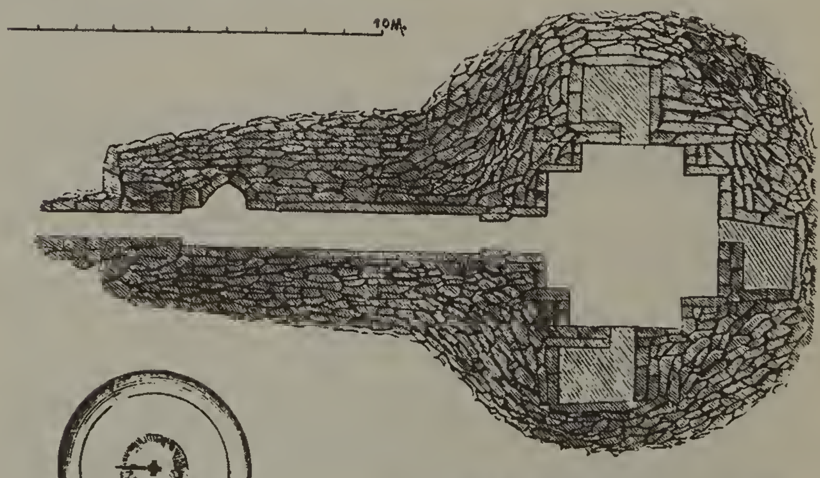
The main chamber in Maes-Howe, showing corbeled monoliths which could be closed at the top by a single movable slab. The jointing in this prehistoric masterpiece rivals that of the Great Pyramid.

shadow almost equivalent to the shadow of the 484-foot Pyramid of Cheops.

One of the most remarkable of these prehistoric European mounds still exists at Maes-Howe, near Stennes, in the Orkney Islands. It is equipped with a 15-foot square observatory chamber and a 54-foot sighting tunnel. The tube is aimed at a conspicuous man-raised monolith 42 chains (2772 feet) from the entrance, which lines up with a spot on the horizon where the sun now rises 10 days before the winter solstice. Another monolith, to the west, called the Watchstone, indicates the equinoxes. Like the Great Pyramid of Cheops, the observatory chamber is built of huge megaliths and its ceiling is corbeled. There are also three "retiring rooms for the observers," somewhat like the Queen's Chamber in the Great Pyramid.



The entrance passage to the Maes-Howe observatory is very similar to that of Egyptian pyramids.

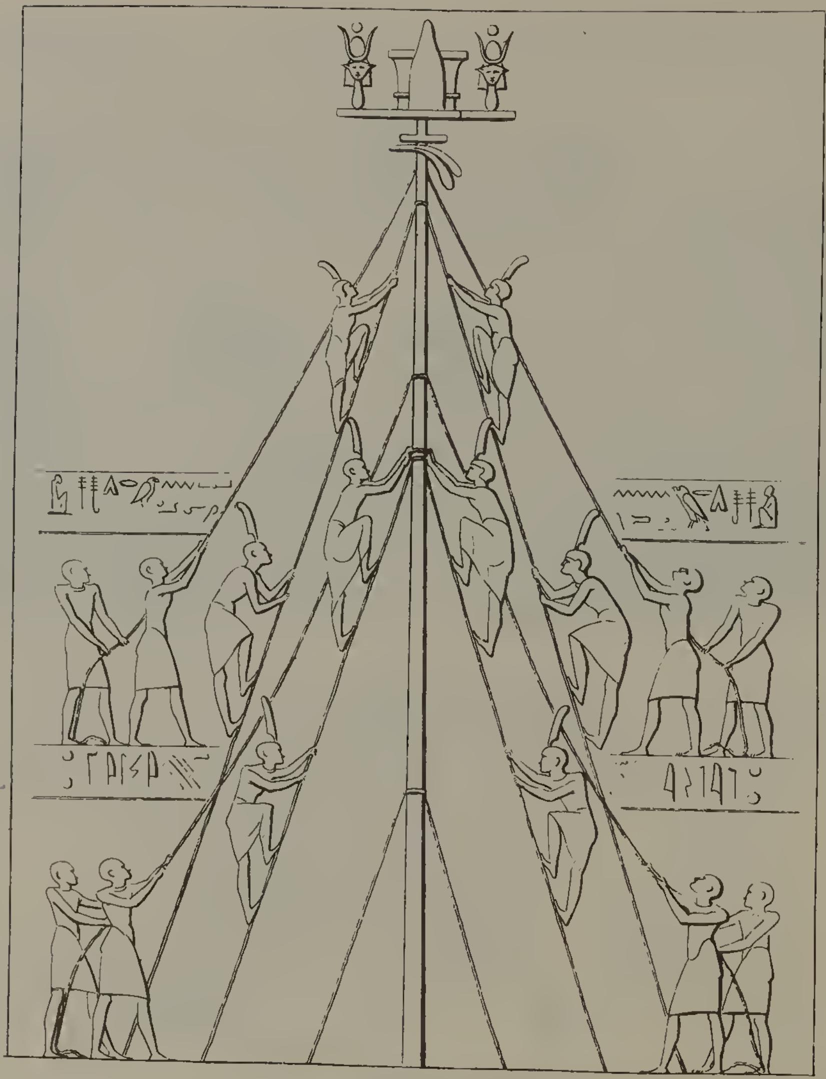


Maes-Howe, near Stennes in the Orkney Islands, is a man-made cone-shaped pyramid 27 feet high and 115 feet across, with an outer circling ditch 45 feet wide and 700 feet in circumference.
It has a 54-foot observation passage aimed like a telescope at a megalithic stone to indicate the summer solstice.
Its central observation chamber, corbeled like the Great Pyramid's Grand Gallery, is built of megaliths weighing 3 tons, carefully leveled, plumbed and so finely jointed they will not admit the blade of a knife.

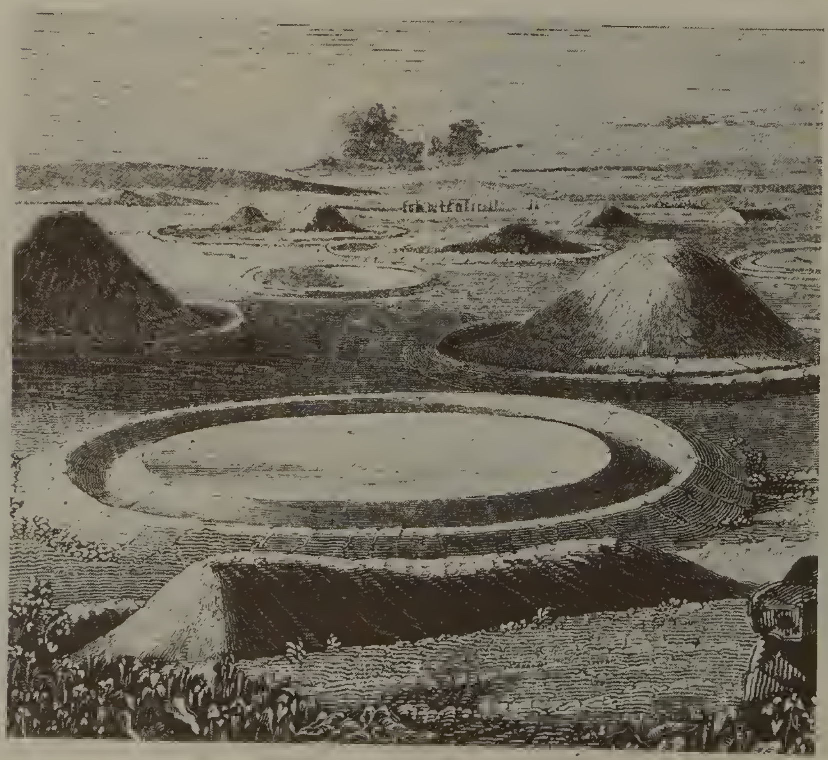
Circular monoliths similar to Stonehenge located at Stennes in the Orkneys near Maes-Howe.

In *Stonehenge, a British Temple Restored to the Druids,* which Piazzi Smyth considered a book "far before its age and perhaps not yet sufficiently appreciated," its author, Dr. William Stukely, attempted to show that such megalithic circles had always been arranged on even and round numbers of the "profane cubit of 20.7 inches nearly," and not in feet or any other known standard of length. Smyth remarked that although the idea "was pooh-poohed by more recent antiquarians, I have never heard of any of them having ascertained by actual measure at the place, that the Stukelian theory would not hold."

Professor Alexander Thom has recently shown they are built on a megalithic yard of 2.72 feet.



An Egyptian Maypole.



Various shaped mounds, or "barrows," were constructed in prehistoric Britain. Cotsworth considered them man-made instruments for observing the movements of heavenly bodies.

Alexander Thom considers Averbury Circle near Stonehenge the greatest and most remarkable circle in Britain, if not in the world. "Its greatness," says Thom, "does not lie in its size alone but in the remarkable manner in which its arcs are built up from a basic Pythagorean triangle so that each retains an integral character, and in the exceedingly high precision of the setting out, a precision only surpassed today in high-class surveying."

The Scottish lairds in residence at Maes-Howe—or Maiden's Mound—still plant a Maypole on the originally flat top, perpetuating the ceremony begun when observations were made of the shadows cast by the pole on the flat terrain to the north of the mound.

In England throughout the Middle Ages and the Renaissance, the Maypole with its tall garlanded and decorated shaft (stowed away for the rest of the year under the eave of a house) was set up on May Day. When Cromwell came to power he banned the Maypole. As the *National Encyclopedia* puts it: "The Puritans, to whom we owe the loss of so many of our public games, and so much of our merriment, ordered all Maypoles to be destroyed by Act of Parliament in 1644, as a 'heathenish vanity, abused to superstition and wickedness,' and fined the constables five shillings weekly as long as they stood."

The custom was revived with the Restoration, and the last Maypole erected in London—all of 100 feet high—stood on the spot where the church in the Strand now stands near Somerset House. It was taken down in 1717 and conveyed to Wanstead Park, in Essex, where it was fixed as part of the support of a large telescope set up by Sir Isaac Newton.

A glance at the outlines and cross sections of the pyramids of Saqqara, Dashur and Medûm will show that, like ancient British observatories, each had a sighting passage, pointed at a northern star. The passage ended in an

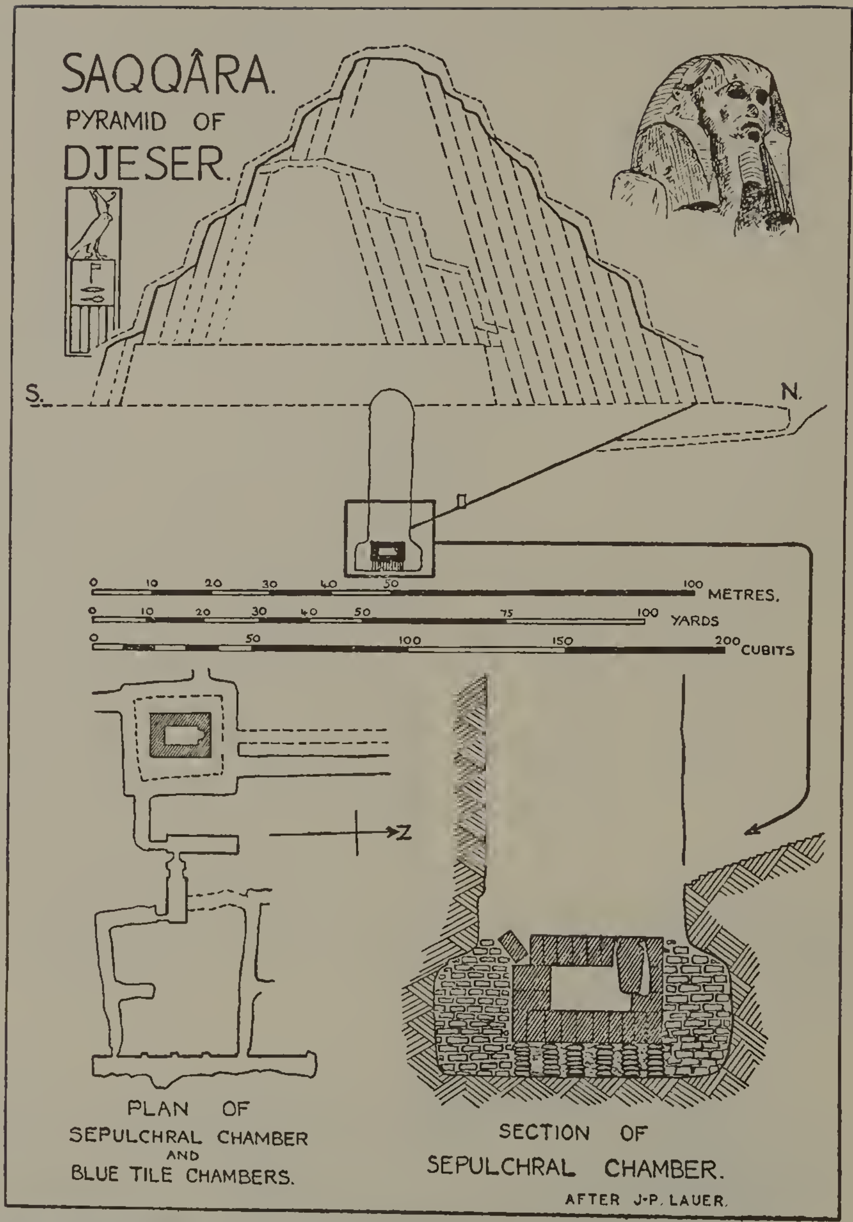
Remains of "Old Sarum," an ancient British stepped pyramid.

The original building of the stepped pyramid was a mastaba 63 meters square built of coarse rubble cased with fine white limestone, above a square pit.

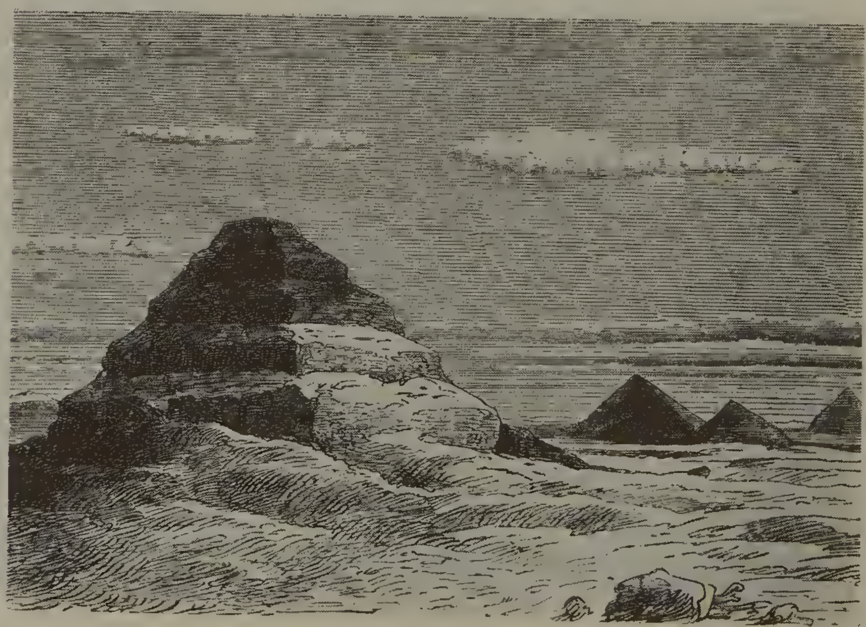
The original entrance was through a hole in the roof directly into a 28-meter shaft lined with granite. The mastaba was subsequently heightened into a stepped pyramid by the superimposition of three more terraces. Extended eastward (ostensibly to include graves for Zoser's family!), the structure was then a rectangle 120 meters by 108. Two more stories were added, so that it became a six-step pyramid, cased with fine limestone, at a slope angle of 72° 30′. A second entrance was placed in the north face leading down a rock-cut flight of steps to a more restricted "sepulchral chamber."

The building was attributed to King Zoser (of the Third Dynasty) on the basis of his cartouche on some stones and is believed to have been erected by his fabulous architect Imhotep.

In 1929 Frith found a bas-relief in the pyramid depicting Zoser, and in the 1950s Prof. Lauer found a mummified foot which he believes to have been Zoser's.



Stepped pyramid of Saqqara, believed to be the oldest Egyptian pyramid.



The pyramid of Medûm, on a square base of 144 meters, rises 92 meters high, and is so situated that it is a landmark for miles in all directions.

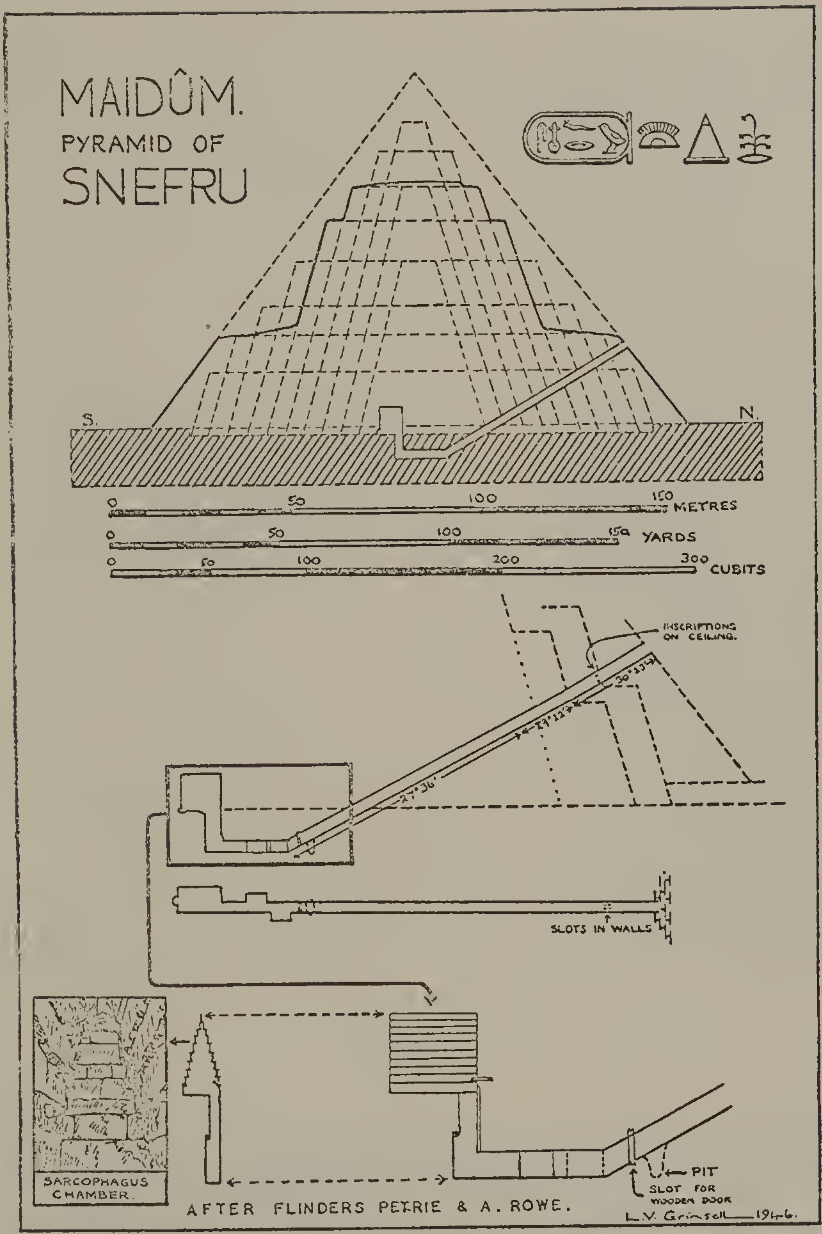
Most of the outside limestone casing, which sloped at 51° 52′, has been removed, showing that the pyramid was built in several stages from an original mastaba about 20 meters long, with slopes of 75°.

The pyramid grew in seven steps by means of a series of accretion walls, each of which was cased in fine white limestone; eventually the spaces between the steps were filled in, and the entire pyramid cased with white limestone, most of which was removed at an early date (possibly during the reign of Rameses II) though portions remain. Three accretion faces are presently visible.

The base is still covered with sand and debris.

An entrance on the north side, 30 meters aboveground, leads down a ramp 57 meters long, sloping at 27° 30′, to two antechambers and a vertical shaft in the center of the building. The shaft rises to the "sarcophagus chamber," which has a fine corbeled roof of limestone built in seven steps.

In 1891 Petrie found fragments of a wooden coffin believed to have belonged to Sneferu; so the pyramid has been attributed to Cheops' father.

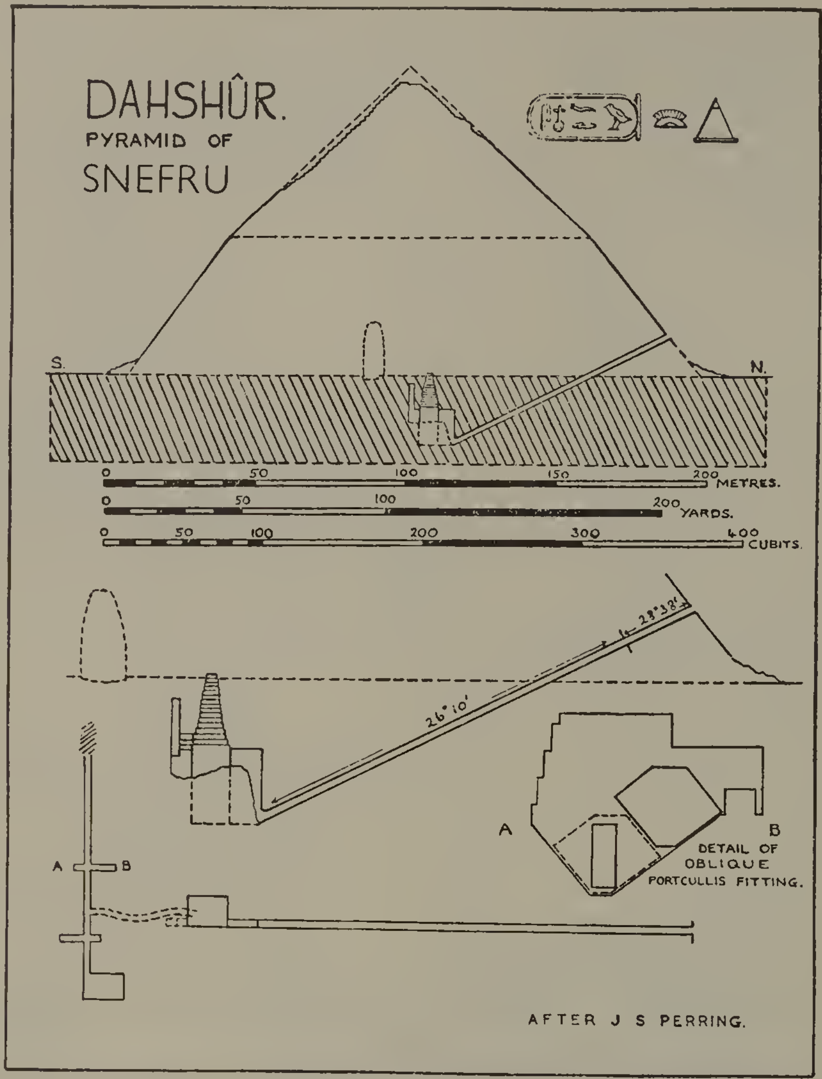


Sneferu's blunted or rhomboidal pyramid at Dashur is 190 meters square at the base and 100 meters high. The lower portion slopes 54° 41′, the upper portion 43°. The casing is of fine white limestone; the body is believed to be of coarser limestone.

There are two entrances, one on the north and one on the west side, leading to two main chambers.

The northern entrance is 11 meters aboveground in the center of the lower face and leads down a ramp inclined at 28° 38′ for the first 13 meters, then at 26° 10′ for the remaining 65 meters. A short horizontal passage 12 meters high leads to a fine chamber whose roof is corbeled on all four sides.

The western entrance, which is 29 meters above the base, leads to a ramp descending at 26° 36′ for 68 meters to a horizontal passage with two portcullis slabs and a chamber with a roughly corbeled roof.

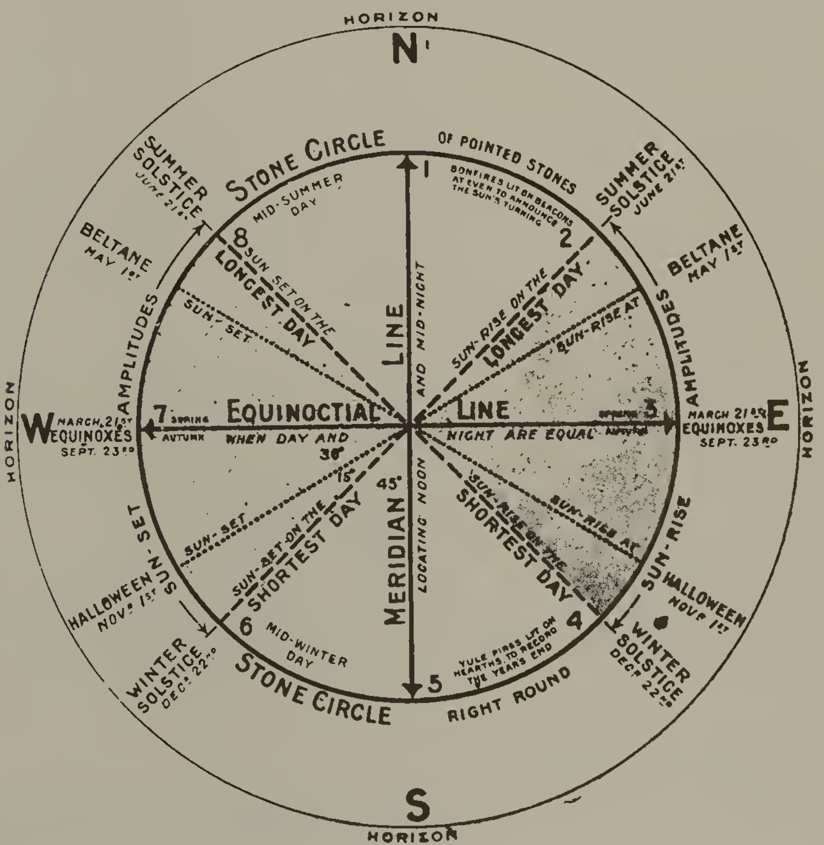


observation chamber with a corbeled roof with a small opening just at ground level, presumably for sighting a star directly overhead at the zenith, or for lowering a plumb line to coincide with a line sighted down the sloping passage. The similarity to the structure at Maes-Howe is indeed amazing. Yet Maes-Howe has also been considered as nothing but a burial chamber. A recent writer on Maes-Howe discarded the theory that the mound might have had astronomical significance, saying that the belief is accepted by no "serious students of archeology."

Scientists of other disciplines are in disagreement, and have produced interesting data on the orientation and purpose of megalithic monuments.

In his *Megalithic Sites in Britain,* published in 1967, Professor Alexander Thom, who for many years held the chair of Engineering Science at Oxford, shows how the stone and wood henges of Britain of the second millennium B.C. were aligned on certain stars, were planned on the basis of a geometry which anticipated Pythagoras, and were uniformly built on a unit of measure which he calls a megalithic yard of 2.72 feet or .829 meter.

According to Thom, megalithic sites in Britain served the purpose of calendars and clocks. During the long winter nights the only indicators of time were the stars. By observing the rising and setting of stars of the first magnitude, or their



Cotsworth's explanation of Druidical circles such as Stonehenge.

transit over the meridian, it was possible to tell the hour of night.

Thom says that in Britain between 2000 and 1600 B.C. there were about ten or twelve stars of the first magnitude whose rising and setting could be clearly observed. Thom also found a great number of stones set to indicate the point of rising and setting of first magnitude stars, and many slabs and alignments which accurately marked the meridian.

For such pointers to be accurate the observer also had to know the date. This was obtained from the sun calendar arrangement of the stones.

As for the accuracy of the alignments, Thom says the ancient engineers managed to raise perhaps ten thousand megaliths from one end of Britain to the other, and set them with an accuracy of 0.1. When they wanted to, says Thom, they could measure with an accuracy of 1 in 500.

R. J. C. Atkinson, professor of archeology at University College, Cardiff, an authority on Stonehenge, and a severe critic in this field, concludes from Thom's data that a high degree of competence in empirical astronomy existed in Britain 4000 years ago.

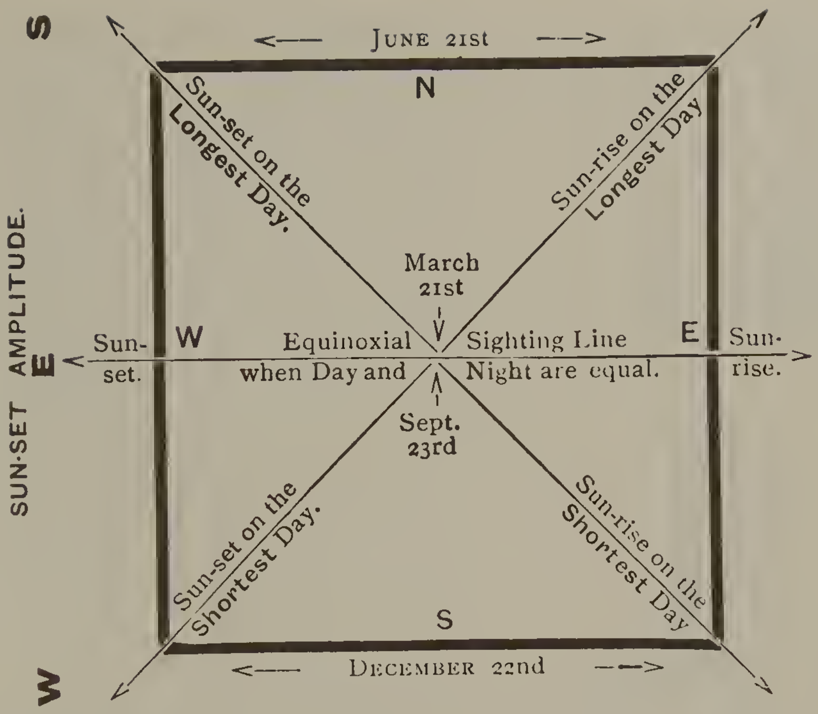
This supports the data of the contemporary Greek astronomer C. S. Chassapis, whose analysis of the Orphic Hymns indicates that the Greeks of the second millennium B.C., also had an advanced knowledge of astronomy.* These ancient Greeks, says Chassapis, knew that the seasons were caused by the earth's rotation around the sun along the ecliptic, and had determined the torrid, temperate and frigid zones. They had established the equinoxes and solstices, and knew that the apparent daily rotation of the stars in the heavens was due to the earth's rotation on its axis, which formed a northern pole in the sky. This knowledge, says Chassapis, was taught by the Orphics to the initiate who distinguished between the "fiery" stars and the seven planets which they called by today's names. The second millennium Greeks used a calendar of twelve conjuctive months from full moon to full moon, and accepted the presence of mountains on the moon. They believed that all phenomena were governed by a universal law, and conceived that space was filled with ether.

Lyle B. Borst, professor of astronomy and physics at New York State University in Buffalo, in an article in *Science* (November, 1969), notes that more than forty churches, mosques and temples have now been identified from Norway

* *Greek Astronomy in the Second Millennium B.C. according to the Orphic Hymns*. Athens, 1967.

Many churches in Europe continued to build with their towers oriented to the cardinal points, or to mark the solstices and equinoxes. Others were oriented to the sunrise of the saint for whom they were named.

St. Peter's Basilica in Rome is oriented due east so that at the vernal equinox the great doors can be thrown open at sunrise and the sun-rays passing through the nave will illuminate the high altar.



to Egypt, all laid out in megalithic yards of .829 to .840 meter.*

Professor Borst, who went to England to make a model of Stonehenge to demonstrate to his students how astronomy was practiced before there were telescopes, suggests that the axes of many early Christian churches in Britain are laid out on top of megalithic foundations originally determined by an alignment with stars; he suggests that Canterbury Cathedral was aligned with the equinoctial rising of Betelguese about 2300 B.C.

Borst also shows that the geometric plans of the megalithic monuments were obtained by means of 3–4–5 triangles and other right-angled triangles laid along the axis of stellar observations.

Alfred Watkins, in his *The Old Straight Track,* published in 1920, pointed out that many churches in England were situated on sight lines between beacon points and that ancient man was inclined to travel in a straight line from beacon to beacon. The churches served as relay points.

Watkins suggested that where topographical features were lacking, observation towers were built, and such geodetic points, initially guarded by the surveyor priesthood, remained hallowed spots even after the reason for them had been forgotten. Later arrivals built churches on these spots, as is indicated by Bede who reports that Pope Greg-

* If .840 meter is taken as a megalithic yard, there are exactly 275 such yards in a 231 meter base of the Great Pyramid of Cheops, 220 in the apothem and 175 in the height.

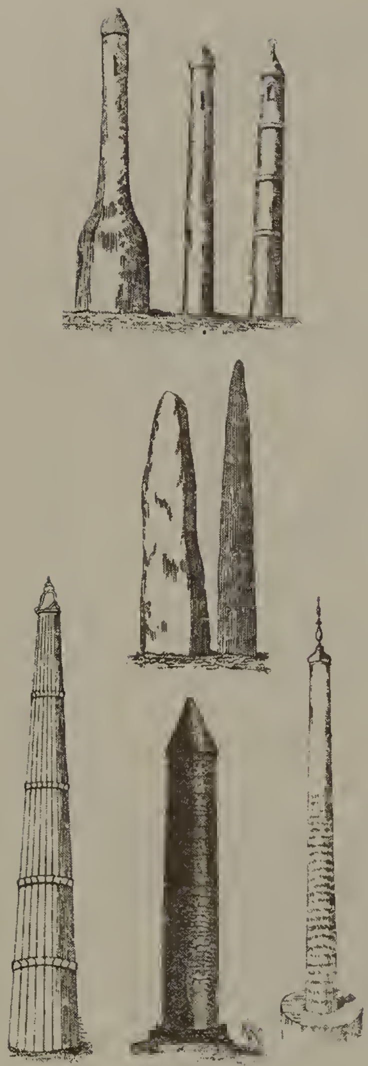
ory I explicitly ordered Bishop Miletus to build churches on pagan shrines.

In the Middle Ages in Ireland, Catholic monks still used tall conical towers with carefully oriented openings at the top to observe the skies and record the passage of the days, months and years by shadows on the walls and floors.

These "Round Towers," as they were called, were fitted for Polaris observations at the north window, for transit observations at the south window, and for noting the moment of the rising and setting of heavenly bodies at the east and west windows. H. G. Wood in his *Ideal Metrology* says that by threads drawn across the openings, like the spider lines in a telescope, the exact position of a star could be noted. The walls being two or three feet thick, the solar shadows of the jamb and lintel cast upon the floor within would show the hour of day and the time of the year. Every month could have its transit floor-mark.

Similar structures have been found in France. In a booklet oddly entitled *Falicon,* privately printed in 1970, the author Maurice Guignaud, a French artist and ceramist, describes a small pyramid in the south of France built in the thirteenth century by Knights Templar on their return from the Middle East.

Guignaud observed that at solar noon of the autumn equinox of September 21, 1969 (which in that region occurs at 12:53 P.M.) the pyramid projected no shadow on the ground around it. Guignaud also noted that a raised area in the doorway caused the sun to cast a shadow that precisely split the end of the entranceway.



Examples of Irish and other round towers.

There are remains of some 120 observation towers in Ireland, twenty of them still in good condition, ranging in height from 60 to 132 feet. The tower at Killcullen is the highest.

Built near churches between the eighth and thirteenth centuries, the towers have door and window jambs that are narrow like the doors of ancient Egyptian temples, which served to measure the shadow of the sun in its daily and seasonal movements.

At the equinox Guignaud measured the shadow of a meter stick held vertical at noon and found it to be exactly one meter long, whereas on June 21 it cast a shadow of .80 meter and on December 22 a shadow of 2.52 meters.

Guignaud found that this exotic truncated pyramid, which is known by the weird name of *Ratapignata* or "The Bat," was also built directly over two subterranean pits, one almost above the other, and that carved signs on its walls indicated it had been used for astronomical and astrological observation.

According to Cotsworth, the value of ancient astronomical observatories cannot be overestimated. The importance of establishing the exact length of the year so as to know when to plant and when to harvest crops could mean the difference between famine and plenty.

Far from being Professor Barnard's "stupendous monument of folly," the colossal effort employed by the ancients in building the Great Pyramid (or the million-ton mounds of the Britons) would have had a vital effect on the citizenry, redounding to the benefit not only of the builders, but of countless generations to come.

Cotsworth took several more photographs at the Great Pyramid to illustrate his thesis, but most of these were stolen from his carriage and irretrievably lost. This particular photograph, taken in 1900 by a third party, shows Cotsworth seated on a camel with the Sphinx and the Great Pyramid as a background. The white-whiskered Arab at the extreme right is none other than the indefatigable Ali Gabri, now over seventy, who added Cotsworth to the list of Great Pyramid explorers he guided round Giza since the time of Caviglia and Howard-Vyse in the 1830s.

Archeologists give varying opinions as to the age of the Sphinx. Petrie considered it possibly prehistoric. Budge refutes its being prehistoric. Most Egyptologists assign it to Kephren's reign in the Fourth Dynasty.

The Sphinx faces due east, which indicated to Cotsworth that it was used as a sighting device by priests who could stand on the flat platform of its rump and sight the rising sun in a direct line to the horizon marked by the point of the asp on the crown on the Sphinx. Cotsworth also found a series of ancient lines fanning out from the neck of the Sphinx which could have served to indicate the point of sunrise at different dates from solstice to equinox.

It has repeatedly taken several hundred men several years to clear the sand from its base and reveal a six-tiered obelisk against its chest (now missing), which Cotsworth believes was used for sighting the midday sun. Each time the base was cleared, windstorms filled it again with sand, indicating that when the Sphinx was originally built the Sahara was almost certainly not a desert.

Lancelot Hogben in *Science for the Citizen* says that "the continuity of careful observations which preceded, and the precision involved in settling the exact length of the year, entitle this achievement to be regarded as one of the half-dozen great cultural feats in the history of mankind."

With the present availability of cheap watches, radio signals and published almanacs, one is likely to underestimate the value to ancient people of a reliable system for telling the day, the season, the year, and, most important in Egypt, where the entire system of agriculture depended on the swamping of the arable land, the forthcoming flooding of the Nile.

For three-quarters of the year the Egyptian peasants would leave their protected villages on the hillsides and move into the flatland with their families, livestock and most of their belongings, to plow, seed and harvest the fields.

When the time came to move their families and belongings back to the hills, they required at least a fortnight's warning lest they linger too long and be cut off and drowned by the yearly rising of the waters.

According to Cotsworth, all efforts at tracing the number of days in the year by purely seasonal signs would have given imperfect and variable results.

In the early dynasties the flooding of the Nile was said to have been heralded by the annual heliacal rising of Sirius, known to us as the Dog Star. Once a year, with the first glimmer of dawn, Sirius, a bright star of the first magnitude, would appear in the eastern sky and dominate the heavens till its sparkle was eclipsed by the splendor of the risen sun. This stunning phenomenon was taken by the Egyptians as a sign that the Nile would be flooding in about twenty days.

But the flooding of the Nile is governed not by the stars but by the sun melting the snows and the rain falling in the Ethiopian highland sources of the Blue Nile. To have continued to date the flooding by the rising of Sirius would have gradually brought the phenomenon out of phase.

O. Muck, in his *Cheops and the Great Pyramid,* postulates that as a result of a series of disastrous inundations during the reign of Cheops, the Egyptians were obliged to change from a stellar calendar of 365.2563 days to a solar calendar of 365.2422 days, and that the historic Cheops introduced a new calendar by which an extra day was added every four years of 1460 days to account for the differing fraction.*

* According to Muck the new calendar was designed for Cheops not by an Egyptian but by a light-skinned European who brought to Egypt an older, more accurate calendar such as that of Dardanie. Muck says there is archeological evidence that Cheops married a light-eyed, white-skinned European with reddish-blond hair who bore him a blond, blue-eyed daughter whom Cheops gave in marriage to a European known as Didoufri who reformed the calendar and redesigned his pyramid. Other Egyptologists suggest that Cheops' wife, who is represented as a blonde in the Giza tomb of her daughter Meresank III, may be merely wearing a wig. Such divergencies give a slight idea of the general lack of concurrence among historians of Egypt. But there is no doubt that the Egyptians developed two basic calendars, a civil calendar of 365 days, and a sothic calendar one-quarter day longer. The extra quarter day caused the sothic New Year to fall back one full day every four years so that each and every day of the civil calendar coincided with the New Year over a period of 365×4, or 1460 years, until the New Year once more fell on its original July 19. Hence was generated what was known as the sothic cycle of 1460 years.

The double dating of sothic and civil years appears in many Egyptian documents, so that it has been possible to reconstruct the years in which the sothic new year coincided with the original new year and establish that sothic cycles began in A.D. 140, 1320 B.C., 2780 B.C., and 4240 B.C.

Muck and others believe the foundation of the sothic calendar occurred in the 2780 cycle, but Schwaller de Lubicz is convinced from his study of ancient texts and hieroglyphs that the year was 4240. He says that tradition always placed the heliacal rising of Sirius in the constellation of the Lion, and that this was so from 4240 on. The main objection to such an early date is the conviction of Egyptologists that the ancient Egyptians were not yet equipped for such careful astronomical observation.

That the Egyptians handled astronomical cycles of even greater duration is indicated by inscriptions recently found by Soviet archeologists in newly opened graves during the period of their work on the Aswan Dam. Here the cycles appear to cover periods of 35,525 years, which would be the equivalent of 25 cycles of 1461 years. The apparent discrepancy of one year in this recording of cycles is due to the sothic cycle of 1460 years being the equivalent of a civil cycle of 1461 years. According to Muck there were three main cycles: one of $365 \times 4 = 1460$; another of $1460 \times 25 = 36{,}500$; and a third of $36{,}500 \times 5 = 182{,}500$ years.

Dürer's woodcut of the zodiac. In the course of a year the earth makes a 360° circle round the sun. Seen from the earth, the sun appears to move through a circular belt of constellations. These are the stars of the zodiac. For convenience, the zodiac is divided into twelve constellations, so that every month at sunrise a new one appears to the earth viewer in the eastern sky; and every year the sequence is repeated, with a slight precession owing to the earth's wobble on its axis.

Schwaller de Lubicz in his *Le Temple de l'Homme* maintains the pharaonic Egyptians adopted neither the sidereal nor the solar tropical year, but a Sothic year based on the cycle of the fixed star Sirius, which is exactly 365.25 days. According to this archeologist and philosopher, who spent twelve years at Luxor measuring and studying its temples, tombs and hieroglyphs, the mere fact that the Egyptians were able to note that Sirius is the *only* fixed star with an unvaried cycle of 365.25 days denotes an extremely long period of previous careful observation.

From the texts it is clear, says Schwaller de Lubicz, that long after the heliacal rising of Sirius was no longer a visible phenomenon, it continued to be accurately computed by the priests of Heliopolis, who then broadcast their observations to the other temples of Egypt, there being a difference of as much as 4 days between the heliacal rising as noted at Thebes and at Memphis.

Muck suggests that to dramatize the importance of the 1460 cycle the figure was built into the pavement around the Pyramid of Cheops in such a way that a cortege of priests dressed in white could liturgically march round the pyramid rythmically counting out 1460 paces—which were subdivided into 25 inches, and again subdivided by 5.

By coincidence, Muck's pace of 25 inches is the same length as Newton's and Piazzi Smyth's sacred cubit, one hundred of which form the side of an English acre.

One incontestable deduction was drawn by Schwaller de Lubicz from the existence of the sothic calendar and the shifting of the annual festivals of the civil calendar: the ancient Egyptians must have been cognizant of and able to measure the phenomenon known as the precession of the equinoxes.

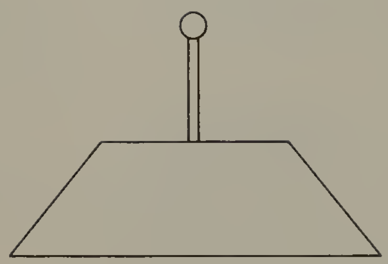
To obtain a simple picture of the precession, an earth observer in the northern hemisphere should be looking due east just before sunrise at the spring equinox. As the dawn tints the sky the observer will see a constellation on the eastern horizon: nowadays it is Pisces. In 2000 B.C. it was Aries. In 4000 B.C. it was Taurus. In A.D. 2300 it will be Aquarius.

The entire circle of the zodiac appears to be slipping back in relation to the sunrise at the equinox, at the slow rate of about 1 degree in 72 years; 30°, or one constellation, in 2160 years; and 360° in 25,920 years.

This *pre*cession of the equinox is said to have been discovered by Hipparchus in the second century. But a number of ancient representations of the zodiac bear the note: "The Bull marks the beginning of spring." This has been interpreted to indicate that astronomical observations of the constellations at the equinox were being made at least as early as 4000 B.C.

The phenomenon of the precession was not explained till Newton postulated that the earth's tilted axis was wobbling as it spun, causing the celestial pole of the earth's axis to draw a slow circle in the heavens around the fixed pole of the solar system, the pole of the ecliptic. To an observer on earth watching the sunrise at the equinox, this slow circling has the effect of making the equinoxes occur about 20 minutes earlier each year in relation to the zodiacal constellations then visible in the sky.

To have figured out the slow rate of the precession of the equinoxes, the ancient Egyptians must have had an appropriate system and equipment. According to Cotsworth, to devise an accurate *star* calendar to record the apparent movement of the stars around the heavens, someone first had to devise a structure that would provide a perfectly oriented meridian for the observation of stars in relation to a fixed point on earth.



According to Muck, to have an accurate *sun* calendar, with which to establish the solstices and equinoxes, someone would have had to build an enormously high obelisk.

Sir Gaston Maspero, director of the Department of Antiquities of the Cairo Museum, found a curious hieroglyph in inscriptions around Saqqara for which he could find no explanation: an obelisk atop a truncated pyramid, with a solar disk balanced on top of it. For Cotsworth he kindly made a drawing of it.

To Cotsworth the similarity of Maes-Howe, the Silbury Hill Maypoles and the obelisks atop a mastaba or unfinished pyramid was inescapable. Only, how did this fit with the Pyramid of Cheops?

XII. ASTRONOMICAL OBSERVATORY

Richard Anthony Proctor.

That the Great Pyramid had originally been designed as an astronomical observatory and that it had contained reproductions of the celestial spheres was repeatedly reported by Arab historians; yet none could put forward a sensible solution as to how its steep polished sides could be climbed as an observatory, or its interior passages employed for observations; that is, until the appearance of a book shortly before the turn of the century by the British astronomer Richard A. Proctor, called *The Great Pyramid, Observatory, Tomb, and Temple.* Proctor found a reference in the works of the Roman neo-Platonic philosopher Proclus to the effect that the Pyramid had been used as an observatory *before* its completion. Analyzing the report, which appears in Proclus's commentary on Plato's *Timeaus,* Proctor theorized that the Pyramid might have made an excellent observatory at the time it had reached the summit of the Grand Gallery, which would have given onto a large square platform where the priests could observe and record the movements of the heavenly bodies.

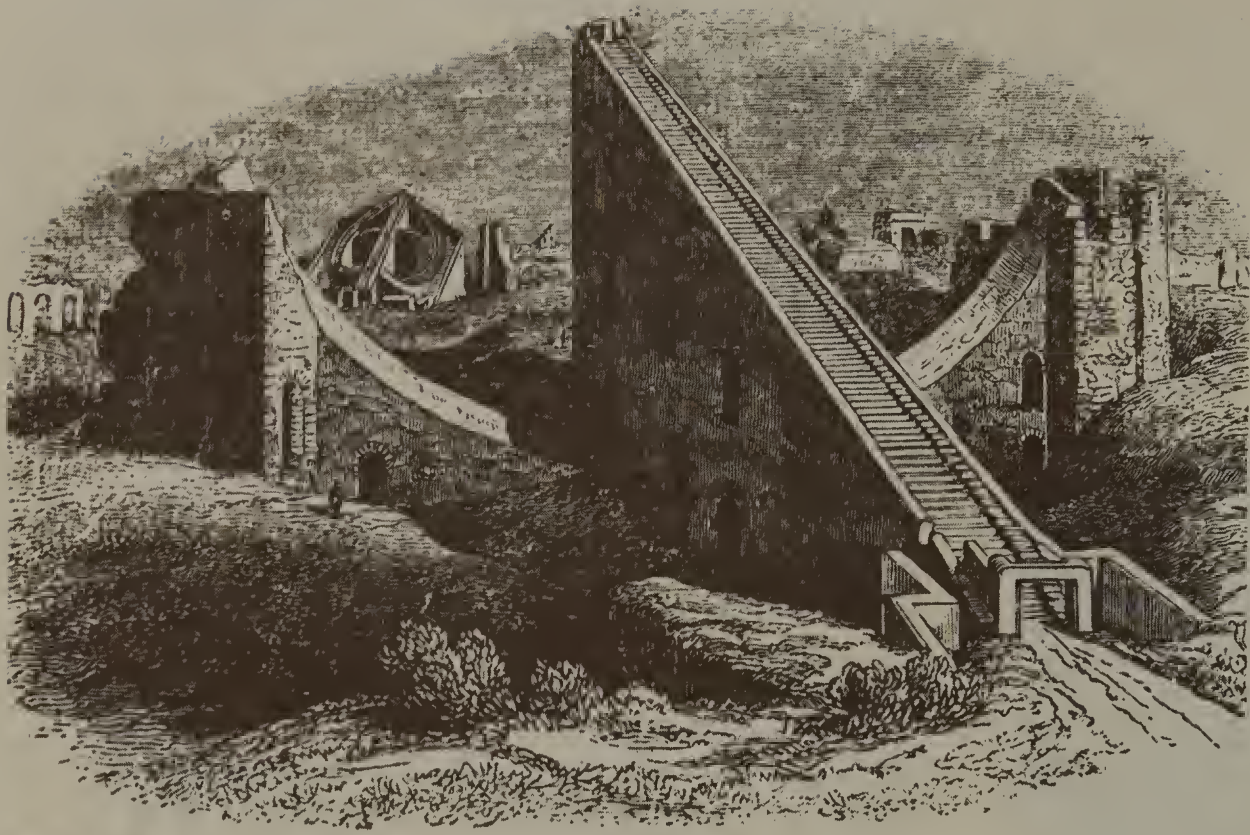
Proctor's theory was so shockingly simple that it was quickly ignored by academic Egyptologists, who were as skeptical of its astronomical value as they were of the value of Stonehenge or the other megalithic observatories scattered about Europe.

In order to create a firm body of astronomical data, the ancients needed a true meridian on the solid earth from which to extrapolate a meridian across the heavenly vault, so as to detect the precise moment when stars, sun, planets and moon transited this meridian in their apparent rotation through the heavens.

In Proctor's analysis the builders of the Great Pyramid had accomplished such a feat by building what he, as a modern astronomer, considered the only sensible instrument short of a great modern telescope.

On the Giza plateau, in the heart of the Great Pyramid, they first built a huge graduated slot, perfectly aligned on the meridian. Through this slot they could observe the apparent movement of the panoply of stars, accurately noting their several transits.

Proctor describes in detail how the ancient architects would have gone about building such an observatory. To



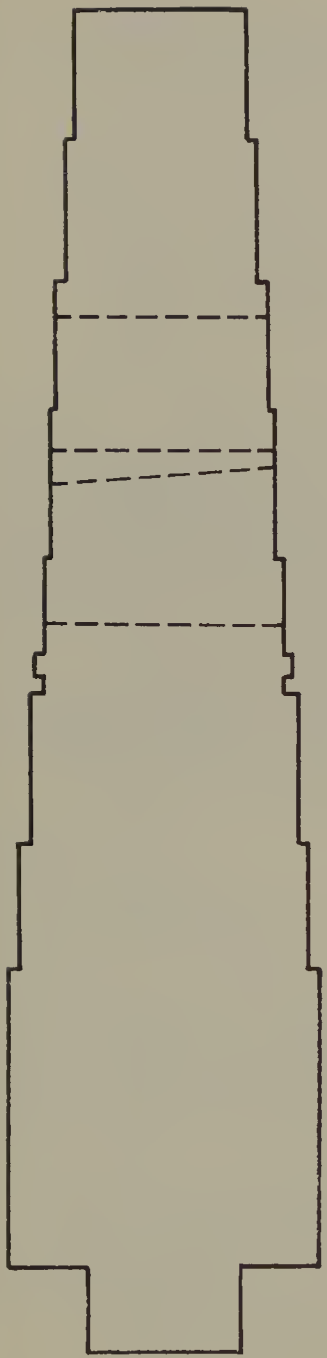
Indian astronomical observatory erected at Delhi by the Maharajah of Jaipur consists of a 56-foot triangular structure which casts a shadow onto an arc of masonry calibrated in hours, minutes and seconds (top).

Another Indian observatory at Benares, known as Yantra, provided fixed angles to check the position of the stars.

obtain a true north-south line for their terrestrial meridian, they would have observed across the tops of a couple of upright pillars whatever star was closest to the celestial north pole (the point around which the stars appear to wheel in their daily motion), then found the star's culmination, or the top and bottom of its circular path. A line through these two points, which could be measured with an ordinary plumb line, would be true north; and any such northern star would do, as all move in a small circle round the celestial pole.

Following the suggestion of Sir John Herschel, Proctor concluded that it might have been alpha Draconis, which was 3° 43′ from the pole in 2160 B.C. and again in 3440 B.C. The French astronomer A. Poge suggests that the ancients could have used Xi Mizar of the Great Bear any time before 1500; but alpha Draconis fits the rest of Proctor's theory quite adroitly.

The question of the method of orienting the pyramids has been the object of a detailed study by the Egyptologist Zbynek Zaba in a recent monograph for the Czechoslovakian Academy of Sciences entitled *L'orientation astronomique dans l'ancienne Egypte et la précision de l'axe du monde.* Far from considering the pyramids monuments to the



Meridian slot for observing the transit of the stars.

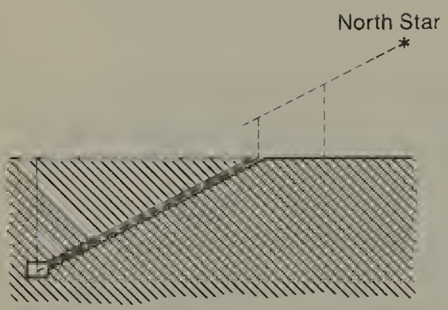
The stars appear to be carried around the pole of the heavens as if they were fixed points in the interior of a hollow revolving sphere. It is therefore possible to determine the position of the pole, even though no bright star actually occupies that point. Any bright star close to the pole revolves in a small circle whose center is the pole.

megalomaniac pride of some theocratic despot, Zaba considers them monuments incorporating the culture, science and technology of the times in which they were built.

The documents adduced by Zaba prove beyond question that the initial operation in erecting an important structure in Egypt was the ceremony of the "stretching of the cord," by which, through the observation of the culmination of some circumpolar star, the north-south direction was determined and marked out on the ground.

An inscription, translated by Johannes Dümichen, describes this royal ceremony: "Looking up at the sky at the course of the rising stars, recognizing the *āk* of the Bull's Thigh Constellation (our Great Bear), I establish the corners of the temple. . . ." "Dümichen says the word *āk* represents the star's culmination as it passes the meridian.*

Having transferred a true meridian from the sky to the ground, the ancient architects, says Proctor, could have begun to consolidate this line by digging it into a descending passage through the live rock, using their polar or circumpolar star to guide the tunnel downward at precisely the angle of its rays.



Proctor's design of how the North Star was sighted along the Descending Passage.

Such a cream-white tube, says Proctor, would have given perfect stability to this fundamental directional line, and the longer the passage the truer its orientation.†

For alpha Draconis, at 3° 43′ from the pole, to have shone directly down a passage at the thirtieth parallel, the passage would have had to be inclined at an angle of 26° 17′—just the angle of the Descending Passage beneath the base of the Great Pyramid.

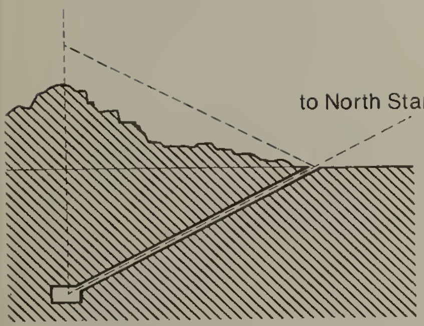
Proctor points out that there would have been no question about the advantage of taking the lower culmination of such a star in preference to its upper one; using the bottom of its circular path as a fixed point would have required far less depth of boring to reach a point directly beneath the center

* The meridian, or great circle through the earth's celestial poles, is the plane in which all the heavenly bodies culminate, or obtain the highest point in their passage midway from the eastern to the western horizon as seen from the earth. Circumpolar stars have a high and a low culminating point on the meridian above and below the celestial pole.

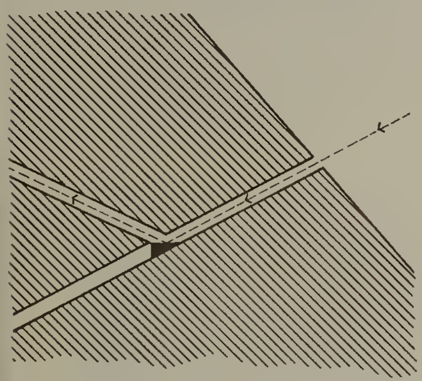
† The advantage of digging such a tunnel is obvious when compared with what would have been needed to achieve the same result aboveground. Someone would have had to hold a plumb line 100 yards high standing at a distance of 200 yards from the observer, who in turn would have had to line up the top of the plumb line with the polar star by night at a slant distance of 260 yards—without benefit of a telescope.

of the proposed building, which was the next object of the operation.

The theory provides an explanation for the quite extraordinary straightness of the walls of the Descending Passage, as measured by Petrie, who was astounded to find a mean variation from a central axis along the entire length of 350 feet of less than 1/4 inch in azimuth—from side to side—and only .1 inch in altitude—up and down. In the part nearest the aperture, which was to be the most important, the exactness is even greater, the mean error amounting to less than 1/50 inch!



How the central point of the Pyramid base could be located by knowing the angle of the Descending Passage.



Reflecting pool at the juncture of the Descending and Ascending Passages.

Once the ancients had measured the length of the Descending Passage and its angle of descent, it would have been simple, by elementary trigonometry, to locate a central spot immediately above the end of the Descending Passage as a center for the proposed pyramid—even if this were on roughly elevated ground.

With a central spot and a true meridian, the architects could set about laying the socket holes for a square base and begin to lay courses on a leveled platform. To obtain true levels, Proctor surmises that the ancient builders used water troughs in conjunction with the light rays from the star.

By continuing the tunneling up through the lower tiers of the growing pyramid, they could maintain a precise orientation for at least the first ten courses, or until the tunnel debouched from the narrowing side of the growing pyramid.

Thereafter their polar star would no longer serve directly, and a new system would be needed to continue the meridian alignment upward in the Pyramid. For this, says Proctor, the builders hit upon the idea of creating an Ascending Passage at precisely the reflecting angle of another 26° 17′. By plugging the Descending Passage and filling it with water, they could reflect the polar star back up an Ascending Passage and continue to keep the passage truly aligned and the building level as it rose another score or more of courses.

For the Descending Passage to have held water, says Proctor, its masonry at the point of juncture would have had to be of hard rock, carefully joined. For no other apparent reason, the stones at this particular point are quite different from the rest of the passage, much harder and smoother and more finely jointed. In fact, the feature escaped observation till 1865.

As Proctor expressed it in his Victorian style: "By using the known properties of liquids combined with the known property of light rays, the ancient builders were able to orient and level a building to a very great height."

But to what purpose? Of a sudden the constricted Ascending Passage changes to an overlapping gallery 28 feet high, in no way essential, or even desirable, to increase or maintain accuracy in orientation for the mounting courses. Yet so extraordinary an architectural design, so carefully executed, must, says Proctor, have served some definite purpose.

Analyzing the problem from the point of view of the astronomer rather than the architect, Proctor came up with an answer. Had an ancient astronomer wished for a large observation slot precisely bisected by a meridian through the north pole, so as to observe the transit of the heavenly bodies, what would he have requested of an architect? A very high slit with vertical walls, says Proctor, preferably narrower at the top, a gallery whose aperture, thanks to the reflected light of the polar star, could be designed so as to be exactly bisected by a true meridian.

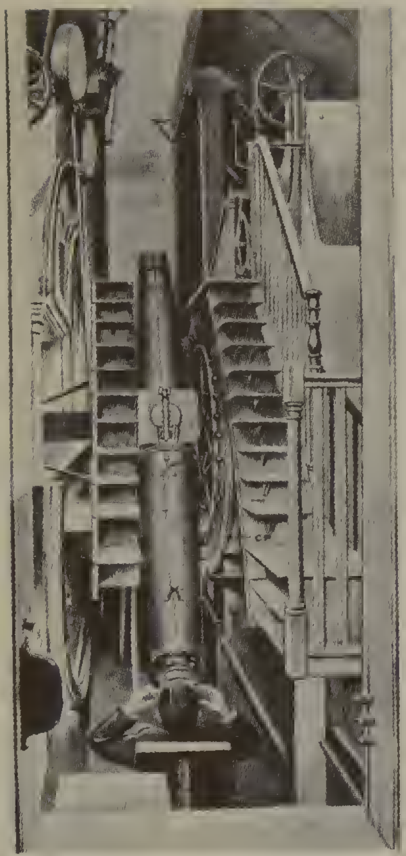
Interior of the Grand Gallery (about one-quarter of its length) showing how it could have been used to observe the stars circling in the southern sky.

Looking up through such a slot, an observer could watch the passage of the entire panoply of the zodiac, easily noting the transit of each star across a perfect meridian—precisely what is done today by the modern astronomer when he sets his transit circle to the vertical meridians. As Proctor points out, such a Grand Gallery might well be described as the *only* very accurate method available for preparing an accurate map of the sky and of the zodiacal cyclorama—before the invention of the telescope in the seventeenth century of our era.

With various observers in the Grand Gallery, placed one above the other on the slanted incline, the southing—or transit across the meridian—of every key star in an arc of about 80° could be observed with remarkable accuracy. As Proctor points out, the most important object of transit observation is to determine the exact moment at which the observed object crosses the meridian. This might have been best accomplished by noting the moment when the star was first seen on the eastern edge of the vertical sky space, and then when it disappeared past the western edge; the instant midway between these two would be the true time of transit.

Proctor surmises that someone in either the Queen's Chamber or on the flat platform of the truncated pyramid above the Grand Gallery could keep time by hourglass or water clock in coordination with the observers in the Gallery, who would signal the beginning or end of transit across the Gallery's field of view.*

* A container with a small hole which drips one drop at regular intervals makes a satisfactory timer. Ancient Chinese astronomers had a system of three such containers in a series to minimize the effect of resistance.



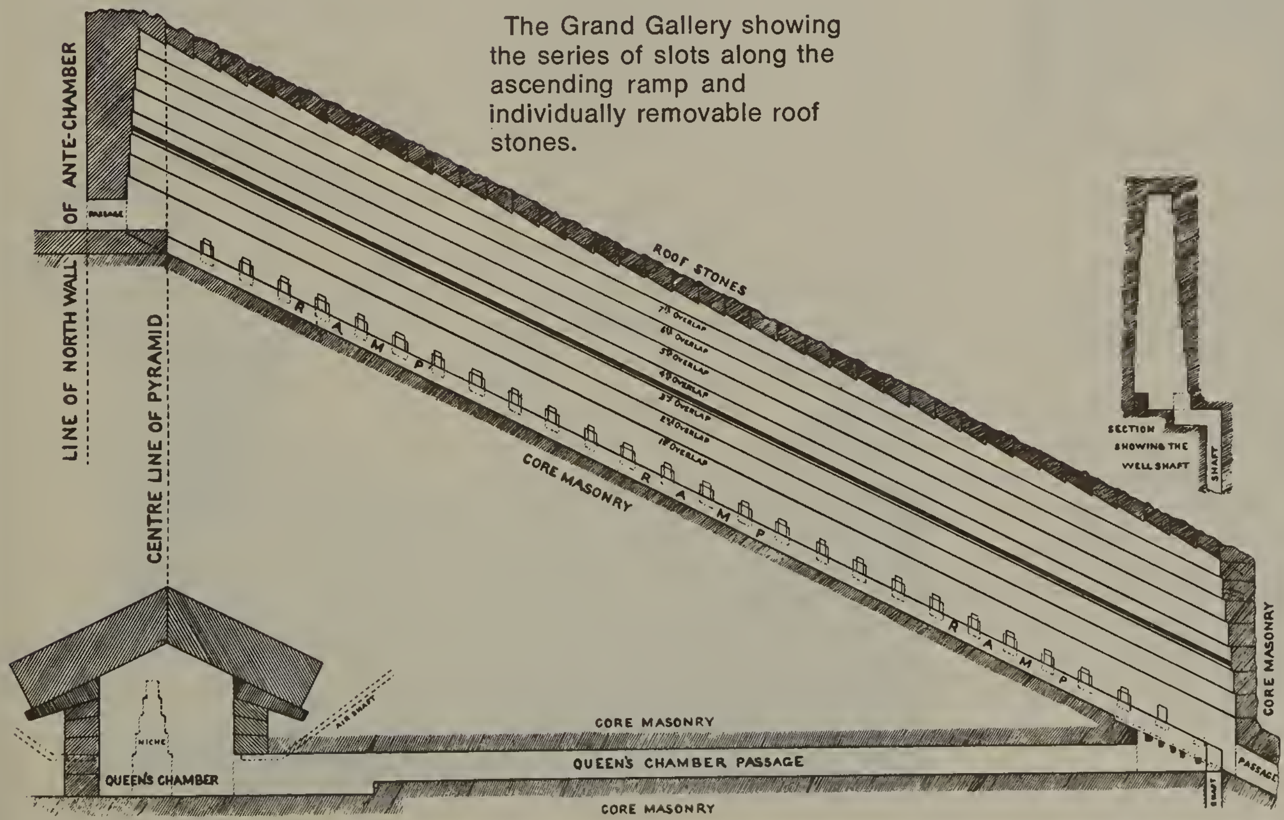
The Transit Circle, Royal Observatory, Greenwich.

By looking down the Descending Passage into a reflecting pool, an ancient astronomer could have noted the exact second of a star's transit, because only at that moment will its rays be reflected. The very same system is used today at the U.S. Naval Observatory in Washington, D.C., where the daily transit of stars is noted to a split second by their reflection in a pool of mercury.

The slope of the Gallery and the corbeling of its walls would also have made it remarkably easy to note the declination of a star—its distance above or below the celestial equator. By combining the observations made by several of what Proctor calls "watchmen of the night," stationed at different levels of the Grand Gallery, a very close approximation of true sidereal time could have been obtained. For such observers to function effectively, cross ramps or reclining benches of some sort would have had to be positioned at different levels of the Gallery.

In support of this theory, there is the series of 27 oblong holes cut vertically along the walls and into the ramps to a depth of 8 or 11 inches. They served to hold some sort of scaffolding across the Gallery. Proctor postulates that there were benches for observers at regular intervals up the Gallery.

The fact that the walls of the Gallery are corbeled like those of the earlier mastabas and of the megalithic observatories, whose top stones could be readily removed, and that each of the roofing stones of the Grand Gallery



The Grand Gallery showing the series of slots along the ascending ramp and individually removable roof stones.

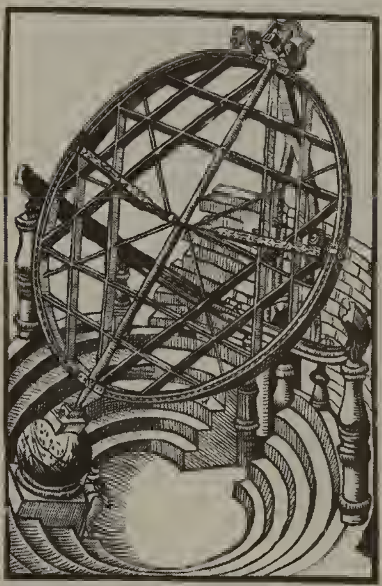
was independently removable (none presses down on its neighbor) may indicate that by the removal of these stones almost as much again of the northern arc of sky could be observed as was visible of the southern sky through the upper end of the Gallery. The movement of particular stars could be pinpointed by the removal of single stones.

Proctor surmises that the method used to determine the declination of a star involved a very practical use of the odd grooves that appear along the walls of the Gallery. At approximately half the height of the Gallery, just above the third overlap on each wall, a narrow groove runs the whole length of the gallery, 6 inches wide and 3/4 inch deep.

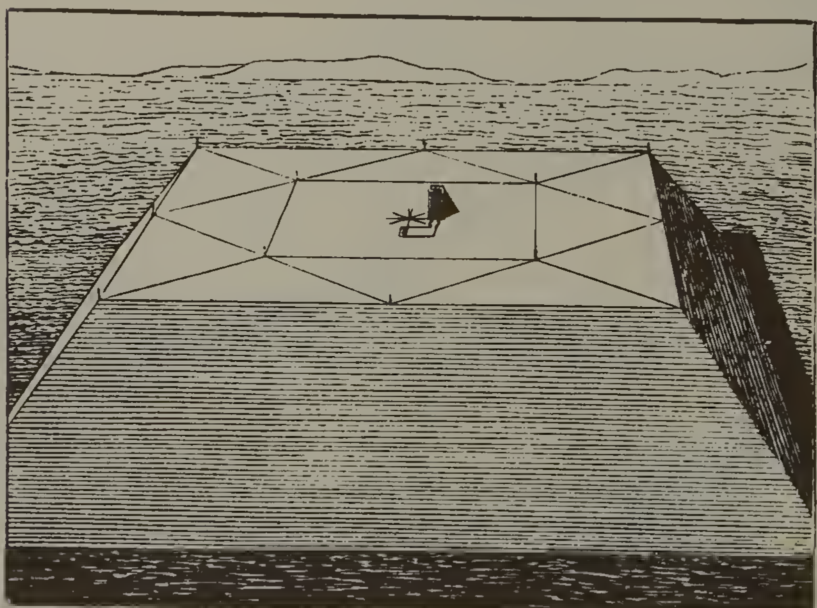
Proctor suggests that horizontal bars carrying vertical rods at suitable distances, perhaps with horizontal lines on them, were held between these grooves, and could be slid to any convenient position. The vertical rods could also have been adjustable.

To locate a star correctly, the transit observers would also have to determine what is called its "right ascension," or distance measured parallel to the equator from a certain assigned starting point on that circle. Knowing the time of transit, it is simple to position the celestial object in its "right ascension."

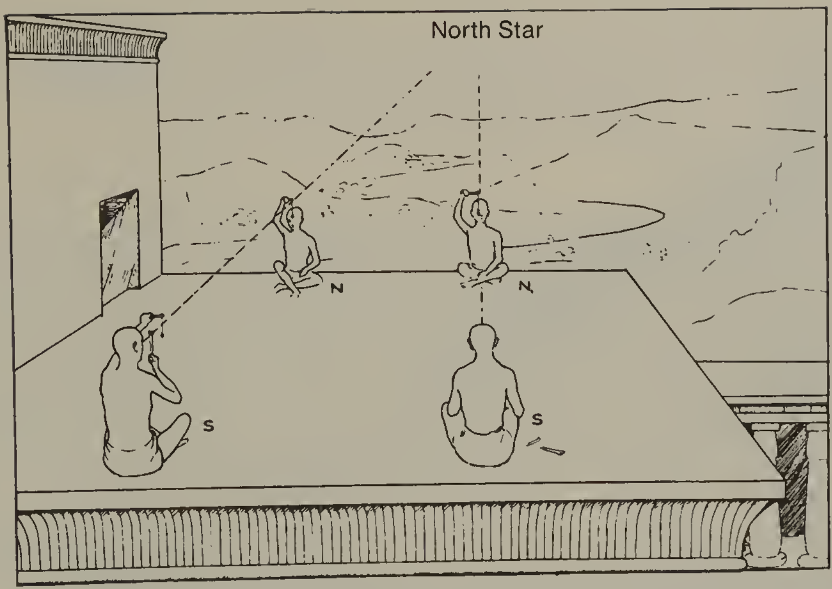
By placing observers not only in the Gallery but outside at the cardinal points of the great truncated pyramid, Proctor says that the entire visible sky could be accurately plotted. The ancient astronomers, says Proctor, would doubtless have made even more observations *off* the meridian, once they had established the meridian observations as their guide marks. They would certainly have made multitudinous observations of the risings and settings of stars at the



Ancient polar astrolabe.



The truncated pyramid, as depicted by Proctor, would have made an observation platform 142 feet high and 175 feet square.
The cardinal points, or compass rose, could have been marked by upright posts on the periphery of the platform. To locate the rising and setting of stars east and west, azimuth observers could occupy the center of the square from which they could command the entire compass.



Ancient method of observing stars with rings and rods.

horizon, and especially their heliacal risings and settings just before dawn and just after sunset.

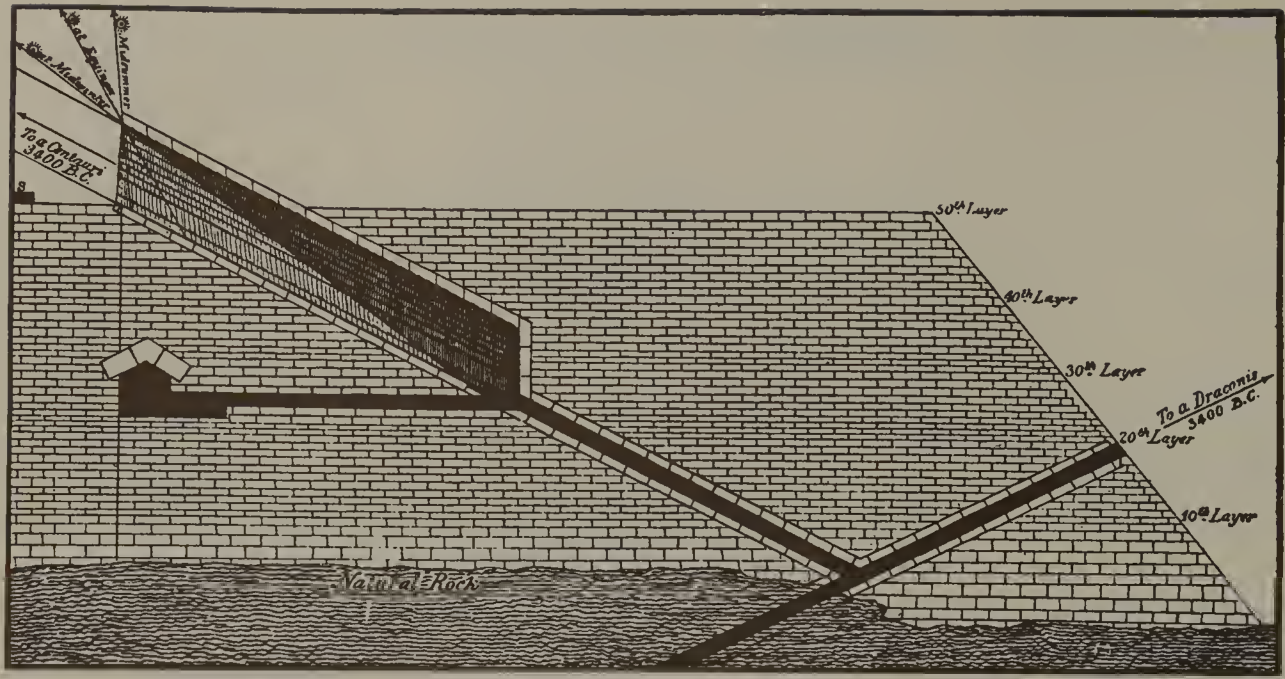
Proctor suggests that there were at least thirteen observers for azimuthal directions around the horizon, whose work could be combined with that of at least seven transit observers at different levels of the Grand Gallery.

The azimuthal observers would be supplied with astrolabes, armillary spheres of reference, direction tubes, or ring-carrying rods. Together with the transit watchers they would be able to make observations which, in Proctor's opinion, would be inferior only to those made in our own time with telescopic adjuncts.

George Sarton, professor of the history of science at Harvard, says the astronomical ability of the early Egyptians "is proved not only by their calendars, tables of star culminations, and tables of star risings, but also by some of their instruments such as ingenious sundials or the combination of a plumb line with a forked rod that enabled them to determine the azimuth of a star."

Proctor adds that for a greater knowledge of the sun's motion, the Grand Gallery slot could have been used to better effect than an obelisk or a sundial by noting the sun's shadow cast by the edges of the upper opening against the walls, sides and floor of the long Gallery. To make observations of the sun more exact, Proctor envisaged the use of screens: by placing an opaque screen at the upper end of the Gallery with a small aperture to receive the sun's light upon a smooth, white surface at right angles to the sun's direction, a much magnified image of the sun would be formed on which any sunspot could hardly have failed to appear. The movement of the spots would have indicated the sun's rotation on its axis.

The moon's monthly path and all its changes could have



Proctor's direction lines show the midday sun at midsummer, midwinter, and the equinoxes as they would strike the Grand Gallery of the Great Pyramid, forming light and shadow marks even more effective than those of obelisks.
He also shows the alignment of alpha Draconis with the Descending Passage, as it was in 3400 B.C. and a line to alpha Centauri, which was then on the meridian, from the Grand Gallery. Proctor believes that through such a sighting tube as the Grand Gallery, alpha Centauri could have been seen transiting in broad daylight.
It is noteworthy that the Grand Gallery debouches at precisely the fiftieth course of masonry, and that at that level the square platform is exactly half the area of the base of the Pyramid.

been dealt with in the same effective way, as indeed the geocentric paths of the planets or their true orbits around the sun: these could have been determined very accurately by combining the use of tubes or ring-carrying rods with the direction lines determined from the Gallery's sides, floor, etc.

Once the diurnal pattern of the stars' apparent rotation past a fixed meridian had become clear to the observers, they could more easily plot the irregular and sometimes apparently retrogressive path of the planets and the moon in relation to the "fixed" stars. The heliocentric pattern of our solar system could well have been extrapolated from a study of the relative motions of these planetary satellites, anticipating Copernicus by several thousand years.

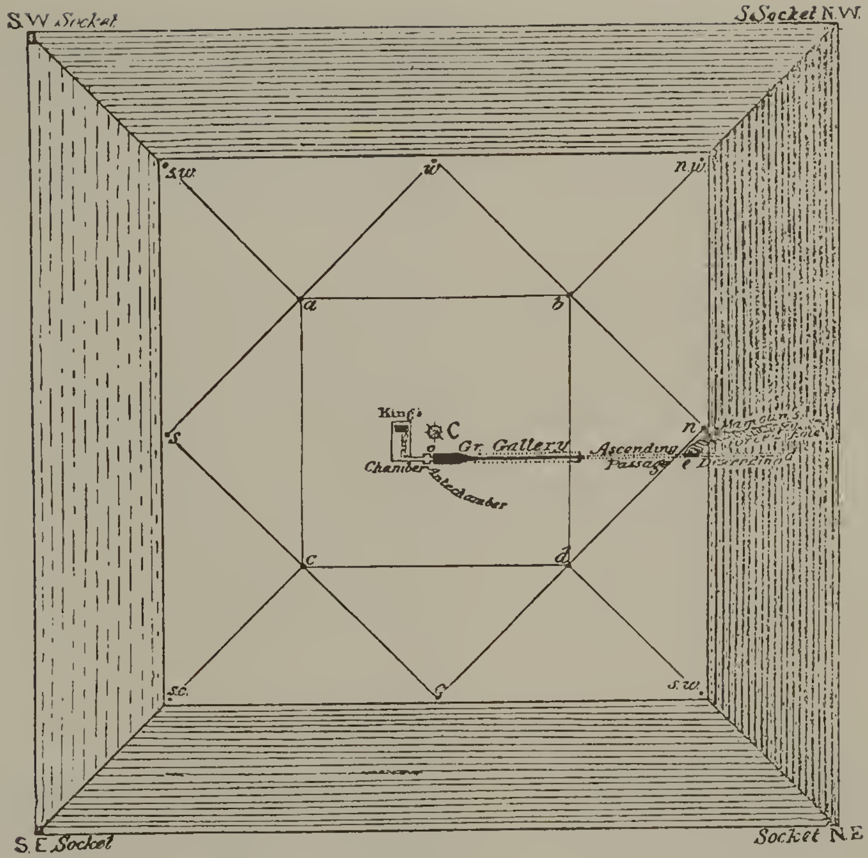
To Proctor, the Great Pyramid thus constructed would have been the greatest observatory and the most perfect till the art of the telescope could reveal a way to more exact observation without the need for such a massive structure.

That the flat top of the truncated pyramid served as the plan for mapping the zodiac is supported by the zodiacal maps of the early astrologers. Even Kepler and Galileo, when making a chart for someone's horoscope, used square charts for their zodiacs, which are the shape of the truncated pyramid.

The French mathematician Funk-Hellet even suggests that the 24 holes in the sides of the Grand Gallery once supported, two by two, movable panels with symbolic figurations of the zodiac.

At the end of a few years' observation it would have been obvious to the ancient astronomers at the moment of the

By placing the gallery slightly to the east of the north-south axis of the Pyramid, the ancient astronomers could make their observations from the center of the truncated square, and a gnomon, or shadow pole, could be raised in dead center. That such a square was the prototype for astrological as well as astronomical computations is strikingly illustrated by the format for horoscopes which persisted into the seventeenth century.



The twelve celestial houses of the zodiac according to astrological authors.

Horoscope prepared by Kepler.

equinox that the whole stellar caravan was returning to its original position just a fraction later—hence each year the equinox itself appeared to move forward. By fine observation of the circumpolar stars, the ancient astronomers could have measured the angle of this precession and deduced its rate to be about 1° in 72 years, making a grand cycle of 25,920 years to cover a full circle of 360°.

Proctor's astronomical analysis of the Grand Gallery was discounted by Egyptologists on the grounds that they had no evidence the ancient Egyptians were capable of making accurate astronomical observations. But in 1934 Proctor received strong support from another professional astronomer, Eugene Michel Antoniadi, who was also an Egyptologist, attached to the Egyptian Observatory of Medûm, in a serious work dealing with the various branches of ancient Egyptian astronomy.* Antoniadi agreed that the Great Pyramid had been used as an observatory before the closing of its inner corridors. He also agreed with Proctor's theory of the alignment and use of the Grand Gallery.

Astronomer E. M. Antoniadi added a refinement to Proctor's theory, showing that the ancients might have used a temporary trestle to help start the alignment of the Descending Passage. However, such a trestle would have had to be 300 feet high and 600 feet long, with a slant height of 780 feet, merely to serve a function that could be better performed by digging the Descending Passage directly. It is more likely the builders avoided the scaffold.

Antoniadi figured that the Grand Gallery would have permitted priests to observe 80° of the sky. He says they should have been able to note the declination of all visible stars from −50° below the celestial equator to +30° above it, and that with the use of clepsydras (water clocks) they should have been able to measure hour angles and deduct the right ascension of stars and planets.

These two data are all that is required for constructing a star map or planisphere. "From a star map," says Lancelot Hogben, "it was a very short step to the recognition that the Earth itself could be divided into similar zones with simple relations to the fixed stars—hence the first world maps with latitude and longitude."

XIII. ASTRONOMICAL TEMPLES OF EGYPT

In his avant-garde book *The Dawn of Astronomy,* written at the turn of the century, Sir Norman Lockyer minutely demonstrated how the Egyptians built and used their temples for astronomical observations from the very remotest antiquity. Lockyer showed how Egyptian solar temples were so arranged that at sunrise or sunset on the longest day of the year, a ray from the sun shot through a skillfully contrived passage into the dark interior of the inner sanctum of the temple. The illumination from the sun was cut off by means of pylon screens so that a concentrated shaft of light cut through the gloom.

Lockyer was the first English astronomer to conclude that Stonehenge had been accurately aligned in about 1680 B.C. to catch the first gleam of the midsummer sun at its solstice, a fact which was recently corroborated on the basis of computerized data by the astronomer Gerald S. Hawkins in *Stonehenge Decoded.*

Both of Lockyer's conclusions were ignored.

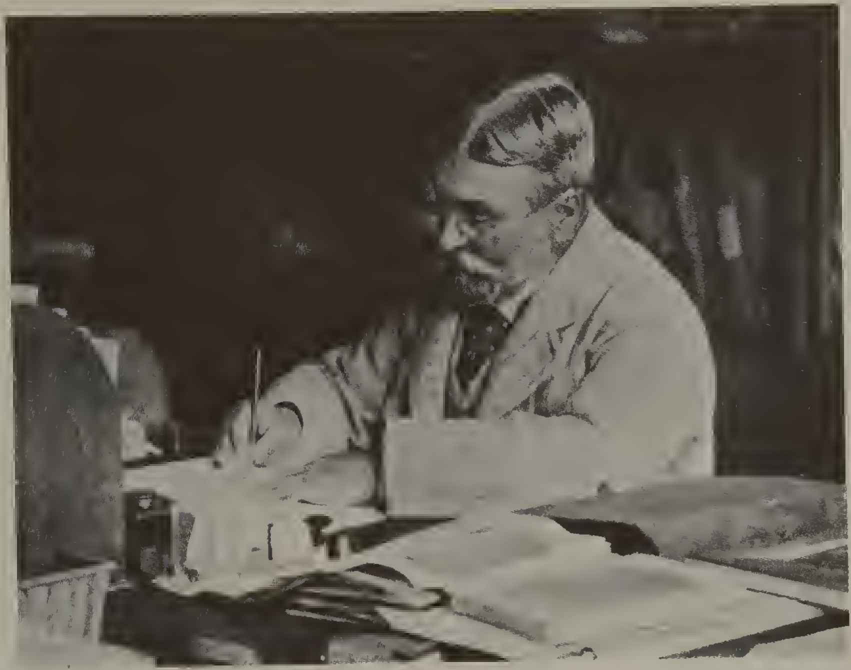
The difference between the megalithic and the Egyptian systems lies in the fact that anyone who can set up a circle of well-placed stones with a sighting avenue can note the farthest points north and south on the horizon where the sun rises at the summer and winter solstices; by taking the halfway mark along the semicircle of stones, the day of the equinox, when the sun is due east at the equator, can be geometrically fixed. To obtain a more precise length of the year—to within a matter of hours and minutes—requires a more sophisticated system.

Lockyer—whom Hawkins describes as "an extraordinary man whose true worth as an astronomer and theorizer concerning the history of astronomy has not yet been adequately appraised"—shows how the esthetically incomparable Egyptian temples scattered along the Nile were astronomical instruments designed like a modern telescope aimed at a specific point on the horizon.

Within the Egyptian temples the light of the sun, or other heavenly body, was funneled between two rows of delicately carved columns which ran through a chain of variously dimensioned halls, like the light of a heavenly body being funneled through the gradually narrowing diaphragms of a telescope.

Temple at Luxor (above) drawn by a member of Napoleon's expedition, showing a row of columns oriented as an astronomical observatory. Temples usually contained a pylon, forecourt, hypostyle hall, and sanctuary.

Astronomical temple at Edfu, later known as Appolonopolis Magna, half buried in the sand as it was found and drawn by Dominique Vivant, one of Napoleon's savants.



Sir Norman Lockyer.

The longer the temple's axis, the longer and narrower the beam, and the greater the accuracy in measuring it. The darker the sanctuary, the more obvious the path of light on the end wall.

The purpose, says Lockyer, was to narrow the beam of light to the point where it could indicate the precise moment of the solstice.

According to Lockyer, a beam of light coming through a narrow passage some 500 yards all the way to a properly oriented sanctuary would remain there no more than a couple of minutes, then pass away. What's more, it would come in a crescendo and go in a diminuendo with an observable peak at the precise solstice.

This would enable the priests to determine the length of the year to within a minute, or four points of decimal—or 365.2422: an otherwise very difficult feat because the sun appears to linger several days around the point of solstice, and its movement of a mere 50″ a day is almost imperceptible without some refined instrumental aid.

Lockyer, who went to Egypt regularly in the summer holidays, found that the sun temple of Amen-Ra at Karnak was built in such a way that at sunset at the summer solstice —the longest day in the year—the sunlight entered the temple and penetrated along the axis to the sanctuary. In Lockyer's words it was "a scientific instrument of very high precision, as by it the length of the year could be determined with the greatest possible accuracy."

Extrapolating backward from the present orientation of the building, and taking into account the small but gradual shift in the tilt of the axis of the earth, Lockyer applied the

(*Overleaf*)
Colonnade to the temple of Amon-Ra at Karnak as it was discovered by members of Napoleon's expedition. Lockyer found that the temple's axis was accurately oriented to the summer solstice and considered it "beyond all question the most majestic ruin in the world."

Reconstruction of the temple of Amon-Ra at Karnak showing how the colonnade was aimed like a telescope toward the sunset of the summer solstice. This romanticized etching was produced by the French savants for the *Description de l'Egypte*.

Chiseled orientation line on subflooring of the temple at Luxor noted by Schwaller de Lubicz. The line was then hidden from view by superimposed finished flooring.

system he had used for Stonehenge and estimated the temple to have been originally laid out about 3700 B.C.

Lockyer found sun temples oriented to catch the sun at the solstice or equinox, and star temples oriented to frame a star rising on the horizon just before sunrise at the solstice or equinox, so as to give warning of the imminent solar event.

Herodotus describes two pillars of gold and green stone in the temple of Tyre which shone at midnight. According to Lockyer, "there can be little doubt that in the darkened sanctuary of an Egyptian temple the light of Alpha Lyrae, one of the brightest stars in the northern heavens, rising in the clear air of Egypt, would be quite strong enough to throw into an apparent glow such highly reflecting surfaces as those to which Herodotus refers."

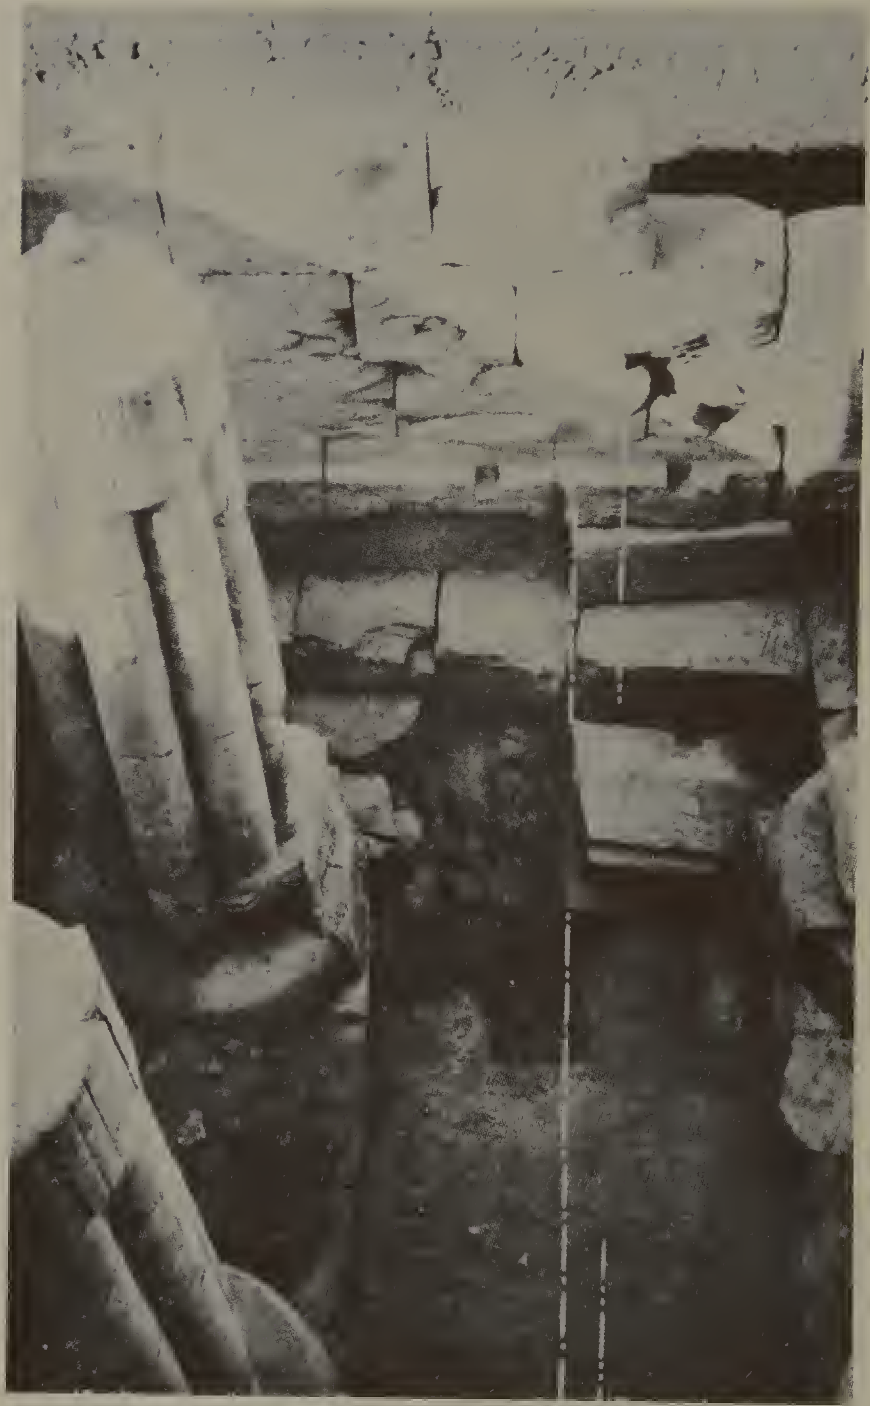
Maspero suggests that the priests were not above "pious frauds" accomplished by means of statues which were animated, spoke, moved and acted. For those not in on the secret, the priests may have achieved quite stunning effects by having a large jewel in the breastplate of a statue suddenly and mysteriously sparkle with light.

Lockyer realized that temples oriented to the sun could provide a useful calendar for thousands of years because the tilt of the earth's axis shifts no more than a degree in six or seven thousand years. But temples oriented to stars could function only for a limited 200 or 300 years because each year the rising or setting of stars just before sunrise or after sunset at the solstice or equinox would occur a little later because of the precession of the equinoxes. The stars' lag behind the sun along the circle of the zodiac—a barely noticeable 1/72° each year—could become as much as 3° in 200 years, superannuating the usefulness of the temple. The temple would then need to have its axis reoriented, or another temple would have to be built. "This change of direction," says Lockyer, "is one of the most striking things which have been observed for years past in Egyptian temples."

Luxor, for instance, has four definite, well-marked changes in orientation. Lockyer measured temples at Karnak and found they were changed to match the precessional change of the stars' declination so that the priests could continue to observe it. Pylons were added, more courts were added, the sanctuary was moved eastward, the front of the temple westward.

As Maspero pointed out, "all the Ptolemaic temples and most of the Pharaonic temples have been reconstructed" during the period of their use.

Gunther Martiny, who tabulated the orientation of Assyrian temples for which the dates of foundation can be established

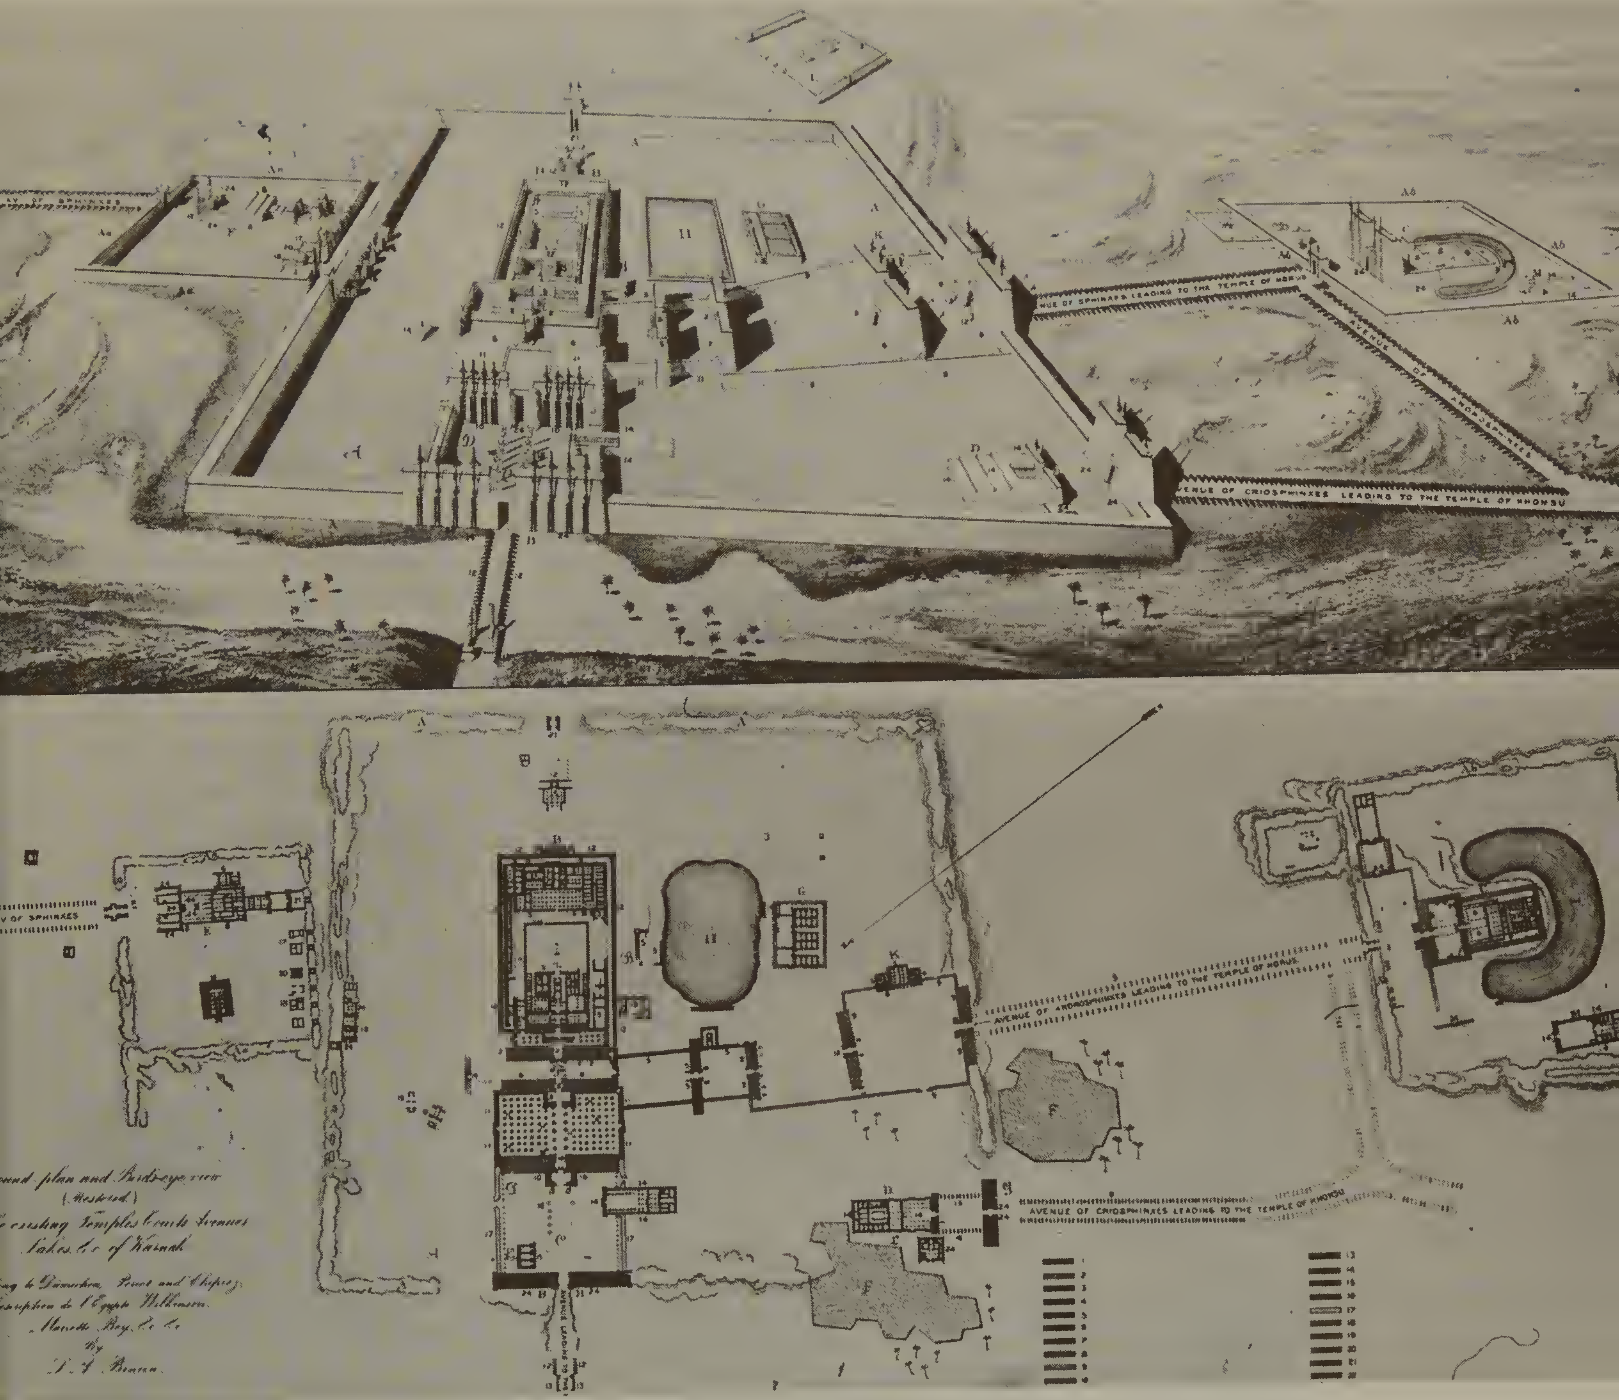


Small stones inserted in the regular masonry indicated a hidden line of orientation for the temple at Luxor.

(the oldest being about 1800 B.C.), found that the orientations also varied according to the angle of the precession of the equinoxes.

Nevertheless, says Lockyer, a temple once oriented to pick up the heliacal rising of a star could be *refitted* at a later time to mark the rising of some other heavenly body.

Lockyer drew up a stellar map with the positions of all the great stars along the sun's zodiacal path for the last 10,000 years, and he named a series of stars which could have been used to herald the solsticial dawn in different temples at different periods. In the course of centuries, according to



Reconstruction of the temple compound at Karnak showing the variation in axis of different buildings and colonnades.

Lockyer, the Egyptians oriented temples to alpha Ursa Major, Capella, Antares, Phact, and alpha Centauri. As early as 6000 B.C. they may have used Dubhe before it became a circumpolar star, and Canopus before 6400 B.C.

Professor Lockyer says that the earliest civilization in Egypt built temples at Annu or Heliopolis oriented to the heliacal rising of northern but noncircumpolar stars at the summer solstice. However, "the Great Pyramids were built by a new invading race representing an advance in astronomical thought" who used northern stars on the meridian and stars rising due east at the equinoxes.

The subsequent break in Egyptian history between the Sixth and the Eleventh Dynasties is associated by Lockyer with conflicts between these and two other races, which ended in a victory of the representatives of the old worship of Annu reinforced by supporters from the south, so that the north-star and south-star cults combined against the equinoctial cult.

Lockyer's deductions about the refurbishing of temples was to rekindle interest in the zodiac of Dendera found by Napoleon's General Desaix, and subsequently dynamited from the ceiling of the temple. It was purloined after a series of incredible adventures, to be sold to Louis XVIII for 150,000 francs and end up on display in the Louvre, where it resides today.

It was clear to Lockyer that there had been two temples of Dendera, one dedicated to Hathor and the other to Isis, both mythological personifications of heavenly bodies. Lockyer says the evidence is overwhelming that these two temples were also horizontal telescopes with the same number of pylons gradually getting narrower toward the holy of holies, so that a beam of horizontal light coming through the central door might pass uninterruptedly into the sanctuary to mark the rising of a celestial body. The columns, says Lockyer, shielded the eye from the sunrise light, so that the rising could be precisely indicated. According to Lockyer the present temples of Dendera were renovated in Ptolemaic times, but were built on much older sites.

The French astronomer Jean Baptiste Biot staked his academic reputation on his analysis of the circular zodiac. He said it represented the skies in Egypt in 700 B.C., and that it had probably been copied from older drawings made on papyrus or stone.

Lockyer confirmed that the Isis temple had been directed at Sirius in 700 B.C., when Sirius rose "cosmically," or in unison with the sun, at the Egyptian new year. But Lockyer quoted an old inscription which described a temple of Hathor at Dendera in the time of Khufu (Cheops) in the Fourth Dynasty (which he dated at 3733 B.C.) "when the star shone into the temple and mingled with the light of her father Ra."

Another inscription in a crypt of the temple indicated it had been built according to the plans of Imhotep, son of Ptah, who was the fabulous architect of the Third Dynasty King Zoser.

In Lockyer's opinion the temple of Dendera may have been rebuilt at least three times since then, once in the reign of King Pepi I (which Lockyer gives as 3233 B.C.), once again by Thothmes III in 1600 B.C., and finally by the Ptolemies about 100 B.C.

According to Lockyer the temple may previously have been directed at Dubhe, which ceased to be circumpolar about 4000 B.C., and before that at gamma Draconis, which ceased to be circumpolar in about 5000 B.C.

Egyptologists greeted Lockyer's astronomical theory about Egyptian temples with the same reserve they treated his theories about Stonehenge—which a computerized age has now shown to be correct. The Egyptologists objected to Lockyer's dragging in astronomy to straighten out the chronology of history, and dismissed his theory "with good-natured laughter, advising the cobbler to stick to his last"; so *The Dawn of Astronomy* dropped out of sight and became very hard to find, until reprinted in 1964 by Giorgio de Santillana at the Massachusetts Institute of Technology.

At the time of publication only Sir Gaston Maspero was impressed. He spent an Easter holiday at the sea studying Lockyer's theory, and he grudgingly agreed that "except for matters of detail I feel that on the whole your demonstration is conclusive, and in principle you must be correct."

Schwaller de Lubicz now supports Lockyer's conclusion, saying there can be no doubt about the orientation of temples or the fact that the ancient Egyptians understood the precession of the equinoxes, which brought a new constellation into position behind the rising sun at the vernal equinox every 2200 years. The mere fact that the cult of the Bull preceded the cult of the Ram in Egypt, and that the dates of these cults correspond with the equinoctial positions

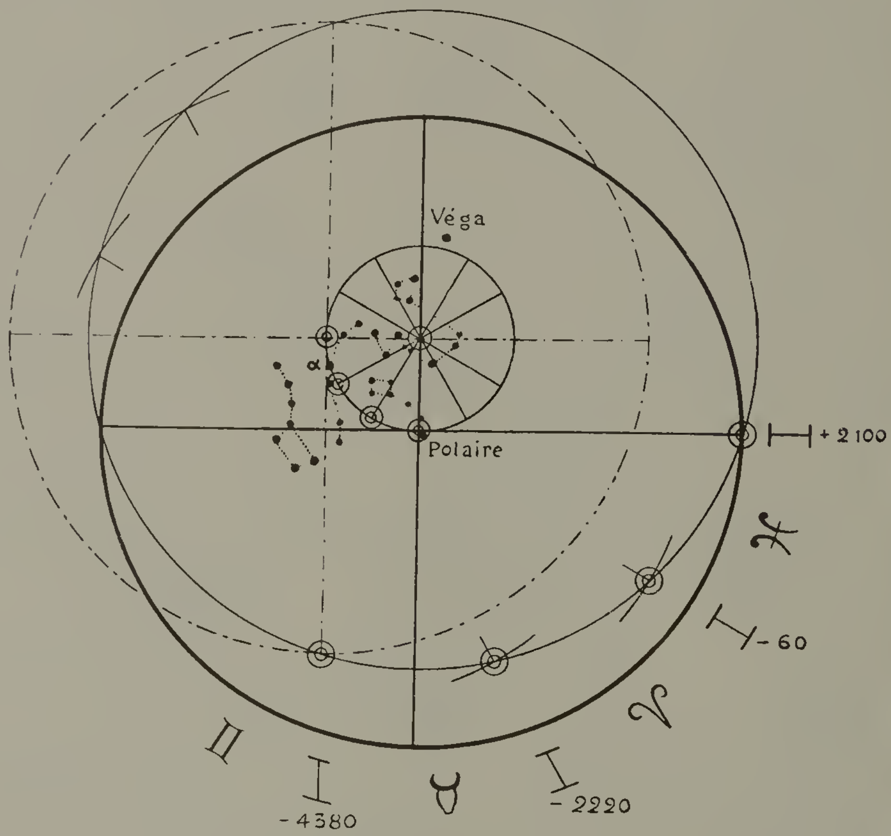
Temple of Hathor at Dendera, as drawn by Denon, showing main axis possibly oriented to gamma Draconis before 5000 B.C., according to Sir Norman Lockyer.

Interior of the temple of Hathor at Dendera as conceived by the French savants.

The circular zodiac of Dendera was on the ceiling of an upper room of the temple believed to have been used as an observatory.
The outer circle of figures, moving counterclockwise like the stars, represent the 36 *decans*, or 10-day weeks of the Egyptian year; the twelve arms of the supporting figures, the twelve months of the year.

of their constellations at the appropriate time—approximately 4000 and 2000 B.C.—is conclusive in his opinion. Furthermore, says Schwaller, an emphasis on duality in the Predynastic Period indicates a cult of Gemini coincident with the dominance of that constellation at the vernal equinox.

Schwaller also agrees with Lockyer that the temple of Hathor at Dendera is built on the remains of much older temples. To prove his point he produced a solution to the arrangement of the constellations in the circular zodiac which has been such a problem to archeologists for well over a hundred years. Schwaller shows that the zodiac discovered by General Desaix was indeed carved in Ptolemaic times, but incorporates a palpable demonstration



Zodiac showing the overlap of the circuit of the earth's celestial pole around the pole of the ecliptic, indicating different dates in the past.

of the precession of the equinoxes as well as three important historical dates.

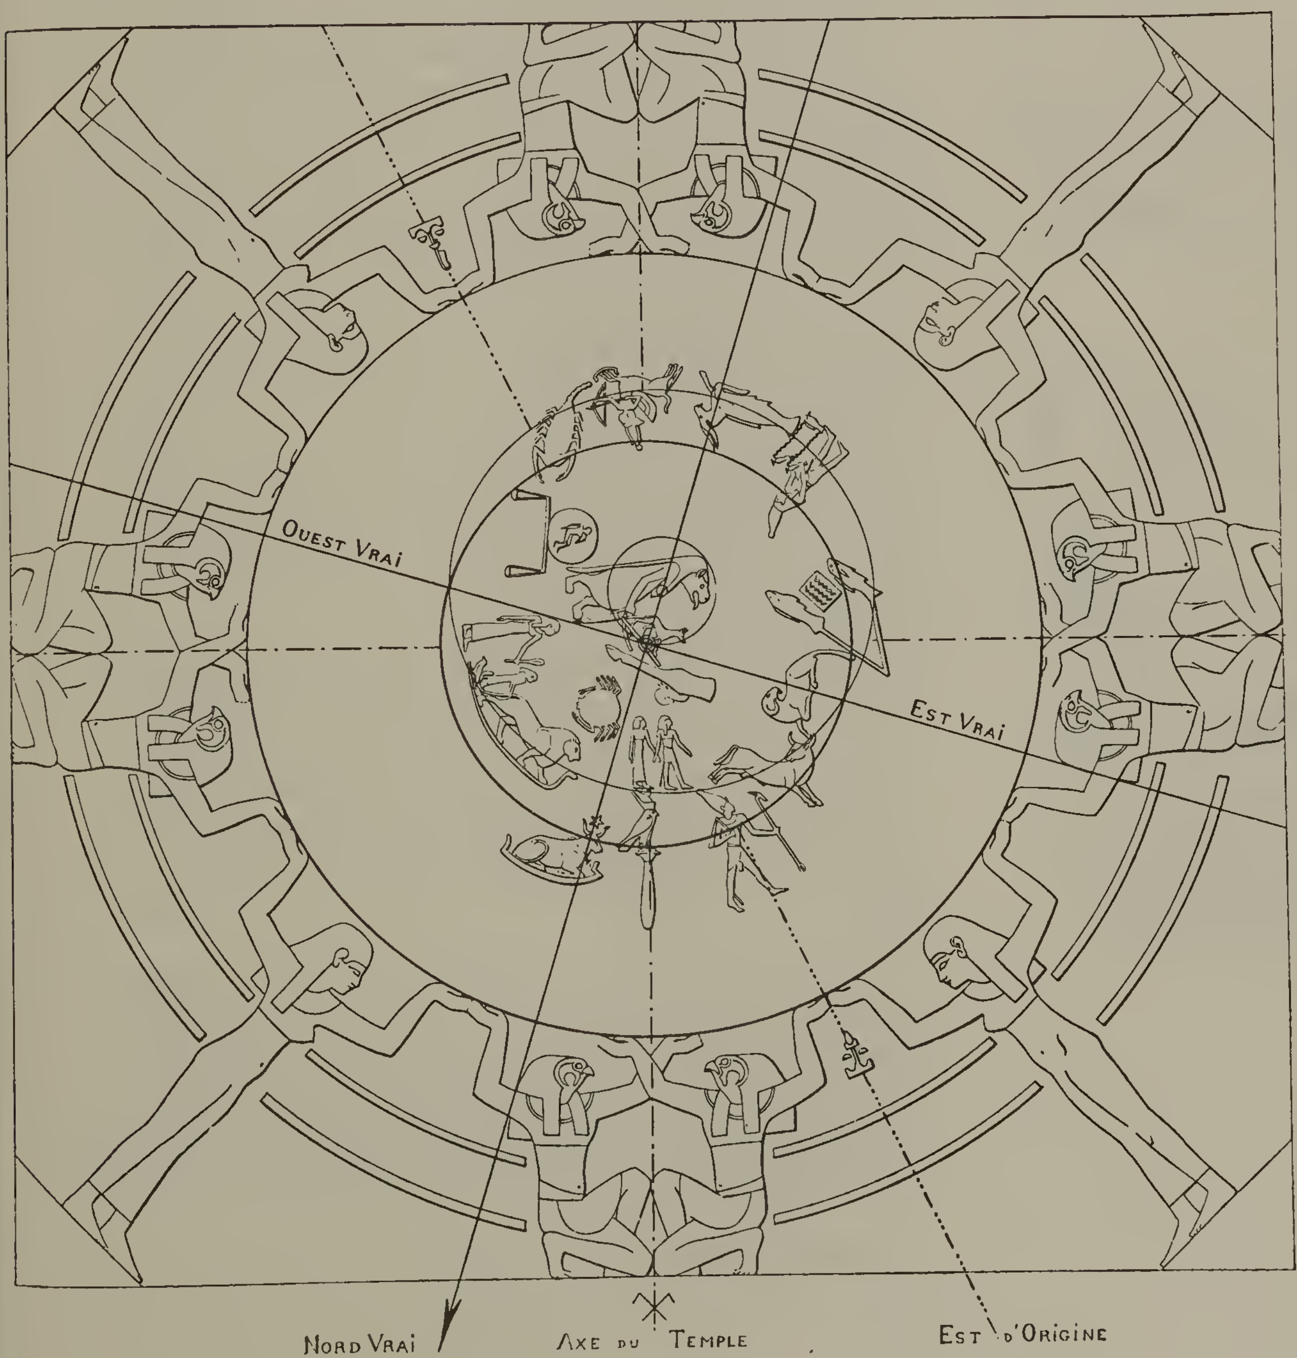
The zodiac is about 8 feet across, carved in relief on hard stone. The constellations are arranged in a spiral and the symbolic figures are marching counterclockwise in the diurnal direction of the stars as seen from the earth. Recognizable mythological figures for the constellations near the pole are a jackal for the Little Bear, an ox-leg for the Great Bear, and a hippopotamus for Drago. Sirius is depicted as a cow in a boat with a star between her horns.

The zodiac is in a circle at the center of which is our

The inner circle of spiraling figures shows the zodiacal constellations such as Gemini (the Twins hand in hand) and Taurus (the Bull) circling around our celestial north pole correctly situated in the Jackal (or Little Bear) which in turn circles around the celestial north pole of the ecliptic, situated in the breast of the Hippopotamus or Drago. Schwaller's lines show that the zodiac of Dendera correctly indicated earlier historical dates when different constellations appeared in the east at the equinox.

north pole. This circle is in a square oriented with the walls of the temple—or about 17° east of north. Our north pole is correctly located in the constellation of the jackal, or Little Bear, as it was at the time when the zodiac was carved, sometime about the first century B.C. But the zodiac also shows the pole of the ecliptic, located in the breast of the hippopotamus, or constellation of Drago.

To Schwaller this explains the spiral formation of the constellations. The mythological figures representing the constellations are entwined in two circles—one around the north pole and one around the pole of the ecliptic. Where these two circles intersect marks the point of the equinox, or due east. The zodiac thus becomes a calendar going back to remote antiquity.



A line due east, which runs between the end of the Ram and the beginning of Pisces, indicates the time when the temple was rebuilt, about 100 B.C. An earlier east line runs right through the Ram, indicating a date about 1600 B.C., at the height of the Amonian domination, during the Twelfth Dynasty.

A special hieroglyph on the ring of the zodiac indicates an equinoctial line running through the end of Gemini and the beginning of Taurus—the date of the founding of the empire of Menes and the beginning of the cult of the Bull and the adoption of the new calendar, sometime in the third or fourth millennium B.C.

In other Egyptian charts of the constellations there appears the figure of a hawk-headed man holding in his outstretched arms a line which ends against the figure of the ox-leg, representing the constellation of the Great Bear.

Hawk-headed man holding a spear (pointing at the Great Bear constellation) indicates the meridian through the pole of the ecliptic, according to Stecchini.

According to Zaba this line held by the hawk-headed man indicates the meridian through our north pole. But Professor Livio Stecchini points out that Zaba did not notice that this line always ends at a very specific position, at times with an arrow point, which divides the seven stars of the Great Bear into four and three. This line, says Stecchini, does not indicate the meridian passing through the north pole, but the meridian passing through the pole of the ecliptic. In Stecchini's opinion, the ancient Egyptians not only understood the precession of the axis of the earth but considered the true meridian the one passing through the pole of the ecliptic of the solar system. Lockyer added that the Babylonians had distinguished the pole of the equator from the pole of the ecliptic, naming the former Bil and the latter Anu.

The evidence leaves little doubt that the ancient Egyptians knew there were two poles in the sky, a north pole, which shifted round a fixed pole, or "open hole" in the heavens; they also knew that this slow circling brought about the precession of the equinoxes. That the phenomenon of the precession was the matrix from which a thousand myths were developed is abundantly illustrated by the work of Giorgio de Santillana and Hertha von Dechend in *Hamlet's Mill.**

There is no doubt in Santillana's mind that the ancient Egyptians were aware of the precession. In his preface to a recent reprint of *The Dawn of Astronomy,* Santillana, then professor of the history and philosophy of science at MIT, remarked that "when a stellar temple is oriented so accurately that it requires several reconstructions at intervals

* Published by Gambit Inc., Boston, 1969.

of a few centuries, which involve each time the rebuilding of its narrow alignment on a star," and "when zodiacs, like that of Dendera, are deliberately depicted in the appearance they would have had centuries before, as if to date the changes," it is not reasonable to suppose the Egyptians were unaware of the precession of the equinoxes.

Santillana was even more forceful in his condemnation of modern archeological scholars who refuse to accept the idea that the phenomenon of the precession was known in Egypt thousands of years before it was *re*discovered by Hipparchus. In *Hamlet's Mill,* Santillana accuses the scholars of having "cultivated a pristine ignorance of astronomical thought, some of them actually ignorant of the precession itself."

The precession was considered the basic mechanism of the universe by the Egyptians, controlling not only astronomical phenomena but all human and biological development.

Since the beginning of history, the spring equinox has moved through Taurus, Aries and Pisces, or almost one-quarter of a whole cycle. Santillana points out that the Copernican system, which for us explains the precession as the wobble of the earth's axis, has stripped the phenomenon of its awesomeness:

"But *if,* as it appeared once, it was the mysteriously ordained behavior of the heavenly sphere, or the cosmos as a whole, then who could escape astrological emotion? For the precession took on an overpowering significance. It became the vast impenetrable pattern of fate itself, with one world-age succeeding another, as the invisible pointer of the equinox slid along the signs, each age bringing with it the rise and downfall of astral configurations and rulerships, with their earthly consequences."

XIV. GEODETIC AND GEOGRAPHIC LANDMARK

The strongest evidence that the ancient Egyptians were capable of accurate astronomical observations comes from the fields of geodesy and geography, sciences whose object is to determine the size and shape of the earth, and to locate landmarks upon it. Until the development of radio and laser beams, coordinates of latitude and longitude with which to locate a spot on this planet could only be obtained by means of accurate astronomical sightings. When a temple or observatory or the remains of a city are found in a geographical location, either of latitude or longitude, or both, specifically related to other established locations, it is clear that its founders must have been able to make the required astronomical observations.

Professor Stecchini—who obtained his doctorate at Harvard in the science of classical mensuration—has now established that the ancient Egyptians not only developed an advanced system of astronomy and mathematics, but an equally advanced system of geography and geodesy.

From ancient hieroglyphs, hitherto neglected, Stecchini has been able to show that from the earliest dynasties in the third millennium B.C., the Egyptians could measure latitude to within a few hundred feet and do almost as well with longitude—a feat which was not repeated on this planet until the eighteenth century of our era.

The ancient texts and hieroglyphs vindicate Jomard in full, and show that at least as early as the unification of Egypt (ca. 2800 B.C.) the ancient Egyptians knew the length of the circumference of the earth very precisely, the length of their country almost to the cubit, and the geographical coordinates of all the main points in their realm from the equator to the Mediterranean. To do so the Egyptians must have been able to make astronomical observations with almost the exactness afforded by the modern telescope and chronometer.

From a twenty-year study of the mathematical and astronomical data contained in the cuneiform tablets of the ancient Sumerians and Babylonians, Stecchini has derived the evidence that astronomical observations of great

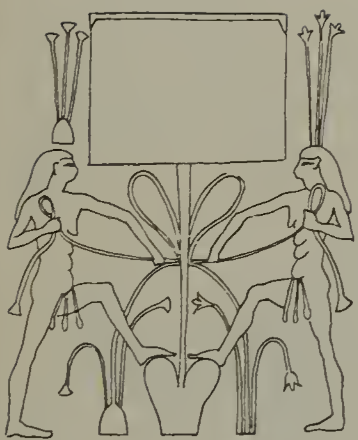
accuracy could be, and were, performed in Mesopotamia as well as Egypt in the third millennium B.C.

From his analysis of the pyramids and stepped ziggurats of the Middle East, Stecchini has demonstrated that they not only incorporate the basic techniques for projecting and mapping the hemisphere of the heavens but for mapping the terrestrial hemisphere; they also reveal a high level of mathematics, capable of resolving and simplifying the problems of trigonometry.

Stecchini points out that Herodotus, who has been ridiculed by scholars for his reported dimensions of Egypt, and accused of having lied about his travels there, turns out to have described ancient Egypt with great accuracy in terms of meridians and parallels carefully worked out by ancient Egyptian astronomers.

Stecchini found a glyph carved on the thrones of virtually all the Pharaohs since the Fourth Dynasty which contained geodetic data and hence astronomical data of extraordinary subtlety, enabling him to determine that the Egyptians used three figures for the tropic of Cancer: a simplified one of 24°, a precise one of 23° 51′, and one of 24° 06′ required for observing the sun's shadow at the summer solstice.

The sophistication of the ancients is demonstrated by the fact that they placed their observatory near Syene on the island of Elephantine, 15′—or half a diameter of the sun—north of the actual tropic because they understood that it was not the center of the sun but its outer rim which had to be observed.



The most important Egyptian text deciphered by Stecchini was a set of three identical hieroglyphs on the back of standard Egyptian measuring rulers found at the temple of Amon at Thebes, the geodetic center of Egypt since the Middle Kingdom. These, says Stecchini, give the clue to the exact dimensions of ancient Egypt.

Ludwig Borchardt, an eminent German Egyptologist, who first published the texts in an article in *Janus* in Vienna in 1921, assumed a *priori* that the figures could not refer to actual latitudes computed astronomically, and did

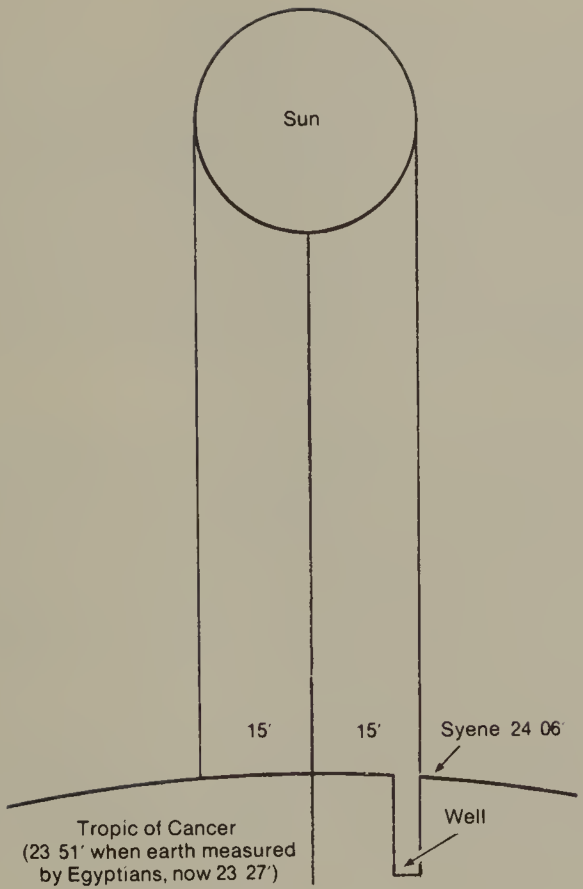
Knotted ropes beneath Pharaoh's throne are used to symbolize the union of Lower and Upper Egypt at the thirtieth parallel, where the apex of the Delta crosses the prime meridian of Egypt, just north of the Great Pyramid.

Three pairs of short horizontal lines at the bottom of the picture are symbols of three distinct values given by the ancient Egyptians to the tropic of Cancer, basic to the geodetic mensuration of Egypt. The central one of these three lines represented the conventional latitude of the tropic at 24°; the lower line represented the actual latitude at 23° 51′; and the upper line a latitude of 24° 6′, which was 15′ north of the true tropic, at Syene, where astronomical observations were made.

not even bother to test them: "One must absolutely exclude the possibility that the ancients may have measured by degrees." Succeeding Egyptologists also failed to compare the texts with actual parallels and meridians. Stecchini found them to apply with astonishing precision.

The texts—which for stylistic reasons have been assigned to the Old Kingdom (third millennium B.C.)—state the length of Egypt to be 20 *atur* from Behdet on the Mediterranean to Pi-Hapy (the apex of the Delta just north of the Pyramid of Cheops) and another 86 *atur* south to the First Cataract of the Nile.

This means that 106 *atur* would span an arc of 7° 30′ from the Mediterranean to Syene. From a composite of texts and geographic evidence an *atur* is the equivalent of 15,000 royal cubits or 17,000 of Jomard's cubits of .4618 meter. This would make Egypt from Behdet at 31° 30′ to Syene at 24° 00′ a length of 1,800,000 of Jomard's cubits, or 831,240 meters. The *Smithsonian Geographical Tables* give the distance from 31° 30′, to 24° 00′ as 831,002 meters. Computing from the third millennium B.C. text, the mean length of a degree of latitude in Egypt would be 110.832 meters. The modern estimate is 110.800 meters.

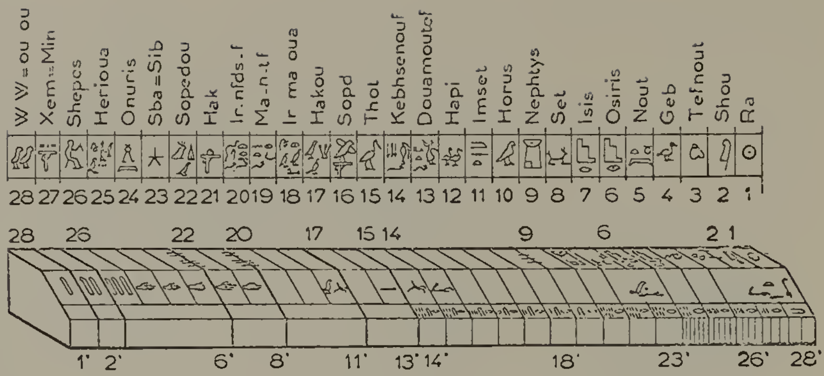


To observe the exact moment the sun fills a well without shadow as it reaches its farthest point north, at the summer solstice, the observation would have to be made under the northern rim of the sun, 15′ further north than the line of the tropic.

When the tropic was at 23° 51′, the ancient Egyptians observed it at Syene at 24° 06′.

Today the tropic is at 23° 27′. By establishing the moment of solstice at the tropic, the ancient astronomers were able correctly to compute the circumference of the earth by the use of deep wells and obelisks.

The island of Elephantine in the Nile near Syene, where the ancient Egyptians had an astronomical observatory and a nilometer to gauge the flood of the Nile.



Royal Egyptian cubit of Memphis. It was divided into 7 palms of 4 fingers each, for a total of 28. The basic unit from which this cubit is derived is the foot of 300 millimeters. One and a half of these feet made a cubit of 450 millimeters, divided into 6 palms of 4 fingers, for a total of 24 fingers. The royal cubit was obtained by the addition of one extra palm, for a total of 7, or 28 fingers, the equivalent of 525 millimeters.

Stecchini points out that a septenary unit was common to Mesopotamia, Egypt and Greece, because it allowed simple solutions to problems of practical measurement. With a π of 22/7, it was simpler to have a septenary cubit; a square of side 7 was considered to have a diagonal of 10, and a square of 10 as having a semi-diagonal of 7.

According to Stecchini, once the Egyptians were in possession of the true proportions of their country, they devised a means of simplifying their geodetic data into a geography that was easily committed to memory without recourse to portable maps, using such obvious natural landmarks as the cataracts on the Nile and the extremities of the Nile Delta as geodetic points for rectangles and triangles with easily remembered angles.

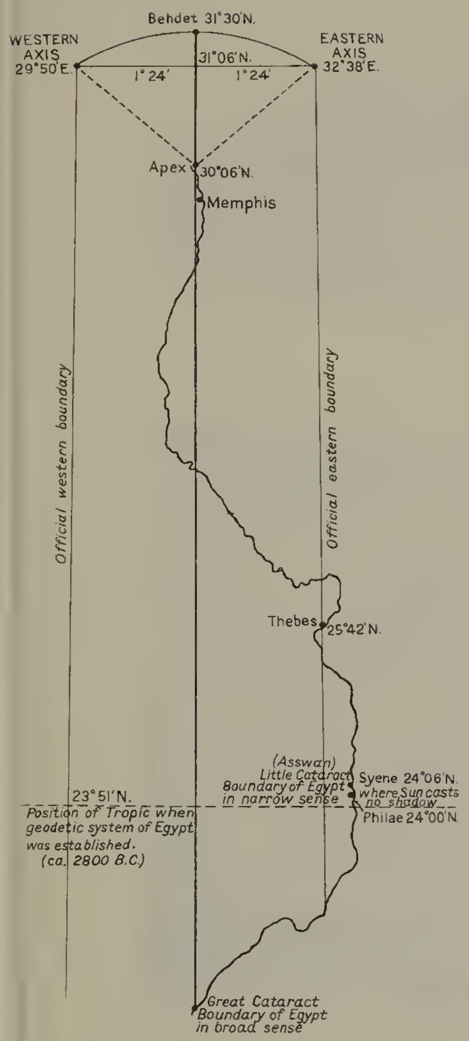
The prime meridian of Egypt was made to split the country longitudinally precisely in half, running from Behdet on the Mediterranean, right through an island in the Nile just northeast of the Great Pyramid, all the way to where it crossed the Nile again at the Second Cataract.*

To simplify the dimensions of Northern Egypt, the Egyptian geographers accurately marked it as a triangle exactly 1° deep, with its apex where the Nile splits (just north of the Pyramid of Cheops), fanning out 1° 24′ east and west to where its widest branches flow into the sea. This became an actual Δ-shaped delta, whose angles were designated by the shadows cast by the northeast and northwest corners of the Great Pyramid.

Southern Egypt was made to run precisely 6° to the First Cataract of Aswan on the tropic of Cancer. Two lines drawn parallel to the prime meridian, starting at the side mouths of the Nile in the Delta, running to the tropic, made a simple rectangle of Lower and Upper Egypt.

Stecchini says that when this particular geodetic system of ancient Egypt was established, the tropic of Cancer was at 23° 51′, which corresponds to a place on the Nile just south of the First Cataract called Parembole in Hellenistic times. On the island of Elephantine—15′ farther north—was the famous "well," whose bottom was said to be completely

* Close to the Mediterranean the meridian may have been marked by a northern pyramid. In 1800 the French Expedition saw the remains of a pyramid near Benha in the Delta, but its superstructure has since disappeared.



The first cataract, near Syene on the Upper Nile, was fabled to have been a land of the deaf because of the constant roaring of the waters over the outcroppings of granite.

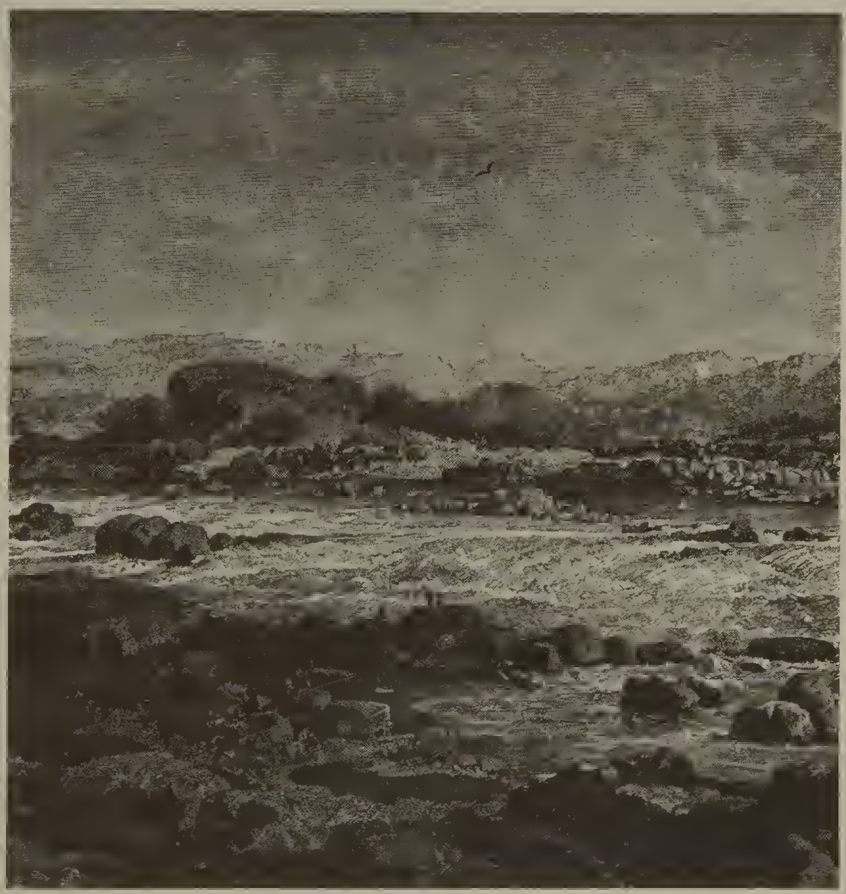
This ancient boundary of Southern Egypt was the source of the hard pink granite from which the monolith beams of the King's Chamber were chiseled, as well as the many great obelisks, weighing as much as a thousand tons, which were set up in Egypt as sundials and geodetic markers.

illumined once a year when the sun stood directly overhead at the solstice.

Were it possible to reconstruct exactly when the tropic was at 23° 51′ it would give a firm date for the establishment of the ancient system of geography; unfortunately no astronomer has yet been able to calculate mathematically the exact rate at which the tropic has moved since ancient times to its present 23° 27′. Schwaller de Lubicz figures it was at Elephantine between 2500 and 3000 B.C.

Cities and temples, says Stecchini, were deliberately built at distances in round figures and simple fractions from the tropic or the prime meridian. The predynastic capital of Egypt was set near the mouth of the Nile at Behdet, right on the prime meridian, at 31° 30′. This gave a length to Egypt of 1,800,000 geographic cubits. Memphis, the first capital of united Egypt, was again laid out on the prime meridian and at 29° 51′, precisely 6° north of the tropic. The northern limit of the Two Kingdoms was set at 31° 6′, and the country was measured by a newer unit, the royal cubit, of which there were 1,500,000 in the length of Egypt.

The geodetic point determining the location of Memphis was called Sokar after the god of orientation (whose name and location are preserved in the present village of Saqqara),



Omphaloi, or "navels," used as geodetic markers.

Geodetic omphalos found by Reisner in the great temple of Amon.

which is exactly on the main axis of the meridian of Egypt, in the necropolis of Memphis.

As each of these geodetic centers was a political as well as a geographical "navel" of the world, an omphalos, or stone navel, was placed there to represent the northern hemisphere from equator to pole, marked out with meridians and parallels, showing the direction and distance of other such navels. In Thebes the stone omphalos was placed in the main room of the temple of Amon, where the meridian and parallel actually cross.

To obtain such precision in their geodesy, says Stecchini, the ancients must have made remarkable astronomical observations.

For the ancient Egyptians to have laid out an absolutely straight meridian of 30° of latitude from the Mediterranean to the equator, over 2000 miles, and drawn two more, equidistant, east and west, as boundaries of the country, must have required an enormous amount of personnel and careful astronomical sightings. Even more sophisticated was their method of establishing longitude, as reconstructed by Stecchini.

With the aid of an elementary system of telegraphy, consisting of a series of beacons, the Egyptians, says Stecchini, were able to note what star was at its zenith at a certain moment, and flash the data, via a string of flares, to other observers so many degrees to east and west.*

H. G. Wood, author of *Ideal Metrology,* assumes that if the Great Pyramid was originally an observatory, signal stations east and west of it once existed which are now in ruins or altogether lost. Wood quotes a Dr. Lieder's description of a little pyramid far to the west in the Libyan desert which could once be seen from the top of the Great Pyramid as the sun went down, but is now lost.

Traveling farther afield, the ancient geographer could establish his longitude with great precision on the basis of accurate tables of the nightly transit of celestial bodies as observed at the Pyramid.†

Fragmented data obtained from such accurate tables, says Stecchini, percolated to the Alexandrine Greeks such as Eratosthenes and Ptolemy, who mixed the accurate data with the inaccurately estimated coordinates of their own period, creating a hodgepodge of good and bad geography. It was not possible to disentangle and correct their work until the development of the chronometer in the eighteenth century of our era.

Because of the advanced geodetic and geographic science of the Egyptians, Egypt became the geodetic center of the known world. Other countries located their shrines and capital cities in terms of the Egyptian meridian "zero," including such capitals as Nimrod, Sardis, Susa, Persepolis, and, apparently, even the ancient Chinese capital of An-Yang.

All of these localities, says Stecchini, were set and oriented on the basis of the most exact sightings. The same applies to the centers of worship of the Jews, the Greeks, and the Arabs.

According to Hebrew historians the original Jewish center of worship was not Jerusalem, but Mount Gerizim, a strictly geodetic point 4° east of the main axis of Egypt. It was only moved to Jerusalem after 980 B.C.

The two great oracular centers of Greece—Delphi and Dodona—were also geodetic markers according to Stecchini.

* Fires such as were lighted by the Druids at the moment of the midsummer solstice may have been the origin of the "midsummer fires" and the Beltane fires of May Day, described in *The Golden Bough.*

† Because every observable star comes to the meridian of every place on the globe once in 24 hours, the interval which elapses between the same star coming upon the meridian of two different places is the difference in longitude of the two places.

Delphi is 7° and Dodona 8° north of Behdet, the northernmost part of Egypt, on the prime meridian of Egypt.

The Moselm shrine of Mecca is 10° east of the western meridian of Egypt and 10° south of Behdet. According to Stecchini the sacred black stone of the Kaaba was originally part of a set of four, placed in what he calls a pyramidical triangle from which the trigonometric functions of the shrine could be derived.

Islamic tradition stresses the point that the Kaaba was originally a geodetic center. The essential element of the Kaaba consisted of four stones marking a square with diagonals running north-south and east-west. The diagonal north-south with the northeast and southeast sides formed what the Egyptians called a pyramid. The angle formed by the diagonal with the southeast side was 36°, from which Stecchini concludes that the trigonometric functions of the shrine were measured along the northeast side.

The northwest side of the building of the Kaaba is completed by a semicircular wall: according to tradition this semicircular wall existed since the very beginning. Most likely, this was used, says Stecchini, as a sighting device.

To make a map projection of the northern hemisphere, the ancient Egyptians found a simple mathematical and geometrical means of reducing the curved surface of the globe to a flat surface suitable for mapping, and with a minimum of distortion: they used the stepped pyramid, or ziggurat, each face of which could represent a 90° quadrant of the hemisphere, and each level of which could represent a mappable zone between two parallels of latitude.

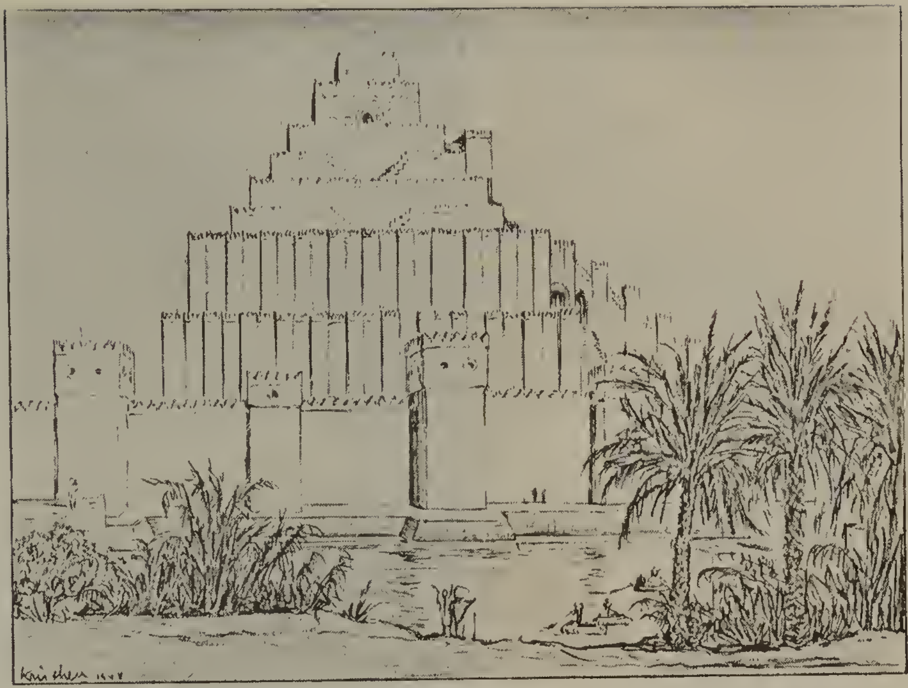
Professor Maspero describes the ziggurats of Mesopotamia as "miniature reproductions of the arrangement of the universe." Professor C. P. S. Menon in his *Early Astronomy and Cosmology* says of the ziggurats: "We can deduce that the shape of the Earth, which appears to have served as a model for the temples, was a terraced pyramid with corners pointing to the South, West, North and East."

Ziggurats at Ur, Uruk, and Babylon reached a height of three hundred feet. The ziggurat of Nabu at Barsipki was called the "House of the Seven Bonds of Heaven and Earth" and was in seven stages said to have been painted in seven "Planetary colors."

The sophistication of the ancients, says Stecchini, is illustrated by the ziggurats of Babylon. These stepped "Towers of Babel," long a mystery to mankind, turn out to incorporate a series of Mercator projections, several thousand years before the advent of the Flemish cartographer.

For the purpose of mapping, the northern hemisphere was reduced to a series of flat surfaces represented by the

Reconstruction of Babylonian stepped pyramid or ziggurat. According to H. G. Wood, the ziggurat of Jupiter Belus at Babylon had an ideal basis in the number 360. In his *Ideal Metrology* it is described as a seven-staged pyramid in which each of the six upper stages is 360 inches shorter than the one next below it; the base side was 3,600 inches, and the total height of the structure was 3,600 inches. According to Wood, the entire system of ancient Babylonian metrology appears to have been derived from 360 × 360 × 100, or 12,960,000.



faces of the stepped ziggurat. The area between the equator and the pole was divided into seven bands or "zones" as the Greeks called them, each diminishing in width to correspond to the shrinking degree of longitude. The base line represented the equator, the first step the thirtieth parallel. Thus, each façade represented a 90° quadrant of hemisphere.

Stecchini says the limits of these four quadrants were established with great precision. Egyptian texts, Greek mythology (including the *Argonautica* and the *Odyssey*), and Greek and Roman writers from Herodotus onward unanimously agree in setting this western limit of the Mediterranean quadrant at 9° 54′ East. Another limit, says Stecchini, was known as the Golden Chersonnesos, that is to say, the peninsula of Malaya at meridian 99° 54′ East at a point where the equator cuts the western coast of the island of Sumatra.

Cuneiform tablets indicate that each level of the ziggurats had a specific area corresponding to standard units of land measure.

Nineteenth-century authors illustrated the ziggurats as astronomical observatories, with bearded Babylonians gazing from the battlements; but John Taylor maintained that such high terraces afforded no better vantage than the ground.

On the other hand, a square or tubular shaft of several hundred cubits, built into their interiors, would have made first-rate telescopes for observing the skies. In Mexico the Pyramid of Xochicalco near Cuernavaca contains a tubular well down which the sun shines perpendicularly without a shadow on a specific day of the year.

Nineteenth-century idea of Babylonian astronomers atop a ziggurat, published by the French astronomer Camille Flammarion.

Sir John Herschel pointed out that "from the bottom of deep narrow pits, such as a well, or the shaft of a mine, such bright stars as pass the zenith may even be discerned by the naked eye."

John Taylor indicated the reference in Ezekiel (XXIX: 10 and XXX: 6) to a "Tower of Syene," suggesting that perhaps the famous well at Syene was inside a sighting tower.

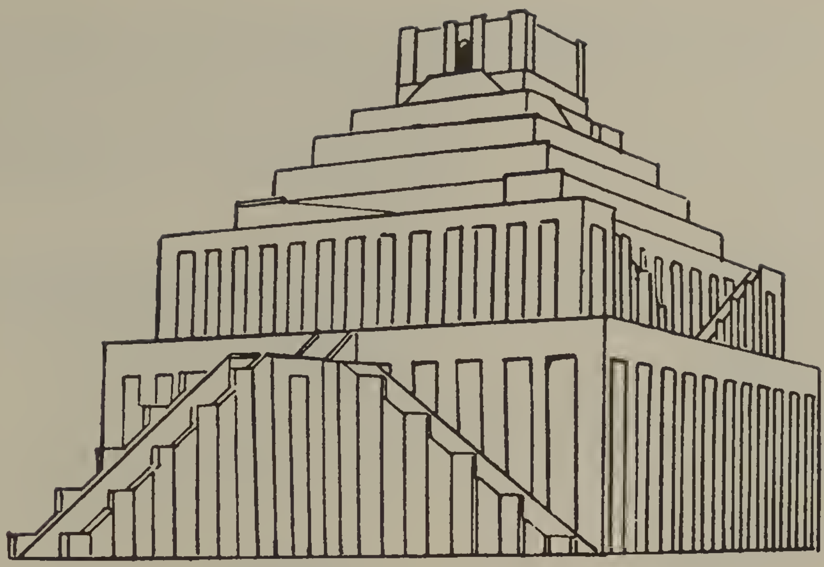
Reconstructing the ziggurat of Babylon on the basis of the cuneiform text known as the Smith tablet, Stecchini established that it rose in seven diminishing steps, each face of which was smaller than the one below it. For mapping, this allows meridians to cross the parallels at right angles, as in Mercator's projection, but avoids his distortion by shrinking each rectangular face in proportion to the shrinking degree of longitude as it approached the pole.

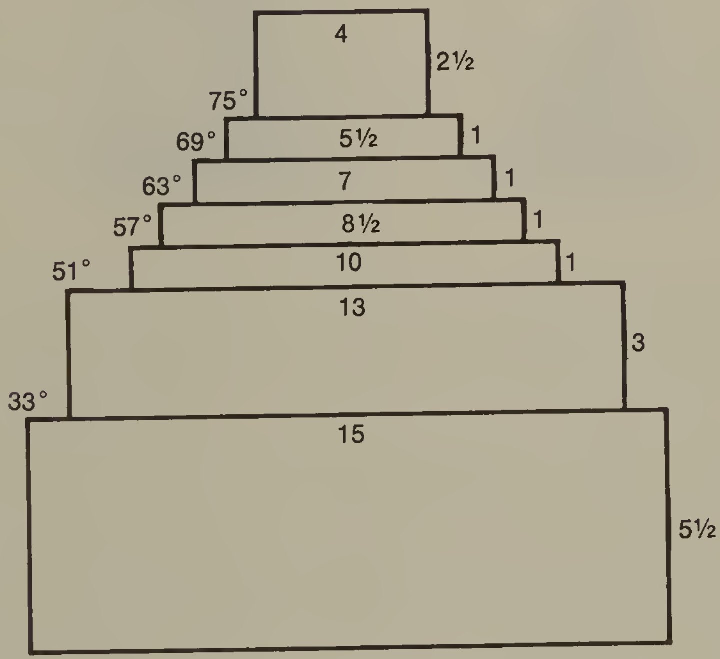
The ziggurat of Babylon, says Stecchini, would have been perfect trigonometrically if the height of the first three steps had been as originally conceived: 30, 48 and 55 1/2 degrees. But the Babylonians raised the first step to 33°, the approximate parallel of Babylon.

The cuneiform description of the ziggurat, known as the Smith tablet, specifically indicates that each level of the ziggurat has an area corresponding to standard units of land surface. Particularly important in Mesopotamian land surveying was the square with a side of 60 double cubits—the surface of the third step.

The slope angles at various heights also give important angles, such as $\sqrt{5}-1$, which is also incorporated into the Great Pyramid. Such triangles, and the number $\sqrt{5}-1$ (in common practice taken as the magic series 1–2–3) were fundamental in the operations of land surveying.

The third, fourth and fifth steps of the ziggurat make triangles with sides related as the Pythagorean 3–4–5 triangle.





In the original design, says Stecchini, the first step of the ziggurat was intended to represent the thirtieth parallel, but in Mesopotamia it was raised to 33°, the approximate latitude of Babylon. Thereafter the Babylonians made each step rise in units of 6° of latitude. This made it possible for them to obtain an easily remembered cosine value for each step by simply dividing its length by two thirds.

As the Babylonians liked to count by sixes, with a hexagesimal ana sexagesimal system, the steps of the ziggurat rose in multiples of 6°. Further to simplify their accounting, the degree of parallel represented by each step could be obtained by multiplying the height of each step by 6; e.g., $6 \times 5\ 1/2$ (first step) $= 33°$.

The system gave the Babylonians an extremely simple way of remembering the trigonometric value of each parallel.

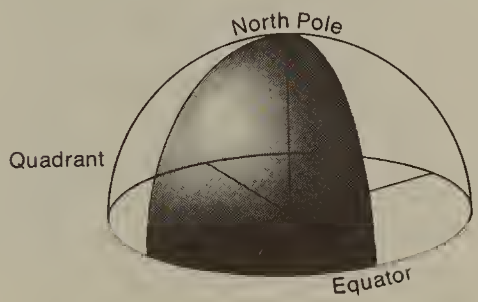
All they had to do was divide the length of each step by .666 (or 2/3). Thus, 2/3 of 15 (width of first step) is 10.000, which is the cosine value of the equator. Thereafter the operation produced a simple progression: 8.666, 6.666, 4.666, 3.666, 2.666 for the cosine value of the angles indicated by each step.

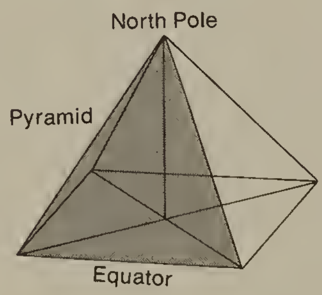
The top step, says Stecchini, was rectangular instead of square, because the average of its sides gives 2.5833, which is the cosine of 75° 01′.

XV. THE GOLDEN SECTION

In the Great Pyramid the Egyptians produced a system of map projection even more sophisticated than the one incorporated in the ziggurats.

The apex of the Pyramid corresponds to the pole, the perimeter to the equator, both in proper scale. This fact was inherent in Jomard's conclusions, but got lost in the babble of cubits.

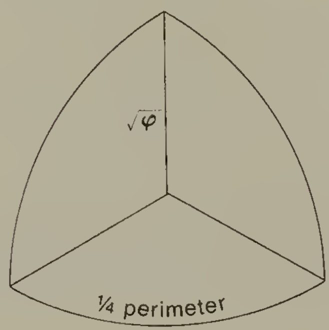


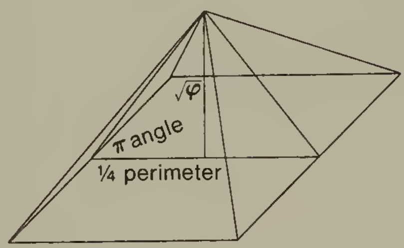


Each flat face of the Pyramid was designed to represent one curved quarter of the northern hemisphere, or spherical quadrant of 90°.

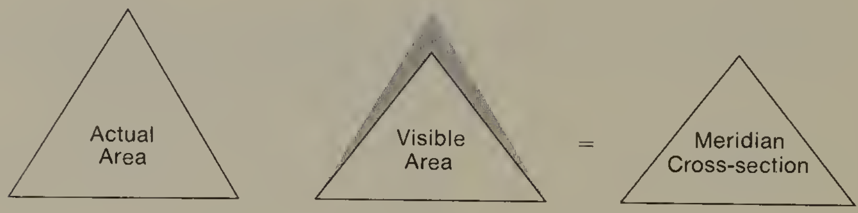
To project a spherical quadrant onto a flat triangle correctly, the arc, or base, of the quadrant must be the same length as the base of the triangle, and both must have the same height. This happens to be the case *only* with a cross section or meridian bisection of the Great Pyramid, whose slope angle gives the π relation between height and base.

John Taylor intuitively suspected something of the sort, but was unable fully to formulate it.



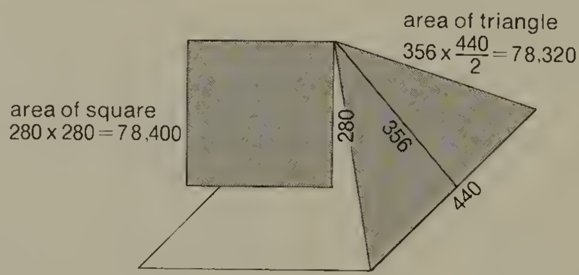


The subtlety of the Pyramid's projection lies in the fact that when viewed from the side, the laws of perspective reduce the actual area of a face (mathematically oversized) to the correct size for the projection, which is the Pyramid's *cross section.*



What the viewer saw, and sees, with the aid of perspective is the correct triangle.

The key to the geometrical and mathematical secret of the Pyramid, so long a puzzle to mankind, was actually handed to Herodotus by the temple priests when they informed him that the Pyramid was designed in such a way that the area of each of its faces was equal to the square of its height.



This interesting observation reveals that the Pyramid was designed to incorporate not only the π proportion but another and even more useful constant proportion, known in the Renaissance as the Golden Section, designated in modern times by the Greek letter φ (pronounced *phi*), or 1.618.*

φ, like π, cannot be worked out arithmetically; but it can easily be obtained with nothing more than a compass and a straightedge.

With the incorporation of the Golden Section, the Great Pyramid provides an effective system for translating spherical areas into flat ones.

Anyone who is not anxious to follow the simplified mathematics in this chapter may more simply skip to the following chapter—which contains the answer to the riddle. But he will miss some odd conceits about the relation of

* If the 356 cubits of the Pyramid's apothem are divided by half the base, or 220 cubits, the result is 89/55, or 1.618.

mathematics to the cosmos and to the creative function of life as embodied in the science of the builders of the Pyramid. The pharaonic Egyptians, says Schwaller de Lubicz, considered φ not as a number, but as a symbol of the creative function, or of reproduction in an endless series: to them it represented "the fire of life, the male action of sperm, the *logos* of the gospel of St. John."

The Golden Section, or φ, is obtained by dividing a line

at a point *C*

in such a way that the whole line

is longer than the first part

in the same proportion as the first part

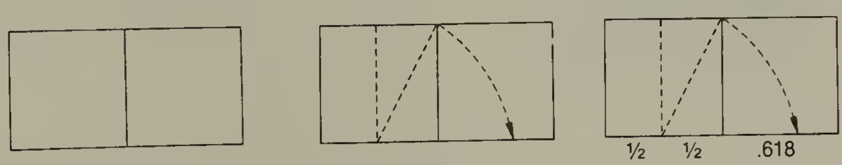
is longer than the remainder.

This will mean that $\frac{AB}{AC} = \frac{AC}{CB} = 1.618.$

This equation, which appears so simple, turns out to be loaded with meaning. Plato in his *Timaeus* went so far as to consider it, and the resulting Golden Section proportion, the most binding of all mathematical relations, and makes it the key to the physics of the cosmos.

In the Great Pyramid the rectangular floor of the King's Chamber (which consists of two equal squares, or a 1×2 rectangle) also serves to illustrate and to obtain the Golden Section.

If you split one of two squares in half and swing the diagonal down to the base, the point where the diagonal touches the base will be φ, or 1.618 in relation to the side of the square, which is 1.*

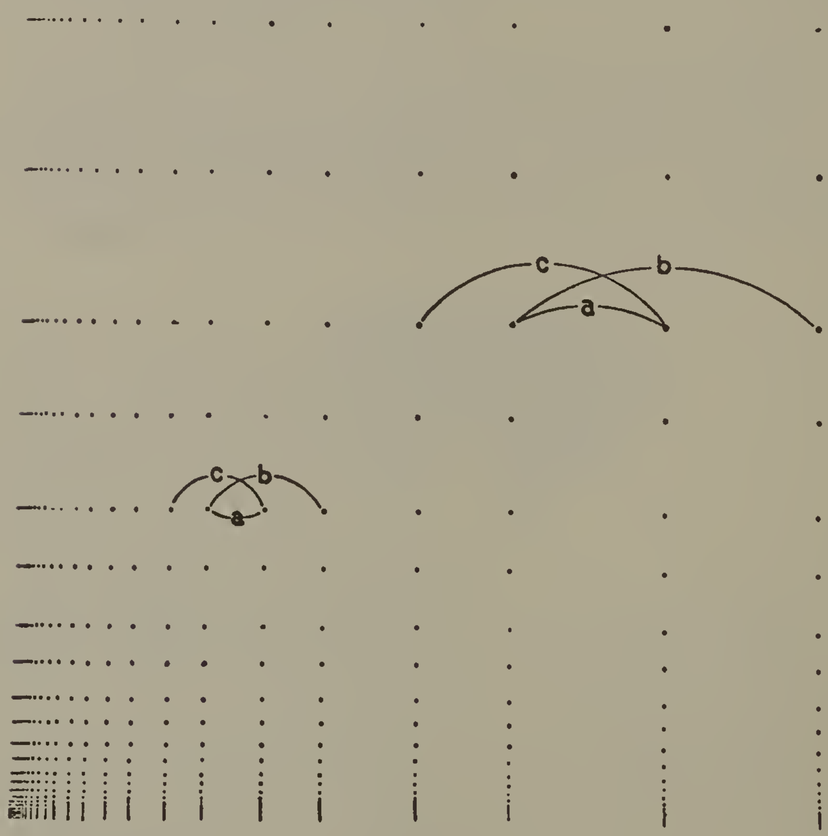


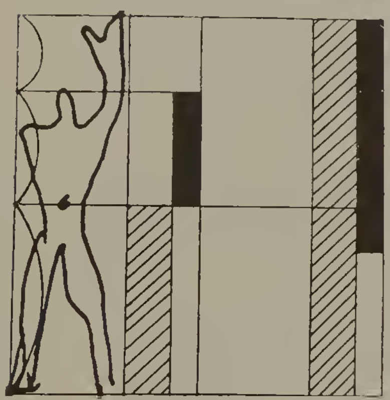
* Pythagoras' theorem will also show that the value of φ will be $1/2 + \sqrt{5}/2$, or 1.618, and that $\varphi - 1$ will be .618.

The odd, if not unique, mathematical fact that $\varphi + 1 = \varphi^2$ and that $1 + 1/\varphi = \varphi$ leads to an additive series, known as a Fibonacci series, in which each new number is the sum of the previous two: 1-2-3-5-8-13-21-34-55-89 . . . etc., and their ratio comes closer and closer to φ.*

In Egypt Fibonacci got wind of the additive series and popularized its mystical quality by bringing to Europe the story of the "rabbit problem," or how to find the number of rabbits born in one year, starting with an original pair. Assuming the rabbits to be enclosed by a wall and that every month they produce a pair of rabbits, and that each new pair in turn produce another pair each month, the answer could be obtained by the additive series 1-2-3-5-8-13-21. . . . In this case it is 377 pairs of rabbits.

This mathematical grid, based on the Golden Section, was to become the backbone of the architectural system developed by the great French architect Le Corbusier for his construction of anything from the United Nations building in New York to the closets in a bathroom.

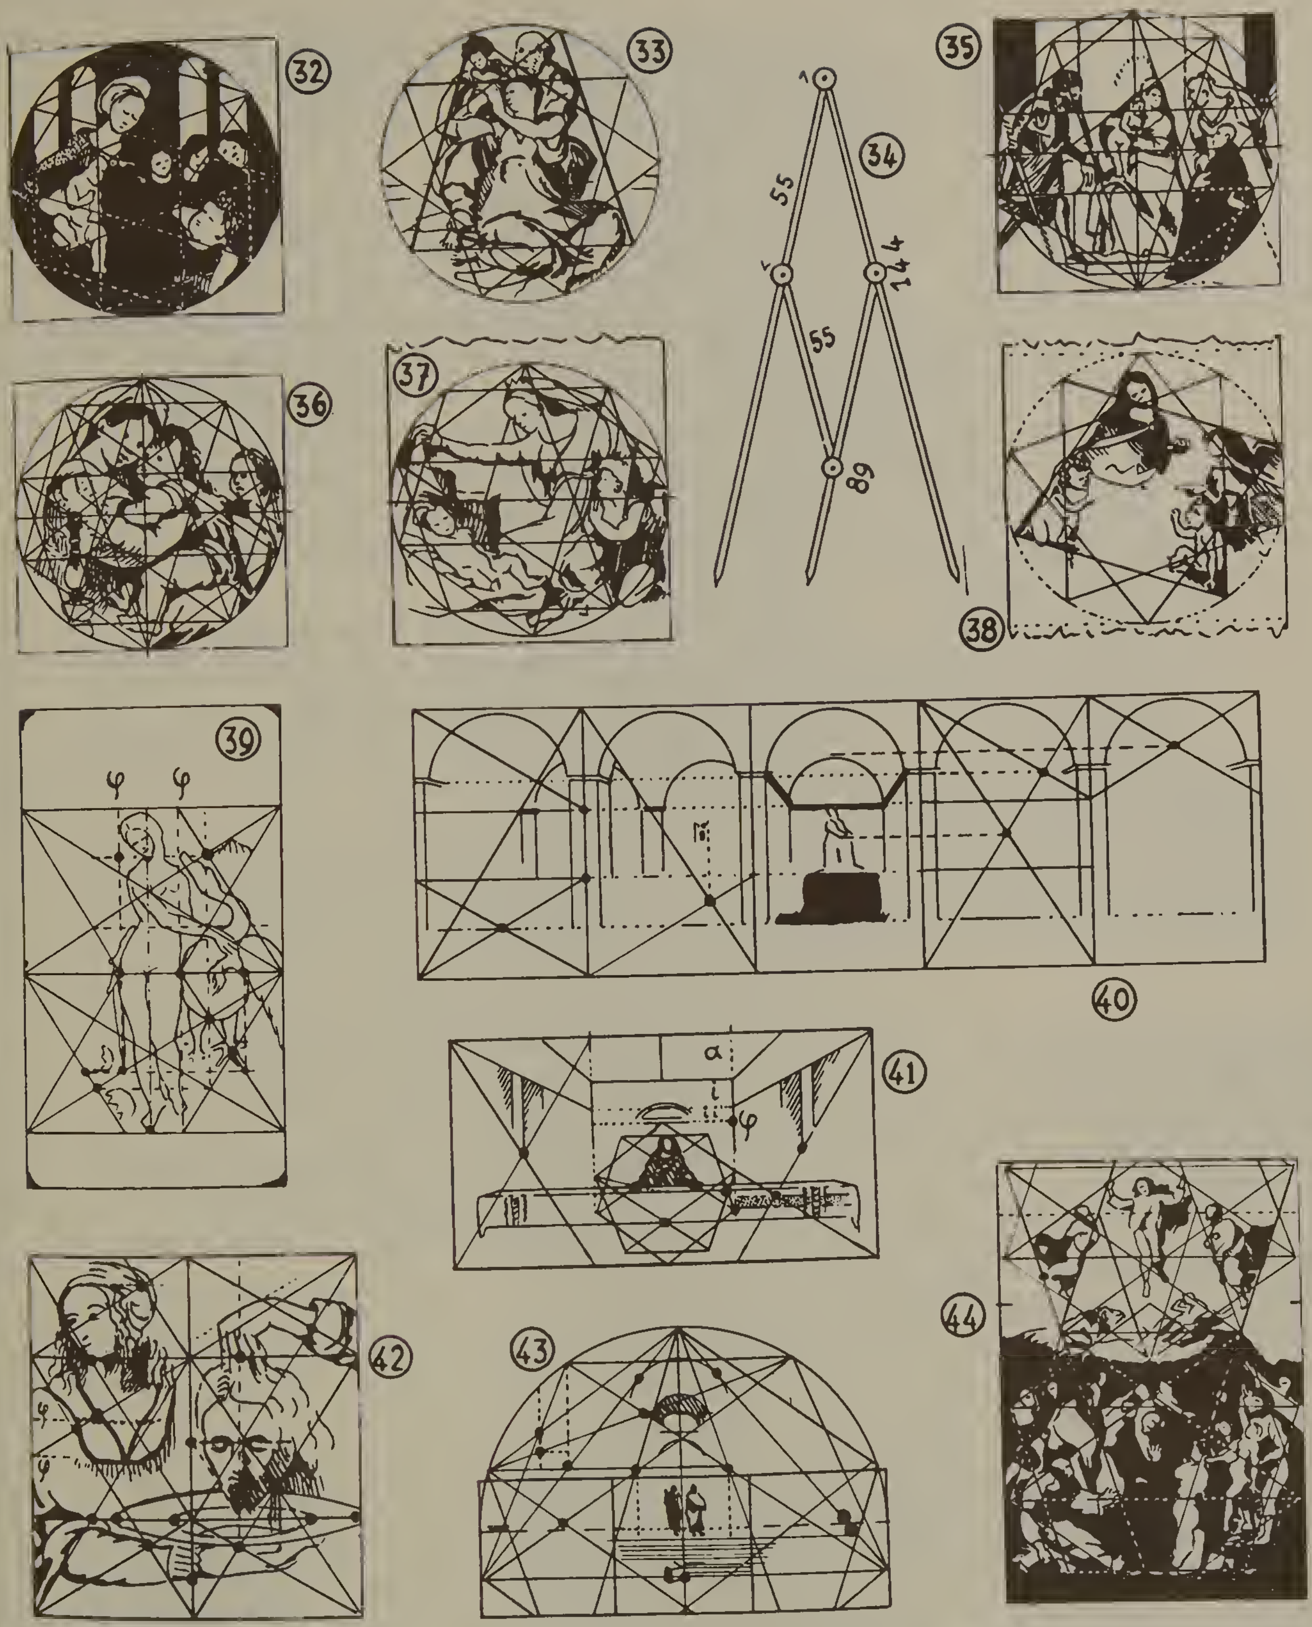




Le Corbusier's "modulor" based on the φ relation in the human body.

The Fibonacci series can be visualized geometrically as a mathematical grid growing larger (or smaller) in which each new unit always bears the relation of φ to its predecessors and successors.

* Leonardo Bigollo Fibonacci, known as Leonardo da Pisa, was perhaps the greatest mathematician of the Middle Ages. Born in 1179, he traveled to Algiers with his father, who acted as consul for the Pisan merchants. From the Arabs Fibonacci learnt the Hindu system of numerals from 1 to 9, which he is credited with having introduced to Europe, where calculations were still being made by the clumsy means of Roman numerals and Greek letters.



Funk-Hellet's analysis of (32) Mainardi, (33) Michelangelo, (34) Golden Section compass: note 55/89 relation, (35) Veronese, (37), (42), (43) Raphael, (38), (39), (41) Leonardo da Vinci, (40) Fra Lippo Lippi.

In the Renaissance the φ proportion, or Golden Section, as it was called by Leonardo da Vinci, served as the hermetic structure on which some of the great masterpieces were composed. Leonardo illustrated a book on the Golden Section for Luca Pacioli, known as "the monk drunk on beauty," which was published in Venice in 1509.

Funk-Hellet has analyzed the φ proportion in a score of masterpieces, including Titian's *Presentation of the Virgin,* Luini's *Sleep of the Infant Jesus,* and Veronese's *The Wedding at Cana.*

The conclusion that the Egyptians of the Old Kingdom were acquainted with both the Fibonacci series and the Golden Section, says Stecchini, is so startling in relation to current assumptions about the level of Egyptian mathematics that it could hardly have been accepted on the basis of Herodotus' statement alone, or on the fact that the φ proportion happens to be incorporated in the Great Pyramid. But the many measurements made by Professor Jean Philippe Lauer, says Stecchini, definitely prove the occurrence of the Golden Section throughout the architecture of the Old Kingdom.

Professor Lauer, for many years the architect for the Egyptian Department of Antiquities, has made thousands of measurements of ancient Egyptian buildings.

Schwaller de Lubicz also found graphic evidence that the pharaonic Egyptians had worked out a direct relation between π and φ in that $\pi = \varphi^2 \times 6/5$.*

In the tomb of Rameses IX there is a strange figure of a royal mummy with one arm raised and an erect phallus. The mummy is lying at the hypotenuse of a sacred 3–4–5 right-angled triangle indicated by a snake.

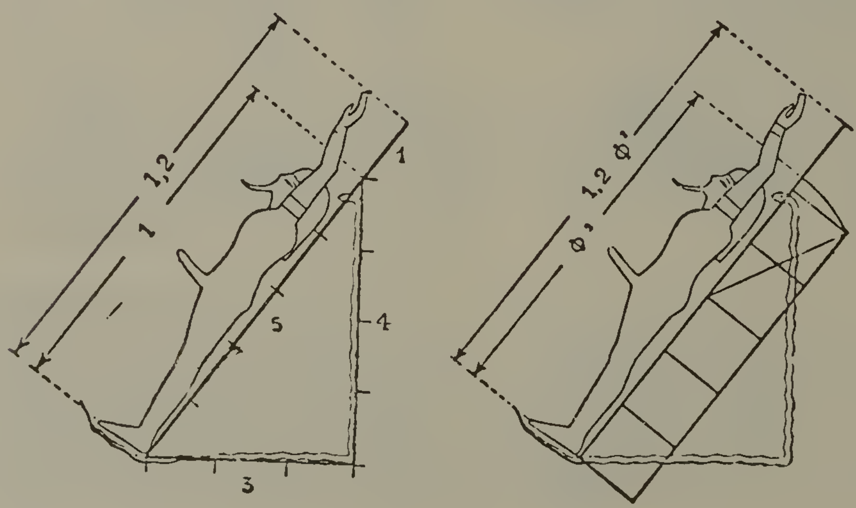
The length of the body, says Schwaller, is clearly 5 cubits and that of the upright arm is one more cubit, for a total of 6. At the same time the body is divided by the phallus in the proportion of 1 and φ, for a total of φ^2.

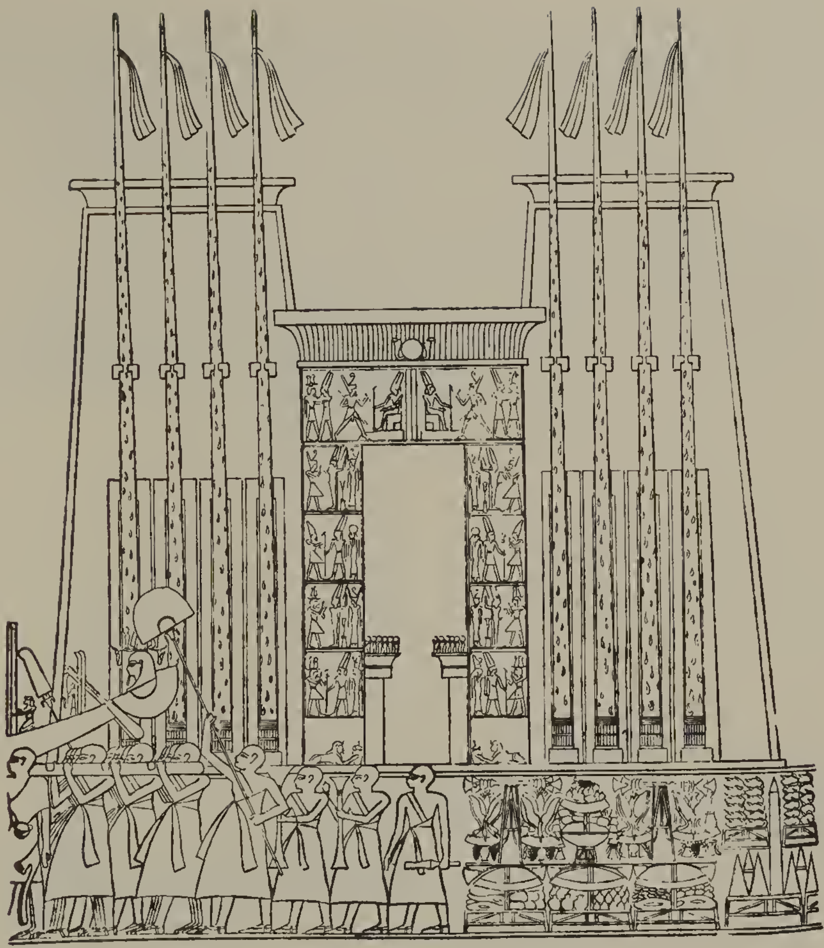
This, says Schwaller, makes the outstretched arm give a value for π of 6/5 of the body, or φ^2, which is 3.1416.

On the east side of the temple of Luxor, Schwaller also

* $2.618 \times 6/5 = 3.1416$.

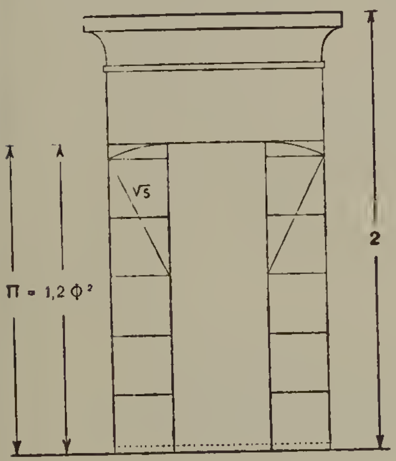
Egyptian king as the hypotenuse of a sacred 3–4–5 triangle formed by a snake.
Schwaller de Lubicz shows the king as φ^2, split into a $\varphi + 1$ proportion by the phallus. The king's raised arm gives a 6/5, or $1.2 \times \varphi^2$, proportion, which is exactly 3.1416, or π.





Priests exiting from third pylon of the Great Temple of Karnak bearing the king's barque.

Schwaller de Lubicz shows how the value of π correct to four decimals, or 3.1416, was incorporated into the great gate whose basic measurement was 1×2.



found a relief depicting a cortege of priests exiting from the great temple of Karnak, carrying the king's "solar barque." Schwaller points out that if the width of the gate of the temple, from outside wall to outside wall, is taken as 1, its full height will be 2, and the doorway $\varphi^2 \times 1.2$, or 3.1416; again the value of π, correct to four decimals.

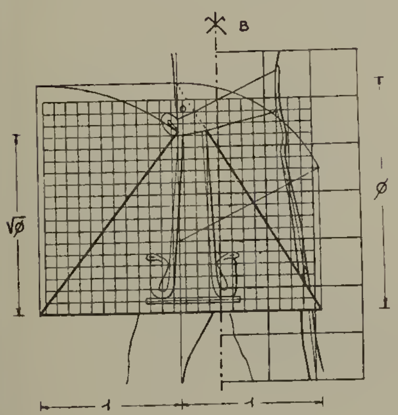
En passant, Schwaller notes the curious coincidence that the Greeks should have adopted for the relation of diameter to circumference the symbol of π, which looks just like the Egyptians' doorway.

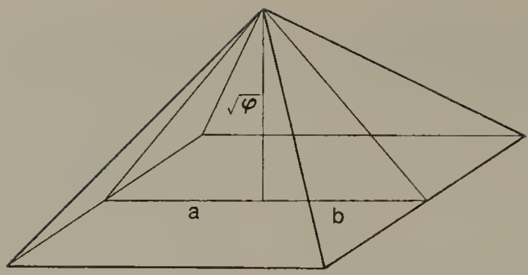
Even more extraordinary is Schwaller's resolution of the symbolic meaning of the triangular loincloth worn by the Pharaohs. Schwaller checked several score of these royal napkins for hermetic significance and found that they invariably gave two angles whose values were respectively φ and $\sqrt{\varphi}$.

Because of the location on the body of the royal napkin—similar to the Masonic apron of today—its phallic character, says Schwaller, was unmistakable.

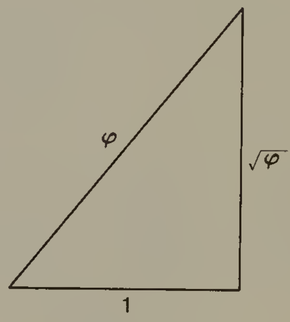
In the Great Pyramid the φ relation is found in the triangle formed by the height, the half base, and the apothem; that is to say, in the basic *cross section* of the structure.

Schwaller de Lubicz measured scores of triangular royal napkins and found that lower angles were invariably φ and $\sqrt{\varphi}$.

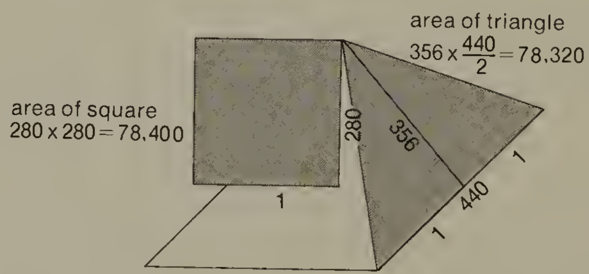




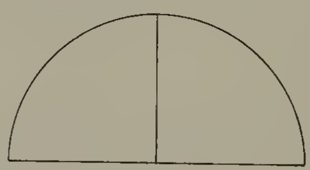
These proportions create a relation between the sides of the triangle such that if the half base is 1, the apothem is φ and the height is $\sqrt{\varphi}$.

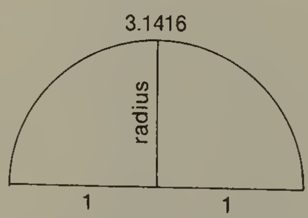


This relation shows Herodotus' report to be indeed correct, in that the square on the height of the Pyramid is $\sqrt{\varphi} \times \sqrt{\varphi} = \varphi$, and the areas of the face $1 \times \varphi = \varphi$.



The simplicity of the system incorporated in the Pyramid makes child's play of the complexities of mathematical map projection. All one need understand is that π is the unchanging value which links a straight diameter to a curved circumference.*

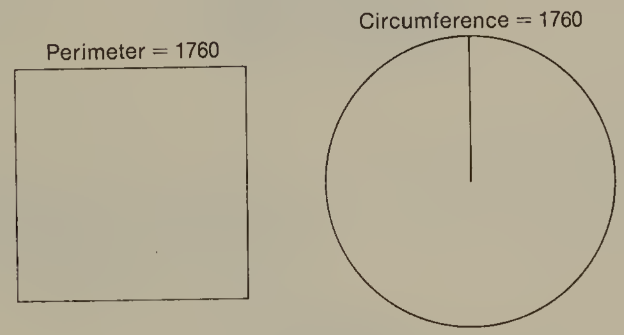




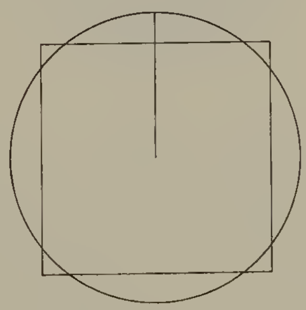
* π times the diameter of a circle will equal its circumference. π times one-half the diameter squared will equal the area of the circle.

Although the squaring of a circle is an insoluble problem if you use the irrational number of π, it is nevertheless practically resolvable as a function of the Golden Number φ. Because $\pi/2 = 2/\sqrt{\varphi}$ to within a thousandth part, π can usefully be taken as $4/\sqrt{\varphi}$.*

The Pyramid is so designed that for all practical purposes it accomplishes the squaring of the circle. The Pyramid's base is a square whose perimeter is equal to the circumference of a circle whose radius is the Pyramid's height.†



Superimpose the square on the circle and you get not only an interesting but an extremely useful diagram consisting of the perimeter of the Pyramid and the circumference of the circle it represents.



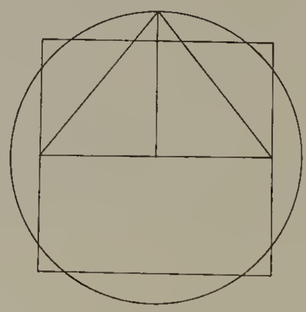
* The following examples are included for the sake of those who might doubt the mathematics; they are not essential to the narrative.

Because π also equals $\varphi^2 \times 6/5$, it is possible to use the Fibonacci series to obtain an accurate relation for the diameter of a circle to its circumference without recourse to π. In the Fibonacci series of 21–34–55, if 21 is taken as the diameter of a circle, its circumference will be $55 \times 6/5$, or 66, accurate to one-thousandth part, giving the Great Pyramid value for π of 22/7, or 3.14285.

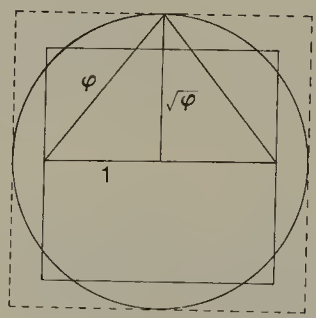
Higher numbers in the Fibonacci series provide increasingly finer values in whole numbers accurate to one ten-thousandth part. Prolonging the series, which goes . . . 89–144–233–377–610 . . . a diameter of 144 gives a circumference of $377 \times 6/5$, with a value for π of 3.1415; a diameter of 233 gives a circumference of $610 \times 6/5$, with a value for π of 3.1416; and so on.

† Four times the base of 440 cubits equals 1760 square cubits. The height of 280 cubits $\times\ 2\pi$, or twice 22/7, equals 1760 square cubits.

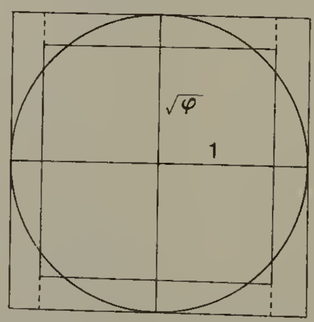
Three more lines will provide the mathematically correct cross section of the Pyramid of Cheops.



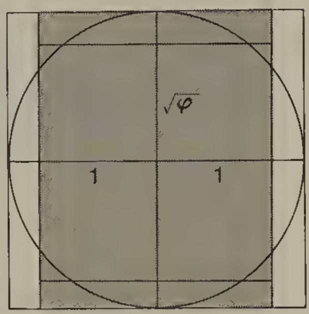
By simply enclosing the diagram in another square, and inserting the φ relationship as it exists in the Pyramid, a key is obtained for readily translating spherical surfaces into flat ones of equal area.



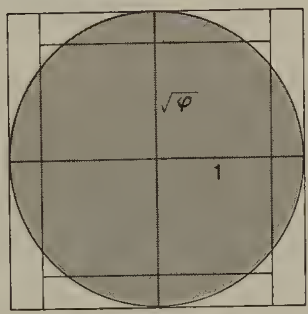
To obtain a rectangle equal in area to the basic circle, two sides of the smaller square need merely be prolonged till they touch the sides of the larger square.



The area of the rectangle is its length times its width, or $2\sqrt{\varphi} \times 2$, which is $4\sqrt{\varphi}$.

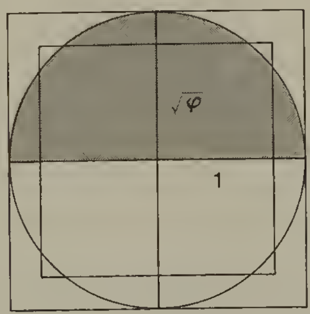


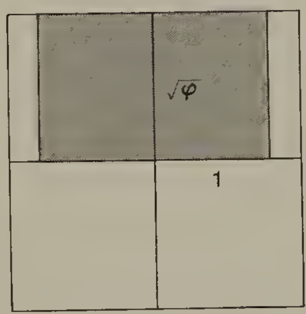
The area of the circle is πr^2, or $\pi\varphi$ in this case, the radius being $\sqrt{\varphi}$. But since $\pi = 4/\sqrt{\varphi}$, the area is also $4\sqrt{\varphi}$, the same as the rectangle.



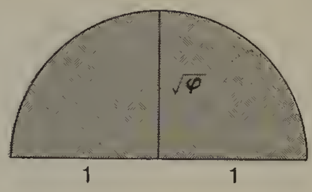
Thanks to the Pyramid's structure it is thus possible, with virtually no mathematics, to draw a rectangle (from the base of the Pyramid and twice its height) which will be equal in area to a circle on its height. This leads directly to being able to draw a rectangle or triangle equal to a spherical quadrant, resolving the main problem of the map maker with the same simplicity.

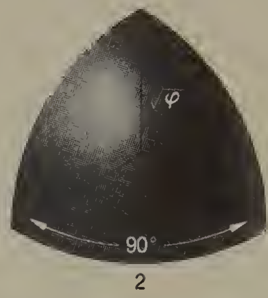
As the whole circle equals the whole rectangle, half the circle is equal to half the rectangle.



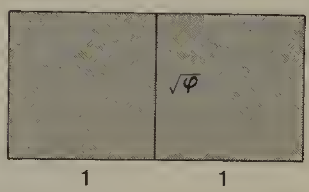


But half a flat circle is also mathematically rigorously equal in area to the spherical surface of a quadrant of 90°.





Thus a rectangle of height $\sqrt{\varphi}$ and a base of 2 is equal to a quadrant of height $\sqrt{\varphi}$ and an arc of 2.



Area = $2\sqrt{\varphi}$

Area = $2\sqrt{\varphi}$

It is thus possible to translate a spherical quadrant of 90° of longitude onto a flat Mercator surface of equal area or onto an undistorted triangle of exactly half that area.

With the Pyramid, the ancient Egyptians had not only squared the circle but effectively cubed the sphere.

XVI. SCIENTIFIC SURVEY GIVES GEOGRAPHICAL PROOF

That the Pyramid of Cheops was intended to represent a geographical rendition of the northern hemisphere was indicated repeatedly in the ancient texts, as Jomard had noted. From a careful analysis of classic Greek authors, Stecchini narrowed the sources of information on the Pyramid —other than Herodotus—down to a single Greek writer, Agatharchides of Cnidus, a peripatetic philosopher who was guardian to the king of Egypt at the end of the second century B.C.

Agatharchides reported that the length of one side of the base of the Pyramid corresponded to 1/8 minute of degree, and the apothem to 1/10 of a minute.

Jomard had hit upon this information and used it to find an almost exact solution: his apothem of 184.722 meters multiplied by 10 gave a minute of 1847.22 meters, which is almost precisely the length of a minute of latitude at the twenty-ninth parallel. This led Jomard to assume that the builders of the Pyramid had chosen to use the mean latitude value for all Egypt, which he figured to be 27° 40′.

What Jomard could not know was that the most ancient geodetic center of Egypt had been placed at 27°45′, precisely halfway between Syene on the Tropic, and Behdet on the coast of the Delta. He could not have known this because the site of the new capital of the young pharaoh Akhnaten called Akhtaten or "Resting point of Aten" had not yet been discovered near the modern Tell el-Amarna, nor had the young Champollion yet deciphered the hieroglyphs.

A stone text found in the ruins of Tell el-Amarna relates to the foundation of the capital. One of the surviving copies is about twenty-five feet high. It gives the length of the new capital as being limited by two boundary stones meticulously set "for eternity" at the extraordinary distance of 6 *atur,* 3/4 of a stadium and four geographic cubits. This indicates an intended accuracy of one in ten thousand. As Stecchini interprets the text, it not only specifically indicates 27° 45′ as the ancient geodetic center of Egypt, but gives the length of the *average* degree of latitude between the equator and the pole to be 240,715 cubits of 111,136.7 meters. The modern estimate is 111,134.1 meters.

As Stecchini points out, Akhnaten's geodetic reform was a return to the predynastic system of computing the length of Egypt in geographic cubits rather than royal cubits.

Had Jomard been able to measure all four sides of the base of the Pyramid with the precision of modern surveyors, he would have realized that the ancient Egyptians intended—quite logically—for the *base* of the Pyramid to indicate the value of a degree at the equator (where they apparently considered the earth to be a true circle and a degree of latitude to be equal to a degree of longitude).

Up until the time of World War I there still remained considerable doubt as to the actual lengths of the four sides of the base of the Pyramid. Petrie had encountered great difficulty in delimiting the exact position of the corners, from which several blocks had been removed. But in 1925, Ludwig Borchardt, then director of the German Institute of Archeology in Cairo, asked to borrow the instruments of the Government of Egypt in order to make a new survey of the Great Pyramid. Borchardt hoped that a really accurate set of measurements might at last separate the strands of fact from fiction in the matter of the geometry of the Great Pyramid.

The Egyptian government agreed to make the survey on condition that Borchardt first clear all the remaining debris from around the base. When this was accomplished, an engineer named J. H. Cole was employed to make a thoroughly scientific survey. Cole used an extensive sounding of the foundations, and was finally able to ascertain to within millimeters the original position of each of the four corners.*

* These were published in *Determination of the Exact Size and Orientation of the Great Pyramid of Giza* (Survey of Egypt, paper 58). Cole gives 230.215 meters (± 6 millimeters) for the south side; 230.454 meters (± 10 millimeters at the west end and ± 30 millimeters at the east end) for the north side; 230.391 for the east side; and 230.253 for the west side.

Stecchini surmises that the apparent discrepancies of a few inches in the lengths of the four base lines might not have been errors on the part of builders who could set casing stones with the precision of a modern optician and dig a descending passage of over 350 feet with a mere 1/4 inch error in azimuth, but *intentional variants* for a definite purpose.

Were the difference in length of the sides to be explained not as the result of imprecision, but as intended skill, it would be possible to explain the lack of squareness in the angles of the base of the Pyramid. In Stecchini's opinion, the Pyramid's sides may have been deliberately planned with angles differing from a right angle in multiples of 15″ in order to correspond to a second time in the apparent motion of the stars.

Ludwig Borchardt's measurements of the angles of the base of the Great Pyramid.

If the base of the perimeter is intended to be 1/8 minute of degree, twice the perimeter will equal one minute.

Cole's mean figure for twice the perimeter is 1,842.91 meters. The modern figure for a minute of latitude at the equator is 1,842.9 meters.

From the figures it is evident that the ancient Egyptians knew that a degree of latitude is shortest at the equator and lengthens as it approaches the pole.

Schwaller de Lubicz arrived at the same conclusion by noting that the Egyptians counted a minute of arc as being 1000 brasses, or 1000 fathoms of 6 feet. According to Schwaller the brasse was a strictly geodetic measure that varied between 1.843 meters and 1.862 meters, depending upon the degree of latitude at which it was figured. The concordance is remarkable in that a minute of latitude is 1,842.9 meters at the equator, and 1,861.65 at the pole.

Stecchini's analysis of the ancient texts also helps resolve the problem of the apothem of the Pyramid which was said to be 1/10 of a minute, or 600 feet.

Agatharchides of Cnidus reported that the Pyramid of Cheops was topped by a pyramidion, or capstone, of four cubits which could be included in a calculation or excluded depending on the problem to be resolved. Like the obelisks, most pyramids were capped by a pyramidion of precious metal that would sparkle in the first rays of sunlight.

Pyramidion, or capstone, from the pyramid of Amenemhet III (1849–1801 B.C.) at Dashur. It is of polished black granite with winged sun disk of gold and carved hieroglyphs.

Discounting 4 royal cubits for the pyramidion leaves an apothem of 352 cubits of .525 meter each, and solves the whole riddle of the cubits in the Pyramid.

It gives an apothem of 600 geographic feet of .308 meter, or 400 cubits of .462 meter. It also gives an apothem of 500 remen, 220 megalithic yards, 320 *pyk belady* cubits, 100 brasses, 60 decapodes, 40 cannes, 10 short schoenia, 6 plethra, or 1 stadium. It is one tenth of a minute of latitude measured at the parallel of the Great Pyramid.

Jomard had been lucky when he found 600 feet to the apothem of the Pyramid. He had measured short, not knowing about the pyramidion, and come up with a very close 184.72—which was derided by his colleagues.

Six hundred feet of .308 meter is 184.8 meters. The modern estimate of 1/10 minute of latitude at the parallel of the Great Pyramid is 184.75.

But Jomard had been absolutely right when he said he found 500 old Egyptian cubits of .4618 meter in the base of the Pyramid, and 400 larger *pyk belady* cubits of .5773 meter. These cubits are based on what Stecchini found to be the oldest foot in antiquity, the geographic foot which was still used in classical Greece and which survived in Europe down to our Middle Ages: in Egypt it was still common when Jomard arrived. Stecchini found evidence of this foot in temples in Mesopotamia in the preliterate era as early as 3500 B.C. The same geographic foot forms the edge of a cube or *artaba* which was the standard unit of grain measure in the Near East down to the Persian Empire.

It is now clear that the minute differences that appear in this foot in Persia, Greece, Mesopotamia and Egypt are due to the fact it was computed astronomically, varying a mere fraction of a millimeter depending on the latitude at which it was measured.

The façade of the Parthenon is 100 geographic feet of .3082765 meter, or 1 second of arc at the latitude of Athens, which is 37° 58′. At the equator a foot is a millimeter less, or only .30715 meter; at the mean latitude of Egypt, at 27° 45′, it is .307795. At the latitude of the Great Pyramid it is what Jomard found it to be: .3079. One and one-half of these feet made a geographic cubit of .4618, the same cubit Jomard found in current use when he arrived in Egypt, and which had been current since the time of Al Mamun (by means of which the Arabs could have correctly computed the circumference of the earth).

If you divide the earth into 360 degrees, and again into 60 minutes of 60 seconds, the result is one second of arc, or 100 geographical feet. Translated into meters by multiplying by .308 the result is 39,916.8 kilometers, which is within one quarter of one percent of our modern earth circumference of 40,000 km. By Akhnaten's average degree it was an even closer 40,009.32 kilometers.

Taylor had come within a hair of resolving the problem when he correctly postulated that the builders of the Pyramid had taken a great circle of 360 degrees and divided it first into 60 minutes and then into 60 seconds for a total of 1,296,000 seconds of arc.

Searching for a unit among the ancient measures that would fit this total, Taylor came up with what he called the short Greek foot, or Ptolemaic foot, which was 1.0101 of an English foot. One hundred of the Ptolemaic feet to a second of arc gave an earth circumference of 129,600,000 Ptolemaic feet, or 130,908,960 English feet, which was a bare one thousandth short of the estimate of the earth's circumference in Taylor's day.

Taylor's Ptolemaic foot was, of course, none other than Jomard's foot of .3079, from which was derived the cubit of .4618 meter, 500 of which fit the base of the Pyramid.

But Taylor couldn't make the sums come out because he was using the base computed by Le Père and Coutelle, which was about six feet too long, and into which neither the Ptolemaic foot nor the cubit would fit.

For lack of Cole's precise survey, poor Taylor, who was hot on the scent, was obliged to discard Jomard's thesis that 500 cubits of .4618 fit the base of the Pyramid along with the idea that it was intended to represent 1/8 minute, or 1/480 of a geographical degree. That Taylor was loath to do so is clear from his comment that he was sure that "it is in this direction, if any, that we may hope to find a satisfactory answer to the question: why was the Great Pyramid built?"

Instead, Taylor pursued the confusing idea that the Pyramid had been intended to indicate a polar axis for the earth of 500,000,000 Pyramid inches, and that the Egyptians had measured the base of the Pyramid in units to fit a solar year of 365.2322 days.

Piazzi Smyth, who also sensed there was truth in Taylor's probings, followed him into this apparent cul-de-sac.*

* Even so Taylor and Smyth may have been on the track of a solution. Taylor suggested that the circumference of the earth had been measured in Ptolemaic feet and common cubits, whereas the *polar* axis had been measured in inches and sacred cubits. In his recent *Historical Metrology,* Algernon Berriman supports Taylor's hypothesis by showing that whereas a "sacred" cubit of 25.064 inches is the ten millionth part of the earth's polar radius, a "royal" cubit of 20.6265 inches is a fraction of the circumference of the earth in that it is 206,265 sexigesimal seconds of arc: in other words the radius laid along a circumference of 1,296,000 seconds becomes a radian of 206,265 seconds.

Why Taylor, Smyth, Petrie and Davidson could not, or would not, avail themselves of Jomard's figures is a mystery. The twenty-one volumes of the *Description de l'Egypte* are bulky, hard to come by, and harder to handle (they are in leatherbound folio and double [Atlantic] folio, weighing as much as fifty pounds), and the information is scattered, without an index, through hundreds of pages of text, mixed with thousands of incongruous or irrelevant facts and figures; but the hard facts and figures are there; and Jomard's handling of them is lucid.

More surprising is the dogged determination of Egyptologists and writers on the Pyramid to continue to overlook or deny these facts. Even so eminent an Egyptologist as Jean Philippe Lauer, architect for the Egyptian Department of Antiquities, who certainly had ready access to *Description de l'Egypte* (his father was a curator of the Biblioteque Nationale) continued to dispute Jomard's conclusions even as late as after World War II.

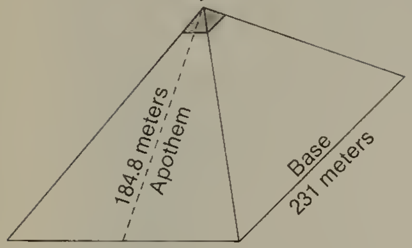
In his book *Le Problème des pyramides,* Lauer writes: "We must recognize that all this pretty hypothesis rests on inexact data. The cubit of .462 meters derived by Jomard from the base and the apothem of the Pyramid appears to be as hypothetical as that of Piazzi Smyth."

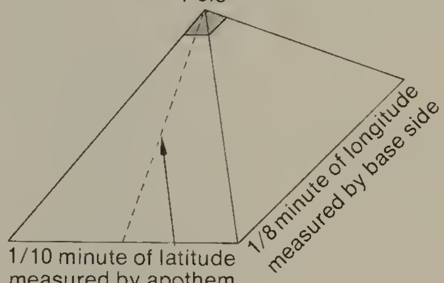
Ironically, the Director of the Department of Egyptian Antiquities, M. Etienne Drioton, who wrote the preface to Lauer's book, complained that it is because of their opposition to such theories as Jomard's that Egyptologists are being treated like "naif, blind, refractory dabblers in science whose quiet routines have been disturbed!"

That Jomard's cubit of .4618 or .462 meter is incorporated 500 times in the base of the Great Pyramid and 400 times in the apothem is no longer a matter of debate. Thanks to Cole it is a simple matter of multiplication. Even the confusing report of the Roman historian Pliny that the base of the Pyramid measured 833 1/3 feet and its apothem 666 2/3 feet becomes easily resolvable. The incongruity is rational when it is realized that Pliny's foot was simply 9/10 of a geographic foot. In other words, 833 1/3 of Pliny's feet turn out to be 750 geographic feet, or 500 geographic cubits.

The 500 cubits base is equal to 230.3625 meters (almost exactly Cole's figure) if measured by a geographic cubit computed at the equator, and 230.925 (almost exactly Jomard's figure) if measured by a cubit computed at the parallel of the Great Pyramid. The difference in cubits—which amounts to a fraction of a millimeter—makes no difference whatsoever to the relative values of the other units. For the sake of clarity the accompanying chart uses a cubit of .462 and a foot of .308.

Ancient Units of Measure Contained in the Great Pyramid in Round Numbers or Exact Fractions





The units of measure, from the short foot of .300 meter, through the various cubits, brasses, megalithic yards, parasangs, and miles, all fit perfectly in either round numbers or exact fractions into the base and apothem of the Great Pyramid because they are *all* fractions of a correct geographical degree of latitude or longitude at the equator. The Great Pyramid is thus a true standard of measure and a scale model of the northern hemisphere.

Apothem	Base
616 Egyptian feet of .300 meter	770 Egyptian feet
600 Greek or geographic feet of .308 meter	750 Greek feet
500 remen of .3696 meter	625 remen
400 geographic cubits of .462 meter	500 geographic cubits
352 royal cubits of .525 meter	440 royal cubits
320 *pyk belady* of .5775 meter	400 *pyk belady*
275 megalithic yards of .84 meter	220 megalithic yards
100 brasses or fathoms of 1.848 meters	125 brasses or fathoms
60 decapodes or rods of 10 feet	75 decapodes
40 rods of 15 feet	50 rods of 15 feet
6 plethra	7.5 plethra
1 stadium of 600 feet (.308)	1 1/4 stadium
1/10 of a mile, or angular minute	1/8 mile or minute
1/600 of a geographic degree	1/480 of a degree

Agatharchides was quite right when he quoted ancient Egyptian sources as saying that the base of the Pyramid was intended to be 1/8 minute of degree at the equator. 500 of Jomard's cubits multiplied by 8 for a minute, by 60 for a degree and 360 for a circumference, equal 86,400,000 cubits.

Relation of the Ancient Egyptian Foot (of .308 meter) and Multiples Thereof to the Circumference of the Earth

In the circumference there are			129,600,000 feet
There are 360 degrees		of	360,000 ft.
3,600	great Egyptian schoene	of	36,000 ft.
21,600	miles	of	6,000 ft.
216,000	stadia	of	600 ft.
1,296,000	plethra	of	100 ft.
2,160,000	schoenia	of	60 ft.
8,640,000	cannes	of	15 ft. (1) cubit
12,960,000	decapodes	of	10 ft.
21,600,000	brasses or ogyie	of	6 ft.
86,400,000	cubits	of	1 1/2 ft.
129,600,000	feet	of	1 ft.
518,400,000	palms	of	1/4 ft.
2,073,600,000	fingers	of	1/16 ft.

Obelisks outside the temple of Amon-Ra at Karnak which was oriented to the solstice. By measuring their shadow at the solstice it was possible to extrapolate the meridian circumference of the planet.

This reveals the source of the Egyptian cubit and foot. There are 86,400 seconds in a day of twenty-four hours, or the time it takes the earth to revolve on its axis. So the distance traveled by the earth at the equator in one second is exacly 1000 of Jomard's cubits.

The builders of the Great Pyramid gave its base a length corresponding to the distance the earth rotates in 1/2 a second. This makes the cubit and the foot doubly earth commensurate: the cubit was equal to 1/1000 of a second of time, the foot to 1/100 second of arc.

How could the ancient observers have established this fact? To compute the polar circumference of the earth the ancients used the sun and the shadows cast by obelisks. To compute the equatorial circumference they observed the passage of stars across fixed points such as obelisks. For the polar circumference they needed merely to measure the distance between two obelisks a few miles apart and the difference in the length of the shadows of the obelisks.

There was no need to measure such a vast distance as separated Alexandria from Syene. The difference in latitude, and hence the fraction of arc separating any two meridian obelisks, can be obtained by the relation of the obelisk's shadow to its height *when measured at the moment of the solstice or equinox.*

To obtain the equatorial circumference, an observer at the base of an obelisk at the thirtieth parallel could signal the appearance on the eastern horizon of a zenith star to an observer at a measured distance in the western desert where the tip of the obelisk would be on the horizon. Noting the interval of time between the signal from the first observer and the moment the star appeared on *his* horizon (and knowing the earth moves through 1,296,000 seconds of arc in 86,400 seconds of time), the observer could figure the equatorial circumference of the earth. At the thirtieth parallel it would vary from the equator by the cosine value of 30° or $\sqrt{3/2}$.

It was thus simply a matter of deciding what *unit of measure* to use in computing these lengths. An observer looking up at the Grand Gallery from a point far enough back to subtend an angle of 2° at the opening, could then note the time it took a star on the celestial equator to cross the opening. He would then possess the necessary data to relate the width of the Grand Gallery to the circumference of the earth.

From the figures it is evident that the ancient astronomers took the earth's daily rotation on its axis as a unit of time and made 1000 cubits the distance traveled by the earth in a second of time.

With a series of obelisks they could physically measure minutes and seconds of meridian arc, along a meridian and extrapolate the distorted distance to the pole.

From many scattered texts Stecchini has deduced that the Egyptians had worked out a simplified method of computing the change in each degree from equator to pole by means of an additive and subtractive series. The geographic cubit was also ideal in that it gave an admirable length for Egypt of 1,800,000 cubits. From Behdet to Syene is 7 1/2 degrees, or 1/48th of the earth's circumference of 86,400,000 cubits.

These cold facts should settle one whole facet of the mystery of the Great Pyramid. Clearly the ancient Egyptians knew the shape of the earth to a degree not confirmed till the eighteenth century when it was established that Newton was correct in his theory that the planet was somewhat flattened at the poles, and they knew the size of tne earth to a degree not matched till the middle of the nineteenth century when it was first remeasured with comparable accuracy by the German geodesist Friedrich Wilhelm Bessel. It is equally evident that they could divide a day into 24 hours of 60 minutes and 60 seconds, and produce a unit of measure that was earth commensurate—just as Taylor, Smyth and Jomard had surmised.

So now that Cinderella's foot has been found to fit her lost slipper without pinching or effort, to go on lengthening and shortening the carbuncled feet of her ugly sisters would indeed be like M. Drioton's naif, blind and refractory dabblers in science. On the other hand, a little cooperative effort by experts on ancient Egypt and Sumeria might help bring to light many more fascinating details of the early history of science.

Sexagesimal, Decimal and Quaternary Relations of Ancient Egyptian Units of Measure

60 palms	= 1 canne
60 feet	= 1 short schoenion
60 decapodes	= 1 stadium
60 short schoenia	= 1 Hebraic mile
60 plethra	= 1 Egyptian mile or minute of degree
60 stadia	= 1 grand schoenion
60 Egyptian miles	= 1 degree or moira
60 grand schoenia	= 1 sexagesime
60 sexagesimes	= 1 circumference of the globe
10 Egyptian feet	= 1 decapode
10 Egyptian cubits	= 1 canne or Egyptian pole
10 orgyie or brasses	= 1 short schoenion
10 decapodes	= 1 plethron
10 cannes	= 1 side of land unit of 100 cubits (aroura?)
10 short schoenia	= 1 stadium
10 stadia	= 1 Egyptian mile
10 grand schoenia	= 1 degree of longitude
4 fingers	= 1 palm
4 palms	= 1 foot
4 cubits	= 1 orgyie or brasse
4 cannes	= 1 short schoenion
4 sides of 100 cubits (aroura?)	= 1 stadium

Number of Greek or geographic feet of .308 meters.

In circumference of world	360,000 × 360
In a geographical degree	360,000
In a long schoene	36,000
In a geographical minute (or mile)	6,000
In a stadium	600
In a brasse	6
In a cubit (geographical)	1 1/2

Geodetic Values Incorporated in the Dimensions of the Great Pyramid

	Base	Perimeter	Apothem
Egyptian foot of .300 meter	770	3080	616
Greek or geographic foot of .308 meter	750	3000	600
Greek or geographic cubit of .462 meter	500	2000	400
Royal Egyptian cubit of .525 meter	440	1760	352
Pyk belady cubit of .5775 meter	400	1600	320
Megalithic yards of .84 meter	275	1100	220
Brasse of 6 geographic feet (1.848 meters)	125	500	100
Decapodes of 10 geographic feet	75	300	60
Plethra	7.5	30	6
Stadium of 600 geographic feet	1 1/4	5	1
Miles or minute of degree	1/8	1/2	1/10
Parasangs	1/24	1/6	1/30
Long schoene	1/48	1/12	1/60
Geographical degree	1/480	1/120	1/600

XVII. DECLINE OF ANCIENT KNOWLEDGE

What remains a mystery is how all the advanced science of the ancient Egyptians could have been lost for so many centuries.

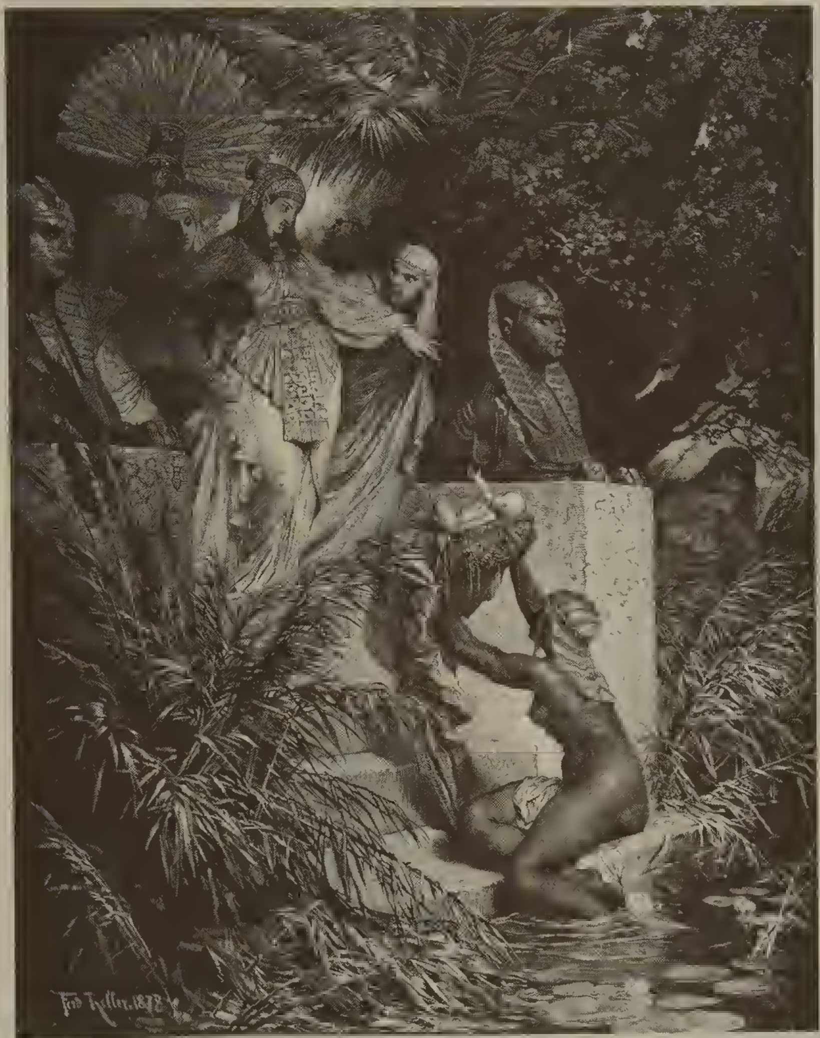
In his reconstruction of preclassic geographical data, Stecchini has traced an advanced science of geography based on accurate astronomical tables which were kept up to date all the way down to the beginning of the first millennium B.C. He has established that the later Babylonians still had excellent maps for their area of the world between the thirtieth and thirty-sixth parallels, made in segments of 6° of latitude by 7° 12′ of longitude, which gave them perfect squares because of the diminished length of a degree of longitude between those parallels.

This same system, says Stecchini, was in use as late as the reign of Darius the Great of Persia, whose empire, centered on the arbitrary geodetic point of Persepolis, ran precisely 3 units of 7° 12′ east of the Egyptian meridian and three units of 7° 12′ west of the Indian border.

But errors were already creeping into the geography because of a lack of direct observation of celestial phenomena and because of the reliance by geographers on ancient astronomical data that were no longer up to date.

As an explanation for this regression of geographic science, especially during the Hellenistic period, and thereafter almost to modern times, Stecchini suggests that when Alexander the Great destroyed Persepolis in the fourth century B.C. he may have exterminated the Egyptian geographers imported by the Persians to do their figuring, and that when he dismantled the center of Egyptian science at Heliopolis in order to build his own capital at Alexandria, he may have compounded the damage.* The destructions of Persepolis and Heliopolis were considered by Alexander

* Heliopolis, the On of the Bible, was considered the greatest university in the world. It had existed since much earlier times under the domination of the priests, of whom there were said to be 13,000 in the time of Rameses III, 1225 B.C. More than 200 years earlier, Moses was instructed at Heliopolis "in all the wisdom of the Egyptians," which included physics, arithmetic, geometry, astronomy, medicine, chemistry, geology, meteorology and music.



Romantic nineteenth-century depiction of Moses being found in the bullrushes.

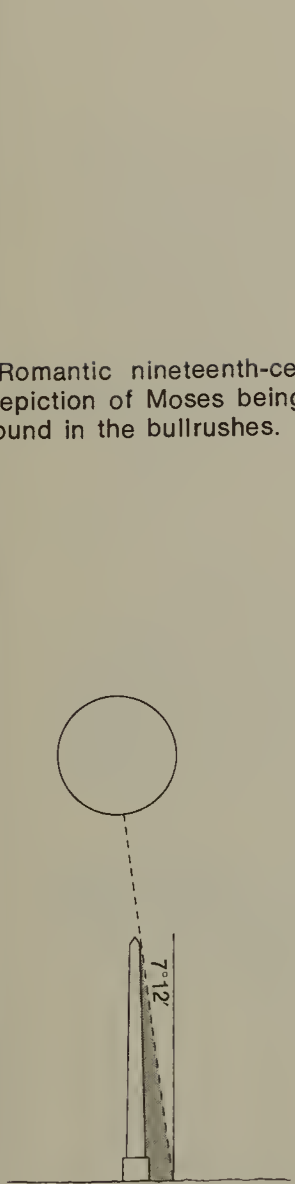
essential in order to destroy the geographic, and therefore the political, basis of the older empires.

Stecchini's evidence shows that far from being the great innovators of geographical knowledge, the Alexandrine geographers of the next half millennium, such as Eratosthenes, Hipparchus and Ptolemy were mainly handling and mishandling traditional data of an advanced science that preceded them, and which they only understood in part.

Current scholarship keeps repeating that the circumference of the earth was first measured by Eratosthenes, the Greek who was put in charge of the library of Alexandria, but it is clear that Eratosthenes merely cited old Egyptian information about the circumference of the earth without really understanding it.

Eratosthenes claimed to have found that a degree of latitude was 700 stadia. This, says Stecchini, was nothing but the traditional Egyptian datum of 14 *atur* to 50 stadia.

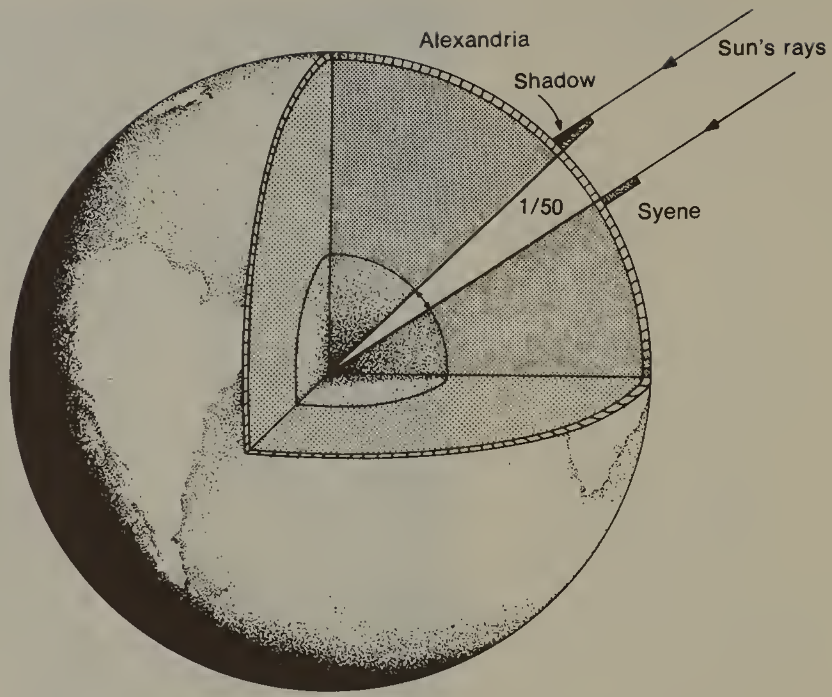
Eratosthenes also claimed to have found by observation that when the sun does not cast a shadow at the southern limit of Egypt, it casts a shadow of 7° 12′ at Alexandria.



Gnomon at Alexandria at summer solstice.

Eratosthenes is said to have measured the circumference of the earth by noting the angle of the sun's rays at Alexandria at the summer solstice, the day he knew the sun would be directly overhead at Syene on the tropic of Cancer.

Finding a shadow angle of 7° 12′ at Alexandria, he deduced the distance from Alexandria to Syene to be 7° 12′ of the 360° circumference of the globe. As 360/7° 12′ = 50, Eratosthenes multiplied the 5000 stadia he believed to separate Alexandria from Syene by 50 and got a figure of 250,000 stadia for the circumference of the earth. Because his various errors canceled out, he was credited with a scientific answer.



In reality Eratosthenes had read the old Egyptian data (then more than 2000 years old) to the effect that the tropic was at latitude 23° 51′ and that the sun did not cast any shadow at Elephantine. What he did not know, and could not measure, was that by his time the tropic had shifted to 23° 45′. Nor did Eratosthenes understand the necessity of adjusting his figures according to the apparent semi diameter of the sun; he believed Alexandria to be 7° 12′ north of 23° 51′; he even claimed that Alexandria was on the same meridian as Elephantine, whereas they are apart by about 3°, or 200 miles of longitude.

Furthermore, Eratosthenes used the "great cubit" of Babylon (532.702 millimeters) to obtain his stadium, instead of the more ancient royal cubit of the Egyptians of 525 millimeters, unaware that the first step taken by the Assyrians when they conquered Egypt in the seventh century B.C. was to substitute their own Mesopotamian cubit for the Egyptian one in order to manifest their own dominion.

On the basis of his research into ancient geography, Stecchini is now convinced that there existed on this planet a people with an advanced mathematical and astronomical science several millennia before classic Greece.

XVIII. WHO BUILT THE PYRAMID? WHEN? AND HOW?

It would be satisfactory to be able to describe the method by which the Great Pyramid was put together, by whom, and when.

But the builders, whoever they may have been, left no description of their method. No one has even found a *later* Egyptian report of how the first pyramids were built. It is only on the basis of shrewd guessing that Egyptologists estimate the stepped pyramid of Saqqara to be the oldest of the Egyptian pyramids and attribute its construction to the legendary architect Imhotep in the reign of King Zoser of the Third Dynasty.

The stepped pyramid of Medûm, which was the first stepped structure to be converted to a true pyramid, is attributed to Cheops' father Sneferu on similarly sketchy evidence; the same goes for the bent pyramid of Dashur.

Lacking solid history, the Arabs (and the Jews) of the Middle East proliferated legend. The most ancient tradition about the Great Pyramid is that it was erected to memorialize a tremendous cataclysm in the planetary system which affected the globe with fire and flooding.

Arab authors recount that the pyramids were built before the deluge by a king who had a vision that the world would be turned upside down, and that the stars would fall from the sky. According to these Arab sources, the king placed in the pyramids accounts of all he had learnt from the wisest men of the times, including the secrets of astronomy, complete with tables of the stars, geometry, and physics, treatises on precious stones, and certain machines, including celestial spheres and terrestrial globes. They also speak of "malleable glass."

The earliest Jewish reports—other than the vague reference in the Bible to "pillars of stone"—is in Josephus, who says the Sethites were inventors of a wisdom which dealt with celestial bodies and their order in the heavens, and that to preserve their wisdom for all mankind they built two monuments—one brick, the other stone—the stone one being still extant in Egypt in Josephus' time, during the first century after Christ.

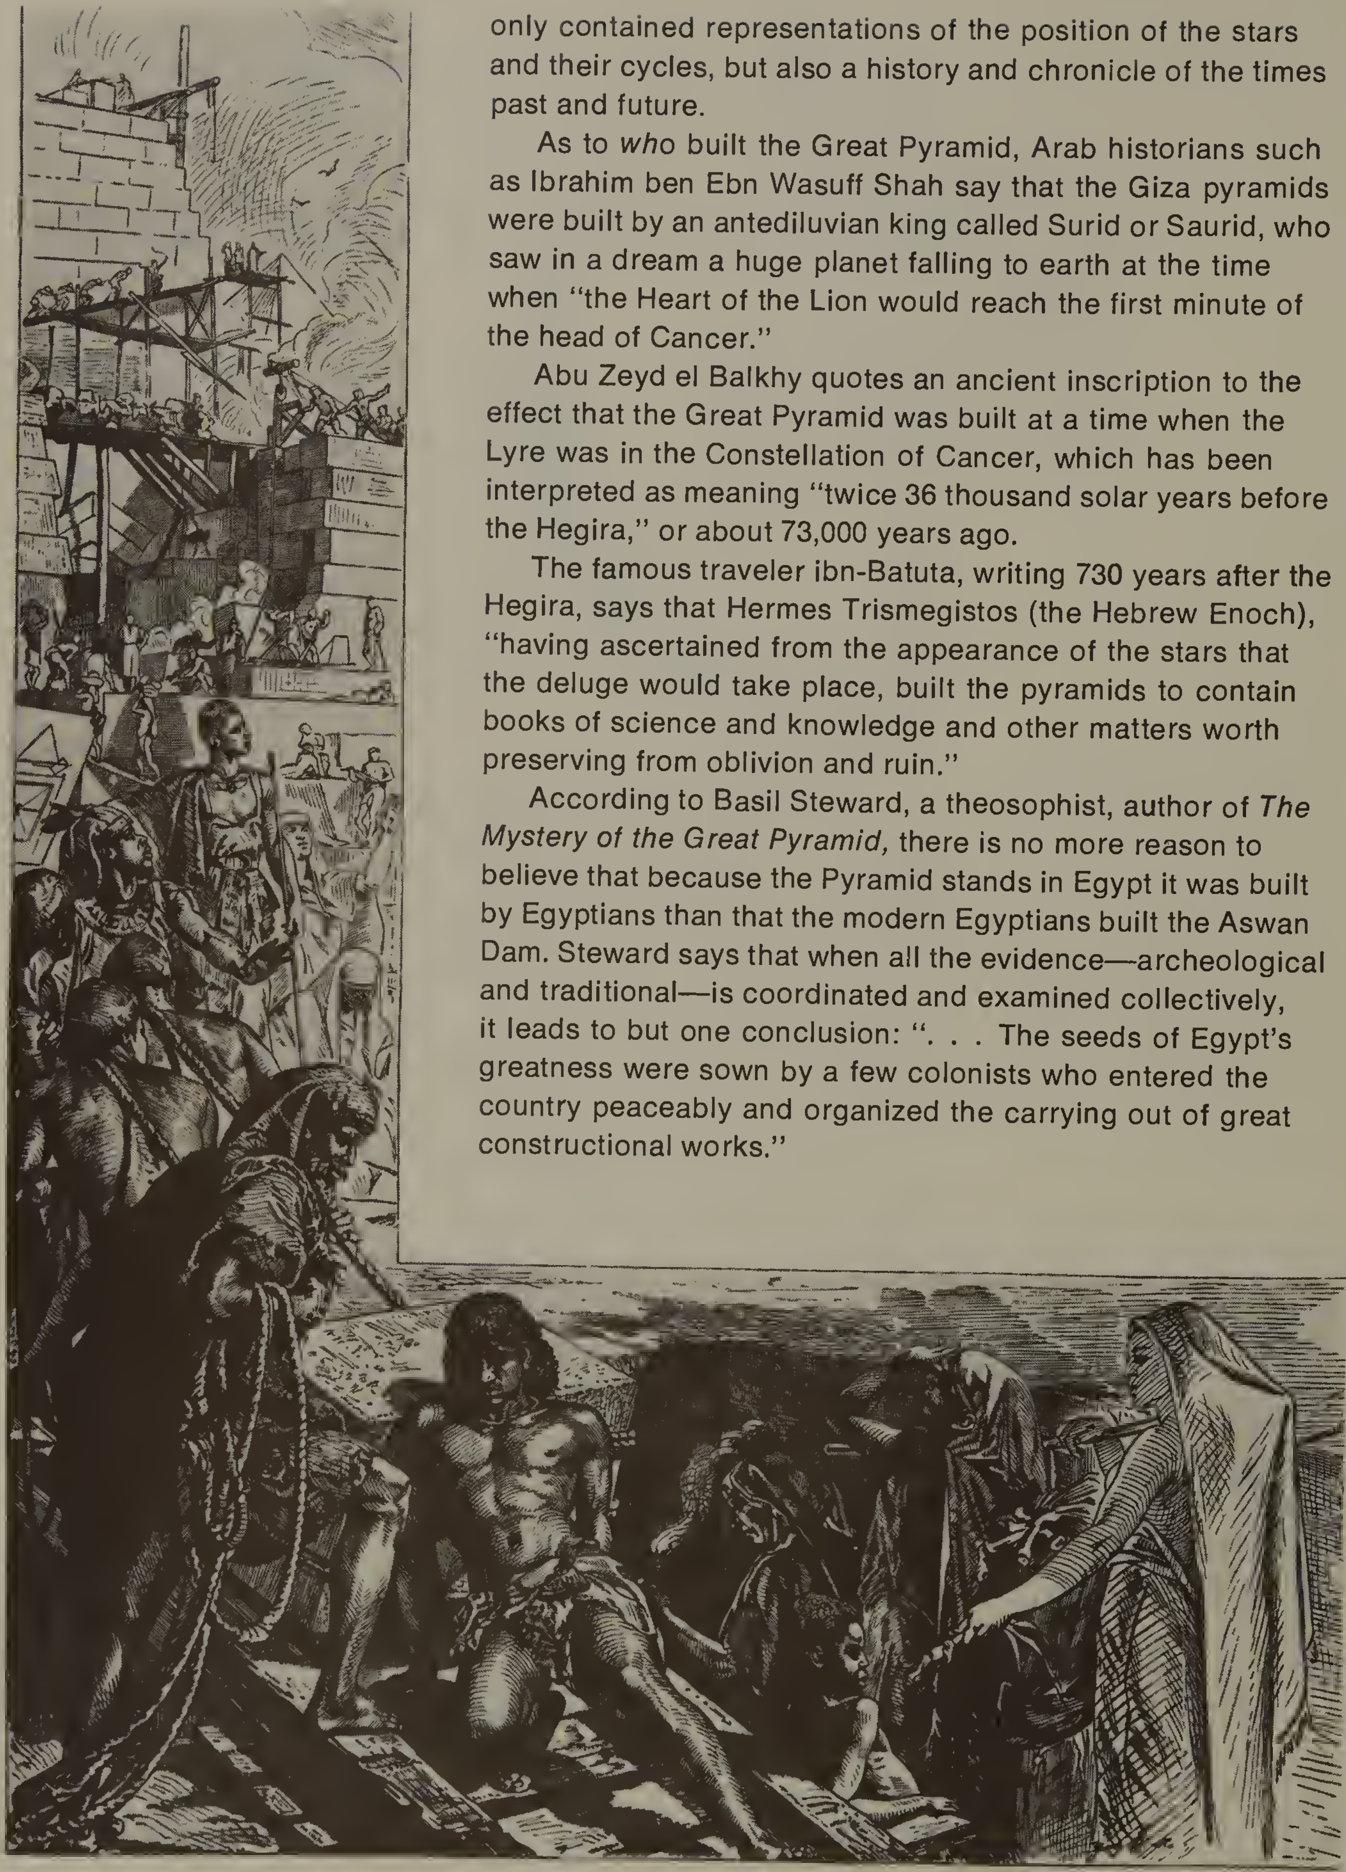
The Arab legends maintain that the Great Pyramid not only contained representations of the position of the stars and their cycles, but also a history and chronicle of the times past and future.

As to *who* built the Great Pyramid, Arab historians such as Ibrahim ben Ebn Wasuff Shah say that the Giza pyramids were built by an antediluvian king called Surid or Saurid, who saw in a dream a huge planet falling to earth at the time when "the Heart of the Lion would reach the first minute of the head of Cancer."

Abu Zeyd el Balkhy quotes an ancient inscription to the effect that the Great Pyramid was built at a time when the Lyre was in the Constellation of Cancer, which has been interpreted as meaning "twice 36 thousand solar years before the Hegira," or about 73,000 years ago.

The famous traveler ibn-Batuta, writing 730 years after the Hegira, says that Hermes Trismegistos (the Hebrew Enoch), "having ascertained from the appearance of the stars that the deluge would take place, built the pyramids to contain books of science and knowledge and other matters worth preserving from oblivion and ruin."

According to Basil Steward, a theosophist, author of *The Mystery of the Great Pyramid,* there is no more reason to believe that because the Pyramid stands in Egypt it was built by Egyptians than that the modern Egyptians built the Aswan Dam. Steward says that when all the evidence—archeological and traditional—is coordinated and examined collectively, it leads to but one conclusion: ". . . The seeds of Egypt's greatness were sown by a few colonists who entered the country peaceably and organized the carrying out of great constructional works."



Sir George Cornewall Lewis, in *An Historical Survey of the Astronomy of the Ancients,* complained of the arbitrary dating used by Egyptologists which he compared to "the manipulation of the balance-sheet of an insolvent company by a dexterous accountant (who, by transfers of capital to income, by suppression or transposition of items, and by the alteration of bad into good debts, can convert a deficiecy into a surplus)." Lewis pointed out that Baron Bunsen and Dr. Lepsius, both eminent Egyptologists, separated the dates of the figure Sesostris by no less than 3793 years, and asked: "What would we think if a new school of writers on the history of France, entitling themselves Francologists, were to arise in which one of the leading critics were to deny that Louis XIV lived in the seventeenth century, and were to identify him with Hercules, or Romulus . . . or Charlemagne."

The only major historian of ancient Egypt was Manetho, a priest, who wrote a history of Egypt for Ptolemy II, but it was lost. Only scraps of it, translated by authors who lived about six hundred years after his death, have survived. His list of dynasties, checked and modified, forms the framework on which the history of Egypt has been reconstructed. But very little detail is known concerning the political history of the first two dynasties, other than the nearly twenty names of Pharaohs listed by Manetho.

Most Egyptologists consider the First Dynasty to have started with Menes about 2900 B.C., and the Fourth, consisting of Sneferu, Cheops, Didoufri, Kephren, and Mykerinos, to have lasted about 120 years from 2680 to 2560 B.C., as the Old Kingdom.

There followed a first intermediate period, a Middle Kingdom from 2052 to 1785 B.C., a second intermediate period, and a New Kingdom from 1580 to 1085 B.C. Post Empire Dynasties XXI to XXVI follow down to 525 B.C.

According to Steward the colonists were probably a band of Asiatic or Euphratean travelers with a very advanced scientific and mathematical knowledge, who entered Egypt and organized the erection of the Great Pyramid, on completion of which they left the country, taking their knowledge with them.

As Steward puts it, the plans for the Great Pyramid were in existence a long time before the actual construction commenced, and were the design of a single individual "who belonged to the Adamic White civilization endowed with moral, scientific and cultural attainments far in advance of all other contemporary civilizations."

Petrie substantiates this theory to the extent that he believes: "the exquisite workmanship often found in the early period (of Egyptian architecture) did not so much depend upon a large school of widespread ability, as on a few men far above their fellows." Referring to the phenomenal accuracy of the work embodied in the Great Pyramid, Petrie says, "It was limited to the skill of one man."

Recent Soviet authors postulate that the Egyptians may have come from Indonesia when their civilization was devastated some ten to twelve thousand years ago as a result of some cosmic catastrophe such as the falling of an asteroid.

According to Peter Kolosimo in *Terra Senza Tempo,* published in Milan in 1969, the Russians have recently brought to light some fascinating secrets of Egyptian archeology.

The Russians are said to have found astrònomical maps of surprising correctness, with the position of the stars as they were many thousands of years ago. The Russians are also reported to have dug up several objects, many not yet identified, including crystal lenses, perfectly spherical, of great precision, possibly used as telescopes. Kolosimo says similar lenses have been found in Iraq and central Australia, but that they can only be ground today with a special abrasive made of oxide of cerium which can only be produced electrically.*

As to the actual dates of construction of the Great Pyramid, apart from the statement that it was built 300 years before the Flood, the legends add little. Egyptologists who worked out that the Fourth Dynasty must have reigned between 2720 and 2560 B.C. believe the Great Pyramid was commenced in 2644; others believe that its construction was begun in 2200 and that 30 to 56 years were required to

* Several attempts to check these data with Soviet academicians have so far been without result.

To Egyptologists Imhotep (above) was a national hero in the reign of King Zoser (below). Imhotep as designer of the stepped pyramid of Saqqara was considered not ony the world's greatest architect but a sage, magician, high priest, medical doctor, diplomat, economist, and poet.

complete it. Still others place the building of the Pyramid a thousand years earlier.

As for the method employed by the builders, the record is equally bleak. I. E. S. Edwards of the Egyptian Department of the British Museum, who spent a lifetime going over the available evidence, points out in his scholarly treatise on the pyramids written in the 1930s that little or no light is thrown on the subject by extant Egyptian records, either written or pictorial.

The result is a congeries of conflicting theories not only about when but about how the Great Pyramid was built.

Nevertheless Egyptologists are in general agreement that the first step required on the Giza plateau was to clear the sand and gravel down to bedrock, then produce a leveled base by removing protuberances and filling in depressions.

R. L. Engelbach, a pupil of Petrie, and for many years Keeper of the Cairo Museum, believes that to obtain a true level the Egyptians surrounded the four sides of the area with low banks of mud from the Nile which they filled with water and through which they cut a network of trenches. The degree of their success is attested by Cole's survey, which found the base rock of the thirteen acre perimeter to be less than 1 inch out of level.

Into the base rock a row of fine rectangular, white limestone slabs were carefully fitted as a pavement on which to lay the first row of casing stones.

When it came to drawing the first straight side, Borchardt and Lauer agree, the correct orientation must have been obtained by means of repeated observations of the rising and setting of circumpolar stars, of which the most likely was alpha Draconis.

The next step would have been to fix the large limestone corner blocks into the rock base so as to form the square corners for the laying of the first rows of casing stones.

Archeologists have had little trouble establishing that most of the limestone blocks for the construction of the Pyramid must have been obtained from the deep Mokattam quarries a few miles across the Nile on the Arabian side of the river, though many of the blocks may have been obtained directly from the Giza hills.

On some of the blocks the names of the quarry gangs were daubed in red ochre, such as "Boat Gang" or "Vigorous Gang."

The nearest source for the 70-ton granite monoliths used to protect the King's Chamber is the Aswan quarry, near Syene about 500 miles up the Nile; from there they were presumably floated downstream on a series of reed barges.

W. Emery has shown that as early as the First Dynasty

The limestone blocks with which the Pyramid is built appear to have been mostly quarried on the spot, or across the Nile in the Mokattam hills about 20 miles away, or from the Turah and Maura quarries opposite Memphis. The 22 acres of casing stones are from the same quarries.

The granite blocks for the Pyramid are believed to have come from Aswan, near the First Cataract, where they were quarried from the face of the rock about a mile from the right bank of the Nile.

Hillsides were hollowed out to provide uniform limestone blocks for the outer casing of the Pyramid.

Limestone was quarried in layers from the top down.

The Aswan granite quarries were 500 miles south of the Great Pyramid.

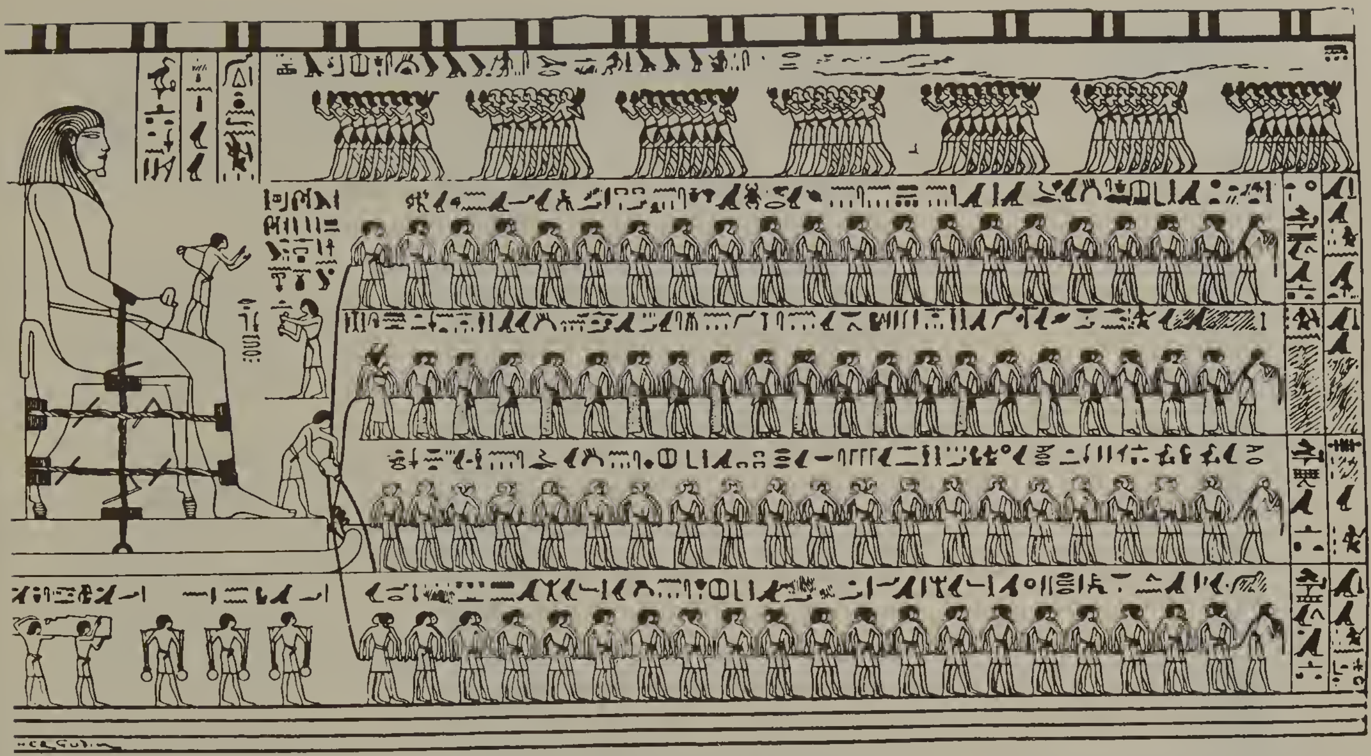
Egyptologists conjecture that in order to cut the stone blocks, the ancient Egyptians must have had some method of tempering bronze unknown in modern times. To cut and finish hieroglyphs and other ornaments would require a tool with an extremely hard-tempered edge.

Few iron tools have been found, probably because of the rapid oxidation of iron in Egypt, where the soil is especially nitrous.

the Egyptians possessed excellent copper tools, including saws and chisels, with which to cut any kind cf limestone, and that their technique of working and polishing granite was developed to a truly remarkable art. As an abrasive material in their sawing operations they are believed to have used moistened quartz sand.

To quarry the rock from the hillside, the Egyptians developed a variety of systems, traces of which can still be found on the Mokattam range. Tunnels were dug several hundred feet into the rock, shelves were cut out between the roof and the block to be detached, then a line was chipped away vertically with a wooden mallet and a copper chisel, which must have been highly tempered by some method unknown today. Wedges were inserted which were moistened till they expanded to crack the rock. Sometimes fires were built along the grooved lines, and water poured on the heated stone to obtain a clear fracture.

The only historical description of the manner in which the limestone blocks were taken to the Pyramid is by Herodotus, who claims that he was informed in Egypt that it took twenty years to build the Pyramid and that levies numbering a hundred thousand men were employed for periods of three months to transport stone from the quarries. Herodotus says that to transport the rough blocks from the edge of the Nile up to the top of the Giza plateau, a great causeway was built, which required ten years to complete. The causeway was said to be 3000 feet long and 60 feet wide, of polished stone, over which sleds could pull the heavy stones.



Several score Egyptians transporting a colossal statue with men harnessed in double rank. Note the timekeeper standing on the statue's knee, and a man pouring liquid on runners to decrease friction.

Commander F. M. Barber, an American naval attaché who was stationed in Egypt at the end of the last century and wrote an informed booklet entitled *Mechanical Triumphs of the Ancient Egyptians,* figured that if the causeway had to rise to a height of 120 feet above the Nile, it would have had an incline of 1 foot in 25, which he considered a very easy grade for a greased stoneway.

Barber estimated that it would take a force of 900 men harnessed in double rank on four draft ropes to drag a 60-ton monolith up such an incline. On the causeway the men would cover a space 225 feet long by 16 feet wide, which Barber considered a sufficiently compact and manageable force.

Barber says that such a force would have no trouble dragging the stone, especially if they were drilled to pull together; he concludes that for this reason men and not animals are pictured hauling wrought stones: men could be drilled to march in absolute cadence to a song or time-keeping instrument. A "one-two-three, surge," says Barber, produces a momentary force represented by nearly the weight of the whole mass of men, or several times their ordinary pulling force. Also, vacancies in the ranks caused by sickness could be filled without materially affecting the drill of the remainder. Cattle could never be so well organized.

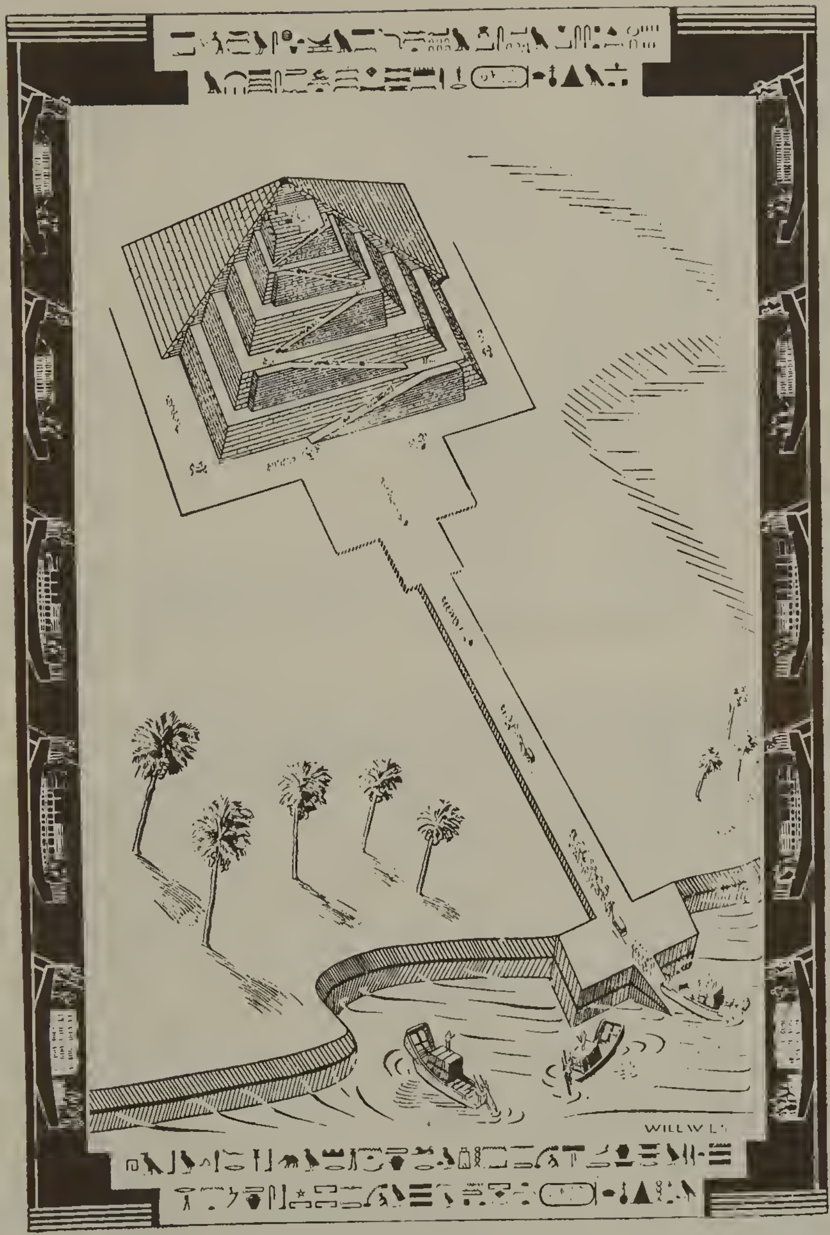
Pictures show Egyptians hauling stone in the manner described by Barber and include a special artisan pouring some sort of grease on the sled runners to reduce friction.

Other Egyptologists have suggested that owing to the great quantity of supplies necessary for building Cheops' pyramid, it was likely that several ramps led from the valley up to the Giza plateau, but very few remains of such possible causeways can now be observed because of modern excavations and the widespread tourist layout.

According to the French scholar E. Amélineau, considerable remains of an inclined plane leading to the pyramid of Kephren still existed at the end of the eighteenth century; and remains of a causeway leading to the pyramid of Mykerinos are still visible today.

The Egyptian archeologist Selim Hassan says that at the edge of the Giza plateau there is a considerable surface composed of large limestone blocks which run in a northeasterly direction and descend to a little less than half the height of the plateau. He believes they may have been part of a construction ramp which was demolished when the Great Pyramid was completed.

Causeway to the pyramid of Kephren.



W. W. Lucker's reconstruction of a pyramid and its causeway to the Nile.

Ahmed Fakhry, another Egyptian archeologist, says that remains of a southern supply ramp composed of rubble mixed with mud still exists a short distance from the south side of the main causeway.

As to how the Great Pyramid was actually constructed, there are differing opinions among Egyptologists. Herodotus reported that the upper portion of the Pyramid was finished first, then the middle, and finally the part nearest the ground. This has been interpreted as meaning that the finished outer casing stones were placed in position against the nucleus starting from the top, presumably by means of a ramp that was removed as the builders worked downward; this would have required four ramps, one against each face.

Herodotus maintains the casing blocks were lifted from the ground, step by step, on pieces of wood, with a machine

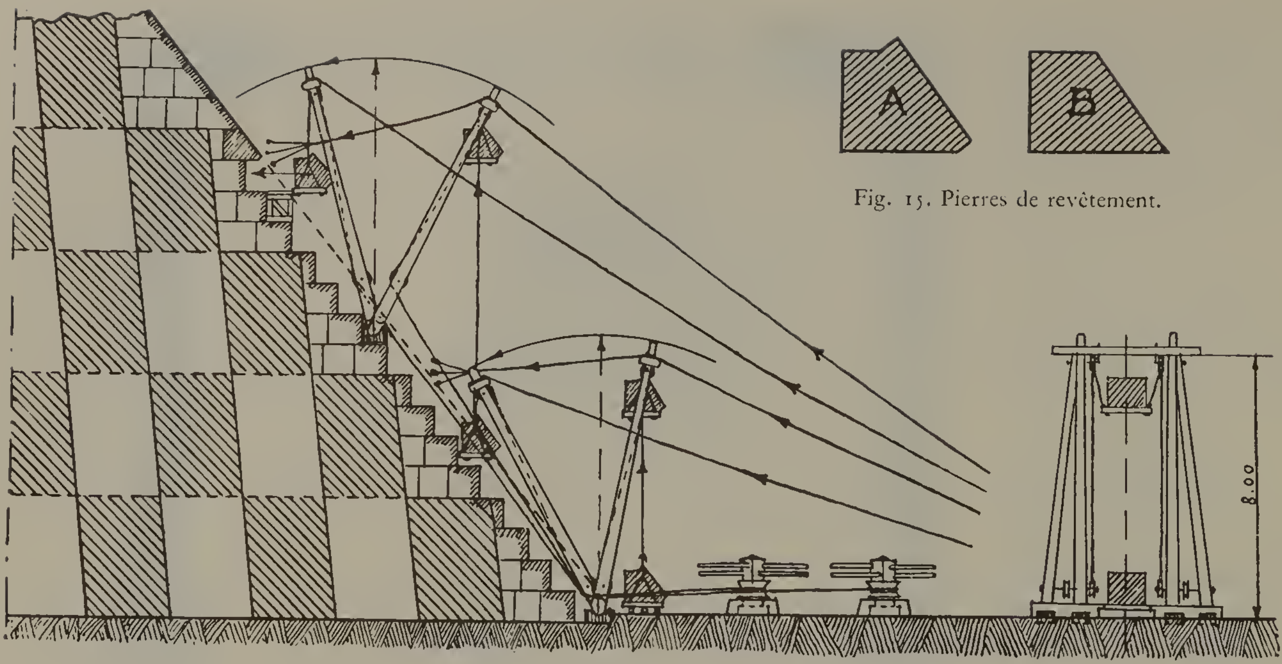


Fig. 15. Pierres de revêtement.

Machine for raising casing stones, as described by Herodotus and reconstructed by H. Straub-Roessler.
A and B are Lauer's indication of how casing stones may have been fitted.

which he does not adequately describe. Cotsworth figures that if the stones had had to be rocked to the top as reported by Herodotus, it would have taken about a month to get each of the final ones up to the summit.

Barber maintains that steel cranes or derricks would have been required to swing such great stones as are found in the Pyramid, and that for lack of such equipment the Egyptians would have had to construct a ramp in order to raise the heavy stones to the required level. Remains of such ramps have been found at the pyramid of Amenemhet at Lisht and also at Medûm. Aerial photographs indicate substantial remains of ramps under the sand at Dashur.

Petrie thinks the casing stones were placed in position at the same time as the core, starting from the bottom and going up course by course. He estimates that about 500 blocks were brought over from the quarries each day and laid in place. As the lower courses contain as many as 50,000 blocks, it would have taken over three months to lay each of these courses.

Petrie says the transporting was done during the three months of inundation, when a vast labor force was available and when advantage could be taken of the flood waters to float the blocks from the quarries downstream and across five miles of swollen Nile. Petrie suggests that even if no more than eight men could work together on an average block of 40 cubic feet weighing about 2 1/2 tons, they could have transported ten such blocks to the Pyramid in three months, taking two weeks to bring the blocks down the causeway from the quarry, a day or two with good wind to ferry the blocks down the Nile, and six weeks to raise them to the required position on the Pyramid. By November the men would be at liberty to return to their usual occupations when the land was again accessible.

Petrie estimated the Great Pyramid to contain about 2,300,000 stones weighing 2 1/2 tons apiece and averaging 50 × 50 × 28 inches. If eight men could bring ten stones in three months, 100,000 men could bring 125,000 stones each season, or the required total in the twenty years reported by Herodotus.

Edwards says there can be little doubt that in addition to the 100,000 men levied for the purpose of transporting the blocks to the Pyramid, many others were engaged in building the Pyramid. These men, says Edwards, consisted of skilled masons and an attendant body of laborers, continually employed throughout the year preparing and laying the blocks and erecting or dismantling the ramps. Presumably these workers could have been housed in the buildings found

Aerial photograph showing ramp under the sand leading to the pyramid of Dashur.

Romanticized modern drawing of barges being rowed down the Nile toward the Giza pyramids.

by Petrie west of Kephren's pyramid, where about 4000 at a time could have lived in barracks.

Petrie figures that 40,000 skilled workers living permanently on the spot could easily cut and finish the 120,000 blocks needed each year; a party of four men would have a whole month to handle each block.

Petrie believes the masons finished and laid the casing and some of the core masonry, course by course, on the ground, before raising them. He found horizontal lines carved on the casing stones and on the core stones showing just how they were to be fitted. He believes that skilled masons planned all the work throughout the year and that at flood time gangs of unskilled workmen raised the finished stones to their indicated positions.

Petrie says the casing stones were dressed by very fine picking or adzing and were moved into position from the *inside,* whereas the core was filled in afterward.

Maragioglio and Rinaldi, two Italian scholars who recently made extensive measurements of the pyramids of Giza which they incorporated into four carefully illustrated quarto volumes entitled *L'Architettura delle Piramidi Menefite,* agree that the casing and the nucleus were built up at the same time; they think the casing blocks were slid into place by means of a thin layer of very liquid mortar that served as a lubricant as well as a filler and binder; they also think the casing blocks were levered into position from the back and sides so as not to show marks or chips on the front.

Ballard believes it would have been impossible to place the finished blocks without damaging their fine edges; he thinks the roughly scabbed blocks were put in place and finished off with the aid of templates.

In support of Petrie, I. E. S. Edwards points out that because the lowest course of casing stones lies on the smooth pavement of Turah limestone which projects a couple of feet beyond the Pyramid base, it would have been impossible to lay the casing stones from the *outer* side without damaging the fringe of the pavement which was to remain exposed; nor could they have been dressed *after* being put in position without damaging the pavement.

The fact that some of the limestone slabs of the foundation pavement are seen to be laid *beneath* the nucleus blocks also indicates the nucleus was filled in after the casing blocks had been placed in position.

Petrie believes the casing blocks were placed side by side on the ground and worked so that the back, sides and bottom would fit perfectly when put in place. The only thing left to do on the spot would have been the leveling of the upper faces.

According to the architect Rex Engelbach and the engineer Somers Clarke, authors of *Ancient Egyptian Masonry,* in order to render the sides of the casing blocks perfectly equal they were placed side by side in the yard and a saw was passed between them. However, Maragioglio and Rinaldi could find no trace of saw marks on the vertical sides of any of the remaining blocks.

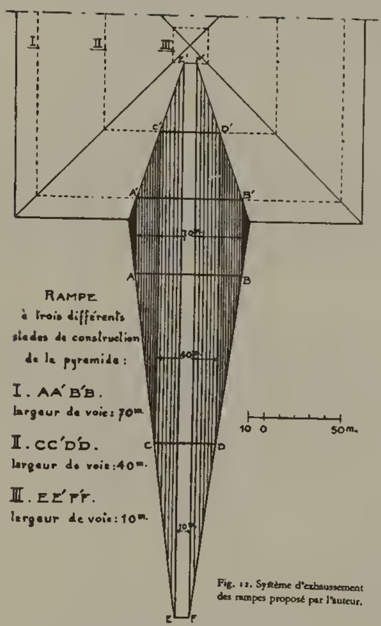
Petrie claimed to have found traces of red ochre on some of the stone faces which had not been perfectly dressed. From this he deduced that the dressing was done by degrees —as a dentist shapes a tooth—the control being made with facing plates covered with ochre.

In any case, the arrangement of casing blocks must have been worked out in detail well in advance of placement so as to assure a variance in the width and height of the backing stones from level to level, so as to prevent the vertical joints from coinciding.

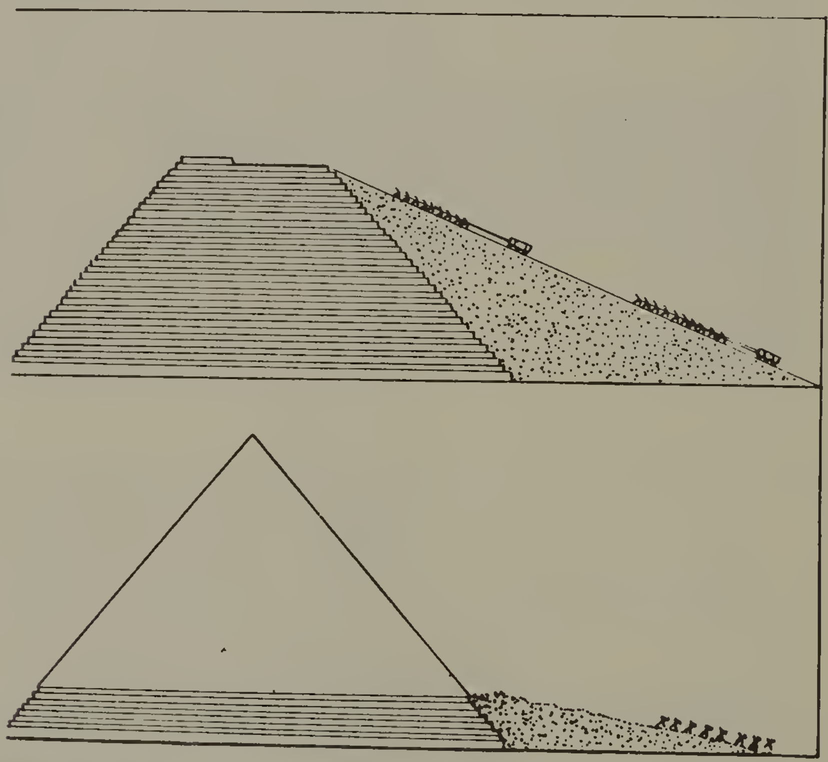
All the stones presently visible in the Pyramid are backing stones specially cut to dovetail and fit behind the outer casing. They are well dressed and squared, but made with fossilized limestone instead of the pure white.

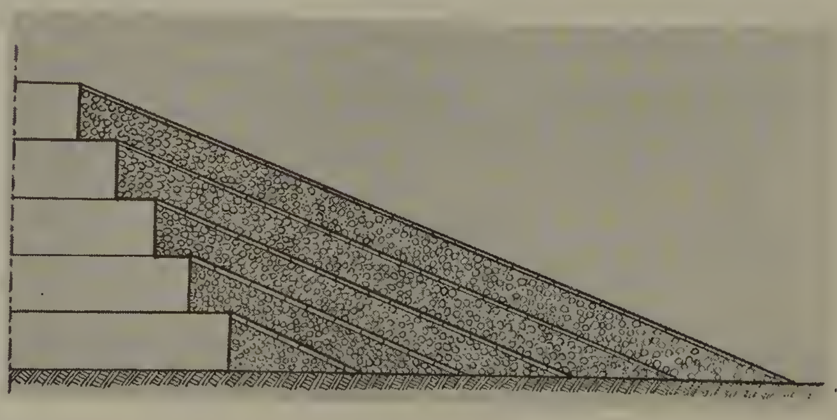
Behind them the nucleus consists of less well-dressed and roughly faced blocks of greatly varying sizes, for easier construction, and to insure that break joints did not coincide in either sense. They are held together by a mortar composed of sand, lime and crushed red pottery, which gives it a slightly pinkish color.

Maragioglio and Rinaldi attribute the concavity of the sides of the visible backing blocks to a means of preventing the facing courses from sliding, especially in the middle, by wedging the backing stones together at the center. On the north side the concavity has been measured as .94 meter. Maragioglio and Rinaldi believe the casing faces may also have been slightly concave, if only for esthetic reasons, as the optic aberration would thus be corrected, the Pyramid edges would appear sharper, the faces flatter; also,



Lauer's idea of how the ramp would grow wider and narrower.





Various methods of building ramps.

any errors in dressing the faces could be more easily distinguished.

Slight variations in the angle of the outer faces of casing fragments found in the rubble at the Pyramid's base may be explained by such a surface concavity.

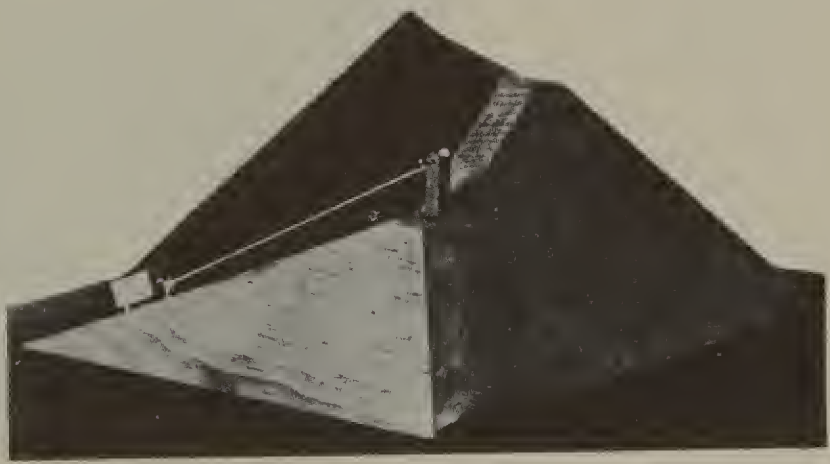
To raise each course of casing stones and nucleus all the way up the Pyramid, Petrie believes a ramp was constructed against one face, and he estimates that its volume would have had to be at least equivalent to that of the Pyramid itself.

Barber points out that to carry an inclined plane to the top of the Pyramid at a grade of one in ten, it would have been necessary to start the ramp 6000 feet away in the Nile valley at a point over 1600 feet before the commencement of Herodotus' causeway. Furthermore, says Barber, there would always have been four times as much work to do on the inclined plane as on the Pyramid.

In order to carry the ramp to the top of the Pyramid, Barber estimates that some 75,000,000 cubic feet of Nile bricks would have been necessary, or four times the number of cubic feet of stone still required to finish the Pyramid. With each additional course of masonry the ramp would grow higher and longer, but it would also grow narrower as the Pyramid narrowed at the top. According to Pliny such ramps were composed of niter and salt which could later be dissolved with water, but the idea seems fanciful as it would have required an ocean.

In *Natural History* of November, 1970, Olaf Tellefsen, an engineer, suggests that the Great Pyramid could have been erected with only a few thousand men using a simple piece of machinery consisting of a sturdy wooden arm balanced with counterweights on a fulcrum fixed to wooden skids—much like the machine drawn by the German engineer L. Croon.

This, says Tellefsen, would have done away with the need



for huge ramps postulated by Egyptologists on the basis of archaeological remains. According to Tellefsen, there was not enough manpower in ancient Egypt to build such ramps beyond the halfway mark of the Pyramid. Egyptologists countered, a little acidly, that from that point on the ramps narrowed rapidly, and that there appeared to be little evidence for Tellefsen's contention.

Cotsworth believes the Egyptians used a more ingenious system for raising the stones by taking advantage of the building itself as a ramp, dragging the stones up the Pyramid's own spiraling outer wall. This would enable the builders to fill in the core as they went up and finish the casing as they came down. Cotsworth says he watched a modern Egyptian peasant build a pigeon house by just this method.

The system has the added advantage that if the south wall of the Pyramid were completed first, the rest of the work could have been carried out in its shade rather than in the broiling sun.

But with or without the broiling sun, if one takes into account the problems of quarrying, roughing out, transporting over two million core stones, and finishing some 115,000 enormous casing stones to a precision of 1/100 inch, then raising, manipulating and mortaring them into their correct

place in a unified polished structure, one must agree with Antoniadi that the mind boggles at the enormity of the effort.

According to Barber's well-trained naval mind, it must have required the organizing capacity of a genius to plan all the work, to lay it out, to provide for emergencies and accidents, to see that the men in the quarries, on the boats and sleds, and in the masons' and smithies' shops were all continuously and usefully employed, that the means of transportation was ample, that the commissariat did not fail, that the water supply was ample and conveniently disposed, and that the sick reliefs were on hand.

Barber points out that public works were essential to keep this population employed and fed during the floods. August Mencken presumes that no less than 150,000 women and children also had to be housed, fed, and policed in nearby settlements. Judging from the texts and the paintings dealing with the subject of forced labor, Barber figures a large portion of the duty of the standing army of 400,000 men must have been that of guards.

Cotsworth says that in the rainless climate of Egypt no housing was needed for the natives who were accustomed to surviving on grain and water, and that the desert provides better sanitation than was available in Victorian England.

The waste chips of the masons were thrown over the

In 1950 the Museum of Science in Boston built a model to the scale of 1:120 showing how they believed the pyramids of Giza to have been constructed with slanting side ramps, three up and one down.

Dows Durham, curator of Egyptian art at the Museum of Fine Arts in Boston, responsible for the technical details, disagreed with the theory of long ramps because every time the building rose a few feet the ramp would become unusable until it was raised and extended.

Durham conceived the side ramps as being about 10 feet wide, or sufficient to handle a sledge with a double row of men to drag the stones over wet timbers for reducing friction. However, turning the corners would not have been easy.

cliffs of the Giza hill on both the north and the south sides, where they formed banks stretching out a hundred yards, occupying a space almost half the bulk of the Pyramid. The slopes formed an angle of rest of about 40°, showing the different qualities of refuse thrown away on different days, varying from large chips to mere sweepings.

In pits which had recently been made in part of the heap close to the edge of the cliff, Petrie noted layers of desert flint and sand showing when a piece of desert ground had been cleared to get more space for working. Among the rubbish he found pieces of workmen's water jars and food vessels, chips of wood and charcoal, and even a piece of ancient string.*

The only report on the daily cost of building the Pyramid is given by Herodotus, who says that an interpreter told him the daily sum spent on radishes, onions and garlic for the workmen was inscribed in Egyptian characters on the base of the Pyramid. But the report sounds apocryphal, as does the one passed on by Herodotus to the effect that Cheops became so broke during the operation that he prostituted his daughter by placing her in a chamber and charging each visitor the equivalent of a finished limestone block for her favors.

Kingsland figured that to position an estimated 2,300,000 blocks in a period of 20 years, or 7300 workdays, would have meant placing 315 stones each day, or 26 stones an hour working 12 hours a day.

Mencken, who has such disdain for the mathematical and astronomical knowledge of the ancient Egyptians, considers it remarkable that they were able to solve some of their problems of construction unless they had "more knowledge, better instruments, and far more ingenuity than is generally believed."

Kingsland wonders what means of illumination the Egyptians used while digging down to the subterranean pit and what method they used for getting air to the diggers. He finds it difficult to resist the conclusion that the Egyptians must have had tools and appliances of which we are totally ignorant, and must have employed methods which today would be termed occult.

Some of their solutions may have been no more arcane than Lockyer's suggestion that with one movable mirror and several fixed ones, sunlight could have been reflected to any part of the interior of the Pyramid.

Though legend attributes to the priests of Heliopolis the

* It would be helpful if more fragments could be excavated and carbon-tested.

knack of being able to cause tempests and levitate rocks that a thousand men could not move, most Egyptologists argue strenuously against the possibility of sophisticated instruments such as laser beams for cutting surfaces, or ground-effect or antigravity machines for raising weights, insisting that the job was accomplished with nothing but primitive appliances and unlimited manpower. Nevertheless the conscientiously academic Edwards fudges the issue by saying: "Cheops, who may have been a megalomaniac, could never, during a reign of about twenty-three years, have erected a building of the size and durability of the Great Pyramid if technical advances had not enabled his masons to handle stones of very considerable weight and dimensions."

Petrie is more specific and gives substance to the hypothesis of unknown methods, pointing out that in the pyramid of Kephren there is a granite portcullis weighing about 2 tons which is in such a position in a narrow passage that only 6 or 8 men could work on it at once. As it would take a force of 40 to 60 men to manipulate such as a mass, Petrie concludes that the Egyptians must have had some more efficient means which remains unknown to us.

Although the Danish engineer Tons Brunés has demonstrated how a block as large as the beams of the King's Chamber could be comfortably raised by a single man with the dexterous use of balancing and wedges, Petrie is convinced that ancient builders possessed some more efficient means of raising and setting stones than mere rollers, levers, ramps and manual hauling.

But perhaps the most puzzling riddle of the Pyramid, requiring an intellectual game of detection, is the one constituted by the three granite plugs wedged into the end of the Ascending Passage.

XIX. WHY WERE THE PYRAMID PASSAGES PLUGGED? WHEN? AND HOW?

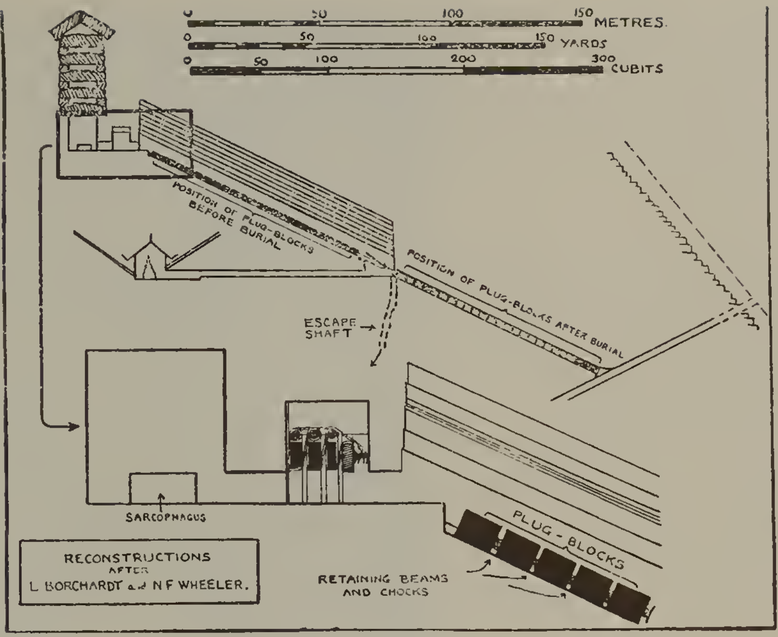
Most Egyptologists conclude that the Pyramid was built as a tomb for some Pharaoh, presumably Cheops. Any mathematical, religious or prophetic theories about the structure they consider to be fanciful, or, at best, coincidental. To Egyptologists the corridors of the Great Pyramid were designed solely as a means of transporting the coffin of the dead Pharaoh to his sarcophagus in the burial chamber, as a means of exiting after the entombment, or as blinds to lead grave robbers away from a hidden chamber.

No other reason is offered for piling up so massive a mound of masonry than to protect the dead Pharaoh from the attention of grave robbers. Oddly, this is the single function which neither the Great Pyramid, nor any of the others, managed to fulfill, there being no reliable report of any body having been found in any of the pyramids, only some fragments of bones whose dates are uncertain.

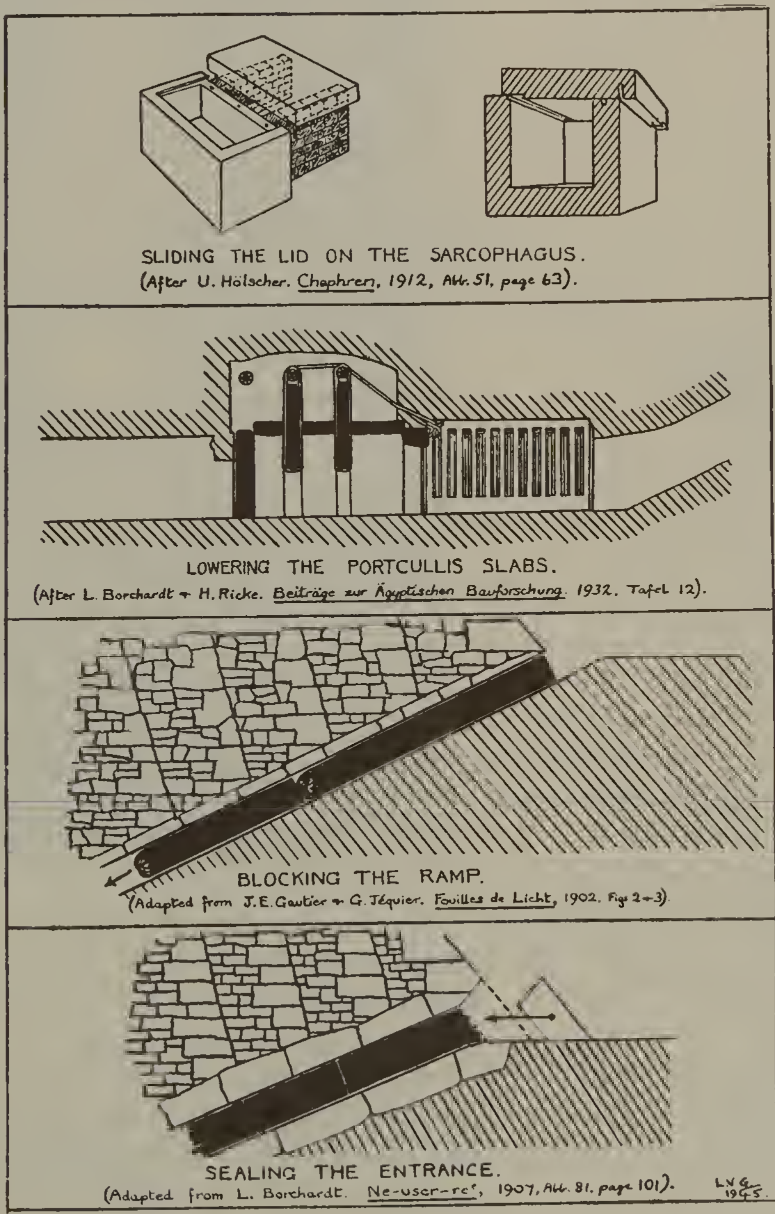
Even the "unplundered" tomb of Cheops' mother, Hetepheres, found in 1925 by the Harvard-Boston Expedition at the bottom of an 85-foot-deep shaft filled with rubble, appeared untouched in 5000 years: yet the sarcophagus was empty and is presumed to have been so placed within the "burial" chamber.

According to the Egyptologists, who include such eminent figures as Petrie and Borchardt, once the body of a Pharaoh had been laid to rest in the Great Pyramid and the burial party had made its exit, the three huge granite blocks, plus several limestone ones, were allowed to slide down the incline between the ramps of the Grand Gallery till they had completely plugged the Ascending Passage.

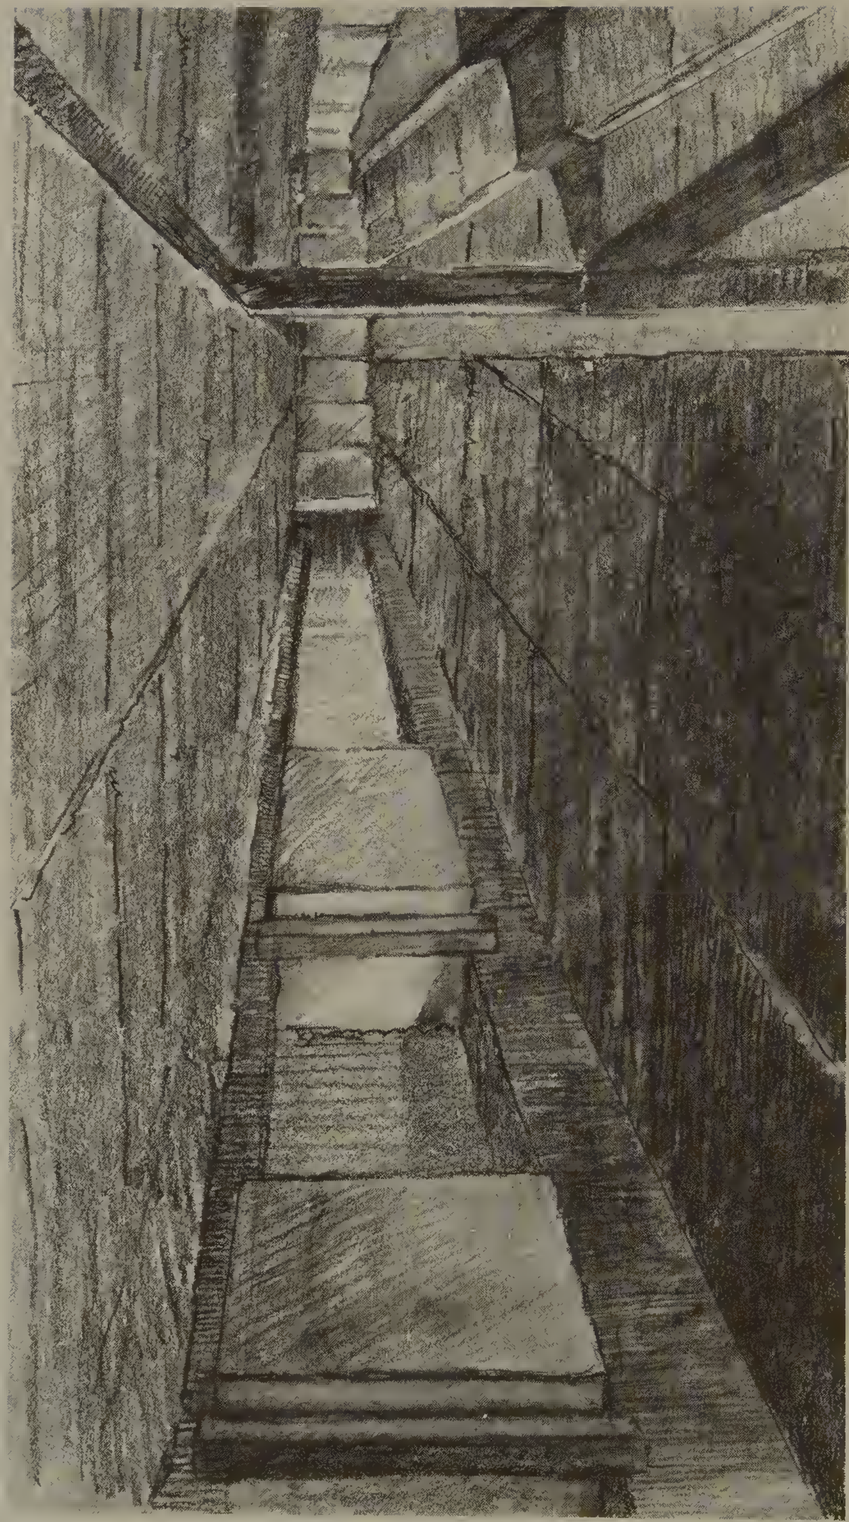
Whether the tripping mechanism could have been operated by remote control from a safe distance below the plugged entrance, or whether the technicians responsible for the tripping device were immured for life, or whether they managed to make their escape down what is known as the "well" are theories supported in different degrees by different Egyptologists.



Method of plugging the Ascending Passage as visualized by Cottrell from the ideas of Borchardt and Wheeler.



Ideas of various Egyptologists of the methods of plugging passages, lowering portcullises and sealing sarcophagi.

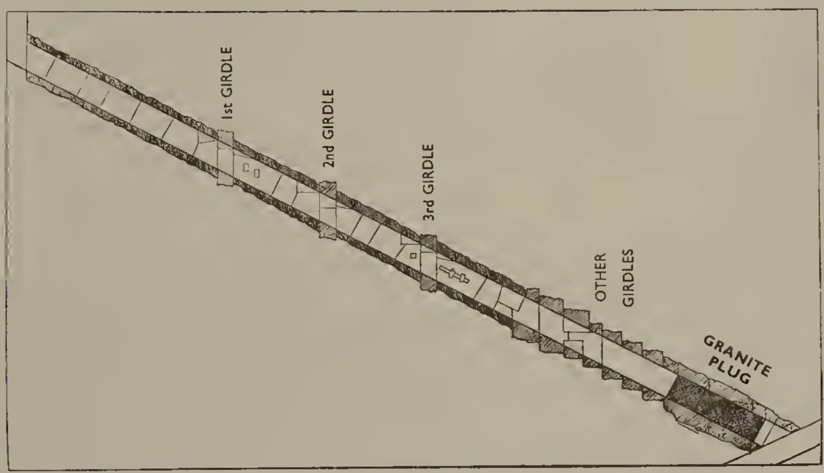


Modern illustration of the granite plugs in the Grand Gallery.

To account for the three granite plugs and the peculiar arrangement of the Pyramid's passages and chambers, Borchardt put forward the theory that the builders started with one plan, but kept changing it as they went along.

Borchardt believes the "original" intention was to bury the dead Pharaoh in the pit carved out of natural rock at the bottom of the Descending Passage, but that this plan was changed. For some unspecified reason, says Borchardt, it was decided to bury the king higher in the body of the Pyramid, which was already several courses high. The pit was therefore left unfinished. An Ascending Passage was carved up through the already laid courses of masonry, and continued as a new passage up to the level of the Queen's Chamber.

While making a careful study of the walls of the Ascending Passage, Borchardt observed that the stones at the lower end were laid approximately parallel with the ground, whereas nearly all those at the upper end were parallel to the gradient of the corridor. From this he deduced that the Pyramid must have already reached a level corresponding to halfway up the as yet nonexistent Ascending Passage before it was decided to use an upper chamber; at that point the Ascending Passage was dug up through the existing level courses; thereafter it was built with blocks parallel to its slope.



Arrangement of girdle stones 10 cubits apart, to tie the Ascending Passage to body of Pyramid, as drawn by Adam Rutherford, director of the Institute of Pyramidology in Great Britain.

Borchardt's theory is supported by Leonard Cottrell, author of a popular book on the pyramids, *Mountains of Pharaoh,* who suggests that when the builders switched plan they got as far as the Queen's Chamber complete with its air channels before they again changed their minds.

Cottrell says a third scheme brought with it the decision to heighten the Ascending Passage into "the magnificently corbeled Grand Gallery," extending it another 160 feet so as to build yet a third chamber, the King's, as the final resting place for the Pharaoh's body.

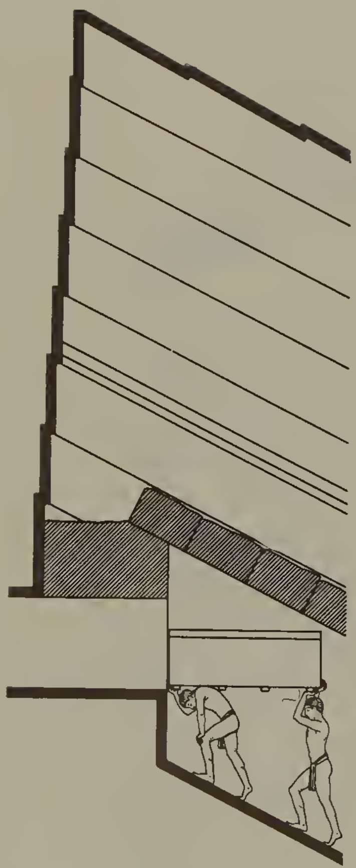
According to Cottrell, the change came about as a sort of afterthought, while the great mass of builders was already in the midst of constructing a building whose base and slopes appeared to have been worked out with such extraordinary precision.

Why the Grand Gallery should have been raised to 28 feet, when less than half that height would have been ample for the bearers and for the storage of the plugs, was not explained by Cottrell.

Borchardt and Cottrell's theory was disputed by Maragioglio and Rinaldi, who point out that the bottom of the Ascending Passage was *intentionally* cut through the lower courses simply as a means of anchoring it to the body of the Pyramid. The Italians say the lower part of the Passage was not dug out of normal masonry or with normal methods, but in masonry especially erected to anchor the end of the Passage, many of the blocks being exceptionally large, laid flat, vertical and edgewise, and of a different quality from the rest of the nucleus, with joints very thin and finely finished; whereas in other areas where the regular nucleus masonry is visible, the joints are wide and coarse.

The object, say Maragioglio and Rinaldi, was to create a bulwark at the juncture of the Ascending and Descending Passages so that the ceiling and floor of the Ascending Passage would not thrust down on the empty space of the Descending Passage. The Italians point out that several monolithic girdle stones are employed at 10-cubit intervals all the way up the Ascending Passage to reinforce its bond with the nucleus of the Pyramid, and prevent its slipping, but that no such girdle stones appear in the Descending Passage, where they are not needed because the whole passage rests against the solid rock of the Giza hill.

Borchardt produced a further refinement to his theory, which not only found few supporters, even among his fellow Egyptologists, but tended to discredit his whole approach to the problem: namely, that the granite and limestone plugs which filled the Ascending Passage could not have been stored on the Grand Gallery floor between the ramps, because they would have provided an "undignified obstacle" for the funeral train to clamber over. As the plugs were too large to be brought in or out of either the Queen's Chamber or the King's, Borchardt theorized that the blocks were raised onto a wooden platform which was fitted into the grooves which appear halfway up the walls of the Gallery.

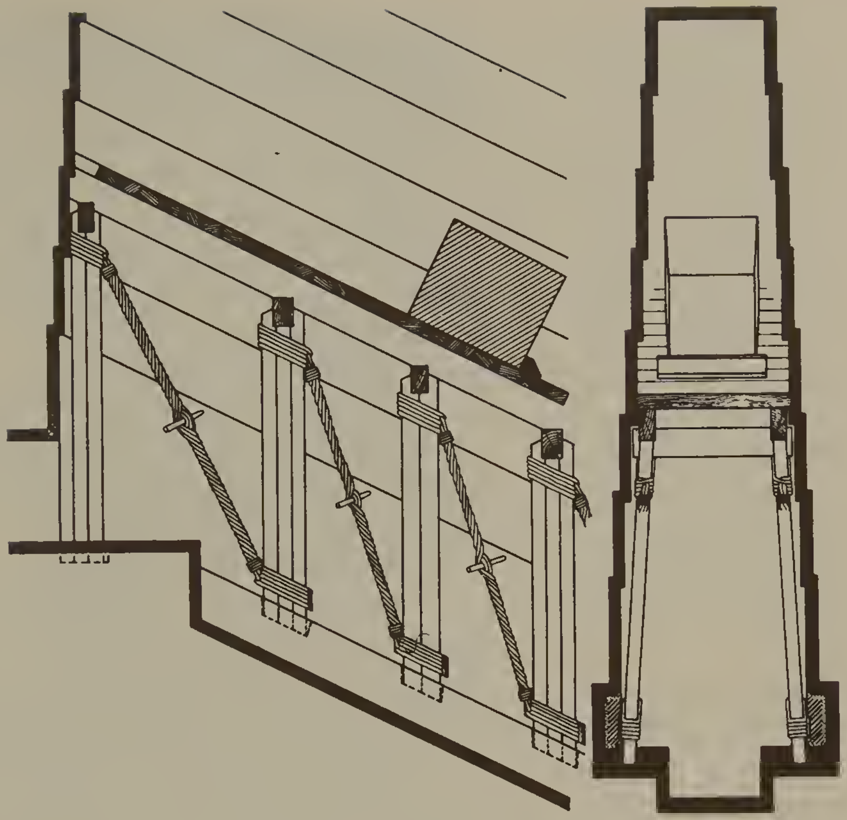


Borchardt's fanciful idea of pallbearers reaching the Great Step at the top of the Grand Gallery, with plug stones supported on a platform above them.

This would have allowed the funeral cortege to move beneath them; though how this would have been any less undignified than having to crawl up the low and narrow Ascending Passage is not explained, nor is it explained how the heavy blocks were brought down from the level of the wooden planking to the level of the pavement on which they were to slide.

That Borchardt's hypothesis is unreasonable, say Maragioglio and Rinaldi, is evident from the fact that few archeologists have paid much attention to it.

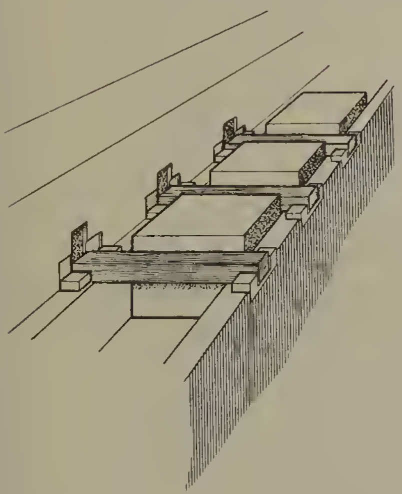
As for the method of triggering the plugs down the Ascending Passage, Cottrell believes the notches in the



Trestle believed by Borchardt to have raised plug stones to a level half the height of the Grand Gallery.

ramp of the Grand Gallery were cut to hold cross beams of wood or limestone to keep each of the massive plugs from prematurely sliding. According to Cottrell, once the funeral cortege had passed, operators standing on the ramps could have released each plug, starting with the bottom one, and allowed them to slide into the Ascending Passage, on the theory that had they all been released simultaneously the momentum and the total weight might have caused damage at the lower end.

The theory raises the question as to what became of the wooden or limestone crosspieces. Had they been made of wood they might conceivably have pulverized and completely disintegrated in the thousands of intervening years. They might also have been carried down the well by the escaping operators, though this would have been something of an ordeal, if indeed possible. The material might also have long since been disposed of by grave robbers. Still, the question is puzzling. Also, why go to all the trouble of plugging the Ascending Passage, only to leave the well shaft as a perfectly simple way for thieves to climb back up to the Grand Gallery? The lower end of the well shaft could have been cleverly concealed; but its whole length could hardly have been plugged or made impassable with fill *after* it had been used as a means of escape.



Goyon's idea of how granite and limestone plugs were held in place by crossbeams fitted into the ramps.

Part or all of the *Descending* Passage could have been plugged and the Pyramid sealed. This would have been the simplest way conclusively to close up *all* the chambers in the Pyramid, making it an almost superhuman job to chisel out 350 feet of solid limestone.

Petrie disputes the notion that the long Descending Passage could have been filled with blocks; and Maragioglio and Rinaldi suggest that traces of the dismantling of such plugs would have been left on the walls of the Descending Passage, which is not the case, with the exception of a few feet beyond the entrance.

The most sophisticated refutation of the theory holds that the Descending Passage may have been purposely left empty and the pit unfinished as a blind to lead any robber who entered by the trap door to believe that no king had been buried in the Pyramid!

As for the well shaft, Maragioglio and Rinaldi have a completely different theory about its function. They do not think it was ever designed as an escape route; they think it was built in from the early stages as a service shaft and to bring air to the lower end of the Descending Passage.

The Italians say the need which led to the building of such a shaft may have arisen shortly after the beginning of the Ascending Passage, most likely as a means of ventilating the lower shaft. They believe the diggers at the bottom of the Descending Passage had difficulty breathing. Plausible at first sight, the theory is open to two objections: as the building went up course by course, above the level of the rock base, there would have been all the air in the world; whereas digging the well shaft *below* rock level, the diggers would have been as cramped and airless digging the well shaft as digging the Descending Passage, at least until the two met at the bottom—by which time the well would no longer have served its ventilating purpose, the digging having been completed.

Such an air vent might conceivably have been useful to bring air to the pit, had the pit been used for any continuing purpose, such as observing the stars.

The Italians also believe that long before any funeral party entered the Grand Gallery, the entire well shaft was filled from the top with debris and loose material. The bottom entrance was then carefully camouflaged, and a stone was mortared into the upper end in the west ramp of the Grand Gallery to seal and hide the shaft from the top. They cite the fact that from classic times till the nineteenth century no one appears to have spotted the bottom entrance to the well shaft.

Maragioglio and Rinaldi agree with Petrie that the Pyramid was violated by thieves or grave robbers soon after it was finished, during the civil wars, which they date between 2270 and 2100 B.C. At this point the theory of the Italians becomes radical. They maintain it was these early despoilers of the Pyramid and not Al Mamun who cut a hole around the granite plugs at the end of the Ascending Passage. These thieves then worked their way up the Ascending Passage, broke through the lowered portcullis, and entered the "crypt." According to the Italians it was these or successive thieves who found the well shaft by noting a difference in the stones at the bottom of the ramp in the Grand Gallery, which they forced in order to clear out the well shaft in search of treasure. The Italians maintain that the marks in the west ramp around the missing stone appear to have been made with a chisel struck from above. They say it would also have been extremely difficult to remove the stone from below in the very restricted passage which leads to the head of the well shaft.

To explain the way the Ascending Passage was plugged, the Italians maintain the tripping mechanism could have been operated by remote control. They point out that it has recently been discovered that in the bent pyramid of Sneferu, the blocks of granite which plug the Descending Passage could *only* have been moved by gravity and not directly levered by workmen, because there *is* no escape route.

The Italians believe the plugs in the Great Pyramid were slid on liquid mortar and that its forced accumulation accounts for the 10 centimeters of empty space between the first and the second granite plug; though they offer no explanation as to what may have become of the mortar, which could hardly have volatilized in the meantime, unless it was some sort of oil and not mortar.

It is also hard to imagine how the antique grave robbers could have immediately found the exact spot halfway down the Descending Passage from which to dig up past the granite plugs if there is any truth in the story of the plug being covered by a prismatic block.

Maragioglio and Rinaldi suggest there was no such block; paradoxically they give credence to the story that Al Mamun's workers heard a heavy block fall—simply because Al Mamun's passage takes a sudden turn to the east in order to break into the Descending Passage.

Another theory which attempts to account for what could have taken place in the plugging of the Pyramid was produced in 1963 by August Mencken, the engineer from Baltimore who has so little regard for the scientific knowledge of the ancient Egyptians. According to Mencken's somewhat farfetched reconstruction of events, when the Great Pyramid had been built up above the ridge of the roof of the King's Chamber, and work was still going on in the Grand Gallery and in the Antechamber, the structure was suddenly shaken by a severe earthquake. It was then, says Mencken, that the ceiling beams of the King's Chamber were cracked, the fissures opened, and, "to the terror of the builders, the triggering device which held the plugs on the floor of the Grand Gallery was sprung and the blocks slid down the Ascending Passage, blocking all exit from the Pyramid."

According to Mencken, the men inside were trapped, but their plight was not desperate. "As soon as the fright and confusion caused by the earthquake had subsided, the men on the outside discovered what had happened to the men on the inside and opened communication with them through the air ducts leading out from the King's Chamber. By the same ducts the trapped men were supplied with food and water."

Mencken figures that to have chipped out the three granite plugs in the restricted space of the Ascending Passage was out of the question, and that to have tunneled around them would have caused irreparable damage to the passageways. Rather than chip out the granite blocks, the Egyptians, says Mencken, decided to dig the well up from the bottom of the Descending Passage all the way to the end of the Grand Gallery.

The trapped men, says Mencken, were informed of what was being done, "and by the time the tunnel reached the opening in the Gallery they had removed the ramp stone." According to this theory an inspection crew was sent to ascertain the damage and examine the King's Chamber ceiling; for this purpose the small tunnel, later known as Davison's, was dug straight through the lowest of the cushioning chambers.

The plugging of the Ascending Passage, says Mencken, put an abrupt stop to all other interior work and made it impossible for the King's Chamber to be used for a burial, either real or token. "So everything above the plug blocks was abandoned and thus ended the first and only attempt of the ancient Egyptians to build elevated chambers."

In criticism of Mencken's theory it may be asked why, if the building had been constructed to just beyond the peak of the King's Chamber, would it not have been easier to remove several blocks from the upper tiers in order to reach the trapped men rather than go through the trouble of boring hundreds of feet up the whole length of the well? Also, if the builders had no further use for the interior of the building, why go to the effort of finishing off the Pyramid and casing it with 22 acres of finely polished limestone?

An entirely different solution to the problem is provided by David Davidson, the structural engineer from Leeds. According to Davidson, the depth and width of the granite plugs which seal the lower end of the Ascending Passage clearly indicate that the plugs must have been built into the passage *at the time the Pyramid masonry had reached the height of the plugs, or 17 courses.*

Davidson, who spent several months in Egypt studying the Pyramid closely, says the half-inch clearance at the sides of the top of the Ascending Passage would *not* be sufficient to insure the granite plugs being slid from the Grand Gallery without jamming.

This raises the question as to why the builders would have bothered to even build the Ascending Passage if they intended to plug it up immediately with three large granite plugs.

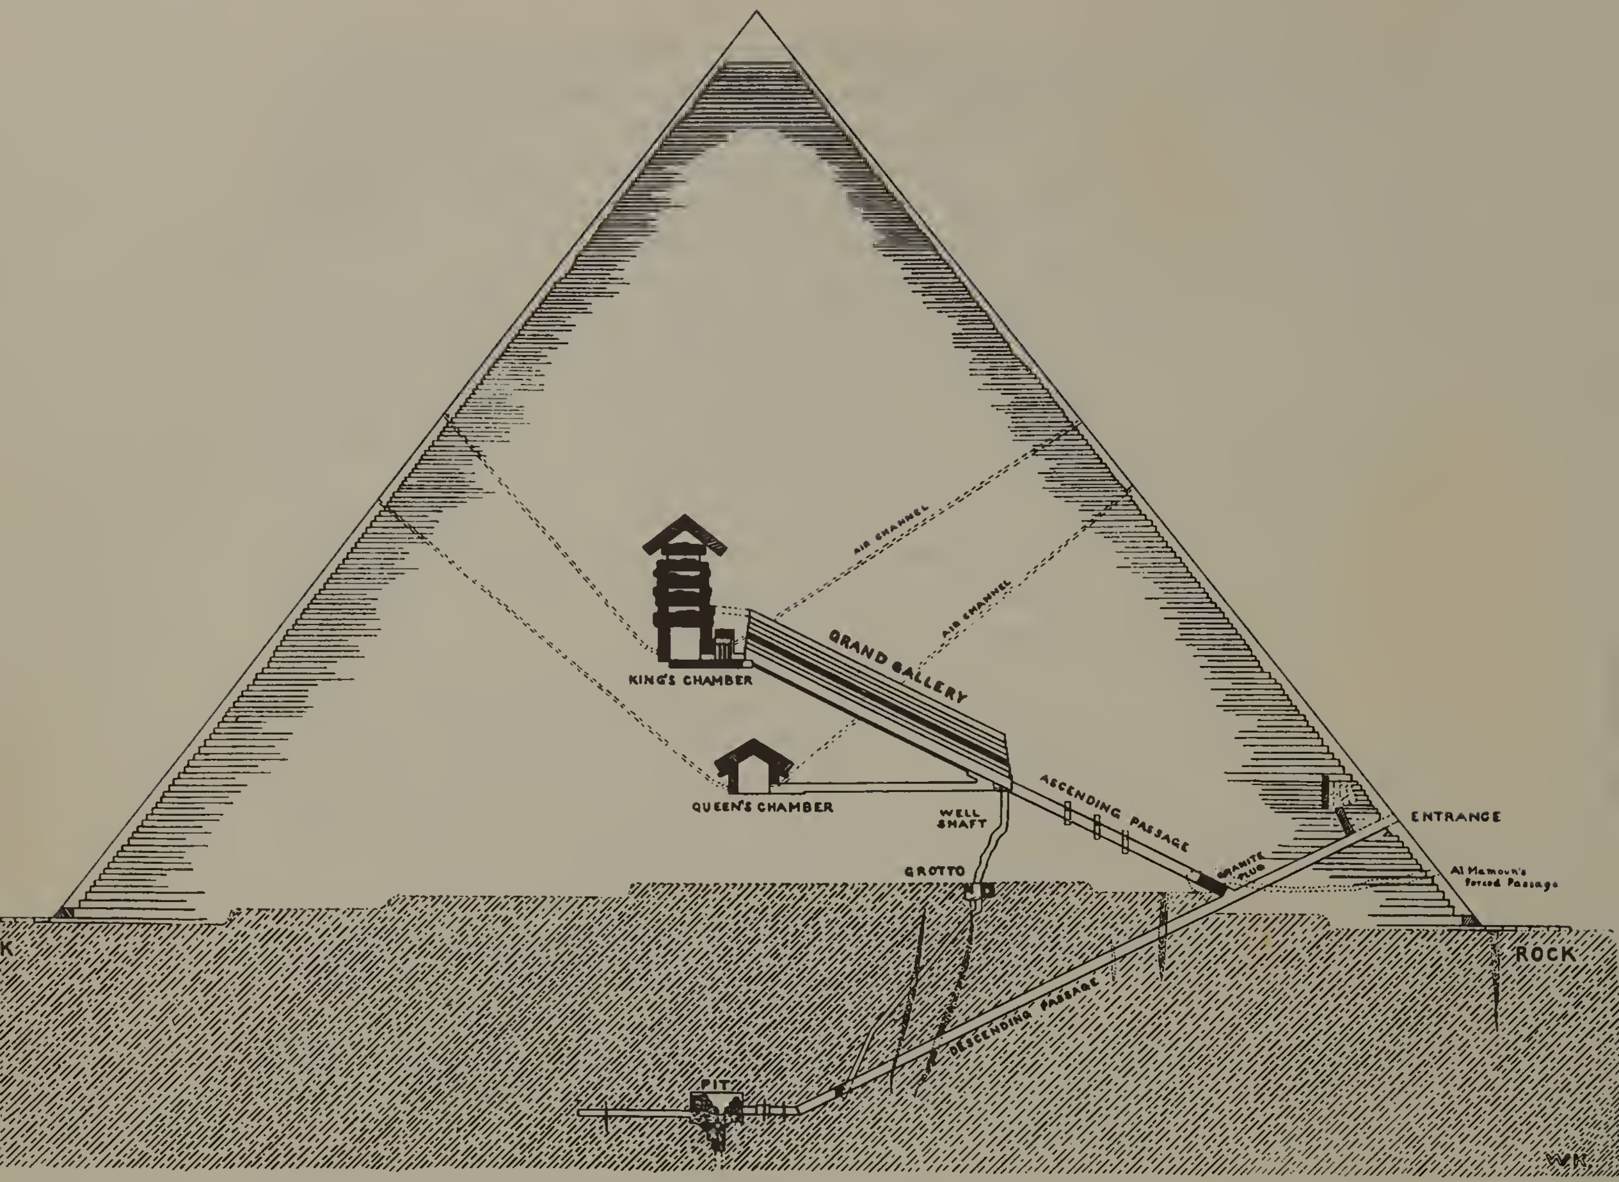
Davidson answers that the inside of the Pyramid was not designed for contemporary use, but was intended to be discovered by people of a much later civilization, rather like our modern time capsules, and that the discoverers would have to break their way in through the series of limestone plugs, much as Al Mamun is reputed to have done.

This raises the question of the presence of the well shaft, which could have led any intrepid explorer straight to the Grand Gallery, bypassing the Ascending Passage. Davidson answers that the well was an afterthought, not planned in the beginning as an escape route after a burial, if for no other reason than because the Pyramid was never intended as a tomb.

Davidson has an ingenious reconstruction of what may have occurred. He maintains that some time not long after the completion of the Pyramid, an earthquake or several disasters severely shook the building. After the disaster the priests or guardians of the Pyramid noted certain subsidence effects on the external surface of the structure, and they decided they must investigate the interior to see if the King's Chamber had collapsed or been badly damaged.

Davidson says this must have happened within a few generations of the completion of the construction, and before precise details and measurements of the internal construction had been lost.

The keepers, says Davidson, entered the Descending Passage and instead of trying to carve their way up through a score or more of limestone plugs in the Ascending Passage, as was later to be done by Al Mamun, they went nearly to the bottom of the Descending Passage and then began to bore a hole upward toward the beginning of the Grand Gallery.



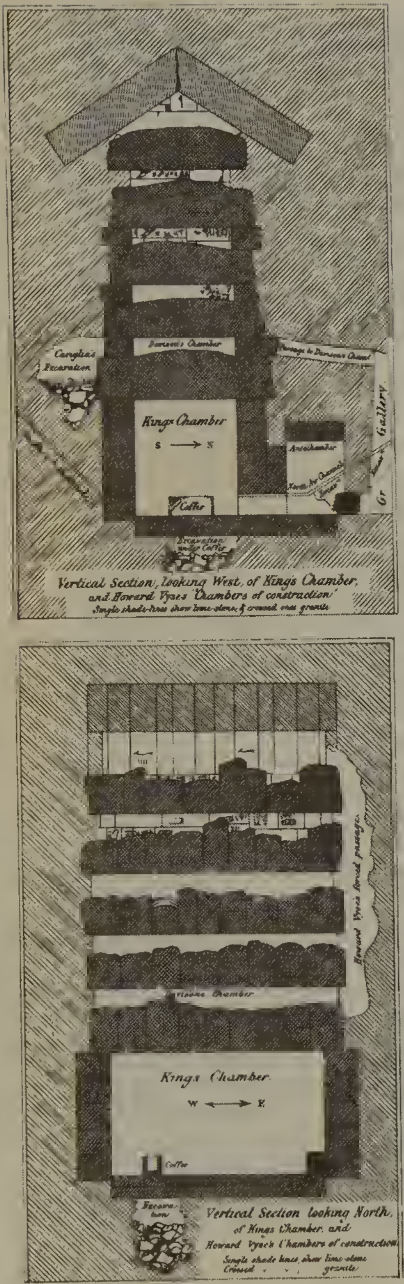
Davidson's rendition of the Great Pyramid passages, showing three large fissures in the natural rock.

Their reason for starting so far down, says Davidson, instead of taking a shorter route past the plugged Ascending Passage, was to cut their way through, and carefully observe, two large fissures that had appeared in the bedrock. A third fissure, present at the time of construction, had already been shored up by the builders.

The problem of the priests, says Davidson, was to determine if the fissuring was severe enough to cause further subsidence.

Digging in a gradual upward slope, says Davidson, the keepers worked their way through both fissures, finding them in not as bad condition as they had expected. At the level of the Grotto the keepers made a staging area for tools, for rest, and for the bypassing of workers and material.

From the Grotto they continued their shaft up toward the commencement of the Grand Gallery. Having somehow made an accurate survey of exactly where they were, they



Davidson's rendering of the way the chambers in the Pyramid are aligned just east of the main east-west axis.

then bored straight up and came out beneath the lowest ramp stone on the west side of the Gallery. To Davidson it is clear from the fractured appearance of the ramp around the well entrance that the stone was forced upward and outward.

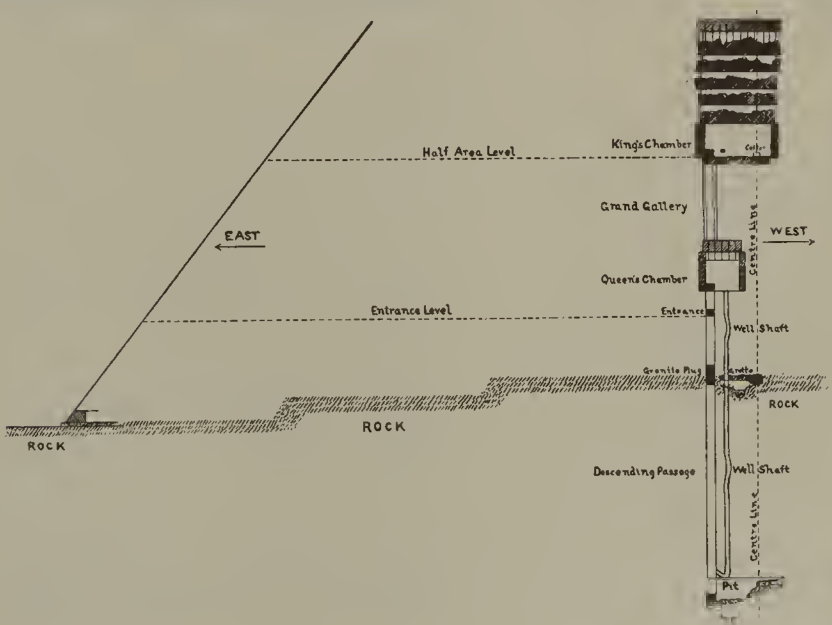
To accomplish such a feat of accurate digging would have meant knowing the precise internal arrangement and measurements of the Pyramid. Anyone boring blindly could have missed the few feet of Grand Gallery and been obliged to bore several hundred more feet through the limestone courses before coming out into daylight. This goes a long way toward discounting the possibility of the well shaft having been dug by either thieves or explorers.

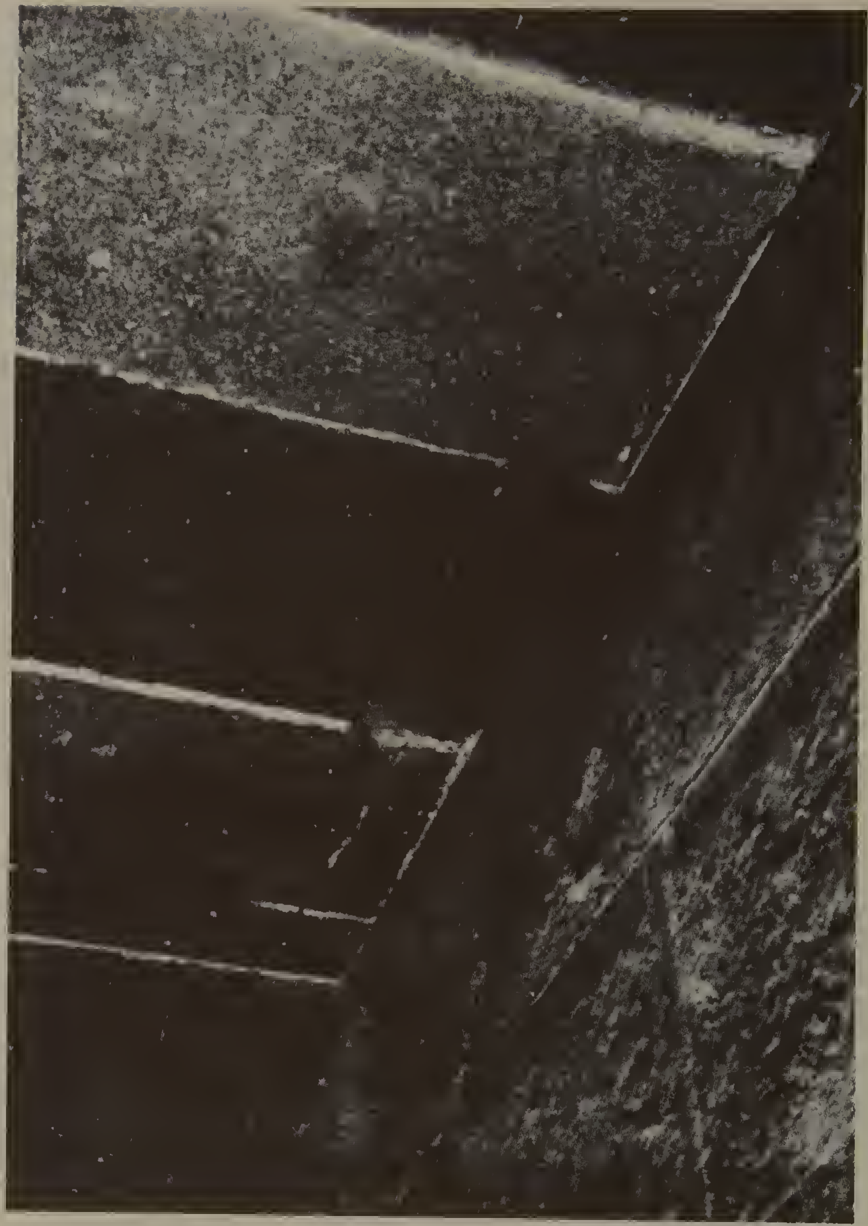
Once they had reached the Grand Gallery, says Davidson, the keepers dismantled the lower section of the Gallery floor for a dozen or so feet and uncovered the passage to the Queen's Chamber. This they inspected carefully, but found little or no sign of failure.

Proceeding to the King's Chamber, the keepers found indications of possible instability due to the movement. Inside the chamber they found the ceiling beams uniformly cracked along the south ends.

According to Davidson, it was then that the keepers smeared the fractures and open joints with cement and plaster. Petrie was later to report that he had found cement daubed on with fingers for about 5 feet on each side of the joints.

When Petrie carefully examined the King's Chamber he discovered that it had been badly shaken, probably by an earthquake, which caused the whole room to expand





Cracks in granite beams at the south end of the King's Chamber.

an inch or so. Every single beam had been wrenched more or less loose from the south end, and cracked through; the whole ceiling, weighing some 4000 tons, was held up solely by "sticking and thrusting." As Petrie summed up the situation, the downfall of the King's Chamber "is a mere question of time and earthquakes." What has saved it so far was not being bonded to the main structure.

Davidson says the five construction chambers were especially designed to take a considerable impact. Instead of resting the uppermost beams on a hard granite wall, the builders rested them on limestone, which could more easily crush and flow in case of subsidence, taking the strain off the lower rows of rafters and keeping the walls of the King's Chamber intact. Davidson says that a more rigid design, uniform from the lowest to the highest chamber, would have been disastrous.

To permit this buffer effect being fully developed, the rafters of the chambers were not tied into the east and west walls. Instead, two immense limestone walls, wholly outside of, and independent of all the granite floors and supporting blocks, were built on the east and west sides. As Petrie put it: "Between these great walls all the chambers stand, unbonded and capable of yielding freely to settlement."

To gain access to these important construction chambers above the King's Chamber, the keepers, says Davidson, next drove an opening into the east wall of the Gallery, starting at its upper, or south, end.

In support of the theory that this hole was bored by keepers who were precisely acquainted with the layout of the Pyramid (rather than by later explorers or thieves), Davidson points out that the hole is bored in exactly the right place, and takes off at the precise angle and direction to reach the lowest of the upper chambers.

Once inside the first chamber (later to become known as Davison's), the Pyramid keepers, says Davidson, found that the indications of instability were not so serious as they had feared. The great granite beams were indeed cracked, but the damage did not seem to be enough to cause any further crumbling or subsidence, nor warrant their boring any higher into the overlaying chambers. Instead, the keepers again daubed the cracks with plaster so as to be able to return at a later date and observe if any further movement had taken place.

According to Davidson, the keepers then climbed back down the well, the bottom end of which they camouflaged, and left by the swivel-stone entrance on the north face.

There is nothing inherently illogical about this version of events. It would have been no easy job to tunnel upward through the solid rock and the various courses of masonry—altogether hundreds of tons of material would have had to be chipped away and taken out of the Pyramid up the Descending Passage—but it would not have been impossible.

It would also have been a problem to get light and air to the men doing the chiseling, and it would have been tricky to raise a platform or system of suspension while chiseling upward; also it would have been a nuisance to have the fragments fall constantly in the face of the chiselers and those below them; but all of this would not have been impossible.

What militates against this theory is the observation of Maragioglio and Rinaldi that the walls of the well shaft upward from the Grotto are built and lined with regular blocks of limestone, apparently as a feature of the original structure.

SINGLE SHADED LINES INDICATE NATURAL ROCK.

Grotto showing walls of the well shaft built out of masonry from the level of the Grotto to the first course of masonry of the Pyramid.

Conceivably these walls could have been lined by the keepers, operating from the Grotto, perhaps to insure a stable surface in this final section of the shaft.

Clear indications that it was *not* designed from the beginning were found by Petrie in the fact that the shaft is irregular and tortuous through the rest of the masonry, and that blocks with sharp corners were left in an irregularly curved shaft.

A French professor of architecture, J. Bruchet, who went to the spot to verify and measure, and who published an illustrated book on the subject in Aix-en-Provence in 1966, agrees with Davidson that the granite plugs could not have been slid down the Ascending Passage; he believes they were put in place at the moment of construction, when the Pyramid was still a truncated body. To have slid them down, with so little clearance, says Bruchet, would have required walls as smooth as glass, whereas he found the walls of the corridor roughly finished.

But Bruchet disagrees with Davidson that the well shaft could have been dug from the bottom up, giving as his reason the fact that the bottom of the well shaft goes slightly below the level of the Descending Passage. Bruchet believes that this would not be so if the shaft had been started from below.

For the well shaft to have been dug from above, the operation could only have been completed *before* the Ascending Passage was plugged, or *after* the opening of "Al

Mamun's hole." In a closed upper Pyramid there would have been no place to store the carloads of rubble from the digging of the well shaft: the King's and Queen's chambers would not have been sufficient, and storage in the sloping Grand Gallery would have required crosspieces and sacks.

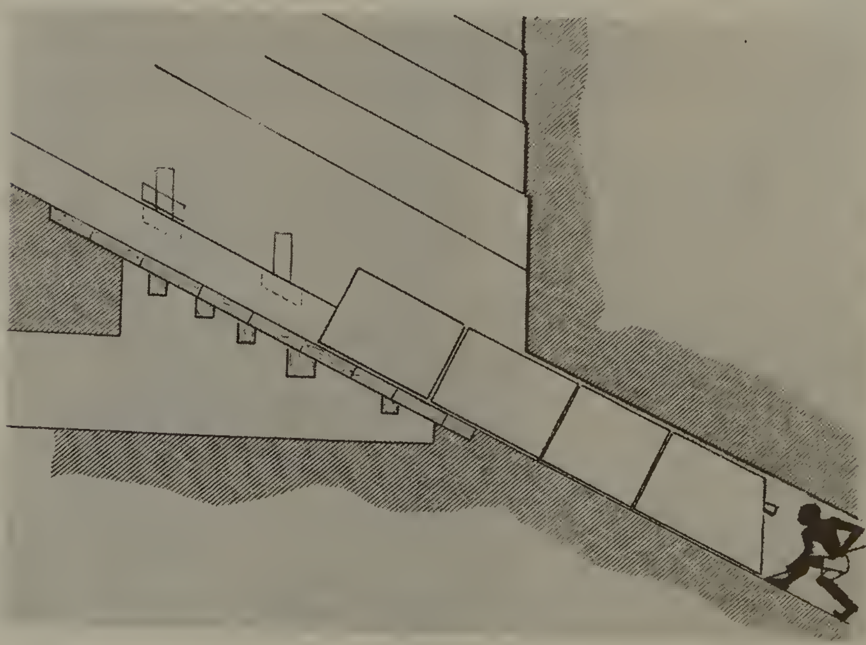
Bruchet points out that the well shaft could not have been dug *after* Al Mamun, because the lower end of the Descending Passage was filled by him with the refuse of broken limestone plugs, which were not cleared out till 1817 by Caviglia. Also, says Bruchet, there are no graffiti to indicate the presence of visitors in the lower passage after the date of the Hegira.

Another Frenchman, Georges Goyon, who collected reproductions of all the graffiti on the Pyramid, which he put into a book dedicated to King Farouk, also does not accept the idea that the service shaft was used as an escape way. He too believes the Pyramid was violated a short time after it was built, and that "Al Mamun's hole" was made at this early period. He even goes so far as to suggest that the first violators entered by the tunnel now attributed to Al Mamun, and that Al Mamun's violation was made *after* the ablation of the Pyramid casing, which is in strict contradiction with the historical record.

Maragioglio and Rinaldi find some of Goyon's theories tenable, but are awaiting the publication of a booklet by Goyon in which he promises to add further material on the subject.

In a recent article in *Revue Archéologique,* entirely devoted to the mechanism of the closing of the Great Pyramid, Goyon suggests that one or two men alone could have manipulated the whole train of blocks down the Ascending

Goyon's view of how a single man could have eased a train of granite plugs down the Ascending Passage with the help of unguents and wooden wedges.



Passage by simply sliding them on clay mixed with cows' milk for greater viscosity, controlling the downward motion by means of wooden wedges on either side of the first block.

Goyon says there are indications on the lowest granite block of two slots 7 centimeters wide intended for wedges.

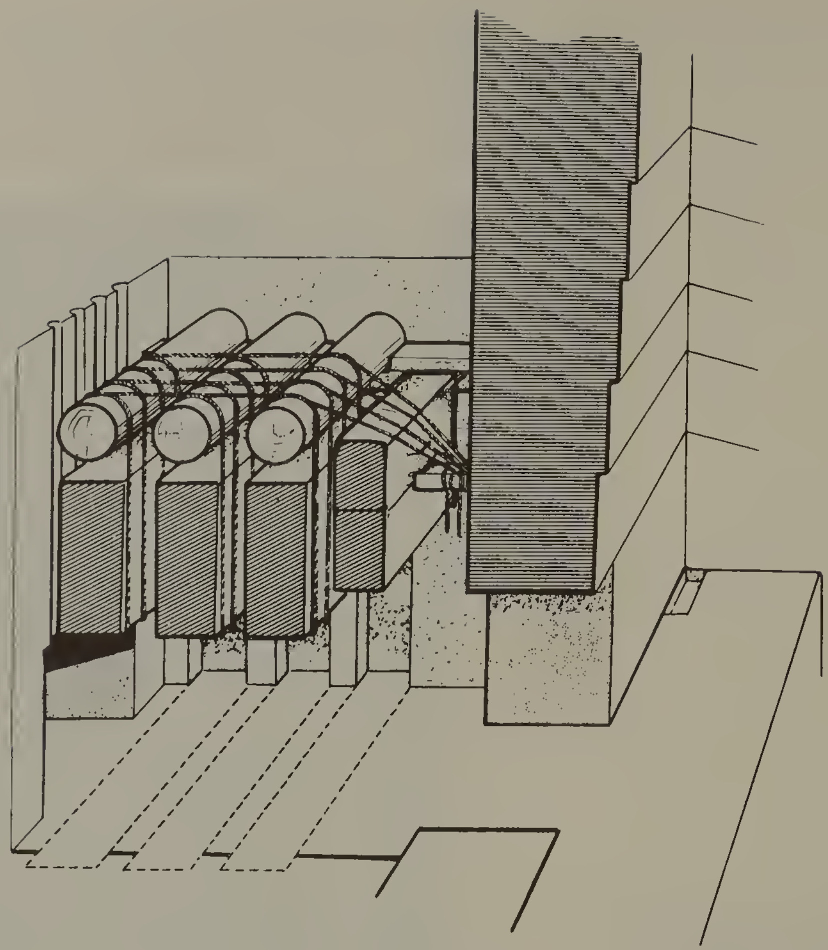
Goyon's arrows indicate slots in the granite plug for the insertion of wedges to control its downward movement.

Goyon disputes the point made much of by Davidson that the purely stylized portcullis outside the King's Chamber indicates it was never used to seal an actual tomb.

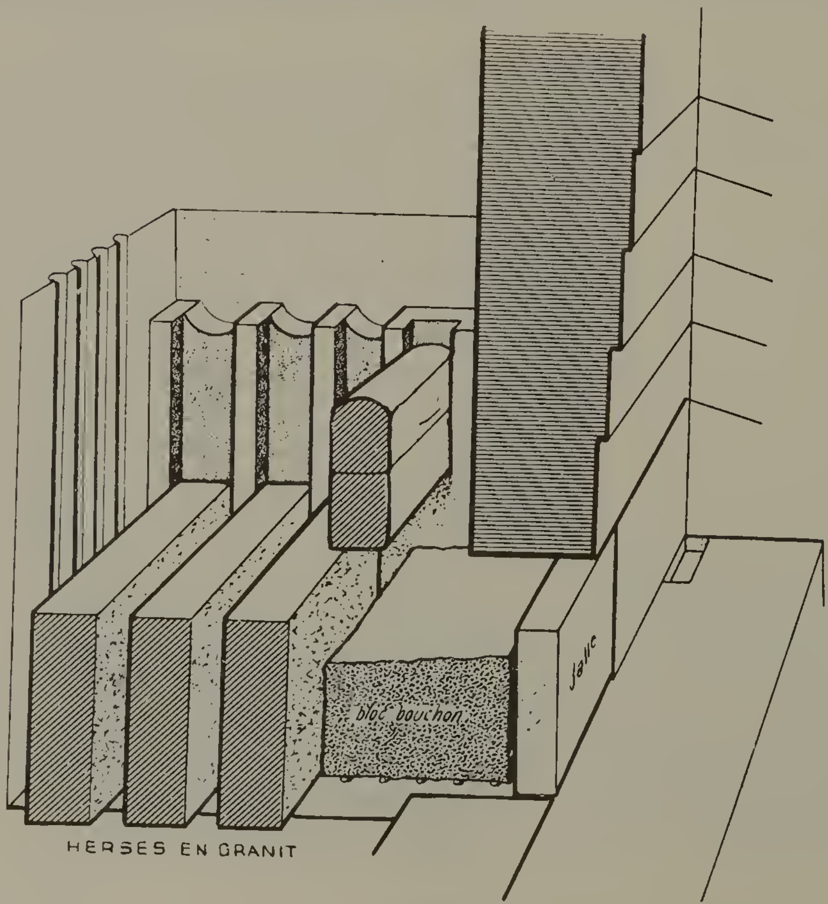
Goyon believes that the granite slabs—long since removed by grave robbers—could have been lowered in the appropriate side slots by ropes run on wooden rollers, and that the four vertical slots carved in the face of the portcullis were intended to allow free play for the ropes.

In the final analysis, the theory which stands up best, and is not in conflict with Davidson's findings, is that of the astronomers Proctor and Antoniadi, which is supported by Kingsland and John and Morton Edgar, that the truncated Pyramid served as a stellar observatory by means of which the ancient Egyptian priests were able to make accurate maps and tables of the visible stars from which to create their entire science of astronomy, geography and geodesy. Once they had obtained what they needed for their astronomical and astrological predictions (and for the secrets of surveying and map making), they may have decided to wall up their instrument so that no one else could know how their lore was obtained.

Borchardt's idea of how ropes around wooden rollers could have been used to lower the granite slabs of the portcullis.



Goyon's rendition of granite blocks plugging passage to the King's Chamber.



It would then have made sense to place the granite and limestone plugs in the Ascending Passage while the top of the Grand Gallery was still open to the level of the King's Chamber. To satisfy this theory, the well shaft could have been carved upward, as suggested by Davidson, or it could have been built in earlier to serve the builders for a variety of reasons, including to serve as a means of coming and going to the pit while the Descending Passage was blocked by a reflecting pool. In any case, the shaft could have been comfortably filled from the top before the builders finished off the building to its apex to serve as a sundial and almanac.

Donald Kingsbury, a professor of mathematics at McGill University, suggests that the well could have been used for observing the passage of stars at the zenith above the Pyramid. There are two vertical sections of the well which could have served this purpose admirably and at different moments in the construction. There is a short vertical passage dug into the plateau which is served by the Grotto and linked to the Descending Passage so that signals could have been freely passed between polar and zenith observers. Another vertical section leads from the bottom of the Grand Gallery and could have been used for zenith observation in conjunction with the Ascending Passage looking south and reflecting north. Kingsbury points out that with two such wells a short distance apart the circumference of the earth could have been computed by observing the passage of a zenith star.

Duncan Macnaughton in *A Scheme of Egyptian Chronology* subscribes to the slightly different theory that ancient scientists used the truncated Pyramid as an observatory, but that a later generation finished it off as a tomb for some Pharaoh.

The custom of burying distinguished citizens in national monuments that were not originally designed for that purpose is common to the world, as in Westminster Abbey, the Invalides, the Pantheon, and Maes-Howe.

Then there is the idea that the sarcophagus was never an actual tomb, but "an open tomb" symbolic of the resurrection, and of a reawakening of the dormant spirit of the great initiates.

XX. TEMPLE OF SECRET INITIATION

Several authors have expressed the opinion that there is a close connection between the Great Pyramid and what are known as the Egyptian mysteries, that is to say, the secret knowledge possessed by a hierarchy of initiates which was communicated to those who could prove their worthiness by passing a long period of probationary training and severe trials, the sort of system that was perpetuated or debased by such societies as the Templars, the Rosicrucians, and the Masons.

In due course the initiates are said to have been shown the great laws and principles of the cosmos and of man's relation thereto, which could not be explained to the more or less ignorant, "who could not rise above the level of a crude realism which takes things to be what they *seem.*"

The Egyptian temple order is described by modern Free Masons as a gradual process of initiation and admission, in which the Great Pyramid was probably used for the initiation of the highest degree, or the three highest degrees in the order.

Throughout the graduated admission, which is said by Masonic writers to have lasted twenty-two years, the prospective initiate was taught the various sciences, of which geometry and numbers were among the most important. "In this context," says Tons Brunés, author of *The Secrets of Ancient Geometry,* "it is not surprising that they should have worked this knowledge into the structure of the initiation temple."

Knowledge of the astronomical cycles and their application also formed part of the ancient initiatory teaching. In those days, says William Kingsland, astronomy was not the mere science of the mechanism of the heavens, but was intimately connected with astrology, "a profoundly esoteric science connected with the great cycles of man's evolution, understood only by the Adepts."

Kingsland adds that if the Great Pyramid was built by initiates for initiates, "What could be more likely than that some of the deeper forces of nature were used in its construction, and that these would—did we but know of them—solve the problems of construction which still remain an enigma to us."

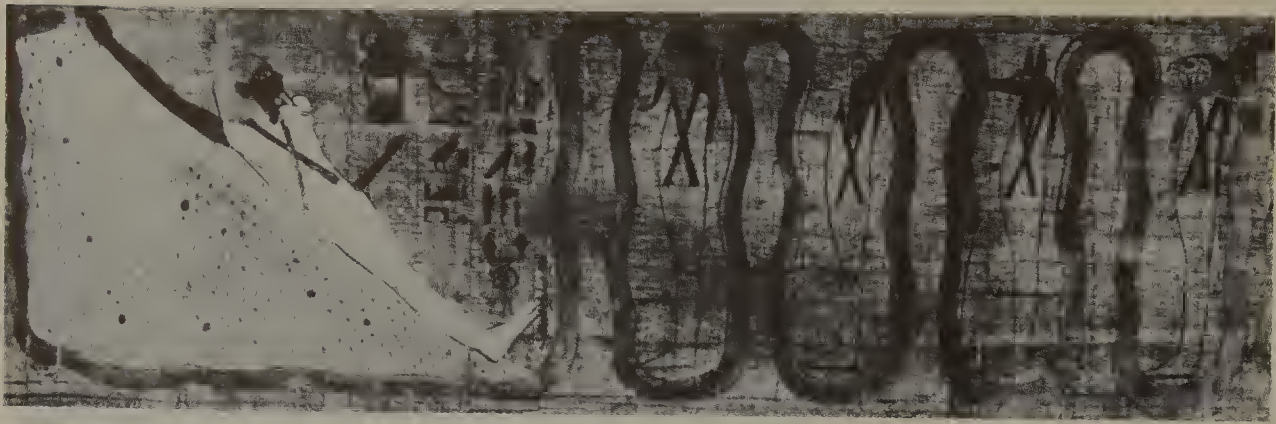
The theosophist H. P. Blavatsky in *The Secret Doctrine* says the Pyramid not only indicated the courses of the

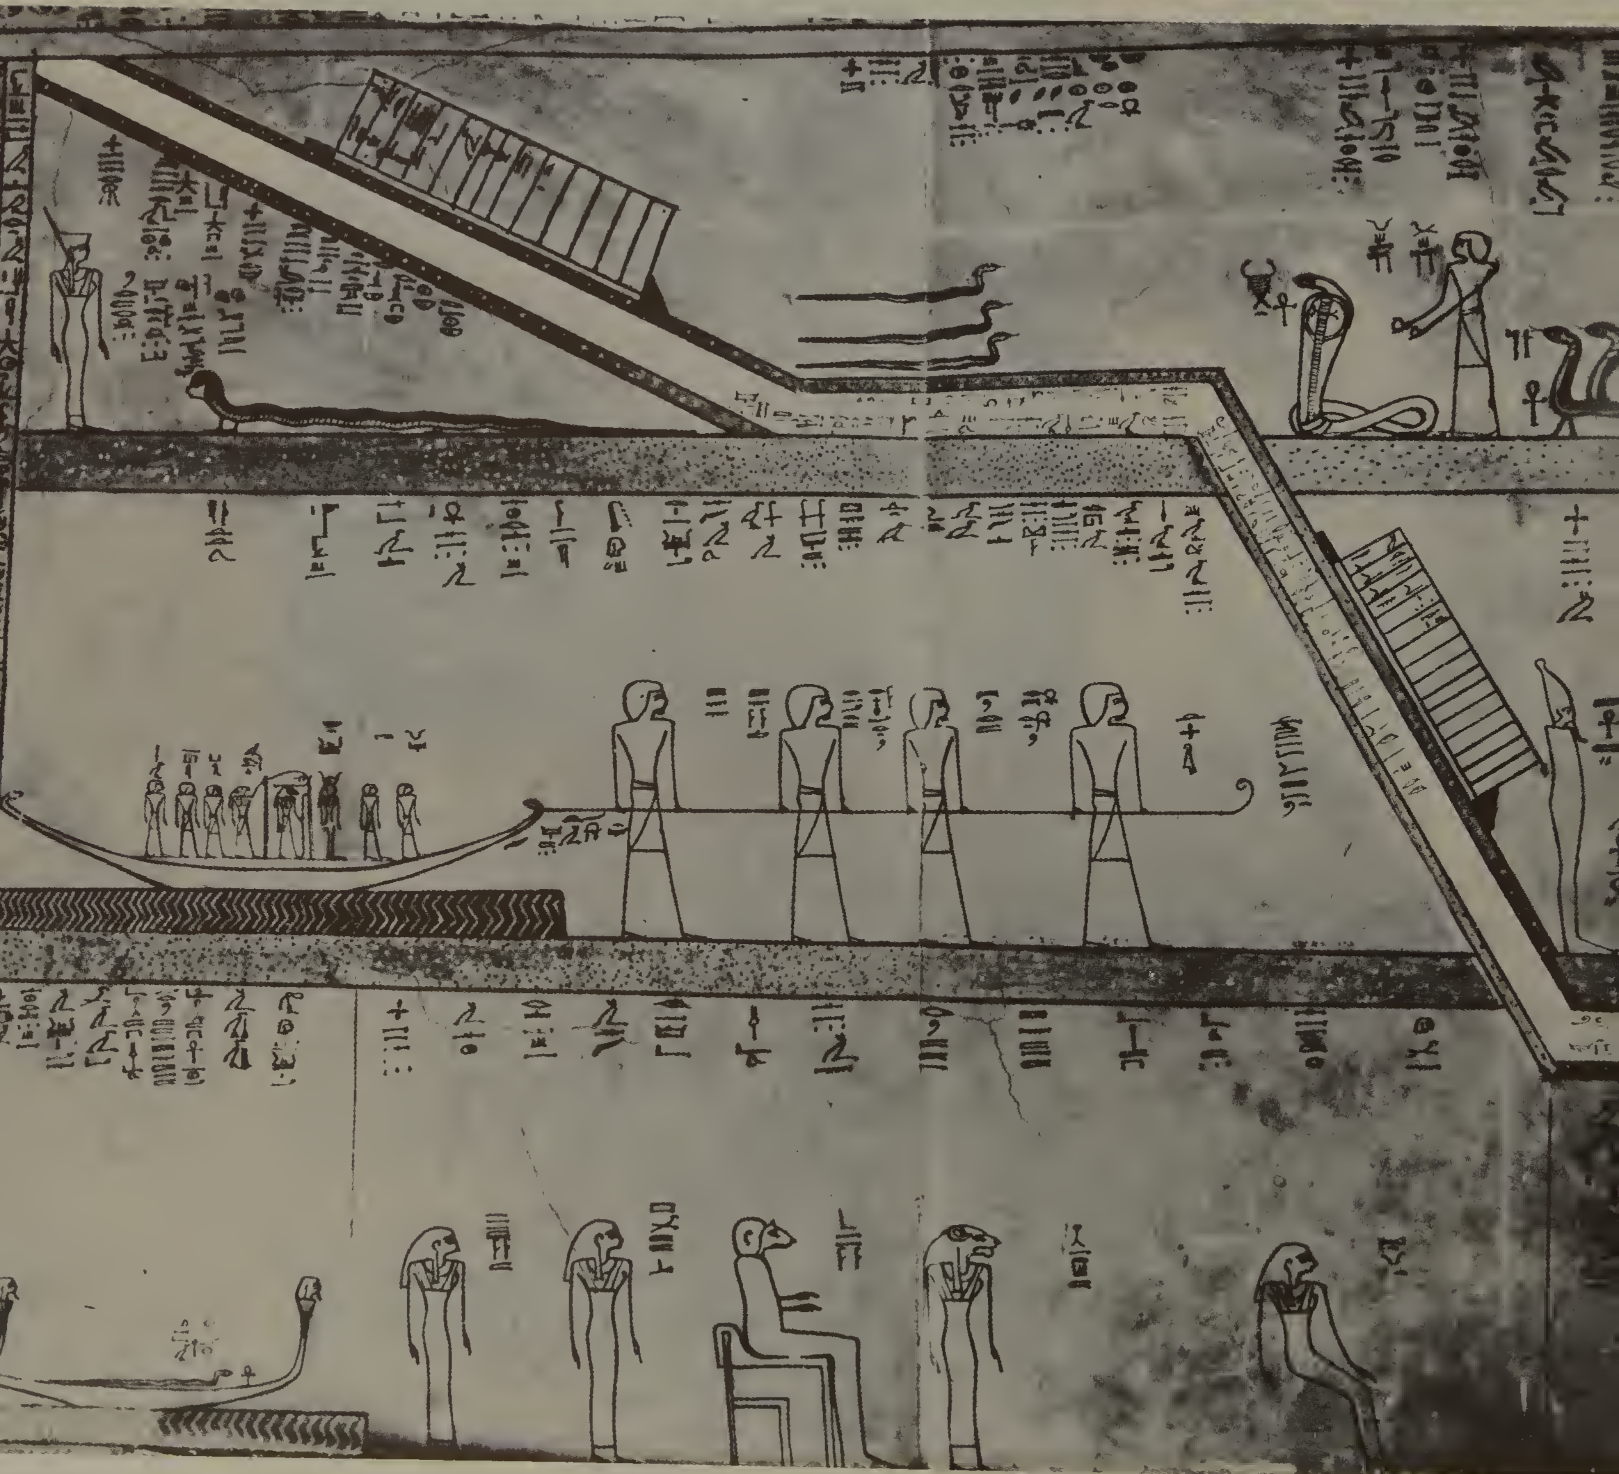
According to Manly P. Hall, the illumined of antiquity passed through the mystic passageways and chambers of the Great Pyramid, entering its portal as men and coming forth as gods.

"The candidate," says Hall, "was laid in the great stone coffin, and for three days his spirit—freed from its mortal coil—wandered at the gateways of eternity. His *Ka*, as a bird, flew through the spiritual spheres of space. He discovered that all the universe was life, all the universe was progress, all the universe was eternal growth. Realizing that his body was a house which he could slip out of and return to without death, he achieved actual immortality. At the end of three days he returned to himself again, and having thus personally and actually experienced the great mystery, he was indeed an Initiate—one who beheld and one to whom religion had fulfilled her duty bringing him to the light of God."

stars in heaven but was "the everlasting record and the indestructible symbol of the Mysteries and Initiations on Earth." In *Isis Unveiled* Madame Blavatsky elaborated, saying that whereas externally the Pyramid "symbolized the creative principle of Nature, and illustrated also the principles of geometry, mathematics, astronomy and astrology," within the building itself was the site of the mysteries of initiation—"a temple of initiation where men rose towards the Gods and the Gods descended towards men." To Blavatsky the coffer was "a baptismal font upon emerging from which the neophyte was born again and became an adept."

Brunés says that during the ceremony of initiation, the candidate was placed by the temple leader in a deathlike trance symbolizing death itself. On awakening from this condition, "having wandered in the world of the gods," he was regarded as having been reborn.





Blavatsky describes the ancient rite: "The initiated adept, who had successfully passed through all the trials, was attached, not nailed, but simply tied on a couch in the form of Tau . . . and plunged into a deep sleep (the 'Sleep of Siloam'). He was allowed to remain in this state for three days and three nights, during which time his Spiritual Ego was said to confabulate with the 'gods,' descend into Hades, Amenti, or Patala (according to the country) and do works of charity to the invisible beings, whether souls of men or Elemental Spirits; his body remaining all the time in a temple crypt or subterranean cave. In Egypt it was placed in the Sarcophagus in the King's Chamber of the Pyramid of Cheops, and carried during the night of the approaching third day to the entrance of a gallery where at a certain hour the beams of the rising Sun struck full on the face of the entranced candidate, who awoke to be initiated by Osiris, the Thoth and God of Wisdom."

For such a rite to have been possible, either the Pyramid must still have been truncated, or it contains secret passages at present undiscovered.

Most of the ancient philosophers and great religious teachers, including Moses and St. Paul, acknowledged or are acknowledged to have derived their wisdom from the Egyptian initiates. Individuals who admitted or hinted they were initiates include Sophocles, Solon, Plato, Cicero, Heraclitus, Pindar and Pythagoras.

Some of the ceremonies of what are sometimes referred to as the lesser mysteries have survived in a more or less degraded and merely formal manner in the ritual of Masonry and of the Christian churches. Kingsland believes the secret of the Pyramid is even known to present-day initiates, but is probably "one of those matters which they do not see fit to disclose to the world at large."

According to Norman Frederick de Clifford, author of *Egypt, the Cradle of Ancient Masonry,* ancient Masonry had its origin long centuries before the dawn of authentic history; he claims the ancient brotherhood "possessed a far greater knowledge of mechanical arts and sciences than is known to architects of the present day."

Several authors, including W. Marshal Adams, believe the Pyramid represented in monumental form the doctrine which *The Book of the Dead* sets forth in script, containing in an allegorical and symbolic manner the secret wisdom of the initiates, or the laws which govern and direct the universe, enabling the initiate to know "how he came into being in the beginning."

The Book of the Dead is the title generally given to a collection of Egyptian inscriptions and papyri found in tombs

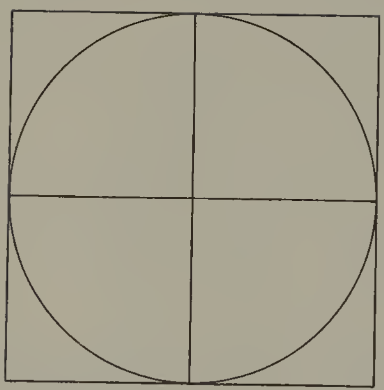
These illustrations from Albert Champdor's *The Book of the Dead* show a mummy with phallus erect sliding into the Seventh Region of the Lower World, described as being "filled with serpent's coils and the four sons of Horus who protect the viscera of the dead." This Twenty-first Dynasty drawing has lost the precise φ proportions of the earlier renditions of the same subject shown in earlier illustrations.

or in mummy wrappings. Sir E. A. Wallis Budge translated it as *The Book of the Mistress of the Hidden Temple*. One late text found with a mummy was on a papyrus roll 20 meters long divided into 165 chapters. It is now in the Turin Museum.

The ancient Egyptians attributed *The Book of the Dead* to Thoth, Lord of Wisdom, and recorder of the deeds of men, which were produced when the soul came to judgment.

Egyptologists in general label it a collection of funerary and ritual texts of different periods in different forms, used by ancient Egyptian priests in their burial ceremonies. But Henri Furville in his *La Science Secrète* claims that the texts of *The Book of the Dead* are incomprehensible to those who never made a careful study of them from the point of view of psychic science. The obscure texts, says Furville, "shine in the light of initiation, and the practices which seem extraordinary and even absurd to the profane, are, on the contrary, the result of the most profound science."

The problem of translating hermetic language from hieroglyphs is highlighted by Giorgio de Santillana when he points out that in the Erman-Grapow Egyptian dictionaries there are thirty-seven terms for "heaven." As a result, says Santillana, the elaborate instructions in *The Book of the Dead* referring to the soul's celestial voyage translate into "mystical" talk, and must be treated as holy mumbo-jumbo. Modern translators, says Santillana, believe so firmly in their own invention, according to which the underworld has to be looked for in the interior of our globe—instead of in the sky—that even 370 specific astronomical terms would not cause them to stumble. He gives as an example the goddess Hathor being described as "lady of every joy," when the literal translation is "the lady of every heart circuit." The determinative sign for "heart," explains Santillana, often figures as the plumb line coming from the astronomical or surveying device, the *merkhet*. "Evidently," says Santillana, "the heart is something very specific, as it were, the center of gravity."



J. Ralston Skinner in *The Source of Measure* was convinced that the Pyramid was not a tomb, but a temple of initiation. He went further and linked the Pyramid to the Jewish cabala, a system of allegorical symbolism among the initiated which sets forth the secret teachings of the Bible, concealing the great cosmic principles of man's origin.

According to Skinner the key to the cabala was said to be the geometrical relation of the area of the circle inscribed in the square, or the sphere in the cube. This gave rise to the relation of the diameter to the circumference of a circle, with the numerical value of the relation expressed in integrals, such as 22/7.

The relation of diameter to circumference, says Skinner, was considered a supreme one, connected with the god names Elohim and Jehovah, the first being the circumference, the second the diameter, which were numerical expressions of these relations.

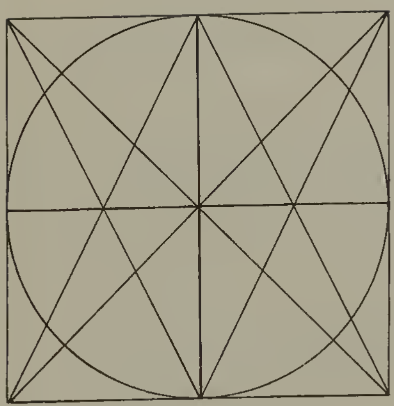
Tons Brunés, who dedicated his *The Secrets of Ancient Geometry* to the Fraternity of Free Masons, shows that the Great Pyramid, like most of the great temples of antiquity, was designed on the basis of an advanced but hermetic geometry known only to initiates, only fragments of which percolated to the classic and Alexandrine Greeks. According to Brunés, the secret of this ancient geometry was so well guarded that the whole of it was not revealed until the publication of his book in 1969.

Brunés shows how the ancient Egyptians used the basic design of a circle inscribed in a square to divide both circle and square geometrically into equal parts from 2 to 10, and all their possible multiples, without recourse to measuring or arithmetical calculations, with the aid of nothing but a straightedge and a compass—common emblems, along with the Pyramid, of the Masonic orders of yesterday and today.

In Brunés' reconstruction of the secret geometry, the cross emerges as the first geometric addition to the circle and square, and is the key not only to the solution of geometric problems but to the development of numerals and the alphabet.

By including the diagonals, every number both Latin and Arabic and all the letters of several alphabets may be obtained.

According to Brunés, both mathematics and the alphabet sprang from geometry, not the reverse. He says that nowadays we use numbers as the primary factor in our calculations, and geometry only as a subsidiary, whereas he believes the Egyptians reversed the order. He uses a detailed analysis of the Rhind Mathematical Papyrus to demonstrate that the ancient Egyptian system of counting was directly governed by geometric factors and that their ideas and theories were bound in geometric rules.



Brunés found that the circle was indeed considered sacred by the Egyptians, as were the square and the cross and the triangle, all of which are intimately incorporated into the Great Pyramid with its square base and triangular faces designed to represent the "sacred" circle.

Brunés demonstrates how the circle inscribed in a square and quartered by a cross enabled the ancient Egyptian geometer to inscribe in a circle the basic figures of pentagon, hexagon, octagon and decagon.

Of these the pentagon with its five-pointed star is perhaps the most important: it automatically produces the Golden Section and the φ proportion in the simplest geometric manner.

Each line of the five-pointed star—the symbolic sign of recognition of the initiated Pythagorean, whose hermetic meaning it meant death to reveal—cuts the other in the proportion of major to minor: the Golden Section.

Furthermore, the side of a pentagon inscribed in a circle whose circumference is equal to the perimeter of the Pyramid will be equal to the apothem, or slant height, of the Pyramid, which will be the value of φ.

A pentagon divides a circle in 72° segments. With the main cross, the pentagon radii form angles of 18°, 36°, 54° and 72°.

Though Greece has been looked upon as the birthplace of mathematics—largely because of surviving written material on the subject of mathematics and geometry—Brunes points out that Pythagoras, the founder of Greek mathematics, spent 22 years in Egypt as a priest of the temple, and only returned to Greece after Cyrus the Great, king of Persia, burnt the temples at Memphis and Thebes in 527 B.C. and dragged him off as a prisoner to Babylon.

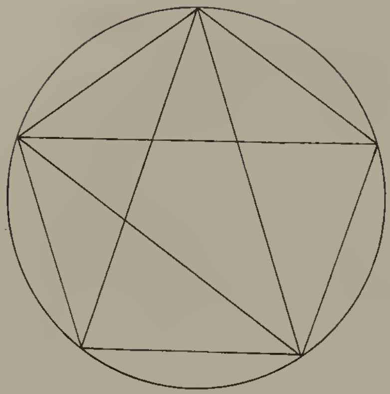
Back in Greece, Pythagoras taught mathematics on the basis of what he had learnt in Egypt; but after his death his followers were persecuted and had to take refuge abroad. Some eighty years later, Plato left Athens after the execution of Socrates and joined the Pythagorean societies. He traveled to Egypt, where he too was initiated into the lower degrees of learning in the temple, which were slowly recovering from being disbanded by the Babylonian-Persian conquerors.

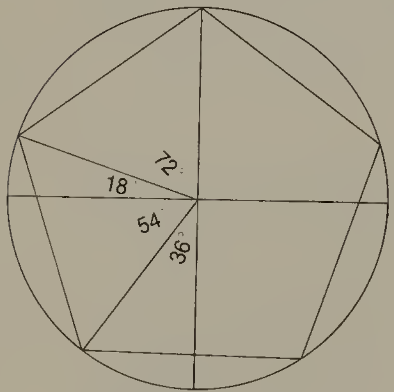
Plato collected documents and writings connected with Pythagoras. In the end he produced the concept that the cosmos was represented by the five regular solids that can be inscribed in a sphere.

Brunés maintains that Plato incorporated into the body of his writings, and especially in the *Timaeus,* the secret teachings of the Egyptians, which he had sworn not to divulge directly, but which he handled in a hermetic language for which Brunés provides a solution.

Brunés says that Moses, who was also an Egyptian priest, had knowledge of the ancient geometry, which he passed hermetically in his instructions for building the Tabernacle, data which eventually reached Jerusalem and were incorporated into holy teaching.

The French archeologist and mathematician Charles Funk-Hellet, in his *La Bible et la Grande Pyramide d'Egypte,* agrees that the cubit of the Bible can only be the Egyptian





$\sin 18° = \frac{1}{2}\varphi$
$\sec 36° = 2/\varphi$
$\sin 54° = \varphi/2$
$\sec 72° = 2\varphi$

The circle in a square with a cross and diagonals, plus a pentagon or decagon, enabled ancient mathematicians to measure lengths of $\sqrt{2}$, $\sqrt{3}$, $\sqrt{5}$, as well as multiples and fractions thereof without arithmetical computation.

royal cubit, which he makes a hair, or 1/2 millimeter, shorter than Stecchini's. According to Funk-Hellet the cubit was incorporated into the Temple at Jerusalem as $\pi/6$, or 523.6 millimeters, instead of Stecchini's 524.1.

Funk-Hellet points out that Solomon had Hiram Abiff build a temple whose columns were 18 cubits high and 12 cubits around. In other words, one cubit equaled the twelfth part of the circumference of the arc of 30°, or $\pi/6$.

By subtracting the circumference from the height, they obtained 6 cubits in a straight line, which was equal to half the circumference, or the exact value of π; so that a thousand years before Christ the Hebrews knew that a cubit was a mathematical entity dependent on the circumference, and were able to resolve π to four points of decimal.

Using *one unit* of measure as the radius of a circle, the ancients found the trigonometric value of 30° to be $\pi/6$, which was the value of the royal cubit, or .5236 of the unit used.

$$\frac{3.1416}{6} = .5236$$

Funk-Hellet found another additive series made by adding 5 to 1, and so on; 1, 5, 6, 11, 17, 28. . . . He developed the series in 18 columns and 36 lines horizontally, with some extraordinary results, including values for π, φ, and the royal cubit; this led him to conjecture that the royal cubit might have had a theoretical value before it had a practical one.

The first line gives the numbers 11, 17 and 28, which are divisions of both the royal cubit and the Chaldean cubit; furthermore, 11 × 17 × 28 equals 5236, which is Funk-Hellet's figure for the royal cubit in millimeters, or $\pi/6$.

The fourteenth column of the series gives the φ^2 value of 2.618, the royal cubit value of 5236, and the π value of 3.1416.

The second row produces the φ, or Fibonacci-type, series of $1/\varphi$, 1, φ, φ^2 with 618, 1000, 1618 and 2618.

The seventh column gives the divisions of a 360-degree circle in halves, quarters, eighths, etc.

Funk-Hellet maintains that as early as the fourth millennium B.C. the Chaldeans had a mathematical series which gave the exact values of the cubit, the meter and π. What's more, he insists that the present *meter,* as developed by the French in the nineteenth century, was already a hermetic measure known in antiquity, and was linked trigonometrically with the cubit.

To Funk-Hellet the Great Pyramid is a geodetic gnomon, or pillar, incorporating values for both the meter and the cubit. He says the finger, palm and cubit are built into the apothem. In the King's Chamber, he says, the double square of the floor is 5.236 meters by 10.472 meters—which varies from Petrie's and Davidson's measurements by a few millimeters.

Funk-Hellet says the basic meter unit from which the cubit was derived had to be kept a deep secret, presumably so that all the calculations, including the means for obtaining the exact length of the year, would remain the sole property of the officiating priests.

Schwaller de Lubicz in *Le Temple de l'Homme* corroborated the evidence that the Egyptians knew the meter, pointing out that on the whole length of a surrounding wall of the Third Dynasty (3000 to 2000 B.C.), "one finds three lines painted at the time, of which the distance between two lines is exactly one meter," adding that this is not an isolated case, "but one of thousands." In ancient constructions of Troy, Heinrich Schliemann found a unit of measure which was exactly half a meter, or 50 centimeters.

Funk-Hellet says the meter and the cubit depended from each other and were both defined by geodetic measurements. He suggests the way the meter was derived by the ancients was by watching from a measured height the moment a light disappeared on the horizon.

At the beginning of the nineteenth century, Sir John Herschel tried to calculate the radius of the earth with two observers placed 10 feet above the sea who ceased to see each other at 12,873 meters. This gave Herschel an earth radius of 6797 kilometers instead of the correct 6378, or an error of 419 kilometers.

Funk-Hellet believes the ancient Egyptians did better. He points out that the full apothem of the Pyramid including the pyramidion is 10,000 fingers long, or 187 meters. He then computes that if 1870 meters is taken as an arc of 30°, the resulting radius will be 3570 meters. Modern experiments indicate that a light disappears on the horizon at 3570 meters when the eye of the observer is exactly 1 meter above the ground.

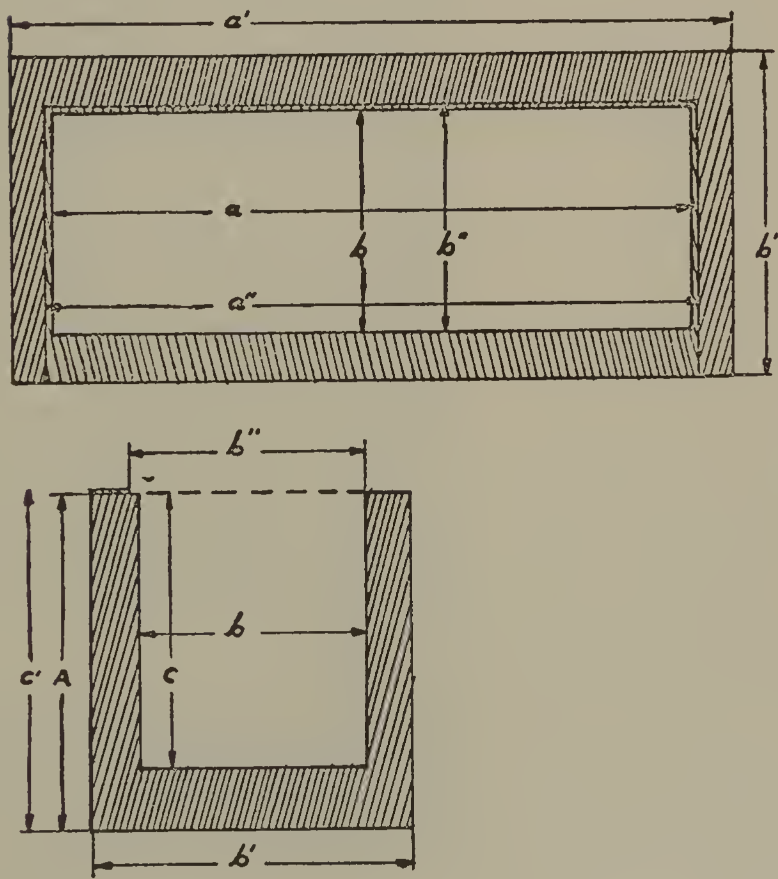
José Alvarez Lopez of Argentina, in his work *Fisica y*

Creacionismo, says that a cubit of 523 millimeters—about half a millimeter shorter than Funk-Hellet's and 1 millimeter shorter than Stecchini's—is exactly half of what he calls an *absolute meter,* which he says occurs as a natural unit in the solar system.

According to Alvarez Lopez the planets of our system orbit in harmonic distances from the sun which are multiples of a single unit of length—his *absolute meter*—in an arrangement which is naturally decimal.

Alvarez Lopez says that beginning with Mars, the planets are disposed in the order of the colors in the solar spectrum—with Mars as red, Jupiter yellow, Saturn yellowish-green, Uranus green, Neptune blue, and Pluto violet. According to Alvarez Lopez the Pyramid may once have been painted with the colors of the spectrum starting with red for Mars, just below the gilded pyramidion representative of the sun, and diminishing through yellow and blue to violet at the base, symbolizing the construction of the solar system both geometrically and with color.

The only evidence that the Pyramid may have once been painted, apart from the legends of the Arab storytellers, are some fragments of casing stone found in the early nineteenth century which were covered with what appeared to be red paint. Subjected to careful chemical and spectrographic



Alvarez Lopez's rendition of the dimensions of the coffer used by the Egyptians for basic astronomical ratios.

analysis at the Sorbonne, it was determined that the casing stones had once been covered with a layer of paint with a red ochre base, and that the paint could not have been caused by any chemical recomposition of the stone itself.

The Great Pyramid, says Alvarez Lopez, represents a decimal schema of the solar system. He figures the height of the Pyramid to be a millionth part of the distance to the sun, measured from the limit of the earth's atmosphere, and its base to be the ten-thousandth part of the surface of the earth.

The dimensions of the granite coffer in the King's Chamber, as worked out by the Argentine professor, are arranged to form a perfect "astronomical atlas": he says the inner measure gives an *absolute cubic meter,* but that the coffer was not designed as a cube so that its various inner and outer measures could also represent the various astronomical constants of the solar system.

He says there was just one way to build a coffer so that it would include not only the distance from the earth to the sun (a basic astronomical unit), but the weight of the earth, the weight of the earth and the moon, the weight of the sun in relation to the earth, the weight of the sun in relation to the earth and the moon, the weight of the earth in relation to the moon, the value of the absolute cubic meter, and the polar radius (one-half the diameter from pole to pole) of the earth in terms of an absolute meter.

Alvarez Lopez considers the original discovery of these figures to have been perhaps the hardest job yet mastered by man, and says this explains the care and trouble taken by the builders of the Pyramid to secrete the information in the heart of the building. Were the coffer not so badly chipped and worn, says Alvarez Lopez, it might give us more exact astronomical figures than we now possess.

All these astronomical constants, says the professor, depend on a precise knowledge of the solar parallax; he is amazed that the builders of the Pyramid could have known the parallax and the earth's polar radius so exactly without the help of telescopes and cameras. It will be interesting, he says, to compare our new figure for the sun's parallax with that of the granite coffer, as determined by the near passage of the small planet Eros, which occurs every 37 years and is due in 1975.

Stecchini is more *terre-a-terre.* He can show that the half meter found by Schliemann is really a Babylonian cubit of .49907 meter and that the meter of Funk-Hellet and de Lubicz is in fact three feet of .3329 meter, both derived from the geographic foot and cubit.

When I reminded Stecchini that Petrie had found the coffer in the King's Chamber to be designed in even numbers of fifths of a cubic cubit, Stecchini resolved the millennial riddle of the coffer by showing that it contains exactly 40 *artaba,* or 40 cubes whose sides are one geographic foot, and that its outside volume is twice this amount, or 80 cubes of one geographic foot.

Would it not be worthwhile, nonetheless, for academic institutions, so admirably equipped with computers and talent, carefully to analyze such conceits as those of Alvarez Lopez and Funk-Hellet and either refute them or support them with reliable data? Some of their ideas may turn out to be no wilder than those for which Jomard, Taylor, Smyth and maybe even Davidson were unjustly lampooned.

Napoleon's French Institute in Cairo.

XXI. MORE SECRET PASSAGES AND CHAMBERS

Many Egyptologists and explorers were convinced—and many still are—that the Pyramid conceals one or more secret and yet undiscovered chambers. It is also believed that the Pyramid is connected by subterranean passageways to other pyramids, to the Sphinx, and to long-demolished reception halls, small temples and other enclosures.

The engineer of the Australian railways, Robert Ballard, believed the Giza pyramids may also have been built above a vast series of catacombs, with chambers and galleries, like the pyramids of Lake Moeris, which are said to have vast subterranean residences for its priests and keepers.

Ballard suggests that much of the limestone for the structure of the pyramids of Giza may have been quarried from such catacombs. He suggests that a good diamond drill with two or three hundred feet of rods be used to make tests on the Giza plateau. Ballard believes that when this subterranean city is discovered, it will be found that it had access passages for the priests and the surveyors linking it to every pyramid.

While the pyramids appeared to the outside world to have been sealed up as mausoleums for the dead, says Ballard, the sealing may simply have rendered more mysterious and private the recesses and abodes of the priests who entered from below, and who were possibly enabled to ascend by private passages to their very summits.

When Perring and Howard-Vyse were exploring the bent pyramid at Dashur in 1839, they noticed an extraordinary phenomenon. The workmen clearing the passages were suffering from intense heat and lack of oxygen when suddenly a strong cold wind began to whistle through the passages. It blew so fiercely for two days that the men had trouble keeping their lamps lit. Mysteriously it stopped and no one has yet figured out the mystery.

Ahmed Fakhry, working in the same pyramid in the 1950s, heard weird noises which led him to conclude that there must be undiscovered passages within or under the bent pyramid.

Edgerton Sykes, an archeologist and author, who is perhaps the best living authority on ancient Atlantis, also

Herodotus speaks of a palace complex of 3500 chambers half above and half below ground at Moeris. The Egyptians called it "the temple at the entrance to the lake." Herodotus called it a "labyrinth," and considered that it outranked the pyramids as a wonder.

believes there is a whole maze of corridors and passages dug into the Giza hill. Sykes quotes an ancient Arab source to the effect that the designers of the Pyramid made "several doors, built over underground vaults of stone, each with a secret stone door revolving upon a hinge."

Peter Kolosimo believes there are more tombs and caves beneath Saqqara, Abydos, and Heluan, of very ancient dynasties, and reports the legends of hidden doors "that could be opened by a mysterious force" such as a supersonic wave length, or specially resonant voice.

According to the Baron de Cologne, as quoted by Robert Charroux in *Le Livre des Secrets Trahis* (Paris, Laffont, 1965), there is an underground kingdom under the Egyptian desert similar to the "Agartha" of Tibet.

Commander Barber, the American attaché who gave such attention to the construction of the Pyramid, wrote that "when one considers the inexplicable and yet exact arrangement of the various chambers and galleries, and that there is room for 3700 more such chambers, provided we could find them, we can almost be tempted to believe that we have not yet discovered all the chambers or even the true chamber of Cheops."

Piazzi Smyth was equally convinced that there was an undiscovered chamber in the Great Pyramid "which will prove to be the very muniment room of the whole monument."

Bent pyramid at Dashur. Arrow points to a secondary entrance to pyramid high on the north side.

When a multitude of chips of black diorite rock were discovered on the Pyramid hill, Smyth surmised that the undiscovered chamber might be lined with black diorite.

Thomas Holland, a Thirty-third Degree Free Mason, believed that if the granite leaf were removed from the portcullis it would disclose the way to "magnificent passages and chambers hitherto undiscovered."

Louis P. McCarty, in a privately printed booklet, *The Great Pyramid of Jeezeh,* published in San Francisco in 1907, says he believes the Pyramid contains at least three more chambers located between the King's Chamber and the apex, and at least one with double the capacity of the King's Chamber. McCarty believes the next largest chamber will be found at the 75th course, and the largest at the 100th course, and that the largest should be of an equal capacity to the three below it. He believes there is a fifth and final chamber on the 120th course of masonry, and that this one should be just half the capacity of the King's Chamber. McCarty also subscribes to the theory that there is a passage somewhere beneath the northeast corner of the Pyramid which leads to the Sphinx.

Funk-Hellet suspects there might have been a room on top of the present platform, now destroyed.

William Kingsland, in his two-volume work on the Pyramid, suggested generating radio waves of 5 meters length in the King's Chamber, and by noting the strength of reception at measured intervals all round the outside of the Pyramid, determine if some hidden chamber might exist.

In the late 1960s Dr. Luis Alvarez, the 1968 Nobel Prize winner for physics, developed a machine for recording the passage of cosmic rays through the pyramid of Kephren, by means of which he hoped to discover any secret chambers or passages within its body.

The operation, which required a team of scientists, turned into an expensive venture in which twelve United States and United Arab Republic agencies became involved, including the U.S. Atomic Energy Commission, the U.A.R. Department of Antiquities, the Smithsonian Institution and the Faculty of Science of the Ein Shams University in Cairo.

Alvarez's project was based on the fact that cosmic rays, which bombard the planet day and night, lose part of their energy as they pass through an object, in proportion to the density and thickness of the object.

By placing a "spark chamber" in the subterranean vault of the pyramid the scientists planned to monitor the number of cosmic rays which made their way through the pyramid walls. Those rays which passed through a void in the body of the pyramid would reach the chamber more frequently than those traversing solid rock, and the variance would indicate the presence of a secret chamber or passage in the pyramid.

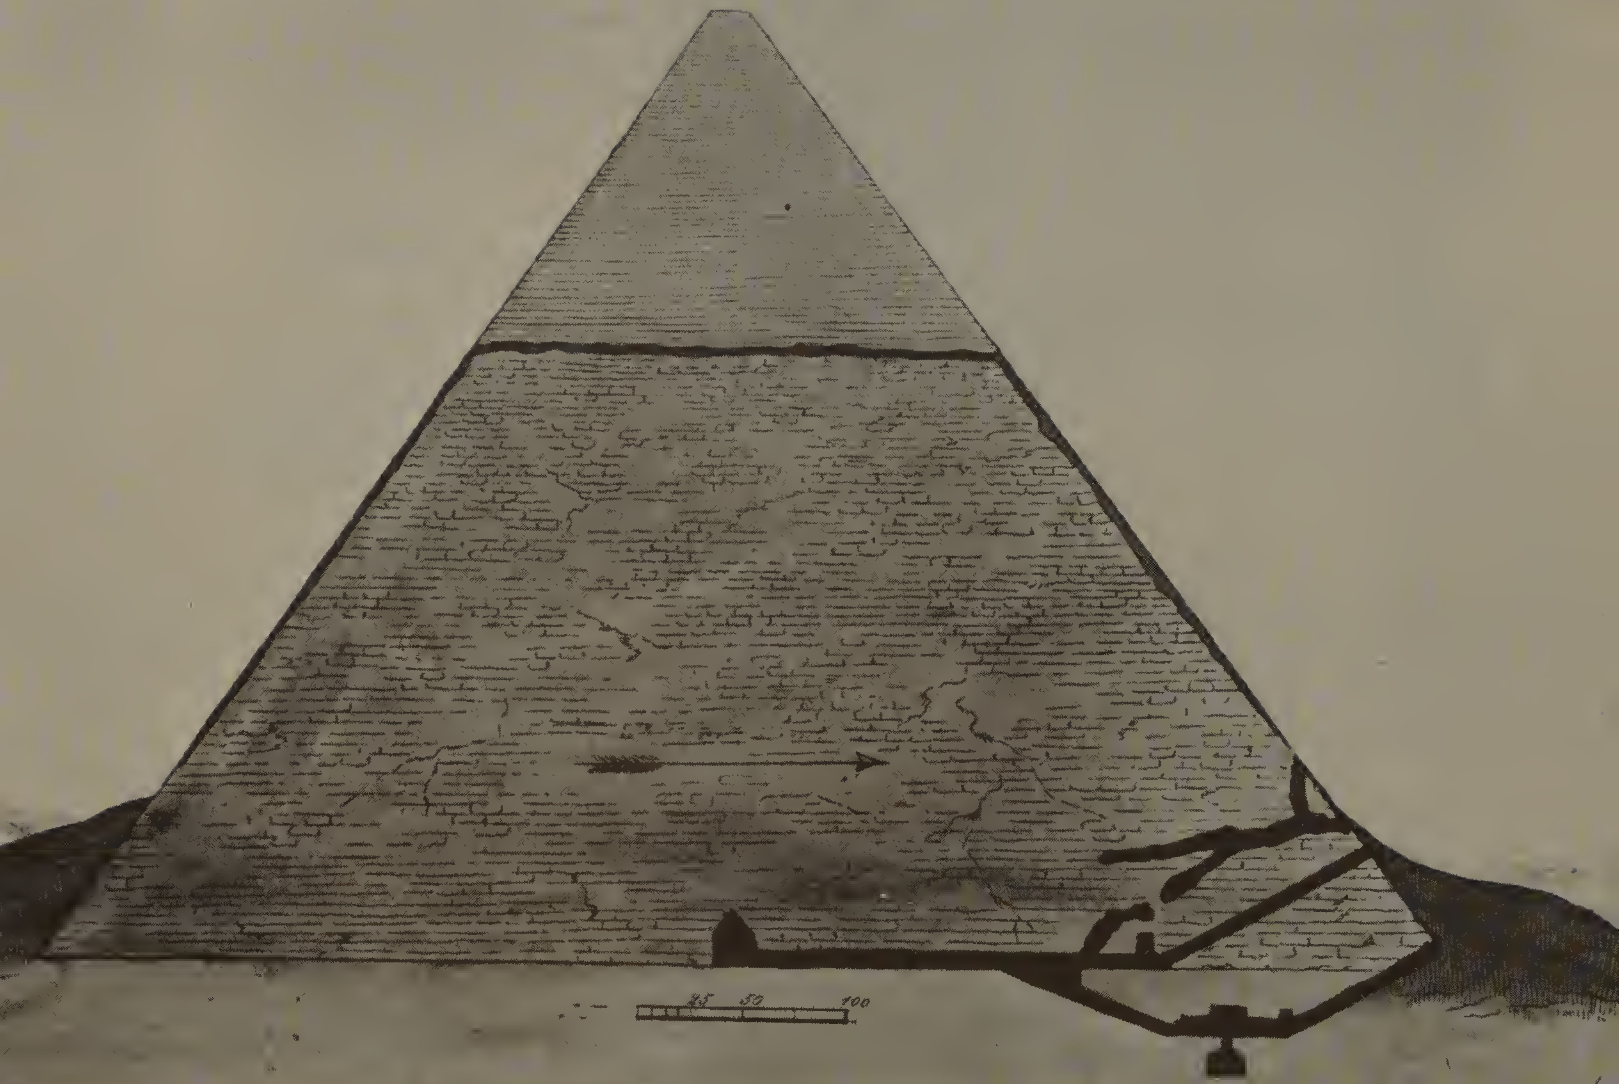
The path of each ray is recorded electronically and stored on a magnetic tape. The tapes are then fed into a computer to calculate and memorize the point at which each recorded ray penetrated the surface of the pyramid.

To pinpoint the location of any cavities which showed up, the scientists planned to shift the "spark chamber" and obtain a sort of stereo picture.

Were any hidden chamber located, it would then be possible to dig directly to it without risking great damage to the rest of the pyramid. The operation would consist of drilling a small hole upward in the indicated direction of any cavity that appeared on their "X-ray plate." Modern optical tools would allow archeologists to look into the chamber through a long hole, perhaps 100 feet long and only 3/4 inch in diameter.

Dr. Alvarez chose the pyramid of Kephren because he considered it unlikely that Kephren, as the son of Cheops, would have had such an imposing pyramid erected without incorporating some secret system of passages and chambers such as have been discovered in the Great Pyramid.

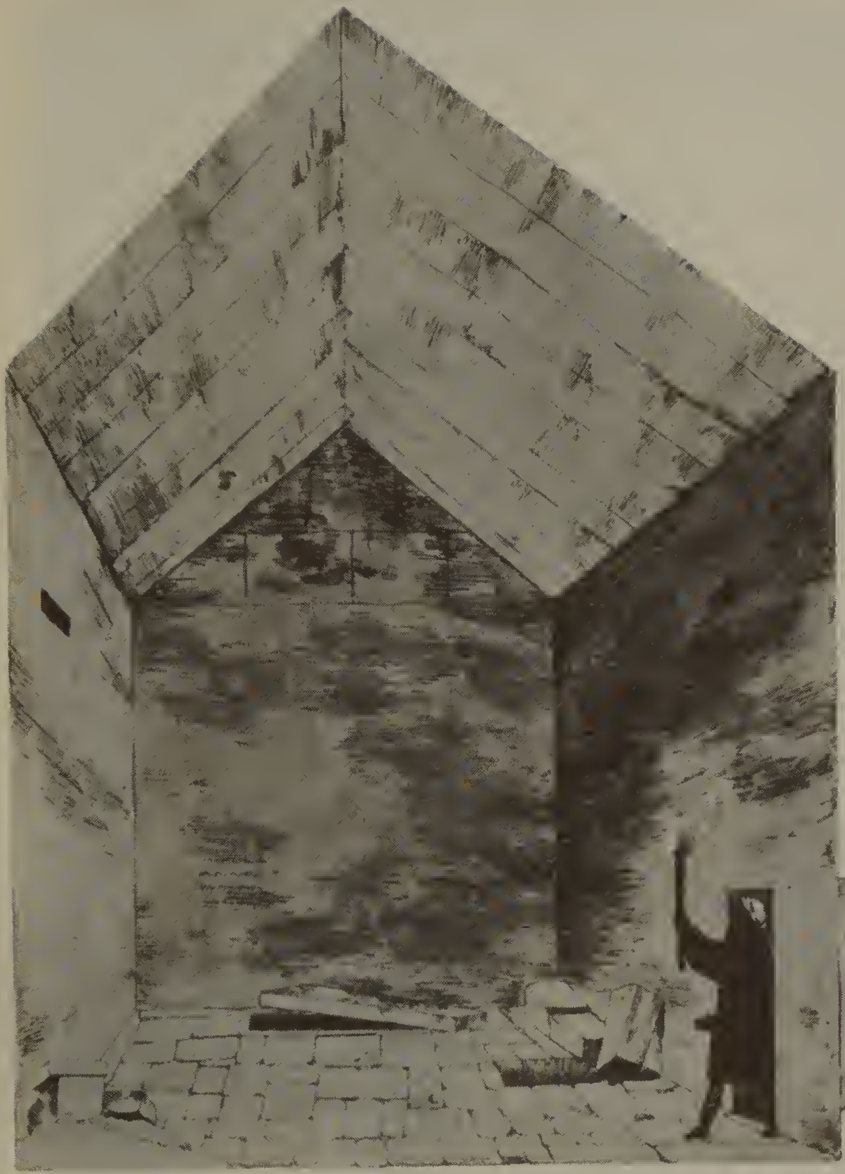
Alvarez assumed that Cheops' architects must have had a choice of clever ideas for secreting chambers, some of which had to be left out of his pyramid, but could have been applied to Kephren's. "My hunch," says Alvarez, "was that younger architects working on Cheops' pyramid would have had their ideas rejected. Later, in Chephren's time, they could have persuaded Chephren to use them, or some other improved plans."

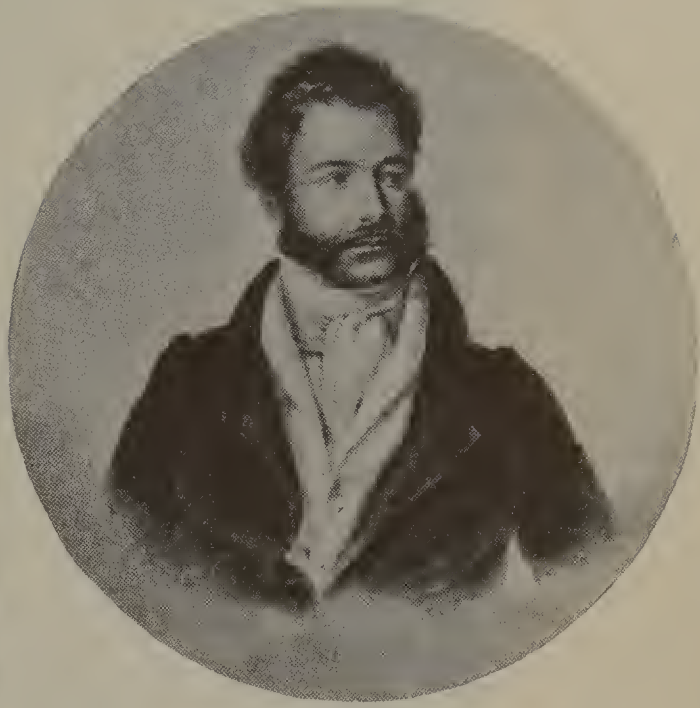


On this tenuous assumption Alvarez hoped to find a secret chamber in Kephren, and perhaps even the sarcophagus of the dead Pharaoh: an Egyptologist's dream.

Alvarez also chose Kephren's pyramid because its central chamber was more convenient for setting up his complex electronic equipment. The subterranean vault discovered in 1818 by the Italian explorer Giovanni Belzoni had recently been cleared of rubble, and other chambers and passages in the pyramid had been lit with electricity by cable from the nearby Mena House.

By September of 1968 two million cosmic-ray trajectories had been measured: these were considered ample for finding any hidden vault within the field of view of the upward-looking equipment. When the tapes were run through the local computer in Cairo for the first analysis, the results looked wonderful. They clearly





In 1818 the Italian adventurer Giovanni Belzoni tried to find an entrance to the second pyramid of Kephren.
He found what appeared to be the original entrance close to the ground plugged by three granite blocks. The passage was cleared all the way down to a funerary chamber containing only a granite sarcophagus. On the west wall of the chamber an inscription in Arabic indicated the chamber had been penetrated some time after the Hegira.

Portrait of Giovanni Belzoni used as a frontispiece for a book edited by his wife commenting on his exploits in Egypt.

showed up the corners and the faces of the pyramid as outlined by the passing cosmic rays, recorded in the central chamber. The equipment appeared to be functioning excellently. But there were some mysterious developments.

As Dr. Lauren Yazolino, Alvarez's assistant, returned to the United States to analyze the tapes on the most up-to-date computer at Berkeley, a correspondent from the London *Times* visited Cairo to check on the results locally. At Ein Shams University, John Tunstall found an up-to-date 1130 IBM computer surrounded by hundreds of tins of recordings.

"It defies all known laws of physics," Tunstall quoted Dr. Amr Goneid, who had been left in charge of the pyramid project since the return to America of Dr. Yazolino.

According to Tunstall's report, each time Dr. Goneid ran the tapes through the computer a different pattern would appear, and the salient points which should have

been repeated on each tape were absent. "This is scientifically impossible," Tunstall quoted Goneid, explaining that earlier recordings which had raised the hopes of a great discovery were now found to be a jumbled mass of meaningless symbols with no guiding pattern whatever.

Tunstall asked Goneid: "Has all this scientific know-how been rendered useless by some force beyond man's comprehension?" To which Goneid is reported to have answered: "Either the geometry of the pyramid is in substantial error, which would affect our readings, or there is a mystery which is beyond explanation—call it what you will, occultism, the curse of the pharaohs, sorcery, or magic; there is some force that defies the laws of science at work in the pyramid."

At Berkeley, Alvarez refuted Tunstall's account, insisting that the equipment was functioning admirably. In the 35° cone scanned by the spark chamber there was no sign of any hidden passageway or chamber. This was the area believed by the scientists to be the most likely to contain them, though there was still hope of finding something in the remaining sections.

As soon as further funds were available the team of scientists planned to resume their scanning of Kephren. Dr. Yazolino added that if sufficient funds were available they might even move their equipment to the Queen's Chamber in Cheops to see if they could find any unknown passages or chambers in the Great Pyramid.

Yazolino explained that the only trouble they had encountered had been poor readings when the spark chamber ran out of neon and produced some mysterious dark spots which looked like a possible chamber till they were carefully analyzed and found to be caused by the gap between two spark chambers.

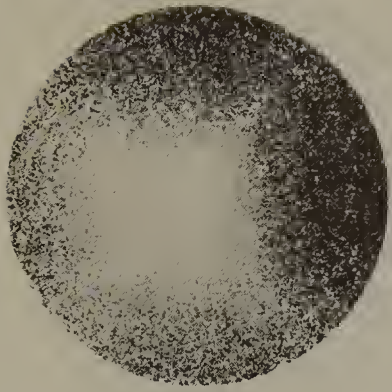
Alvarez stressed his confidence in Dr. Goneid as a very able physicist, saying that he thought so much of him he had invited him to spend a year at his lab at Berkeley. "If I thought for a moment that he had said any of the nonsense attributed to him, you can be sure I wouldn't want him as a member of my research group."

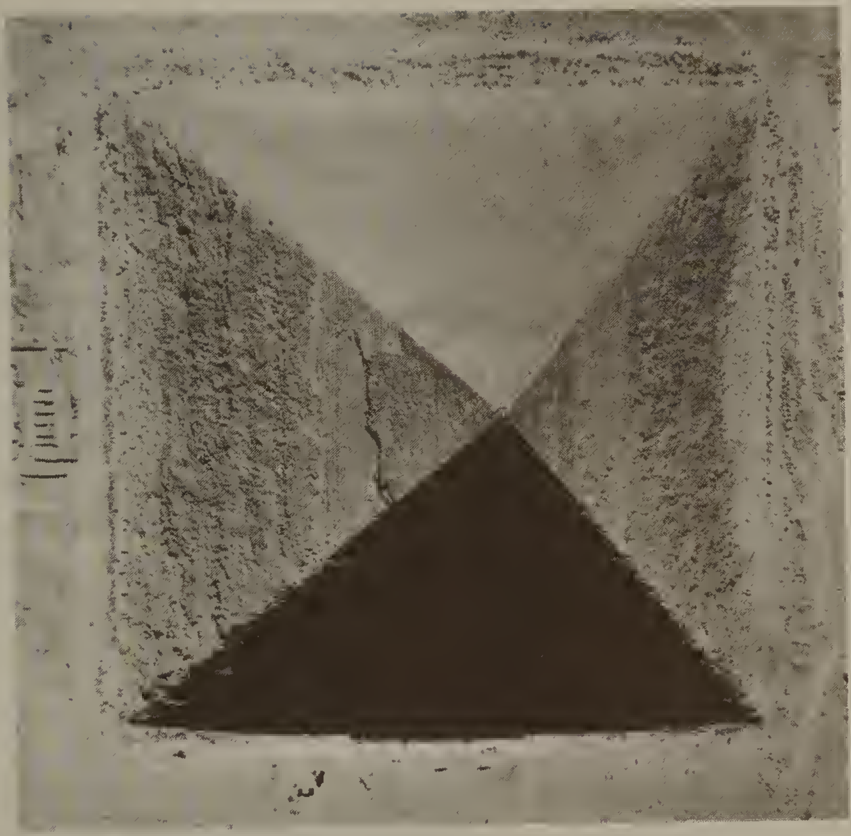
Yet there remains something mysterious about the pyramid which needs to be explained.

When a Frenchman, M. Bovis, visited the Great Pyramid he noticed that some garbage cans in the King's Chamber contained dead cats and other small animals that had apparently wandered into the Pyramid and died.

There was something odd about these corpses: there was no smell or decay to them. Curious as to the cause

Diorite statue of Kephren dating from the Sixth Dynasty found by Marietta Bey in the so-called Temple of the Sphinx, now in the Cairo Museum.





of this phenomenon, Bovis examined the animals and found them dehydrated and mummified, despite the humidity in the chamber.

Bovis wondered if the mere shape of the Pyramid could have been responsible for this natural process of embalming: so he made a wooden model of Cheops with a base three feet long, and oriented it due north. Inside the model, a third of the way up, he placed a freshly dead cat. After a few days it mummified. Bovis then placed other organic materials in the model, especially matter that normally decays very quickly, such as calf's brains, and when these failed to putrefy, he concluded there must be something about the shape of the Pyramid which prevents decay and causes dehydration.

A Czechoslovakian radio engineer named Karel Drbal read Bovis's reports and made some further experiments with pyramid models, concluding that there is "a definite relation between the shape of the space inside the pyramid, and the physical, chemical and biological processes going on inside that space."

The same phenomenon has been noted in Italy and Yugoslavia where milk packaged in pyramidal cartons keeps fresh indefinitely without refrigeration. A French firm has also patented a pyramidal container for yogurt.

Drbal wondered if the shape might be responsible for an accumulation of electromagnetic waves or cosmic rays, or of some unknown energy. Placing a used razor blade within a six-inch-high cardboard model of Cheops' pyramid, oriented to true north, Drbal found that the edges of the blade automatically recovered their sharpness after use, that he could shave with one Gilette blue blade as many as 200 times. He concluded that the environment inside the pyramid somehow made the crystals in the blade return to their original form. Drbal was issued patent no. 91304 by the Czechoslovak patent office and began manufacturing "Cheops Pyramid Razorblade Sharpeners" out of cardboard. Today they are being made of styrofoam.

An engineer and former professor of radio, L. Turenne, maintains that all sorts of different forms—being combinations of different frequencies—act as different types of resonators for energy in the cosmos. This has led to speculation that the Pyramid might be some sort of gigantic lens which is able to focus an unknown energy simply by means of its shape.

Even the coffer in the King's Chamber has been considered such a device by Worth Smith, who points out that the cubic capacity of the coffer is *exactly* the same as that of the biblical Arc of the Covenant.

According to Maurice Denis-Papin, descendant of the famous inventor, the Arc of the Covenant was a sort of electric capacitor capable of producing an electrical charge of 500 to 700 volts. The Arc is said to have been made of acacia wood, lined inside and out with gold: that is to say, two conductors separated by an insulator. On either side were garlands which may have served as condensors. Denis-Papin says the Arc was placed in a dry spot where the magnetic field reached a normal 500 to 600 volts per vertical meter.

Insulated from the ground, the Arc is said to have given off fiery rays, acting like a Leyden jar. According to Denis-Papin the capacitor was discharged to earth by means of the garlands. To move the Arc, two golden rods were slid through rings attached to the exterior.

The similarity of such an "energy accumulator" to the orgone box developed by Wilhelm Reich, which was such a puzzle to Albert Einstein, is also striking.

Sir W. Siemens, the British inventor, related that one day while he was standing on the summit of Cheops' pyramid an Arab guide called his attention to the fact that whenever he raised his hand with his fingers outspread an acute ringing noise was heard.

Raising just his index, Siemens felt a distinct prickling in it. When he tried to drink from a wine bottle he had brought along he noted a slight electric shock. So

Siemens moistened a newspaper and wrapped it around the bottle to convert it into a Leyden jar. It became increasingly charged with electricity simply by being held above his head.

When sparks began to issue from the wine bottle, Siemens's Arab guides became distrustful and accused him of practicing witchcraft. One of the guides tried to seize Siemens's companion, but Siemens lowered the bottle towards him and gave the Arab such a jolt that he was knocked senseless to the ground. Recovering, the guide scrambled to his feet and took off down the Pyramid, crying loudly.

Such weird but soberly recounted tales about the Pyramid are tame compared to the wilder conceits that have been propounded by pseudoscientific, science-fiction and sensational authors. According to one science-fiction theory, the Pyramid was used as a huge protecting baffle for ancient scientists who had found a way to tap the energy of the Van Allen belts by letting it flow on an ionized path through the atmosphere to the peak of the Pyramid, possibly on a laser beam. The authors of this science fiction recount how an error was committed in the length of time the energy was allowed to flow, causing an avalanche of power which knocked the planet off its axis.

Another popular idea is that the truncated Pyramid served not merely as an observatory but as a landing pad for extraterrestrial space ships. The polished sides of the Pyramid would have made such a platform inaccessible to the hoi polloi, so that godlike visiting astronauts could have confabulated in security with the high priests who had access to the platform from interior passages. Herodotus lends romance to the idea that ziggurats and pyramids were steppingstones for the gods from heaven and that the King's Chamber—which Petrie found to be built quite separately from the surrounding Pyramid—could have served as a reception room on the truncated platform.

Herodotus describes a reconstructed ziggurat which he visited in Babylon. "On the topmost tower there is a spacious temple, and inside the temple stands a great bed covered with fine bed-clothes, with a golden table by its side. There is no statue of any kind set up in the place, nor is the chamber occupied at night by any but a single native woman who—say the Chaldean priests—is chosen by the deity out of all the women of the land. The priests also declare—but I for one do not credit it—that the god comes down in person into this chamber, and sleeps upon the couch."

In the light of recent scientific discoveries, one more theory must be added to this world of fable: that the Great Pyramid was built not only as an astronomical observatory but as an astrological one in order to make accurate large-scale horoscopes for the reigning monarch.

XXII. ASTROLOGICAL OBSERVATORY

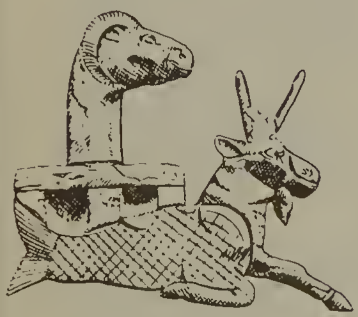
Though many of the doctrines of astrology appear to be preposterous, modern science is beginning to indicate that in its original form astrology may have been based on some reasonable theories.

Proctor points out that the ancient Egyptians viewed the king as the representative of all the people in their relations with the forces of the cosmos, and the world of spiritual powers.

On the theory that what was good for the king was good for the country, Proctor suggested that the Egyptians made no move in either domestic or foreign policy without the recommendation of their astrologer priests, whose opinions were based on the movement of heavenly bodies as scanned from a pyramidal observatory.

Once the king was dead, Proctor believes, his body may have been buried within the pyramid and the platform finished off to a point.

The idea that the shifting of heavenly bodies bears some relation to man's fate is so ingrained that people are still called martial, jovial, saturnine or lunatic; the days of the week are still named for sun, moon and planets; and our religious festivals are still based on the astrological system of ancient Egypt, with Christmas tied to the winter solstice and Easter to the spring equinox.



In his *The Scientific Basis of Astrology,* published in 1969, Michel Gauquelin describes some of the effects of the motions of the sun and moon upon terrestrial phenomena. Apart from such obvious effects as the seasons, the growth of vegetation and the tides, he deals with the less apparent but equally powerful effects of the eleven-year cycle of sunspots on our flora, fauna and inhabitants.

Sunspots, which appear like dark flowers on the surface of the sun, spring up, develop and disappear. As they do so, the sun spews up fantastic incandescent clouds of gas, and whips up huge magnetic whirlwinds.

Rotating on its axis in a twenty-seven-day cycle, the sun periodically aims these spots and eruptions directly at the earth. The result is an increased projection of waves and particles towards the earth. In the words of Gauquelin, "we terrestrians can regard ourselves as living in the interior of the sun."

The position of the earth in its orbit also affects the sunspots: when Venus and Earth are on the same side of the sun, their effect on the sunspots is combined. The sun's vagaries induce earthquakes and even alter the duration of the day; the earth's magnetic fields are disturbed; there are radio interferences and other such mysterious phenomena. At the same time the earth is subject to bombardment by galactic particles such as Alvarez's cosmic rays, which also have their effect.

Sunspot activity has been related to such different phenomena as the number of icebergs in the North Atlantic, the level of water in lakes, the concentric rings in the growth of trees and the number of rabbit skins taken by the Hudson's Bay Company. Even the quality of wines in Burgundy is affected, excellent vintages corresponding to periods of maximum solar activity.

Sunspots have been proved to affect the smallest cells, and the world of microbes is disturbed to the point that waves of epidemics can be generated. Gauquelin quotes a Doctor Fauré to the effect that the frequency of diphtheria cases in Central Europe and of smallpox victims in Chicago follow the eleven-year cycle of sunspots, as did the recurrent great plagues of typhus and cholera in Europe.

Indirectly, most of the phenomena of weather, such as barometric pressure and the rate of winds, depend on the eruptions of sunspots. Gauquelin wonders if there may not be more subtle effects on the air we breathe, on our physical and mental states, and even on the way we think.

Recent experiments indicate that subjects breathing air charged with positive ions are likely to feel discomfort, headaches and giddiness; whereas when the atmosphere is full of negative ions the same subjects feel cheerful, relaxed and in top form.

The concentration of positive and negative ions in the air we breathe depends in the final analysis on solar activity. The ionosphere is filled with positive and negative ions. Particles which induce a very high ionization in the upper atmosphere are directed toward the earth by the sun. Unfortunately, negative ions have a tendency to attach themselves to clouds, whereas positive ions tend to accumulate on the ground.

Such data tie in with the theories of Wilhelm Reich about the healthful effects of what he calls "orgone energy" and the toxic effects of its counterpart "deadly orgone," which was reputed to turn rocks brown, make strong men giddy and bring on women's menses out of season.

Current research and experiments behind the Iron Curtain as reported by Ostrander and Schroeder in their *Psychic Discoveries Behind the Iron Curtain** have added even more fantastic details to the use of astrology as a science.

These authors describe a Czechoslovak Ministry of Health center, complete with modern computers, run by gynecologists and psychiatrists. It is called Astra Research Center for Planned Parenthood and uses astrological data, or the position of sun, moon and planets in relation to the birth of an individual, in order to assure a safe and reliable means of birth control without pills, contraception or operations. The same system is being used to help seemingly sterile women become fertile, help women who have had nothing but miscarriages deliver full-term babies, and even allow them to choose whether they will have a boy or a girl child.

In a book called *Predetermining the Sex of a Child,* Eugen Jonas, a Czech medical doctor who developed the Astra clinic, maintains that women's cycles are affected not only by the phases of the moon, but that each individual at birth is affected by the basic pattern of sun, moon and planets. From this basic pattern Dr. Jonas claims to be able to figure out the exact days in a woman's entire lifetime when she can conceive, as well as the ones which are the best or worst for a forthcoming child. The woman may then take advantage of such days, or avoid them.

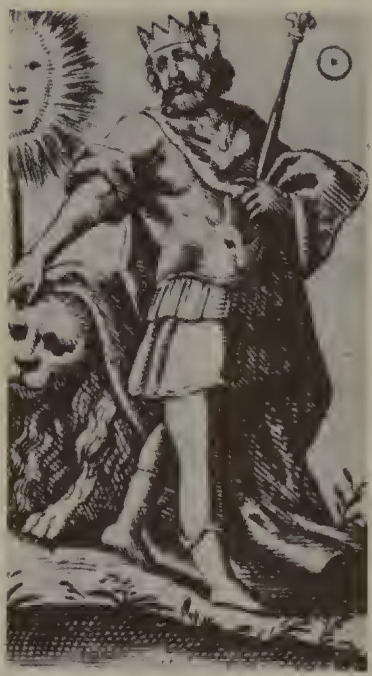
Jonas found that dead, deformed and retarded children were produced when women conceived during certain oppositions of the sun, moon and major planets.

The system is now being tested in Hungary as well as Czechoslovakia, where Dr. Kurt Rechnitz, former director of the Budapest Obstetric Clinic prescribed astrological birth control for one hundred twenty women. None was reported pregnant.

It has been too short a period to establish the validity of such data, but the endeavor could prove more rewarding than voyaging to the moon. It would certainly be simpler for a lady in New York to step into the booth of an astrological computer in Grand Central Station in order to arrange her calendar of engagements for the year. And it might do wonders for an overpopulated planet.

Jonas' good-humored complaint is that most gynecologists know as little about astronomy as astronomers know about obstetrics, and that both believe

* Prentice-Hall, Englewood Cliffs, New Jersey, 1970.



astrology to be superstitious nonsense. If the disciplines were combined, the results, says Jonas, might be great for mankind. Had the designers of the Great Pyramid been able to monitor the sunspots with a screen across the Grand Gallery, as suggested by Proctor, and had they been aware of such phenomena as has been described by Dr. Jonas, they may well have been able to use the Great Pyramid as a means of providing accurate astrological data on which to formulate the charts for individual behavior, if not for the thronging masses, at least for the pharaohs, priests or nobles.

In his book on the Great Pyramid William Kingsland declares flatly that the ancient Egyptians used "their profound knowledge of what we call the outer facts of astronomy" to connect them astrologically with the principles of man's relation to the cosmos, and that this formed part of the concealed knowledge contained in the mysteries.

Kingsland notes that from the very remotest antiquity the Egyptians believed firmly in an afterlife and were not afraid to think cosmically in terms of millions of years. He quotes an introductory hymn to *Ra* in *The Book of the Dead* as saying: "millions of years have gone over the world; I cannot tell the number of those through which thou hast passed. . . ."

To Kingsland *The Book of the Dead,* though it appears to be a ritual for funerary rites of a deceased king or high official, was actually a description of the trials, temptations and difficulties which the adept had to meet and overcome as he progressed from knowledge to knowledge and from power to power, as he penetrated the superphysical regions from plane to plane. The ultimate goal of initiation, says Kingsland, was "the full realization of the essential *divine nature of man,* the recovery by the individual of the full knowledge and powers of his divine spiritual nature, of that which was his source and origin, but to the *consciousness* of which he is *now* dead through the 'Fall of Man' into matter and physical life."

The old Greeks, says Kingsland, learning from the Egyptians, embodied these trials and difficulties of the great initiates into the legends of their heroes and demigods.

Manly P. Hall, a lifelong researcher into the mysteries of ancient initiation, says the Great Pyramid was dedicated to the god Hermes, the personification of Universal Wisdom; it was not only a temple of initiation but a repository for the secret truths which he calls the foundation of all the arts and sciences. The time will come, says Hall, when the secret wisdom shall again be the dominating religious and philosophical urge of the world: "Out of the cold ashes of lifeless creeds, shall rise phoenix-like the ancient Mysteries . . . . The unfolding of man's spiritual nature is as much an exact science as astronomy, medicine and jurisprudence."

Whatever mystical, occult or science-fiction tales may be associated with the Great Pyramid, it is still an extraordinary piece of masonry, and its designers must have been extraordinary beings. Who they were and when they built their Pyramid remains a mystery. So the quest continues.

But certain facts must be confronted, and the textbooks amended to conform with them. Eratosthenes was obviously not the first to measure the circumference of the earth. Hipparchus was not the inventor of trigonometry. Pythagoras did not originate his famous theorem. Mercator did not invent his projection—though he did visit the Great Pyramid and leave his graffito to prove it.

Whoever built the Great Pyramid knew the dimensions of this planet as they were not to be known again till the seventeenth century of our era. They could measure the day, the year and the Great Year of the Precession. They knew how to compute latitude and longitude very accurately by means of obelisks and the transit of stars. They knew the varying lengths of a degree of latitude and longitude at different locations on the planet and could make excellent maps, projecting them with a minimum of distortion. They worked out a sophisticated system of measures based on the earth's rotation on its axis which produced the admirably earth-commensurate foot and cubit which they incorporated in the Pyramid.

In mathematics they were advanced enough to have discovered the Fibonacci series, and the function of π and φ. What more they knew remains to be seen. But as more is discovered it may open the door to a whole new civilization of the past, and a much longer history of man than has heretofore been credited.

APPENDIX

NOTES ON THE RELATION OF ANCIENT MEASURES TO THE GREAT PYRAMID

by LIVIO CATULLO STECCHINI

The following pages constitute an abstract from a lifelong research into the history of measures. I became interested in this subject toward the end of my secondary education, when I was trying to put to some use my eight years of Latin and Greek grammar. It was then that I became an acolyte of Angelo Segré, whom I knew as a fellow law professor with my father at the University of Catania. Segré was a scholar of Roman law, but, coming from a family of distinguished scientists and mathematicians, had specialized in the study of ancient measures.

Upon completing my secondary education, I ended my study with Segré to register as a student at the University of Freiburg, Germany. Since at that age one believes that a thinking person must have a philosophical foundation, I chose Freiburg because it was the university where Husserl taught, whose philosophy appealed to me because of its mathematical rigor. But at Freiburg at the moment the focus of attention was the philosopher Heidegger, who had just announced to the world the discovery of something called existentialism. I did not share the excitement of my fellow students for the new dispensation (although I liked the lectures on existentialist mathematics by Oskar Becker), but there were a couple of things that I learned from Heidegger. One was that the idea of the progress of human civilization, on which practically all historians operate, is a theological doctrine developed by the Church Fathers. The other, more specific, was that scholars of Greek culture have murdered the texts of early Greek philosophers, on the assumption that since they were early philosophers they must have had infantile conceptions. In the area of my vocational studies, I identified myself with a group of professors, led by Fritz Pringsheim, who had dedicated themselves to one topic, the contract of sale in ancient times. Since seminar work consisted in interpreting contracts from several areas of the eastern Mediterranean, I focused my attention on the clauses relating to measures, which these contracts contain in abundance. My teachers were tolerant of my passion; for instance, Otto Lenel in his *privatissimum,* dedicated to the development of postclassical Roman law, allowed me to read a paper on the length of the miles in the Syro-Roman Law Book.

After the Freiburg group was disbanded by Hitler, I returned to Italy, where I received a doctorate in the field of Roman law. On that basis I became assistant to the chair of history of Roman law at the University of Rome and a member of the Institute of Roman and Oriental Law of that University. During my Roman years, I learned the most from Edoardo Volterra, later holder of the chair of Oriental law at the University of Rome; he was sympathetic to my interests, since he was the son of the famous mathematician Vito Volterra.

When World War II brought me to the United States, since my interests were historical rather than legal, I registered as a candidate for a doctorate in ancient history at Harvard University. There I discovered that those who come to ancient history from literature have a completely different view of the ancient world from the practical, realistic, and utilitarian view which prevails in legal studies: in substance they see the ancient world as the realm of poetic fantasy. My Harvard teachers used to admonish me to understand "the spirit of the ancients," but the only image that their perorations could stir in my mind was the image of the ancients in a constant state of alcoholic stupor. As to my special field of research, my teachers thought that my notion that the Greeks were concerned with precision in measurement was intellectually preposterous and historically impossible.

The terms of the controversy were clarified for me by Werner Jaeger, who tried to support me by suggesting that I write under him a thesis on the concept of *akribeia,* "precision," in Greek thought. In outlining the proposed thesis, Jaeger explained that with Isocrates there was developed in Greece a new conception of humanism opposed to *akribeia.* Jaeger was impliying that my critics were followers of Isocratean humanism. Because of youthful stubbornness, I declined the flattering offer of Jaeger, being convinced that what counts is to put precision into practice, rather than to talk about it. I tried to prove my point by submitting a thesis on "The Origin of Money in Greece." It was accepted as containing much that was valuable, but I received the advice that before publishing it I should cut down on "all those numbers."

After this, I thought that I could still achieve a result by expanding my documentation. From the study of Greek monetary weights and the operation of Greek mints, I passed to the topic of the dimensions of Greek temples. The study of Greek temples much later led me to the study of ancient geography and geodesy. But I was gradually forced to accept the fact that scholars of ancient history do not read numbers, neither in ancient texts nor in research papers. I noticed a number of times, when I submitted a paper for judgment to a specialist of a particular area, that he would quickly turn a page if he saw numbers on it. In many different guises I was told that "numbers do not constitute evidence in ancient studies." Finally, I learned that I had no choice but to pursue my interests in splendid isolation.

About ten years ago I exchanged manuscripts with Hertha von Dechend, who was then beginning to write her book *Hamlet's Mill*. As an expert of ancient cosmology, she raised a strong objection to the fact that I would discuss length, volume, and weight for hundreds of typewritten pages, without ever mentioning time, whereas the ancients were dominated by the preoccupation with cosmic time, with the movement of the vault of heaven. I answered that she was right, but that I had not yet found in the texts anything that would establish a connection between time and other measures. Giorgio de Santillana, who was writing *Hamlet's Mill* together with Dechend, teased me in a friendly way by saying that I had become so stuck in the mire of economic documents that I could not lift myself out of it; I replied in the same half-serious tone that I was willing to lift my eyes to heaven only on condition of being sure that my feet remained firmly planted on the ground.

Although I recognize that astronomical measurements are extremely important, I have always been wary of dealing with them, because studies of ancient astronomy have become cluttered with metaphysical and theological doctrines. My opposition to the view that the ancients lived in a world of fantasies or even of outright hallucinations (as it is specifically claimed by scholars of ancient astronomy) is such that, after years of dealing with all sorts of measurements, I still feel most at ease with agrarian measures in cuneiform tablets, rates of money exchange in Greek inscriptions, or the volume of jars in papyri from Egypt. Yet the techniques of land surveying used in Meso-

potamia are a key to the understanding of how the ancients mapped the sky.

Because of my horror of metaphysical or pseudo-metaphysical intrusions, I had several times picked up and then dropped the problem of the dimensions of the Great Pyramid of Giza. It was only after Peter Tompkins took upon himself the task of organizing the literature in the field, separating sense from nonsense, that I gained the courage to deal with the problem to the point of some conclusion. In the course of discussing with me the geometry of the Great Pyramid, Tompkins explained how the Great Pyramid with its galleries could have been used to measure the movements of the vault of heaven. In describing the possible procedures, he pointed out how a second of time in the motion of the vault of heaven corresponds to a definite length on earth. For me this was a Galilean revolution in that it permitted me to see ancient astronomy in terms of observational techniques based on measurements, rather than systems based on the theological persuasions or the psychological projections of the modern investigators. Once I was able to link time together with length, volume, and weight, a number of scattered researches suddenly became related to each other. Up to that moment I had had the uncanny feeling that somewhere there was a piece missing, and I knew that a missing piece, even a little one, is vital when one deals with measurements.

Since Tompkins has asked me to write a summary of my findings that relate to the problem of the Great Pyramid, I have tried to comply with his request.

I. EGYPTIAN GEODETIC SYSTEM

1. The present Arabic name of Egypt is *al Misri*, which is the equivalent of the biblical *Miṣraîm*. This name is derived from the Semitic root which in Akkadian gives the verb *aṣaru*, "to cut, to delimit, to delineate," and hence "to draw a picture, a plan," and the noun *eṣertu*, "drawing plan, representation," applied in particular to the specifications for the construction of a building. In Semitic language an "m" before the root of a verb forms what we would call a past participle: Egypt is the country built according to a geometric plan.

The Egyptians expressed this idea by calling their land *To-Mera*, "the land of the *mr*." The word *mr* is used to refer to the pyramids, but more specifically it refers to the meridian triangle of a pyramid, whose hypotenuse is the apothem. The *mr* essentially is a right triangle with an angle of 36° and another angle which of necessity is 54°.

Since the Egyptians did not have trigonometric tables, they used this triangle to obtain the value of trigonometric functions. They conceived of this triangle as the basic building block of the cosmos. They used this triangle or modifications of it by a few degrees in geometric constructions, in the planning of buildings, in surveying, and in geography.

In the last century the Egyptologist Karl H. Brugsch noticed that the hieroglyphic sign for *mr* when used in the name *To-Mera* is accompanied by a determinative in the form of a fret or Greek key. In hieroglyphic writing a determinative is an extra sign which helps in understanding the meaning of a word by indicating the class of concepts to which the word belongs. Brugsch observed that this fret is "a peculiarly shaped geometric figure which in principle could represent the entire land *Mera* and must have a meaning pertaining to a specific peculiarity of Egypt." But, although he was much more sympathetic to science than Egyptologists usually are, he did not pursue this line of reasoning. He resisted accepting the notion that the Egyptians conceived of their country as having an exact geometric shape.

The Egyptians were proud that their country had some unique geographic features which could be expressed in rigorous geometric terms and had a shape which related to the order of the cosmos as they saw it. They believed that when the gods created the cosmos they began by building Egypt and, having created it perfect, modeled the rest around it.

2. Everybody knows that Egypt is a most peculiar, almost unique, country. Since it seldom rains there, the entire life of humans, animals, and plants depends on the water of the Nile. It is also known that the Egyptians linked the regular flood of the Nile with the movement of the sun and other heavenly bodies, such as the star Sirius. But the Egyptians put great stress also on the geographic peculiarities of the course of the Nile.

The Nile originates at the equator from lakes so immense that their water could be identified with the primeval water of the ocean. From the equator it moves north following substantially the meridian of its source at Lake Albert. It follows this line up to latitude 30°, one-third of the distance from the equator to the pole.

The key geographic position in Egyptian geography was the southern tip of the island today called al-Warraq, at the northern limit of the city of Cairo, where the Nile begins to divide into branches to form the estuary which the Greeks called Delta, after the triangular shape of the fourth letter of their alphabet. The apex of the Delta, the tip of the island al-Warraq, is cut by meridian 31° 14′ east. This meridian indicates the main line of the course of the Nile from the equator to the apex of the Delta and divides the Delta into two equal parts. It was considered the main axis of Egypt.

But in terms of latitude the apex appeared at first not as perfect as it should have been, since it was at latitude 30° 06′ north and not at the perfect latitude 30° 00′ north, which is the latitude of the Great Pyramid of Giza. But the Egyptians reassured themselves by observing that the southern limit of Egypt is indicated by the First Cataract. The upper edge of this cataract is at the perfect latitude 24° 00′ north, whereas its lower edge is at 24° 06′ north. Hence, they could say that Southern Egypt has an extension of 6° 00′, which may be counted either from 24° 00′ to 30° 00′ north or from 24° 06′ to 30° 06′ north. They adopted as a principle that geographic distances are measured by units of 6 minutes (1/10 degree). They assumed that the interval between the equator and the pole was divided into belts (in pictures they portrayed actual belts with clasps) of 6′; on the basis of this the Greeks introduced into our geography the term *zone,* which in Greek means "belt."

For the benefit of those who understand mathematics, I may add that the Egyptians analyzed curves by dividing the area under a curve into a series of rectangles, which is the basic principle of integral calculus. It seems that in analyzing the curvature of the earth, they used rectangles 6′ wide.

Geographically Egypt is divided into two different parts. Southern (or Upper) Egypt is essentially a canyon cut into the desert plateau by the Nile; it is long and narrow. Northern (or Lower) Egypt is a typical estuary, swampy and wide. In spite of the efforts of the rulers to stress the unity of the country, the two parts continued to be conceived as different even in political and administrative terms. This is the reason why the Hebrew word for Egypt, *Miṣraîm,* has the grammatical form of the dual. The Pharaoh wore two crowns on his head: a red straw hat for Northern Egypt and a white wool cap for Southern Egypt.

Although not much is known about the history of predynastic Egypt, it seems rather well established that in this period the two Egypts were unified for a time, with a capital at Behdet at the extreme north of the curved coastline of the estuary, as far north as one could go in Egypt. Although archeologists have not yet identified the location of Behdet, the data of geography indicate that Behdet, either as a geodetic point or as an actual city, was at 31° 30′ north 31° 14′ east. It was on the main axis of Egypt and of the

Nile, on the meridian of the apex of the Delta, at a distance of 7° 30′ (1/12 of arc of meridian) from the southern boundary of 24° 00′ north and at a distance of 1° 24′ = 1.4° from the apex. The distance from latitude 30° 00′ north is 1° 30′, so that it could be assumed that Southern Egypt relates to Northern Egypt as 4:1. Southern Egypt is 1/15 of arc of meridian and Northern Egypt is 1/60. We shall see that the total length of Egypt from 24° 00′ north to Behdet was calculated as 1,800,000 geographic cubits. Since 400 cubits is a stadium and 600 stadia is a degree, it is a length of 4500 stadia (3600 stadia for Southern Egypt and 900 stadia for Northern Egypt).

This is the way in which the dimensions of Egypt were rationalized in the predynastic period.

3. The dynastic period begins with the final unification of the two Egypts. At this moment Egypt emerged from prehistory, because writing was invented in the form of hieroglyphs. At the same time the geodetic system of Egypt was revised, stressing the importance of the number 7 and linking the geography of Egypt with the geography of the heavens.

The main feature of the map of the sky is that the sun follows a course which is at an angle with the equator. The circle marked by the sun is called the ecliptic and the angle of this circle with the circle of the equator is the angle of the ecliptic (roughly 24°). The ecliptic cuts the plane of the equator at two points and reaches its highest and lowest points in relation to the equator at celestial latitudes which are marked on the surface of the earth by the tropics.

The moon and the planets in their movements around the earth follow substantially the line of the ecliptic, being at times north and at times south of the course of the sun. (The body which deviates most sharply from the ecliptic is Mercury. Mercury can be as much as 7° 00′ north or south of the ecliptic.) For this reason it was conceived that there was marked in the heavens a great "highway" (*hodos* in Greek) in which there moved the sun, the moon, and the planets. This path is 14° wide and is the origin of the concept of the zodiacal band. Since Mercury determines its dimensions and determines them by a perfect figure, in ancient religions this planet was associated with the god of measurement. It was conceived that the sun, the moon, and the planets were engaged in competing with each other running in the racing course of the zodiacal band. Another conception was that there were two walls, running parallel 14° apart, within which there was going on a ball game. The notion of a wall accounted for the fact that the heavenly bodies could not go beyond a given distance from the ecliptic; they appeared to run away from the ecliptic, hit a wall, and bounce back past the ecliptic to hit the wall on the other side. This is the ritual origin of racing competitions (such as the Olympic races, on foot or in chariots) and of ball games. The most vivid expression of the second conception is the famous ball court in the Mayan city of Chichen Itzá; the structure of this ball court can be understood when one realizes that its two parallel side walls are unfolded cylindrical projections of the sky.

The zodiacal band was conceived to be the inhabited part of the sky; the rest of the sky was still and lifeless (*erēmos*, "desert, desolate," in Greek), because nothing moved in it, except for the rotation of the vault of heaven in a solid block. Hence, in order to make a map of the sky for the study of the moving heavenly bodies, it was enough to draw a map that reaches latitude 31° (24° + 7°). Such a map could be drawn in the form of a cylindrical projection without substantial deformation; this cylindrical projection was unfolded to form a rectangle.

On the basis of this conception, stress was put on the fact that Egypt begins at the line of the tropic of Cancer (the upper edge of the First Cataract is at 24° 00′ north) and extends north for 7°, so that Egypt could be considered as the equivalent on earth of the northern half of the zodiacal band. For the sake of mapping the earth from the equator to the northern limit of Egypt, one could use a cylindrical projection. The maximum deformation in such a type of projection could be determined; it was established that a degree of longitude at parallel 31° 06′ north is exactly 6/7 of a degree of longitude at the equator. According to the Clarke Spheroid a degree of equator is 111,321 meters, of which 6/7 is 95,418 meters; according to the same Spheroid a degree of longitude at 31° 06′ is 95,407 meters. To the north of latitude 31° 06′ north there was the expanse of the Mediterranean, the "Great Green" for the Egyptians, which could be compared with the expanse of the empty sky, north of the same celestial latitude.

The angle of the ecliptic has decreased slowly (today it is 23° 27′; it was about at 23° 45′ in the age of Ptolemy), and accordingly the tropic of Cancer has moved south. This movement is due to the gravitational pull of the planets, particularly Jupiter and Venus. Nobody as yet has succeeded in constructing a valid formula for calculating the angle of the ecliptic in ancient times. But, it is a fact that when the second geodetic system of Egypt was established it was assumed that the tropic of Cancer was at 23° 51′ north. Greek scholars living under the rule of the last Egyptian dynasty, the Ptolemies, continued to quote this figure, although it was not correct at their time.

If the tropic is at 23° 51′ north, it would follow that the southern border of Egypt is out of place. But the discrepancy was rationalized by considering the fact that when one follows the movement of the sun along the ecliptic by observing the shadow cast by a pointer, there must be introduced a correction of about 15′. The position of the shadow is not determined by the center of the sun, but by the upper limb of the disk. The apparent diameter of the sun is about half a degree; calculating exactly, it varies between 32′ 30″ and 31′ 28″, according to the seasons, but, considering the corrections that have to be made for the phenomenon of irradiation, the figure of 15′ for the half diameter of the disk of the sun is satisfactory.

If the tropic of Cancer is at 23° 51′ north, the point at which the sun is at the zenith at noon of the day of the summer solstice is at 24° 06′ north, that is, at the latitude of the lower edge of the First Cataract. Hence, the Egyptians conceived that the line of the tropic of Cancer was marked by three parallels: 23° 51′, 24° 00′, and 24° 06′ north.

For this reason the hieroglyphic symbol for Southern Egypt consists essentially of three parallel lines with a vertical line rising at the middle. Since hieroglyphic writing aims at being colorful and pictorially decorative, this symbol was stylized in the shape of a trunk of a tree from which there sprout three parallel tiers of branches. Egyptologists who do not want to recognize the existence of scientific thought in Egypt have stressed the incidental vegetal appearance of this symbol. They have understood that the name for Southern Egypt, which is *To-Shemau,* "the land of the heat, of the sun, of the summer solstice," means "the land of the plant *sh-m-a.*" But if there was such a plant associated with Southern Egypt (which as yet has not been identified), it is possibly the same plant which is called *šamšu,* "sunflower" in Akkadian; the word *šamšu* means "sun" in Akkadian (Hebrew: *šemeš*). In a text of the Old Kingdom in which the hieroglyphs are drawn with particular care, in the symbol for *shemau* there is only one tier of branches, but the trunk starts from a little arc, a semicircle, which obviously symbolizes a parallel. But what probably is most revealing is that in most hieroglyphic texts the tiers of branches sprout from the bottom of the trunk and not from its top.

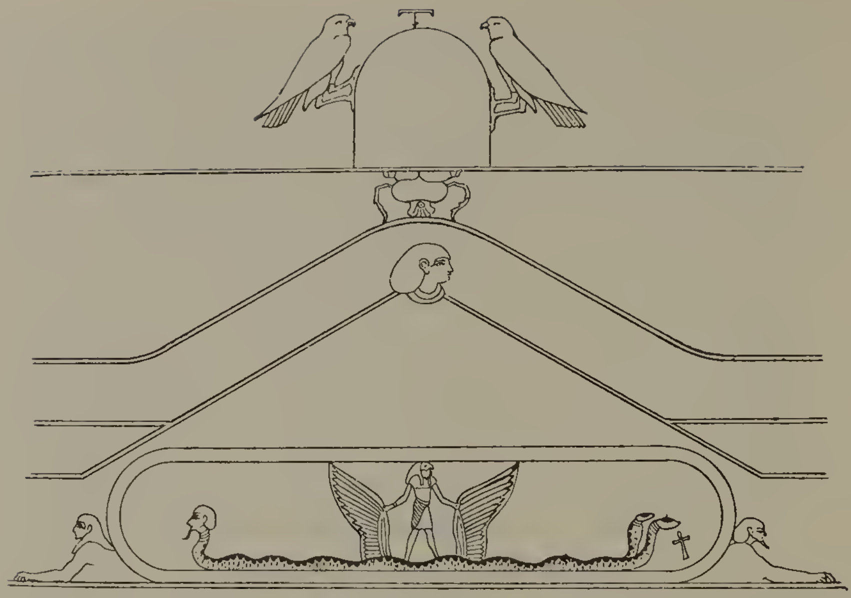
4. Once the latitudes of the southern limit of Egypt were rationalized by identifying the line of the tropic with three parallels (the first of which cuts the lower edge of the First Cataract at 24° 06′, the second cuts the upper

edge of it at the perfect latitude 24° 00′, and the other cuts the Nile at 23° 51′ north, at a place which the Greeks called Parembole, "supplement, addition"), it became possible to rationalize the boundary between Southern Egypt and Northern Egypt. This boundary was understood as marked by three parallels, the first at 30° 06′, the latitude of the apex of the Delta, the second at the perfect latitude 30° 00′, and the third at latitude 29° 51′.

In the administration of Egypt, the area between 29° 51′ and 30° 06′ north was organized as a special district which did not belong either to the list of nomes (provinces) of Southern Egypt nor to that of nomes of Northern Egypt. The hieroglyph for this district is a rectangle which is either empty or filled with water or fish. A distinguished Egyptologist, being at a loss for a better explanation, has read this hieroglyph as "fishpond." He did not realize that a rectangle, either empty or filled with water or fish, is the symbol of the Square of Pegasus. In *Hamlet's Mill*, de Santillana and Dechend have presented illustrations of this symbolism occurring all over the globe (between pages 434 and 435). There are in the sky four stars which are at a distance of about 15° from each other and mark a square with sides that run according to the celestial meridians or parallels; these four stars form the Square of Pegasus. In iconography this square was at times portrayed as filled with water or fish, because it was in the constellation of Pisces. The Square of Pegasus was considered the starting point in the mapping of the sky. The ancients, from the Sumerians to the Romans, in surveying land began by marking a square of a standard dimension and then proceeded to measure out of it in a checkerboard pattern. In cuneiform texts the name *ikū* is given to the basic surveying square, to a unit of land surface, and to the Square of Pegasus. The hieroglyph used to refer to the district extending for 15′ from Memphis-Sokar to the apex of the Delta indicates that this district was considered the basic reference unit from which there started the mapping of Northern and Southern Egypt.

The capital of united Egypt was established at Memphis, at latitude 29° 51′ north. But, since the capital city of necessity had to be on the bank of the Nile, which here runs slightly east of the apex, the geodetic point was set to the west of the city in the funerary area (the city of the dead is always to the west of the city of the living), on the basic meridian 31° 14′ east. This was the point called Sokar, the name of which is preserved by the present village of Saqqara (29° 51′ north, 31° 14′ east). In the religion of the Old Kingdom, Sokar is an important god of orientation

Egyptian papyrus depicting Sokar, the god of orientation. The gadget on top of the *omphalos* is a standard Egyptian measuring ruler (and also the symbol for the sky). The two pigeons facing each other are the standard glyph for the laying out of parallels and meridians.



and of cemeteries. The god and the geodetic point were represented by the stone object which the Greeks called *omphalos,* "navel"; it is a hemisphere (the northern hemisphere) resting on a cylinder (the foundations of the cosmos). Usually on top of Sokar, as on top of any *omphalos,* there are portrayed two birds facing each other; in ancient iconography these two birds, usually doves, are a standard symbol for the stretching of meridians and parallels.

The practice of placing the geodetic center in the city of the dead was followed by King Darius the Great, when he established a new capital for the Persian Empire, Persepolis. Historians have wondered why Darius should have chosen for Persepolis a most inconvenient location; actually the capital of Persepolis was seldom used except for ritualistic purposes. Persepolis is at latitude 30° 00′ north and three units of 7° 12′ east of the main axis of Egypt (31° 14′ east). The reason for choosing units of 7° 12′ is that the Persian Empire was mapped by drawing a series of geodetic squares, east and west of Persepolis, which extend 6° in latitude from 30° 00′ to 36° 00′ north and have a width of 7° 12′ of longitude, since 7° 12′ of longitude is equivalent in actual length to 6° of latitude at the middle point between 30° 00′ and 36° 00′ north. Hence, these geodetic squares are true squares. The geodetic point of Persepolis, 30° 00′ north, 52° 50′ east, is north and west of the wide expanse of the royal buildings and is identified by the tomb of King Darius, around which there were built the tombs of his successors. At the geodetic point 30° 00′ north, 52° 50′ east, there could be erected tombs, but there was not the kind of ground on which there could be stretched a capital city.

The location of Memphis-Sokar had the advantage of being exactly 8° north of the point where meridian 31° 14′ east cuts again the course of the Nile at the Second Cataract. In a new imperialistic spirit, Egypt in a wide sense was understood to end at the Second Cataract.

5. According to the new conception which links Egypt with the sky, if Southern Egypt extends 6° from the tropic, Northern Egypt must extend only 1° to the north of the apex, in order to be in agreement with the order of the cosmos. Hence, the northern limit of Egypt was set at parallel 31° 06′ north.

This was achieved by identifying the northern limit of Egypt with the line that joins the two outer ends of the estuary of the Nile. This line extended 1° 24′ = 1.4° east and west of the axis 31° 14′ east. Hence, there was marked a triangle, which the Greeks called the Delta, with a base line extending from 31° 38′ to 29° 50′ east along parallel 31° 06′ north and a vertex at the long-established point of the apex of the Delta. This isosceles triangle is divided by meridian 31° 14′ into two right triangles of the type *mr*. In calculating the proportions of this triangle, one must keep in mind that at latitude 31° 06′ north, 1.4° of longitude corresponds to 1.2° in actual length, since the degree of longitude is shrunk by 1/7 at this latitude.

The base line of the mathematical triangle of the Delta fell perfectly at the eastern end. Here the corner of the Delta coincides with the well-defined natural boundary point Pelusium, along the shore. On the western side the corner of the Delta did not fall right on the shore, but at the middle of a coastal lagoon; even today the eastern boundary of the Western Desert province of Egypt passes through it.

The old geodetic center of Behdet was not completely ignored, since it could be fitted into the system by considering that it is 1.4° north of the apex of the Delta.

I have stated earlier that it was assumed that at latitude 31° 06′, the degree of longitude is 6/7 of the degree of equator. This calculation permitted the rationalization of the shift of the key positions of Egypt by 6′ to the north of the perfect latitudes 24° 00′ and 30° 00′ north. The shift was related to the polar flattening of the earth, which, according to the septenary order of the cosmos, was assumed to be 1/280. If the earth were a perfect sphere, the degree of longitude which is 6/7 of degree of equator would be at latitude 31° 00′ (cosine 31° 00′ = 0.85717; 6/7 = 0.85714).

Anticipating what I will explain in greater detail later, I must mention here that the dimensions of Egypt were recalculated in terms of a new unit of length, the royal cubit, which is obtained by adding a seventh hand to the usual six which compose a cubit. In terms of this longer cubit, the length of Egypt from 31° 06′ to 24° 00′ north was set at 1,500,000 cubits. The royal cubit summed the septenary spirit of the new geodetic system.

In hieroglyphic writing the name for Northern Egypt is *To-Meḥu*. Most Egyptologists, following the line of reasoning which I have mentioned in relation to Southern Egypt, have understood that *To-Meḥu* means "the land of the papyrus," but the name of the papyrus is *ḥly,* and the symbol for Northern Egypt cannot be compared with a papyrus plant by any stretch of the imagination. The name of Northern Egypt can be explained when we consider that it is similar to the name of the cubit (*maḥe* in Coptic), which comes from a root which means "to fill up." Hence, *To-Meḥu* may mean "the land which fills up the dimensions of Egypt." Northern Egypt corresponds to the seventh hand added to the cubit.

From what we have of early writing attempts from predynastic Egypt, it is absolutely clear that the symbol for Northern Egypt used to be the red straw hat. With the beginning of the dynastic period, the creation of hieroglyphic writing, and the new geodetic system, the symbol of Northern Egypt becomes a plant with three stems springing from one root. In some cases the reference to the triangularity of the Delta is emphasized by putting at the end of each stem a flower with a triangular calyx. In carefully drawn representations the plant springs from a rectangle either empty or filled with the wavy line for water, which is the symbol for the intermediary district, extending from 29° 51′ to 30° 06′ north.

At times the stems in the symbol for Northern Egypt are broken and bent at the top. This may be a reference to the fact that in the new geodetic system the northern limit was lowered from 31° 30′ to 31° 06′ north.

On the two sides of the throne of the Pharaoh there was a design which Egyptologists call "Unity of Egypt." We know it well because it appears in all statues of Pharaohs sitting on the throne; the series of such statues starts with the Fourth Dynasty, but occasional drawings indicate that the design "Unity of Egypt" is older. In the course of centuries the design varied somewhat and the artists who carved the throne stylized it according to different tastes; but on the basis of what I have explained above, one can always recognize that it represents the geodetic system of Egypt.

The center of the design is the hieroglyphic sign for the verb "to unite," which is a windpipe with two lungs.

However, in the design "Unity of Egypt" the windpipe is stretched, so that it looks like a long trunk of a tree, in order to indicate the main axis of Egypt; the lungs are reduced to a diminutive size. On one side of the windpipe there is the symbol for Northern Egypt and on the other side the symbol for Southern Egypt. But what is most significant is that the entire drawing is tied together by a system of ropes and knots, which indicate the geodetic lines and points of Egypt.

The design called "Unity of Egypt" is the standard decoration of the royal throne, because it symbolizes all that the Egyptians held fundamental in their political, ethical, religious, and cosmological conceptions, a cluster of ideas which they summarized by the word *maet,* a word with which I will deal in a following chapter. Nevertheless, this design has received only casual attention. The best way in which I can convey in brief how this design is pregnant with meaning is by referring to Hebrew Cabalistic literature. The Cabala is a Hebrew underground religion or philosophy. The starting point of Cabalistic doctrine is that God in creating the world began by creating the ten numbers and arranged them according to a diagram of points and connecting lines, which proves to be modeled on the design "Unity of Egypt." Actually, what gave me the first insights into the Egyptian geodetic system was the reading of the Italian Renaissance scientists who were influenced by Hebrew Cabalists.

The state of Israel has adopted as its national emblem the Cabalistic symbol of two overlapping triangles. These two triangles should be seen as inscribed in a circle: they represent the poles, the tropics, and the ecliptic, besides having the added meaning of the male and female elements coming together to generate the cosmos. The Founding Fathers adopted as the seal of the United States a pyramid; they wanted to convey the notion that a perfect society had been organized, and in order to convey it they adopted a symbol which, through the tradition transmitted by masonic societies, goes back to the Egyptian idea of *maet.*

6. The geodetic system established at the beginning of the Old Kingdom was modified in part with the advent of the Twelfth Dynasty, the most dynamic of the Egyptian dynasties as far as we know. The advent of this dynasty marks the beginning of what scholars call the Middle Kingdom period. But probably more significant in Egyptian terms was that the advent of this dynasty coincided with the beginning of the age of Aries. It became necessary to revise the system of cosmology, since the sun had moved out of the constellation of Taurus to enter into that of

Aries. The kings of this dynasty identified themselves with the god Amon, symbolized by the ram. The first king of the dynasty called himself Amenemhet, introducing the custom of theophoric names, that is, of personal names composed with the name of a god. The god Amon was made to spring from relative obscurity into the position of the main official divinity of Egypt. It seems that up to that time Amon was a local god of the desert area west of Thebes or that Amon was identified with a local god of that area.

The Twelfth Dynasty moved the capital and the geodetic center of Egypt to a more central position, Thebes. The longitude of the new capital was determined by the point where the eastern axis of Egypt (32° 38′ east) cuts the course of the Nile. The latitude was 2/7 of the distance from the equator to the pole (25° 42′ 51″ north). This latitude was marked by the central room of the temple of Amon, in which the god and the geodetic point most probably was indicated by the same object, the *omphalos*, "navel," which used to represent the god Sokar. What is certain is that when centuries later in the capital of Nubia, Napata, there was built a second temple of Amon in order to link Nubia with Egypt politically, in the center of this temple there was placed such an object.

Egyptologists have tried to torture Egyptian linguistics in order to explain why the Greeks should have given the name Thebes to a city which the Egyptians called Wast. The likely explanation is that the Greeks learned the name of the city from the Phoenicians, who in their own language called it *thibbûn*, "navel." There is textual evidence that in Hebrew, which is practically the same language as Phoenician, the word *thibbûn* is used to refer to a geodetic navel.

The choice of the latitude emphasized the septenary system of Egyptian geography. The ancients divided the space between the pole and the equator into seven zones. This is indicated not only by Greek writers of geography, but also by the ziggurats of Mesopotamia and the earliest pyramids of Egypt, which are step pyramids.

7. It was possibly on the occasion of the transfer of the capital and geodetic center to Thebes, which stresses the importance of the eastern meridian of Egypt (32° 38′ east), that something was done to rationalize the longitude of the First Cataract. The First Cataract happened not to be included in the rectangle of Egypt, being somewhat to the east of meridian 32° 38′, at 32° 53′ east. The lower edge of the cataract, at 24° 06′ north, 32° 53′ east, is 15′ north of the right position and 15′ west of it. It must have been

disturbing that the southern boundary of Egypt should not fit with the system of three meridians passing through the three angles of the Delta triangle. Hence, the area of the First Cataract was extended southward along the course of the Nile up to the point where meridian 32° 38′ east cuts the course of the Nile. This point happens to be at 23° 00′ north. The new point 23° 00′ north, 32° 38′ east was called Sacred Sycamore and was set as the legal boundary of Egypt. The stretch of the Nile from the Sacred Sycamore to the First Cataract was attached to the district of the First Cataract. In Hellenistic times this attached district was called Dodekaschoinos, which in Egyptian would be "twelve *atur*." The *atur*, as I will explain later, was a unit of length such that slightly more than 14 (14 in practical computations) went into a degree. If the distance of 51′ between 23° 00′ and 23° 51′ north, the correct line of the tropic, is calculated as 12 *atur*, it means that counting exactly a degree would be 14.11765 *atur*. The Egyptians used two types of *atur:* an *atur* of 17,000 geographic cubits (7848.8 meters) and an *atur* of 15,000 royal cubits (7862.2 meters). Now, 51′ at latitude 23° to 24° is about 94,135 meters, whereas 12 *atur* of the first kind is 94,186 meters and 12 *atur* of the second kind is 94,346 meters.

Even though the district Dodekaschoinos was attached to Egypt purely for mathematical reasons, it continued to be included in Egypt into the Roman period.

I suggest that the establishment of the supplementary district Dodekaschoinos with a new southern boundary of Egypt at 23° 00′ north was linked with the transfer of the capital to Thebes, because there is a text which gives the dimensions of Egypt from the sea at Pelusium (eastern corner of the triangle of the Delta) to the end of the district Dodekaschoinos, that is, all along meridian 32° 38′ east. The distance is divided into two-thirds from Pelusium to Thebes and one-third from Thebes to the Sacred Sycamore. If we round the latitude of Thebes from 25° 42′ 51″ north to 25° 42′ north, the calculation is perfect:

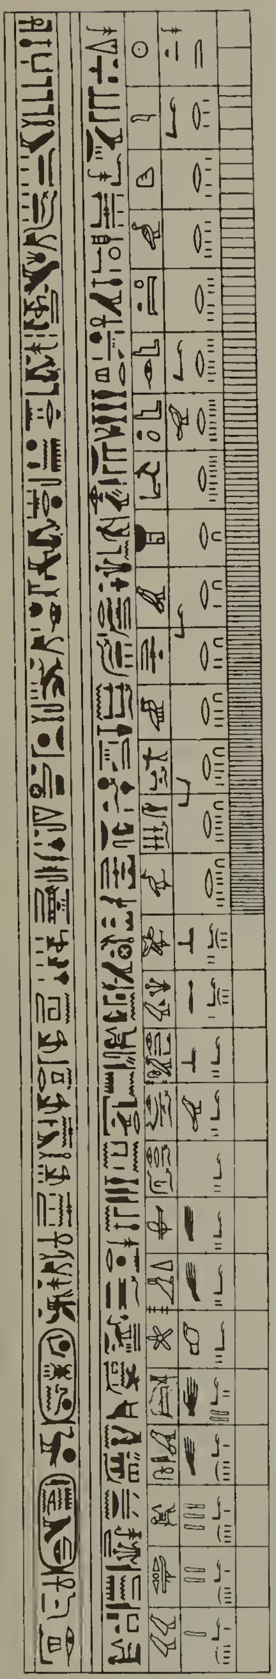
31° 06′ to 25° 42′ north = 5° 24′
25° 42′ to 23° 00′ north = 2° 42′

When the southern boundary of Egypt is moved to the Sacred Sycamore by adding the district Dodekaschoinos, the Temple of Amon in Thebes is in a rational position not only in relation to arc of meridian, but also in relation to the extension of Egypt.

The text that gives the information just mentioned indicates also that the latitude of Thebes has a further peculiarity: at this latitude the degree of longitude is 9/10 of degree of equator.

1. All the measures of length, volume, and weight of the ancient world, including those of China and India, constituted a rational and organic system, which can be reconstructed starting from a fundamental unit of length. I have not yet completed the gathering of data concerning the units of pre-Columbian America, because these are difficult to obtain, since the metrology of the American continent has received meager attention; but the figures that I have succeeded in establishing so far suggest that the American units agree with those of the Old World. The units used in Europe up to the adoption of the French metric system were the ancient ones or modifications of them introduced for specific reasons. The ancient system of measures continues to be used today in the form of English measures; we find the basic units of the English system, such as the pound of 453.8 grams, used in Mesopotamia in the third millennium B.C.

The effort to reconstruct the original and unitary system of measures was started by scholars of the Renaissance as a result of the beginning of the age of geographical discoveries. Their investigations, although they took the form of antiquarian research, had two practical purposes: to interpret correctly the data provided by ancient geographers and to establish an absolutely reliable and fixed standard of length. Although the major concern of Renaissance investigators of measures was to establish the exact value of the ancient Roman foot, they were also concerned with a tradition to the effect that all measures were derived from the Egyptian ones. This is the reason why John Greaves went to measure the Great Pyramid of Giza, in order to complete his researches on the length of the ancient Roman foot. In Egypt Greaves met with Burattini, who had gone to measure the monuments of Egypt, in order to establish the linear starting point (for which he coined the name *meter*) in his proposal for a new metric system which would be strictly decimal, like the one later adopted as the French metric system. Greaves had the advantage of having spent a long time in Rome measuring buildings, vessels, and weights and of being provided with accurate measuring tools, based on English units; Burattini had the advantage of having already measured a number of Egyptian buildings. Greaves and Burattini joined forces in measuring the Great Pyramid of Giza, which they hoped would provide a solution to their problems. After this survey Greaves returned to England, leaving his measuring tools with Burattini, who continued the study of Egyptian monuments. On his return Greaves published the results obtained at Giza,



Egyptian measuring rule carved out of wood showing various fingers, palms, and cubits (at present in the Turin Musem).

results which were later interpreted by Newton. But Burattini had the ill luck to be robbed of his notes by Hungarian brigands while on his way to Poland. As a result, when he published his proposal for a decimal metric system, for lack of a better alternative, he advocated that one should start with the English foot and divide the cube of this foot decimally in order to obtain the units of volume and weight.

The study of Egyptian measures received a new impulsion with the Napoleonic expedition to Egypt and the consequent decipherment of Egyptian hieroglyphs by Champollion. This decipherment had been unsuccessfully attempted by Father Athanasius Kircher, who had sponsored Burattini's expedition to Egypt. In the first half of the nineteenth century, it was established that the Egyptians had a septenary system of linear units.

In the ancient world one measured by feet and cubits. The cubit is equal to 1 1/2 feet. The cubit is divided into 6 hands of 4 fingers each (24 fingers) and the foot is divided into 4 hands (16 fingers). The division of the foot into 12 inches, with which we are familiar, became common only with the Romans. According to the Roman reckoning the cubit is 16 inches. The inch was considered to be the thickness of the thumb; generally in the ancient world one preferred to reckon by fingers, assumed to be the thickness of the other four fingers. It must be kept in mind, however, that terms like foot, cubit, finger, and inch were introduced in order to give a name to units obtained scientifically, units which correspond only vaguely to the natural units of the same name.

Scholars of Egyptology concluded that the Egyptians had started with a foot of 300 millimeters and a corresponding cubit of 450 millimeters, divided into 16 and 24 fingers as in the rest of the ancient world, but then had adopted as their linear basic unit a cubit, called a royal cubit, of 525 millimeters. The royal cubit is composed of 7 hands, or 28 fingers: it is an ordinary cubit with a seventh hand added.

2. One can find examples of septenary units also outside Egypt. The use of measuring rods of seven feet is common in medieval and early modern Europe. A typical example of septenary units is the Russian *sajen'*, which is composed of 7 English feet and is divided into 3 *arshin* of 28 inches. The *sajen'* was the basis of the Russian system of measures until the Soviet government adopted the French metric system in 1918.

The reason for the occurrence of septenary units is that they were convenient in practical reckonings. Agrarian units of surface were arranged in a series in which each was double of the preceding one. It was assumed in practical reckonings that a square with a side of 100 was the double of a square with a side of 70 and the half of a square with a side of 140. This implies that $\sqrt{2} = 1.414214$, taken as equal to 1.4. A typical example of this reckoning is the area of 5000 square cubits, within which a Jew can move on the Sabbath, which is described by the Talmud as "the square of seventy cubits." When greater precision was desired in practical reckonings, one averaged the results of considering the diagonal of a square as 10/7 of the side and as 14/10 of the side ($1.42857 + 1.4/2 = 1.41428$).

Septenary units were used also in order to facilitate other practical reckonings. The height of an equilateral triangle being equal to $\sqrt{3}/2$ of the side, the relation can be taken as 7:6, since $12/7 = 1.71428$ and $\sqrt{3} = 1.73205$.

According to the septenary system of reckoning, the circumference was considered 22/7 of the diameter; the approximation $\pi = 3\ 1/7 = 3.142857$ is still used today as an adequate approximation in many problems of engineering.

The figure 22/7 used to obtain the value of π in practical reckonings is related to the fact that the ancients used both septenary and undecimal (i.e., eleven-based) units in order to achieve easy computations in practical reckonings. Undecimal linear units were common in the ancient and early modern world; an example of them is the English chain of 66 feet. An acre, originally a square with sides of 70 yards, is now 10 square chains (4840 sq. yards).

An important practical problem involving the number π was solved by the use of undecimal units. Units of volume were legally defined as cubes, but measuring vessels were built as cylinders. All that an ordinary potter, who could be an illiterate person, had to know was that, in order to construct a cylinder equal in volume to a given cube, he had to take the height and width of the cube and use them as the height and diameter of the cylinder, provided he measured the cylinder by a ruler based on a unit of length increased by 1/10. The procedure results in a cylinder of slightly excessive volume. If we assume a cube with a side of 10 fingers, its volume is 1000 cubic fingers. A cylinder with a diameter of 11 fingers and height of 11 has a volume of 1045.4 cubic fingers. But this small excess was automatically corrected in practice, since a measuring vase must have a rim and cannot be filled to the brim. A filling line marked on the measuring vase slightly below the brim took care of the difference. I first became aware of this procedure in interpreting cuneiform mathematical texts, but later I found it referred to in Athenian inscriptions and applied concretely in Athenian measuring vessels.

By combining calculations by the factor 7 and calculations by the factor 11, one could solve practically a number of geometric problems involving irrational numbers. This practice is one of the reasons why the builders of the Great Pyramid began their plan with a height of 280 royal cubits and a side of 440.

A simple example of the combination of reckoning by septenary and undecimal units is the following. As I have said, in agrarian units it was assumed that a square with the side of 100 is the double of a square with a side of 70 and half of a square with a side of 140. This procedure would result in units of the following surface:

49,000
100,000
196,000

In order to make the series more regular, the middle unit was often taken as a square with a side of 99, so that the series became:

49,000
98,010
196,000

When Herodotus reports the surface of the sides of the Great Pyramid, he reckons by units of surface calculating by the second pattern.

Although the use of septenary units had been common in ancient times and later, in Egypt the septenary cubit became a national symbol related to the essential structure of Egypt and of the cosmic order.

3. In the second half of the nineteenth century, some scholars of ancient measures tried to derive them from the Egyptian units of length. Although in the last fifty years it has become fashionable among scholars of ancient cultures to deny that they had any knowledge of a scientific system of measures, all serious scholars of ancient and medieval measures have always known that all measures of volume and weight are derived from the units of length. Units of volume were obtained by cubing the units of length. Units of weight were obtained by filling the units of volume with rain water at ordinary temperature; this water has the same density as distilled water at 4° Centigrade adopted by the French metric system, since in the earlier procedure the impurities of the rain water compensated for the higher temperature.

Friedrich Hultsch, who was the most authoritative investigator of ancient measures in the later part of the last century, concluded his lifelong research by announcing just before his death that all ancient measures could be derived from the Egyptian foot of 300 millimeters and from the corresponding ordinary (not septenary) cubit of 450 millimeters. He also supported the view expressed by others that the Egyptian unit of weight called *qedet,* of 9 grams, is the basic unit of weight of the ancient world.

But Hultsch left a difficulty unsolved. If we cube an Egyptian foot of 300 millimeters, we obtain a cube of 27,000 cubic centimeters or grams, which is divided into 3000 *qedet* of 9 grams. If we cube an Egyptian ordinary cubit of 450 millimeters, we obtain a cube of 91,125 cubic centimeters or grams, which is divided into 10,000 *qedet* of 9.1125 grams. Sample weights indicate that both *qedet* were used in Egypt. A *qedet* of 9 grams relates to a *qedet* of 9.1125 grams as 80:81.

The same discrepancy occurs all over the ancient world. Prince Mihail Sutzu, Director of the National Bank of Rumania, having dedicated his life to the study of ancient weights, in 1930 concluded that the *qedet* of 9 grams is the *bazele fundamentale ale metrologiei ponderale din antichitate,* but, in order to explain the mentioned discrepancy in weights, supposed that there had been a gradual decrease from a unit of 9.20 grams established in the neolithic period.

But in presenting this explanation Sutzu contradicted one of his basic assumptions, which is the amazing stability of measures throughout history. From the very beginning of literate cultures, documents indicate an extreme concern with the preservation of exact metric standards. The concern with precision seems to have lessened in the course of history. Early modern Europe was less careful than medieval Europe. The Greeks of the Hellenistic age were less careful than those of the classical age. Even though the Greeks of the classical age seem to have been obsessed with the problem of correct standards, they did not reach the subtlety of Egypt and Mesopotamia. One of the reasons why the study of the history of measures was actively pursued in the late Renaissance was that by that time standards had started to waver.

There were two factors which determined extreme concern with absolutely exact standards: units of length were used to measure geographic distances, and units of weight were used to measure gold and silver used as means of exchange.

The amazing stability of measures is indicated by the circumstance that the kilogram was established by relating it to the Paris livre which was directly related to the Roman *libra*. The official definition of the kilogram is such that the livre equals 489.5058466 grams. Since the livre was divided into 9216 grains (16 ounces of 24 scruples of 24 grains), the Paris grain according to this definition is 0.05311478 gram. Historically the Paris livre was established by fixing the Paris grains as 1/6100 of the ancient Roman *libra,* the Roman *libra* being 324 grams (5000 English grains) or 36 Egyptian *qedet.* If the original standard had been preserved, the grain of Paris would have been found at the moment of adoption of the French metric system to be 0.05311475 gram and the livre to be 489.5055737 grams. In substance the standard of the Paris livre and hence of the Roman *libra* appear to have been well preserved, even though those who established the French metric system did not consider the theoretical foundations of the livre, but simply averaged several sample weights which were available. However, scholars of the seventeenth century complained that Paris measures were not very clearly defined and had concluded that English units of weight were more exactly defined.

The English grain has remained stable as 1/5000 of a Roman *libra*. English weight units have not changed at all since Sumerian times. The oldest weights of which I have found mention in an archeological report are those excavated at Tepe Gawra in Iraq, near the present oil center of Mosul. The lowest strata of Tepe Gawra embody the very first steps of the transition from village life to urban life. The earliest weights of Tepe Gawra precede by about a millennium the invention of writing. According to my interpretation these weights are fractions of the present English ounce avoirdupois of 28.350 grams (1/16 pound, which is 7/5 of a Roman *libra*).

4. Before explaining why there was a *qedet* of 9 grams and a *qedet* of 9.1125 grams, I must deal with a much more serious difficulty met by Hultsch.

He assumed that all measures of the ancient world can be derived from the Egyptian foot, but could not solve the absolutely essential problem of explaining how the Roman foot of roughly 296 millimeters could be derived from the Egyptian foot of 300 millimeters.

The key to the solution of this problem was provided to me when in 1942 the archeologist August Oxé, at the end of lifelong research, published a monograph explaining that almost all units of volume and weight of the ancient world exist in two varieties, related as:

12.5	25	50	62.5	75	100	125	150
12	24	48	60	72	96	120	144

He called the first series units *brutto,* and the second series units *netto*. The reason for the existence of the second series is that it is impossible from the practical point of view to divide decimally a cube into smaller cubes.

Developing the discovery of Oxé, I arrived at the logical consequence that units of length must usually occur in two varieties, one which is the edge of a cube containing a unit *brutto* and one which is the edge of a cube containing a unit *netto*. The two varieties of units of length are related as $\sqrt[3]{25}:\sqrt[3]{24}$. I call the first group of units of length by the name of *natural* units and the second group by the name of *trimmed* units.

From an Egyptian cubit of 300 millimeters we derive:

Basic talent *brutto* of 27,000 cubic centimeters or grams
1000 Roman ounces of 27 cubic centimeters or grams
3000 Egyptian *qedet* of 9 grams

It follows that the cube of the Roman foot (which the Romans called *quadrantal,* or *pes quadratus*) must be 24/25 of the preceding unit:

Basic talent *netto* of 25,920 cubic centimeters or grams
960 Roman ounces of 27 cubic centimeters or grams
2880 Egyptian *qedet* of 9 grams

The Roman quadrantal or basic talent *netto* is divided into 80 librae of 324 grams (12 ounces or 36 *qedet*). The libra is equal to 5000 English grains.

Accordingly I could establish that the Roman foot relates as $\sqrt[3]{24}:\sqrt[3]{25}$ to the Egyptian foot of 300 millimeters, and hence is a unit of 295.9454 millimeters, which is a figure in agreement with the empirical evidence.

Having established the theoretical basis of the Roman foot and of the Roman quadrantal, I could dispose of a difficulty which had bedeviled scholars since the Renaissance. By examining the empirical evidence it had been established that the Roman foot existed in two varieties, one shorter (called *pes Statilianus* by Renaissance scholars) and one longer (called *pes Aebutianus*). Correspondingly, there were two varieties of Roman libra.

The explanation for this difference is that units of volume and weight may occur in two varieties related as 80:81, with a difference which I call discrepancy komma. In 1909 Jean Adolphe Decourdemanche, at the end of his book on Arabic measures, added a proviso explaining that all Arabic units of weight and volume occur in two varieties related as 80:81. My teacher Angelo Segré, in studying the measures of Hellenistic Egypt, found that, although the cube of the cubit is 3 3/8 of the cube of the foot, given that $(1\ 1/2)^3:1^3 =$ 3 3/8:1, often this relation between the cube of the cubit and the cube of the foot is taken as a relation 3 1/3:1 for the sake of easy reckoning, with the result that there is a discrepancy of 1/80, since 3 1/3:3 3/8 = 80:81.

The most striking example of the discrepancy komma (1/80) is that next to the quadrantal (cubed Roman foot) of 80 librae there is a quadrantal of 81 librae. This larger quadrantal has an edge which constitutes a special Roman foot of 297.1734 millimeters (instead of 295.9454 millimeters), which was called geometric foot in the Middle Ages. The Roman foot of the geometric variety was the scientific foot of early modern science. Scientists began to calculate by the French *pied de roi* (which originally was the undecimal version, 11/10, of the Roman foot) after Picard used it in his famous calculation of the circumference of the earth, and Newton quoted Picard's figures in presenting the empirical proofs for the theory of gravitation. The *pied de roi* was used in calculating the length of the Paris meter, theoretically defined as 1/10,000,000 of the arc of meridian: the meter is 1/10,000,000 of 30,784,440 *pieds de roi,* which was then the assumed length of the arc of meridian from the equator to the pole.

By dividing the quadrantal of 81 librae into 80 librae, the Romans obtained a libra of 328.050 grams, which was called the *geometric libra* in the Middle Ages. The edge of the larger quadrantal, the Roman *geometric foot,* was the standard unit in the planning of most monuments of classical Athens.

The larger Roman quadrantal (81 regular librae = 80 librae of the geometric variety), cube of a Roman geometric foot 297.1734 millimeters, contains 26,244 cubic centimeters or grams. It survived up to recently as the Russian *chetverik* (this Russian term has the same meaning as the Latin *quadrantal*). The law of 1918 that introduced the French metric system in the Soviet Union fixed the *chetverik* at 26,239 cubic centimeters.

The reason for the small difference is that Czar Peter the Great, according to his westernizing policy, had the length of the Russian *sajen'* readjusted to make it equal to 7 of the feet used in England. But the exact standard of the English foot had been lost in the Elizabethan age, and the length of the English foot has wavered until in England there was established the Imperial Yard of 1824, which makes the foot equal to 304.79974 millimeters, and in the United States the foot was defined by the Paris meter as 304.8 millimeters (act of Congress of 1928). The reform of Peter the Great caused uncertainties in the definition of Russian measures. The action of one autocrat extended the damage caused by another. As far as I can understand the record, the problem of the length of the English foot arose when Queen Elizabeth, following her policy which aimed at reducing the power of the municipal body of London, downgraded the authority of the standard of Guild Hall (*pes Curiae Londinensis*), which was considered by scholars the best standard of English foot. Incidentally, Piazzi Smyth suggested that a way to reconstruct the authentic value of the English foot is to compare the actual dimensions of the King's Chamber of the Great Pyramid with the report of the survey conducted by Greaves.

On the other side, I have examined the reports about the dimensions of the Church of St. Sophia in Novgorod, the oldest stone monument of Russia, in order to establish what was the original value of the Russian counterpart of the English foot. From the point of view of my investigations, it is lucky that an effort has been made to restore this church exactly as it was before it was destroyed by the German army in World War II.

5. Once I was able to establish the relationship between the Roman foot and the Egyptian foot (the former being the trimmed version of the latter) and succeeded in clarifying the history of the units called Roman by distinguishing two varieties of libra related as 80:81, I came to the conclusion that the root of the ancient system of measures is not the Egyptian foot of 300 millimeters, but another unit which is the geographic foot of 307.7957 millimeters.

If we take 9/8 of a Roman quadrantal of 80 regular librae or 10/9 of a Roman quadrantal of 81 such librae, we have a unit of 90 librae, which metrologists call the *artaba*. Artaba is the Persian name of this unit. Metrologists employ it because after this unit was adopted as the official standard by the Persian Empire, the use of its Persian name became general in the ancient world: we find it in Greek, Latin, Hebrew, Syriac, and Arabic texts. But the unit itself is as old as any other known unit of the ancient world.

The artaba has the following contents:

29,160	cubic centimeters or grams
90	Roman librae
1080	Roman ounces of 27 cubic centimeters or grams
3200	Egyptian *qedet* of 9.1125 grams
3240	Egyptian *qedet* of 9 grams
450,000	English grains

The artaba was a unit of paramount importance in Egypt and several other areas of the ancient world, because it was the standard ration of wheat for a month. This was the ration for an adult free male; women, slaves, and children were assigned fractions of it. The artaba was also the standard monthly ration of rice in China.

In cuneiform mathematical and economic texts the most common unit of volume is a pint (*sila* in Sumerian, *gā* in Akkadian) of 486 cubic centimeters, which is 1/60 artaba. The pint of cuneiform texts is divided into 60 sheqels of 8.10 grams (9/10 of an Egyptian *qedet*).

The paramount importance of the artaba continued up to modern times. I have established that the key to the metric systems of medieval Europe is an ounce of 29.160 grams, which is 1/1000 of an artaba of water. This ounce was made important in Europe by the monetary reforms enacted by the Frankish Kings Pepin and Charlemagne. The artabic ounce was known in Europe as the Cologne ounce, because Cologne was the seat of one of the important mints of the Carolingian Empire. In England the artabic ounce was called ounce Tower, after the mint of the Tower of London.

In England the ounce Tower remained stable at 450 English grains (29.160 grams) or 16/15 of ounce Troy. The ounce Tower is no longer used today because it was used only to weigh coins. On the European continent the Cologne ounce remained less stable, because often it was computed as 451 grains (to my knowledge this figure is first mentioned in a document A.D. 1275). The reason for this shift was an effort to adjust the Cologne ounce to a shift in the Paris livre. The Paris livre was divided into 9216 grains (16 ounces of 24 scruples of 24 grains). For technical reasons of monetary economics, the Paris ounce had to be 22/21 of an artabic ounce. Hence, in the early Middle Ages the Paris ounce was 30.54857 grams and the Paris livre 488.77714 grams, with a grain of 0.0530357 gram. Since there were 6109.1 of these grains in the Roman libra of 324 grams, in the later part of the Middle Ages, in order to relate easily the Paris units to a well-established standard, the Paris grain was recalculated as 1/6100 of a Roman libra and the Paris ounce and livre were increased accordingly (livre of 489.50557 grams). The Paris grain (0.05311475 gram) came to be 50/61 of the English grain. This small and apparently reasonable readjustment of the Paris units was enough to create a spreading wave of uncertainty in the value of European weight units which did not come to rest for centuries. For instance, one can trace its consequences in metric and economic documents of the Low Countries, Scandinavia, and Russia.

Because of the increase in the Paris units, the Cologne ounce came to be often calculated as 451 English grains instead of 450. At the beginning of the nineteenth century, when the German states were taking steps toward national unity, it was thought expedient to try to unify the German coinage in terms of the Cologne ounce. A survey conducted in 1829 established that in Cologne itself the Cologne mark (8 ounces) was 233.8123 grams; 8 artabic ounces would be 233.280 grams and 8 ounces of 451 English grains would be 233.79840 grams. The standards of other German cities were found to be slightly different from that of Cologne, reaching a minimum with the mark of the mint of Bonn, which was

233.612 grams. On July 30, 1838, the German states signed a convention to establish a uniform monetary mark defined in terms of the French metric units as 233.855 grams; but the mine administration of Saxony continued to consider as correct the mark of Dresden, which had been set at 233.5804 grams in an assembly for the testing of monetary weights (*Münzprobationstag*) held at Regensburg in 1737. Apparently the assembly of Regensburg had followed the pattern of the medieval Assizes of Weights and Measures, who when called to resolve discrepancies between different standards of the same measure usually settled the matter by selecting an intermediary value. I may finally mention that when the French metric system was adopted in Spain, it was decreed that the pound of Aragon, composed of 12 ounces, would be thereforth considered equal to 350 grams; 12 artabic ounces is 348.720 grams.

6. The edge of the cube containing an artaba is a foot of 307.7957 millimeters (cubit of 461.6935 millimeters), which I call geographic foot, because it was the unit most commonly used in geographic measurements in all areas of the ancient world, Egypt being excepted for reasons that I will explain.

The multiple of the geographic foot is the stadium of 600 feet (400 cubits). The stadium is 1/600 degree, so that there are 360,000 geographic feet in a degree. It was assumed that a stadium (184.677 meters) corresponds to a double minute of march, implying that a man makes a step of 5 feet in a second. It was assumed that a man marching or a ship under oars covers 30 stadia (5540.3 meters) in an hour. Since it was assumed that a man can march or row for 10 hours a day, 300 stadia was considered the distance normally covered in a day. There are a great number of texts from Egypt and other areas of the ancient world which have not been understood, because they speak of 1,2,3,4, . . . days of march, when they mean a geographic distance of 30′, 1°, 1° 30′, 2°. . . . It was assumed that the speed of a ship under sail is 5/4 of that of a ship propelled by oars, so that a ship under sail covers 37.5 stadia in an hour and 900 stadia (1 1/2 degrees) in 24 hours.

In the ancient world the degree of latitude was usually reckoned as 360,000 feet (600 stadia). Sailors and travelers of the eastern Mediterranean and of the Middle East reckoned the degree of longitude as roughly 500 stadia, or 300,000 geographic feet (92,339 meters); this calculation is correct between parallels 34° and 35°.

The calculations of the degree of latitude as 360,000 geographic feet (240,000 geographic cubits) proves to be of Egyptian origin, since a degree of 110,806.5 meters proves to be correct at parallel 27° 45′ north, which is the middle latitude of Egypt according to the predynastic geodetic system, which counted 7° 30′ from Behdet to the southern limit of Egypt, latitude 24° 00′ north. According to the *Smithsonian Geographical Tables,* a degree at parallel 27° 45′ is 110,803.0 meters.

The Egyptians preferred to reckon by cubits (stadium of 400 cubits and degree of 240,000 cubits), because it is expedient to divide the circumference of the earth not only into 360 degrees but also into 24 hours. According to the second system a degree is equal to 4 minutes of time and a minute of degree is equal to 4 seconds of time. I shall deal with this matter more extensively later.

Two great scholars of this century who have dedicated their lives to the study of ancient measures concluded that these are so strictly defined and so rigorously organized that they must have a basis on some absolute natural standard. Since it is obvious from the reading of ancient texts that the ancients had a deep concern with cosmic time, with the movement of the vault of heaven, these two scholars concluded that the system of measures must have coordinated not only length, volume, and weight, but also time.

The first of these two scholars, Sir Flinders Petrie, whose major concern was Egyptian measures, thought that the starting point of ancient measures was the length of the pendulum. He advanced the theory that the Egyptians began with a pendulum that swings 100,000 times a day at the latitude of Memphis (29° 51′ north). Having established that this pendulum has a length of 740.57 millimeters, they would have taken as standard of length the side of a square the diagonal of which is the length of the pendulum. This would be the origin of the Egyptian royal cubit. Calculating by this procedure, the royal cubit would be 523.66 millimeters, but Petrie estimates it as about 524 millimeters.

Carl Friedrich Lehmann-Haupt, a scholar of ancient history who, after the death of Hultsch, took over the role of the great German specialist of ancient measures, making them his major concern up to his death in 1936, followed the same line of reasoning. Since he started his activities as one of the decipherers of the Sumerian language and was particularly competent in the reading of cuneiform mathematical texts, he argued that the ancient system of measures was organized in Mesopotamia from the pendulum that beats the second at latitude 30°. The early inhabitants of Mesopotamia would have taken the half of this length as their cubit (cubit of 491.16 millimeters according to Lehmann-Haupt).

The idea was not completely new: in the period of the adoption of the French metric system, there occurred to a scholar of ancient measures that the Roman foot might have been calculated as the length of the pendulum that beats the half-second.

Unfortunately, Petrie and Lehmann-Haupt were not so well informed about the history of measures as they should have been. Soon after Galileo discovered the law of isochronism of the pendulum, since scholars were debating among themselves the project for a new decimal system of measures, it was suggested by several of them that the new system should be based on the length of the pendulum, in order to link together time, length, volume, and weight. But in the course of the eighteenth century it was realized that the pendulum does not provide a reliable standard of length. First of all, it was established that the period of oscillation of the pendulum changes according to the latitude; this led to the discovery of the polar flattening of the earth. It was also successively established that the period of oscillation is influenced by the density of the earth and by any presence of large masses of matter, since the period depends on the gravitational pull. Hence, by the time of the adoption of the French metric system, it had been decided that the new decimal system should limit itself to coordinating length, volume, and weight.

When the Constitution of the United States was drafted, there was included a special clause to prepare the ground for the adoption of a new decimal system of measures, which was advocated by all enlightened people. When the French Revolution in one of its first steps put into law the decimal metric system, the Congress of the United States considered adopting the French system. But Thomas Jefferson, whom Congress respected as the authority on such matters, opposed the plan on the ground that the French system was inadequate, since it did not coordinate time with length, volume, and weight. This opposition from inside the camp of the progressive forces doomed the adoption of the decimal system in the United States.

Jefferson was correct in principle, and so were Petrie and Lehmann-Haupt. A truly desirable system of measures should coordinate time, length, volume, and weight, but what these people did not know is that the ancients had found an easy and reliable method to coordinate length with time. All that is needed is to relate the unit of length to the speed of the rotation of the vault of heaven, since this is the basis of our calculations of time. As I will explain later, today we calculate time by the length of the mean solar day, but since this is a highly artificial concept, astronomers set the length of the solar day by the apparent motion of the vault of heaven (sidereal time), which flows evenly.

The problem of coordinating time with the other measures is so important that after decades of research on ancient measures I was still fumbling for one element which would allow me to fit all my findings together, until Peter Tompkins ripped the veil from my eyes by pointing out to me that speed of rotation of the vault of heaven is 1000 geographic cubits a second.

The Egyptians set their standards of length in a manner that permits an easy correlation with time, but still the standard which was scientifically defined had to be the standard of length.

7. The tradition of what was the ancient procedure has been preserved by the scientist and mathematician Girolamo Cardano (1501–1576). Like other Renaissance scholars he was concerned with the establishment of an absolutely inalterable standard of length. In his book *De Subtilitate* (Chapter XVII, edition of Basel, 1553, p. 475) he discusses the length of the ancient Roman foot and passes from it to the problem of how to base length and weight on a *mensura perpetua*. He observes that such an absolute standard should be searched for in the heavens, but, since this is impossible for practical reasons, he declares that the standard is provided by the pyramids of Egypt, the Labyrinth of Thebes, cities like Cairo, and the river Nile. The meaning of this statement is perfectly clear, when we consider the geodetic system of Egypt, as I have reconstructed it; but its form is cryptic. This should not be surprising, since it is known that Cardano has been cryptic in announcing some of his major mathematical discoveries. It had been the practice of scientists and mathematicians up to the age of Newton to put into print the data which they considered of essential importance in a form such that the meaning would become obvious only after an explanation had been communicated orally, because this was the only method they had of protecting their copyright.

The Egyptians decided that the distance of 7° 30′ from Behdet to the southern boundary of Egypt should be reckoned as 1,800,000 geographic cubits. According to the *Smithsonian Geographical Tables* the interval from 31° 30′ to 24° 00′ is 831,091 meters. According to my findings 1,800,000 geographic cubits are 831,048 meters. The figures of the *Smithsonian Geographical Tables* are an estimate of the average length of the degree of latitude, based on the assumption that the earth is a regular geometric body. It would be necessary to consider what is the actual length of the degree in Egypt. Up to now I have deliberately avoided obtaining this information, because I did not want my interpretation of the texts to be influenced by the knowledge of the possible results.

In order to appreciate the nicety of the Egyptian figure, we must keep in mind that in the first French legislation the length of the meter was established by assuming that the arc of meridian is 30,794,580 *pieds de roi,* on the basis of the survey conducted in 1740. Later the length of the meter was revised to the present one, because according to the survey conducted in 1792–98 the arc of meridian is 30,784,440 *pieds de roi.* After this survey the meter was no longer revised, although it has been ascertained that the arc of meridian is about 2000 meters more than 10,000,000 meters.

8. From the geographic cubit, defined as 1/1,800,000 of the length of Egypt, there was derived the geographic foot of 307.7957 millimeters. By cubing this there was fixed the volume of the artaba as 29,160 cubic centimeters.

The artaba was divided into 64 pints of 455.6250 cubic centimeters, that is, into 64 cubes with a side of a hand (4 fingers = 1/4 foot). This unit is the standard pint of Egypt. The pint was divided into 50 *qedet* of 9.1125 grams, employed to weigh gold and silver used as a means of exchange. Sutzu is correct in concluding that, although the *qedet* of 9 grams is the more current unit of weight in advanced civilizations, the heavier *qedet* appears common in prehistoric or early times.

From the artaba there was derived a unit of 3 artabas, which is the cube of the Roman cubit. This is the origin of the Roman foot. There was also derived a unit which is the *brutto* version of the preceding one; since in the cube of the Roman cubit there are 9600 *qedet,* this second unit contains 10,000 *qedet* of 9.1125 grams. The edge of the cube which corresponds to this second unit is the ordinary Egyptian cubit of 450 millimeters. This cubit implies a foot of 300 millimeters. The cube of this foot is the talent of 27,000 cubic centimeters or grams, which was divided into 3000 *qedet* of 9 grams or 1000 Roman ounces of 27 cubic centimeters or grams. The *netto* version of this unit is the cube of the Roman foot (25,920 cubic centimeters or grams). Since the cube of the Roman foot is 8/9 artaba, this cube was divided into 80 librae of 36 *qedet* of 9 grams, whereas the artaba is composed of 90 librae. Three *qedet* of 9 grams makes the Roman ounce of which 1000 makes the cube of the Egyptian foot of 300 millimeters (27,000 cubic centimeters or grams). However, following the reckoning of a *qedet* of 9.1125 grams there continued to be in common use a larger quadrantal (Russian *chetverik*), the edge of which is the Roman geometric foot, and which contains 80 geometric librae

(81/80 of regular libra of 324 grams). This larger quadrantal is 9/10 of artaba.

The organization of the units according to this pattern had a practical purpose. The unit of 3 artabas was the cube of the cubit (443.9181 millimeter) called Roman, a unit of 87,470 cubic centimeters or grams. This was considered a unit *netto*, to which there corresponded a unit *brutto* (25/24) of 91,125 cubic centimeters or grams, which is the cube of the common Egyptian cubit of 450 millimeters. The units of 87,470 grams and of 91,125 grams, that is, the weight of the cubes of the Roman and of the common Egyptian cubits filled with water, are called by me basic load *netto* and basic load *brutto*. I have given them these names because they were considered the standard amount that could be carried by a pack ass. In Akkadian these units are called *imēru*, which means "ass." The Masoretic text of the Old Testament uses a different punctuation of vowels under the consonants to distinguish between the term *ḥmr* as referring to an ass and the same term as referring to the unit of measure, but there are puns in the Old Testament which indicate that one could confuse one meaning with the other. Since the language of measures is very international, there is a transfer of terms among Semitic, Indo-European, and Fenno-Ugrian languages, in which the same terms are applied at times to the measure and at times to the animal. Some easy examples are the following. In Hellenistic Egypt the ass was called *gomarion*, from *gomos*, "load"; the ass is called *gomari* in modern Greek. In Italian the ass is called *somaro*, from the Greek *sagma*, "pack saddle." The corresponding English word is *sumpter*, which corresponds to a German *Saumtier*, a term in turn corresponding to the Italian *bestia da soma*, "pack animal." In German *Saum* means "burden" and also refers to a large unit of measure. In Italian *salma* is both a large unit of weight or volume and a corpse carried on a stretcher, which has on the average the weight of what I call a basic load.

The cube of the foot was called talent in Greek or by equivalent terms in other languages of the ancient world. There was a basic talent *netto* of 25,920 grams and basic talent *brutto* of 27,000 grams, which were respectively the cube of the Roman foot of 295.9454 millimeters and the cube of the Egyptian foot of 300 millimeters. Names such as talent refer to the fact that these weights were considered half of the amount that could be transported by a man. It was assumed that a man transports burdens by suspending them at the two ends of a carrying yoke. At each end of the yoke there were weights, which ideally had to be identical; each of these weights was called a talent. It is evident that this is the origin of the idea of equilibrium and of the measuring scale. Incidentally, I may also mention that it was assumed that the carrying yoke has a length of 2 cubits or three feet.

9. Since the development of units from the artaba had started with the cube of the Roman cubit, which is equal to 3 artabas, there was developed a unit equal to 5 artabas. The edge of the cube containing 5 artabas is the origin of the Egyptian royal cubit. Five artabas were the volume of a basic load of barley (barley was assumed to have a specific gravity between 0.6 and 0.666).

The edge of the cube which contains 5 artabas was interpreted as the septenary version of the Egyptian cubit of 450 millimeters, that is, as a cubit of 7 hands (28 fingers) instead of the normal 6 hands (24 fingers). But, if we reckon exactly, the cube of the cubit of 525 millimeters contains 144,703.125 cubic centimeters, which is something less than 5 artabas = 145,800 cubic centimeters. A unit of 5 artabas should contain 16,000 *qedet*. By dividing the cube with an edge of 525 millimeters by 16,000 there is obtained a *qedet* of 9.043945 grams, which is intermediary between the *qedet* of 9 grams and the *qedet* of 9.1125 grams. The analysis of the distribution of the weights of Egyptian sample weights indicates that there were in use three standards of *qedet:*

9.000000 grams
9.043945 grams
9.112500 grams

Correspondingly, the study of the monuments and of the measuring rods indicates that there were three values of the royal cubit:

524.1483 millimeters
525.0000 millimeters
526.3231 millimeters

The first royal cubit is the edge of the cube containing 16,000 *qedet* of 9 grams. It is the standard of the Great Pyramid and of the immense complex of buildings erected by the architect Imhotep around the pyramid of King Zoser of the Third Dynasty. This royal cubit was the scientific unit of Egypt, employed in the calculation of geographic distances.

The second royal cubit was exactly 7/6 of the Egyptian cubit of 450 millimeters. It was the one most commonly used in ordinary life. It is the standard of the Second Pyramid of Giza.

The third royal cubit had the virtue of being the edge of the cube containing exactly 5 artabas (16,000 *qedet* of 9.1125 grams). It is the standard of the coffers of the mentioned two pyramids of Giza.

The royal cubit had the advantage of being a septenary unit, a type of unit which had been found convenient in the practical solution of problems involving irrational roots such as $\sqrt{2}$, $\sqrt{3}$, and π. But, when the reorganization of the Egyptian geodetic system with the unification of Egypt stressed the number 7 as the link between the dimensions of Egypt and the order of the heavens, the septenary royal cubit was raised to the status of a national symbol and became the official standard of the Egyptian monarchy.

It may be worth pointing out, in order to indicate how the great majority of scholars deal with these problems, that Eduard Meyer, whose ideas and method dominate contemporary history of antiquity and of Egypt in particular, explained the origin of the royal cubit by asserting that the Pharaohs demanded contractors to build by the cubit of 7 hands, but exercised their royal prerogatives by paying them as if they had employed the regular cubit of 6 hands (a discount of 37 percent). Let us not forget that the current opinions about the Egyptian ability to measure time astronomically are based on the calculations of Eduard Meyer.

10. According to the second geodetic system of Egypt, the length of Egypt, from the base line of the Delta (31° 06′ north) to the usual southern boundary at 24° 00′ north, was recalculated as 1,500,000 royal cubits of 524.1483 millimeters. This is the reason why the cubit of 524.1483 millimeters became the one used in geographic measurements.

This second calculation of the length of Egypt is derivative and, hence, is not as precise as the one that made the geographic cubit equal to 1/1,800,000 of the length of Egypt. The length of Egypt according to the dynastic system is 7° 06′; 1,500,000 royal cubits equals 786,222 meters. According to the *Smithsonian Geographical Tables*, the interval from 31° 06′ to 24° 00′ is 786,741 meters. There is a difference of about 1000 royal cubits.

For the sake of geographical calculations the royal cubit was given as multiple the *atur* of 15,000 royal cubits, so as to make Egypt equal to the perfect figure of 100 *atur*. The term *atur* literally means "river"; it could be translated as "river measure." It was understood that an *atur* (7862.2 meters) corresponds to an hour of navigation along the Nile.

The *atur* fitted the septenary spirit of the system of measures, since it could be assumed that a degree of latitude is 14 *atur*. This was a practical approximation, which was corrected by adding decimal points to the figure of 14 *atur*, reaching a maximum of 14.1 *atur* at the north of Egypt.

A degree of 14.1 *atur* is 110,857.4 meters. According to the *Smithsonian Geographical Tables,* degree 30°–31° is 110,857.0 meters.

The length of Egypt was divided into 14 *atur* for Northern Egypt and 86 *atur* for Southern Egypt. If we divide 100 *atur* by 7° 06′, we have a degree of 14.084507 *atur* = 110,735.6 meters, which is the length of the degree at parallel 23° 00′ (110,736 meters according to Helmert). A reason why the length of Egypt was extended south to the Sacred Sycamore, at 23° 00′ north, appears to have been that of giving a more exact scientific basis to the calculation of the royal cubit as being such that 211,267.605 royal cubits (14.0845 *atur*) makes a degree.

We shall see that the Pharaoh Akhenaten attacked the authority of the Temple of Amon at Thebes by questioning the scientific exactitude of the second geodetic system of Egypt and of the calculations by royal cubits. There is a possibility that the extension of the boundaries of Egypt from latitude 24° 00′ to latitude 23° 00′ north was part of the counterattack against the reforms of Akhenaten. The purpose may have been that of calculating the value of the royal cubit independently of the value of the geographic cubit.

III. COFFER OF THE GREAT PYRAMID

1. On the basis of my reconstruction of the Egyptian system of measures, it is possible to solve the riddle of the coffer placed inside the King's Chamber of the Great Pyramid.

Many investigators have tried to explain the dimensions of this coffer, but none has reached a positive conclusion. However, the majority of the investigators agree on two basic assumptions: the coffer embodies some numerical conundrum and the contents of the coffer corresponds to some standard of volume. According to my interpretation both of these assumptions are correct: the contents of the coffer is 8 cubic royal cubits = 40 artabas (1166.40 liters), and the walls were given a thickness such that the outside volume of the coffer is twice that of the contents, that is, 16 cubic royal cubits = 80 artabas (2332.800 liters).

The investigators who have preceded me have been hampered by not knowing that there were three possible values of the royal cubit. For this reason they could not realize that the standard of measure of the coffer is a royal cubit different from that employed in planning the King's chamber and the rest of the Pyramid. The King's Chamber was planned by the royal cubit of 524.1483 millimeters, because this is the standard of the Pyramid, chosen because this was the royal cubit usually employed by the Egyptians in calculating geographic distances. The coffer, on the other hand, was planned by the royal cubit of 526.3231 millimeters, because this was the unit employed in calculating the fundamental units of volume and weight.

Before the Cole survey of the dimensions of the Great Pyramid, the only datum available to scholars to determine the exact value of the cubit of the Pyramid was the dimensions of the King's Chamber. It was Newton who, on the basis of the survey conducted by Greaves, realized that the King's Chamber measures 10 by 20 cubits. Having established this fact, he calculated that the cubit of the Pyramid is 1732.5/1000 of an English foot and rounded the figure to 1732/1000. Calculating by the British Imperial standard foot established in 1824, the figures of Newton indicate a cubit of 528.0655 or 527.9131 millimeters. Newton was interested in the length of the Egyptian royal cubit, because he wanted to interpret the statement of Eratosthenes that a degree of latitude is 210,000 cubits.

Petrie proceeded to an extremely accurate survey of the dimensions of the King's Chamber, taking into account the fact that the blocks have been spread apart by the action of earthquakes. By deducting from the length of the sides the spaces which today separate the blocks, he concluded that the cubit of the King's Chamber is 20.632 ± 0.004 English inches $= 524.0523 \pm 0.1016$ millimeters. This empirical datum agrees with the figure of 524.1483 millimeters which I have obtained by considering the mathematical structure of the Egyptian system of measures and all the empirical evidence available.

The coffer is not calculated by the cubit of the King's Chamber, but the cubit of 526.3231 millimeters, because this cubit when cubed contains 145.800 liters = 5 artabas = 16,000 *qedet* of 9.1125 grams.

The reports about the dimensions of the coffer show some discrepancies, because the coffer was cut rather roughly. Petrie relates that an entire side was cut by the strokes of a huge saw, which at times was backed up after it had dented the stone as much as one inch out of plumb. However, by comparing the reports of Greaves, Piazzi Smyth, Petrie, and others, I have identified the intended dimensions of the coffer, since I have the advantage of knowing the exact value of the unit of measurement.

The coffer was computed in hands of 1/7 of the cubit of 526.3231 millimeters. Its inner dimensions are:

Width:	9 hands =	676.70 mm
Length:	26.3 hands =	1977.47 mm
Height:	11.6 hands =	872.19 mm

The corresponding figures in the reports of Greaves and Petrie are:

26.616 English inches = 676.15 mm	26.81 inches = 680.97 mm
77.856 English inches = 1,977.54 mm	78.06 inches = 1982.72 mm
34.32 English inches = 871.73 mm	34.42 inches = 874.27 mm

The report of Smyth agrees substantially with that of Greaves. Petrie's figures are slightly excessive, because he computed the inner dimensions by deducting the thickness of the walls from the outer dimensions, and he thought that it would be proper to measure the walls at the point of their minimum thickness.

The lateral walls were intended to be 2 hands thick, so that the outside dimentions are:

Width: 13 hands = 977.46 mm
Length: 30.3 hands = 2278.23 mm

Petrie's figures for these two dimensions are:

38.50 English inches = 977.90 mm
89.62 English inches = 2276.35 mm

The height of the outside was intended to be 2 cubits = 14 hands, but in order to establish a link between the coffer and the rest of the Pyramid these two cubits were calculated by the cubit of the Pyramid and the King's Chamber. Two cubits of 524.1483 millimeters is 1,048.29 millimeters. In terms of the cubit of 526.3231 millimeters, this means 13.9422 hands; possibly the figure was rounded to 13.9333 hands = 1,047.63 millimeters. I assume that the bottom of the coffer was given a thickness of 2.333 hands = 175.44 millimeters (Petrie reports 6.89 inches = 175.01 millimeters). I assume that the height was 13.9333 hands = 1,047.63 millimeters (Petrie reports 41.31 inches = 1049.27 millimeters).

According to Greaves's figures the contents of the coffer is 71,118 cubic inches = 1,165.428 liters. According to Petrie's figures the contents is 72,033 cubic inches = 1,180.405 liters; I have explained why Petrie overestimated the inner dimensions. According to my interpretation the contents is 2745.72 cubic hands. Now, 2744 cubic hands is 1,166.400 liters = 8 cubic cubits = 40 artabas.

If the outside of the coffer is 13 by 30.3 by 13.933 hands, its volume is 5488.3 cubic hands. Now, 5488 cubic hands is 16 cubic cubits = 80 artabas.

Since the two volumes of the coffer are 8 and 16 cubic cubits, it is not possible to be certain that a measurement by artabas was in the mind of the builders, although I cannot think of any other reason why the builders should have chosen the cubit of 526.3231 millimeters, unless they intended to choose the cubit which when cubed has a contents of exactly 5 artabas. A clearer proof that the calculation was intended to be by artabas is provided by the similar coffer of the Second Pyramid of Giza.

2. From the dimension of the sides of the Second Pyramid of Giza, it can be established that it was planned by the royal cubit of 525 millimeters. Nevertheless, as in the case of the Great Pyramid, the coffer was planned by the cubit of 526.3231 millimeters.

Petrie reports the following data about the coffer of the Second Pyramid, expressed in English inches:

	Length	Width	Height
Outside:	106.68 = 2,709.67 mm	41.97 = 1,066.04 mm	38.12 = 968.25 mm
Walls:	21.95 = 557.53 mm	15.28 = 388.11 mm	8.53 = 216.66 mm
Inside:	84.73 = 2,152.14 mm	26.69 = 677.93 mm	29.59 = 751.59 mm

As in the Great Pyramid, the coffer was planned in hands (1/7) of the cubit of 526.3231 millimeters. The dimensions are the following:

	Length	Width	Height
Outside:	36 = 2,706.80 mm	14.2 = 1,067.68 mm	12.88 = 968.43 mm
Walls:	7.4 = 566.40 mm	5.2 = 390.98 mm	2.88 = 216.54 mm
Inside:	28.6 = 2,150.41 mm	9 = 676.70 mm	10 = 751.89 mm

Petrie's figures imply an inside volume of 1,096.554 liters. According to my interpretation the volume is 2574 cubic hands = 1094.137 liters. If we assume that the volume was intended to be 2572.5 cubic hands = 1093.500 liters, the contents of the coffer corresponds to:

7.5	cubic royal cubits
37.5	artabas
12	basic loads *brutto*
120,000	*qedet* of 9.1125 grams
121,500	*qedet* of 9 grams

The contents of this coffer is 15/16 of the contents of the coffer of the Great Pyramid.

Because the Second Pyramid had been planned by the royal cubit of 525 millimeters, the coffer, although measured by the cubit of 526.3231 millimeters, indicates a volume expressed best of all in basic loads *brutto;* the basic load *brutto* is the cube of the cubit of 450 millimeters, which is the common cubit coresponding to the royal cubit of 525 millimeters.

Petrie's figures imply an outside volume of 2796.883 liters. According to my interpretation the volume is 6584.25 cubic hands = 2798.786 liters. If we assume that the outside volume was intended to be 6585.4 cubic hands = 2799.360 liters, the volume corresponds to:

19.2	cubic royal cubits
96	artabas
32	basic loads *netto*
307,200	*qedet* of 9.1125 grams
311,400	*qedet* of 9 grams

The outside volume of this coffer is 6/5 that of the coffer of the Great Pyramid.

The coffer of the Second Pyramid was planned so as to embody the key units of the Egyptian system of volumes:

Artaba of 29,160 cubic centimeters (cube of the geographic foot)
Basic load *netto* of 87,480 cubic centimeters (cube of the Roman cubit)
Basic load *brutto* of 91,125 cubic centimeters (cube of the Egyptian common cubit)

IV. DEGREES OF LATITUDE

1. The calculation of the dimensions of Egypt by royal cubits was less precise than that by geographic cubits, but it had the advantage of stressing the number 7 as the key to the dimensions of Egypt and as the link between the structure of Egypt and the order of the cosmos.

Following the septenary system of measurement, the stadium, a tenth of minute of degree, was reckoned as 350 royal cubits (183.45 meters). This stadium is somewhat shorter than the stadium of 400 geographic cubits (600 geographic feet = 184.68 meters). It implies a degree (600 stadia to the degree) of 210,000 royal cubits = 110,071.1 meters. But the calculation of the stadium as 350 royal cubits was considered a first approximation which could be employed in practical computations. Just as in the calculation by *atur*, a degree of latitude was considered basically equal to 14 *atur*, but in exact calculations a decimal point was added to the figure of 14, so in exact calculations a few cubits were added to the figure of 350 royal cubits to a stadium.

In round figuring the Egyptians calculated the stadium at the equator as 354 stadia; but more accurate figures were known. By this round figure they obtained an equatorial minute of degree (10 stadia) of 1855.485 meters, which is 88 millimeters more than the figure of the International Spheroid (1855.398 meters). A stadium of 354 cubits implies an equatorial circle of 76,464,000 cubits = 40,078,491 meters, whereas according to the International Spheroid the equatorial radius is 6,378,388 meters ± 18 meters, so that the equator would be 40,076,594 meters ± 113 meters. Since the Egyptians preferred to count by 90 degrees of equator, the figure of 354 cubit for a stadium of equator contains a numerical game, such as frequently occurs in ancient computations for mnemonic reasons. Ninety degrees of equator is 54,000 stadia of 354 cubits.

Assuming a stadium of 354 royal cubits, a degree of equator is 212,400 cubits, which is a good round figure. We shall see that the Egyptians estimated the exact figure as between 212,380 and 212,392 cubits.

An absolutely exact calculation of the length of the equator was a matter of scientific interest, whereas the Egyptians put much greater stress on the exact calculation of the length of the degrees of latitude, since the anchor of their geodetic conceptions was the course of the Nile.

For the stadium of latitude of the equator they used the figure of 351.6 cubits = 184.2905 meters, which is as exact as any modern calculation can be. According to the Clarke Spheroid a minute of latitude at the equator is 1842.787 meters; according to the International Spheroid it is 1842.925 meters. We shall see that the base of the Great Pyramid is calculated by a stadium of 351.6 cubits.

To those who may not be conversant with these matters, I must explain that, since the shape of the earth is irregular, modern scholars have tried to construct a regular geometric figure, called the spheroid, the dimensions of which fit as closely as possible the actual dimensions of the earth. Different scholars have constructed different spheroids, in part because they have based their work on surveys conducted in different areas of our planet. For instance, in the United States many agencies and institutions continue to use the spheroid calculated by the English geodesist Clarke in 1866, because its data fit rather well with the shape of the earth in North America. Many scholars prefer the computation published by the German Helmert in 1907. But the calculation most usually considered authoritative by scholars is that completed by the American Hayford in 1910, known as the International Spheroid. This calculation is based on a gigantic survey conducted under the auspices of the British Empire from the tip of South Africa to the Equator and then up to the Mediterranean along the Nile. This survey happens to overlap the Egyptian calculations along the course of the Nile.

The stadium of latitude increases as one moves to the north from the equator, reaching the value of 354 cubits, equal to the length of the stadium of equator, between parallel 55° and parallel 56°. It reaches a maximum estimated as 355 cubits at the pole. This figure of 355 cubits for the stadium of latitude at the pole, which indicates a minute of 1860.726 meters, was a convenient round figure which was refined in exact reckonings. A stadium of 355 cubits implies a polar degree of 213,000 cubits = 111,643.6 meters; if 1/2000 was the amount added to the latter figure we would have 213.106.5 cubits = 111,699.4 meters. According to the *Smithsonian Geographical Tables*, degree 89°–90° is 111,699.3 meters.

For navigation along the Nile, there was used the following formula for the length of the degrees of latitude:

211,500 cubits = 110,857 meters at latitude 31° 06′
211,300 cubits = 110,753 meters at latitude 24° 06′
211,100 cubits = 110,648 meters at latitude 15° 36′

Latitude 15° 36′ north is the latitude of the confluence of the White Nile with the Blue Nile.

2. One of the major difficulties of ancient mathematical science was that it could not rely on printed tables, although some numerical tables, such as exponents, roots, and logarithms, are occasionally found in cuneiform tablets. Even maps were so drawn that the key positions could be memorized. The lack of the printing press is the reason why in ancient mathematics we find a variety of formulas and mnemonic devices for obtaining trigonometric functions. In the same spirit the Egyptians had developed a simple formula for calculating the length of the degree of latitude at all parallels between the equator and the pole.

The scheme was based on the circumstances that the Egyptians used three values for the length of the degree of latitude at the equator—an exact value based on a stadium of 351.6 cubits and two rounded values:

A. Exact value. Stadium of 351.6 cubits, degree of 210,960 cubits = 110,574 meters.

B. Value rounded to degree of 211,000 cubits = 110,595 meters.

C. Value rounded to arc of meridian of 19,000,000 cubits, degree of 211,111 = 110.654 meters.

Value *B* was considered exact for a degree at 9° and value *C* for a degree at 16°.

The length of the degree was calculated by taking the second value, 211,000 cubits, and assuming that each degree is longer than the preceding degree by a number of cubits equal to the number of the degree.

Degree	Cubits added to degree	Cubits added to length of degree at 0°
1°	1	1
2°	2	3
3°	3	6
4°	4	10
5°	5	15
6°	6	21

This pattern was followed up to degree 36°, which is 36 cubits longer than the degree at 35° and 666 cubits longer than the degree at 0°. For six degrees, from 37 to 42°, the amount added to each degree is 37 cubits. For the following six degrees, from 43 to 48°, the amount added to each degree is 38 cubits. Then for six degrees, from 49 to 54°, the amount added is again 37 cubits. For the remaining 36 degrees, from 55 to 90°, the amount added is the same as that applied to the first 32 degrees but in the inverse order.

The scheme gives immediately the length of the degrees from 24 to 58°, that is, for 35 degrees. For the first 23 degrees and for the last 32 there are introduced simple corrections:

(1) For the first eight degrees, from 1 to 8°, the amount is added to the exact value of the degree (value *A*, 210,960 cubits to degree). From a degree at 9° one begins to count by value *B* (211,000 cubits), but 45 cubits is deducted from the amount added to this degree; this deduction is reduced by 3 cubits for each of the following 13 degrees, until 3 cubits is deducted from 23°.

3. At 90° the amount added according to the scheme is added to a basic degree calculated by value *C* (211,111 cubits). For the 32 degrees from 59 to 90°, an adjustment is

Degree	Cubits added to each degree	Cubits added to 0° degree	Correction	Egyptian ESTIMATE, meters	Helmert's ESTIMATE, meters
1°	1	1		110,575	110,573
2°	2	3		110,576	110,574
3°	3	6		110,577	110,575
4°	4	10		110,580	110,577
5°	5	15		110,582	110,579
6°	6	21		110,585	110,582
7°	7	28		110,589	110,586
8°	8	36		110,593	110,591
9°	9	45	−45	110,595	110,596
10°	10	55	−42	110,602	110,602

made for a transition from value *B* to value *C*. Thus, to a degree at 59° there is added 111.11/32 cubits, or practically 3.5 cubits ($32 \times 3.5 = 112$); to a degree at 60° twice as much is added; to a degree at 61° there is added three times as much.

This scheme gives values of the degree of latitude which differ most from the one we use today in the area near the pole. This could be connected with the fraction that the Egyptians used in calculating the polar flattening of the earth. I shall deal with this fraction in a following chapter. According to the scheme, the degree between parallel 89° and the pole is 213,115.11 cubits = 11,703.9 meters. According to the Clarke Spheroid the minute of degree of latitude at the pole is such that the corresponding degree is 111,699.36 meters; but in 1880 Clarke revised the figure to 111,702,06 meters. According to the International Spheroid the figure is 111,700 meters.

4. The scheme which I have presented provides excellent values for the length of the degree of latitude, but probably was intended to be only a practical device, not the most exact calculation. There is evidence which suggests that efforts were made to calculate the lengths of the degrees with greater mathematical refinement.

The Egyptians invented the column as an architectural element. If one observes the decoration of Egyptian columns with a scientific attitude, he will recognize that the column represents the map of Egypt: the capital is Northern Egypt and the shaft is Southern Egypt. This explains why among the Greeks, who learned the use of the column from the Egyptians, for the Doric order, the most conservative of the Greek orders, there was the rule that the shaft should be six units high and the capital one unit high. In the Greek orders the base of the column preserves the arrangement on three horizontal lines, which are the symbol of the tropic of Cancer (parallels 24° 06′, 24° 00′, and 23° 51′ north). The column basically represents the three meridians of Egypt and through its curvature suggests the extension of the system of meridians to the east and west of Egypt. But, since the column is circular, the structure of the column was related to the problem of presenting the map of Egypt as part of a cylindrical projection of the surface of the earth from the equator to latitude 31° 06′ or latitude 31° 30′ north. The elaborate numerical rules for the proportions of Greek columns, which archeologists treat as numerological superstitions, can be explained when one considers the two interrelated problems of describing mathematically the curvature of the earth and of projecting a curved surface on a flat map. The theory of conic sections, which is considered the highest achievement of Greek mathematics, may have been developed in order to solve these problems. Greek columns taper from the bottom to the top, but to the rectilinear line of the shrinking there is applied a curved line, so that the column seems to swell slightly toward the middle. If we consider the scheme I have presented for the calculation of the lengths of the degrees, a scheme in which a basic simple progression was modified by the addition of another progression, we can understand why Greek columns diminished in diameter from bottom to top according to a combination of two lines. In the case of the columns of the Parthenon, the added curvature, called *entasis* by the Greeks, is a hyperbolic curve, but in other temples we meet with more complex mathematical curves. It may be enough to say this much here: if one assumes that the bottom of the colonnade of the Parthenon represents the equator and its top the latitude of Athens, the proportions of the entire colonnade can be readily explained.

V. TEXTUAL EVIDENCE

For lack of space, it is impossible for me to present here the evidence for what I have stated to be the Egyptian estimates of the length of the degrees of latitude, since this evidence was obtained by gathering scores of scattered pieces of information, the interpretation of which often involves delicate issues of textual interpretation. But the preoccupation with geographical distances was so dominant in Egyptian civilization that one can find many documents the meaning of which is obvious; several of these documents are well-known texts. It has taken me a great deal of painstaking research to fit these documents together, in order to arrive at a unified view of what was the Egyptian system of geography; but the interpretation of single documents *per se* in many cases did not present difficulty. What is difficult to explain is why Egyptologists have stubbornly refused to accept these documents at their face value. In order to illustrate how Egyptologists operate in order to slough off the evidence, I shall present two examples of such nature that the issues involved can be understood by the non-specialist.

Inscribed Cubit Rules

1. In 1921 the famous Egyptologist Ludwig Borchardt wrote a report on three Egyptian measuring rules found at the Temple of Amon in Thebes. These three royal cubit rules

bear an identical inscription. The inscription appears to be a traditional one; for reasons of style the text of the inscription has been ascribed to the Old Kingdom, although the rules themselves belong to a later period. It is known that at times measuring rules were given a sacred meaning, although nobody has ever asked why; it should be evident to the reader of these pages why a measuring rule could be a sacred object for the Egyptians. The cubit rules studied by Borchardt, according to his report, seem to be of the type used as sacred objects rather than as instruments of actual measurement.

Borchardt did not test the length of these rules, but concentrated his attention on the inscription. The essential meaning of the inscription is open and clear, even though a professional Egyptologist may find difficulty with some of the hieroglyphs, as it often happens when archaic hieroglyphic texts were copied centuries later when the language and the writing style had changed. The inscription states that the distance between Behdet and Syene, the area of the First Cataract, is 106 *atur,* and divides this distance into 20 *atur* from Behdet to a place called Pi-Hapy, and 86 *atur* between Pi-Hapy and Syene.

Borchardt considered the evident possibility that the distances should be understood as differences of latitude, but dismisses it outright: "one must absolutely exclude the possibility that the ancients may have measured by degrees." No further words are added to justify this drastic pronouncement. Then he states that it must be a matter of measurements taken along the actual course of the Nile, the only measurements of which the Egyptians were capable. By referring to modern data about the length of the line of navigation along the Nile, he concludes that the inscription expresses a rough estimate.

He proceeds by remarking that the inscription provides an excellent opportunity to establish the value of the important Egyptian linear unit *atur*. He observes that by reading documents that contain calculations in *atur* one gathers that the value of the *atur* in royal cubits must be expressed by numbers such as 5000 or 10,000. Finally, he concludes that, given the length of the course of the Nile from one end to the other of the country of Egypt, the *atur* must be 20,000 royal cubits.

I have concluded that the *atur* is 15,000 royal cubits (7862.225 meters), and this inscription bears me out. The difference of latitude between Behdet and the southern limit of the First Cataract is 7° 30′. Now, 106 *atur* is 1,590,000 royal cubits = 833,395.8 meters. The distance between 24° 00′ and 31° 30′ is 831,091.6 meters according to the

Smithsonian Geographical Tables. The Egyptian figure is in excess by 2300 meters, or 2/7 *atur*. The excess is not surprising, since the calculation of the length of Egypt as ending at Behdet was originally related to the geographic cubit and not the royal cubit. I have explained that the geographic cubit was defined as 1/1,800,000 of the length of Egypt to Behdet. In *atur* of 17,000 geographic cubits, this length could be expressed as 106 *atur* (1,802,000 geographic cubits) = 831,971.7 meters, with only a small excess over the initial figure of 1,800,000 geographic cubits = 831,048.4 meters.

The calculation of the length of Egypt to Behdet as 106 *atur* of 15,000 royal cubits has the virtue of indicating the length of the arc of meridian from the equator to the pole; since the length of Egypt to Behdet is 7° 30′, it is 1/12 of this arc. Multiplying 106 *atur* by 48, we have a great circle of 5088 *atur* = 40,002,998 meters, which is an excellent figure (212,000 cubits to a degree); Helmert's figure of 40,008,268 meters differs by less than an *atur*.

The purpose of the inscription on the rules which were found at the Temple of Amon in Thebes is to stress the scientific value of the calculations by the septenary royal cubit, which was a matter of essential political interest to this temple, as I will explain in the second part of this chapter.

The calculation of the length of Egypt as 106 *atur* had also the purpose of indicating by one of the usual numerological games that the average degree of latitude is 212,000 royal cubits = 111,119.4 meters; 212,000 was the Egyptian round figure for the average length of the degree of latitude (stadium of 353,333 royal cubits). If the average degree is identified with the middle degree, the degree at parallel 45°, this figure is only 2 cubits short of the Egyptian estimate of 212,002 cubits = 111,120.5 meters for this degree. The estimate of the *Smithsonian Geographical Tables* is 111,121.0 meters.

2. The inscription on the rules divides the interval of 106 *atur* into 86 *atur* from Syene to Pi-Hapy and 20 *atur* from Pi-Hapy to Behdet. It occurs immediately that the two figures must refer to Northern and Southern Egypt. But the figure of 20 *atur* is slightly too much for Northern Egypt and that of 86 *atur* is slightly too little for Southern Egypt.

If the degree is calculated as 212,000 royal cubits, 20 *atur* = 300,000 cubits is too much for the interval between Behdet and the apex of the Delta, since 1.4° × 212,000 = 296,800 cubits. Conversely, 86 *atur* would be 1,290,000 cubits, whereas the distance from 24° 00′ north to the apex is 6.1°, and 6.1° × 212,000 = 1,293,200 cubits. In either case there is a difference of 3200 cubits. Hence, the breaking point in the calculations must be somewhat south of the apex of the Delta.

Even though Egyptologists ignore scientific geography, there are specialists of Egyptian toponymy, that is, the study of local names. These have wondered about the identification of the locality of Pi-Hapy, "House of the Nile," mentioned in the inscription we are discussing. They have observed that in Egyptian texts Pi-Hapy is usually mentioned together with Kher-aha, although Pi-Hapy is a different place. They have concluded that Pi-Hapy was on the right bank of the Nile about 2 kilometers south of Kher-aha. But specialists of Egyptian toponymy have failed to identify Kher-aha, which was a fundamental point of Egyptian geography; Kher-aha, called Kerkasoros by the Greeks, was the apex of the Delta, the point 30° 06′ north, 31° 14′ east, at the southern tip of the island al-Warraq. Pi-Hapy, called Nilopolis by the Greeks, was on the right bank of the Nile, facing the southern tip of the island al-Warraq. Since the Nile in its course comes to the island al-Warraq from the west, the point Pi-Hapy was on meridian 31° 14′ east and could be considered to be on the right bank of the Nile directly opposite the apex of the Delta, or point Kher-aha. The width of the Nile between Kher-aha and Pi-Hapy, measured along meridian 31° 14′ east, fits well with what I have calculated to be the distance between the apex and Pi-Hapy (3200 royal cubits = 1,677 meters).

The breaking of the distance of 106 a*tur* into a segment of 20 a*tur* by establishing a new reference point called Pi-Hapy may have been influenced by the calculation of the length of Egypt up to the base line of the Delta as 100 *atur* (1,500,000 royal cubits).

In the inscribed royal cubit rules, the original estimate of 106 *atur* of 17,000 geographic cubits was interpreted in terms of 106 *atur* of 15,000 royal cubits, in order to link more closely the dimensions of Egypt (1/12 of arc of meridian counting to Behdet) to the measurements of the arc of meridian. As I have stated, 12 × 106 a*tur* = 1272 a*tur* = 19,080,000 royal cubits = 10,000,749.6 meters is an excellent estimate of the length of the arc of meridian, obtained with an extreme economy of reckoning. Let us not forget that the French metric system was established on the assumption that the arc of meridian is 10,000,000 meters. Even today in practical reckoning we take 111,111.1 meters as the round figure for the average degree of latitude, whereas the figure of 106 a*tur* for the length of Egypt indicates a round figure of 212,000 cubits = 111,119.4 meters, which is more precise, and is almost perfect if we take 212,000 cubits to mean the length of the degree at the middle parallel.

1. Because Egyptologists have ignored the issue of geodetic points and of the linear units, the figure of the revolutionary Pharaoh Akhenaten has turned out to be the most mysterious and controversial in the long history of the Egyptian monarchy, although this Pharaoh was unusually articulate and self-expressive in his utterances. The archeologist Cyril Aldred, who is the author of the most recent study of the reign of Akhenaten, begins his book (page 11) with this observation.

> With the possible exception of Cleopatra, no ruler of Ancient Egypt has provoked a greater flow of ink from the pens of historians, archaeologists, moralists, novelists and plain cranks than the Pharaoh Akhenaten who governed almost half the civilized world for a brief span during the fourteenth century B.C.

The Pharaoh Akhenaten.

The reason why even "plain cranks" write interpretations of the historical role of Akhenaten is that professional scholars have given the example. Because they have resisted accepting the solidly documented facts, established scholars have devoted their energies to debating theories such as that Akhenaten was impotent, was a practicing homosexual, or a woman masquerading as a man; there are historians who profess to be informed about the intimate relations between him and his wife, the beautiful Nefertiti. Since the picture of Akhenaten has remained indefinite and blurred, scholars have used it to project their own emotions. Those who do not like Akhenaten present him as a psychopath and dispute about the clinical definition of his illness. In the middle are those who describe him as a playboy Pharaoh. Those who admire him have chosen to portray him either as some sort of Christian evangelist, an Anabaptist preacher thrown into the midst of the history of Egypt, or, at the opposite end of the psychological personality scale, as an *artiste* type, bent on freeing Egyptian culture from its formalistic tradition in order to release untrammeled individualistic self-expression. If one were to look for a common denominator among all the conflicting interpretations, one fact could be considered as universally accepted, in spite of the heated controversies, namely, that Akhenaten was as far as possible from being a rational scientific thinker. Nevertheless, the documentary evidence suggests a style of thought that today we would call scientific naturalism.

There is a phrase which occurs again and again in the pronouncements of Akhenaten and represents his effort to summarize his program by a slogan: "Living in *maet*." This is so obvious that Aldred declares (page 67):

> There is in Akhenaten's teaching a constant emphasis upon *maet*, "truth," as is not found before or afterwards.

It is agreed that *maet* was the central concept of Egyptian civilization and that the role of a Pharaoh was to be the defender and the living embodiment of *maet.* This concept was so basic in Egyptian culture that Aldred has no difficulty in explaining it in a few words (page 25):

> The king was the personification of *maet,* a word which we translate as "truth" or "justice," but has the extended meaning of the proper cosmic order at the time of its establishment by the Creator. For it was believed that the gods had first ruled Egypt after creating it perfect.

Akhenaten, his wife Nefertiti, and two daughters (Berlin Museum).

The reader can easily grasp what was meant by *maet* by referring to what I have said about the geodetic system of Egypt. But, having admitted what is indisputable, that Akhenaten saw himself as the Pharaoh who would truly uphold *maet,* Aldred stops cold and does not draw the implications. Like other interpreters, he wanders afar and regales us with a chapter entitled "The Pathology of Akhenaten."

2. If instead of trying to imagine what were the hieroglyphic notes of the psychoanalyst of the royal family, we consider the documented facts, the most important action in the revolutionary reign of Akhenaten proves to be the establishment of a new capital for Egypt, the city of Akhet-Aten, "Resting-point of Aten." The miles-long remains of the buildings of this city have been found and excavated in the locality today known as Tell el-Amarna. During the reign of Akhenaten a substantial percentage of the national resources was dedicated to the construction of this city.

Scholars of the last century, who had not yet adopted the psychologizing fashion, at least recognized the political meaning of the shift in the location of the capital of Egypt. Akhenaten intended to cut at the root the power of the priests of the Temple of Amon in Thebes, who through their control of the national oracle, identified with the god of this temple, had usurped the royal functions. But what these scholars did not know is that the Temple of Amon was the geodetic center of Egypt, the "navel" of Egypt, being located where the eastern axis (32° 38′ east) crosses the Nile, at the parallel which is at 2/7 of the distance from the equator to the pole (25° 42′ 51″ north), and that the god Amon was identified with the hemispheric stone which marked this point.

The new city which was intended to replace Thebes as the capital and geodetic center of Egypt was planted in a position which seems most undesirable in terms of what we would consider the function of a capital city. Some scholars have interpreted this fact as further evidence of the mental derangement of its founder. It was in an area of difficult access, where there had never been any known significant center; some scholars have doubted whether even villages had existed there. It did not provide large flat areas for a major urban development. When maintenance was suspended after the fall of Akhenaten, large sections of the new buildings were washed away by the rainwater rushing down torrentially from the surrounding cliffs. Even the climate was inferior to that of many other areas along the course of the Nile. Unless one assumes that there was a compelling mathematical reason for choosing this location, one must agree that there is justification in claiming that what is often called the "Tell el-Amarna Revolution" was the product of a playful young man, or a religious fanatic, or a degenerate obsessed with his sex problems. Akhenaten himself relates that his courtiers raised objections to the selection of the new site, although he states that it was pointed out to him directly by his father, the god Aten.

The new capital for the god Aten, who was raised to the status of the one true god, was set at latitude 27° 45′ north, at the middle point between the northernmost point Behdet and the southern limit of Egypt at latitude 24° 00′ north. The longitude could not be equally as significant, since the capital had to be on the banks of the Nile. It was one degree east of the western axis of Egypt, that is, 30° 50′ east.

The longitude, although it was not as crucial as the latitude, was significant according to the system that the Egyptians used to describe the east coast of Africa. In order to describe this coast, down to the equator, the

Aerial view of the Tell el-Amarna (RAF photo).

Egyptians used a system of right triangles, in which one side was one of the three axes of Egypt and the other a perpendicular to it; the hypotenuse usually indicated the course of a segment of the east coast of Africa. The most important of these triangles was one obtained counting from Behdet 19° 30′ south along the central axis of Egypt and then 19° 30′ to the east, to reach a point 12° 00′ north, 50° 44′ east, near Ras Alula (11° 59′ north, 50° 46′ east), a point which was considered the extreme limit of the Arabian Gulf. The ancients took the Gulf of Suez, the Red Sea, and the Gulf of Aden as a single entity, the Arabian Gulf, which at times they described as a river similar to the Nile. The geographical point in question is called Notou Keras, "horn of the East," by Strabo; it had a counterpart in the "horn of the West," the innermost point of the Gulf of Guinea on the west coast of Africa. The segment of parallel reaching the "horn of the East" from the meridian of Behdet marks the basic latitude 12° 00′ north, halfway between the equator and the basic latitude 24° 00′ north, and bisects Lake Tana, the source of the Blue Nile. The Nile was considered to have two sources, one at the equator (White Nile) and one at latitude 12° 00′ north (Blue Nile). This system of calculations for the geography of the area east of the course of the Nile has an importance which carries beyond ancient history, since the establishment of a geodetic point 10° south of Behdet and 10° east of the western axis of Egypt explains the origin of the religious importance of Mecca. The essence of this system of calculations was that points to the east of Egypt were identified by drawing perpendiculars to the course of the Nile. Considering this system in relation to the position of Akhet-Aten, if one counts east from it as much as it was south of Behdet, that is 3° 45′, one reaches the sea at a point presently called island Ghānim (off Cape Az Zaytīyah, called Drepanon Promontory by Ptolemy, which is at 27° 47′ north, 33° 35′ east); Cape Az Zaytīyah together with the island south of it was considered the southernmost limit of the Gulf of Suez on the Egyptian side; it was assumed that the line drawn from Behdet to this point gave the course of the coast of Egypt on the Gulf of Suez.

3. The most revealing pieces of evidence uncovered in the area of the new capital established by Akhenaten are the so-called "Boundary Stelae." Along the outskirts of the new city there have been found huge inscriptions, either cut on pillars or cut on the cliffs, which contain a text substantially identical in the fourteen samples which have been uncovered so far. These inscriptions proclaim what was for Akhenaten the leading idea behind the establishment of the new capital.

The inscribed text relates in detail the rituals performed in the establishment of Akhet-Aten, "Resting-point of Aten"; but the greatest emphasis is placed on the setting of two boundary pillars, one at the extreme north and one at the extreme south of the sacred territory of the city, at a distance of 6 *atur,* 3/4 *khe,* and 4 cubits from each other. After setting these pillars the King took a solemn oath, to be repeated at regular intervals, never to remove or displace them and to restore them in the same identical place in case they were moved or damaged.

It should be obvious that the figure of 6 *atur,* 3/4 *khe,* and 4 cubits, given with numerical precision, is the key to the reason for the establishment of the new capital. Nevertheless, only one Egyptologist has made an effort to interpret these figures. This effort was a half-hearted one; it ignored Egyptian geographical texts and parallel occurrences of the terms *atur* and *khe* in Egyptian writings. Nevertheless, ever since, scholars quote this interpretation if they bother to mention the dimensions of Akhet-Aten in dealing with its establishment. The interpretation took as a starting point the distance between the relatively northernmost and the relatively southernmost of the fourteen inscriptions which have been found, and divided this distance by 6 to conclude that an *atur* must be 4000 royal cubits. It can be objected

Boundary stelae at Tell el-Amarna.

that the pillars which in some cases were erected to carry the text of the inscription cannot be the boundary pillars of which the inscription is speaking, since the latter must be of such a nature and form that their position could be established to the inch. It stands to reason that when, after the collapse of the revolution, masons were sent to demolish or deface the monuments of the accursed Akhenaten, not sparing even the tombs of the members of his family, the work of destruction must have started with the boundary pillars; we are not likely to find them, unless broken pieces were scattered around. In any case, the Egyptian texts which mention distances measured in *atur* positively exclude that an *atur* can be as short as 4000 royal cubits (2097 meters).

As to the *khe,* the interpretation stated in a hit-or-miss manner that it is equal to 100 royal cubits. Nobody asked why Akhenaten should have selected a figure refined not only to 3/4 of *khe,* but also to 4 cubits. It was a matter of such precision that the inscribed text indicates that even knocking the limit markers or hitting them with stones would interfere with their function.

According to Egyptian practice, geographic distances could be measured either in geographic cubits or in royal cubits. The natural multiple of the geographic cubit was the stadium, called *khe* in Egyptian, of 400 geographic cubits (600 geographic feet), whereas the natural multiple of the royal cubit was the *atur* of 15,000 royal cubits. But the two systems were merged by using an *atur* of 15,000 royal cubits (7862.2 meters) and an *atur* of 17,000 geographic cubits (7848.8 meters), and a *khe* of 350 royal cubits (183.45 meters) and a *khe* of 400 geographic cubits (184.68 meters). In the case of the inscriptions of Akhet-Aten, the occurrence of the figure of 3/4 of *khe* suggests that a calculation by geographic cubits is involved, since 3/4 of a stadium of 350 royal cubits would be an odd figure. It is my understanding that the dimensions of the district of Akhet-Aten were:

	6 *atur* of 17,000 geographic cubits
	3/4 of a stadium of 400 geographic cubits
	4 geographic cubits
Total:	102,304 geographic cubits = 47,233.1 meters

4. Even without considering the exact value of the units mentioned by Akhenaten, the figure of 6 *atur* should have rung a bell in the mind of Egyptologists, calling to their attention the traditional figure of 106 *atur* for the length of Egypt. Akhenaten wanted to emphasize that the "Resting-point of Aten" was at the middle point of Egypt. By giving to the new geodetic center a dimension of 6 *atur,* he left 50 *atur* from it to Behdet and 50 *atur* from it to parallel 24° 00′ north. This was particularly significant since there was another basic estimate of the length of Egypt as 100 *atur,* from the base line of the Delta (31° 06′ north) to parallel 24° 00′ north.

Before proceeding any further I must remind the reader that the traditional figure setting the length of Egypt at 106 *atur* did not intend to convey information only about Egypt itself, but also to indicate the length of the arc of meridian, 12 × 106 *atur.*

Since the length of the geographic cubit was defined by considering the distance from Behdet to parallel 24° 00′ north equal to 1,800,000 cubits, if the district of Akhet-Aten had had an extension of 0° 25′ 30″, it would have had a length of 6 *atur* = 102,000 cubits. This length was increased to 6 *atur,* 3/4 stadium, 4 cubits = 102,304 cubits, in order to indicate that the average degree of latitude on earth is 240,715 cubits.

The figure of Akhenaten indicates that the average degree of latitude was estimated as 240,715 cubits, since 0° 25′ 30″ of a degree of 240,715 is 102,303.875 cubits. A degree of 240,715 cubits is 111,136.6 meters; the corresponding arc of meridian is 21,664,375 geographic cubits = 10,002,301 meters. Hayford's figure is 10,002,286 meters.

Akhenaten wanted to prove that Thebes could not properly claim to be the geodetic center of Egypt and that he had chosen the geodetic center conforming to an absolutely rigorous interpretation of *maet,* the cosmic order of which the dimensions of Egypt were an embodiment. In order to follow absolutely exact standards of measurement, he reverted to the predynastic geodetic system which counted in geographic cubits starting from Behdet. This system was more precise than the system which counted in royal cubits (septenary units) starting from the base line of the Delta, making Egypt equal to 100 *atur* of 15,000 royal cubits. Thebes could claim to be a geodetic center only in terms of the second system, which is septenary and makes the meridian of Thebes coincide with the eastern corner of the Delta. In terms of the system based on the predynastic capital of Behdet, there could be no question that Akhet-Aten is the "true and just" navel of Egypt.

This conclusion implies that one should reevaluate the entire historical role of Akhenaten, taking as the starting point what he himself considered the initial step in his program to establish true and just conformity with *maet.* There is a possibility that his revolutionary reforms, which extended from religion to art and family relations, were understood as a general return to predynastic ideas and practices.

5. Since the Egyptian monarchy set the style for the trappings of royal power thorughout the world, the prescriptions of Akhenaten about the dimensions of the territory of his capital did not remain without parallel in history. A striking parallel can be found in what may appear a most unlikely time and place, Saxon England.

Scholars are so bent on principle to interpret the history of measures and measurement in terms of the most crude primitivism, that in most works of history that deal with English measures one reads that the English foot was originally set by the length of the foot of an English king. The name of the king whose lower extremities were so decisive varies from scholar to scholar, although, when one thinks about it (which is not done in matters of measurement) kings of average human size should be excluded. There is agreement among scholars that the king in question reigned in the centuries following the Norman conquest, since it is assumed and often stated that before this time England did not have set units of measure. A variant of the fairy tale about the English foot is provided by the historians who tell us that it was not a matter of the foot but of the arm of a king which decided the length of the yard (three feet). Usually the length of the arm of King Henry I (1068–1135) is mentioned in this connection.

Such statements are made in spite of the fact that it is not necessary to be a specialist in the history of measures to find out that a foot equal to the English foot was the basic standard of Russia, from the time of the first available historical records to the Soviet revolution. I grant that it takes a specialized historical training to trace the linear standard of England and Russia to the ancient Orient, but I may also observe that there are well known Greek temples which have been planned in English feet, and that archeologists of English and American nationality have studied them without realizing what they had before their eyes.

Historians could have developed less benighted notions about the origin of English measures, even without extending their horizon beyond the British isles, because there is a law of King Athelstan (924–940) which defines the length of the English foot. The text of this law is included in the standard collections of medieval English laws. The words of law of Athelstan were repeated exactly in the legislation about measures issued by King Henry I. The law of Athelstan provides the most fundamental text for the study of English measures, but it has been ignored.

Athelstan prescribed that the king's girth shall extend from the royal residence for a distance of 3 miles, 3 furlongs, 9 acres, 9 feet, 9 palms, and 9 barleycorns. The King's girth was the area considered a direct extension of the King's place of residence and as such the area in which the King's peace was in force. This was the area in which attacks on private persons were crimes against the Crown.

The picturesque language of the law means that the King's girth extends for a radius of 18,250 feet, since it is a matter of the following units:

mile	5280 feet
furlong	600 feet
acre	66 feet
palm	3/4 foot
barleycorn	1/3 inch

The law employed a form of expression which had a particular numerological rhythm and at the same time defined the value of the multiples and submultiples of the foot.

My understanding of the law of King Athelstan is that the radius of the King's girth was defined as 3 minutes of latitude. The King's girth extended 6 minutes or 1/10 of degree from north to south. This implies that a degree was understood to be 365,000 English feet, which is the length of the degree at the latitude of towns like Winchester.

A more detailed analysis of the law of Athelstan belongs to a study of English measures. What is important to stress here is that the English foot was defined by length of a stretch of 1/10 latitude around the king's place of residence. The political conditions of the feudal society of Saxon England were very different from those of Pharaonic Egypt, but the method used by King Athelstan in order to relate his power to the system of measures and to the cosmic order bears a remarkable similarity to that adopted by the Pharaoh Akhenaten.

VI. DEGREES OF LONGITUDE

1. When the Egyptians fixed the value of their fundamental unit of length, the geographic cubit, they chose as standard degree the degree of latitude at 27° 45′ north, taken as the middle latitude of Egypt. When they recalculated the dimensions of Egypt in terms of royal cubits, they chose as the middle latitude 27° 33′ north. These latitudes were chosen taking into account the length of a degree of longitude at the equator. Latitude 27° 45′ is the half of latitude 55° 30′ and latitude 27° 33′ is the half of latitude 55° 06′. The Egyptians assumed that at the two higher latitudes a degree of latitude is equal in length to a degree of equator.

According to the *Smithsonian Geographical Tables,* a degree of latitude at parallel 55° 30′ is 111,324.7 meters, but probably the Egyptians calculated it as 361,680 geographic feet = 111,323.5 meters: this degree is equal to the fundamental degree of 360,000 geographic feet (600 stadia) plus 2.8 stadia or plus 1/214.28. According to the *Smithsonian Geographical Tables* a degree at parallel 55° 06′ is 111,317.3 meters. According to the Egyptian table of the lengths of the degrees of latitude which I have reconstructed, it is 212,378.5 royal cubits = 111,317.3 meters. This length could be expressed also as 361,660 geographic feet = 111,317.4 meters, that is, as 600 stadia plus 2.7666 stadia. This implies that the Egyptians estimated the equatorial circle either as 130,204,800 geographic feet = 40,076,478 meters or as

130,197,600 geographic feet = 40,074,261 meters. I suspect that they began with an estimate of 130,200,000 geographic feet (degree of 361,666 feet = 360,000 feet plus 1/216) = 40,075,000 meters, and then modified the figure in order to establish a relationship between the equatorial degree and the degree of the middle latitude of Egypt. The Egyptian estimate agrees with our current ones: the equator is 40,075,452 meters, according to the Clarke Spheroid and 40,076,596 meters according to the International Spheroid.

Very revealing is that a base line was marked along parallel 45° 12′ north on the north side of the Black Sea. This base line started from the mouth of the Danube, cut across the Crimea, and ended at the foot of the Caucasus. Beginning from this base, Russia was surveyed for a length of 10 degrees, along the three meridians which formed the three axes of Egypt, up to latitude 55° 12′ north. The river Dnieper was understood to be a symmetric counterpart of the Nile, running between the same meridians. Key positions along the course of the Dnieper were identified with corresponding key positions along the course of the Nile, up to the point of transferring Egyptian place names to Russia. The information about the existence of this geodetic system is provided by the description of a map of Russia which is based on it. The description of the map indicates that it was used at the end of the sixth century B.C., but the map may be older; in any case there are other sources of information about the base line which indicate that it was marked in very early times.

The figures of the geodetic system on which the map of Russia was based are most intriguing. The base line at parallel 45° 12′ north suggests that it was decided that it is at this latitude that the degree of latitude has a length equal to the average length of the degree of latitude. The fact that the meridians of Egypt were followed for 10° up to parallel 55° 12′ north suggests that it was decided that a degree of latitude at this parallel is equal to the length of a degree of equator.

The designation of 45° 12′ north for the location of the average degree indicates what the Egyptians assumed to be the degree of ellipticity of the earth. According to the *Smithsonian Geographical Tables,* the length of the degree of latitude at the point 45° 12′ north is 111,134.9 meters; from this figure we would get an arc of meridian of 10,002,141 meters. According to the Egyptian table of the length of the degrees of latitude that I have reconstructed, the degree at the point 45° 12′ north is 212,028.6 royal cubits = 111,134.4 meters; this length implies an arc of meridian of 10,002,099 meters. According to the *Smithsonian Geographical Tables* the degree ending at parallel 55° 12′ is 111,319.3 meters; if this is taken as the length of the degree of equator, the equatorial circle is 40,074,948 meters. According to the Egyptian table of the length of the degrees of latitude, the degree at 55° 12′ north is 212,381 royal cubits = 111,319.1 meters; this would indicate an equatorial circle of 76,457,160 royal cubits = 40,074,890 meters (stadium of equator = 353.96833 cubits).

2. In performing astronomical observations it is necessary to express differences of longitude in terms of units of time. The equator and all parallels are divided into 360 degrees, but considering the rotation of the earth it is expedient to divide the equator and all parallels into 24 hours. Given 360/24 = 15, a minute or a second of time is equal to 15 minutes or 15 seconds of degree.

In astronomical calculations, there are employed two different kinds of time, solar time and sidereal time. Solar time is our ordinary time. Solar time assumes that the day is the interval between two successive passages of the sun at the meridian. The length of the day so defined varies greatly according to the seasons of the year; it varies by more than 1/90. The reason for this variation is that the speed of the earth along its orbit around the sun is not constant and that the apparent motion of the sun around the earth does not follow the line of the equator, but of that of the ecliptic. Hence, in ordinary life we reckon by mean solar time, which is obtained by assuming that a fictitious sun moves along the celestial equator at a speed equal to the average speed of the sun along the ecliptic.

Mean solar time is a highly artificial concept and we can use it because we have mechanical clocks. The ancients calculated by sidereal time, which they could measure by observing the apparent movement of the vault of heaven. Sidereal time has the advantage of flowing evenly. There are small variations due to the nutation of the earth under the influence of the gravitational pull of the moon and the planets; but these variations are too small to be relevant to the calculations we are considering.

A sidereal day is the interval between two passages of a star at the meridian. A sidereal day is shorter than a solar day. If one observes a star at the meridian today, that star will be again at the meridian in less than a solar day. In other words, if one counts by solar time, the vault of heaven rotates about one degree more than a full circle in a day. The difference between mean solar time and sidereal time can be easily computed, because in a year the vault of heaven makes exactly one more circle around the earth than the number of circles made by the sun.

Hence the ancients could reckon:

$$\frac{\text{Solar time}}{\text{Sidereal time}} = \frac{366}{365} = 1.00273972$$

or more precisely:

$$\frac{\text{Solar time}}{\text{Sidereal time}} = \frac{366.25}{365.25} = 1.00273785$$

They did not need a formula more precise than the second one; today we reckon by the ratio 1.00273791.

The ancients simplified this complex matter by counting by the speed of movement of a point at the equator. That speed was taken by them as constant; the infinitesimal variations in speed of the rotation of the earth on its axis are relevant only to some calculations of modern astronomy.

The speed of a point at the equator in terms of mean solar time was obtained by dividing the length of the equator into 24 hours = 1440 minutes = 86,400 seconds. But the ancients were concerned particularly with the speed of a point at the equator in terms of sidereal time. A minute of time (solar time) corresponds to the length of 15 minutes of degree of equator. A minute of time (sidereal time) is equal to the same length multiplied by 365.25/366.25, that is, it is shorter.

3. When the Egyptians standardized their system of measures by establishing that the degree at the middle latitude of Egypt is 240,000 geographic cubits (360,000 geographic feet = 600 stadia) or that 1/48 of great circle measured from 24° 00′ north to 31° 30′ north is 1,800,000 geographic cubits, they must have had in mind the following equivalence:

1 second (sidereal time) = 1000 cubits
1 minute (sidereal time) = 60,000 cubits =
1/4 length of degree of latitude in Egypt

This calculation was convenient, but implied an equatorial degree (degree of latitude in Egypt × 1.00273785) of 111,109.8 meters, which is slightly too short; it is the length of a degree of longitude at about 3° 30′ from the equator.

In order to obtain the right length of the second and minute of sidereal time, one must take as reference a degree of latitude further north than Egypt. The degrees at the latitudes of Dodona and Delphi provided the correct values.

Classical Greece was not a unified country, being divided into cities proudly clinging to their absolute political independence; but, most incongruously, it had a national oracular center, just as Egypt, a strongly unified country, had a national oracular center at the Temple of Amon in Thebes. In Greece there were two centers which competed

Another Greek conception of an *omphalos* as derived from the Egyptians.

Omphalos of Delphi depicted with two pigeons (usually facing each other), evidently carrier pigeons used for establishing geographic distances. According to Greek legends, a central geodetic point was obtained by loosing two birds of equal strength and using the mean of the time employed in flight. This would allow for differences in wind current and other variables. By repeated flights even more accurate measurements could be obtained.

for the role of national oracle, Dodona and Delphi. The oracle of Dodona was considered more ancient and many Greeks considered it more authoritative, but it was at a practical disadvantage because it was located beyond the limits of solidly Greek territory in an area of most difficult access. In modern Greece, which extends more widely than ancient Greece, Dodona is near the Albanian frontier. The position of the oracle of Delphi, even though not as surprising as that of the oracle of Dodona, was peculiar; it was located in the mountains, north of all major centers of Greece.

The Greeks narrated that two doves flew from the temple of Amon in Egypt in order to establish the oracles of Dodona and Delphi. In ancient literature and iconography the flight of two doves is the standard symbol for the stretching of meridians and parallels.

Because the oracle of Delphi was less isolated, it received more attention and consequently we are better informed about it. Delphi was considered the geodetic center of Greece. The god of Delphi, Apollo, whose name means "the stone," was identified with an object, the *omphalos*, "navel," which has been found. It consisted of an ovoidal stone (the ovoidal shape indicated the lengthening of the degrees of latitude as one moves north) covered by a net. The net was the symbol of what even today we call the net of meridians and parallels. The *omphalos* of Delphi was similar to the object which represented the god Amon in Thebes, the "navel" of Egypt. In 1966 I presented to the annual meeting of the Archeological Institute of America a paper in which I maintained that historical accounts, myths, and legends, and some monuments of Delphi, indicate that the oracle was established there by the Pharaohs of the Ethiopian Dynasty. This is the reason why the Greek portrayed Delphos, the eponymous hero of Delphi, as a Negro.

The relevance of the latitude in the location of Delphi is indicated by a number of Greek accounts which associate Delphi with Sardis, the capital of the kingdom of Lydia in Asia Minor, which is on the same parallel (38° 28′ north).

The role of geography in the oracular importance of Delphi is indicated also by the method employed in obtaining oracular responses. Modern scholars who have been impervious to the rational elements of ancient thought and prefer to ignore that Apollo, the god of Delphi, was a god of reason and scientific thought, are generally inclined to think that the oracular responses were given by a priestess who, put in a trance by drug fumes, uttered gibberish. But there is abundant pictorial evidence which shows vividly how the oracle was consulted. An object which resembles a roulette

Egyptian *omphali* with twin birds. Carrier pigeons are depicted in Egypt as early as the Fourth Dynasty, and were evidently used to establish parallels and meridians from prehistoric times. Homing pigeons, which fly in a straight line (as the crow flies!), could cover the more than five hundred miles from one end of Egypt to the other in a single day.

wheel, and actually is its historical antecedent, was centered on top of the *omphalos*. The spinning of a ball gave the answers; each of the 36 spokes of the wheel corresponded to a letter symbol.

In studying ancient computing devices, I have discovered that they were used also to obtain oracular answers. This is the origin of many of the oracular instruments we still use today, such as cards and ouija boards. The psychological foundation of this phenomenon is simple. If I have a problem in interpreting an ancient text or an archeological report, I "consult" my calculating machine which "gives me the answer." By stretching this imagery further, one could assume that the calculating machine is an oracle. The roulette wheel of Delphi originally was a special kind of abacus for calculating in terms of angles.

The latitudes of Dodona and Delphi are significant. The length of the degree of latitude at the parallels of these two oracular centers gave the length of the minute or second of sidereal time, that is, the distance covered by a point at the equator in a sidereal minute or second of rotation of the earth.

Dodona is at 39° 32′ north. According to the *Smithsonian Geographical Tables* a degree at this parallel is 111,014.0 meters. This means that the degree must have been calculated as 360,673 geographic feet (360,000 plus 1/535) = 111,013.6 meters. If we multiply this length by 1.00273785, we obtain 361,660 geographic feet, the length of the degree of latitude at parallel 55° 06′, which is equal to the length of a degree of longitude at the equator.

If the figures employed in the reckoning of Dodona are rounded to a degree of 360,600 geographic feet and to a second of sidereal time of 1001.666 geographic cubits (that is, 1000 plus 1/600), we obtain the length of the degree of latitude at the parallel of Delphi, which is 38° 28′ north. A degree of 360,600 geographic feet is 110,991.1 meters; a degree at parallel 38° 28′ is 110,993.5 meters according to the *Smithsonian Geographical Tables* and 110,992.1 meters according to the Egyptian table of the length of degrees of latitude. Latitude 38° 28′ north may also have been chosen because it is at the standard distance of 6′ from latitude 38° 34′ north, which is at 3/7 of the distance from the equator to the pole, whereas the Temple of Amon in Thebes was set at 2/7 of this distance.

4. Metrologists of the past have wavered in establishing the value of the geographic foot (and hence of the artaba), because they confused this unit with a similar one, the Greek foot, which is about half a millimeter longer.

Roman writers mention a Greek foot which is 25/24 of the Roman foot and a Greek stadium which is equal to 600 Greek feet or 625 Roman feet. The Romans used the two units in conjunction. Roman roads were divided into miles of 5000 Roman feet, but at times between the milestones there were smaller markers which divided the road into 8 Greek stadia ($8 \times 625 = 5000$). In giving itinerary distances, writers of the Roman period usually reckon by Roman miles on land and by Greek stadia at sea.

Because Roman authors indicate that the degree is 75 Roman miles or 600 Greek stadia, since the Renaissance metrologists have been concerned with establishing the exact value of the Greek foot; but in examining the empirical evidence they met with data that appear conflicting, for the reason that they did not separate sources of information which apply to the geographic foot. Travelers and sailors of the eastern Mediterranean and the Middle East used to assume that a degree of latitude is 600 geographic stadia (110,806 meters) and a degree of longitude is 500 geographic stadia (92,339 meters); Greek and Roman travelers and sailors used to assume that a degree of latitude is 600 Greek stadia = 75 Roman miles (110,980 meters) and a degree of longitude is 500 Greek stadia = 60 Roman miles (92,483 meters). As a result scholars have confused information concerning two different types of units. The confusion occurs easily, unless one assumes high standards of precision and accuracy in ancient measurements, since we have:

Geographic foot	= 307.7957 millimeters
Geographic cubit	= 461.6935 millimeters
Greek foot	= 308.2764 millimeters
Greek cubit	= 462.4147 millimeters

A degree of latitude of 600 Greek stadia = 75 Roman miles is correct at parallel 37° 42′, which is the latitude of Mycenae. The system of calculation used by the Greeks and Romans goes back to the Mycenean ancestors of the Greeks.

Archeologists assume that, if the Greeks of the classical period measured badly, the Greeks of the Mycenean age did not measure at all. It is assumed that when the Myceneans erected their buildings they placed one stone on top of another without much of a plan. However, we know that the Myceneans were engaged in extensive long-distance trade and through it they accumulated huge quantities of gold of African origin; long-distance navigation and exchange of precious metals were the two activities which created for the ancients the most compelling need for exact standards.

By examining the dimensions of Mycenean citadels, I have established that they were planned by a foot which is 15/16 of the Roman foot, a foot of 277.4488 millimeters. This foot has been called Oscan or Italic by metrologists of the last century, who noticed its occurrence in pre-Roman Italy and in the earliest remains of Rome. I call this foot Mycenean.

The Mycenean foot not only is 15/16 of the Roman foot of 295.9454 millimeters, but also is 9/10 of the Greek foot of 308.2764 millimeters. The Greek foot is 25/24 of the Roman foot and $25/24 \times 16/15 = 400/360 = 10/9$.

A degree of 360,000 Greek feet (75 Roman miles), a degree of latitude at the parallel of Mycenae, is equal to 400,000 Mycenean feet. The occurrence of the factor 4 indicates that a calculation by time units is involved, since there are 4 minutes of time in a degree. A minute of time is equal to 100,000 Mycenean feet. Hence, by using the Greek cubit and the Mycenean foot, one could obtain the following easy formula:

Second of time = 1000 Greek cubits
Minute of time = 100,000 Mycenean feet

These units are slightly too short for a second and a minute of sidereal time. If we take the degree of 360,000 Greek feet = 400,000 Mycenean feet = 110,979.5 meters and multiply it by 1.00273785, we obtain a degree of 360,986 Greek feet = 110,283.4 meters, which is the length of a parallel circle at about 1° 30′ from the equator.

But the numerical structure of the units indicates how the exact length of the degree of equator was obtained by introducing an easy correction. One starts with these data:

1000 Greek cubits = 1 second of time
Day of 86,400 seconds = 86,400,000 Greek cubits
100,000 Mycenean feet = 1 minute of time
Day of 1440 minutes = 144,000,000 Mycenean feet

These figures can be modified as follows:

Equator = 86,666,666 Greek cubits = 40,075,939 meters
Equator = 144,444,444 Mycenean feet = 40,075,939 meters

Similarily, one may start with the Greek foot and obtain

100 Greek feet = 1 second of degree
Circle of 1,296,000 seconds = 129,600,000 Greek feet

The last figure can be modified to

Equator = 130,000,000 Greek feet = 40,075,939 meters

All that was needed in order to obtain the exact length of the equator was to assume that a circle is equal to 1,300,000 seconds of degree, instead of 1,296,000.

It is possible that this formula was used to calculate the actual length of the solar day in the different seasons of the year. Today almanacs assign the value of 1200 to the length of the mean solar day and list a figure greater or smaller than 1200 in order to indicate the actual length of the solar day for each day of the year. Possibly the ancients proceeded in a similar way, assigning the value of 1300 to the mean solar day.

Archeologists and historians assume that the Myceneans had no concern with science, but the most famous remains of Mycenean civilization proclaim otherwise.

Lion Gate at Mycenae.

The best known monument of Mycenae is the entrance gate which today is called the Lion Gate, because he who approaches the city is overpowered by a huge relief sculpture on the triangular capstone of the entrance; the relief consists of a column between two facing lions. The column is sandwiched between two sets of parallel horizontal lines. At the bottom the column rests on a support on which three parallel lines are strongly marked. These three lines are the same three lines which occur in the hieroglyphic symbol for Southern Egypt; they represent the tropic of Cancer, which was identified with parallels 24° 06′, 24° 00′, and 23° 51′ north. The column represents the three basic meridians of Egypt; the curvature of the column suggests the development of the system of meridians to the east and the west of Egypt. On top of the capital of the column (symbol for Northern Egypt) there rests what appears to be a segment of a floor. This segment of floor is on three levels. The bottom and the top levels are two horizontal lines, whereas the middle level consists of four circles. I have explained the significance of the factor 4 in the Mycenean system of linear units. The top part of the relief represents the parallel of Mycenae.

The grave circle at Mycenae excavated by Schliemann. A geodetic point for astronomical observation similar to the circular henges and mounds of the second millennium B.C. elsewhere in Europe.

The two lions which face each other on the sides of the column represent a circle closing on itself. The easiest way to convey the meaning of this symbol is to refer to pieces of ancient jewelry which consist of a bracelet open at one side with a head of a lion on each open end. The lions represent the summer solstice. The stance of the lions, with the front paws on the line of the tropic and their hind paws extending below it (this stance will later become the heraldic symbol of the lion rampant), indicates the spread of the zodiacal band north and south of the ecliptic. The ancients established their astronomical system when the spring equinox was in Taurus, which ceased to be true at the beginning of the second millennium B.C.; for them the point zero of the sky was between the two horns of Taurus. Today we count from the constellation of Aries, although the spring equinox has not been in Aries since the time when the Roman Emperor Antoninus Pius (A.D. 138–161) celebrated the end of the age of Aries and introduced new cults and religious beliefs in accordance with the beginning of a new cosmic age. When the spring equinox was in Taurus, the summer solstice was in Leo.

The cosmological meaning of the Lion Gate of Mycenae should not have been lost to archeologists, since next to this gate there is the second most impressive relic of ancient Mycenae, the so-called Grave Circle. It consists of a circular arrangement of stone blocks. If excavators had not been completely blinded by their belief in the primitiveness of the Myceneans, they would have immediately assumed that this circle must have some cosmological meaning. Instead the Smithsonian Institution spent time and energy to proceed to measurements of the skeletons found buried within the circle, arriving at the conclusion that they were bones of ordinary size men and not of giants. But the dimensions of the stone circle have not received attention; it may be enough to report here that the inner diameter of the circle is 100 Mycenean feet.

When the first circuit of walls of Mycenae was erected, the Circle was outside the walls directly in front of the Gate; the middle of the Gate is on the line of the north-south diameter of the Circle. Later the circuit of the walls was extended so as to include the Circle within the citadel.

5. A splendid illustration of the Mycenean system of linear units is provided by the Parthenon of Athens.

The Parthenon of Athens is the only Greek temple which has been surveyed with an adequate level of accuracy. But unfortunately for my investigation of the dimensions of Greek temples, the system of proportions of the Parthenon is an aberrant one. I have established the mathematical formula that determined the dimensions of Greek temples and the mathematical formula that determined the dimensions of Mycenean throne rooms; the Parthenon conforms to the latter and not to the former. The reason is that the Parthenon was built as a replacement on a larger scale of the Temple of Athena destroyed by the Persians, when they sacked Athens in 480 B.C. The old Temple of Athena in turn was built on top of a Mycenean throne room, some remains of which have been found by deep excavations. For this reason the Parthenon was planned in Mycenean feet, whereas most of the other monuments of the Acropolis of Athens were planned in Roman feet. However, the major dimensions of the outer colonnade of the Parthenon were so chosen that they could be expressed also in Greek feet, which was easy since Mycenean foot and Greek foot relate as 9:10.

For the study of the Parthenon we can rely on data that are satisfactory for some of the major dimensions, because at the middle of the last century an English architect and scholar of the history of architecture, Francis Cranmer Penrose, who was also an outstanding dilettante astronomer, on the basis of reports on the mathematical curvatures of the lines of the temple became convinced that the Parthenon

The so-called Treasury of Atreus at Mycenae built into a mound with corbeled roofing similar to the Maes-Howe mound.

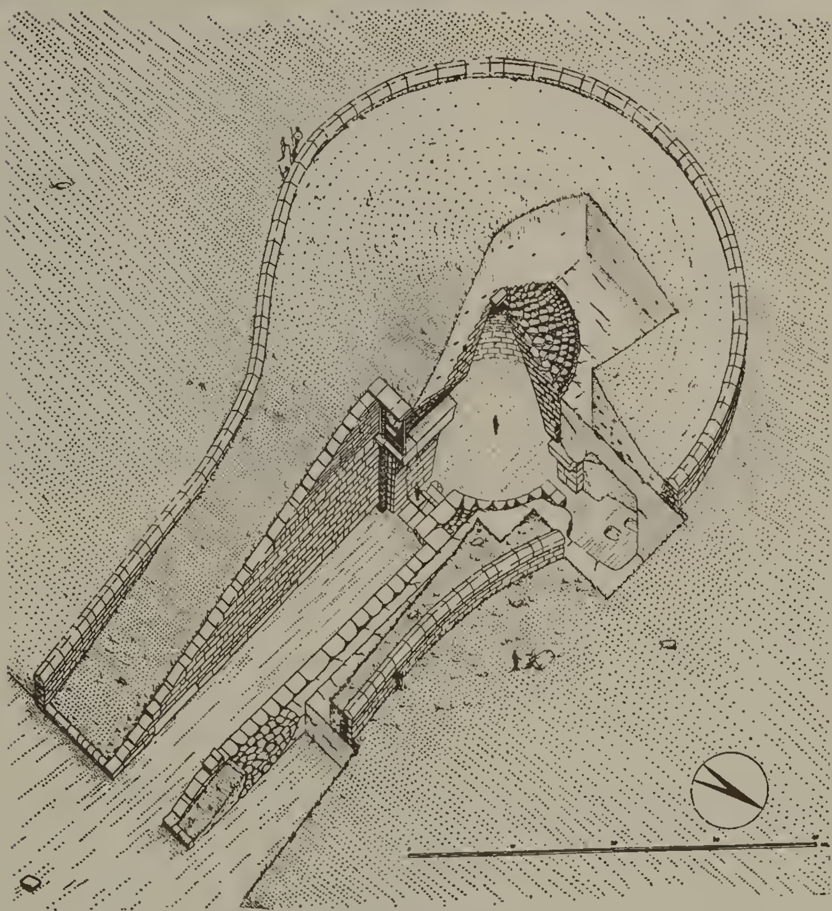
had been planned and executed with high standards of mathematical skill. In order to prove his point he measured it accurately with the precision of one-thousandth of an English foot.

Penrose, however, was ridiculed by archeologists, and no other Greek temple has been surveyed with comparable care ever since. The Archeological Institute of America does not support any survey or publication which does not assume that the maximum precision achieved in construction of reference foot rules by the ancient Greeks was a fifth or at the very best a tenth of centimeter. Naturally, the precision achieved in the construction of buildings was much less than the precision of the official reference rules.

Penrose was not able to convince scholars of his major contention, because he was obsessed as an architect with the notion that buildings should have perfectly square corners. He put this notion into practice when he planned the building of the British School of Archeology in Athens, of which he was director for two short periods, after its foundation in 1882. Because of this obsession, when Penrose found that the western front of the Parthenon is longer than the eastern front and that the south flank is longer than the north flank, he concluded that this was the result of mistakes in construction. His opponents were quick to point out that, if it is so, his major contention is disproved.

Penrose believed that the difference in the lengths of the sides of the Parthenon results from mistakes in the marking of the four corners which were intended to be perfectly square. In reality, the four corners of the Parthenon

Nineteenth-century view of the Parthenon.



The Treasury of Atreus at Mycenae (isometric view, after Hood), which has a striking resemblance to the Maes-Howe burrow and appears to have been designed for azimuth and zenith observation, like the subterranean chambers of the pyramids.

were not intended to be exactly square, but to deviate by set small amounts from a right angle, as is the case with the four corners of the Great Pyramid. I have established that the west front of the Parthenon was intended to be 1/48 of a Mycenean foot longer than the east front, and that the south flank was intended to be longer than the north flank by the same amount. The two longer sides join at the southwest corner, which is also higher in level over the other three corners. Taking these intended deviations into account, the actual findings of Penrose about the length of the sides agree almost perfectly with the theoretical dimensions obtained by mathematical principles.

Even with the intended lengthening of the west and south sides, the northeast corner, which joins the two most important sides, could have been a right angle, but instead it was acute by a figure close to a minute of degree. Unfortunately, Penrose measured the angle of this corner rather casually, because he thought that the lack of exact squareness was the result of a mistake in construction, and nobody else has tested the angle of this corner again in more than 120 years.

East end of the Parthenon.

There are many problems in the architecture of the Parthenon that cannot be solved, because archeologists prefer to go on building fanciful theories rather than establish the facts by an accurate survey. It is a basic principle of epistemology that our ability to reject erroneous theories increases in proportion with the precision and accuracy of the measurements; the converse is true, and this is what archeologists like, because, as they put it, it permits the spirit to soar. For instance, if one were to accept the loose standards of measurement dogmatically adopted by the Archaeological Institute of America, it would not be too difficult to present an argument to the effect the the surface of the earth is concave.

In the specific case of the Parthenon, I can point out that Penrose tested the orientation of the north flank, and that on the basis of his finding I could establish that the Parthenon is correctly oriented according to the latitude and longitude of Athens. But details of construction have led me to realize that the orientation of the inner part of the temple, the cella, was a trifle different. Since the difference of azimuth between the two longitudinal axes of the Parthenon has never been tested, I am left in the dark about the fine points in the orientation of the Parthenon.

An essential datum is that there are similarities between the mathematical structure of the Parthenon and that of the Great Pyramid. In both constructions the corners deviate deliberately from a right angle. I have established that the elevation of the fronts of the Parthenon was calculated by the factor φ and that the elevation of the flanks was calculated by the factor π. According to the data available, I have interpreted the elevation of the Great Pyramid to be such that the north side was calculated by the factor φ and that the west side was calculated by the factor π.

Here, I will deal only with the horizontal dimension, width, of the two fronts of the Parthenon, because it is directly connected with the Mycenean system of measures.

Before Penrose proceeded to a careful measurement of the sides of the Parthenon in the winter 1846–47 (the season of winter was deliberately chosen in order to reduce the effects of changes in temperature which may be macroscopic under the sun of Greece), an attempt at careful measurement was conducted in 1753, under unfavorable political and physical circumstances, by the painter James Stuart and the architect Nicholas Revett, who had become interested in the measurements of ancient buildings while studying in Rome. The expedition of these two English antiquarians had been carefully planned and created great stir in Europe at the time. One of their specific aims, indicated in the campaign for the raising of the necessary funds, was to ascertain the exact length of the Greek foot and by inference of the Roman foot, which is 24/25 of Greek foot. The Parthenon is called *Hekatompedon,* "one hundred foot temple," in Greek texts and these texts indicate also that its width was 100 feet. Earlier visitors to the Parthenon had concluded that the two fronts of the temple measured 100 Greek feet. For this reason Stuart and Revett provided themselves with highly reliable instruments of measurement and paid the greatest attention to the measurement of the two fronts.

They were so concerned with the length of the Greek foot that they reported the dimensions of the temple in such a way as to arrive at the results that were expected. Their figures for the length of the fronts are scanty. But they arrived at the conclusion that the value of the Greek foot is 12.137 English inches = 308.2795 millimeters, which agreed well with what scholars had estimated to be the length of the Roman foot (24/25 of Greek foot). According to my reckonings the Greek foot is 308.2765 millimeters.

Stuart and Revett used a yard rule prepared by the famous instrument-maker John Bird of London. A few years later (1762) Bird prepared a yard rule on behalf of the Parliamentary Committee appointed in 1758 "to inquire into the original standards of weight and measure of this kingdom." Although Bird had to follow the instructions of the committee, it can be presumed that the rule he built in 1762 did not differ in a manner significant for the present research from those he had built earlier. The Bird rule of 1762 was the main basis in the calculation of the Imperial Standard Yard made legal by Parliament in 1824.

What Stuart and Revett did not know is that the fronts of the Parthenon were intended to be slightly more than 100 Greek feet.

If the fronts had had a length of 100 Greek feet = 111.111 Mycenean feet = 111 1/9 Mycenean feet, they would have had a length equal to a second of degree of latitude at the parallel of Mycenae (37° 42′ north), whereas the latitude of Athens is 37° 58′ north.

The fronts of the Parthenon were planned to have a length of 100 1/5 Greek feet = 111 1/3 Mycenean feet. This length was increased by 1/48 of a Mycenean foot on the west front. Hence, the lengths of the fronts, according to my interpretation, was:

Eastern front = 30,889.3 millimeters
Western front = 30,895.1 millimeters

Penrose reported the following findings:

Eastern front = 101.341 English feet = 30,888.7 millimeters
Western front = 101.361 English feet = 30,894.8 millimeters

The western front is better preserved.

These figures prove how accurate was the planning of the Parthenon and how justified was Penrose in testing the dimensions of this temple with the greatest care of which he was capable.

But all the horizontal lines of the Parthenon have a parabolic curvature. The sides of the temple have a double parabolic curvature: they are curved upward and inward. The spacing of the columns proves that dimensions that were relevant were those measured along the parabolic line.

The two parabolic curvatures increased the length of the sides. What I have been able to establish with certainty is the effect of the combined double parabolic curvature on the edge of the sides, because of necessity the spacing of the columns which were placed all along the sides had to be based on the actual length of the edge of the sides. The two curvatures added 8/48 = 1/6 of foot to the length of the fronts, so that the eastern front measured 111 1/2 Mycenean feet = 100.35 Greek feet = 30,935.5 millimeters, when measured along the edge of the blocks. But in calculating the width of the temple one should consider only one parabolic curvature, the curvature upward, that is, in substance, the curvature of the floor. Before expressing exact conclusions I would like to see the results of a new survey of the curvatures of the Parthenon, but I can definitely state that the width of the temple measured along the curvature of the floor was halfway between 111 1/3 and 111 1/2 Mycenean feet, that is, close to 111 5/12 feet = 30,912.4 millimeters.

If we add to this amount the 1/48 foot added to the western front, we have a length of 111 7/16 feet = 30,918.2 millimeters. This length would indicate an equatorial degree of 111,305.5 meters and an equatorial circle of 40,069,988 meters.

It can be concluded that the width of the fronts of the Parthenon was intended to indicate the length of a second of degree of longitude at the equator. But further testing of the dimensions of the Parthenon is necessary in order to establish what was exactly the length of the second of degree that the builders had in mind.

As I have indicated, the Mycenean system of measures, which was followed by the Greeks of the classical age, assumed an equatorial circle of 144,444,444 Mycenean feet and hence a second of degree of equator of 111.45404 feet. This would imply a width of the Parthenon of 30,922.8 millimeters.

VII. DIMENSIONS OF THE GREAT PYRAMID

1. Since the dimensions of the Great Pyramid have been endlessly debated, and studies of them have often degenerated into mysticism, it is proper that in approaching the subject I clarify my method. The essence of my method is to be absolutely pedestrian. I have spent years of my life in trying to ascertain the exact length of the Roman foot, eliciting from the academy the reaction that it is a disgrace for a classical scholar to waste energy on such mechanical trivialities. Similarly, after reading scores of studies on the architecture of the Parthenon, I set myself two tasks: to determine the length of the foot employed in the construction, and to compare item by item all available modern

reports on the actual dimensions of this temple. I followed this line of research although I was warned by the learned that a person guilty of such *banausia,* which in Greek means behavior worthy of a manual wageearner, would always remain blind to the lofty mind of the ancient Greeks. In dealing with the geometry of the Pyramid, I have taken as starting points my conclusions about the length of the Egyptian royal cubit and the survey of the dimensions of the Pyramid conducted by Cole, who was not an Egyptologist but a professional surveyor.

Up to now the Cole survey has been neglected. Trust has been put on the survey conducted by Petrie, but, although Petrie considered himself an expert of measurements (he started his career as an Egyptologist under the guidance of his father, who was an engineer) and used all the diligence of which he was capable, his survey proves to have arrived at misleading results when compared to that of Cole.

In order to justify my method, I shall refer to another great scientific issue which, as we shall see, happens to be related to the problem of the dimensions of the Pyramid. In the *Principia* Newton argued that because of the centrifugal force generated by its rotation, the earth must be flattened at the poles. Reasoning purely on mechanical grounds, he concluded that the polar flattening is 1/230, which means that the polar radius is shorter than the equatorial radius by 1/230 of the latter. The calculation was based on the assumption, which is not true, that the earth is a homogeneous fluid body. Following the survey of Picard, for which Newton waited before publishing his *Principia* in 1686, other scholars of the French Académie des Sciences applied themselves assidiously to the problem of determining by geodetic surveys what was the actual shape of the earth. Their results were contradictory, but they were such that for seventy years after the publication of the *Principia* the empirical evidence could be understood to indicate that the earth, far from being flattened at the poles, was elongated. This caused most serious controversies in the field of physical theory. I have reexamined the records of this gerat debate to find that the French scholars were successful in advancing mathematical theory, in developing correct methods of triangulation, and in refining the techniques of astronomical observation, but had neglected the need of setting a reliable unit of linear measurement. The several surveys of the length of the degree of latitude, up to and including the famous survey conducted by Father Ruggiero Boscovich in Italy in 1751–53 (a survey which took as a starting point the Roman milestones of the Appian Way), kept using standards of the *pied de roi* which were different from each other.

The history of these surveys is a comedy of errors. This was sensed by the keen mind of Voltaire who, when Maupertuis announced triumphantly that his survey of the degree conducted in Lapland had proved that the earth is flattened at the poles, called him *le grand aplatisseur,* "the great flattener," building a pun on the extracurricular activities of Maupertuis with a Lappish maid.

The difficulties of scientists arose from the circumstance that the original standard of the *pied de roi* had been lost. The *pied de roi* used to be a fraction of the ancient Roman foot, and good reference standards of the Roman foot and of the *pied de roi* were kept by French trade guilds. But, the French absolute monarchy followed a policy of eliminating the public functions of the guilds. Finally the minister Colbert issued an ordinance prescribing that the only reference rule that could be used should be that kept at the Châtelet, the seat of royal administration and justice in Paris. But the standard of the Châtelet was poorly defined and badly protected from accidental damage. This is the reason why many scholars could arrive at the startling scientific conclusion that the earth is elongated at the poles. The intellectual confusion came to a rest because the engraver Langlois built his own private standard of the *pied de roi,* by assuming that the *pied de roi* is the edge of a cube that contains 70 Paris livres of water. Langlois's standard was used in establishing the Paris meter of the French metric system.

2. Although Petrie's survey of the length and orientation of the sides of the Great Pyramid proves to be unreliable, his survey of the dimensions of the King's Chamber proves to be superior to the several ones conducted since the seventeenth century. Since Petrie's survey of the King's Chamber has established that the royal cubit of the Pyramid measured 524.05235 $\pm$ 0.1016 millimeters, it permits the conclusion that the royal cubit employed in the construction was 524.1483 millimeters.

Cole began his survey of the length and orientation of the sides of the Pyramid by trying to establish the exact location of the corner points. By an extensive sounding of the foundations, he located the corner points with a possible margin of error which he estimated as follows:

West side:	30 millimeters at either end
North side:	6 millimeters at either end
East side:	6 millimeters at either end
South side:	10 millimeters at the west end
	30 millimeters at the east end

Next, Cole examined the alignment of the four sides and concluded that they meet to form angles which deviate as follows from a right angle:

Northwest corner:	−0° 00′ 02″
Northeast corner:	+0° 03′ 02″
Southeast corner:	−0° 03′ 33″
Southwest corner:	+0° 00′ 33″

I interpret these data to mean that the west side was drawn first and that the north side was intended to be perfectly perpendicular to it. The east side was intended to be at an angle of 3′ with the perpendicular to the north side, and the south side was intended to be at angle of 30″ with the perpendicular to the west side. In other words, the four corners were intended to deviate from a right angle according to the following pattern:

Northwest corner:	0
Northeast corner:	+3 minutes
Southeast corner:	−3 1/2 minutes
Southwest corner:	+ 1/2 minute

Having established the alignment of the sides according to the figures mentioned above, Cole calculated the length of the sides to be the following:

West :	230,357 millimeters
North :	230,253 millimeters
East :	230,391 millimeters
South:	230,454 millimeters

There is a contradiction in Cole's report about the length of the north side. In the summary of the lengths of the sides, Cole states that this side is 230,253 millimeters; but in an earlier part of his report he states that the north side is divided into a segment of 115,090 millimeters and a segment of 115,161 millimeters (total of 230,251 millimeters) and confirms these figures by explaining that the difference between the two segments is 71 millimeters. This contradiction is most unfortunate, because it is a conclusion of mine that the lengths of the two segments of the north side provide a key to the determination of the vertical dimensions of the Pyramid. I am inclined to infer that Cole found the north side to have a length of 230,251 millimeters.

I interpret Cole's figures to mean that the basic length of the side was 439 1/2 cubits = 230,363.18 millimeters. According to Cole the average length of the sides is 230,363.25 millimeters. Each side was intended to have a length of 1 1/4 stadia according to the stadium of 351.6 cubits; for the Egyptian this was the stadium (1/10 minute) of the degree of latitude at the equator. The perimeter of the Pyramid was intended to be 1758 cubits = 921,452.71 millimeters; Cole reports a perimeter of 921,453 millimeters. The perimeter was intended to be equal to 1/2 minute of latitude at the equator. The length of the minute of degree of latitude at the equator was calculated 3516 cubits = 1842.905 meters; it is 1842.925 meters according to the International Spheroid.

In the calculation of the Pyramid the royal cubit was divided into 24 fingers, each finger being 21.8395 millimeters. Egyptian measuring rods indicate that the royal cubit, which in principle is composed of 28 fingers (fingers such that 24 make an Egyptian common cubit), at times was divided into 24 fingers according to the ordinary division of the cubit. There are Egyptian measuring rods in which the royal cubit is divided into 28 fingers on one face and 24 fingers on the other face.

The west side was drawn first and then the north side was drawn perpendicular to it. The south and the east sides were at an angle different from a right angle with the two neighboring sides. This caused variations in the length of the sides, but steps were taken in order to assure that the average length of the sides remained 439 1/2 cubits.

The south side was intended to be at an angle 90° 00′ 30″ with the west side. Reckoning by tangent 0° 00′ 30″, this would cause a lengthening of the east side of 33.494 millimeters. Apparently this lengthening of the east side was computed as 1 1/2 fingers = 32.758 millimeters. The lengthening of the east side was compensated in part by shortening the west side by 1/4 of finger. In other words, the south side was moved backward by 1/4 of finger. The west side came to be 439 1/2 – 1/96 cubits = 230,363.1778 – 5.4597 millimeters = 230,357.72 millimeters. The east side was lengthened by 1 1/4 fingers, so that it came to be 439 1/2 + 5/96 = 230,363.1778 + 27.2994 = 230,390.48 millimeters.

The western side was rotated at the middle point by 3 minutes, so as to shorten the north side and to lengthen the south side. Multiplying the length of half of a side by tangent 0° 03′ 00″, there would be a shortening and a lengthening of 100.519 millimeters, which could be understood as 4 5/8 fingers = 101.008 millimeters. Since the east side had been lengthened by 1 1/4 fingers and the west side had been shortened by 1/4 finger, there remained an increase of a finger to be compensated. Hence, the north and south sides were shortened by 1/2 finger each. In other words, the east side was moved backward by 1/2 finger.

The length of the north side came to be 439 1/2 cubits – 4 5/8 fingers – 1/2 finger = 439 55/192 cubits = 230,251.250

millimeters. The length of the south side came to be 439 1/2 cubits + 4 5/8 fingers − 1/2 finger = 439 129/192 cubits = 230,453.266 millimeters. The difference between the two sides is 74/192 cubits = 202.016 millimeters.

This analysis of the method followed in planning the base of the Pyramid arrives at the striking conclusion that my estimates of the lengths of the sides, based on theoretical principles, do not differ by a millimeter from those obtained empirically by Cole (length of sides expressed in millimeters).

	My estimate	Cole's report
West side:	230,357.72	230,357
North side:	230,251.25	230,251
East side:	230,390.48	230,391
South side:	230,453.27	230,454
	921,452.72	921,453

3. In his survey Cole paid attention to a detail which in my opinion provides the key to the entire geometrical structure of the Pyramid. The Egyptologist Borchardt had noticed that, at about the middle of the north side, a small line is marked on the pavement which extends outward from the bottom of the Pyramid. Cole measured the position of this line and found it to be at a distance of 115,090 millimeters from the northwest corner and 115,161 millimeters from the northeast corner, with a difference of 71 millimeters between the two distances. He stated that this line is "probably the original line of the axis." Cole apparently did not pay much attention to this detail, since he reported also that the north side has a length of 230,253 millimeters. Reginald Engelbach, in presenting Cole's findings to the academic world, failed to notice the discrepancy in Cole's figures. I suspect that the figure of 230,253 millimeters for the length of the north side crept into the Cole report as a result of a mistake of 2 millimeters in placing the end of the tape against the pin that marked the position of the line of the axis.

If the north-south axis of the Pyramid is off center, it follows that the apex was off center. Petrie, when he surveyed the slope of the Pyramid, on the basis of preliminary tests suspected that each face of the Pyramid had a different slope, but did not try to establish whether this suspicion was justified. Instead he concentrated his efforts on establishing the slope of the north face, which is the best preserved one. As far as I know, none of those who tried to interpret the geometry of the Pyramid on the basis of Petrie's report considered the possibility that the four faces of the Pyramid had different slopes. Nobody has ever utilized Cole's survey in order to interpret the geometry of the Pyramid. If the four faces have different slopes, it follows that the apex is off center.

I have concluded that the north side had a length of 439 55/192 cubits = 230,251.250 millimeters. Hence, I understand Cole's figure to mean that the line which divided the north side into two parts is at a distance of 219 137/192 cubits = 115,162.479 millimeters from the northeast corner, and a distance of 219 55/96 cubits = 115,088.771 millimeters from the northwest corner. The difference between the two segments is 27/192 cubits = 73.708 millimeters. I suspect that there was a mistake of 2 millimeters in setting the end of the tape against a pin at the middle of the north face; this is the reason why Cole reports that the north side has a length of 230,253 millimeters with an excess of 2 millimeters. This type of mistake is common in surveying.

A great number of those who have tried to explain the geometry of the Pyramid can be placed into one of these two categories: those who conclude that the Pyramid was calculated by the factor π, and those who believe that the Pyramid was calculated by the factor φ. In my opinion both explanations are correct, in the sense that the slope of the west face was calculated by the factor π and the slope of the north face was calculated by the factor φ. The inclination of the other two faces was affected by the fact that the angles at the northeast and the southwest were more than right angles.

For reasons that I shall explain below, I have concluded that the height of the Pyramid was either 279.53 cubits = 146,515.174 millimeters or a figure very close to 279.53 cubits.

According to what I have said above, the distance of the apex from the west side was 115,088.771 millimeters. If the west face was calculated by the factor π, the height of the Pyramid had to be $\pi/4$ of the base of the meridian triangle of the west side. Now, 146,515.174 millimeters relates to 115,088.771 millimeters as 0.78550752, which would imply $\pi = 3.142030$. If π was reckoned as 3.1420, the height would have been 146,516.522 millimeters. By the exact value of π, the height would have been 146,535.569 millimeters.

Because of Cole's report we know the distance of the apex from the west side, but we do not have direct information on the distance of the apex from the north side. However, it can be presumed that the west-east axis was not displaced from the middle position. It can also be presumed that the line of the west-east axis was set according to the basic length of sides, before the length of the sides was altered by the widening of the southwest and northeast corners. Since the basic length of the sides is 439 1/2 cubits = 230,363.178 millimeters, it can be presumed that the apex was at a distance of 219 3/4 cubits = 115,181.589 millimeters from the north side. If this is the length of the base of the meridian triangle of the north face, and the height of the Pyramid is 279.53 cubits = 146,515.174 millimeters, the base of the meridian triangle of the north face is 0.78614103 of the height. If the north face was calculated by the factor φ, the height should have been equal to $\sqrt{1/\varphi}$ of the base of the meridian triangle. If one had recokoned by the exact value of φ, the height would have been 146,513.250 millimeters. If the height was 146,515.174 millimeters, as I tentatively assume, and the northern half of the north-south axis was 115,181.589 millimeters, $\sqrt{1/\varphi}$ was reckoned as 0.786141 (the exact value is 0.7861514) and hence $1/\varphi$ was reckoned as 0.61801767.

If $1/\varphi$ was reckoned as 0.6180, the height would be 146,517.274 millimeters, which would imply $\pi = 3.141985$. Therefore, I would conclude that the height possibly was reckoned as 279 15/28 cubits = 279.53714 cubits = 146,518.169 millimeters. According to Petrie the slope of the north face is 51° 50′ 40″ ± 1′ 05″. If the north face had been calculated by the exact value of φ, the slope would have been 51° 49′ 38″. This angle can be easily calculated, because if the meridian triangle of the north side is calculated by φ, the secant and the tangent of the angle of the slope must be equal to each other, that is, must be equal to $\sqrt{\varphi}$. If the west side had been calculated by the exact value of π, it would have had a slope 51° 51′ 14″.

4. Most interpreters agree that the Pyramid had a height of 280 cubits. Even Borchardt, who is so opposed to the idea that Egyptians had any knowledge of mathematics that he calls Herodotus an "idiot" for having said that the Pyramid was calculated by φ, agrees that the Pyramid had a height of 280 cubits.

In general one could establish a consensus of the responsible interpreters to the effect that the meridian triangle of the Pyramid was the following:

Height:	280 cubits
Base:	220 cubits
Apothem:	356 cubits

In my opinion, this triangle was purely the starting point of the calculations. It was chosen in order to indicate the relation π and the relation φ, since 22/28 is the value of $\pi/4$ used in practical reckonings ($\pi = 3\ 1/7$), and

$356/220 = 89/55 = 1.6181818$ is an approximation to the value of φ according to the initial terms of the Fibonacci series. But the initial meridian triangle was modified for several reasons, the first one being that it is impossible to construct a right triangle with sides 280, 220, and 356, since we have:

$$280^2 = 78{,}400$$
$$220^2 = 48{,}400$$
$$356^2 = 126{,}736$$

We have seen that the basic length of the sides was reduced to 439 1/2 cubits (semiside of 219 3/4).

In my opinion, the height of 280 cubits was chosen in order to indicate the polar flattening of the earth. The Egyptians calculated the polar flattening as 1/280, but this was a round figure adopted on the assumption that the order of the cosmos must be septenary.

Information about the Egyptian estimate of the size and shape of the earth is provided by Chapter LXIV of the *Book of the Dead*. This chapter was the most important one: reciting it was considered almost as effective as reciting the entire book. In one of the papyri of the *Book of the Dead* there is an annotation to the effect that this chapter was found in the shrine of the solar boat during the reign of Udimu, the fourth or fifth Pharaoh of the First Dynasty. Chapter LXIV states that the spirits of the Nether World (that is, all that is below the surface of the earth) are 4,601,200 and that each is 12 cubits high. The occurrence of the factor 12 indicates that it is a matter of geographic cubits. Now, $12 \times 4{,}601{,}200$ cubits $= 55{,}214{,}000$ cubits $=$ 138,036 geographic stadia, is equal to two diameters of the earth. In order to explain the figure of 138,036 stadia, one must assume that the Egyptians reckoned as if the polar flattening occurs only in the northern hemisphere. On the basis of this assumption the figure of 138,036 stadia can be decomposed into the following four earth radii:

34,538 stadia = 6,378,388 meters = equatorial radius
34,538 stadia
34,538 stadia
34,422 stadia = 6,356,966 meters = polar radius
138,036 stadia

These figures imply that the flattening of the North Pole is $116/34{,}538 = 1/297.74$.

With extreme economy of numerical expression the Egyptians had arrived at values which are as good as the best modern ones. The figure for the equatorial radius happens to coincide to the meter with that calculated by Hayford. But Hayford calculated the polar flattening as 1/297. Helmert, however, set the polar flattening at 1/298.3, a figure which has been adopted in several of the recent surveys and calculations of the size of the earth which aim at achieving the maximum possible exactness.

At the beginning of the dynastic period the above mentioned figures were revised in order to make them fit into the septenary system of measures and cosmic order. The polar flattening was set at 1/280. This was achieved by decreasing slightly the polar radius and increasing slightly the equatorial radius. The equator which used to be reckoned as 217,000 geographic stadia = 40,074,999 meters, was calculated by a stadium (1/10 of minute) of 354 royal cubits, which made it 40,078,476 meters. It is conceivable that the data mentioned in the *Book of the Dead* was reinterpreted as follows:

34,540 geographic stadia = 6,378,758 meters = equatorial radius
34,540 geographic stadia
34,540 geographic stadia
34,416 geographic stadia = 6,355,858 meters = polar radius
138,036 geographic stadia

The figure of 1/280 for the polar flattening was adopted because it fits into septenary reckoning also in a second and more subtle way. If the polar flattening is 1/280, the arc of meridian is 0.7840 of equatorial diameter. Now, $0.784 = 280^2/100{,}000 = 78{,}400/100{,}000$. This is the reason why Herodotus put emphasis on the fact that the surface of each face of the Pyramid is 78,400 square cubits, being equal to the square of the height, which is 280 cubits. However, the figures reported by Herodotus apply only to the initial plan of the Pyramid. When the figures were further refined the height was calculated as 279.53 cubits. If the polar flattening is 1/297.74, the arc of meridian is 0.7408 of equatorial diameter. This means that an arc of meridian is $0.78408/\frac{1}{4}\pi = 279.53/280$ of a fourth of equator. Hence, the height of the Pyramid in the final plan indicated the correct figure for the polar flattening.

VIII. ADDITIONAL REMARKS ON THE DIMENSIONS OF THE GREAT PYRAMID

1. Herodotus provides only two pieces of information about the dimensions of the Great Pyramid. He states that the surface of each face is equal to the square of the height, which means that the Pyramid was calculated by the Golden Section (by the factor φ). He states also that this surface of each face is equal to 8 Egyptian acres. The Egyptian acre is a square with a side of 1000 royal cubits (2747 square meters). The Egyptian acre, the amount plowed in a day, is similar to the Roman acre (*jugerum*), which is 2524 square meters. Herodotus's figure indicates that he had in mind a

height of 280 royal cubits. He reckoned by half acres, which, as I have explained earlier, were taken to have sides of 70 cubits. If the Pyramid has a height of 280 cubits, the square of the height is 16 half acres (78,400 square cubits). If Herodotus assumed a side of 440 cubits, in order to have this surface the faces should have had an apothem of 356.4 cubits; but if he assumed a side of 439 1/2 cubits the apothem should have been 356.8 cubits. But Herodotus's figure for the surface of the faces was not intended to be exact.

The Roman geographer Pomponius Mela (I,9) paraphrases Herodotus in these terms: *quatuor fere soli jugera sua sede occupat, totidem in altitudinem erigitur,* "it occupies almost four acres with its base, and it rises as much in height." Mela expresses himself awkwardly, but the main point is clear. In order to make the reckoning more easily comprehensible he counts by double acres which have sides of 140 cubits. If the Pyramid had a height of 280 cubits, it would be immediately clear that the square of the height is 4 (double) acres. But Mela states that the surface of the faces and the square of the height is *almost* 4 acres. It was a current practice in all ancient cultures to double units of measure, while continuing to refer to them by the name of the simple unit. Mela erroneously speaks of the surface of the base, whereas it is a matter of the surface of the faces. The error probably originated through an inept translation from a Greek author who used the technical term *epipolēs,* which means "in elevation, by the lateral surface," but may also mean "in surface." The same error occurs in Pliny. It is likely that the error in translation originated with Varro, who almost certainly was the common source of Mela and Pliny. The polymath Varro, who lived in the first century B.C., proves inept in mathematical matters, and Mela and Pliny were certainly no more adept in these matters. But, the text of Mela, in spite of its shortcomings, supports my contention that the height of 280 was merely an initial figure in the calculation of the Pyramid, a figure which was reduced in the course of the development of the calculation.

I have analyzed all other ancient authors who provide information about the dimensions of the Pyramid. By a careful collation of their words and phrases, I have established that they all draw, directly or indirectly, on a single source. These authors wrote in Greek or in Latin during the first century of the Roman Empire. They are the historian Diodorus of Sicily (I, 63), the geographer Strabo (XVII, 1, 33), the encyclopedist Pliny the Elder (XXVI, 12, 78–80), and the engineer Philon of Byzantium (*Wonders of* *the World,* II). Their common source is the Greek grammarian Agatharchides of Cnidus, who toward the end of the second century B.C. was guardian to one of the Ptolemy kings of Egypt. Quotations from Agatharchides' lost works indicate that he wrote extensively on the geography of Egypt, with particular emphasis on natural science.

The interesting feature of Agatharchides' report about the dimensions of the Pyramid is that he excludes the pyramidion from the reckoning. We know from the descriptions of other pyramids that the very top of the structure was a small pyramid of metal, usually a precious metal such as gold or silver, which shined in the sun. From Agatharchides' account one gathers that the Great Pyramid of Giza was topped by such a pyramidion, "small pyramid," as the Greeks called it. In the case of this Pyramid, at least, the pyramidion was used to achieve a mathematical result.

In ancient mathematics extensive recourse was made to a mathematical procedure which we no longer use, but which was extremely convenient. If the square root of a number cannot be expressed by an integer, the number is conceived as the product of two integers of which the second is the same as the first, but increased or decreased by a small quantity, usually the unit. Similarly, if the cubic root of a number cannot be expressed by an integer, the number is conceived as a cube in which one side is longer or shorter than the others. For instance, the number 8400 is conceived as a cube with sides 20, 20, and 21. This procedure is called *basi* in Sumerian. I have established that the calculation by what I call near-squares and near-cubes was common not only in theoretical mathematics but also in architecture, land surveying, and the construction of measuring vessels.

The procedure just described was applied in geometry by removing a small part of a figure. For instance, a problem of geometry could be solved by cutting off a slice from a side of a parallelogram. Most commonly the procedure was applied by cutting off a corner of a triangle; this is the reason why the part cut off is called *gnōmōn* in Greek. Most usually *gnōmōn* means "pointer of a dial" in Greek; hence, the term applies perfectly in our case in which the top of the Pyramid was conceived as cut off in the computation presented by Agatharchides.

An essential point of Agatharchides' account is that he describes the Pyramid as having an apothem which measures a stadium up to the pyramidion and having a side which measures 1 1/4 stadia. The term stadium has a double meaning: it refers to 1/10 minute of degree and it refers to a specific unit of measurement. Agatharchides uses the term in both senses.

I have already indicated that the base of the Pyramid has a length of 1 1/4 times 351.6 royal cubits, which for the Egyptians was the length of the stadium (1/10 minute) of the degree of latitude at the equator. From the authors who drew on Agatharchides we gather that he said that the perimeter is 5 stadia, that is, 1/2 minute of degree.

One would have expected the perimeter of the Pyramid to have been calculated by the length of the degree of longitude at the equator, but the builders instead calculated by the degree of latitude, because their concern was the length of the arc of meridian. From Agatharchides we learn that the apothem up to the pyramidion had a length of a stadium, that is, 1/10 of a minute of degree. This permits us to understand what was the specific function of the pyramidion. Since the degrees of latitude increase in length from the equator to the pole, the apothem of the Pyramid up to the pyramidion gave the length of the shortest degree of latitude, the degree at the equator. The pyramidion may have been graduated, giving the length of all the degrees from the equator to the pole. According to Egyptian reckonings, the stadium of the degree of latitude at the equator is 351.6 royal cubits and increases to a length which at the pole the Egyptians assumed to be 355 cubits in practical reckonings and slightly more than 355 cubits in exact reckoning. The apothem of the full Pyramid came to be something less than 356 cubits.

Agatharchides interprets the dimensions of the Pyramid also by taking the word stadium as referring to the stadium of 600 geographic feet. The geographic stadium was the unit most commonly used by the ancients in calculating geographic distances. A stadium was 600 geographic feet, and 600 stadia made a degree. This calculation was correct for the degree of latitude at the middle latitude of Egypt, for the latitude of the capital built by the Pharaoh Akhenaten. According to Agatharchides the side of the Pyramid is 1 1/4 stadia or 750 feet (230,847 millimeters), and the apothem is a stadium or 600 feet. The side of the base of the pyramidion is 9 feet. The figures indicate that Agatharchides was not concerned with presenting the actual dimensions of the Pyramid, but in illustrating the mathematical principles according to which the Pyramid had been conceived.

The figures quoted from the text of Agatharchides by later authors suggest that he began his analysis of the meridian triangle of the Pyramid by presenting a triangle with the following dimensions:

Height:	480 feet
Base:	377 feet
Apothem:	610 feet

This approach gives excellent values of φ and π.

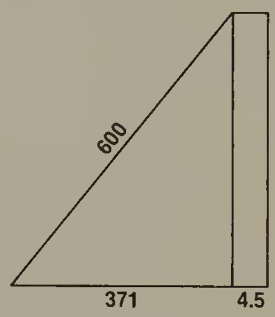
$$\varphi = 610/377 = 1.6180371 \text{ (exactly } \varphi = 1.6180339887)$$
$$1/\varphi = 377/610 = 0.6180328 \text{ (exactly } 1/\varphi = 0.6180339887)$$
$$\pi/4 = 377/480 = 0.785\,41666$$
$$\pi = 3.14166$$

It is impossible to construct a right triangle with sides 480, 377, and 610, since we have:

$$480^2 = 230{,}400$$
$$377^2 = 142{,}129$$
$$610^2 = 372{,}100$$

But the calculation I mention is less off the mark than the calculation by the triangle 280, 220, and 356, which was the one with which the builders of the Pyramid actually began.

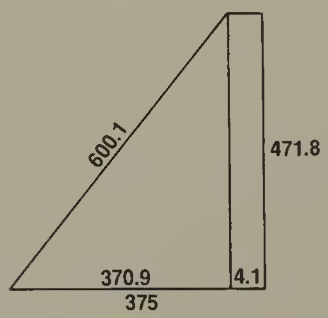
Having started with the mentioned meridian triangle, Agatharchides cut off the side so as to reduce the apothem to 600 feet and the base to 371 feet, excluding the part of the base below the half of the pyramidion.



Since Pliny in quoting Agatharchides does not give the length of a side of the pyramidion (which another author describes as being 9 feet), but the combined length of two sides, I have concluded that the pyramidion had an average side of 9 feet, but had different lengths of different faces.

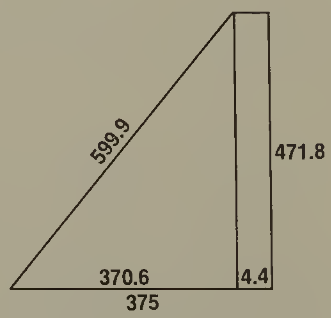
I presume that Agatharchides presented two different meridian sections of the Pyramid, one calculated by the factor φ and one calculated by the factor π.

By φ:



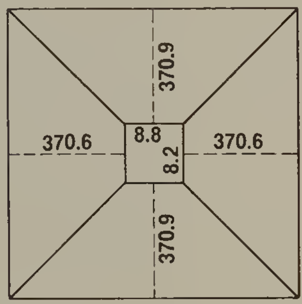
$1/\varphi = 0.61806368$

By π:



$\pi = 3.1420090$

The two possible meridian sections were combined so as to obtain two faces calculated by π and two faces calculated by φ. The Pyramid seen from above would have had the following dimensions:



Like Herodotus, Agatharchides was not concerned with reporting the exact dimensions of the Pyramid, but with presenting the general principles of the mathematics of the Pyramid. This was the point which was of the greatest interest to a Greek audience.

I do not pretend to have reconstructed the authentic reckoning of Agatharchides, but I feel confident that I have understood the general drift of his interpretation. It seems to me that he intended to improve on the presentation of Herodotus, who had only mentioned the factor φ, by stressing the roles both of the factor φ and of the factor π. Agatharchides wanted also to emphasize that the dimensions of the Pyramid were related to the length of the degree of latitude. This was a point of essential importance which had not been mentioned at all by Herodotus.

2. The Egyptians ascribed the invention of the art of building with stone to Imhotep, vizier and architect of King Zoser, who reigned about fifty years before the building of the Great Pyramid. And in fact there has not been found any important building made only of stone blocks which dates before the reign of Zoser. The Egyptians described Imhotep as a sort of Leonardo da Vinci of Egypt, mathematician, scientist, engineer, and architect. Not many years after his death he was made into a demigod, son of Ptah, the god of craftsmen and technicians. Up to recently there were Egyptologists who insisted that Imhotep was a legendary figure. One argument was that there is no other instance in Egyptian history of an ordinary person having bene divinized. But more basic was the argument that a person with all the gifts ascribed to Imhotep could not have existed in the Old Kingdom. It is only in the last few years that it has been definitely accepted that Imhotep was a real person, since it has been possible to gather some specific details of information even about his physical appearance. His genius was recognized even during his life, since King Zoser

covered him with all sorts of honors, although he was a man of humble origin.

But, even though it is now granted that the Egyptians were not living in dreams when they idolized the genius of Imhotep, Egyptologists have failed to investigate what were the scientific achievements of Imhotep other than that he was the first one to have designed a pyramid, the step pyramid of Saqqara. This pyramid is just one element in an enormous group of buildings which is known as Zoser's Complex. This group of buildings is not only so extensive but also so elaborate that nothing of the sort was produced again in the long history of Egypt. In spite of this, not one Egyptologist has tried to investigate this monument and other constructions directed by Imhotep in terms of what the Egyptians said were his talents. Scholars are willing to grant that a man with the name of Imhotep walked on the land in Egypt, but they are not yet willing to grant that Egypt could have produced a mind like his.

The French archeologist Jean Philippe Lauer has dedicated many years to the study of Zoser's Complex. He is a highly competent archeologist and essentially factual and realistic. Actually he has been criticized for insisting too much on technical problems of architecture. For instance, the German Egyptologist Herbert Ricke has disputed point by point Lauer's interpretation of the monuments of Zoser's Complex, claiming that the architecture must be understood in terms of the conflict between the psychological attitudes of nomadic hunters and that of sedentary agriculturists. But Lauer has learned how far the academic community is willing to go in tolerating rational thought in the area of ancient studies. In 1944 he published a short paper in which he tried to deal with the geometry of the pyramids and enlisted the cooperation of a professional mathematician, Paul Montel. But, four years later, when he published the book, *Le Problème des pyramides,* he backtracked and dismissed any mathematical interpretations.

In reporting about Zoser's Complex, Lauer keeps stumbling into mathematical problems, but ignores them. For instance, he found that the wall that surrounds the entire Complex forms a rectangle 544.90 by 277.60 meters. He concludes that it is a matter of a dimension of 1040 by 530 cubits. I would understand that the intended dimensions were 545,114 by 277,799 millimeters, according to the cubit of 524.1483 millimeters. Lauer is surprised at meeting with the figure of 1040 cubits, whereas he would expect 1000 cubits, and explains it away by assigning arbitrarily 40 cubits to the thickness of the walls. But in another part of his work he points out that the same proportions occur in some First Dynasty royal tombs which have dimensions of 54 by 27 meters. It may be enough to point out here that the dimensions of the enclosure of Zoser's Complex are based on the near-square with sides 52 and 53, a mathematical entity of which I have spoken earlier. It is a matter of two near-squares with sides of 520 and 530 royal cubits. It is relevant to what follows that such a near-square has a diagonal of 742.49579, which is 6 times 123.749.

Lauer notices in Zoser's Complex four instances of the occurrence in important positions of the anomalous dimensions of 123 cubits, whereas in the Complex dimensions are generally decimal multiples of the cubit. One of the most impressive remains of the Complex, the monumental entrance gallery, has a length of 123 cubits. Lauer suggests that the Egyptians may have been fascinated by a magic number composed by the first three integers. This is a way of shunting off a problem by appealing to that undefinable entity called magic and by implying, at the same time, that the Egyptians, and their hero Imhotep in particular, were frivolous in matters of mathematics.

Lauer did not realize that the number 123 is an expression in terms of integers of the number $2/\varphi = \sqrt{5} - 1 = 1.236068$. In his book on the pyramids Lauer had denied the occurrence of the factor φ in their architecture.

It is a matter of the right triangle with an angle of 36° which the Egyptians called *mr.* I have suggested that the name *To-Mera,* which the Egyptians gave to their country, was a reference to this triangle. If a right triangle has an angle of 36° and the longer side is 100, the hypotenuse is $2/\varphi\ 100 = 123.6068$, the other side being 72.6542.

Since I have argued that the Great Pyramid was calculated both by the factor φ and by the factor π, I might point out here that there is a close relation between these two numbers, which goes beyond the fact that there is a numerical similarity between $\pi/4 = 0.7853981$ and $\sqrt{1/\varphi} = 0.7861514$. The number φ was used to obtain the value of circular functions, since we have

$$\begin{aligned}
\sin\ 18° &= \cos\ \ 72° = 1/2\varphi \\
\sin\ 54° &= \cos\ \ 36° = \varphi/2 \\
\sec 36° &= \operatorname{cosec} 54° = 2/\varphi \\
\sec 72° &= \operatorname{cosec} 18° = 2\varphi
\end{aligned}$$

In practical reckonings the right triangle with an angle of 36° was taken as a triangle with a side of 100 and a hypotenuse of 123. The side opposite the angle of 36° was taken as being 72; this permits us to calculate in terms of half degrees all the trigonometric functions of the angles between 0° and 36°. Since the angle of 36° is 2/5 of a right angle and 1/10 of a full circle, one can calculate from the mentioned triangle the trigonometric functions for all angles.

This is the reason why the triangle *mr* was considered the basic constituent of the cosmic order.

In order to recognize the importance of the right triangle with an angle of 36°, one may start by considering how much attention it received in Euclid's *Elements*. It plays an even greater role in early Greek mathematics. The symbol of the Pythagorean sect, the five-pointed star, was a combination of such triangles.

I have explained that the right triangle with a hypotenuse of 123 was a practical simplification of the triangle of 36° built according to the Golden Section. A further simplification was the right triangle with sides related as 3:4:5. If this triangle is enlarged to the scale of the one with hypotenuse of 123, it has sides 120, 100, and 75, instead of 123, 100, and 72.

I need to point out that the Great Pyramid incorporates the relation 4:5 in the proportion between the length of the apothem up to the pyramidion and the length of the side. This provides a point of transition to an analysis of the dimensions of the Second Pyramid.

The Great Pyramid tried to compress a great number of mathematical relations, whereas the Second Pyramid limited itself to embodying the triangle *mr.*

The basic idea of the Great Pyramid was that it should be a representation of the northern hemisphere, a hemisphere projected on flat surfaces, as is done in mapmaking. This was the principle according to which was built the ziggurat of Babylon, the biblical Tower of Babel, and according to which were built the earlier pyramids. The Great Pyramid was a projection on four triangular surfaces. The apex represented the pole and the perimeter represented the equator. This is the reason why the perimeter is in relation 2π with the height. The Great Pyramid represents the northern hemisphere in a scale 1:43,200; this scale was chosen because there are 86,400 seconds in 24 hours. But then the builders became concerned with the problem of indicating the ratio of polar flattening of the earth and the length of the degrees of latitude which depends on the ratio of this flattening. Next, they incorporated into the Pyramid the factor φ as the key to the structure of the cosmos. The Second Pyramid, on the contrary, limits itself to embodying the trangle *mr,* which is based on the number φ, at least as far as I have been able to establish up to the present moment.

According to Petrie's survey the sides of the Second Pyramid have the following lengths:

West: 215,278 millimeters
North: 215,186 millimeters
East: 215,269 millimeters
South: 215,313 millimeters

The royal cubit of this pyramid is that of 525 millimeters. The basic length of the sides is 410 cubits = 215,250 millimeters.

The meridian triangle of the pyramid is a triangle with proportions 3:4:5. The base is 205 cubits, the height is $4/3 \times 205 = 273.33$ cubits, and the apothem is $5/3 \times 205$ cubits $= 341.66$ cubits.

Reckoning by third of cubits, we have:

Base: 123×5
Height: 164×5
Apothem: 205×5

Possibly the pyramid was calculated by a rod of 5/3 of a cubit, which is called *nbyw* (*nebiu* in Coptic).

It is clear that this pyramid was intended to incorporate the number 123 as a round figure for $2/\varphi$.

The slope of the pyramid is the same as the angle of problems 67–69 of the Rhind Papyrus. The tangent $164/123 = 1.3333$ corresponds to a slope 53° 07′ 48″. The angle of the apothem with the height is 36° 52′ 12″. This angle was intended to be an approximation to the perfect angle 36°

The geometry of the Second Pyramid could be considered crude in relation to the sophisticated one of the Great Pyramid, but it emphasizes the importance that the Egyptians attached to the triangle *mr.*

3. Petrie's survey of the Second Pyramid helps in clarifying the problem of the orientation of the sides of the Great Pyramid.

Petrie reported that the four sides of the Second Pyramid are oriented as follows:

West	side:	0° 04′ 21″	west of true north
North	side:	0° 05′ 31″	north of true east
East	side:	0° 06′ 13″	west of true north
South	side:	0° 05′ 40″	north of true east

Petrie warns that the triangulation of Egypt existing at his time did not permit him to establish the direction of north with absolute certainty. Hence, his figures can be taken only as an indication of the angle of the sides in relation to each other.

Petrie's figures prove that the deviation from the right angle in three of the four angles of the Great Pyramid was intentional and not the result of mistakes in construction, as claimed by professional archeologists. The north side of the Second Pyramid is shortened in relation to the south side, as it occurs also in the Great Pyramid. But in the Second Pyramid the shortening of the north side and the lengthening of the south side was achieved by constructing a more regular figure. The base of the Second Pyramid has the shape of a trapeze or a trapezoid. The north and south sides were drawn parallel to each other. Possibly the west side was intended to be at an angle of one minute with the north-south axis, and the west side was intended to be at an angle of half a minute with the north-south axis.

In any case the approximate findings of Petrie indicate that, if one proceeded to a new survey of the Second Pyramid and then surveyed the orientation of the sides of other pyramids and possibly of other major constructions of the Old Kingdom, one could recognize a pattern on the basis of which it could be established what was the purpose in making the angles of pyramids and possibly of other major constructions different from a right angle. It is impossible to formulate a reliable explanation for the differences among the angles of the base of the Great Pyramid without establishing what was the general practice in establishing the angles of the base of pyramids.

I have come across the same difficulty in dealing with the dimensions of Greek temples. I have ascertained that the four angles of the Parthenon were intended to deviate slightly from a right angle. Further, in the case of the Parthenon the north side is shorter than the south side, as in the case of the two major pyramids of Giza. But it is impossible to advance hypotheses in order to explain the differences among the angles of the Parthenon, as long as the angles of other temples are not surveyed so as to make possible the identification of a regular pattern.

There is one further problem to be considered in relation to the orientation of the faces of the Great Pyramid. The west face, which in my opinion was drawn first and is the basic face, is not oriented to the north, but is oriented 2′ 30″ west of true north.

This deviation from orientation to the north is the result of the precession of the equinoxes.

From cuneiform texts one gathers that in Mesopotamia there was a distinction of roles between the mathematician who formulated the general plan of a building and the architect who executed the plan. Whether this distinction existed in Egypt or not, it can be assumed that in the construction of a pyramid the first step was the drawing of a mathematical plan. This plan would include the alignment of the stars to be observed in establishing the direction of the north. If my interpretation of Egyptian sky charts is correct, the line that indicates the north used to be marked so as to pass through the celestial pole and through the pole of the ecliptic.

In any case, it appears that there was drawn a plan of the Great Pyramid which included the calculation of the stars to be observed in order to obtain the direction of the north. After this plan was drawn, the ground of the Pyramid had to be cleared in order to proceed to the ceremony called "stretching of the cord," which for the Egyptians was the equivalent of our laying of the first stone. This ceremony had the purpose of establishing the direction of true north and, as the Egyptians saw it, suspending the building from the sky by tying the building with an imaginary string to the axis of rotation of the vault of heaven.

If there had passed exactly three years from the drawing of the plan to the ceremony of the "stretching of the cord," the clustering of stars, which gave the exact north of the moment of the drawing of the plan, would give an orientation 2′ 30″ west of north, because of the precession of the equinoxes, which displaces the star taken as the polar star in practical calculations to the west at a rate of about 50″ a year.

The Second Pyramid too is oriented west of true north, but unfortunately Petrie's figures for the orientation of this pyramid are not exact, as he himself warns.

The question to be asked is whether the incorporation of the rate of the precession of the equinoxes into the dimensions of the Great Pyramid and of the Second Pyramid was accidental or intended. I am inclined in favor of the second alternative, since in the case of the Great Pyramid the angle corresponds exactly to three years in the precession of the equinoxes. In their book *Hamlet's Mill* de Santillana and Dechend have used mythological and iconographic evidence in order to prove that all ancient cultures of the world were deeply preoccupied with the phenomenon of the precession of the equinoxes. They intended to prove that the movement by which the celestial pole in about 25,920 years (Platonic year) makes a full circle around a point called the pole of the ecliptic was conceived as the basic movement in the life of the universe. This cycle determined all other movements, including biological developments, and determined the length of human life (taken as equal to 72 years, or the time that it takes the celestial pole to move a degree) as well as historical events. The authors of *Hamlet's Mill* have kept their conclusions vague, probably in the hope that thereby their findings would be less readily attacked by the academy. They open their book with the statement: "This is meant to be only an essay. It is a first reconnaissance of a realm well-nigh unexplored and uncharted." This is a most gentle way for a professor of the history of science at the zenith of his career to present a thesis which, if accepted, should have the impact of a Copernican revolution on current conceptions of the development of human culture. Since the essence of my method is quantitative, I cannot indulge in the luxury of such linguistic niceties. I have collected a mass of numerical evidence which shows that the inhabitants of the ancient world were acquainted with the rate of the precession of the equinoxes and attached a major significance to it. But in order to deal with this evidence, I would have to open an entirely new topic. I beg the indulgence of the reader in asking him to remain satisfied for the moment with the mere hint that there is yet another lesson about the level of Egyptian science to be drawn from the stark nakedness of the Great Pyramid.

GLOSSARY OF NAMES AND TERMS

Abd-al-Latif (1179–1231) — Arab historian who taught medicine in Baghdad. Author of one of the early Arab histories of Egypt: *Relation de l'Égypte*. In 1220 he explored the Great Pyramid, reporting that he came out of it "more dead than alive."

Abdullah Al Mamun (d.833) — Caliph of Baghdad, son of Harun al-Rashid. Patronized literature and science; built an astronomical observatory outside Baghdad; ordered a degree of latitude to be measured across the plain of Palmyra. Is reputed to have broken into the Great Pyramid in 820 in search of treasures, but to have come away empty-handed after opening the way to the King's Chamber.

Agatharchides of Cnidus — Greek historian and geographer who lived in the time of Ptolemy Philometor (181–146 B.C.) and dealt with the geography of the Near East.

Akhnaten (1388–1358 B.C.) — Revolutionary pharaoh of the Eighteenth Dynasty who changed his name from Amenophis IV, and broke with the priests of Amon at Thebes. He built a new capital, Akhtaten, between Thebes and Memphis near the site of Tell el-Amarna. Of his religious reform, which was monotheistic and recognized the sun as the symbol of living energy, Petrie remarked: "no such grand theology had ever appeared in the world before."

Akhtaten (Resting point of Aten) — Capital built by the young pharaoh Akhnaten at the predynastic geodetic center of Egypt, halfway between the Tropic and the Mediterranean coast, near the site called Tell el-Amarna. The city, which was decorated with splendid temples and palaces, was destroyed after Akhnaten's death.

Ali Gabri (1830–19?) — Arab guide, sometimes referred to as Alee Dobree, who was an assistant to Howard-Vyse, Piazzi Smyth, Sir Flinders Petrie, and Moses B. Cotsworth over a period of nearly seventy years, helping them explore and measure the Great Pyramid.

Alvarez, Luis Walter (1911–   ) — Nuclear physicist. Professor of physics at Lawrence Radiation Laboratory, Berkeley, California. Nobel Prize winner for physics in 1968. Developer of radar. Helped develop A-bomb and flew in B-29 observer following the plane that bombed Hiroshima. One of the youngest members to be elected to the National Academy of Science. Author of several scientific articles. Adapted spark chamber to X-ray the pyramids with cosmic rays.

Amèlineau, Emile (1850–1915) — Studied Egyptian and Coptic under Maspero. Did much excavating but was criticized by Petrie and Maspero for unscientific methods. Professor of history of religions in École des Hautes Études in Paris, where he died in 1915. Author of several volumes on ancient Egyptian history and science.

Amenemhet — Four Pharaohs of the Twelfth Dynasty, the first of which reigned from ca. 1991 to 1962 B.C.

Amon	A god who was related to the wind, promoted to an imperial divinity at the beginning of the Twelfth Dynasty as Amon-Ra. Amon was considered the creator of other gods, and to have had no beginning and no end.
Ancient Empire	From the Third to Sixth dynasties, variously estimated, but approximately 2780 to 2280 B.C. There is little historical data on this period, most of the relevant papyri having disappeared. Under the influence of King Zoser and his architect Imhotep, brick structures gave way to stone. The political center was at Memphis
anomalistic year	365 days, 6 hours, 13 minutes, 48 seconds. The time it takes the earth to return in its elliptical orbit to the point nearest the sun —about 4¾ minutes longer than the sidereal year.
apothem (of a pyramid)	The distance from the apex down one face to the center of a base side.
Arya-Bhata (b. 476–?)	Hindu astronomer and mathematician, author of Aryabhatiya which gave the rules of mathematics as known in his time. Most of his work deals with astronomy and spherical trigonometry. Gave a value for π of 3 177/1250, or 3.1416. Taught that the daily rotation of the heavens was an appearance due to the earth's rotation on its axis.
Aten	God of the solar orb, raised to a prime position by Akhnaten. Represented by a golden disc radiating rays that end in hands. Was considered a universal deity who could have held sway over a universal empire.
azimuth	Angle of arc around the horizon, or angular distance of an observed point from geographic north (or other fixed point).
Ballard, Robert T.	Australian engineer who made a study of the pyramids in 1882 which he wrote up in "The Solution of the Pyramid Problem; or, Pyramid Discoveries with a New Theory as to Their Ancient Use."
Barnard, Professor F. A. P. (1809–1889)	President of Columbia University (1864) and president of the American Association for the Advancement of Science. An authority on weights and measures, he took issue with the conclusions about the Pyramid drawn by Piazzi Smyth and other pyramidologists.
Behdet	Town in lower Egypt which was the capital of Egypt in predynastic times. In Ptolemaic times it was the capital of a nome and was known to the Romans as Hermopolis Parva. In Stecchini's reconstruction of the ancient geography, Behdet was the northern limit of Egypt, 7 1/2° north of the Tropic.
Belzoni, Giovanni Battista (1778–1823)	Italian explorer and adventurer. A large and powerful man, six feet seven inches, who exhibited himself in feats of strength. He came to Egypt to demonstrate a hydraulic machine he had invented, but when the machine proved unsuccessful he turned to archeology and discovered several tombs as well as the entrance to Kephren's pyramid. A narrative of his exploits was published in 1820.
Biot, Jean Baptiste (1774–1862)	French physicist, professor of mathematics at Beauvois and professor of physics at the Collège de France. A prolific writer, he covered a wide field of physical science, becoming a member of the Academy of Sciences and a commander of the *Légion d'Honneur*. He was especially interested in the astronomy of the ancient Egyptians.

The Book of the Dead	An Egyptian collection of hermetic inscriptions and papyri purportedly providing funerary and ritual texts.
Borchardt, Ludwig (1863–1938)	German Egyptologist. Studied Egyptology at Berlin University under Professor Johan Erman. Worked at Philae in Egypt in 1895, and conducted many excavations in subsequent years. Inaugurated the great Catalogue of Cairo Museum with Professor Gaston Maspero. Founded German Institute of Archeology in Cairo. A bibliography of his many writings was issued in 1933.
Bouchard, Pierre-François-Xavier, Captain (1772–1832)	Engineer working on Fort Julien near Rosetta, 70 kilometers east of Alexandria, in 1799 found the Rosetta Stone as part of an old wall.
Brugsch, (Pasha) Karl H. (1827–1894)	German Egyptologist sent to Egypt by the Prussian government in 1853. Consul general in Cairo, 1864, then professor of Egyptology at Göttingen, 1868. Director of School of Egyptology in Cairo. Published a demotic grammar, a hieroglyphic dictionary, and a history of Egypt.
Brunés, Tons	Danish consulting engineer and Freemason who devoted a score of years to resolving the problems of ancient geometry. In 1967 he published a six-hundred-page two-volume book, *The Secrets of Ancient Geometry,* in which he attempted to substitute a "Sacred Cut" for the Golden Section or phi relation.
Budge, Sir Ernest Alfred Wallis (1857–1934)	Orientalist. Keeper of Egyptian and Assyrian Antiquities at the British Museum. Large published output including popular and semipopular works. Compiled an Egyptian dictionary, and a full edition of *The Book of the Dead.*
Burattini, Tito Livio (16?–1682)	Italian follower of Father Athanasius Kircher. Made several trips to the Great Pyramid and took measurements with Greaves which were used by Newton in his first calculations for the theory of gravitation. A Venetian by birth, Burattini spent the better part of his maturity in Poland. Author of works on standards of measure and the use of pendulums.
Cabala	A system of mystical interpretation of Scriptures practiced by certain medieval Jewish rabbis and certain Christian sects, on the assumption that Scriptures have an occult meaning.
Campbell, Patrick, Colonel (1779–1857)	Army officer and diplomat. British consul general in Egypt, 1833 to 1840. Associate of Colonel Howard-Vyse in exploration of pyramids, who named for him one of the construction chambers above the King's Chamber in the Great Pyramid.
Cardano, Girolamo (1501–1576)	Milanese doctor, mathematician, and astronomer, author of several books. His works in mathematics include treatises on arithmetic and algebra. He referred to ancient traditions as indicating the Great Pyramid incorporated an earth commensurate unit of measure of great exactness.
cardinal points of the compass	North, east, south, west.
cartouche	An oblong figure containing a Pharaoh's name.
Cayce, Edgar (1877–1945)	American clairvoyant whose thousands of readings while in trance are filed in a foundation created in his memory at Virginia Beach, Virginia. Had many memories as a being at the time of Atlantis and the construction of the Pyramid, but readings lack solid data.
Cassini, Gian Domenico (1625–1712)	French astronomer and geodesist of Italian origin, founder of a family of geodesists. He measured meridian arc through Paris.

Was assisted by his son Giacomo (1677–1756), who was assisted by his grandson Cesare Francesco (1714–1784). His great-grandson, Giacomo Domenico, also a geodesist and astronomer, was born in Paris in 1747 and died 1845.

Caviglia, Giovanni Battista (1770–1845)	Genoese mariner, owner and master of a trading vessel in the Mediterranean based on Malta. Regarded himself as a British subject. Explored the pyramids and the Great Sphinx, from whose base he had great quantities of sand removed. An ingenious excavator, he discovered the outlet to the well in the Great Pyramid and was in charge of several hundred men excavating for Colonel Howard-Vyse until they quarreled. Caviglia was given to occultism and mysticism, and spent his final years in Paris as a protégé of Lord Elgin.
celestial equator	A great circle produced by projecting the earth's equator outward to the celestial sphere.
Champollion, Jean-François (1790–1832)	At 16 at the Academy of Grenoble, Champollion presented a thesis in support of Father Athanasius Kircher's idea that Coptic was a degeneration of ancient Egyptian. The discovery of the Rosetta Stone by Napoleon's troops helped Champollion to decipher the system of ancient Egyptian hieroglyphs.
clinkstone	Compact grayish rock which clinks like metal when struck.
clinometer	A device to measure angle of slope.
Cole, J. H.	British surveyor who carried out the official survey of the Great Pyramid for the Egyptian government in 1925. His measurements made it possible to know the dimensions of the base of the Pyramid to within a few millimeters, and put an end to years of controversy.
corbeled masonry	An arrangement of stones in which successive courses project beyond those below.
Cotsworth, Moses B. (1859–1943)	British legislative enthusiast who wrote a series of pamphlets and books advocating a more rational almanac and demonstrating how the pyramids, obelisks, Druid circles, and mounds were erected as yearly almanacs. Expatriated to Canada, where he died during World War II.
Cottrell, Leonard (1913–)	British author of several books on Egyptian history and the pyramids. Writer and producer for radio and television.
Davison, Nathaniel (?–1783)	Accompanied Edward Wortley Montagu on his travels in the East. Arrived at the Great Pyramid in July of 1765, where he discovered the first construction chamber over the King's Chamber, which has since been named for him. Was later British consul general at Algiers until his death in 1783.
decans	Ten-day periods marked by the passage of constellations by which the Egyptians divided the year into thirty-six units.
declination	Angular distance of a heavenly body north or south of the celestial equator; analogous to latitude on the stellar vault.
Dendera	Ancient site of a Ptolemic temple compound about 60 kilometers north of Luxor on the east bank of the Nile dedicated to Hathor and Isis. Several temples are believed to have been constructed on the site, attributed to Cheops, Pepi I, and earlier monarchs. A zodiac on the ceiling of an upper room was removed and is now on display at the Louvre where it has been the object of heated controversy as to its age and significance.

Denon, Baron Dominique Vivant (1747–1825)	French antiquary and man of letters. Joined Napoleon's expedition and made many remarkable drawings. Published *Voyage dans la basse et la haute Egypte,* 1802, which was an instant success; translated into German and English. Appointed director-general of French Museums.
Didoufri	Fourth Dynasty king who succeeded Cheops and preceded Kephren.
Diodorus Siculus	Greek historian of the first century B.C. Published a history, or *Bibliotheca historica*, the first surviving book of which deals with Egypt, to which he traveled about 60 B.C. In his geography he quotes various lost sources.
diurnal pattern	The apparent movement of the stars in each rotation of the earth.
Dümichen, Johnnes (1833–1894)	German Egyptologist. Professor of Egyptology, Strassbourg, 1872–1894. Several publications. Traveled frequently to Egypt.
dynasties	Thirty dynasties of Egyptian kings were listed by the priest Manetho, from Menes to Ptolemy II Philadelphus. Though erratic, the list has formed the basis of Egyptian history for succeeding Egyptologists.
Edfu	Ancient temple said to have been built during the Third Dynasty. Capital city of second nome of Upper Egypt on the west bank of the Nile, 100 miles downstream from Thebes. Site of huge sandstone temple dedicated to Horus, constructed in Ptolemaic times, and found half buried in the sand by Napoleon's forces during their campaign in Upper Egypt.
Edwards, I. E. S. (1909–)	British author and Egyptologist. Keeper of Egyptian Antiquities British Museum since 1955. Visiting professor at Brown University, 1953–1954.
Egyptian mysteries	Secret knowledge of the cosmos possessed by initiates.
Elephantine	Island in the Nile just north of the first cataract, which was used as a geodetic point. Known as the city of the elephants, capital of the first nome in Upper Egypt on the border of Nubia. Opposite Syene, the modern Aswan.
Engelbach, Reginald (1880–1946)	British engineer and Egyptologist. Assisted Petrie in several digs. Appointed Chief Inspector in Upper Egypt for the Services des Antiquités. Keeper of Cairo Museum 1931. Published work on obelisks and Egyptian masonry.
equinox	Time at which the sun crosses the equator in March and September (vernal and autumnal) when day and night are of equal length all over the earth.
Fibonacci, Leonardo Bigollo (1179–1250)	Italian mathematician, known as Leonardo da Pisa. His *Liber Abaci* (1202) was for years a standard work on algebra and arithmetic. In *Practica Geometriae* (1220) he organized and extended material in geometry and trigonometry. The Fibonacci series, which he popularized in Europe in the thirteenth century, appears in the construction of the Great Pyramid several millennia earlier.
Fibonacci series	A sequence of numbers in which each is the sum of the two previous numbers—1, 2, 3, 5, 8, 13 . . . The limit of this series gives the exact value of φ.
Firth, Cecil Mallaby (1878–1931)	British Egyptologist. Served thirty years in Service des Antiquités.
geodetic gnomon	A vertical pillar whose shadow can be used to determine time, distance, and latitude.

Golden Section (ϕ proportion)
Division of a line (or geometric figure) so that the proportion of the smaller section to the larger is the same as that of the larger to the whole. For example, in the line below, the Golden Section is such that AB:AC = AC:CB.

Greaves, John (1602–1652)
Mathematician and antiquarian. Son of Rector of Colemore in Hampshire. Educated at Baliol College, Oxford. Professor of geometry at Gresham College, London. Traveled to the East to collect Arabic and Persian manuscripts. Made the first accurate survey of the Great Pyramid during a trip to Egypt in 1639. Author of *Pyramidographia*. Appointed Savilian professor of Astronomy in reign of Charles I; dismissed by Roundheads.

Hapy
The animating spirit of the Nile, self-engendered; lord of the fish represented by an androgynous divinity crowned by a papyrus reed.

Hathor
Egyptian goddess, originally a personification of the sky. In the Dendera cult, Hathor was considered the wife of Horus. The Greeks identified Hathor with Aphrodite.

heliacal rising (or setting)
Observation of a star as close as possible to the rising or setting of the sun.

heliocentric pattern
The arrangement of the planets in orbits around the sun.

Heliopolis (or On or Annu)
Northeast of Cairo on the edge of the desert; believed to be the capital of a prehistoric state. City of the Sun, embellished by a series of kings from the Third Dynasty on, it was the seat of temple of priests who numbered as many as twelve thousand. Ancient center of theological learning. It was reduced by Alexander the Great in the fourth century B.C. One of the earliest obelisks was found still standing at Heliopolis.

Herodotus (484–425 B.C.)
Greek historian born in Asia Minor. Visited Egypt towards the end of the first Persian domination. In his *History* he devoted a book (called Euterpe, after the muse of lyric song) to Egypt, giving many interesting and accurate details of geography.

Herschel, Sir John (1792–1871)
Astronomer, only son of astronomer Sir William Herschel. Made a fellow of the Royal Society at twenty-one for a brilliant mathematical investigation. Author of books on mathematics and astronomy considered among the elevating influences of the century.

Horus
Prehistoric Egyptian sky god in the form of a falcon whose eyes were the sun and moon; also called the "Behdetite" in the form of a winged sun-disk. Later incorporated in the Osiris cycle. Identified by the Greeks with Apollo.

Howard-Vyse, Colonel (later Major General) Richard William (1784–1853)
Son of General Richard Vyse and grandson of Field Marshal Sir George Howard. Retired as Colonel of Second Life Guards, 1826. Equerry to the king of Hanover. Member of Parliament. Traveled to the Middle East in 1835, where he organized excavation of the pyramids in 1837, employing Caviglia and hundreds of other workers. Discovered original casing stones and found chambers above Davison's. Author of *Operations Carried on at the Pyramids of Gizeh in 1837.*

Hyksos
Asiatic kings who invaded Egypt and formed the Fifteenth and Sixteenth dynasties. They were chased out of Egypt by Ahmosis I who founded the Eighteenth Dynasty.

ibn-Batuta (ca. 1352)	Mohammedan traveler. Said the pyramids were built by Hermes, who is the same person as the biblical Enoch, to preserve the arts and sciences, and other scientific acquirements, during the flood. Said dream occurred to King Surid that the Pyramid would be opened on the north side, so he deposited a sum of money equal to the expense of excavation.
Imhotep (ca. 2800 B.C.)	King Zoser's architect, who is accredited with the building of the stepped pyramid of Saqqara, of limestone. He is reputed to have been an author, diplomat, architect, and physician.
Ka	Metaphysical part of human being. Lived only on the essence of foods and was satisfied with facsimiles of food and mock buildings which had only façades.
Lepsius, Karl Richard (1810–1884)	German Egyptologist. Led Prussian expedition to Egypt and Nubia. Published seventeen folio volumes of *Denkmäler,* mostly epigraphic material. Keeper of Egyptian collections of Berlin from 1873.
Lieder, Rudolph Theophilus (1797–1865)	German missionary. Member of the Egyptian Society of Cairo, 1836. Collected antiquities.
Lindsay, (Lord) Alexander William Crawford (afterwards 25th Earl of Crawford and 8th Earl of Balcarres) (1812–1880)	Traveler and writer on art. His *Letters from Egypt,* etc., contain particulars on Caviglia.
Lockyer, Sir Joseph Norman (1836–1920)	English astronomer, educated on the continent of Europe; knighted for his work in spectroscopy and for identifying helium in the sun. The author of several books on the astronomy of ancient peoples, he was the first to demonstrate convincingly how ancient Egyptian temples were used as solar and stellar observatories and almanacs.
Luxor	Part of the ancient site of Thebes. A huge temple dedicated to the god Amon was built in the reign of Amenhotep III, and altered by succeeding Pharaohs, especially by Rameses II, who had many colossal statues of himself erected on the grounds.
Mandeville, Sir John (fl. 1356)	Fabulous writer of traveler's guidebooks. Most of his data were available in contemporary travel books and encyclopedias. His "voyages" are believed to be the work of a notary in Belgium who never traveled abroad.
Manetho	Egyptian priest and annalist in the reign of Ptolemy I who wrote a history of Egypt in Greek, only fragments of which remain. His division of the kings of Egypt into thirty dynasties is still the basic structure underlying Egyptian history.
Mariette, (Pasha) Auguste (1821–1881)	French Egyptologist. Traveled to Egypt to collect Coptic manuscripts and engaged in excavations. Appointed Conservator of Egyptian Monuments by the Khedive and settled in Egypt, where he made numerous finds which became the nucleus of the Cairo Museum.
Maspero, Sir Gaston Camille Charles (1846–1916)	French Egyptologist of Italian origin. Professor of Egyptology at Collège de France. Succeeded Mariette as director of the Services des Antiquités. Wrote many scientific memoirs and a large number of popular books and reviews.
mastaba	An oblong masonry structure with sloping sides and a flat top, usually above a deep pit.

Menes (fl. 3400 B.C. [3500?])	First historic ruler of the First Dynasty of ancient Egypt, who is reputed to have united the southern and northern kingdoms and settled on a new capital on the Nile at the point of juncture at Memphis.
mensuration	The science of measurement.
meridian	A great circle passing through the poles of the celestial sphere and the zenith of a fixed point on earth.
Meroe	Village in the Sudan on the Nile north of Khartoum which still has ruins of temples and pyramids.
Middle Kingdom	Twelfth to Fourteenth dynasties, from 2000 to 1600 B.C. Follows first intermediate period of chaotic conditions. The capital was at Thebes.
Minutoli, Johann Heinrich Carl, Freiherr von (1772–1846)	Prussian officer of Italian origin. Collected large quantities of antiquities. Published *Mes souvenirs en Egypte*.
New Kingdom	Covers Eighteenth and Nineteenth dynasties, 1580–1350 and 1350–1200 B.C. The Hyksos invaders were crushed and a military state embarked on wide conquest from as far as Cush to the Euphrates.
nilometer	An instrument for measuring the height of the Nile.
Nubia	Ancient region, originally called Cush, extending from the Nile Valley near Aswan southward to the modern Khartoum, east to the Red Sea and west to the Libyan desert.
obelisk	A tapered four-sided pillar used for measuring shadow length, usually inscribed with hieroglyphs proclaiming the achievements of a Pharaoh.
omphalos	Navel, or a central point on the surface of the earth.
Pepi	Two pharaohs of the Sixth Dynasty.
Perring, John Shae (1813–1869)	British civil engineer. Assistant to manager of public works for Khedive Mohammed Ali. Assisted Colonel Howard-Vyse in survey and exploration of the pyramids. In 1839 wrote and drew pictures for a large folio, *The Pyramids of Gizeh from Actual Survey and Measurement on the Spot.*
Petrie, Sir (William Matthew) Flinders (1853–1942)	Egyptologist, son of William Petrie, a civil engineer, and Anne, daughter of Matthew Flinders, the explorer of Australia. Surveyed ancient British sites such as Stonehenge before making first scientific survey of Giza hill. Founded the British School of Archaeology in Egypt. Responsible for many excavations and numerous books. He is considered the father of modern scientific archeology.
ϕ (phi) proportion	See Golden Section.
π (pi)	The constant by which the diameter of any circle may be multiplied to give its circumference.
Picard, Jean (1620–1682)	French astronomer, noted for having made the first accurate modern measurement of a degree of the earth's meridian. His figures enabled Newton to calculate the force of gravitation. Occupied the chair of astronomy in the Collège de France in 1655. Largely responsible for the establishment of the Paris Observatory and the appearance of *Connaissance des temps,* the first two volumes of which he authored.
Pococke, Richard (1704–1765)	Traveler and divine, bishop of Ossory (1756–1765). Ascended the Nile as far as Philae. The manuscript journal of his travels is in the British Museum.

precession of the equinoxes	Each year at the spring equinox the constellation in the sky where the sun rises due east appears to have fallen back about twenty minutes. This phenomenon, or precession, is caused by a slow toplike wobble of the earth on its axis which takes about 26,000 years to cycle.
Proctor, Richard Anthony (1837–1888)	English astronomer and popular writer on scientific subjects. Founded the popular scientific magazine *Knowledge*. Lectured in the United States and Australia. Author of many books on science and astronomy. Developed the theory that the Great Pyramid had been designed and used as a great astronomical observatory while still a truncated body at the level of the King's Chamber.
Ptah	Called Hephaistos by the Greeks. Egyptian god of the city of Memphis, portrayed as a human figure in a tight mummy wrapping. Considered the creator of the world who produced visible phenomena through thought and the word. The protector of artisans. His high priest was the doyen of master craftsmen.
Pylon	A double tower with rectangular base pierced by central door to a temple. The temple of Karnak had ten pylons.
Pythagoras' theorem	The square of the hypotenuse of a right triangle is equal to the sum of the squares of the other two sides.
Ra	The sun, later deified. Creator of the world, was said to be swallowed at night by Nut and recreated fresh each day.
Reisner, George Andrew (1867–1942)	American Egyptologist (Ph.D., Harvard University, 1893). Director of the Hearst expedition to Egypt 1905–1907. Excavated for Harvard University for many years in Egypt, particularly at Giza. Professor of Egyptology at Harvard (1914–1942). Curator of Egyptian Department, Boston Museum of Fine Arts (1910–1942). Author of several books on archeological excavations.
Rhind, Henry Alexander (1833–1863)	Scottish lawyer and traveler. Owing to ill health was obliged to winter in Egypt. Excavated at Thebes and bequeathed collection to National Museum of Antiquities, Edinburgh. Noted for the Mathematical Papyrus (BM10057–8), which was sold to the British Museum, and is considered the oldest manuscript dealing with Egyptian mathematics.
right ascension	The arc along the celestial equator which separates a star from an arbitrary zero point; analogous to longitude around the stellar vault.
sacred triangles	Right triangles with sides in such proportions as 3–4–5 or $2–\sqrt{5}–3$, which were credited with magic or esthetic properties.
Saqqara	Situated 28 kilometers south of modern Cairo, just west of Memphis and south of Giza. Ancient burial site named after Sokar, the god of measure. Graves date from the First Dynasty. Pyramids attributed to the Fifth and Sixth dynasties. Site of the stepped pyramid built for King Zoser of the Third Dynasty by the architect Imhotep.
Schwaller de Lubicz, R. A. (?–1961)	Philosopher, archeologist, and author who spent twelve years at Luxor reconstructing the philosophical and theological system of the ancient Egyptians. Born in Alsace, he was granted the title Chevalier de Lubicz by O. W. de Lubicz Milosz for his help after World War I in obtaining independence for the Baltic States.
sextant	An instrument for precise measurement of angular distances to determine latitude and longitude.

sidereal year	The time it takes the earth to revolve around the sun so that an observer will see a given star reappear in the same position—about 20 minutes longer than the solar year.
Sneferu (ca. 2700 B.C.)	First king of the Fourth Dynasty. Father of Cheops. Built bent pyramid at Medûm.
solar parallax	The angle formed by the semidiameter of the earth as regarded from the sun, or 8.80″.
solar year	The time between two successive equinoxes 365 days, 5 hours, 8 minutes, 49.7 seconds 365 days, 5 hours, 48 minutes, 46 seconds
solstice	The two points—in summer and winter—when the sun is at its greatest declination north or south of the equator.
Sothic year	365 days, 6 hours—introduced in ancient Egypt to correct the civil calendar year of 365 days. A "Sothic cycle" began when civil and Sothic new year coincided.
Syene	Site of the modern Aswan. The southern limit of Egypt at the First Cataract of the Nile, close to the Tropic of Cancer. Nearby quarries supplied the hard granite monoliths for the King's Chamber in the Great Pyramid and for the tall Egyptian obelisks used for measuring shadows.
Taylor, John (1781–1864)	Devoted his early years to publishing in London, becoming editor of the *London* Magazine. An amateur astronomer and mathematician, he was also a student of Scripture and devoted much time to mastering Old English, Welsh, French, and Italian. His *The Great Pyramid: Why Was It Built & Who Built It?,* published in 1854, established the π proportion in the pyramid, but his theory, that the Great Pyramid had been built under divine guidance, caused his work to be disputed and he was given little recognition.
Thebes	Ancient city in upper Egypt renowned in antiquity for its hundred gates. Became prominent with the Eleventh Dynasty (c. 2160 B.C.) for the worship of Amon. Went into decline when the locus of power shifted to the Nile Delta. There is a nearby large necropolis where kings and nobles were entombed. It was sacked by the Assyrians in 661 B.C. The remains of the temples of Luxor and Karnak are still among the most impressive in the world.
theodolite	A telescopic instrument for precise measurement of horizontal angles, used in land surveying.
Thoth	Lunar god in form of Ibis, patron of scribes and calendars. The Hermes of the Greeks.
triangulation	By carefully measuring a base line and the angles formed by either end of it with a distant point, the distance of the point may be calculated by trigonometry.
vernier	A small moveable scale attached to a large scale for obtaining finer fractions of measurements.
ziggurat	The stepped-pyramid temples of Mesopotamia.

PART IV RAISING THE SHROUD

PART V SCIENTIFIC ANALYSIS

PART VI PREHISTORIC REAPPRAISAL

Acknowledgments

I am most indebted to the authors and artists whose works are analyzed, reproduced, and credited within this volume, and to those at Harper & Row who made the volume possible, especially M. S. Wyeth, Jr., Gayle Jaeger, Kathleen Hyde, Lynne McNabb, Florence Goldstein, and Bill Janson, whose constant and invigorating collaboration made the work a pleasure. To Nicholas Vreeland and Edward Michell I wish to express my thanks for their care in making prints for the many reproductions. Indeed to all who gave me help, and in particular to the librarians of the Library of Congress and of the University of Miami for the kind use of their facilities, my gratitude.

Preface

Deep in the jungles of Mexico and Central America, in the tight embrace of root and vine, clawed by jaguar or caressed by rattler, lie the remains of perhaps thousands of ancient pyramids, pyramids on pyramids, many still undiscovered, abandoned by unknown builders at an unknown time for unknown reasons. In their secret places may lie more of the precious codices and hieroglyphic writings—celestial mathematics sculptured into geometric form—which make it possible to reconstruct the brilliance of a civilization which the Church of Rome did all in its power to obliterate. Under the axe and torch of Spanish conqueror the ancient wisdom was reduced to superstition.

For centuries this brutal story lay buried in the archives; when it surfaced it was disbelieved. Mesoamericans were described as ignorant and brutish.

Just as Egyptologists could not believe that in ancient Egypt someone had accurately measured the circumference of the earth, placing geodetic markers by astronomical observation as accurately as surveyors do today, orienting their buildings within seconds of true north, so Americanists were reluctant to recognize or admit that in their ancient glyphs and codices the Maya showed astronomical computors so sophisticated they could and still can be read by a schoolboy. The Maya, it is now clear, constructed calendars of the synodic return of the planets laced with the cyclic phenomena of solstices, equinoxes, and eclipses of the sun and moon.

Though the Aztec calendar stone has become the shopworn memento of a tour of modern Mexico, there is still reluctance in the academies to acknowledge that its superlatively aesthetic and intricate design is a perpetual cosmic clock accurately marking for the layman cycles of the visible bodies of our solar system not only in the present but deep into the future and the past.

There is no science without measure. The Maya saw their supreme deity, *Hunab Ku,* as sole dispenser of movement and measure, whose symbol, the compassed circle and the square, was identical with that of the Great Architect of modern Masonry. In the Middle East the ancients adopted the second of arc, of which they counted 1,296,000 to a circle ($360 \times 60 \times 60$), and the second of time, of which they counted 86,400 to the circuit of a day ($24 \times 60 \times 60$).

From the first second they derived their foot (of .3079 meters). One hundred such feet, they said, will be one second of arc. From the second second they derived their cubit (of .4618 meters). One thousand such cubits, they said, is the distance traveled by the earth at the Equator in one second of time.*

With these units Middle Easterners measured the cosmos and its cycles, incorporating the results, along with the mathematical constants of its structure, into their architecture—as in the proportions of the Tower of Babel and the Pyramid of Cheops. Middle Americans did likewise, as can now be extrapolated from their pyramids.

One look at the passages of the Egyptian temples was enough for astronomers Proctor and Lockyear at the end of the nineteenth century to conclude that the structures had been designed and used in antiquity for astronomical observation and for the recording of such vital data as the equinoxes and the soltices. One look at the pyramidal structures of Yucatan and Chiapas, with their corbelled walls rising to single moveable capstones (like the Grand Gallery at Ghiza, or the "tombs" of Mycenae, or of Maes-Howe), is enough to show that they were built for astronomical observation, with frets and cockscombs that could function as markers for the rising, transit, and setting of heavenly bodies.

As with the Great Pyramid of Ghiza, the Sun Pyramid at Teotihuacan was used to mark the solstices, zenith days, and equinoxes. The stelae of Guatemala, intricately carved or stuccoed, clearly served the same function as the intaglioed obelisks of Egypt, by means of which the ancients accurately measured the size of the earth, mapped it, and chronometrically ticked off the cyclic passage of the ages.

* Both units are truly earth-commensurate fractions of the earth's circumference in that $129{,}600{,}000 \times .308$ or $8{,}640{,}000 \times .462 = 39{,}916.80$ kilometers—very close to the 40,000 kilometers adopted as the circumference of the earth by the devisors of the meter in the eighteenth century.

The study of the extraordinary effects on this planet of the comings and goings of other planets in conjunction with each other and with the sun and moon, only to be monitored by constant and accurate observation and the most sophisticated coding, has been derided by moderns as "astrology"; yet, with blinding science, we treat our nursing mother earth as dirt beneath our feet, and the living cosmos as a bottomless pit for our onanistic spaceshots.

We live in a Dark Age, and have, for several thousand years. It is time for a renaissance—with the wisdom of the past.

Architecture, says architect Robert Stacy-Judd, consists of frozen symbols, which can be thawed into a palatable language, "where measures and motifs are words and sentences." Augustus Le Plongeon calls architecture an unerring standard of the degree of civilization reached by a people, "as correct a test of race as is language, and more easily understood, not being subject to change." If it is true that a nation's capital reflects its standards of architecture, we risk being judged by the phony cyclopean walls of the Office Building of the U.S. House of Representatives unless we engender architects sensitive to the cosmic values of geometry, such as R. Buckminster Fuller would envisage.

The ancient civilizations attached great importance to numbers as an exact language in which physical and spiritual ideals could be expressed and preserved; hence, they built their numbers into buildings.

As John Michell has pointed out, their monuments contain, both in their dimensions and their relative geographical positions, the whole vocabulary of the sacred language of the past. Michell believes such buildings as the Great Pyramid of Cheops were built by men who knew something of the laws which govern the intergalactic flow of living energy and their application to the development of life on earth. "The enormous task of building the Great Pyramid, the crowning achievement of prehistoric science," says Michell, "could only have been undertaken by men whose faith in the value of their labours derived from a certain knowledge of universal law. The key to every art and science may one day be rediscovered within the effortless harmony of the Pyramid's numerical scheme." To which he adds: "Written across the face of the country in letters of earth and stone the cosmic knowledge of the ancient world is now within reach."

PART

SETTING THE STAGE

1. Return of the "Gods"

Hernan Cortes shortly after the fall of Mexico.

A freebooter who had betrayed his superiors in Havana, Cortes was 34 years old when his armada of eleven ships landed at Veracruz on the east coast of Mexico in April of 1519. Syphilitic and bowlegged from an injury acquired in a fall from a room during an amorous quest, Cortes was described by his countrymen as robust, with a deep chest and broad shoulders. His hair and beard were black and thin. Considered a good horseman, swordsman, and a great infighter with a knife, he was also renowned as licentious, gluttonous, fond of dice, and avid for women and gold. Born in the Estremadura region of Spain, Cortes had an inborn genius for treachery and could be unbelievably brutal and cruel, boasting to Charles V of Spain that he had massacred unarmed women and children in order to impose his will upon the natives.

In the Mexican highlands, in a pocket valley protected from the cold north wind by the bulk of an extinct volcano, lie the monumental remains of an ancient civilization. These weird and majestic ruins, dominated by two pyramidal mounds, lay undisturbed for centuries. First seen by Europeans when Hernan Cortes and his rabble army invaded Mexico in 1519, they have remained a source of conjecture to succeeding generations. Only now, since the beginning of the twentieth century, is the riddle of their nature beginning to unravel.

While William Prescott and others have told the story of the Conquest of Mexico in detail vivid enough to dazzle, the more sinister story of the burial, destruction, and vilification of the lore enshrined in these pyramids has largely gone untold. Intertwined, the stories reveal a struggle between two powerful forces vying for the souls of men.

Native historians described the arrival of the conquistadores as a succession of grim fatalities.

Though all the omens had foretold their coming, and an impending destruction of the Aztec empire, the actual landing of the Spaniards was so astounding to the first eyewitness that despite the loss of all his toes he climbed seven thousand feet to Mexico's highland capital of Tenochtitlan to inform King Montezuma II that towers and small mountains were floating in the sea, bearing strange beings from an unknown world with very light skin, long beards, and hair only to their ears.

Montezuma, a slender aristocratic man with a long spare face, was aware from the sacred texts of the Mexica that Quetzalcoatl, man or god, had promised to return from the East in the year 1-Reed. And this was the year 1-Reed.

In his fifties when Cortes landed in Mexico, Montezuma II looked more like forty and was described by the Spaniards as of good height, well proportioned, slender and spare, with a brown complexion and hair that just covered his ears. His beard was thin, black, and well shaped, giving his face an expression of both tenderness and gravity. He was considered very neat and clean and affected the Spaniards by the airs and gestures of an accomplished prince. His name was an honorary title meaning "our angry-looking lord," because an Aztec ruler was admonished "never to laugh and joke again as he had done previous to his election, and to assume the heart of an old, grave and severe man." He was considered a temporary representative and mouthpiece of an invisible, impersonal dual divinity. "You are the image of our lord god and represent his person. He reposes in you and he employs you like a flute through which he speaks, and he hears with your ears." Considered a learned astrologer and philosopher who was skilled in the arts, Montezuma succeeded to the Aztec throne in 1502 at the age of 36, elected by a Council of Six from among members of his predecessor's family, chosen because of his high attainments. Head of the army and of the church, with the official title of First Speaker, Montezuma governed through a Council of Three: the commander of the army (known by the title of "Snake Woman"), the high priest, and the governor of Tenochtitlan. Montezuma is reported to have ruled well and administered impartially and rigorously. To investigate how his ministers executed their offices he would disguise himself and move about his realm incognito. Montezuma told Cortes his forefathers had come from a land far away called Aztlan, where there was a high mountain and a garden inhabited by the gods.

As Cortes moved toward the Mexican capital with his gang of four hundred Spaniards, supported by thousands of native tribesmen happy to rebel against what they considered Montezuma's tyrannical rule, more messengers reached Tenochtitlan describing the newcomers as supernatural creatures riding on hornless deer, preceded by wild animals on leashes, dressed in iron, armed in iron, fearless as gods.

Spaniards say that when Cortes reached the city of Cholula, with its hundreds of whitewashed temples over which loomed the remnants of the largest pyramid in the Americas, his ambassador, whom he had sent ahead to seek peaceful surrender of the city, was returned with severed wrists dangling from flayed elbows. True or not, Cortes massacred six thousand Cholulans.

Cortes advanced on Mexico with fourteen horses and many cannon, neither of which had ever been seen by his Mexican opponents.

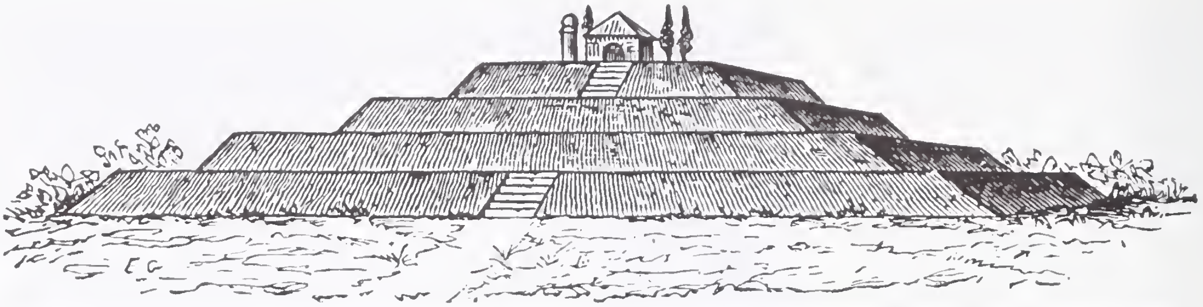
To reach Tenochtitlan entailed crossing two passes 10,000 feet high where hail fell and an icy wind drove down from the snowy mountains; it also meant crossing a desolate plateau of volcanic ash forty miles wide. Cortes, outnumbered thousands to one, hoped to seize the Aztec capital by guile rather than force.

The prime weapon in his arsenal, apart from the thousands of rebellious natives who supported him, was psychological. Their legends told the Mexica that white gods from the East would return to conquer Mexico, and there was no struggling against their fate.

Shocked by the news, Montezuma vacillated between defiance and surrender. Cortes and his followers were described to him as advancing in battle array, the dust rising like whirlwinds, their spears glittering in the sun, their pennons fluttering like bats, their armor rattling in the cold November wind.

At the Pass of the Eagle, by the snowcapped volcanoes of Popocatepetl and Iztaccihuatl, Montezuma's envoys knelt before the Spaniards and adored them as the Sons of the Sun, their gods. Had not the divine Quetzalcoatl dressed in black velvet as did Cortes? And, they whispered, judging from the size of the latter's stuffed codpiece he had the makings of a god.

Ahead of Cortes stretched the Valley of Mexico, a lovely plateau half filled with shallow lakes, called "Of the Moon," alive with fish and waterfowl, its clear waters mirroring the surrounding mountain forests, its shores brightened by the villages and cities of the Mexica.



At Cholula, Cortes was greeted by girls singing, dancing, and playing on instruments, while others brought bread and fowl. Nobles, chieftains, and common folk, "unarmed, with eager and happy faces, crowded in the great courtyard of the Temple of Quetzalcoatl to hear what the white men would say." The Spaniards then closed the entrances and at a signal fell upon the Cholulans. "Those of Cholula were caught unaware. With neither arrows nor shields did they meet the Spaniards. Just so they were slain without warning. They were killed by pure treachery; they died unaware."

Montezuma planned to recognize Cortes, by sending him—along with many fine presents—the insignia of the God Quetzalcoatl, whom he believed him to be. This way Montezuma hoped to keep Cortes from Mexico City.

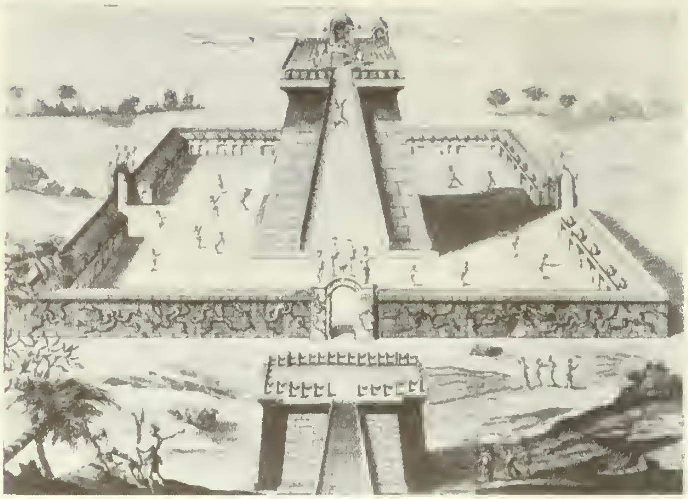
The ambassadors were told to tell Cortes that the treasures were "all priestly ornaments that belonged to him." Among the presents were two circular calendars as large as cartwheels, one of gold, the other of silver, both elaborately engraved with hieroglyphs, and both of which were melted down for ingots. Some of the presents reached the Emperor Charles V and were greatly admired by Dürer.

With Montezuma's ambassadors went a group of enchanters and witchmasters to try to keep Cortes away.

In his famous speech to Cortes, which the latter carefully reported to the Emperor Charles V, Montezuma stated that: "We [the Mexican rulers] were brought here by a lord, whose vassals all of our predecessors were, and who returned from here to his native land. He afterwards came here again, after a long time, during which many of his followers who had remained, had married native women of this land, raised large families and founded towns in which they dwelt. He wished to take them away from here with him. But they did not want to go, nor would they receive or adopt him as their ruler, and so he departed. But we have always thought that his descendants would surely come to subjugate this country and claim us as their vassal."

Nahuatl pyramids usually had two stairways leading to two temples, as with the central Aztec pyramid in Tenochtitlan, dedicated to Tezcatlipoca, believed to have been built six years before Columbus rediscovered America.

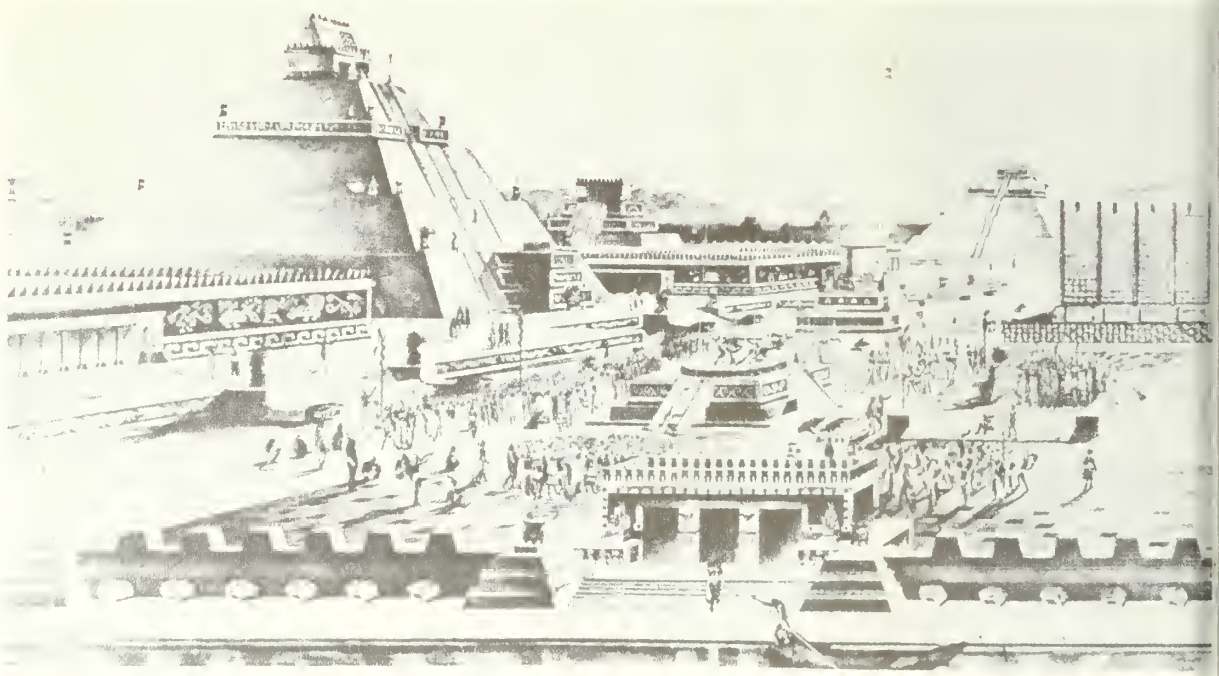
Bernal Diaz said it was 54 meters high with 114 steps, and that it measured 97 meters at the base. In the interior of the top sanctuary there existed a small stepped pyramid dedicated to the sun, known as the Cuauhcalli, "House of the Eagles." Here the steps represented the heavenly planes, the highest level corresponding to the hour of zenith or midday.



The city of Tenochtitlan, divided into four quarters, each of which had five subdivisions (*calpullis*), actually consisted of two distinct parts. One of these was Tenochtitlan proper, where the Great Temple stood and where Montezuma and the lords resided; the other was Tlatelolco, where the lower classes dwelt and the merchant class prevailed.

A large temple occupied the center of Tenochtitlan, a city, according to Cortes, of five hundred palaces, well built of stone, whose walls were crowned with battlements and ornamented with serpents.

Cortes said there were "forty very high houses in the enclosure of the Great Temple" and that they were all "sepulchres of the lords." The more substantial houses occupied the central sections of the capital, where the land was higher and firmer. Canals, bright green with water vegetables, encircled and crisscrossed the city, which an Aztec poet described as spread out in circles of jade, radiating flashes of light like quetzal plumes.



According to Bernal Diaz' eyewitness report, when the great Montezuma came forth in state to meet Cortes, he was conveyed on a sumptuous litter with a baldaquin over his head adorned with light greenish-blue feathers, gold, pearls, and jade to represent "the verdant or blue sky." He was supported by his four principal lords; and the golden soles on his sandals prevented his feet from coming into direct contact with the ground. Other lords preceded him, "sweeping the ground and spreading blankets upon it so that he should not tread upon the earth. All of these lords did not dare to think of raising their eyes to look at his face—only the four lords, his cousins, who supported him, possessed this privilege." On state occasions Montezuma, like his predecessors, was the only person privileged to sit on a throne or raised seat with a high back.

When the Spaniards first glimpsed the island capital of Tenochtitlan—glimmering like an exotic Venice at the end of a wide causeway, with stunning palaces, temples, and pyramids, stuccoed pink with volcanic ash, rising from the cerulean waters of the lake—they thought they were dreaming.

Though many had seen the splendors of Rome and Constantinople, they were amazed at a city of 300,000 inhabitants fed by fresh-water aqueducts, laced with canals and carefully paved streets, adorned by arcaded squares twice as big as Salamanca's, serviced by a market place where 70,000 Indians daily bought and sold a thousand different products, from filigreed jewelry to mountains of polychrome feathers, including those from the rare quetzal bird.

The Spaniards were enchanted by such luxuries as botanical and zoological gardens, by elegantly towered palaces, higher than the cathedral of Seville, surrounded by large and beautiful private houses with fragrant gardens shaded by bright cotton awnings where courtly nobles feasted on fruits and vegetables, sauces and soups, fish and meat, cakes and pies, varied by such delicacies as maguey grubs with hot chili, winged ants with savory herbs, and rats in chocolate sauce.

According to Aztec tradition, the city of Tenochtitlan was modeled after the lost capital of their original homeland, situated on an island in the middle of a lake surrounded by rings of canals and interconnecting dams.

Migrant Chichimecs serving in the Toltec army, who called themselves Aztecs after their mythical home in Aztlan, built the city of Tenochtitlan on a marshy island in the Lake of the Moon in A.D. 1345. The city was connected to the mainland by three causeways: north to Tepeyacac, west to Tlacopan, and south with two branches to Ixtapalapa and Coyoacan. The city, including Tlatelolco, covered some 7 1/2 square kilometers built around temples and public buildings. According to the Aztec legend, their god, Huitzilopochtli, sometimes in the guise of a hummingbird, had urged them on until they reached the island, which was said to have the same magical properties of their homeland in Aztlan.

Searching for a mote in the Mexican eye, the Spaniards claimed to be horrified by the native indulgence in unbridled sodomy, by their orgies of ritual sacrifice in which priests, each with his own penis slit to achieve pure chastity, would roast alive or rip out the pulsing hearts of an estimated 50,000 human victims a year to feed the local gentry and satisfy the theory that their solar divinity needed human blood lest it vanish from exhaustion.

On the excuse of bringing to the natives a better form of religion, the Spaniards, tough, mean, and hungry for gold, massacred without warning the unarmed cream of their hosts' warrior nobles who were innocently celebrating a feast day with a dance.

Blood-encrusted Aztec priests were accused by the Spaniards of performing 50,000 human sacrifices a year. Diaz accused them not only of human sacrifice but of cannibalism, sodomy, incest, and such drunkenness that when they could no longer stand "they lay down and did have the liquor injected by squirt into the breach." Diaz gives a description of Aztec priests half roasting a man, pulling him off the coals with grappling irons to cut out his still beating heart. He says the walls of the temple were splashed and encrusted with blood whose stench was unbearable.

Montezuma was reputed to have been fed on the little fingers of small boys as a delicacy. But Cortes stated that he never actually saw a ritual sacrifice, that the only human sacrifices he witnessed in Tenochtitlan were the normal executions of prisoners of war during the siege. Voltaire believed the Spaniards to have fabricated or grossly exaggerated the charges of Aztec human sacrifice to justify their own brutality.

Later historians have attributed subtle metaphysical motivations to Aztec sacrifices, pointing out that the Aztecs believed the earth to have already been through four cataclysmic periods, and that the only way to stave off a fifth was by human sacrifice. As "Sons of the Sun," the Aztec priests saw the earth as metaphysically nourished by a sun which in turn needed the sacrifice of human blood for its nourishment. Hence the hearts of victims—perhaps by the thousands—were ripped out to stave off cosmic disaster.

This act of infamy brought such retribution from Montezuma's braves that on what came to be known as "The Night of Sorrows" Cortes lost the better part of his army and had to flee the city. Pursued by the braves of Tenochtitlan, Cortes escaped along the river north of Lake Texcoco into a gentle valley dominated by the peak of volcanic Cerro Gordo. There, in the shadow of two pyramidal mounds, the remnants of Cortes' forces, all of them wounded, faced the greatest number of enemy warriors ever mustered for a single battle in the Indies. Tens of thousands of Indians from Otumba, Texcoco, and the cities around the lakes crowded into the valley waving shields, banners, and plumed helmets, convinced they had come to witness the death of every Spaniard.

With no hope of retreat, Cortes and a small group of horsemen charged the center of the enemy forces, where they killed their captain general, the "Snake Woman," causing such panic in the guard that it spread to the hordes of Indians, who retreated, leaving Cortes to live another day. Decimated, bedraggled, and in fear of their lives, the Spaniards paid little attention to the amazing sight around them of a great sleeping city dominated by two gigantic mounds. No one could tell them who had built the great ceremonial center, whence the builders had come, or whither they had gone. All they could learn was that two centuries earlier, when the Mexica had arrived in the valley, they had found the mysterious city already in an abandoned condition, covered with earth and vegetation. Because of the legend that the gods had used the center in antiquity, the Mexica

La Noche Triste.

On the night of June 29, Cortes and his men slipped out of Tenochtitlan along the Tacuba causeway carrying a portable bridge to cross the eight bridges destroyed by the Aztecs. Attacked by Montezuma's followers, Cortes lost half his forces, many being drowned by the weight of the gold they had looted. All would have succumbed had the Aztecs not taken time out for a ritual sacrifice of the captured Spaniards atop their sacred pyramids. In this hiatus Cortes and his surviving wounded forces managed to reach the plain of Otumba by the pyramids of Teotihuacan.

had named the spot Teotihuacan, which they interpreted as meaning either "the burial place of kings" or "the place where the lords of the people woke from the dream of life to become gods."

The greater mound, venerated by the Mexica till the arrival of the Spaniards, was called "Tonatiuh" in the native Nahuatl, meaning "House of the Sun." The smaller mound was called "Metzli Ytzaqual," or "House of the Moon." The great avenue which joined the two pyramidal mounds was called "Huicautli," or "Way of the Dead" because of the smaller mounds which flanked it, assumed by the natives to be tombs.

Claiming that only giants could have constructed the larger mounds, the Mexica said they must have been built in remote antiquity when giants and sages inhabited the earth. As evidence they showed the Spaniards the femurs of elephants or mastodons dug up in the neighborhood which they believed to be the bones of giants. But the Spaniards, intent upon their own survival, paid no heed, escaping southward to the safety of their allies, the Tlaxcalans, where they plotted a revengeful comeback.

The destruction of Tenochtitlan.

A year after *La Noche Triste* Cortes returned with 450 Spaniards, forty horses, nine field guns, and 10,000 Tlaxcalan allies. He also brought a secret weapon in the form of a dozen brigantines built in Tlaxcala, carried overland to the edge of Texcoco Lake. To capture the city, Cortes planned to advance along three of the causeways on a narrow front with bunched musketeers, cannon, crossbows and cavalry, using the ships to protect his flanks. However, just before the attack, Cortes' Mexican allies, who identified him with Quetzalcoatl, deserted because the planet Venus had gone into its yearly eight-day disappearance as the evening star. When nothing bad happened to Quetzalcoatl-Cortes during the dark of Quetzalcoatl-Venus, and the planet reappeared as the morning star, 100,000 allies flocked to Cortes' aid. On August 13, 1521, after a seventy-five-day siege, and one of the most remarkable naval operations in history, Tenochtitlan fell to the Spaniards, leaving more than 240,000 Aztecs dead from wounds or disease. The people of Tenochtitlan, in the account of Lopez de Gomara, one of the eyewitness conquistadores, were "tormented by hunger, and many starved to death. There was no fresh water to drink, only stagnant water and the brine of the lake. . . . The only food was lizards, corncobs and the salt grasses. . . . The people ate water lilies and seeds of colorin, deerhides, and even pieces of leather. . . . They ate even dirt. Almost all of the nobility perished; there remained alive only a few lords and the little children."

According to C. Harvey Gardiner, author of *Naval Power in the Conquest of Mexico,* Cortes' daring naval maneuvers on Lake Texcoco were unparalleled; no similar victorious naval engagement ever concluded a war and ended a civilization. "One sees in kaleidoscopic panorama," wrote Gardiner, "the sweep of naval history from Ancient Salamis to Korea, ships under sail and oar—ramming, boarding, fleet action, task-force operations, blockade, liaison duty, Marine-like raids by naval landing parties, close support of land operations and psychological warfare. Like Salamis, which was fought for the control of the eastern Mediterranean, the battle of Tenochtitlan also involved the mastery of a world."

2. Indian Sacrifice

After plundering Tenochtitlan, Cortes branded the faces of its inhabitants with hot irons and attempted to force divulgation of the location of the fabled Aztec treasure. Though $15,000,000 worth of gold was found this represented only part of what was known to exist.

For his efforts Cortes was ennobled by the King of Spain and made marquess of the Valley of Oaxaca, captain general, and given a large estate with 23,000 vassals. But Cortes became bitter at not having been appointed viceroy to the country he had conquered. He did grant Montezuma's son a quarter of Mexico City as a fief, and in Spain arranged for the marriage of Montezuma's surviving daughters to members of the Spanish nobility. Having given to one of his subordinates as wife the native mistress of his adventures, La Malinche, without whose intermediary efforts he could hardly have conquered New Spain, Cortes married Doña Juana de Zuniga, niece to the Duke of Bejar.

When Cortes returned with enough Spaniards and native allies to defeat the Mexica, he ordered the great and beautiful city of Tenochtitlan destroyed; palaces, columns, and gods were buried in the mud. To avoid the stench of the dead, the Spaniards set up camp in the nearby village of Coyoacan. Groups of captive Indians razed every last building of the Aztec capital and filled in the canals till not a stone was standing. On the leveled ruins Cortes founded his own great capital, Mexico City, patterned on a feudal model already dying in Europe.

Mexican slaves by the thousands, many of them highly skilled as sculptors, carpenters, masons, and gardeners, hauled stone and timber from the debris of Tenochtitlan. Iron

chisels and iron hammers enabled them to cut the porous red stone of the valley into palatial European houses, over the doors of which the new hidalgos could place their carved escutcheons. Where Indian palaces and pyramids had stood, churches and monasteries sprang up complete with battlements, buttresses, and heavy grilled windows against the Indians who had built them.

The Flemish artist Theodore de Bry depicted Indians hanging themselves or taking poison in acts of mass suicide from shock at the overthrow of their culture. So great was the terror in Mexico about 1530 that Indians desisted from relations with their wives to avoid having children doomed to slavery. When asked to describe Christians, an old chief replied, "They ask for maize, for honey, for cotton, for women, for gold, for silver. Christians will not work, they are liars, gamblers, perverse, and they swear."

Surviving on drinking water and a few tortillas, the Indians, at their own expense, supplied all the work and all the material. Brought up from childhood to a Spartan life, trained to endure pain, they worked long hours without showing fatigue, constantly subjected to unbelievable savagery by the Spaniards.

Individuals were torn from their families to work as slaves in gold and silver mines, branded on their faces each time they changed masters. The prettier women were raped and infected with the pox, smallpox, leprosy, and all manner of plagues. By 1545, in Tlaxcala alone, a quarter of a million Indians had died of the plague: altogether 3 million were to

The Plague.

As a result of the Spanish Conquest, the population of Mexico was reduced to one-tenth. Indians, formerly in very good health, were weakened by hunger and fatigue and became easy prey to disease and the pox, large and small.

Fray Bernardino de Sahagun tells how he personally buried more than 10,000 victims of the plague, often in great trenches 100 at a time.

die as disease spread to Tabasco and Yucatan. Spanish apologists retorted that their presence had saved 600,000 Indian lives from being sacrificed on the altars in the first thirty years of the Conquest. They said of the Indians that "God truly did them a great service by entrusting them to the Spaniards who converted them and treated them so well."

As land was stolen from the natives, great famines ensued, yet heavy taxes were laid on Indians; those who failed to pay were tortured to death. Indians who refused to join the Catholic Church were horsewhipped, had their heads shaved, and were forbidden to hold office or title in their villages. For failing to attend mass, or for practicing any of his old rites, an Indian could receive a hundred lashes.

According to the Spaniards, Indians were supposed to know only the Our Father, Ave Maria, Credo, and Ten Commandments: reading and writing were considered as dangerous as the devil.

In Spain an eminent jurist, Juan Gines de Sepulveda, invoked the authority of Aristotle to stigmatize the Indians of the New World as natural slaves. He maintained that as inferior beings they would benefit from the labor they performed for the superior Spaniards and that war against the Indians to force them to Christianity was not only expedient

Designed for the detection and punishment of heretics, the Inquisition was used as a giant pork barrel for the enrichment of crown, Church, and Inquisitors, while cheerfully eliminating dangerous radicals: those who had been taught medicine, geography, rhetoric, chemistry, physics, mathematics, and astronomy by Moorish philosophers in universities such as Cordova, whose libraries had since been destroyed. The Inquisition was also an excuse to rid the planet of such organized mystics as Illuminati, Pantheists, Manicheans, and Albigensians. As a result no Spaniard could write, speak, or even think without taking into consideration the torture racks and fires of the Holy Office.

All the accused were presumed guilty before trial, a trial which took place in absolute secrecy. The defendant was afforded no counsel. Accuser and judge were the same person. The names of witnesses against the defendant were withheld from him. Women, children, and slaves could not be used as witnesses by the defendant, but could be used by the prosecution, who could order them tortured to obtain further accusations. There was never any case of acquittal pure and simple.

Minor penalties could be commuted for payoff. Major penalties were either the dungeon, with single or double fetters, or the secular arm for death by fire or strangling. The crown did not interfere with the operations of the Holy Office, which could, with impunity, arrest bishops and persons close to the king.

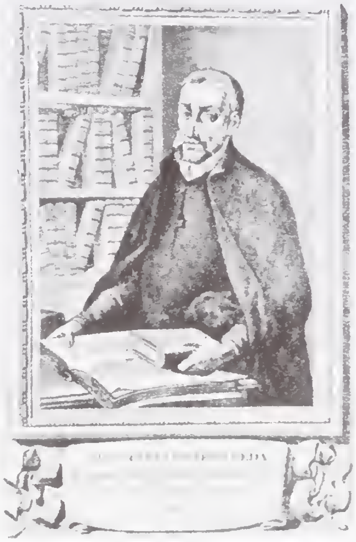
The victim's goods, subject to confiscation, were incorporated into the royal and Church domains. The Inquisitors, who paid no taxes and gave no account of confiscations effected, took their share. As a deterrent to possible opposition in New Spain thirty-four Negroes, including four women, were hanged and decapitated in Mexico City.

but lawful. Sepulveda—who never went to America and never saw an Indian in his natural habitat—considered the Indians "homuncoli, in whom you will scarcely find even vestiges of humanity, who not only possess no science but also lack letters and preserve no monument of their history except certain obscure reminiscences of some things in certain paintings."

By comparison Sepulveda considered Spaniards to be unequaled for their "frugality, sobriety, freedom from gluttony and lasciviousness," adducing as evidence their behavior during the sack of Rome, in 1527, when, as even their own historians admitted, the Spanish indulged in "the worst outburst of savagery in the annals of the period, burning monasteries and churches, violating nuns, and putting pregnant women to the sword."

In putting down the Indians, Sepulveda's ploy was to not "awaken curiosity or excite the cupidity of more scientific and enterprising nations."

Don Martin Cortes, the bastard son of Cortes and La Malinche, who was legitimized by the Pope, was tortured by the Inquisition with water forcibly poured down his throat for his alleged participation in the first major Creole conspiracy to make New Spain independent of Spain, with the Marques of Oaxaca, legitimate heir to Cortes, as first King of Mexico.



The Spanish jurist Juan Gines de Sepulveda said it was right to wage war against the Indians for four reasons:

1. For the gravity of the sins which the Indians had committed, especially their idolatries and sins against nature.
2. On account of the rudeness of their nature, which obliged them to serve persons having a more refined nature, such as the Spaniards.
3. In order to spread the faith, which would be more easily accomplished by the prior subjugation of the natives.
4. To protect the weak among the natives themselves.

Other ecclesiastics, opposing Sepulveda, especially the Dominican friar Bartolomé de Las Casas, who had crossed the ocean many times and spent a lifetime in America, appealed to divine and natural law to obtain better treatment for the Indians, telling succeeding Spanish kings, often to their face, of the sins committed by the conquerors of New Spain. To Charles V, Las Casas argued that the Aristotle quoted by Sepulveda was a gentile, probably burning in hell, whose philosophy should be accepted only when consistent with Christian doctrine. Las Casas believed the Indians should be Christianized without the use of soldiers or force, only by peaceful means, by the persuasion of the Gospel preached by godly men. He said the Indians were in no way inferior to the Greeks or Romans, not a whit less rational than the Egyptians; their temples, he said, were no less worthy of admiration than were the Egyptian pyramids.

Showing a healthy disregard for the orders of his ecclesiastical superiors, which forbade the baptizing of Indians

In New Spain, whereas "women of ill repute" were publicly stripped, whipped, and rubbed with honey to be bitten by insects, Jewish women had to appear naked before their judges and were put to the rack for practicing their religion.

While bands of Spaniards roamed the country destroying palaces and monuments, leveling cities, burning archives, and looting the temples of their gold and jewels, a few friars like Bartolomé de Las Casas labored for the Indian cause and tried to reconstruct the records of the past. In their villages, the Indians tried to save what artworks and manuscripts they could by burying them in their huts or taking them into the woods where they also hid and protected their medicine men.

unless instructed in the Christian religion, Las Casas was willing to baptize uninstructed children about to die disemboweled by Spanish soldiers.

To combat such unwanted opinions as those of Las Casas and to keep from the world the true story of the horrors perpetrated in New Spain, the Council of the Indies forbade possession or reading of the pamphlets published by Las Casas in Seville in 1552: they even went so far as to forbid the reprinting of the works of Cortes, Lopez de Gomara, and other conquistadores, though these were mostly apologias written to obtain favors from the crown.

The same censorship was reserved for the works of a whole series of enterprising monks who arrived early in New Spain and set about accumulating data on the history of Mesoamerica, traveling throughout the country, often at great pains, the most impressive of whom were the Franciscan friars Toribio Motolinia, Diego Duran, and Bernardino de Sahagun.

Franciscan friar Diego de Landa, born of the noble family of Calderones, arrived in Yucatan in 1549 at the age of twenty-five. Before becoming bishop of Yucatan, he was elected guardian of the convent of Izamal, east of the modern city of Merida. There he was told to erect a building for his monks, who had been living in houses of straw. As a site Landa chose a mound which had been used by the Maya as a "residence of the priests of the gods," in order, says Landa, "that the devil might be driven away." Vandalizing one of the greatest and oldest pyramids of Mexico, Landa eventually built for himself a fortress cathedral.

In the public square of Mani, south of Merida, Landa then amassed and burned, in the presence of the Spanish nobility resident in the country, the accumulated codices and inscribed statues of the natives.

The Jesuit Domingo Rodriguez noted that Landa destroyed 5,000 idols, 13 great stones that served as altars, 22 smaller stones, 27 rolls of hieroglyphs on deer skin, and other precious curiosities not described.

Cogolludo, in his *Historia de Yucatan,* described Landa as an "extravagant fanatic, and so hard hearted that he became cruel."

Not that it was easy for these friars to reconstruct what had actually occurred in the Valley of Mexico and surrounding Mesoamerica before the arrival of the Spaniards. The higher clergy that followed Cortes into conquered Mexico adopted his policy of destroying everything they could find of the native culture, burning whatever documents or codices fell into their hands, obliterating carefully chronicled history, myth, and legend, the worst culprits being the bishop of Mexico, Juan de Zumarraga, and the bishop of Yucatan, Diego de Landa. In the words of Landa: "We found great numbers of books written in these characters, but as they contained nothing that did not savor of superstition and lies we burnt them all, at which the natives grieved most keenly and were greatly pained."

To remedy this folly, dedicated Franciscans hit upon the device of teaching the surviving cultivated Mexicans to write in their own tongue with Latin characters, in lieu of their complex glyphs, so as to record what the natives could remember of their cultural heritage, much of which had been incorporated into songs and epic poems, passed down from generation to generation.

From such sources—including three surviving Mexican nobles, the princes Ixtlilxochitl, Tezozomoc, and Chimalpahin—the friars learned that the Mexica were members of an Aztec tribe which had only recently entered the Valley of Mexico in the middle of the thirteenth century and had established themselves on an island in the great Texcoco Lake at the beginning of the fourteenth century.

The Mexica said that around the lake they had found remnants of a high degree of civilization which they believed had existed in the area for more than a thousand years, and to which they gave the name of Toltec, meaning "artist" or "builder" in Aztec.

According to the Aztecs, the Toltecs had created a great capital city at Tollan, where, under the aegis of a divinely inspired leader, Quetzalcoatl, they had developed "superb artisans, devout worshippers, skillful tradesmen, stone masons, carpenters, bricklayers, workers in feathers and ceramics, spinners and weavers, tall, virtuous men who sang and danced, and had priests skilled in astronomy who kept an accurate count of days, years, and the movements of the stars and planets."

According to the Aztec tradition, the Toltec leader Quetzalcoatl had fallen on evil days and been obliged to depart eastward about A.D. 950 of our era. Thereafter the Valley of Mexico was invaded by less civilized Indians from the north, among the last of which were the Aztecs, who burned their own records and rewrote their history to bury their obscure

In Spain, Juan de Zumarraga had been ordered by the Emperor Charles V to exterminate the witches of Navarre, which he did by burning thousands of them at the stake. Appointed Bishop of Mexico, he boasted of having destroyed 500 Indian temples and 20,000 "idols." On Sunday, November 30, 1530, Zumarraga had Don Carlos Ometochtzin, lord of Texcoco, publicly burned at the stake in Mexico City's Plaza Mayor, accused of having worshiped the god of rain.

Familiars of the Holy Office had found two "idol" temples hidden in his palace: during the trial it developed that Indians covertly resorted to their old religious practices of inducing the powers of nature when the rain failed, much as was successfully accomplished by Dr. Wilhelm Reich in the United States in the 1950s, for which the satisfied blueberry growers of Maine paid him with money, whereas the U.S. Food and Drug Administration paid him with the public burning of his books and a prison sentence which cost him his life in the penitentiary.

In the market place of Texcoco, Zumarraga had a pyramid formed of the documents of Aztec history, knowledge, and literature, their paintings, manuscripts, and hieroglyphic writings, all of which he committed to the flames while the natives cried and prayed.

Into the holocaust went the codified laws of Texcoco's King Netzahualcoyotl (forefather of Don Fernando de Alva Ixtlilxochitl), who had reigned in Texcoco a century before the arrival of Cortes and had acquired the reputation of a Solomon distinguished for his courage, wisdom, and virtue, a refined astronomer and lover of plants and animals, who had composed sixty hymns in praise of the creator of heaven.

(Left) The Nahuatl word for Montezuma was written with the composite picture of a mousetrap, *montli*, for the sound *mo*, an eagle head for *quauh*, transfixed by a lance, *zo*, surmounted by a hand, *maitl* for *ma*—which came out *mo-quauh-zo-ma*.

origins and pass themselves off as true descendants of the indigenous noble Toltecs.

With this ready-made lineage, the Aztec Mexica—by their own saying—set about cruelly fighting for political dominance of the central plateau, stretching their power further and further afield, proclaiming their mission to be the gathering of all nations together into the service of their own god of war Huitzilopochtli.

By 1519, when the Spaniards arrived in highland Mexico, Montezuma's Aztecs ruled a polyglot colonial empire of several million people, stretching from the Pacific to the Gulf, from central Mexico to what is now Guatemala, most of whom were only waiting for an occasion such as the arrival of Cortes to rebel against their masters, and thus, inadvertently, destroy what remained of Indian civilization and turn over to the Spaniards the control of all of Central America.

Throughout the sixteenth century, by a careful sifting of the evidence obtained from Indian sources, the brighter minds among the historian friars, such as Bernardino de Sahagun, concluded that a truly great civilization had indeed existed in the Valley of Mexico, prior to the Aztecs, which had lasted over two thousand years. Sahagun also concluded that before Tollan this civilization had been centered in the great abandoned city of Teotihuacan, with its mysterious mounds, which he figured to have been destroyed almost a thousand years before the arrival of the Spaniards. It also seemed reasonable to Sahagun that so great a city must have prospered for at least a thousand years before it was abandoned or destroyed, which meant that it had been peopled five hundred years before the birth of Christ, a city as Sahagun described it, "very rich and well ordered, very wise and powerful, which suffered the adverse fortune of a Troy."

More open-minded than most of his ecclesiastical colleagues, Sahagun even managed to capture a feeling for the metaphysics of this lost civilization, establishing from the chronicles that Teotihuacan had been called the "City of the Gods" because

> the Lords therein buried, after their deaths, were canonized as gods, and it was said that they did not die, but wakened out of a dream they had lived; this is the reason why the ancients say that when men died they did not perish but began to live again, waking almost out of a dream, and that they turned into spirits of gods . . . and so they said to the dead: "Lord or Lady, wake, for it begins to dawn, now comes the daylight for the yellow-feathered birds begin to sing, and the many-colored butterflies go flying"; and when anyone died, they used to say of him that he was now *teotl,* meaning to say he had died in order to become spirit or god.

Fray Bernardino de Sahagun.

So handsome a youth was Bernardino de Sahagun that the older monks of the Order of St. Francis secluded him to prevent temptations from the outside world. Born Bernardo Ribeira in the province of Leon in 1499, he was given the name of his home town when he joined the order.

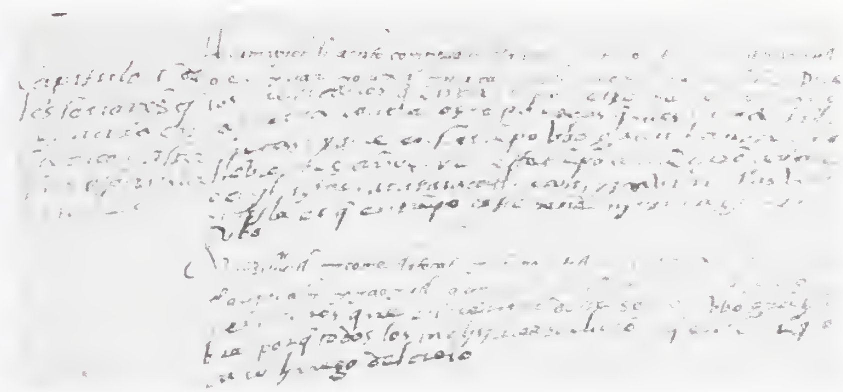
In 1529 on a ship for New Spain with eighteen other Franciscan monks, he learned to speak Nahuatl from repatriating Mexican Indians whom Cortes had dragged to Spain to show off to the Spanish court. Having mastered the language of the Mexica, Sahagun traveled through the country acquiring a vast lore which he turned into a twelve-volume anthropological, mythological, and social history of ancient Mexico, laboriously compiled over a period of fifteen years in the Monastery of Tlalmanalco at the foot of the two volcanoes Iztaccihuatl and Popocatepetl. Realizing that the Spaniards, in their zeal to destroy a religion they considered idolatrous and barbarous, were destroying the Aztecs' whole way of life, Sahagun did much to restore to the Mexicans their rightful reputation. Brother Sahagun sought out the most learned and often the oldest natives, and asked each to paint in his Aztec picture writing as much as he could clearly remember of Aztec history, religion, and legend. He also taught the natives to transcribe their Aztec words in Latin letters. Sahagun's story of the Conquest as told to him by contemporary Indians who had witnessed the events so displeased the Spanish authorities, Sahagun was forced to revise the text to suit the victors, only salvaging his conscience by retaining the original text in Aztec. Even so, his great work never saw the light. The original manuscript was buried and is lost to this day. An incomplete copy surfaced during the French invasion of Spain in 1808, and was published by Carlos M. Bustamente in 1840, to be translated into English a century later.

Unacclaimed by his peers, "America's most remarkable historian of the sixteenth century" died in poverty and oblivion of an epidemic of catarrh at the age of 91, mourned only by a vast crowd of saddened Indians whom he had lovingly befriended and taught.

But the reports of Sahagun and other industrious friars, who conscientiously accumulated long manuscripts giving fine details of the history, customs, and religion of the Indians, might just as well not have been written. They were buried in the archives to keep from the world the shame of what the conquerors, lay and cleric, had done to the inhabitants and culture of Mesoamerica.

In the mother country, where only writings which glorified the Church and its servants were thought worthy of the press, a few works were allowed publication, all derived from highly controlled sources, most of whom had never been to America, and whose material was already superannuated before it got into print. No book couid be printed except under license, nor could it be imported or exported without permit, on pain of death and confiscation of goods. All libraries, public and private, were subject to rigorous inspection, and students could not travel abroad. Access to Mexico was forbidden to foreigners in order to prevent commercial competition, espionage, and the possible contagion of Protestant heresies.

Not till the end of the seventeenth century did an observant Neapolitan traveler manage to visit Mexico and bring out detailed news. A strictly practicing Catholic with a penchant for hobnobbing with the higher clergy, considered a loyal subject of Spain because Charles II was also king of the Two Sicilies, Giovanni Gemelli Careri was able to travel freely about Mexico and bring out what amounted to the first outside report on the country and its antiquities.



Part of Sahagun's original manuscript.

PART III

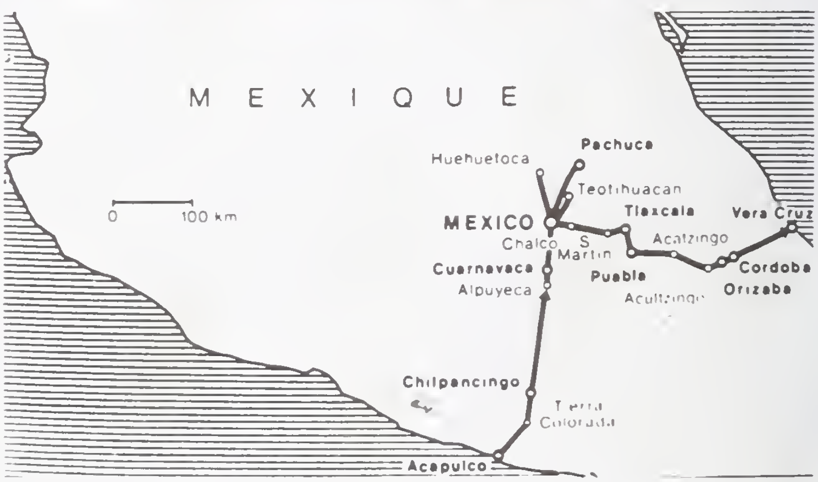
ARLY OBSERVERS

During the century after the Conquest, when Spain was virtually sealed off from the rest of the world, one Englishman, Thomas Gage, did manage to visit Mexico as a Dominican friar. A student of the Jesuits and the Dominicans in both France and Spain, he could pass for a Spaniard, and was therefore able to do missionary work in Central America between 1627 and 1637.

Gage was most struck in Mexico City by the women, the apparel, the houses, and the streets. He noted that almost half the population of the city sported coaches, many of which exceeded in cost the best of the court of Madrid and other parts of Christendom, "for they spare no silver, nor gold, nor the best silks from China to enrich them." Gage admired the broad streets lined with goldsmiths and silversmiths, and was astounded by the freedom enjoyed by the women to gamble: "Day and night is too short for them to end a *primera*."

Gage found men and women excessive in their apparel. "The attire of this baser sort of people of blackamoors and mulattoes is so light, and their carriage so enticing, that many Spaniards even of the better sort (who are too prone to venery) disdain their wives for them." Noting that "their bare, black and tawny breasts are covered with bobs hanging from their chains of pearls," Gage concluded that "most of them have been slaves, though love has set them loose at liberty to enslave souls to sin and Satan."

In 1640 Gage renounced his Catholicism, embraced Protestantism, and, back in England, informed against a number of English Jesuits, contributing to their deaths. In *A Survey of the West Indies* he gave a broadside attack against the corruption of the Roman Catholic Church, encouraging Cromwell's government to plot invasions of the New World in order to seize Spanish territory.



3. Reports from New Spain

On the last leg of a hazardous five-year trip around the world which had taken him to Armenia, Persia, India, and China, Careri, a jurist born in Calabria, arrived in Acapulco in January of 1697 after a gruesome five-month non-stop voyage from Manila in a small ship with two hundred passengers ravaged by scurvy.

Careri found the town of Acapulco, which he had expected to be Mexico's gateway to the East, no more than a fishing village with straw-roofed shacks inhabited, almost exclusively, by Negroes, mulattoes, and very few Indians. Only when a ship was in port would Spaniards appear from nowhere. Merchants aboard a ship from Peru brought ashore 2 million pieces of eight with which to buy silk and porcelain from China, cloth from Bengal, pearls from Persia, turning the town of Acapulco overnight into a thriving mart of free-spending Spaniards. Careri, who dabbled in commerce to help defray his traveling expenses, was quick to see that trading fortunes could easily be made in Acapulco. Even the local curate, whose yearly salary was a mere 120 pieces of eight, managed to increase his fortune to 14,000 a year by soaking the relatives of foreign merchants 2,000 pieces for a Christian burial in the local hallowed ground.

Giovanni Francesco Gemelli Careri, Neapolitan jurist, at the age of 48 when he traveled to Mexico in 1699.

Setting off on muleback for the 14,000-foot climb over the massif to Mexico City, Careri was delighted to find the bare mountains around Acapulco alive with deer, rabbits, parrots, and turtledoves with which to improve the abominable fare at the first wayside inn, a conglomeration of straw huts where he was devoured by horseflies. Of delicate health, suffering constantly from "intestinal flux," Careri traveled in short hops and long stopovers, amazed along the way to find oranges, lemons, apples, peaches, and pomegranates flourishing beside exotic capulins, avocados, mameys, sapodillas, custard apples and bananas. He was even more amazed to find that oranges and lemons lay rotting on the ground because the natives, accustomed to subsisting on tortilla pancakes and kidney beans, would not bother to pick the fruit.

As he climbed, Careri found that the soil, rich in iron, yielded bountiful harvests. The woods abounded with boars, panthers, eagles, royal herons, and wild geese.

Mexico City Careri found to be a metropolis of 100,000 souls which, to his traveled eye, rivaled Italy in the beauty of its buildings and churches and outdid Italy in the beauty of its charming, well-built women, who, according to Careri, preferred men from Europe, no matter how poor, to the Mexican-born Creole Spaniards because of the latter's pronounced taste for mulatto women, a taste, so he explained, acquired as children suckling mulatto breasts.

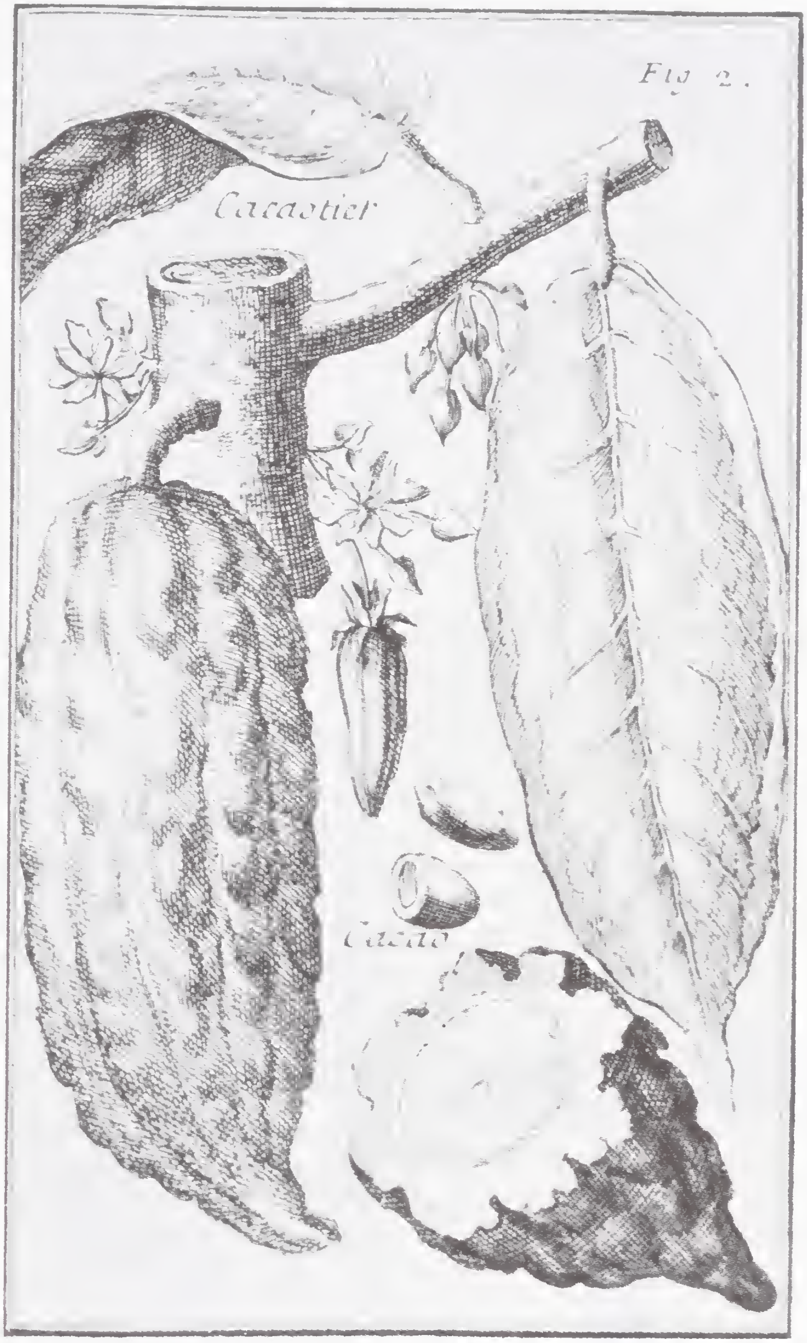
By ten years after the Conquest, Acapulco was already a thriving port, the point of entry and departure for a vast trade, much of it based on the demand for the epicurean specialties of the New World. Spanish seamen made possible a globe-circling trade from Madrid to Havana, to Veracruz, and then overland to Acapulco for continuation across the Pacific to the Philippines and beyond.

Cacao beans, of which the Mexicans got three crops a year, were used as currency in the markets, being worth 60 or 80 to a real. A real was a quarter of a peseta.

Of the cacao bean an anonymous conquistador wrote, "These seeds which they call almonds or cacao are ground and made into powder, and some other small seeds they have are also ground, and the powder put into certain vessels that have a spout. Then they add water and stir with a spoon, and after it is well mixed, they pour it back and forth from one vessel to another until it is foamy. The foam is gathered and put in a cup and when they are ready to drink the beverage, they beat it with some small spoons made of gold or silver or wood. To drink it one must open the mouth wide, for since it has a froth it is necessary to make room for it to dissolve and go in gradually.

"This drink is the most wholesome and substantial of any drink of the world, because whoever drinks a cup of this liquor can go through the day without taking anything else even if he is on a journey, and it is better in warm than cold weather because it is a cold drink."

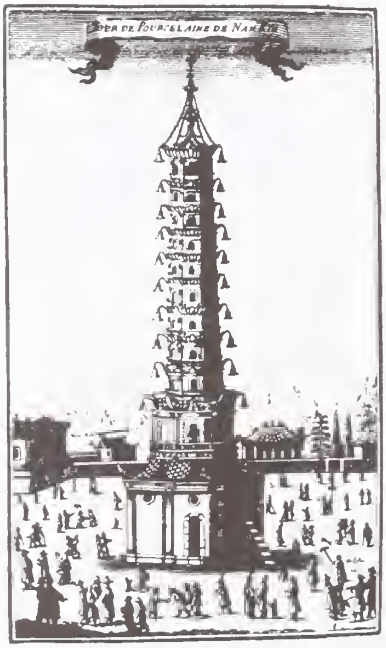
Another chronicler describes the care taken by the Mexicans in raising the delicate cacao tree: "It grows only in a warm climate, and before they plant it, they plant two or three other trees that have large leaves. When these are two estados high, they plant the cacao tree between them so the two can protect this delicate tree from the sun and wind and provide a covering for it. They hold this tree in great esteem because its grains are the principal money circulated in this country, each one being worth half a marchetto. It is the most commonly used coin, but very unhandy after gold or silver."



In the growing city, Careri found Mexicans largely preoccupied with the centuries-old problem of draining and lowering the level of the surrounding lakes to prevent the city from recurrently flooding, a program which involved millions of man-hours of backbreaking slave labor to dig canals and clear subterranean waterways.

The Spanish viceroy, Count of Montezuma, greeted Careri "very civilly"; and an old friend from Naples who had recently been appointed governor general of the province of New Mexico introduced him to a society which was delighted

The progenitors of the Mesoamericans gave to the world not only cacao but maize, pumpkins, squashes, potatoes, sweet potatoes, tomatoes, lima beans, kidney beans, peppers, pineapples, strawberries, persimmons, peanuts, alligator pears, cassava, quinine, cascara, cocaine, copal, balsam, cochineal, anil, alpaca, the llama, the guinea pig, turkeys, and rubber. To have developed such produce and animals would have been the work of thousands of years.



Careri's view of the porcelain tower in Nankin.

to entertain a traveler who could tell them stories of adventures in Peking, with vivid descriptions of such remote wonders as the Pyramid of Cheops and the Great Wall of China, rarely visited by Europeans.

To Careri, Mexico was a colony grossly exploited by a handful of Spanish merchants interested primarily in gold, silver, and pearls, who had managed with the support of the higher clergy to reduce the Indians to serfdom or brigandage; the penalty for which was branding of the testicles with a red-hot poker followed by two hundred lashes on the back.

On his way around the world, Careri visited the Great Pyramid of Cheops on the Gizeh plateau, where he obtained this sketch.

Careri noted that Strabo believed the Great Pyramid had originally been used as an astronomical observatory.

In Careri's day, in Mexico, at the beginning of the eighteenth century, religious institutions owned two-thirds of all the real estate but produced very little with their vast hoarded wealth. Twenty-nine monasteries for men and twenty-two convents for women had grown up in Mexico City, plus so many churches with sub-buildings and large gardens that it was hard to find land for new civilian houses in the lake-surrounded city.

Blacks and mulattoes, who had been forcibly added to the population, were kept strictly segregated and forbidden to wear Spanish dress, with the result, as Careri noted, that they dressed in the most bizarre fashion, "wearing a sort of skirt sideways across their shoulders."

The real owners of Mexico appeared to be the ecclesiastical authorities, who made it tough for Spaniards from Europe to get an economic stake in the country. Of an inquisitive nature that often got him into trouble, Careri discovered that the archbishop's yearly salary was a princely 60,000 pieces of eight, with access to another 200,000 income from his see. In the thirty years since the founding of the city's cathedral, 1,052,000 pieces of eight had been spent on adorning it.

When not going to mass or to the theater, Careri amused himself by searching out people of interest, and it is thanks to his rambles in seventeenth-century Mexico that the world was to get its first real glimpse of what the culture had been like before the arrival of the Spanish.

The most interesting of Careri's contacts was a long-faced lorgnetted priest, Don Carlos de Sigüenza y Gongora, then in his fifties, with a variety of duties, and a passion for probing into the historic past of the Mexicans.

Born in Mexico of noble Spanish parents, Sigüenza had been expelled from the Jesuit order, but had maintained friendly relations with his former comrades. Cultivating friendships with the native Indians, and winking at his duties for the Inquisition, Sigüenza managed to induce the Indians to bring forth manuscripts and paintings which they had carefully hidden for fear of being burned at the stake like the former King of Texcoco.

Don Carlos de Sigüenza y Gongora.

Professor of mathematics at the University of Mexico, General Examiner of Gunners, Corrector of the Inquisition, poet, astronomer, historian, and geographer, Don Carlos was by far the most erudite Mexican in his times, a Renaissance man who had made all of human knowledge his province, peering into dark corners to ferret out the facts.

From Sigüenza's collection of Aztec kings and warriors.

Sigüenza, on the contrary, specifically cultivated the friendship of the direct descendants of the kings of Texcoco, especially Don Juan de Alva, son of Fernando de Alva Cortes Ixtlilxochitl, author of the first history of the Mexican people written in Latin after the Conquest. In return for this friendship, Don Juan taught Sigüenza the language of the Nahua, showed him how to decipher many of the native hieroglyphs, interpreted the Indian myths, and, in the end, turned over to him an invaluable prize: the complete collection of his family papers.

Another great haul of precious original documents had come into Sigüenza's possession during the riots and ensuing fire which had swept the center of Mexico City a few years earlier. Hiring some Indians at his own expense, Sigüenza had placed ladders up to the windows of the flaming archives, smashed his way in with an axe, and thrown out all the manuscripts, codices, and capitulary books not yet consumed by the flames. With the help of his nephew, this priceless secret material was brought to the Hospital del Amor de Dios, a refuge for sufferers from the "French disease" or from bubas, where Sigüenza, as chaplain in residence, had his quarters.

There Careri paid a visit to Sigüenza and was shown remarkable writings and drawings relating to the antiquity of the Indians, including such prized items as a manuscript history of the Mexicans by Fernando de Alvarado Tezozomac, son of the successor to Montezuma; some original writings of Chimalpahin Quauhtlehuanitzin; a book, since lost, by Archbishop Zumarraga; and, most important, the works of Fernando de Alva Ixtlilxochitl.

With the help of these rare documents and a great many calculations based on eclipses of sun and moon and passages of comets as depicted in the paintings, Sigüenza was able to reconstruct an Indian chronology of Kings, tracing them back through the centuries. With his penchant for mathematics, Sigüenza was able to tackle complex calendrical problems that had baffled the earlier friars.

From Ixtlilxochitl, Sigüenza learned of an ancient Mexican calendar, which had vanished at the time of the Conquest, by means of which the Aztec priests had been able to keep an accurate chronology over very long periods of time in 52- and 104-year cycles, noting the solstices and equinoxes, the transits of Venus, and many subtle computations on the movements of heavenly bodies.

A careful study of these data enabled Sigüenza to fix certain dates with precision, such as the year 1325 for the founding of the city of Tenochtitlan and the beginning of the Aztec empire.

Portrait of Montezuma II given by Sigüenza to Careri.

From the evidence, Sigüenza concluded that a race called the Olmecs had preceded the Toltecs, coming from the East, perhaps from legendary Atlantis—as suggested by the Spanish chronicler Gonzalo Fernandez de Oviedo y Valdes —to settle on the gulf coast of Mexico. That a continent or group of islands known as Atlantis had existed, Sigüenza was convinced; he felt that they had served as stepping-stones to and from the Americas. The rest of the tribes of the

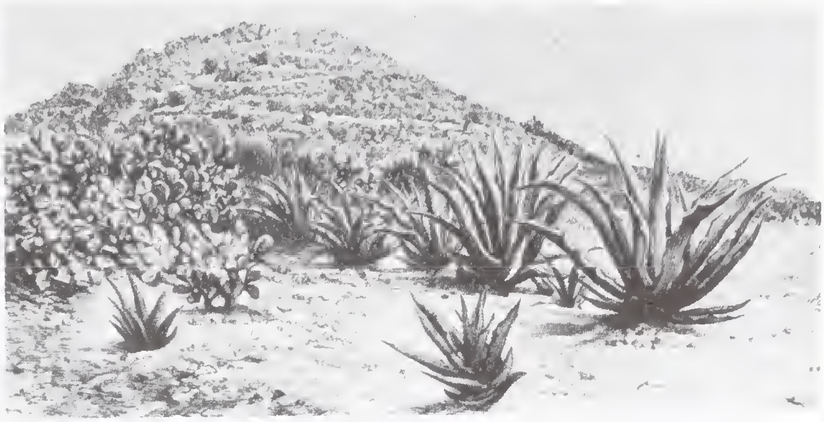
Western Hemisphere, he believed, had come from the north and northwest, possibly from Asia. But to Sigüenza, the similarity between Mexican and Egyptian pyramids, hieroglyphs, and calendars was too strongly indicative of the existence in the Atlantic of an intervening continent or group of islands, for which Plato's account of Atlantis fit the bill.

Pyramids, hieroglyphs, and calendars bound Sigüenza closely to the family of Ixtlilxochitl, who were still titular lords of San Juan Teotihuacan, site of the pyramid complex. This close link enabled Sigüenza to indulge in a more than superficial investigation of the ancient ruins. Whereas others attributed the construction of the great mounds to the Toltecs, Sigüenza believed them to be the work of the earlier Olmecs who had dwelt near the hills of Tlaxcala. As several sixteenth-century writers had reported the Indian tradition that the interior of the pyramids might be hollow, Sigüenza endeavored to dig into the two biggest ones, but with the limited means at his disposal was unable to uncover any passageway or chamber.

So fascinating was Sigüenza's description of these pyramids, that Careri decided he should "not miss some Indian antiquities before leaving Mexico." Rousing himself, he rode out to San Juan for a personal inspection.

On the route around Lake San Cristobal, Careri spent the night at Acolman. Inside this massive sanctuary Careri found a baroque church with a pleasant inner courtyard adorned with carvings by native Indians in the European style of the sixteenth century.

Route from Mexico City past the lake of San Cristobal to San Juan Teotihuacan. In the foreground is the monastery of Acolman. The town was famed under the Aztecs for a breed of fat little castrated dogs especially raised for the tables of the rich, and under the Spanish for its fortresslike Augustinian monastery. In the background are the hills of Sierra del Malpais.



After a night spent like the Jesuits on a pillow made of leather which could be inflated like a balloon and deflated in the morning, Careri set off at sunrise for the village of San Juan Teotihuacan, six leagues away, noting that the local Indians painted their cheeks with crushed herbs to protect them from the cold, and that they put mud in their hair to make it soft and shiny.

With an introduction from Don Carlos de Sigüenza, Careri was able to spend the night at San Juan with Pedro de Alva Ixtlilxochitl, grandson of Juan de Alva, who promised to show him the pyramids on the morrow.

At daybreak they explored first the smaller of the "mounds" called "Of the Moon," which Careri described as being a pile of stones with a slope like an Egyptian pyramid, but differing in that it was not constructed of solid stone. He found the base measured 650 palms north to south and 500 palms east to west: the height, since he had no instruments with which to measure, he estimated to be 200 palms. Taking the Aztec palm, or cemitztl, as 17.5 centimeters, this would have made the Moon Pyramid 105 meters wide at the base by 35 meters high. Its present reconstructed size is 152 meters wide by 42 high. Either Careri's palm was incorrect, or, more likely, the base of the pyramid was so covered in earth and rubble that only a smaller portion of it was visible, as was the case at that time with the Pyramid of Cheops.

Aztec idol known as the God of Rain.

From Sigüenza, Careri had heard that this pyramid had once been crowned with a "huge idol of the Moon clumsily carved from hard stone," which had been destroyed on orders from Bishop Zumarraga. That such an idol, eighteen feet tall, had once stood on the "Hill of the Moon" had been officially reported to Phillip II of Spain in 1580 by a local magistrate, Don Francisco de Castañeda, as part of the earliest-known official description of the pyramids of Teotihuacan. Castañeda also reported the presence of many more idols around the pyramid, the largest of which were "six

All over Mexico, statues of what the Spaniards called "idols" were smashed or destroyed after being stripped of their gold or jewels.

idols called the Brethren of the Moon," three large pieces of which, said Careri, still lay at the foot of the pyramid.

Two hundred paces to the south, Careri and his noble Indian guide explored the pyramid known to the Aztecs as "Tonatiuh," or "House of the Sun." Careri says that two of its sides were 1000 palms long (or 175 meters instead of about 230), whereas the other two were 650. The height he estimated to be a fourth more than the height of the Moon Pyramid. In fact it is one-half.

According to Castañeda's report, there had once stood on the summit of the Sun Pyramid, facing west, an "idol" of very hard, rough stone, all of one piece, eighteen feet high, six feet wide and six feet thick, called "Tonacatechuhtli," or "Sun God," but whether these statues formed part of the original pyramid complex or were added by later generations there was no way to tell.

Careri says he found part of this statue halfway down the pyramid; he described it as having a slot in the stomach "where one put the sun," adding that two large pieces which had formed the arms and feet still lay at the base of the pyramid. Careri was told that the statues which had once adorned the summits of the two pyramids had originally been covered in gold, which was removed by the Spaniards at the time of the Conquest.

According to Castañeda, there had also been "a small temple" at ground level at the base of the great pyramid atop which stood a smaller idol called "Mictlantecuhtli," or "God of the Underworld"; but Careri saw no sign of it. He was puzzled as to how the Indians could have cut such "idols" out of hard stone without the use of metal chisels; he also wondered how they had managed to raise such great weights to the top of the pyramids when "they had neither machines nor the wit to invent such machines."

How, asked the Italian, had the Indians been able to transport heavy stones from distant quarries when they had neither mules nor horses before the arrival of the Spaniards—a question which no one in Mexico could satisfactorily answer for him.

From the crumbling walls which he saw spread out in all directions, and the number of smaller mounds which he believed to have been erected to honor other idols, Careri had

Though Sigüenza had corresponded as far afield as with the extraordinary prelate Father Athanasius Kircher, who was determined to discover the secret lore contained or built into pyramids and obelisks, the rest of the world was not yet ready for the subject.

no doubt that a large city of Teotihuacan had once existed around the pyramids. But when it came to giving a date for the possible construction of these pyramids, Careri considered that no historian had discovered anything reliable.

Echoing the thoughts of Sigüenza, Careri attributed the construction to the Olmecs, possibly refugees from Atlantis, or to Europeans who had crossed the Atlantic, pointing out that even Aristotle had known that the Carthaginians had sailed beyond the Strait of Gibraltar to a "new world," but had been forbidden further such voyages by a senate fearful that the richness of the newly discovered lands would make the sailors forget their home. On his way back to Mexico City, it began to rain, and Careri's horse, overtired from the strenuous journey, lay down in the mud and died, a fate which was to overcome Careri's interest in the world of pyramids prospected for him by his friend Don Carlos de Sigüenza y Gongora. After eleven months in Mexico, Careri sailed for Havana and Seville, where he landed in 1698 with a handy supply of cochineal (for scarlet dye), Havana cigars, indigo, cocoa, and vanilla, discreetly hidden to avoid the duty. Because of his round-the-world trip, King Charles II of Spain received Careri but was not overly impressed.

In a six-volume opus, *Giro del Mondo,* or "Around the World in Eighty Months," which was quickly translated and condensed, Careri gave his contemporaries exotic glimpses of the Near, Middle, and Far East, plus the first and best description of Mexico to have reached the outside world. For his efforts he was quickly labeled an imposter who had never left Naples, a fiction to which historians were to cling till very recent times. Oliver Goldsmith and Adam Smith were both convinced that Careri was a fraud, and William Robertson, the eighteenth-century Scottish historian, in his monstrously inaccurate *History of America,* refused to include Careri's reports.

According to Robertson, neither the Mexicans nor the Peruvians "were entitled to rank with those nations which merit the name of civilized." He described the palaces attributed to the Indians by the Spanish conquistadores "as more fit to be the habitations of men just emerging from barbarity than the residence of a polished people. . . . Nor does the fabric of their temples and other public edifices appear to have been such as entitled them to high praise. . . . These structures convey no high idea of progress in art and ingenuity. . . . If buildings corresponding to such descriptions had ever existed in the Mexican cities, it is probable that some remains of them would still be visible. . . . It seems altogether incredible that in a period so short, every vestige of this boasted elegance and grandeur should have disappeared. . . . The Spanish accounts appear highly embellished."

And the Dutch-born historian Cornelius de Pauw, in his *Recherches Philosophiques sur les Américains,* claimed that "the so-called palace occupied by the Mexican kings was a hut."

Calendar wheel obtained by Careri from Sigüenza. Encircled by a snake, the Mesoamerican symbol of time, the outer wheel shows a 52-year cycle divided into thirteen repetitions of the 4-year cycles of rabbit, house, cane, reed. The next circle shows the eighteen months of the Aztec year. In the center are the symbols for the four seasons.

Only a few Europeans of progressive outlook such as Giordano Bruno and Montaigne refused to believe in the inferiority and depravity of the Indians of Mesoamerica.

Sadly, as the first edition of *Giro del Mondo* came off the presses, Don Carlos de Sigüenza y Gongora, responsible for most of what Careri reported of value from Mexico, died, too poor to have had his manuscripts put into print. In line with the policy of the Inquisition to allow a man to accumulate manuscripts during his lifetime, but see to it that after his death they got no further dissemination, twenty-eight of Sigüenza's own manuscripts along with his priceless collection of books, manuscripts, and codices were quickly scattered, stolen, or destroyed. Luckily, the Jesuits salvaged the lion's share of their former novice's own manuscripts; but when their order was thrown out of Mexico in 1767 these manuscripts were also buried in some archives or lost.

Ironically, what was known of some of Sigüenza's writings was to reach the world through Careri's flimsy reports, such

as his interpretation of the Mexican calendar taken from Sigüenza's lost work *Ciclografia Mexicana*, which Sigüenza had been kind enough to lend Careri when he was in Mexico City, but which the Neapolitan jurist, weak on mathematics, had poorly understood and miserably transmitted.

With venom, De Pauw attacked the reliability of the Mexican calendar found by Sigüenza and interpreted by Careri, writing that "with breathtaking impudence and ignorance Careri has followed the explanation of a certain creole professor named Congora [sic] who had not dared to publish a work he had written on the subject because his friends and relatives assured him it abounded in absurdities." De Pauw could not countenance the possibility that Mexicans had recorded the passage of centuries with the use of "calendar wheels." Such reckoning, he said, supposed a long series of astronomical observations "incompatible with the prodigious ignorance of those people." How, asked De Pauw, could they have perfected their chronology "if they did not have words enough to count to ten?"

After Careri's departure, almost a century was to pass before the veil of obscurantism was once more to be pierced by the arrival in Acapulco of another famous traveler—Baron Friedrich Heinrich Alexander von Humboldt.

4. Humboldt's Mission

When Humboldt arrived in Acapulco on March 23, 1803, aboard a frigate aptly named *Atlante,* he was in his thirty-fourth year, and one of the most popular individuals in Europe. A friend of Goethe, Schiller, Metternich, and Chateaubriand, he was almost as well known as Napoleon Bonaparte, with whom he had failed to go to Egypt during the 1799 expedition only because the ship on which Humboldt was to have sailed from Marseilles was sunk in a sudden storm, obliging him to seek adventure in the Americas.

From Guayaquil in Ecuador, Humboldt brought with him to Mexico his good friends Aimé Bonpland, the botanist, and Carlos de Montafur, a fighter for freedom in Latin America. The trio brought an enormous pile of luggage containing telescopes, surveying instruments, minerals, plants, mastodon bones, skins of jungle creatures, and specimens of birds.

In contrast to the port of Acapulco which Humboldt and his companions considered one of the prettiest in the world, they were struck by the lugubrious atmosphere and burned landscape surrounding the town, which they described as a miserable and unhealthy spot, hot and tropical, a haven for escaped convicts and rum-filled slaves.

Humboldt's original plan in coming to Acapulco had been to reverse Careri's route toward the Philippines, but because his instruments were beginning to rust he decided instead to return immediately to Europe. This plan was scotched by an outbreak of yellow fever in the gulf port of Veracruz, which determined Humboldt to stay in Mexico at least till the

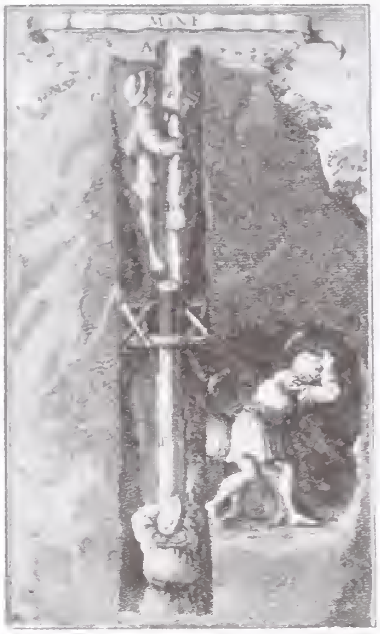
fall of the year (when the disease was less catching), or better still, the following spring so as to avoid a winter crossing of the Atlantic.

In Acapulco, Humboldt and his companions made astronomical observations to correct the misplaced coordinates of the town, and they spent some time observing the nature of earthquakes, which were frequent in the area. Finally, in a 104-degree heat wave, they set off in Careri's footsteps up the dusty mule trail toward the capital, climbing slowly because of the number of pack animals carrying their biological and mineral specimens, stopping here and there to study rocks and plants and to make astronomical and barometric observations.

During the starlit nights Humboldt obtained accurate readings of his location so that by day he could produce graphs of the geological structures he encountered, invaluable to later surveyors. He even mapped an easy way to convert the mule path into a proper roadway to the capital once traffic might warrant the endeavor.

Aimé Bonpland, aged 40.

Portrait of Alexander von Humboldt at the age of 25.



The sight of the Mexican mines led the almost radically liberal Humboldt to observe that "there can be no durable prosperity for the two Americas until this unfortunate race, humiliated but not degraded by long oppression, shall participate in all the advantages resulting from the progress of civilization and the improvement of social order."

In his own mining career in Germany, when still in his twenties, Humboldt had learned to double production of a mine by improving its working conditions and safety measures, and by providing night school for the miners, often at his own expense.

Between Chilpancingo, in the Sierra Madre del Sur, and Taxco, clinging to its hillside, Humboldt came across the great silver mines of Mexico. Indian laborers, panting by day under heavy loads of ore, blasting by night in an inferno of powder smoke and dust, were still being treated like mongrel dogs.

Leaving Taxco, the travelers wound their way through limestone mountains to Cuernavaca, where Cortes had built his first palace and planted Mexico's first sugar plantation. A day's ride took them to the crest of the continental divide, 11,000 feet above the sea, from where they could look eastward down onto the City of Mexico with its cluster of churches, palaces, and gardens, which, from their vantage point, appeared to be floating on the surrounding lake.

As a botanist, Humboldt was struck by the beauty of the cypresses at intervening Xochimilco, lovely great trees which had rooted beneath the lake to form a world of "floating gardens called *chinampas*." These gardens provided an abundance of vegetables which could be floated by the Indians along narrow waterways right to houses and convents near the viceroy's palace in the great Plaza Mayor, where the main temple of Tenochtitlan had stood.

As Humboldt and his companions approached the city, a messenger brought word of welcome from Viceroy Don José Iturrigaray, granting Humboldt passports to travel wherever he pleased in New Spain, a special treatment arranged for Humboldt in Madrid by the minister of Saxony, who had convinced the Spanish crown that such a distinguished scientist and "conservative" young nobleman would not rock the boat of state with his reports from Mesoamerica. Actually the arrangement had every earmark of being a Masonic ploy to facilitate an intelligent reconnaissance of Mexico, possibly on behalf of long-term mining interests in Europe.

Within the city, with its wide clean avenues, flanked by iron candelabra, resplendent at night with lighted palaces and churches, Humboldt was welcomed as an erudite and learned visitor. It was his charm, however, and his apparent sincerity and ease, along with his sociability and brilliance of conversation, which really opened doors to him. Wherever he went, cultivated persons gave him their confidence; in Mexico he got help from peasant and governor, missionary and bishop, savant and noble, being welcomed indiscriminately into palace or snack, workshop or hacienda. Almost everyone had heard of Baron Humboldt as either astronomer, physiologist, botanist, economist, archeologist or philologist; but seldom had any of them had occasion to frequent so distinguished a personage.

The chinampas or so-called floating gardens of the Valley of Mexico, of which Xochimilco is the most famous, date back more than 2000 years, and were the main source of food-stuff for the inhabitants of the entire valley, producing as many as seven different crops in a year, two of which were maize.

Properly maintained, they could remain fertile for centuries without having to lie fallow.

Xochimilco consisted of a network of canals of various widths laid out generally at right angles to form a grid. Rafts and water vegetation were cut from the surface of the canals and towed to strips where they were built up in layers and covered with rich mud scooped up from the canal bottom.

Many such chinampa towns surrounded by lovely canals and cultivated strips developed on the western and southern shores of the Lake of the Moon.

An added asset in the canals was an abundance of fish and axolotls, large salamanders prized for their tender meat and scarcity of hard bones.

Most amazing, the viceroy immediately opened up for Humboldt the country's classified archives. To help him with his research, Humboldt found, in circumstances that seemed more than fortuitous, a former classmate from Freiberg University, Don Andres Manuel del Rio, who had providentially become director of Mexico's school of mines. A young savant, Dr. M. Oteyza, was selected to tutor Humboldt on the history of Mexico and to show him where he could obtain rare Indian picture writings which had escaped the *autos da fe* of the Conquest, picture writings so scarce in New Spain, according to Humboldt, that the majority of educated persons had never seen one.

With access to the official files and a bent for statistics, Humboldt estimated the population of Mexico City to be 137,000 inhabitants, or twice that of contemporary New York, with the difference that in Mexico City there were only 2,500 Europeans, the rest of the population was composed of 65,000 Creoles, 33,000 Indians, 26,500 mestizos, and 10,000 mulattoes.* Like Careri, Humboldt found both town and county pullulating with priests, monks, and nuns—one priest for every sixty inhabitants, or 100,000 priests in a country of 6 million souls. To Protestant Humboldt, the higher clergy of Mexico appeared to be living in clover, some receiving incomes greater than that of the then president of the United States, Thomas Jefferson.

* Creoles were Spaniards born in Mexico; mestizos were part Spanish, part Indian; mulattoes were part Negro.

When Humboldt arrived in Mexico City, it was the largest city on the continent of America; he found it "undoubtedly one of the finest ever built by Europeans in either hemisphere."

After several months of studying the statistics and geography of the country, and of analyzing Mexico City as the political, commercial, industrial, and ecclesiastical capital of New Spain, Humboldt turned to the city's antiquities to observe it as an ancient center of civilization. He was shocked to discover the extent of the destruction of Tenochtitlan, as well as of ancient statues and painted codices. He also learned that since Sigüenza's death another great collection of books, manuscripts, and codices had been pillaged and dispersed, that of the eighteenth-century Milanese traveler Lorenzo Boturini Benaducci, which had been burned, stolen, or taken abroad, where part of it was seized by British pirates who destroyed it without understanding its value.

Perhaps the greatest collection of ancient Mesoamerican documents was accumulated by another Italian, Lorenzo Boturini Benaducci, born in the see of Como in 1702, who liked to trace his family back to the ninth century A.D. After studying in Milan and Vienna, Boturini was driven to Madrid by the war between Spain and Austria. There he found Doña Manuela de Oca Sylva y Montezuma, who convinced him to go to New Spain to collect a pension of a thousand pesos owed her as a direct descendant of Montezuma II. Armed with a papal Bull authorizing him to make a collection to provide a crown for the Virgin of Guadalupe, Boturini scoured Mexico for documentary evidence in proof of the miraculous apparition of the Virgin at Guadalupe, and in so doing came across scores of priceless ancient historical documents. Arrested as a foreigner soliciting funds for the Virgin, Boturini was jailed and his documents seized.

Deported back to Spain, he was captured by British pirates on the high seas and put ashore at Gibraltar minus clothes and belongings. Vindicated by the Spanish authorities, Boturini was given a pension and the job of writing a history of New Spain, but by that time his collection of documents in Mexico had been pilfered and wantonly destroyed. Of two hundred manuscripts only thirty-eight remained, partly destroyed by soldiers from a nearby barracks who were entertained by the exotic drawings. Of Boturini's work, all that survived of value was a booklet entitled *Idea for a New General History of North America* with a tantalizing catalogue of his unique but scattered manuscripts.

Francisco Javier Clavigero, who entered the Jesuit Order in Mexico in 1748, found in the Jesuit College Library the remaining works of Sigüenza y Gongora and what was left of Boturini's collection, which he studied and used to become what a later Jesuit historian Charles E. Ronon called "the eighteenth century's *Voice of America*."

When the Jesuits were expelled from Mexico in 1767 by Charles III, Clavigero took refuge in Bologna where he witnessed the suppression of his order in 1773. Left with little to do, he produced his *Storia Antica* (written in Italian because few in Italy could understand Spanish) largely to preserve for posterity a record of the achievements of the native civilization of Mexico and refute to the world the misinformation of such historians as De Pauw and Robertson, who had wounded his Creole feelings.

The Inquisition took objection to Clavigero's comparison of the Spanish rule in New Spain with the Turkish oppression of the Greeks, and held up publication of his work in Spanish, insisting on compiex amendations. In the end they lost the manuscript. When Clavigero died in Bologna in 1778, fellow Jesuits retrieved his original manuscript, but also managed to lose it. Early in the twentieth century a dusty manuscript was identified as Clavigero's by Manuel Diaz Ramon, S.J., but it too disappeared only to reappear in the hands of a U.S. dealer. The Mexican scholar Mariano Cuevas had it published, but omitted Clavigero's dissertation on the origin of syphilis, which he attributed to Spanish conquerors rather than to native Mexicans. Modern historians, with access to wider sources, accuse Clavigero of having plagiarized material directly from Torquemada's unpublished *Monarquia Indiana.*

Codex from the collection accumulated in Mexico at the beginning of the eighteenth century by researcher J.M.A. Aubin.

Because of the revolutions and counterrevolutions in Mexico, and twenty-six changes of government between 1830 and 1848, Aubin was able to buy cheaply many manuscripts and paintings, including some rare items from the son of Leon y Gama, which, as an astronomer, were of great interest to him. From Mexico, Aubin managed to smuggle his collection to France by taking the manuscripts and books out of their bindings and jumbling them up to confuse the customs officials at Veracruz. He published some in Paris in 1855, but mostly kept them secret from everyone except Brasseur de Bourbourg.

In 1870, because of losses in an investment in Panama Canal shares, Aubin was obliged to sell his collection, including many of Boturini's documents, to Eugene Goupil, a Frenchman interested in Mexican documents because of his Mexican mother—and so they have survived.

Calendar Stone.

Leon y Gama recognized the great Aztec stone as a sophisticated calendar. He believed its central cloverleaf design represented the legendary Aztec epochs of four suns. In the third circle he recognized the twenty Aztec symbols for the days of the month and the hieroglyph for 4-ocelot, the day when the sun stood at the zenith over Mexico City. As for the two enormous snakes around the outer edge, Leon y Gama believed they represented the Milky Way.

From the perfection and uniformity of the circles on the great stone and the exact division of it into parts, Leon y Gama said it was clear the Indians had a fine understanding of geometry. He also pointed out the ability of artisans capable of so perfectly engraving inscriptions on the stone though they were not supposed to have had tempered chisels but only harder stones. The volume and weight of the stone, said Leon y Gama, showed the Indians' knowledge of mechanics, without which they could never have cut a stone weighing over 24 tons and brought it from its place of origin, a quarry assumed to be in the mountains near Xochimilco, thirty miles away, from which it had been dragged on greased rollers by large groups of natives to the main square of Tenochtitlan. Leon y Gama, who considered the stone an Aztec clock by which priests could tally the movements of the heavenly bodies, believed that holes found in the perimeter of the stone might have been drilled to insert gnomons, or small obelisks, to throw shadows to indicate the days of the solstice, equinox, and zenith. At the beginning of the nineteenth century Sir Norman Lockyer, the English astronomer who first recognized the astronomical function of Stonehenge and the Egyptian temples, was amazed at the brilliance of the Mesoamerican

Among the few important relics which had survived from the Aztec empire, one of paramount interest surfaced only a dozen years before the arrival of Humboldt. In 1790, when the viceroy had ordered repairs to the paving of the great Plaza Mayor to improve the drainage in front of the cathedral, workmen had struck a large stone two feet below the surface, almost in front of the viceroy's palace. The stone, a solid piece of gray-black basalt, measured twelve feet across and was almost three feet thick.

Its presence was explained by the fact that when Cortes razed the city of Tenochtitlan he had ordered all large statues and stonework too solid to be broken up to be buried so that no remnant of the great Indian capital be left to remind Indians of their former glory, or as the parvenu clergy who considered the stone a "sacrificial altar" put it, "to bury with the stone the memory of the abominable acts perpetrated on it."

With great pains the enormous relic was righted, and the underside, which had been face down in the mud for over two centuries, was seen to be covered with the most intricate and delicate carving, as incomprehensible to its discoverers as it had been to Cortes and his early followers.

But there lived in Mexico City in 1790 a historian who had spent a lifetime studying ancient Mexican documents and who, like Sigüenza, had mastered the Nahuatl language and learned to interpret some of its hieroglyphs. Antonio de stone calendar which he found recorded not only the annual rotation of circumpolar star groups but also the annual apparent course of the sun. He called it "an achievement which has never been surpassed in primitive astronomy."

At the turn of the century, archeologist Zelia Nuttall, who considered the calendar "the most precious and remarkable monument ever unearthed on the American Continent," and "one of the most admirable and perfect achievements of the human intellect," saw in the Sun Calendar not only the embodiment of longstanding primitive observations, but a calendar designed to control the actions of all the human beings of the state, bringing their communal life into accord with the periodic movements of the heavenly bodies.

As the four-branched Ollin sign divided the 52-year cycle into four 13-year periods, it also divided the day into four equal parts, consonant with the four quarters of the Aztec world named for their four elementals—fire, air, water and earth. Nuttall says there were four human lords under the Aztec king, and these governed four divisions of the population, classified by the four elements.

The earth people, says Nuttall, specialized in agriculture and pottery; the water people in providing irrigation, drinking water, fishing, etc.; the fire people worked on combustibles, lighting, cooking and metalworking; the air people were the builders, masons and artificers. As a person was given the name of the day on which he was born, this determined his position in the commonwealth, his class, his future occupation.

Seen by Nuttall, the great stone was the work of a master mind "who destined it to be the image of a plan based on the idea of a central and yet all-embracing, dual, yet quadruple force or power."

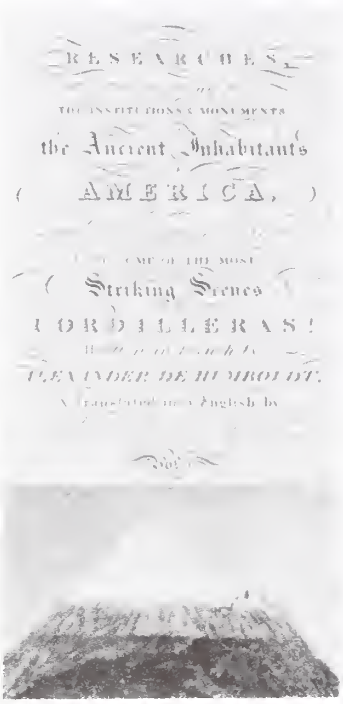
Leon y Gama, then in his fifties, recognized the stone as the famous Aztec calendar, of which Sigüenza had written, taking his information from the descendants of Ixtlilxochitl.

To Leon y Gama the discovery of the calendar proved beyond doubt the assertion of Sigüenza, cautiously reported by Careri, that the pre-Conquest Indians had possessed an advanced and remarkable knowledge of mathematics and astronomy which they had used to make accurate observations of the movement of sun, planets, and stars to produce a calendar with cycles of 52 years of 365 days, each divided in 18 months of 20 days, whereto they added 5 on regular years and 6 on leap years.

In a monograph explaining the calendar stone, Leon y Gama tried to show how falsely the ancient Mexicans had been described as "irrational and simpleminded beings." But his explanation was too embarrassing to the Spanish clergy. Without elementary notions of astronomy, they continued to insist that the "calendar stone" was a sacrificial altar, arguing that the very fact that the intertwined recurrent cycles were put together in such a complex and aesthetic manner obviously meant they were ornamental, adducing as evidence the fact that the same symbols appeared on earrings, necklaces and other purely decorative objects.

When Humboldt saw the great stone, it was propped up against the west wall of the cathedral, already wantonly disfigured by a populace exhorted by its priests to execrate anything connected with their former religion. As an astronomer, Humboldt was quick to validate Leon y Gama's interpretation of the stone, supporting him with a long essay on the significance of the Aztec calendar. Humboldt accepted Leon y Gama's interpretation that eight triangles radiating from the central sun alluded to eight divisions of the day, pointing out that the Aztecs had evidently reckoned the civil day in the same manner as the Persians, the Egyptians, the Babylonians, along with the greater part of the nations of Asia with the exception of China, dividing the day from sunrise to sunrise into eight intervals of three hours.

It was equally clear to Humboldt that the Indians had started and divided the year by the solstices, equinoxes, and days of the zenith. Humboldt pointed out that most of the names by which the Mexicans denoted the twenty days of their month were the same as those given to the signs of the zodiac in use from remotest antiquity among the nations of Eastern Asia—tiger, hare, ape, dog, serpent, and bird, heavenly asterisms that bore the same names in the Tartar and Tibetan zodiacs. From all of this Humboldt concluded that the people of the two continents might have derived their astrological ideas from a common source.



In his *Atlas Pittoresco,* Humboldt devoted more than a hundred pages to a discussion of the Mexican calendar stone and the relationship between the mathematical and astronomical systems of Aztecs, Toltecs, Peruvians, Nootkas, and other native American peoples, with those of the Chinese, Hindus, Oigones, and other Oriental peoples.

He found a vast amount of evidence for a common origin of the cultures of the two continents, including the systems of both the solar and lunar zodiacs, with many similar animals allotted, and even similar sounds of some of the astrological terms.

Humboldt's conclusion that the people of Mexico at the time of the Spanish Conquest had enjoyed a greater degree of civilization handed down from antiquity than they had been credited with, and that the American Indian in antiquity had a sophisticated understanding of astronomy, was derided by reviewers, who conceded that the Indians might have had a calendar chronology but would not admit "that a nation so barbarous as the Mexicans had any knowledge of the causes of eclipses."

Humboldt turned to other subjects. Though he traveled extensively in the country on sociological and geographical quests, he appears to have relied more on the reports of Mexican friends than on firsthand observation to fill in his knowledge of other Mexican antiquities. The Xochicalco pyramid near Cuernavaca he passed without even knowing it was there, relying on others to describe it; he did likewise for the ruins of Mitla. Though he did travel to Tula and express the opinion that it might have been the site of the Toltec capital, Tollan, he did not bother to look for archeological evidence.

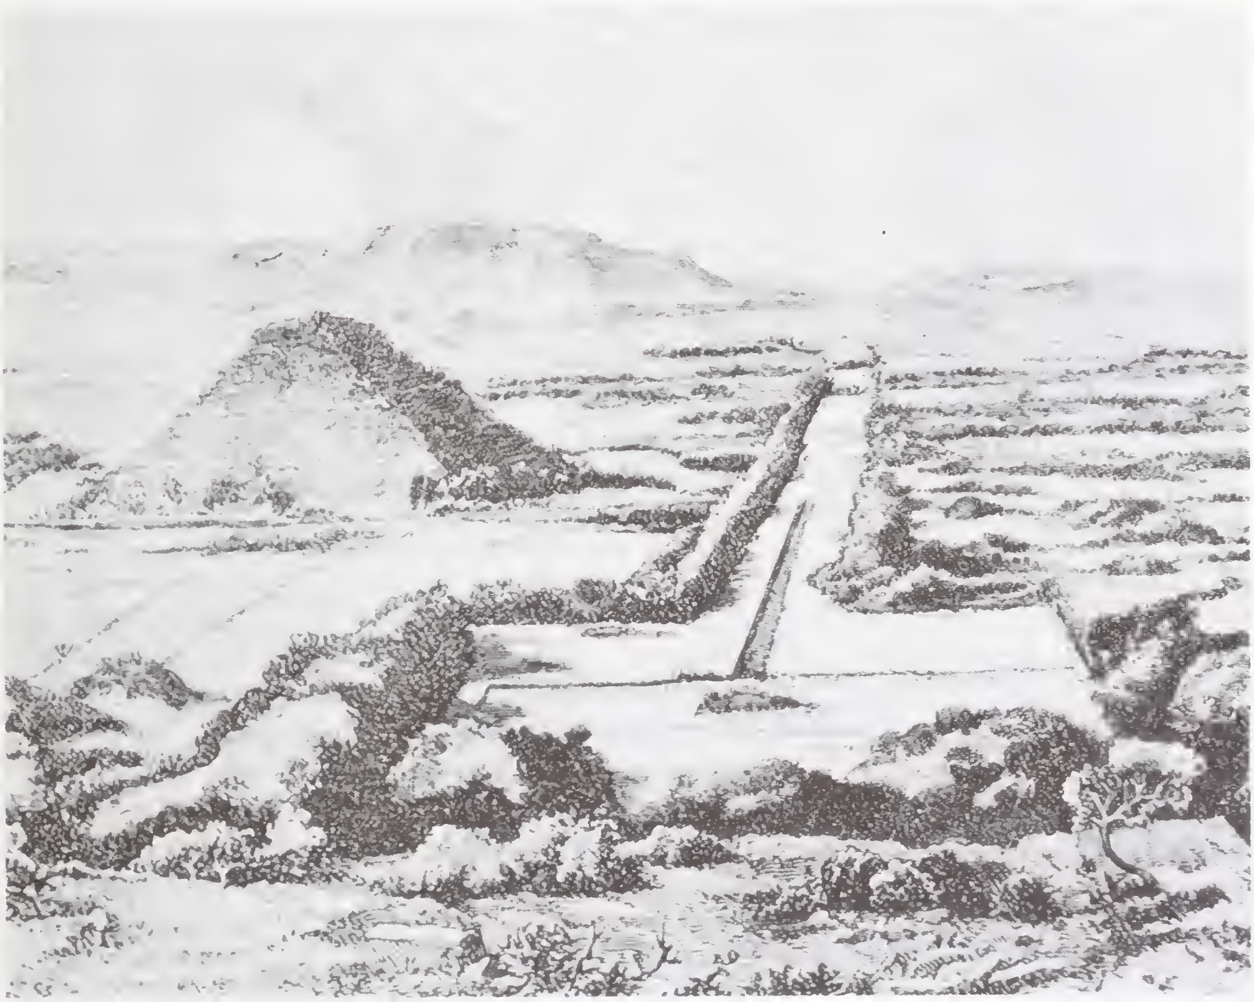
Humboldt claimed that "the only ancient monuments in the Valley of Mexico imposing enough in size and grandeur for European eyes" were the ruins of the pyramids of San Juan Teotihuacan. Historians have recounted that he traveled to these pyramids by horse and coach with Bonpland and Montafur and was "immediately struck by the extraordinary geometric symmetry of the great ruined complex, marveling at what the buildings and temples must have looked like a thousand years earlier, with platforms adorned with the gilded images of gods." However it is more likely that Humboldt again relied for his description of the site on the work of Careri; and for the measurements of the Sun and Moon pyramids on the figures given him by his young friend Oteyza.

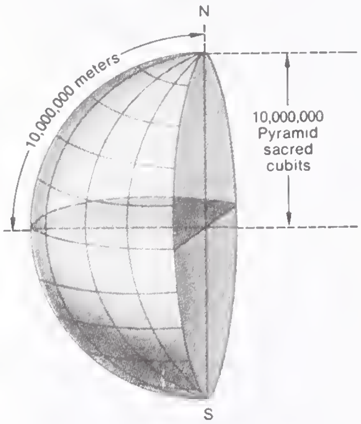
Humboldt had carefully read Careri before embarking on his exploration of Mexico; but until he arrived in Acapulco he had no way of knowing whether Careri had been telling the truth or, as his critics maintained, inventing fables. Humboldt soon discovered that Careri had indeed preceded him, and he was categorical in his defense of the authenticity of Careri's descriptions of Mexico: "Having covered a great deal of the territory so minutely described by the Italian traveler, I can affirm that there is no doubt that Careri was in Mexico. . . . Careri's descriptions have that touch of local color only found in those who have had the advantage of seeing with their own eyes."

Ironically, Humboldt's description of the Teotihuacan complex appears to have been seen through Careri's eyes.

Pyramid of Cheops as model of earth's Northern Hemisphere.

Humboldt could hardly have surveyed the Sun and Moon pyramids at Teotihuacan as being oriented "within 52 mintes exactly placed from north to south and east to west," as he describes them, when they were, and are, in fact, oriented more than 15 full degrees (or almost 1000 minutes) east of true north. A surveyor as preoccupied as was Humboldt with accurate calculations of latitude and longitude (who observed an error of mere seconds of arc in the location of Acapulco, and who calculated the latitude of the eastern tower of the cathedral of Mexico to within 600 feet of the modern calculation) is unlikely to have been capable of so gross an error. Humboldt also described the slope of the Sun Pyramid as being 52 degrees, very similar to that of the Great Pyramid of Cheops, when in fact the Teotihuacan slope is a much gentler 43 degrees, 35 minutes—an error of more than 10 degrees. Humboldt also erroneously described "a system of smaller pyramids about 10 meters high, several hundred of them along wide avenues which follow precisely the line of parallels and meridians leading up to the faces of the pyramids."





Herschel suggested that the most practical system of measures should be based on the length of the polar axis of the earth which he believed had been calculated in antiquity as 20 million Pyramid Sacred Cubits. This gave an ancient inch within one part in a thousand of an English inch. The notion first propounded by Isaac Newton was used by astronomer Charles Piazzi Smyth as the basis for his often incorrect but brilliantly intuitive conceits about the Great Pyramid and ancient units of measure.

Equally amazing is the fact that Humboldt, who was such a dedicated astronomer and geographer, should have missed the geodetic and astronomic functions of pyramids, whereas his contemporary colleague, Edmé François Jomard, with whom he was to have traveled to Egypt on Napoleon's expedition, and with whom he later corresponded, had brilliantly confirmed the scattered reports of classical Greek authors to the effect that the Pyramid of Cheops was a geodetic scale model of the Northern Hemisphere whose apex represented the North Pole and perimeter an exact fraction of the equatorial circumference of the earth—or 1/2 a minute of degree.

The only reasonable deduction is that Humboldt never visited the Teotihuacan complex, or if he did, did so in a manner so cursory that he might as well have never seen it. A careful reading of Humboldt on Teotihuacan shows him to be most circumscribed in his description, never using the first person.

For the dimensions of the pyramids he had the work of Oteyza, who had recently measured the Sun Pyramid's base at 208 meters or 665 English feet; again, because of the rubble at its base, about 8 meters or 24 feet short. To convey to Europeans an idea of what this meant, Humboldt pointed out that the northerly facade of the Hotel des Invalides in Paris, where Napoleon was eventually to be buried, was exactly 600 feet long—in French feet or *pieds du roi,* the sixth of a toise, or one French fathom. In English feet this would have been 636. Confusing, but indicative that somewhere there might be a relation between the pyramids of Egypt and those of Teotihuacan, in that 600 Egyptian feet had been found by Jomard to be one Egyptian stadium, or 1/10 of a mile, equal to 6 seconds of arc, or 1/600 of a degree of longitude.

To convey an idea of the cubic capacity of the Sun Pyramid, Humboldt relied on Oteyza's estimate of 33,743,201 cubic French feet, though actually Oteyza had measured in neither French feet nor English feet, nor even in meters, but in the Mexican *vara,* one of which consisted of 31 inches of the old *pied du roi*; all of which made it hard for anyone but a mensurational aficionado to be moved by the fact that Humboldt and Oteyza considered the height of the Sun Pyramid to be 171 French feet or 180 English—equal to 2160 English inches.

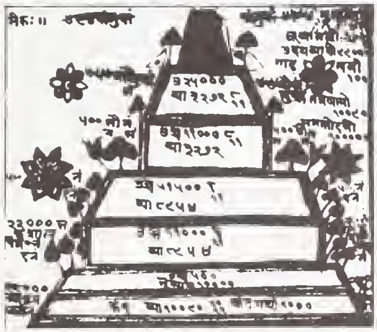
Curious as to whether the pyramids of Teotihuacan had been built entirely by man or whether the builders had taken advantage of natural hillocks to cover with stone and cement, Humboldt tended to the conclusion that they were entirely man-made, saying "their position in a plain with no other hills makes it unlikely they were built on outcroppings." He also concluded that the Indian tradition that the structures were hollow was too vague to credit and that until the pyramids were pierced horizontally there would be no way of knowing.

Humboldt was amazed that whoever built these pyramidal structures should have done so in a manner so similar to the Ziggurat of Belus in Babylon, the remains of which he had observed. It led him to wonder whether the constructors had been allied to a Mongolian race from the East, as had first seemed plausible, or whether they were somehow linked to the Middle East, as indicated by the botanical and geological data. Again Humboldt was apparently unaware that the ziggurats of Mesopotamia had also been constructed as geodetic scale models of the Northern Hemisphere, like a stack of diminishing blocks, each facade of which gave a rectangular Mercator-like projection of the seven classic zones between the equator and the pole.

Humboldt disputed the attribution of construction of the pyramids to the Toltecs, which would have placed them in the eighth or ninth century A.D., and was inclined to favor Sigüenza, some of whose manuscript notes he had read, who attributed the pyramids to the Olmecs, the first people mentioned in the Indian chronology of New Spain, who were supposed to have come from the East, or even from Europe.

Humboldt referred to the Toltec leader Quetzalcoatl as a "Mexican Buddha," and he was amused to quote Spaniards who described him as white, bearded, and accompanied by strangers wearing black soutanes, saying they believed him to be either a Carthaginian or an Irishman, either possibility of which Humboldt was not ready to envisage.

Though Humboldt's description of the Teotihuacan complex appears to be secondhand, he devoted firsthand attention to the Great Pyramid of Cholula. After eleven months in Mexico, Humboldt decided to leave via Veracruz, stopping at



Humboldt found the Cholula Pyramid to be the largest in America, a truncated structure with four terraces, 367 feet from east to west, by 348 feet from north to south. It appeared to have been in constant use up till A.D. 1200. The interior he found to be made of mud and small stones covered by a thick wall of amygdaloid porense. On the outer layer were stones bound together by traces of mortar called *tetzontli* by the natives.

The mound could be entered through a small opening on the eastern side. Inside was a bewildering maze of passages, with here and there a frescoed wall adorned with butterflies and insects in yellow or black, and the evidence of seven superimposed constructions.

Humboldt says the pyramid had been surmounted by a jade image of Quetzalcoatl, "Lord of the Breath of Life." The Cholula Pyramid is the largest known structure in the world in terms of cubic content. Two hundred and ten feet high, it covers forty-five acres. The pre-Conquest Mexican legend about Cholula is very similar to the Biblical account of the Tower of Babel. According to the legend, after the deluge which destroyed the primeval world, seven giants survived, one of whom built the great pyramid of Cholula in order to reach heaven, but the Gods destroyed the pyramid with fire and confounded the language of the builders.

On September 16, 1810, Miguel Hidalgo y Costilla, a parish priest in the dusty little town of Dolores in the province of Michoacan, raised the cry which came to be known as the "Grito de Dolores," calling for an end to Spanish rule in Mexico. Hidalgo, who was born in Dolores, a few miles from San Miguel Allende (named for his co-insurrectionist, Captain Ignacio Allende) was a tall gaunt second-generation *criollo,* trained by the Jesuits, impressive in his black cassock and white-fringed hair.

His revolutionary ardor came from having watched government constables chop down the olive trees, vineyards, and mulberries he had taught his parishioners to grow, in contravention to the Peninsular law against the production in the colonies of olive oil, wine, or silk.

Naming himself "Captain General of America," he seized the icon of the Virgin of Guadalupe, the Morenita, most holy of all symbols to the native Indian, as banner for his army. Spaniards and officials fled before him. But at the gates of Mexico City, which the more intrepid Allende wished to attack, Hidalgo vacillated. When his forces turned to indiscriminate pillage and massacre, the *criollos,* who also longed for liberation from Spain, became afraid for their lives, especially after the example of Haiti, where native blacks had slaughtered all the native whites. The *criollos* supported the Spanish Viceroy, who ordered the summary execution of all rebels taken in arms. In recaptured towns, one man in ten chosen by lot was hanged or shot. Hidalgo's forces retaliated by garroting Spaniards. The Spanish retaliated by burying their enemies in quicklime.

Defeated and captured, Hidalgo was shorn of his vestments. Shot by a firing squad, on July 30, 1811, his skull was hung in an iron cage as a deterrent to further revolution.

Puebla to inspect the enormous pyramid, which he described as "a mountain of unbaked bricks" once dedicated to Quetzalcoatl, whom he regarded as "the most mysterious being in the whole Mexican mythology," a hero whom he now believed to have reigned much earlier, in a Golden Age of the Anuacs, "when all animals and all men lived in peace, and the earth brought forth without culture the most fruitful harvests, the air being filled with birds of marvelous song and plumage."

On his way from Puebla to Veracruz Humboldt noticed ice carriers from the snowfields of Mount Orizaba bringing ice to the sherbet makers of Veracruz, much as the Ottoman refiners of sherbet had brought it in carts to the Sublime Porte from the peaks of Mount Olympus.

Determined to visit Thomas Jefferson, a fellow naturalist, democrat, creator of an effective democracy, and brother

After Hidalgo's execution, the banner of revolt was taken up by another priest, José Maria Morelos y Pavon, who was of mixed Spanish, Amerindian, and Negro origin. Born in Michoacan, he had worked as a laborer and muleteer until he was 25. Starving himself to gain an education, he entered holy orders, where he studied under Hidalgo.

A short, squat man, Morelos was a taciturn and humble genius, ravaged by malaria and constant headaches, against which he wore a tight bandana over his balding head. Too radical for the *criollos,* who longed for Mexican independence, Morelos drove them into the royalist ranks. They feared the insurgent warfare would destroy the economy: already, commerce and agriculture were at a standstill.

Morelos was betrayed by an auburn-haired mestizo, Augustin de Iturbide, who managed to pass himself off as a *criollo* and tell all he heard about the revolutionaries to the royalists, for which service he quickly rose from lieutenant to colonel in the royalist army. When he learned that Morelos had ordered his insurgents to blacken their faces so that they could recognize each other in close combat, Iturbide, against orders, had a troop of his cavalry darken their own faces. After dark on Christmas Eve of 1813, Iturbide led a reckless mounted charge into the heart of the Morelos camp, bursting in upon the surprised insurgents. Morelos' regiments fired on each other, and the insurgent army dissolved in the face of inferior royal forces. A royalist officer, one of Morelos' old lieutenants who had changed sides, caught Morelos as he tried to remove his spurs for flight. Asked what he would do if the situation were reversed, Morelos replied he would confess the officer and shoot him. Convicted of treason and branded as a Protestant, Morelos was unfrocked and shot to death three days before Christmas 1815.

Mason, Humboldt sailed from Veracruz to New York in March of 1804, loaded with minerals, plants, sculpture, and the few ancient manuscripts he had managed to collect, all of which were to help him produce several volumes on his travels in the Americas, which, when published in expensive folio editions, opened the eyes of Europe to the astounding possibility that a civilization had existed in the Americas far more cultivated and knowledgeable than anyone had theretofore believed, scotching the general opinion that the Indians conquered by Cortes were nothing but barbarous feathered sodomites devoted to the worship of monstrous serpentine idols to whom they ghoulishly sacrificed thousands of victims.

Humboldt's stay in Mexico caused him to be suspected of having helped foment the Mexican revolution against Spain which broke out a few years after his departure. But although he had been sought out by sensitive souls because of his philosophical and metaphysical bent, and by liberals and political actionists because of his penchant for liberal and egalitarian doctrines and his open pronouncements against the economic and social system of exploitation in New Spain, Humboldt must have considered himself too indebted to the crown of Spain, for receiving him so well and granting him such freedom, to risk writing what might have been considered subversive to his royal benefactor. But with or without his help, the revolution broke out a few years after his departure.

For a long time Humboldt dreamed of going back to Mexico.

Iturbide.

Having risen to the rank of general in the royalist army fighting against the insurgents, Augustin de Iturbide grew so rich on graft he overstepped himself by taking too much from a convoy of silver he was supposed to protect. Disgraced, he entered a lay retreat in the convent of La Profesa, where he plotted a revolt against the viceregal regime to detach Mexico from Spain. To subvert the army, he seized an entire pack train carrying half a million silver pesos to Acapulco. Making lavish offers of promotion, Iturbide managed to lead his army into Mexico City in September of 1821, riding on a black horse and wearing a plumed hat, surrounded by a gang of new generals decked in gold braid. As president of the council of regents, Iturbide fomented a barracks revolt to have himself proclaimed Emperor Augustin I. Of the first year's national income, 80 percent went to the army, 11 percent to Iturbide, and the rest to administer a country whose economy had been ruined by ten years of civil war. When congress complained, Emperor Augustin I disbanded it and ruled by decree in imitation of Napoleon I. But others could play the same game. One of Iturbide's lieutenants, Antonio Lopez de Santa Anna, who had risen to the rank of general, called for a republic (though he admitted candidly he did not know the meaning of the word), and Iturbide was sentenced to perpetual exile.

Once the revolution, which started in 1810 and dragged on for ten years, had rid Mexico of Spanish rule, he would have liked to return to organize "a great scientific establishment for all of Free America." In October of 1822 he wrote to his brother Wilhelm from Verona that "the Emperor of Mexico, Iturbide, whom I know, is about to fall and make way for a Republican government. . . . I have the notion of ending my days in a pleasanter way and more useful for science in a part of the world where I am extraordinarily well liked, and where everything indicates I would be happy. It is a way not to die without some glory, to unite around me many educated people, and enjoy that independence from opinions and feelings which is necessary to my well being."

Humboldt wished to make a base in Mexico City from which to explore all the places he had only heard of or written about secondhand. But his expensive publications cost too much of his fortune, and though there was mention that in France 4 or 5 million francs were being collected to reorganize the mines in Mexico, nothing came of the venture, and Humboldt, growing old and depressed, was obliged to live out his life in the constricted atmosphere of the court at Potsdam without ever seeing Mexico again.

His large illustrated works, however, were to spark an unquenchable interest in a whole new breed of adventurers who set out to explore the antiquities of Mexico.

5. British Enterprise

Antonio Lopez de Santa Anna.

William Bullock, a Liverpool jeweler, amateur naturalist, and antiquarian, was so impressed by Humboldt's massive volumes on Mexican antiquities that he decided to travel to Mexico and bring back specimens of his own to exhibit in London to a public whose taste for the exotic had been stimulated by the recent discoveries of Napoleon's savants in Egypt, just published in the monumental twenty-volume *Description de L'Egypte.* As a merchant, Bullock was in the *avant garde* of a whole company of English entrepreneurs who wished to profit by trading with an independent Mexico open to foreigners.

In December of 1822 Bullock sailed for Veracruz in the company of his twenty-year-old son aboard an English merchantman armed with twelve cannon for protection against ubiquitous pirates. Though he had been told to expect "the most stable government" in Mexico, Bullock found the port of Veracruz in the hands of republican insurgents under General Antonio Santa Anna, while the self-appointed Emperor Iturbide had retreated to Puebla with his royalist army.

Heading for the highlands, the Bullocks were disappointed by their first wayside inn, where they were kept awake by mosquitoes, barking dogs, and braying asses; in the morning they were obliged to "clean our persons from the deposits of the poultry that had roosted over our heads."

In Puebla, the first impressive city reached by the Bullocks, they learned that the emperor had resigned the government into the hands of the republicans and fled the country, which had installed General Santa Anna as president of the Mexican republic; so the Bullocks followed Humboldt's footsteps to Cholula, where they examined the ruins

Veracruz.

Villa Rica de Vera Cruz, or the Rich Town of the True Cross, had been a mere campsite of huts until Cortes declared it a town as a device to bypass the authority of his boss Velasquez in Cuba so as to seize Mexico for the crown in his own name. By having himself elected chief magistrate of the municipality of Veracruz, Cortes became directly subordinate to Charles V and so cut Velasquez out of a fifth of the booty. Thereafter Vera Cruz became the port of entry to Mexico from Europe.

To Bullock, Veracruz had an Oriental look, with low cupolas, something like mosques without the elegance of minarets. To the south were the cemetery and the slaughterhouse, to the north the flat yellow-fever marshlands inhabited by iguanas, snakes, herons, and wild duck.

Whereas Careri had complained of being devoured by field lice, Bullock found the city hot, dusty, and with filthy streets cleaned of offal by carrion vultures. Humboldt, more scientifically, had noted that all the buildings were built of stone dredged up from the sea, called *madreporicas,* there being no other stone available.

of the pyramid, which they found covered with prickly pear, tuna, copal, and other vegetation, on top of which the Spaniards had built an imposing church.

"It was here," noted Bullock, with his penchant for establishmental history, "that Cortes, on his first advance, was welcomed as a liberator and brother, but having accidentally discovered that it only arose from a deep-laid plan to assassinate him and all his followers, he, with his accustomed presence of mind and decision of character, secured the chief persons of the place; and, to strike terror in others, made a terrible example, by putting to death 70,000 of the inhabitants."

In the spring of 1824, Iturbide, like Napoleon returning from Elba, tried to recapture his empire, landing by boat at a port in Tamaulipas with a packet of paper money and printed proclamations, unaware that the congress had voted a bill of attainder if he ever set foot again on Mexican soil. The local authorities seized and shot him.

A good bourgeois, Bullock was as impressed by the broad streets of Puebla that were paved with large stones in checkered or diamond patterns as he was by the splendid equipages and retinues of the wealthy Pueblans, whose handsome carriages were drawn by richly caparisoned mules attended by servants in showy liveries, parading through the streets and parks.

To show the flag, and *épater* the natives, Bullock sported a walking-stick gun, a portable chair and table, a camera lucida,* "and other little specimens of English ingenuity."

Approaching Mexico City, the Bullocks came upon suburbs they considered "mean and dirty, the people covered with rags," but they were well pleased by the center of the city with its wide streets and grand houses.

* The camera lucida is an optical instrument for drawing in perspective, invented at the beginning of the nineteenth century by an Englishman, Dr. William Hyde Wollaston. By looking with one eye vertically through a strip of plain glass tilted at an angle of 45 degrees, an image is reflected onto the surface of a sheet of paper so that the outline can be accurately traced with a pencil. A helpful device for transferring architectural structures onto paper, it had the advantage of being cheap, small, and portable.

Whereas in Puebla Bullock was astonished to find that the wives of mining magnates kept houses in a princely state, and would go to church escorted by hundreds of servants and twenty ladies in waiting, in Mexico City Bullock was most impressed by the streets, which were two miles long, perfectly level and straight, ending in a gorgeous view of the surrounding valley with snowcapped volcanic mountains in the distance.

As snobbish as any merchant, Bullock was happy to secure the services of Count Luchese, uncle to the Duke of Monteleone, a descendant and heir of Hernan Cortes, to guide him through the city. Luchese graciously escorted his English visitors around the 700-foot-long palace of the viceroy with its 1,100 windows overlooking the Plaza Mayor, which Bullock deemed to be "the finest in the world." In the palace grounds they saw not only the mint and the prison, but a botanic garden with fountains and fragrant plants unknown to Europeans before Humboldt, aflutter with pretty, tame birds.

In the Hospital of Jesus, Bullock was even shown an iron chest in which were kept the bones of Cortes. Thirty years earlier these grisly remains of the conquistador had been removed to the hospital from the Church of St. Francis to be venerated in a crystal coffin secured by bars and plates of silver, and were only just saved by royalist "friends of the family" from a mob of republicans who wished to scatter to the winds the bones and ashes of this "detestable old Spaniard." Pensively Bullock examined the skull, which he found to be small, with some missing teeth. Later scrutinizers found evidence in the bones of degenerative symptoms corresponding to dwarfism and a condition of congenital syphilis in the osseous system.

In the city, the English merchant was most impressed by the comfort of the three-storied houses, painted in dis-

Bullock found that the sumptuous house of Emperor Iturbide had been turned into a stagecoach hotel.

temper, highly decorated, with rows of wrought-iron balconies and porticoed courtyards scented by flowers and trees. He thought the climate ideal, a perennial spring, and was enraptured by the clear atmosphere, not yet contaminated by smog, a bourgeois's dream, in which even the execution of a felon appeared to be done in a "solemn and decent manner," so different from the executions he had witnessed in France after the revolution, where "the rabble behaved with the most disgusting ribaldry and obscenity." Here the victims, two Indians accused of robbery and sacrilege, were led to the public scaffold on the backs of asses, dressed in white gowns and caps with red crosses, there to be discreetly garroted "without the public witnessing the horrible contortions often seen in our executions."

Officers of the Inquisition leading "heretics" to the stake.

As Humboldt had declared that apart from the nearby pyramids of Teotihuacan the only objects in Mexico City worthy of the notice of an antiquarian were the great calendar stone and another "sacrificial" stone found near it, Bullock decided to make large plaster casts of both to be shipped to London. With the influence of the Mexican prime minister he was able to obtain permission from the clergy to erect a scaffold by the Aztec calendar and take several separate impressions. Bullock believed the stone to have once formed part of the roof of the great temple of Tenochtitlan, much like the Zodiac of Dendera, the original of which had only just been dismantled and carried to the Louvre. Like Humboldt, he considered the Aztec stone "proof of the perfection the nation to which it belonged had attained in some of the sciences." Few persons, he maintained, even in the most enlightened cities of Europe, would have been capable in his day of executing such a work.

A hundred yards from the calendar stone the so-called sacrificial stone lay buried in the cathedral square with only

On the upper surface of this monolith there are 6 × 6 = 36 single glyphs, which yield 9 groups of 4. If these 9 × 4 are added to the 4 × 4 glyphs on which the chieftains are respectively seated, 13 groups of 4 are obtained, equivalent to the 52 years in the Mexican cycle. Each group is accompanied by the name of a tribe and its capital. Again it took a hundred years before some meaning was found for these mysterious glyphs.

its upper surface exposed, "to impress on the populace," says Bullock, "an abhorrence of the horrible and sanguinary rites that had once been performed on this very altar."

From the clergy Bullock again obtained permission to expose the sides of the stone and to make casts of the twenty-five-foot circumference on which were carved fifteen groups of figures representing the conquests by Mexican warriors of different cities. The casting performance greatly aroused the curiosity of bystanders, who, says Bullock, wondered if the English still worshiped the same gods as had the Mexicans before their enforced conversion to Christianity.

But the antique relic which most appealed to Bullock and on which he most counted to shock or titillate a London audience was reported by Humboldt to have been dug up and reburied in a gallery of the University of Mexico by Dominican priests who considered it too scandalous to be viewed by Christian students.

Bullock had great difficulty persuading the authorities to let him dig it up, but with the help of Humboldt's friend Don Manuel del Rio, who had graduated to professor of mineralogy at the university, he finally obtained permission. The burial spot was ascertained with not too much difficulty, and a few hours' digging disgorged from mother earth the Mexican goddess of earth and mother of the entire Nahuatl pantheon.

"I had the pleasure," says Bullock, "of seeing the resurrection of this horrible deity, before whom tens of thousands of human victims had been sacrificed in the religious and sanguinary fervor of its infatuated worshippers."

To Bullock it was scarcely possible that an artist "combining the ingenuity and imagination of a Brueghel and a Fuseli"

In Bullock's time, the university was a mere survival of medievalism in government and curriculum, the men of learning of the viceroyalty being dedicated to the perpetuation of a doctrinal theology that was already becoming obsolete.

could have conceived so awesome a sight. Bullock described the "colossal and horrible monster" as being hewn out of one solid block of basalt, nine feet high, its outlines giving the idea of a deformed human figure "uniting all that is horrible in the tiger and the rattle-snake." Instead of arms the figure was supplied with large serpents, its drapery was wreathed snakes, interwoven and terminating in the wings of vultures. The "idol's" feet, between which lay the head of another rattlesnake descending from its body, were those of a tiger or jaguar, claws extended in the act of

Coatlicue.

This squat, massive twelve-ton basalt statue, embodying pyramidal, cruciform, and human forms, dug at Bullock's request, and which he considered monstrous, was quickly reburied by an outraged priesthood. Only later was the statue understood to incorporate the essence of Nahuatl cosmological thought. "Nowhere in the history of art," says Professor Leo Gatz, "has a single monument achieved such a complete synthesis of human and abstract universal relations."

In the opinion of Mexico's art critic Justino Fernandez the statue represents "the embodiment of the cosmic-dynamic power which bestows life and which thrives on death in the struggle of opposites."

To Frank Waters, Coatlicue emerges as the concrete embodiment in stone of the ideas of a cosmic being who generates and sustains the universe. "It adumbrates the cruciform orientation of the quadrants of the universe, as well as the dynamic quality of time, which creates and destroys through struggle."

Author Lewis Spence points to the strong similarities between Coatlicue of Mexico and the goddess Cleito, wife of Poseidon, founder of Atlantis: each, says Spence, presided over a Sacred Hill, and each bore seven sets of twins, two of whom—Atlas and Quetzalcoatl—were mountain-born supporters of the world.

seizing a prey. A necklace, above huge deformed breasts, was composed of human hearts, skulls, and chopped-off hands fastened together by entrails. It took Bullock a week to make a cast of Coatlicue, as the goddess was called, whereupon the university authorities ordered the statue reburied "so as to hide it from the profane gaze of the vulgar."

His casting completed, Bullock was free to visit the pyramids of Teotihuacan. On Whitsunday of 1823, accompanied by his son and a co-national, Mr. Gilton, Bullock set off toward Texcoco with an Indian guide and letters of introduction furnished by the viceroy's wife, the Countess of Regla, to the principal inhabitants of this onetime capital.

Leaving the great square of Mexico City, the Bullocks passed a thousand horses and mules loaded with silver being prepared to leave for Veracruz to be shipped to Europe.

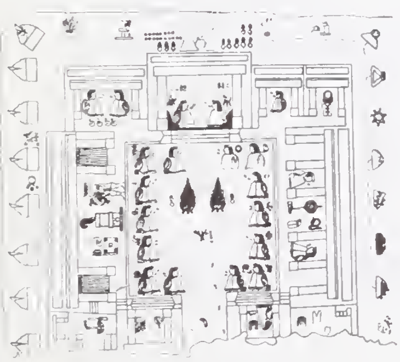
Thereafter for several miles they proceeded along the original causeway across the old lake of Texcoco, which seven weeks earlier at their arrival in the city had been covered with water and myriads of shoveler ducks but was now dry for lack of rain.

Gardens of Texcoco.

Approaching Texcoco—the Athens of America, as Bullock termed it, "residence of historians, orators, poets, artists, and the great men of every department of the sciences who existed in those days"—they crossed the "Bridge of Brigantines" from which Cortes had launched his flotilla to recapture and destroy Tenochtitlan.

In the market place of Texcoco they viewed the spot where Bishop Zumarraga had burned the Aztec heritage of manuscripts and hieroglyphic writings.

Bullock was much moved by the palace of the ancient caciques, or tributary kings of Texcoco, which extended three hundred feet, forming part of a large square built up on sloping terraces, the original walls of which were composed of huge blocks of basaltic stone, four and five feet long, two to three feet thick, cut and polished with great exactness, many of which had gone to build the nearby Catholic church.



Sixteenth-century drawing of an older map of the palace court of Texcoco.

As the sky darkened with thunder clouds, Bullock inquired about the "celebrated pyramids of the Sun and Moon, or for San Juan of Teotihuacan." But his inquiries were fruitless, so he headed for Otumba in the expectation of finding them near that place.

For a couple of hours they rode over fine country on which the number of handsome Spanish churches and haciendas exceeded those of any part of Mexico through which Bullock had yet traveled.

At one point he passed a stand of olive trees, the finest he had ever seen. "Those of Tuscany are not half the size; they

must many of them be thirty feet in diameter." At the foot of some low mountains Bullock described the landscape as being soft iron-colored stone without vegetable soil or vegtation, in which the continual passing of horses had worn deep tracks up to the knees of animals.

By evening, thunder turned to torrents of rain, which filled the dry beds of the rivers, pouring muddy waters toward the great flat lakes.

On the far side of the mountain, Bullock at last caught sight of the two great pyramids on the plain before them, five or six miles away; an hour's ride brought them to Otumba just before dark, "the first place," noted Bullock, "reached by Cortes after his defeat of *La Noche Triste*." An old lady gave them refuge in a carpenter's shop where they could dry their clothes and sleep. In the morning, after bread and hot chocolate, they queried the local padre for information about the pyramids, but he could give them none, though they were in full view of the windows of his house, about a league and a half away.

As Bullock and his party approached the shrub-covered mounds, they could see the "square and perfect form of the largest," and distinguish its terraces. Attacking the smaller pyramid first, they found it much dilapidated, but ascended to its top over masses of falling stones and ruins of masonry with less difficulty than they had expected. On the summit Bullock found the remains of "an ancient building, forty-seven feet long and fourteen wide with walls three feet thick and eight feet high, mostly of unhewn stone with three win-

Bullock's illustration of the Sun Pyramid on the summit of which he says he found the remains of an ancient temple.

dows on each side." The northern end of the building appeared to them to have been divided at about a third of its length.

Bullock says that he and his companions sat atop the Pyramid of the Moon, with the great Pyramid before them, "contemplating this scene of ancient wonders." His eye took in not only the greater part of the Valley of Mexico, with its surrounding mountains, but also Mexico City, some thirty miles away, a feat quite impossible now because of the smog.

Cortes winning the battle of Otumba by killing the "snake woman" leader of the Aztec forces.

Bullock was of the opinion that when Cortes came through the valley the large pyramids were in the same condition in which he found them—covered with dirt and shrubbery—and that it was on ascending one of them that Cortes was able to see the approach of the great Indian army which Francisco de Aguilar (who was with Cortes at the time) estimated at the incredible number of "five to six hundred thousand selected men." Bullock says there was no other eminence nearby which could have answered the purpose, concluding that "It was at this place that Cortes fought and defeated the innumerable army of Indians; after the horrible night of desolation he expressly says that he arrived on the plains near Otumba; he ascended an eminence, and discovered the whole district covered with armies; despair filled every breast, except the intrepid leader's." Paraphrasing Bernal Diaz' account of how a mere four hundred wounded and weary Spaniards with two score

Pulque is a liquor made from the fermented juice of the maguey plant, whose flower grows as high as 20 feet, with 10-foot leaves. Some yield as much as 600 liters of liquid, drawn from a hollow in the center, from which first honey then pulque is derived.

For the Aztecs, pulque was not only a nutritive drink but a medicine and a ritual intoxicant related to their complex pantheon. It was also given to conquered warriors about to be immolated.

Excessive drinking of pulque was controlled among the Aztecs, if not eliminated, by a taboo on the "fifth cup." This was reserved for priests, in whom it induced an ecstatic reaction, often causing them to dance. Even a fourth cup was frowned upon, since it might result in drunkenness, a punishable offense in Tenochtitlan except in privileged cases (the sick, the aged, or celebrants at certain festivities).

The early Spanish churchmen considered pulque detestable, the cause among Indians of "idolatry, thieving, murders, sacrilege, sodomy, incest and other abominations.' But the viceregal government soon used it as a source of revenue, the tax bringing in a yearly 100,000 pieces of eight.

When the green leaves of the maguey are crushed and the fibers separated on a stone with water, hemp is produced from which cloth can be woven which takes the place of linen. Ropes are also entwined. The spines are used for needles; and the leaves, when intact, can be used to roof houses. The shoots nearest the earth, which are white and tender, can be cooked and eaten. Dry, the leaves provide fuel for a gentle smokeless fire, whose ashes are medicinal. When the root is drawn from the center of a dead plant it can be used as a rafter.

horses got out of this iron trap, Bullock pontificated romantically: "The unnumbered host of Indians arrived, and closed round the small band of Spaniards, when the dauntless Cortes, with a few horsemen, charged furiously that part of the enemy where the royal banner was carried, the bearer was killed, the banner taken, and the whole of the immense multitude fled in consternation from the field, offering no further interruption to the retreat of Cortes."

Bullock's romancing led to the conjecture that the Indians, like the Trojans in a Homeric epic, were overcome by what they considered supernatural forces, as if the Spaniards were demigods descending on them from Teotihuacan, the "home of the Gods."

At the base of the Moon Pyramid Bullock had a drink of pulque and tried to make friends with some native children, but they "seemed much terrified at our white faces and odd dress." To Bullock the smell of fresh pulque was acceptable, but very disagreeable when matured to the point it was appreciated by the Mexicans.

When Bullock asked an old woman if she could tell him who had built the pyramids, she replied, *"Si, señor. San Francisco."*

According to an old legend told to Sahagun, a woman, Mayahuel, later regarded as a goddess, and the mother of Centzon Totochtin, the patron of Tepozteco, invented pulque and knew how the maguey should be pierced in order to extract the honey. In the Borgia Codex, which originated in Puebla or possibly Tlaxcala, Mayahuel is a prominent figure dressed in white, the color of pulque. The Borgia Codex also shows another pulque god, Patecatl, who discovered how to supplement the honey from the maguey to aid in the fermentation process. His name, like that of his associate deities, was taken from the locality in which he was worshiped. Several place names survive to identify the first makers of pulque with a mountainous place called Chichinahuia. Because this drink was topped with foam, the snowcapped peak was also called Popocatepetl, meaning "Foamy Mountain."

The Codex Magliabecchiano, probably painted between 1562 and 1601, has several representations of pulque deities, including Mayahuel and Atlacoaya. Eduard Seler noted that the face of a pulque god was usually painted in two colors, one half in red and the other in black or dark brown with yellow spots. This decorative scheme also characterized representations of Tlaloc and Quetzalcoatl. Pulque deities were further distinguished by a crescent-shaped ornament worn directly under the nose.

Not far from the great pyramid, near a gate, they found an enormous stone with sculptured ornaments, which appeared to Bullock to be of great antiquity. A boy who had followed them beckoned Bullock's son toward a plantation where they found another great stone covered with sculpture with a hole in the top, which Bullock supposed to be a "stone of sacrifice."

The ascent of the large pyramid was less difficult than they expected. All the way up they found lime and cement mixed with fallen stone. Bullock described the terraces as clearly visible, particularly the second, which he estimated to be about thirty-eight feet wide, covered with a coat of red cement eight or ten inches thick, composed of small pebblestones and lime. But in many places, the copal trees had destroyed the regularity of the steps, though "nowhere injured the general figure of the square," which, Bullock says, "was as perfect in this respect as the great pyramid of Egypt."

Wherever they climbed, the party found broken pieces of obsidian knives, arrowheads, and spear heads. On reaching the summit, they came upon "a flat surface of considerable size, but which had been much broken and disturbed." Here they rested and again Bullock rhapsodized on the view which included the city of Mexico some thirty miles distant.

On top of the pyramid Bullock found fragments of small statues, earthenware, and, surprisingly, oyster shells, the first he had seen in Mexico. On the way down they picked up several ornamental pieces of earthenware, the relief pattern on one of which resembled those of China.

Bullock says that on the northeast side of the Sun Pyramid, about halfway down, an opening had been attempted at some remote period. He maintained that any passage should have been from south to north, on a level with the ground, or only a few feet above it, as "all the remains of similar buildings have been found to have their entrances in that direction."

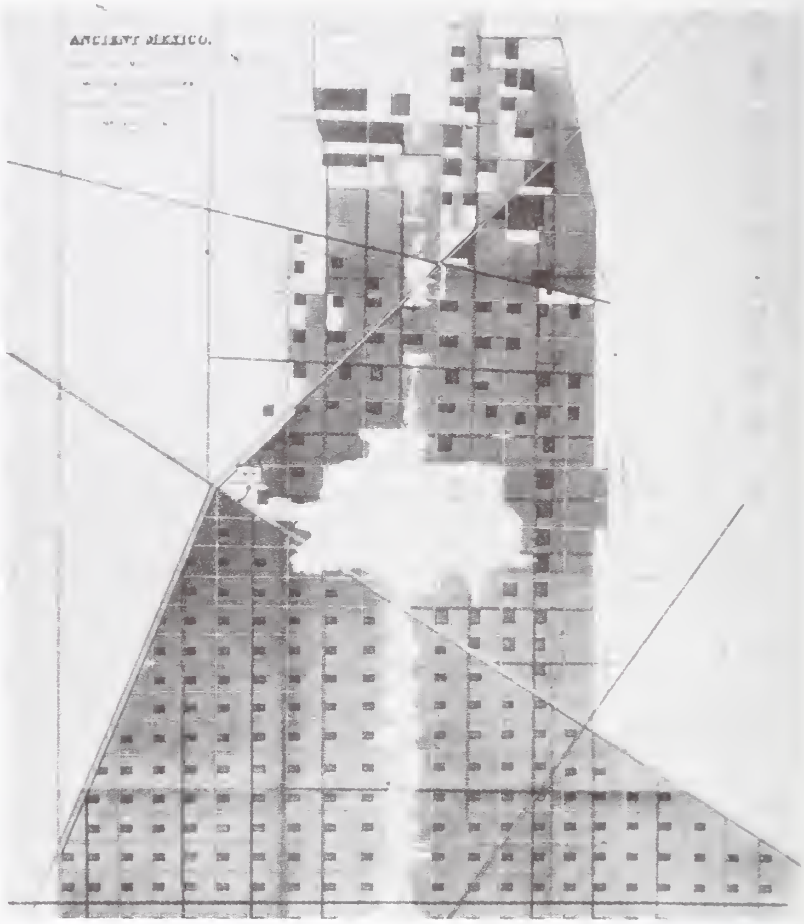
In the village of San Juan Teotihuacan, Bullock and his party procured refreshment and provender for their horses. By evening they reached the town of San Cristobal, once again soaked with rain, having come by way of the long causeway built to prevent the flowing of the waters of the Lake of San Cristobal into that of Texcoco; thence they returned to Mexico City by way of Guadalupe.

Much impressed by the monumental ruins of Teotihuacan, Bullock was amazed that no one in Mexico City seemed to care the least about them or could give him any information regarding them. His three-day excursion had convinced him of the veracity of accounts of ancient Mexican splendor such as were given by Francisco Clavigero; what he had seen enabled Bullock to discount the theories of such denigrators as De Pauw and Robertson. "Had Monsieur Pauw," says Bullock, "or our better informed countryman Robertson, passed one hour in Texcoco, Tezcotzingo, or Huexotla, they would never have supposed for a moment that the palace of Montezuma in Mexico was a clay cottage or that the account of the immense population was a fiction."

Further to convince his compatriots of the splendor of ancient Mexico, Bullock had models made of the Teotihuacan pyramids to be shipped to England. He then set off on the return journey via Puebla and Veracruz, this time carried on a litter strung between two mules, taking with him a menagerie of several armadillos, deer, parrots, curassow birds, quans, and tiger cats, most of them running around loose, to the dismay of his Puebla hostess. He also took with him a variety of flowers and ornamental plants as yet unknown to European botanists. His extensive collection of preserved animals and birds astounded the natives, who could only imagine they were being taken to his homeland for medicinal purposes.

Typically, what appealed most to Bullock from his stay in Mexico were the parts of the countryside which reminded him most of Devon; fields covered with verdure, woods with

Collection of calendar stones and "idols," reproductions of which Bullock took back to England for exhibit.



Map of Tenochtitlan.

Among the mementos of manuscripts and hieroglyphic pictures brought back to England by Bullock was an original map of the ancient city of Tenochtitlan made by orders of Montezuma for Cortes to be transmitted to the King of Spain. The map shows how the city was divided into squares with chinampa gardens linked by canals and pathways.

Tenochtitlan was a chinampa city with six to eight plots to each house, each chinampa about 300 feet long and 15 to 30 feet wide. The map shows the profile of each householder and his name.

flowers and blossoms and fruits, hills smaller and more diversified than in England, "clothed with trees, shrubs and flowers in such endless variety that no part of Europe can vie with it."

What he liked least were the bullfights, with their tearing, mangling, and killing of bulls, horses trailing their entrails, and the wounded and dying matadors who gave "as exquisite delight in Mexico as Madrid."

Back in London, Bullock the impresario redecorated his "Egyptian Hall" for an exhibition of Mexican curios. Avid Piccadilly strollers could now view the "monstrous" Coatlicue and the Aztec calendar stone—which came to be known as "Montezuma's Watch." Except for a few rare Aztec manuscripts and the drawings in Humboldt's expensive folios, these were the first Mexican antiquities to reach Europe, the "first exotic peep at pre-Columbian America."

On the profits of the exhibition, Bullock acquired a silver mine in Mexico and would have dropped into oblivion except for the publication by John Murray of a booklet, *Six Months Residence and Travels in Mexico,* in which Bullock summed up his Mexican adventures.

6. Spanish Reappraisal

In their concentration on the pyramids of Teotihuacan and and the Aztec calendar stone, Humboldt and Bullock managed to miss a whole world of ancient and amazing ruins in the lower-lying jungles of Chiapas, Yucatan, and Guatemala. During the next two decades these ruins were to intrigue Europeans and North Americans as greatly as had the discoveries of Napoleon in Egypt.

The first to be discovered included a pyramid which many years later was to reveal a secret walled-up burial chamber as impressive and difficult of access as had been the so-called King's Chamber in the Great Pyramid of Cheops in the time of Caliph al Mamun.

In 1773 Friar Ramon de Ordoñez y Aguilar, canon of the cathedral town of Ciudad Real in Chiapas, then a Guatemalan province sandwiched between Yucatan and Tabasco, heard from an Indian a tale so amazing it was hard to believe. Not far from the village of Santo Domingo del Palenque, within a few miles of where Cortes was known to have passed with an escort of Indians but made no mention of the fact, there appeared to be a whole abandoned city beautifully built of stone and carved statuary, quite different from anything on the Mexican plateau, entirely smothered by the jungle. Titillated by the prospect of being the official discoverer of such an amazing relic, Brother Ordoñez had his parishioners fashion for him a palanquin to transport him sixty miles to the wattle and daub village of Santo Domingo del Palenque.

From there Ordoñez' parishioners carried him another eight miles into the jungle, where they came upon a stone complex completely overgrown with vegetation. The site was so stunning that Ordoñez was prompted to dash off an im-

Santo Domingo del Palenque.

Founded in 1564 on the grassy savannah of Tumbala by a Dominican missionary, and described as a "small Eden" shaded by huge ceiba trees, Santo Domingo received the additive Palenque, or "palisade," when the Spaniards ordered high walls built to protect themselves from the unfriendly natives resistant to conversion.

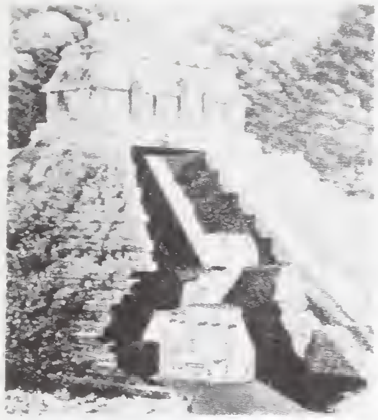
mediate *memoria* to his political superior in Guatemala City, Don José de Estacheria, which he followed with a weightier monograph entitled *A History of the Creation of Heaven and Earth,* in which he attempted to explain that the ruins—which he named the "Great City of Serpents"—must have been built in remote antiquity by a people who had appeared from the Atlantic guided by a leader called Votan, whose basic symbol was a serpent.

Ordoñez claimed to have gotten the material for his story from a book written by Votan himself in the Quiché language, asserting that the original book had been burned by Nuñez de la Vega, Bishop of Chiapas, in 1691, who before destroying it had copied parts of it which he showed to Ordoñez.

Votan was said to have set out from the land of Chivim (not specifically identified but believed to be transatlantic), and to have come to Yucatan via the "Dwelling of the Thirteen" (identified as the Canaries), with a stopover on a large Caribbean island presumed to be either Hispaniola or Cuba, but more likely the former. From there Votan is said to have crossed to the east coast of Mexico, where he made his way up the Usumacinta River to found the city now known as Palenque.

Votan is described as having arrived with a retinue dressed in long robes, of having exchanged ideas and customs with the natives, who submitted to his rule and who gave to the strangers their daughters in marriage.

Bishop Nuñez de la Vega also quoted Votan's book in a publication of his own entitled *Constituciones Diocesianos de Chiapas*. According to Nuñez de la Vega, when Votan came to America he listed the names of all the provinces and cities in the area in which he tarried. One was known as Huehueta, where Votan is claimed to have placed a treasure in a damp, dark subterranean house, appointing a woman as



Secret burial chamber in Palenque pyramid.

According to Ordoñez, Nuñez, and the native Mexican sources, the Chivim were Hivites, descendants of Heth, son of Chaanan, grandson of Noah, expelled from Geth by the Philistines a few years before the Hebrews went out of Egypt. One of their tribe, Cadmus, was believed to be the son of Ogyges who was on Mount Hermon beyond the Jordan, east of Chaanan, and was, according to Ordoñez, killed by Moses during the Exodus, which he dates as 1447 B.C. The tribe, expelled by the Hebrews, is said to have conquered Sidon and founded Tyre, from which Votan sailed for America.

chieftain of the treasure, with keepers to guard her. Nuñez de la Vega says that as bishop he carefully inspected the whole province to identify the locality where the treasure had been buried, and when he found it ordered its guardians to surrender what turned out to be nothing more than several lidded clay jars, green stones, and manuscripts. These the bishop publicly burned in the market place along with Votan's manuscripts.

Four times Votan is said to have returned to his former home across the Atlantic known as Valum Chivim, which Ordoñez eventually identified as the city of Tripoli in Phoenicia. After one of these return voyages, Votan is described as having come to a great city where a magnificent temple was under construction which was intended to reach to heaven, but was doomed by a confusion of languages. In his *Constituciones,* Nuñez de la Vega was even more specific, saying that what Votan saw was "the great wall, the Tower of Babel."

In a manuscript written in Quiché in 1554 by several Maya Indians, its Spanish translator, Padre Dionisio-José Chonay, had this to say: "It is supposed in the manuscript that the three great Quiché nations mentioned in particular are descendants of the Ten Tribes of the Kingdom of Israel, whom Shalmaneser reduced to perpetual captivity, and who, finding themselves in the confines of Assyria, decided to emigrate." The actual text ran: "These, then, were the three nations of Quichés, and they came from where the sun rises, descendants of Israel, of the same language and the same customs."

In attestation of what they had written, the Indians signed the document on September 28, 1554, saying: "We have written that which by tradition our ancestors told us, who came from the other part of the sea, from Givan-Tulan, bordering on Babylonia."

In another manuscript, Votan's arrival is dated at 1000 B.C., which led modern scholars to suggest that Votan and his "men in Petticoats" could have been Phoenicians. Constance Irwin, in her book *Fair Gods and Stone Faces,* agrees that Votan and his followers could well have been Phoenicians, but places the date somewhat later. She says the great city which Votan could have visited for trade might have been Babylon, the greatest city in the Middle East, a favorite market for Phoenician merchants, where stood the magnificent Tower of Babel rebuilt by Nobopolassar and his successor Nebuchadnezzar in the seventh and sixth centuries B.C.

After his death, Vctan was associated with jade and snakes. Constance Irwin points out that two intertwined

Goya's portrait of his patron, King Charles III of Spain (1759–1788), who is described as one of the enlightened despots of the eighteenth century. After a long apprenticeship in Naples he came to Spain at the age of 43. During the American Revolutionary War he sided with the American colonists against the British. It was under Charles III that the Jesuits were expelled from Spain and from Spanish possessions. He also put some restraints on the hated Inquisition.

snakes formed the emblem of healing, wisdom, and fertility in Babylon, whence it spread east and west, the caduceus becoming a common object on Phoenician and Carthaginian stelae.

Ordoñez' story of Votan did not cause much of a stir in Guatemala City, but his description of the ruins of Palenque sparked his boss, Estacheria, who was president of Guatemala's Royal Audiencia, into ordering the mayor of Santo Domingo, José Antonio Calderon, to make an official survey of the ruins with the help of an Italian-born architect resident of Guatemala City, Antonio Bernasconi. Their report, forwarded to Madrid, was placed in the hands of Charles III of Spain, who, being also King of the Two Sicilies, had developed a penchant for Greek and Roman ruins. The prospect of finding similar antiquities in New Spain induced King Charles to order a systematic exploration of the architectural ruins near Palenque.

To implement the royal edict Estacheria selected a captain of artillery stationed in Guatemala City, Don Antonio del Rio. Decked in a three-cornered hat and powdered wig, "wafting" according to one account "through the jungles of Palenque an aroma of the latest fashionable scent," Del Rio set off on horseback to ascertain the age of the ruins, the extent of the population which had built the ruins, the cause of their abandonment.

Arriving on the scene, *el capitan* found the jungle so thick he couldn't distinguish a neighbor at arm's length. To clear the ruins he hired two hundred natives with axes and machetes, who soon uncovered more extraordinary buildings, palaces, temples, and pyramids, adorned with stucco sculpture and embellished with hermetic hieroglyphs in elaborate carved tableaux, all of which appeared to extend for miles into the jungle, where they had lain undisturbed for centuries. Within the buildings the captain found a maze of rooms, corridors, and subterranean passages, of which he took careful measurements.

With him, Del Rio had brought an artist, Ricardo Armendariz, who made rough sketches of the buildings and figures carved in stone or cast in stucco relief, with which to prepare a pictorial report of twenty-five plates. In his final report, Del Rio suggested the ancient Romans may have visited America, and that there had been a connection between Mexico and ancient Egypt. He quoted Father Jacinto Garriod, who visited Principe in 1638, to the effect that the northern parts of America had been visited by Greeks, English, and others. This final report, illustrated by Armendariz, was forwarded to Madrid, where Charles III had been replaced by his weak son, Charles IV. Because of systematic

Castañeda's renditions of Mayan reliefs are strikingly similar to motifs in Buddhist countries. In Buddhist tradition the Buddha's third week of meditation was spent under a Muchalinda tree, and it was during this time that Muchalinda the serpent king was said to have come forth and spread his hood as a canopy over the Buddha to protect him from the heat of the sun. It was then that the serpent became sacred. The sun, the tree, and the serpent are three of the most sacred symbols of the Buddhist; they appear in practically all decorative art, stylized or natural, throughout Mesoamerica. As with the Mesoamerican, Buddhist doctrine teaches a life after death, that the earth will be destroyed five times, that four destructions have already taken place, and the last will be by flood. Both the Buddhist and the Aztec maintained monasteries for retirement to a life of meditation and both had carvings that they worshiped, placed in niches in the walls of their sacred buildings.

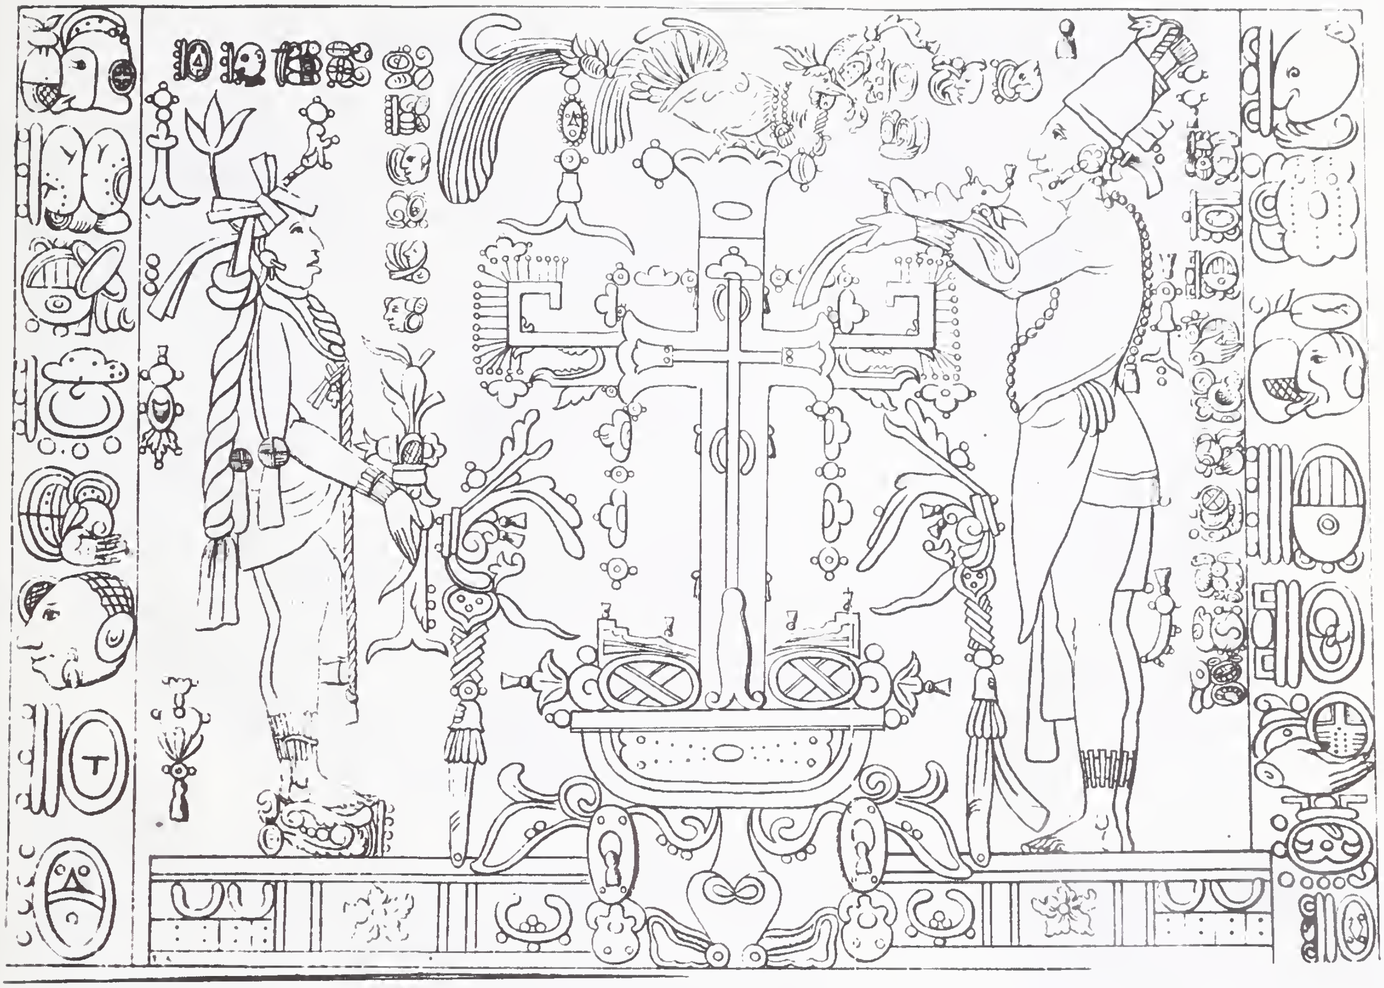
opposition by the clergy, the report was buried in the archives.

Fortunately a manuscript copy made in Guatemala City was edited by an Italian, Dr. Paul Felix Cabrera, described as "a gentleman of fatuous erudition" who not only cleaned up Del Rio's "barracks language" but attached to the report a preface wherein he also ascribed to the ruins of Palenque a Near Eastern origin. In this report, Cabrera also developed the tradition of Sigüenza and Boturini, who believed the Olmecs had arrived on the east coast of Mexico from somewhere across the Atlantic with a stop on the island of Antilia or Hispaniola. Cabrera suggested that the strangers were Carthaginians, and that the first colony had been sent out from Carthage to America before the First Punic War. In the New World, said Cabrera, these Carthaginians had interbred with native women to produce the Olmecs. Cabrera's report was also buried.

Charles IV of Spain was a handsome, amiable near-imbecile and cuckold whose queen took a 25-year-old lover, Manuel de Godoy, to rule the kingdom first as the Duke of Alcudia, then as a prince. Godoy managed not only to disgrace and destroy the crown but to turn Spain into a pawn of revolutionary France so that the Spanish fleet was destroyed by the British. In New Spain, Godoy imposed a series of such grossly corrupt and looting viceroys that he paved the way for revolution.

Cabrera says one of Castañeda's drawings represents Votan or a Hivite from Tripoli in Phoenicia. He says Votan was called a *culebra,* or snake, and later was "placed among the Gods." Cabrera adds that Amaguemecan was in the province of Chiapas, where the Indians carefully preserved the remembrance of their origin, and of "their ancestors' early progress from the voluntary or enforced abandonment of Palestine on the ingress of the Hebrews."

Votan is said to have declared himself "a snake," descendant of Imos of the line of Chan, and said that he came to America from a distant place by the command of God. According to Manly P. Hall, Votan founded Palenque, built a temple with many subterranean chambers called the "House of Dark-ness," and there deposited the records of his nation.



Throughout Mesoamerica a cult of the serpent existed from the most ancient times, spreading as far north as the mound builders of Ohio; it is still perpetuated today in the rituals of the Zunis in New Mexico and the Hopis in Arizona. Frank Waters points out that the plumed serpent was a primary symbol throughout Alabama, Georgia, and Oklahoma, and that the famous Hopi snake dance in which priests dance with snakes in their mouths is the most dramatic ritual still emphasizing the serpents. As for the jaguar, or Mexican *tigre,* it has been the symbol for the earth and earthbound matter since the earliest glyphs. It was so used by Teotihuacanos, Olmecs, Maya, Toltecs, Zapotecs, and Aztecs.

By this time, Humboldt was giving such wide publicity in Europe to the possibility of an impressive pre-Hispanic culture in America that Charles IV, feeling himself obliged to involve Spain in the proceedings, ordered a thorough exploration of all of Mexico for any pre-Conquest antiquities that might be located.

The job was given to Guillermo Dupaix, a retired army captain of Mexican Dragoons, evidently for no greater reason than that he had spent thirty years in the army. As a draftsman to make a record of whatever ruins they might discover, Dupaix selected a young Mexican aficionado of antiquities, José Luciano Castañeda, who had been sought out by Humboldt because of his not undistinguished collection of antiquities. Together Dupaix and Castañeda set out in 1805 to scour Mexico for remnants of pre-Columbian culture.

For three years they traveled about the country, crossing rough mountains, breaking their way through heavy jungle, delayed by sickness, bad weather, bandits, and machete-wielding natives. Their horses slipped cut from under them

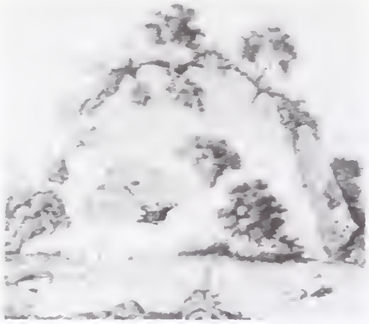
Archeologist Henriette Mertz points out that the fish seen eating lotus flowers in these Palenque panels, as well as the placement of the fish, resemble *makaras,* or fishlike monsters, in the lotus panel at Amaravati. In her opinion, such highly symbolic and stylized forms are unlikely to arise in two totally unrelated places, separated by thousands of miles, without some reason.

Gordon F. Eckholm, outstanding authority on Ancient Mexico, has pointed out that some of the most significant parallels between Hindu-Buddhist and late classic and post-classic Mayan art are those classifiable under the heading of lotus panels. He points out that a principal factor of the lotus panels in Buddhist art is that the rhizome of the lotus plant forms a sinuous pattern along the length of the design area, curving back and forth across the width of the panel and leaving spaces which are filled with leaves, buds, and flowers. The same pattern is followed in these temple reliefs at Palenque. The undulating path of the rhizome of the plant is apparently not a natural feature of either the Asiatic lotus or the American variety.

over steep cliffs or were swept away by turbulent currents. In the end, when Dupaix's legs became so swollen by insect bites he could no longer travel by horse, he suffered (because of his heavy French accent) the added indignity of being detained by the Mexicans as a spy for the French, Napoleon's brother Joseph having temporarily replaced his patron, Charles IV, on the throne of Spain. With all this trouble, Dupaix and Castañeda still managed on their peregrinations to visit and make sketches of the ruins of Xochicalco, Cholula, Mitla, Oaxaca, and many other areas, ending up at Palenque.

Wherever they traveled they became more and more impressed by the extraordinary achievements of the pre-Hispanic Indians. At Mitla, Dupaix found stone structures which he thought displayed "a lavish magnificence worthy of ancient Rome." He was much impressed by the symmetry and accurate measurements of the buildings. The carved stones and the arrangement of the structures gave evidence of the builders' knowledge of mathematics and geometry; artifacts indicated they had a well-formed knowledge of astronomy.

The workmanship of sculptors appeared of "singular beauty of proportion," the pottery of unusual brilliance. From finely cut and splendidly finished masonry, Dupaix was convinced that some metal had been used, though he could find no trace of any, nor of the method used to transport and



hoist into position stones weighing as much as thirty tons. From the well-built aqueducts they encountered, Dupaix concluded the ancient builders had a knowledge of hydraulics; from the construction of their roads and causeways, he felt that their architects rivaled those of Rome.

In the ruins of Palenque, Dupaix was surprised to find glyphs which were like neither those of Egypt nor those of the Valley of Mexico. The work seemed quite original. Unable to compare them with anything he knew in antiquity, either Gothic, Arabic, Chinese, or Phoenician, he concluded he was dealing with a race unknown to historians, who were not necessarily the forefathers of the local Indians. In the end he favored the conclusion that the builders of Mexico's extraordinary pre-Hispanic ruins had come from legendary Atlantis.

As Dupaix was neither archeologist, historian, naturalist, nor entrepreneur, his report, with 145 of Castañeda's sketches, was duly filed in the Cabinet of Natural History in Mexico City, whence, because of the republican efforts at independence from Spain, no one would forward it to Madrid.

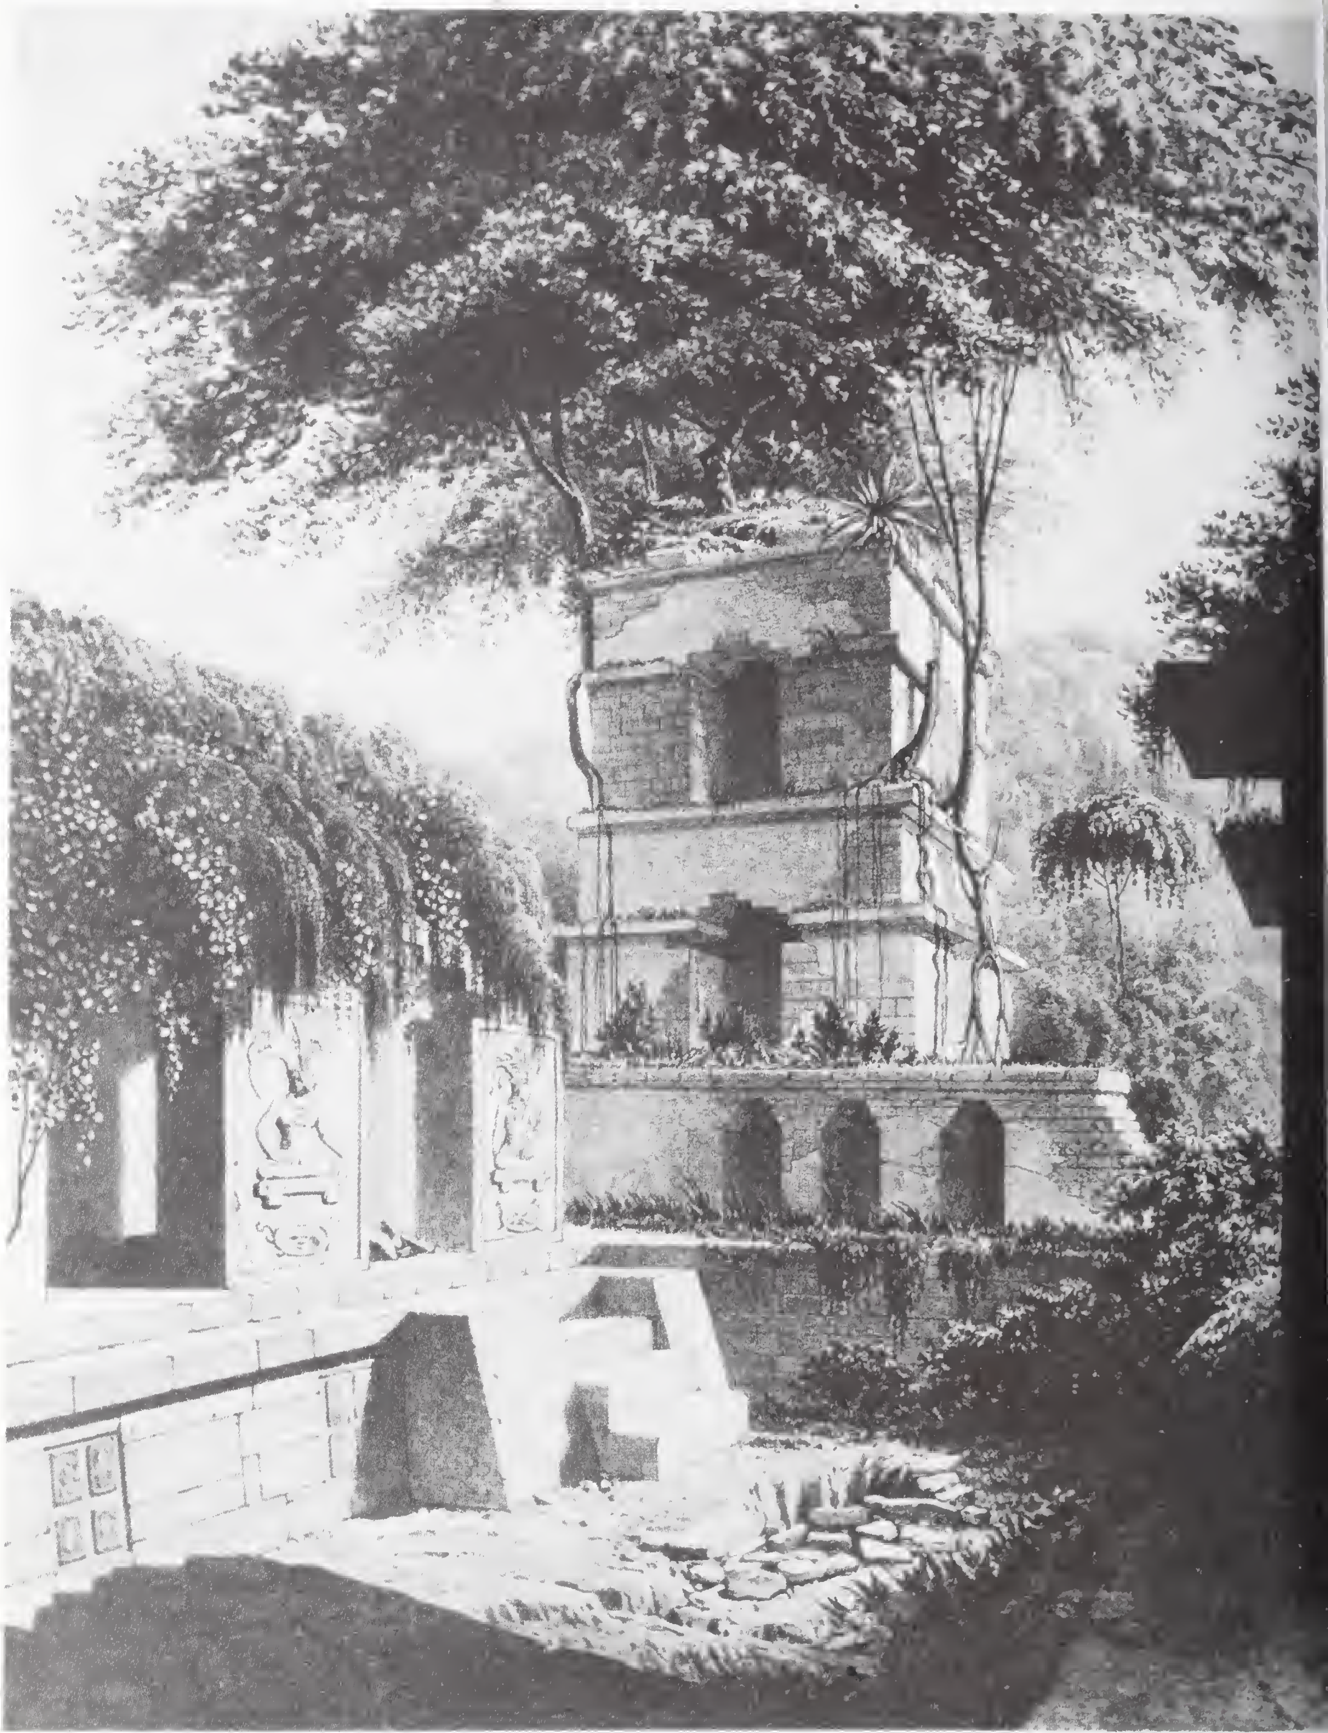
Having done his best, Dupaix disappeared, while Castañeda survived as professor of drawing and architecture at the University of Mexico. There Bullock found him early in 1823 and was so impressed by the originality of his drawings that he had twenty-five of them copied to exhibit in England, only to find on his return to London that he had been scooped by a local bookseller, Henry Berthoud, who had acquired from a British resident in Guatemala City, Dr. Thomas McQuy, a copy of Del Rio's manuscript with Cabrera's unwieldy preface, which he had translated and published as *Description of the Ancient City Discovered Near Palenque,* thus getting into print the first report on the ruins of Palenque.

Dupaix's report and Castañeda's sketches, partly consumed by fungi and cockroaches, were rescued from the Spanish archives by the French Abbé H. Baradère, and ended up in a very expensive folio edition in Paris in 1836 under the auspices of those rival but eminent ministers of state Louis Adolphe Thiers and François Guizot.

Entitled *Antiquités Mexicaines,* the edition was so limited that few could buy it. Yet those into whose hands it fell were so amazed by what they saw they could hardly be restrained from traveling to Mexico. The work was to motivate a series of French adventurers and explorers, prodded and subsidized by the state, who came to open the way for commercial, cultural, and military followers.

PART III

OMANTIC EXPLORERS



7. Discovery of Mayaland

View of the tower at Palenque, seen from the northern gallery, painted as it was at the time, with vegetation growing out of the third floor. To gain sustenance the trees sent their roots some thirty feet to the ground. Waldeck recounts that these roots were stretched so tight that the wind blowing through them at night produced sounds like a harp, only deeper, which caused the Indians to travel several miles at dusk to get away from an area they believed to be haunted. The pillars on the right belong to the western galleries of the palace. The pillars on the left are decorated with stucco figures.

To illustrate Del Rio's report, the publisher Berthoud employed a romantic skirt-chasing French adventurer and former pupil of the painter Jacques Louis David, Jean-Frédéric Maximilien Waldeck, who was so smitten with the scenes he engraved from the sketches of Ricardo Armendariz that he determined, despite his fifty-six years, to explore the site himself, signing himself on as a hydraulic engineer for an English silver-mining company in Mexico in order to obtain his passage.

Boasting of his friendship with Humboldt, Lord Byron, Beau Brummell, and Marie Antoinette (whom he claimed to have visited in prison), and of having accompanied Napoleon on his expedition to Egypt, where he had become intimate with Edmé François Jomard, Waldeck soon quit the mining company and took up residence in Mexico City, no longer as Citizen Waldeck, the revolutionary vogue being momentarily over, but as the Count of Waldeck. There he supported himself painting portraits of the local gentry, soliciting right and left for a grant to explore and record the ruins of Palenque. His days he spent collecting rare books and artifacts, investigating the history of the Nahua, about whom he was to write an unpublished history. His evenings were passed at the opera, the ballet, or the theater, complaining all the time that whereas he had expected to find a lively cultivation of the arts and letters in Mexico City, he found only "an elite notorious for its neglect of cultural life."

Eventually, obtaining sufficient subsidy to take him to Palenque, Waldeck was able to spend a whole year in the village of Santo Domingo plus four months in a hut he built on the site of the ruins, shacked up with a dark-skinned,

Waldeck says that the two reliefs had been removed from the ruins of Palenque and were mortised into the walls of the living room in the house in the village belonging to a deputy called "Bravo," who said he would sell them only on the condition that the buyer marry one of his daughters.

This lion throne originally drawn by Armendariz was thus embellished by Waldeck. At Palenque Waldeck found wooden beams, stone pillars, and entrance posts, all carved in low relief. Everywhere were symbols and human figures, some in masks and bearded, all clothed in ornate regalia, with strange weapons and the flowing plumes of the quetzal covering their surfaces.

firm-breasted mestiza, braving the densest rainfall in the Western Hemisphere to produce ninety quite extraordinary drawings, till his legs broke out in boils and he believed he had contracted a venereal disease.

When revolution and cholera swept Tabasco, Waldeck took off for Yucatan to make more drawings. There he heard that the Mexican government, suspecting him of being a British spy, was about to seize his drawings. Carefully copying the lot, Waldeck says he allowed the Mexicans to seize the copies while he successfully smuggled the originals to England with the help of the British consul.

Making no effort to suppress his feelings about the Mexicans in general and the governor of Yucatan in particular, whom he enviously accused of keeping a harem, Waldeck took ship and followed his drawings to London. There he used them to publish a handsome folio volume of twenty-one plates accompanied by a hundred pages of text in which he concluded that the Chaldeans and the Hindus had been responsible for the construction of Palenque, a city whose collapse he dated as having occurred about A.D. 600.

The so-called Temple of the Cross drawn by Waldeck from the doorway of the palace. At the foot of the pyramid is the shack Waldeck built for his stay at Palenque with his mestizo mistress. Waldeck said the palace was 273 feet wide at its east base and rested on a pyramid 60 feet high.

John Lloyd Stephens aged 36.

At 3,200 francs, or several hundred dollars a copy, Waldeck's book was more of a collector's item than a popular best seller. When a copy reached John Russell Bartlett's bookstore in New York, Bartlett immediately showed it to one of his best customers, the thirty-two-year-old author of *Incidents of Travel in Egypt and Arabia Petraea,* John Lloyd Stephens, who was as amazed as he was impressed by Waldeck's drawings and the possibility of a civilization in the Western Hemisphere as advanced as that of the Egyptians. But Waldeck's reputation as a faker had accompanied his book; puzzling were his drawings of pyramids in the Egyptian style decorated with Romanesque statues in the full round. So Stephens determined to mount an expedition of his own to Central America to establish if the ruins existed in fact, or were, as suggested by many, the hoax of a romantic draftsman—a perfect possibility in that age of P. T. Barnum.

Stephens' English friend Frederick Catherwood, who had traveled widely in the Near and Middle East to make sketches of rare antiquities, was equally dubious about Waldeck, but enthusiastic about Stephens' offer to accompany him to Central America to illustrate whatever ruins they might actually encounter. In London, Catherwood had read Del Rio's book; in Paris Dupaix's; now he was anxious to check them out. But how, he wondered, were two foreigners to crash their way into an uncharted jungle through territory being fought over by revolutionaries and counterrevolutionaries?

Luckily Stephens had helped elect the Democratic President Martin Van Buren, and so was able to get himself appointed U.S. Diplomatic Agent to the government of the Republic of Central America, a flimsy appointment, in that no one at the State Department knew whether such a government existed, where its capital might be, or who might be its president or minister of foreign affairs, neither of whom had been recognized by either Spain or the Pope.

On October 3, 1839, Stephens and Catherwood sailed from New York's North River aboard the British brig *Mary Ann*

Belize, in Honduras, was part of the so-called Republic of Central America, which embodied the Spanish provinces of Guatemala, El Salvador, Honduras, Nicaragua, and Costa Rica. They had been temporarily united under Iturbide's short-lived Mexican Empire, but had since federated under their own constitution, with a coat of arms of five volcanoes crowned by the liberty cap of the sans-culotte and overcast by a hopeful rainbow. When Stephens and Catherwood arrived in Belize, the only news from the country had been of revolution and counterrevolution.

Catherwood's view of a section of the Great Hieroglyphic Stairway, overgrown by the jungle, with its two thousand glyphs mostly collapsed into rubble. In the foreground lies a Mayan head in the mouth of a great serpent which had formed part of the main staircase. At a glance, Catherwood and Stephens realized that whoever had built these ruins had indeed been part of a great culture. Huge monoliths weighing thirty tons had been carved, polished, and decorated with extraordinary art. Though Catherwood rendered the architecture and sculpture with extraordinary care, Victor von Hagen, the most readable authority on Catherwood and Stephens, says the monkeys in the view are apocryphal rhesus monkeys from Africa, whereas only Capuchins and spider monkeys are supposed to be indigenous.

bound for Belize in Honduras. Their immediate object was to locate a mysterious city in the depths of the jungle which appeared on no map of the area: Copan.

They had chosen to search for this lost site because of an Irishman whose real name they did not know, but whose *nom de guerre* was Colonel Juan Galindo. A naturalized citizen of the Central American Confederation, Galindo had risen to be governor of Peten and had been led to Copan by an unpublished Spanish account of an extraordinary lost city. When he reached the ruins, he was so impressed that he claimed the pre-Columbian inhabitants of Central America had achieved a civilization superior to all other native cultures in the Americas.

Arriving in Belize, Stephens was supposed to accomplish his duty as a diplomat and seek out the seat of government to present his credentials, but both he and Catherwood were more anxious to get to their exploring. On the basis of Galindo's report, Stephens and Catherwood set off into the gloom of the Guatemalan jungle, "where shafts of sunlight seeped through as in a cathedral," little realizing that they would be "dragged through mudholes, squeezed in gulleys, knocked against trees, and tumbled over roots." Crossing the Mica mountain range and coping with every conceivable hurdle placed in their way by the local bigwigs, the unwary travelers finally broke through the jungle into the remains of what they realized was a whole new world, the ruins of a civilization so obscure it didn't even have a name, a great city complex whose inhabitants had vanished without a trace several centuries earlier.

Colonel Juan Galindo.

Here were structures unlike anything either of them had ever seen before, pyramids studded with sculptured figures, Copan, Honduras.

The broken stele lying by a large lava-stone tortoise was described by Catherwood as "one of the most beautiful of Maya carvings in the round." Catherwood and Stephens found the glyphs unlike anything they had ever seen in their wide travels and study of exotic architecture, quite outside the Indo-European tradition. So intricate and complicated were the designs, so entirely novel and unintelligible, that Catherwood had great difficulty accurately copying them, but a later historian was to remark of Catherwood's drawings: "When it is taken into consideration that the Maya hieroglyphic writing was a sealed book at the time he visited Copan, and that he knew nothing about the subject matter of the glyphs he drew, such accuracy is remarkable."

Half a century after Stephens stumbled on this "altar" half buried in the jungle near Copan, his prophecy about it was corroborated by archeologists who concluded that the altar commemorated a congress of priest-astronomers who had met in Copan in A.D. 765 to make some important change in their Mayan calendar.

great plazas surrounded by stepped temples, stones carved with mysterious and quite unfamiliar hieroglyphs. Most of the buildings were so overgrown with vegetation and trees that Catherwood, standing up to his ankles in mud, his hands gloved against swarms of mosquitoes, had a hard time drawing them.

In the underbrush Stephens stumbled upon a rectangular stone altar carved with sixteen cross-legged figures, which he prophetically noted must "beyond doubt, record some event in the history of the mysterious people who once inhabited the city." A broader survey of the jungle ruins revealed a huge acropolis with five large plazas, two main courtyards, and three tall but crumbling pyramids, the whole complex laid out on a plateau a hundred feet above the river.

To facilitate his operations at Copan, Stephens had the happy thought of acquiring the whole site from its rightful native owner, which he was able to do for the sum of fifty U.S. dollars.

After weeks of exploring and drawing, Stephens and Catherwood realized they had barely scratched the surface of what lay hidden around Copan. Anxious to get to Palenque, three hundred miles to the north, they set off on muleback along ribbon trails that wound through the high pine-studded mountains of Guatemala, crisscrossed by deep barrancas and torrents—a road described by one traveler as "made only for birds."

Only the monkeys disturbed the quiet as they swung through the trees, forty or fifty at a time, with little ones in their arms, appearing to Stephens like "wandering spirits of the departed race guarding the ruins of their former habitations."

A couple of Guatemala City Englishmen, John Herbert Caddy and Patrick Walker, privy to the plan that Stephens was first going to Copan, deliberately set out to beat him to Palenque. Though they did so, by a matter of weeks, Stephens was able to beat them into print by a hundred years.

As Stephens approached the ruins of Palenque, he chose to ignore the blanket order issued by the Mexican dictator Santa Anna forbidding all access to foreigners. Stephens' first sight of the ruins convinced him that Waldeck, Del Rio, and Dupaix had not been exaggerating. Nothing in the world, Stephens noted, "ever impressed me as forcibly as the spectacle of this once great and lovely city, overturned, desolate, and lost . . . overgrown with trees for miles around, and without even a name to distinguish it."

On the walls of the building known as the "Palacio" Stephens found Waldeck's name carved beside the faded drawing of a woman and the scribbled date of 1832. He also found the names of Captain John Herbert Caddy and Patrick Walker.

With measuring rod Stephens laid out the floor plan of the Palacio as a mathematical basis for Catherwood's rendition, finding it to be 228 feet by 180, a measurement that was to stand through the years.

Noting the similarity between the hieroglyphs of Palenque and those of Copan, Stephens concluded that the whole intervening area of some 60,000 square miles might have once been inhabited by a civilization that spoke the same language or at least used the same glyphs.

For weeks Stephens worked at uncovering the ruins while Catherwood struggled to capture their incredible lineaments. Soon they were groggy with malaria, their feet swollen with nits that buried eggs beneath their toenails, their faces swollen from the blood-sucking bites of Diptera. When Catherwood finally collapsed, they staggered out of the jungle and sailed for New York with the makings of what was to become one of the great best sellers of the century. Nicely bound and reasonably priced by Harper Brothers, beautifully illustrated by Catherwood, *Incidents of Travel in Central America, Chiapas, and Yucatan* brought to a wide and fascinated public news of the mysterious and unknown Maya, a word that up till then had not appeared in any dictionary. In three months the book went through ten printings.

General view of Uxmal seen from the upper terrace of the governor's palace, showing the Pyramid of the Dwarf, or House of the Magician, on the far right. In the center is the great "nunnery" quadrangle, so called by the Spaniards because of its ninety cell-like rooms. Catherwood and Stephens found that the ruins of the city covered an area of two square miles. The local Indians believed the buildings at Uxmal to be haunted and that all the ornaments were "animated" and would walk around at night. They believed the ornaments harmless during the day but, on the advice of their priests, constantly disfigured them with their machetes so as to quiet their potentially wandering spirits. Within less than twelve months from their first visit to Uxmal, Catherwood and Stephens found the place so overgrown with shrubs and small trees that nothing but the top of the highest pyramid and the base outlines of the other monuments could be discerned.

Labna.

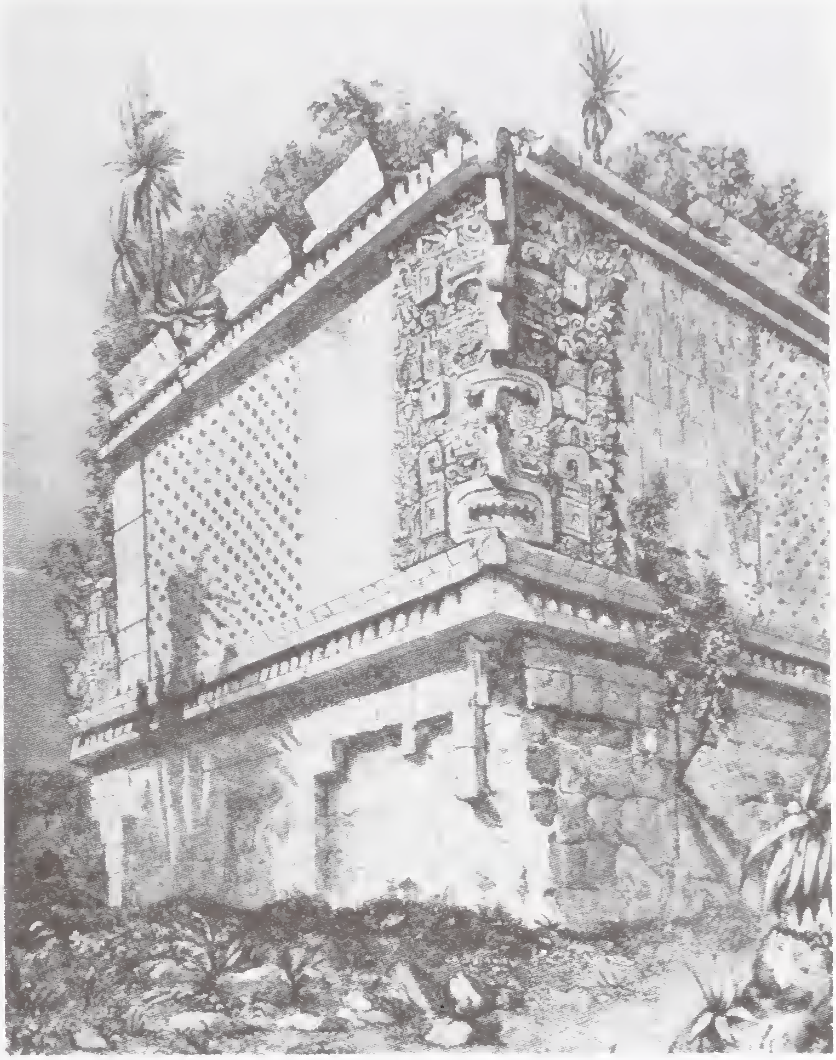
Gateway to Labna, a city in the Mayapan League, between Uxmal and Chichen Itza. Stephens, in frock coat, is standing by the gate. Labna's palace with motifs of masks and columnettes is one of the largest in Yucatan, 400 feet long by 250 feet wide. Catherwood noted that the mortar with which it was built was similar to the pozzuolana found in the ancient buildings in Rome.

Uxmal.

Catherwood and Stephens found that the quadrangular courtyard of the building called "Monjas," or "nunnery," had walls ornamented from end to end with what Stephens called the "richest and most intricate carving, presenting a scene of strange magnificence, surpassing any that is now to be seen among its ruins." The facade, which still showed signs of having been painted, displayed several masked faces with tongues hanging out, and "two colossal entwined feathered serpents running through and encompassing nearly all the ornaments throughout its whole length." Stephens was told that as recently as 1835 one of the facades had still stood intact, whereas he and Catherwood found them all badly dilapidated and overgrown with bushes alive with quail. The dilapidation enabled Stephens to note that some of the buildings had been erected over, and completely enclosed, older ones.

Uxmal.

One of two archways 20 feet high and 25 feet deep which pierce the facade 60 feet from either end of the governor's palace. The design shows repetitive patterns of the elongated snout of what was known as the "rain god."
The main body of the palace was a huge trapezoidal building 320 feet long by 40 feet wide, set on three stepped terraces. The entire length of its second story was covered by a facade of exquisitely cut stone of intricate design, a mosaic of some 20,000 sculptured stones, described by Stephens as a "mass of rich, complicated and elaborately sculptured ornaments forming a sort of arabesque," whose meaning or function entirely escaped him. Catherwood climbed a makeshift ladder to make accurate drawings of the "incomprehensible subjects sculptured on the facade." Later they discovered them to be hieroglyphs, "which from their conspicuous position," Stephens presumed to have some important meaning; but such was the limit of even his open-mindedness, he assumed they could only have dealt with some such prosaic banality as construction details of the building.



This series of pyramidal walls (which looked to Stephens like the fronts of Dutch houses), which was called the "Casa de Palomas" or "Pigeon House," had once been covered with figures and ornaments in stucco, only portions of which remained. In the center, an archway led to a courtyard overgrown with shrubbery. To Stephens, there was something mournful about this particular set of ruins. "Entering under the great archway, crossing two noble courtyards, with ruined buildings on each side, and ascending the great staircase to the building on the top, gave a stronger impression of departed greatness than anything else in this desolate city. It commanded a view of every other building, and stood apart in lonely grandeur, seldom disturbed by human footsteps. On going up to it once Mr. Catherwood startled a deer, and at another time a wild hog."

Half a century was to pass before archeologists recognized in the frets of the "Pigeon House" a highly sophisticated astronomical observatory.

Once Catherwood had regained his health, he and Stephens returned to Yucatan to describe and draw the abandoned Mayan centers of Uxmal, Kabah, Zahil, Labna, Izamal, Chichen Itza, and Tulum, which produced an even better seller: *Incidents of Travel in Yucatan,* considered by Edgar Allan Poe "perhaps the most interesting book of travel ever published." As entertaining as its predecessor, largely because of Stephens' anecdotes and descriptions of odd personalities, it was in substance less illuminating about the mysterious Maya.

Stephens did manage to acquire in the ancient capital of Mani, where Diego de Landa had burned the Mayan codices and documents, a weathered Spanish transcription of the books of Chilam Balam, which included a chronology of ancient Yucatan as told by the natives to sixteenth-century Spanish friars, from which Stephens was able to learn something of the history and customs of the natives. From a lover of ancient lore, Don Pio Perez, who produced a work entitled *A True Exposition of the Method Used by the Indians for Computing Time,* Stephens was able to learn the dot and bar numeration system of the Maya. This gave him an understanding of their solar calendar of eighteen months of twenty days plus an extra five or six, very similar to that of the Aztecs, a system of chronology based on names and numbers for days and months which enabled the ancient Mayan to designate a particular day which could not be mistaken for any other through thousands of years.

The ruins of Kabah, south of Uxmal, another Mayan city abandoned to the jungle. When Stephens first saw this building at Kabah, called by the natives the "House of Justice," it was "so beautifully shrouded by trees that it was painful to be obliged to disturb them." To get this picture with his camera lucida, Catherwood had to stand under an umbrella held by a tranquil Indian while a tropical downpour created what appears to be a lake in the foreground.

The magnificent ruins of the ancient city of Chichen Itza, with its Castillo dedicated to Kukulcan, the Maya Quetzalcoatl, "casting a prodigious shadow" over the flat Yucatecan plain, had as great an emotional effect on Stephens as had Palenque. But he merely gilded Catherwood's lily by noting that "at the foot of the staircase, forming a bold, striking and well-conceived commencement to this lofty range, are two colossal serpents' heads, ten feet in length, with mouths wide open and tongues protruding." Unable to give a rational explanation for these extraordinary pieces of sculpture, Stephens employed the subterfuge of his age by adding, "No doubt they were emblematic of some religious belief, and in the minds of an imaginative people, passing between them to ascend the steps must have excited feelings of solemn awe."

Caracol.

Stephens was seized with the picturesque qualities of what he described as a circular building "unlike any other we had seen, except one at Mayapan, much ruined," with terraces and a winding inner staircase. Noting the novel plan of the building, he remarked that "instead of unfolding secrets, it drew closer the curtain that already shrouded with almost impenetrable folds the mysterious structures." He found the walls of both inner corridors plastered and ornamented with paintings, and noted again, without being able to explain it, a balustrade of gigantic serpents. It was not until the end of the century that archeologists realized the astronomical functions of the building.

Noting the similarities between the Aztec and the Mayan calendars, Stephens facilely concluded that both civilizations had been endemic to America, that the pyramidal structures of Yucatan had been built by neither Egyptians, Carthaginians, Greeks, Romans, nor Israelis, but by native Americans, possibly the forefathers of the natives then living in Yucatan, possibly no more than a thousand years earlier.

Stephens planned one more great work on American antiquities to contain over a hundred folio engravings by Catherwood designed to bring together in one book the works of Humboldt, Prescott, Gallatin, and Wilkinson. Stephens even traveled to Potsdam to pay his respects to an aged Humboldt. But Harper's could not raise sufficient subscriptions to produce so expensive an endeavor. In the end the idea was dropped. Though Stephens' conclusions about the origin of the Mayan civilization remained open to question, his books established him as a gifted writer, and his rediscovery of the Maya opened the way for serious archeology in the Americas.

Another monjas which Stephens found in a good state of preservation and elaborately decorated was believed by him to be the oldest building in the Chichen Itza complex. Over the doorway were twenty small cartouches of hieroglyphs in four rows, five to a row, and a circular niche with seated figure. Stephens noted the similarity between this curved projecting ornament like an elephant's trunk and those of Uxmal. These masks were said to be of Itzamna, the protean god of rain, writing, and learning. Stephens also concluded that the hieroglyphs were similar to those at Copan and Palenque.

Gymnasium.

Stephens described the ball court at Chichen Itza as a gymnasium or tennis court, pointing out that the two massive stone rings, four feet in diameter, carved with two entwined serpents mortised into the opposing walls twenty feet above the ground, probably served for the celebration of some public games. He then quoted Herrera on the diversion of Montezuma.

"The king took much delight in Seeing Sport at Ball, which the Spaniards have since prohibited, because of the mischief that often hapned at it; and was by them call'd *Tlachtli,* being like our Tennis. The Ball was made of the Gum of a Tree that grows in hot Countries, which, having Holes made in it, and moulded together, turns as black as Pitch. The balls made thereof, tho' hard and heavy to the Hand, did bound and fly as well as our Footballs, there being no need to blow them; nor did they use Chaces, but vy'd to drive the adverse Party that is to hit the Wall, the others were to make good, or strike it over."

Tulum Castillo.

Stephens and Catherwood arrived at Tulum on the east coast of Yucatan (now known as Quintana Roo) from Cozumel Island by boat and large canoe. They found the Castillo to be the main temple of the complex, which had been first spotted from the sea by the Spaniards several years before the arrival of Cortes. The site was overgrown with trees which, with their deep green foliage and mysterious buildings, presented to Stephens "an image of a grove sacred to Druidical worship." He described the surrounding scenery as the wildest he had yet found in Yucatan. Clearing a platform in front of the Castillo, whose base they measured as 100 feet long, they could look down over an immense forest on one side, and on the other could see deep in the clear water at the foot the the cliff, "gliding quietly by a great fish eight or ten feet long." No drawing, said Stephens, could convey a true idea of the solemnity of the living shroud that covered the Castillo, "or of the impression made upon us when the ring of the ax first broke the stillness that had so long prevailed around." The back or sea wall of the Castillo rises on the brink of a high, broken precipitous cliff. It commands, said Stephens, "a magnificent ocean view, and a picturesque line of coast, being visible from a great distance at sea." At night the howling of the winds, the cracking of branches in the forest, and the dashing of angry waves against the cliffs added a romantic tone to their sojourn; but Stephens lamented that "we were rather too hackneyed travellers to enjoy it, and were much annoyed by moschetoes."

With Catherwood, Stephens found some low buildings which, because of the lowness of all their doorways, were attributed by the natives to *covenbados*, or "hunchbacks."

Tulum.

The Temple of the Frescoes at Tulum was accidentally discovered when Stephens' companion Dr. Cabot went hunting for a pair of flushed oceloted turkeys. Dr. Cabot is seen off to the left. Stephens (in short coat) and Catherwood (in frock coat) are seen in front of the temple, which they reported to be 45 feet long and 26 feet deep, resting on a 6-foot terrace. The walls of the corridors of the building were found to be covered with paintings "green and mildewed from the rankness of vegetation."

(Above) Izamal.

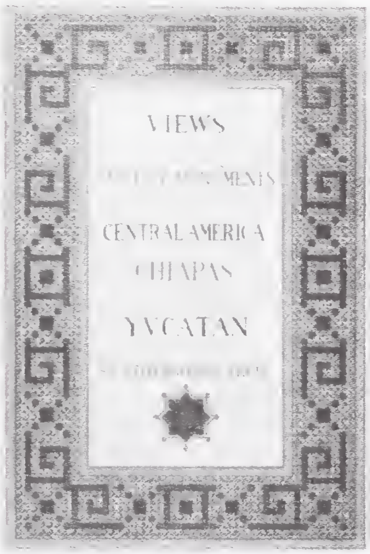
This head, now destroyed, was seven feet wide and almost eight feet high when drawn by Catherwood. It was near what Stephens called the most stupendous mound he had seen in the country: six or seven hundred feet long and sixty feet high, built with cyclopean rocks, and containing mysterious inner chambers. In this romanticized picture, Dr. Samuel Cabot, Jr., is hunting a jaguar at the base of one of several large pyramids.

(Left) Well at Bolonchen.

Stephens and Catherwood seized torches and descended 210 feet into a dark, damp cavern, where they were taken down another 80 feet by means of a large, rudely constructed, and very slippery ladder, 12 feet wide, lashed together by withes. Beyond this another ladder descended a further 75 feet. Crawling along a low stifling passage for about 300 feet, they came upon a rocky basin full of water. By this time the two gringos were so dirty and exhausted, they not only drank of it but took off their clothes and bathed in it. The cave was called "Xtacumbi Xunan," or "hidden lady," because of some pretty girl who had been stolen from her mother and hidden in its depths by her lover. Every year when the wells went dry in the village, a festival was celebrated for the opening of the cave, and the villagers would begin their daily stint of descending 1400 feet to fetch their water. As there are no rivers in Yucatan, the only available water flows beneath the limestone shelf appearing here and there in deep cenotes. The original of this drawing by Catherwood is in the collection of Henry Schnackenberg of Newton, Connecticut.

The only known likeness of Frederick Catherwood, a self-portrait from *Views of Ancient Monuments* as he stands by the ruins of Tulum in Quintana Roo, helping Stephens measure the front of the Temple of Frescoes. Round-faced, sandy-haired, and with blue eyes, Catherwood was six years older than Stephens, taller and more solidly built. Of Scottish ancestry and a well-to-do English background, he received a classical education from Oxford. As artist, archeologist, and explorer, he had visited and drawn almost every important archeological site in the Near East, going into forbidden areas dressed as a Moslem. In Rome he was so entranced by the architectural drawings of Piranesi that he developed a brilliant technique of his own for reproducing ancient sites.

Aldous Huxley in an introduction to a monograph by Victor von Hagen wrote of Catherwood, "From dawn till dusk, day after day and for weeks at a stretch, this martyr to archaeology had exposed himself to all the winged and crawling malice of tropical nature. Ticks, ants, wasps, flies, mosquitoes; they had bitten him, stung him, drunk his blood, infected him with malaria. But the man had grimly gone on drawing. Itching, swollen, burning or shuddering with fever, he had filled whole portfolios with the measured plans and elevations of temples, with studies of Mayan sculptures so scientifically accurate that modern experts in pre-Columbian history can spell out the date of a stele from Catherwood's representations of its, to him, incomprehensible hieroglyphs."



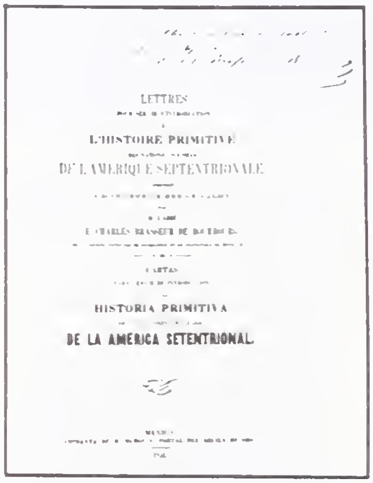
Having failed to receive credit for his work for Stephens, even on the title page of Stephens' books, and having lost the greater part of his originals in the fire that destroyed his rotunda exhibition in New York, Catherwood sailed for England to produce in London a folio volume with twenty-five of his favorite views of Central America. For a really first-class opus, Catherwood gathered six of England's outstanding lithographers, and he had the printing executed by an intimate friend, Owen Jones, in his own studios. The resulting *Views of Ancient Monuments of Central America, Chiapas, and Yucatan* appeared on April 25, 1844. The ordinary edition sold for five guineas, and a smaller number of hand-colored sets "delicately done by an expert hand" were issued at twelve guineas.

Prince Albert, consort to Queen Victoria, bought a copy as a present to send to Humboldt in Potsdam in reciprocation for a copy of his *Kronos* which the Queen had recently received.

The edition of three hundred copies was soon exhausted; and in order to make a living, Catherwood substituted for his cherished title of architect that of civil engineer and sailed for tropical British Guiana in November of 1845 to organize the building of a railroad between Georgetown and Mahaica. When the native director was run over by the engine after the line had stretched a mere 5 1/2 miles for the exorbitant cost of £127,000, Catherwood moved to California by way of Panama.

Successful, at last, in the railway business of that booming state, Catherwood decided on a holiday in England. For the return trip to the States he boarded the S.S. *Arctic*, which sailed from Liverpool on September 20, 1854, with 385 passengers and crew. In mid-Atlantic the *Arctic* was rammed head-on by a French screw-propelled vessel, the *Vesta*. The *Arctic's* crew seized the lifeboats and pulled away from the ship, leaving the passengers—male, female, and children—to shift as best they could. By dusk the *Arctic* sank with its complement of passengers excepting the Duc de Gramont, who, determined to return to his diplomatic post in Washington, successfully jumped into the first officer's boat. Among those who sank beneath the ocean waves was Frederick Catherwood, Archt.

8. Another Champollion



LETTRES

L'HISTOIRE PRIMITIVE

DE L'AMERIQUE SEPTENTRIONALE

CARTAS

HISTORIA PRIMITIVA

DE LA AMERICA SETENTRIONAL

Facsimile of Brasseur de Bourbourg's letters to the Duc de Valmy designed to serve as an introduction to his *Early History of the Civilized Nations of North America.* Published in Mexico City in 1851, it is personally dedicated by the author to the Smithsonian Institute in Washington, D.C. The letters contain erudite essays on the value and veracity of Cabrera's and Nuñez de la Vega's theories about the Hittite, Carthaginian, and Phoenician origins of the people of Palenque.

While pathfinder Stephens had done a reporter's job of bringing to the world knowledge of some forty ruined cities with detailed examinations of Copan, Quiché, Palenque, and Uxmal, what was needed was a detective intellect to unravel the deeper mysteries of these ancient sites. Just looking at the buildings and illustrating them, no matter how beautifully or accurately, had not done the trick; some Champollion was needed with a Rosetta stone.

The man to make the next significant breakthrough toward explaining the origin and history of the mysterious Maya was a Fleming from near Dunkirk, who admitted that his teenage reading of Del Rio's book had "decided my archeological vocation for the future."

Encouraged by the success of Stephens' book, and anxious to resolve more riddles, Charles Etienne Brasseur de Bourbourg set off for America in 1845 at the age of thirty-one, freshly ordained to the priesthood. Tall, courtly, and strikingly handsome, he had mastered the art of journalism as a young man in Paris writing for *Le Monde* and *Le Temps;* and the art of novel writing by doing such potboilers as *Selim or the Pacha of Salonika* under the pseudonym of de Ravensburg, which developed for him as easy a literary style as Stephens'. What he needed next was academic standing. This he obtained by studying for the priesthood in Rome, sensing it would be easier to obtain access to people of substance and to the restricted archives of this planet by approaching them neither as a journalist nor as a novelist but as the Abbé Brasseur de Bourbourg, an ecclesiastical title which, along with his ecclesiastical duties, was to rest lightly on his shoulders. Not so his detective quest.

In this he became a ferreter out of rare books and valuable manuscripts, so indefatigable that he was to throw a whole new light on the origin of the natives of America.

Already in New York, on his way to Mexico, Brasseur had been able to obtain manuscript copies of the histories of New Spain by Las Casas and Duran, which had not yet appeared in print. In Mexico City, through the intercession of a friendly cabinet minister, the viceregal archives were opened to him, and Brasseur was able to read in manuscript the original history of the Aztecs written by Ixtlilxochitl. Other friends got him into other restricted libraries where he kept himself busy for a couple of years, adding to his twelve spoken languages and twenty reading ones by learning Nahuatl from a descendant of a brother of Montezuma.

To explore the country, Brasseur traveled on mule and horseback in Dupaix's footsteps, going to Tula, Queretaro, Guanajuato and the Pacific Ocean, all the time searching for rare manuscripts and artifacts. In Central America he went as far as Nicaragua, San Salvador, and Guatemala, where he found two extraordinary prizes: the *Annals of the*

Brasseur de Bourbourg.

On shipboard en route to America, Brasseur de Bourbourg met the French Minister to Mexico, Levasseur, who made him chaplain to the French Legation, a position which gave Brasseur official access to many libraries in Mexico City where he found the works of Bernardo de Lizana, one of the earliest Spanish historians of New Spain, who believed Hispaniola had been colonized by Carthaginians who spread to Cuba and Yucatan. The notion was supported by Ixtilxochitl who believed the Olmecs had come to Eastern Mexico from the Antilles via Florida.

Poking about in secret archives, Brasseur found that thirteen separate chiefs appeared to have landed in the Gulf of Mexico at different times before Cortes.

From Ordoñez' manuscript on Palenque, which he also found in Mexico City, Brasseur learned that Cabrera had plagiarized and misunderstood Ordoñez. According to Ordoñez, though Votan's forefathers had come to the Antilles from Africa via the Canaries, Votan, the sixth chief of that name, was born in Cuba, whence he sailed up the Uzamacinta to found Palenque.

Cakchiquel and the *Popol Vuh,* both important historical documents which he translated by mastering the local dialects of Cakchiquel and Quiché. The *Popol Vuh* proved to be one of the great primitive epics, a collection of myths, history, and customs of the Indians.

1861

The *Popul Vuh* or "common book of the people" containing national legends of the Quiche Maya was written at an unknown date in Latin script in the Quiche dialect by some native familiar with the ancient records. It was first translated into Spanish in the eighteenth century by the Spanish priest Francisco Jimenez and published in Vienna in 1857, attracting little attention. Brasseur's original text with his French translation in 175 pages of octavo was published in 1861.

Back in Paris, where he published the *Popol Vuh* in a French translation, Brasseur was given access to a private collection of unique Mexican documents and manuscripts collected over the years by J. M. A. Aubin, who had previously not allowed any scholar to view them. Aubin had gone to Mexico in 1830 attached to a scientific expedition, but the loss of all his instruments and thus of his means of working had obliged him to take a job as tutor to a rich Mexican family. The job allowed him enough leisure to search for rare and ancient documents, such as a priceless ritual calendar of the Aztecs, part of Boturini's scattered collection, which he obtained from the nuns of the Convent of Tonalama for a mere eight pesos.

With access to Aubin's collection and from his own research among the Indians, Brasseur was able to produce and publish a much more impressive four-volume *Histoire des Nations Civilisées du Mexique et de l'Amérique Centrale,* which was greeted by the critics as the most comprehensive treatment of Mesoamerican history to have appeared in print. So impressed were the Spanish academicians, they immediately agreed to open their archives to Brasseur, so that in Madrid he was able to make even more significant discoveries. Buried in the archives of the Academy of History, where it had been lost for several centuries, Brasseur found Bishop Diego de Landa's manuscript *Relacion de las Cosas de Yucatan,* still today the single greatest source of information about the ancient Maya culture of Yucatan, which Brasseur immediately translated into French and published side by side with the original Spanish.

Landa's manuscript raised Brasseur's hopes of deciphering the Maya glyphs. In this he was only partially successful,

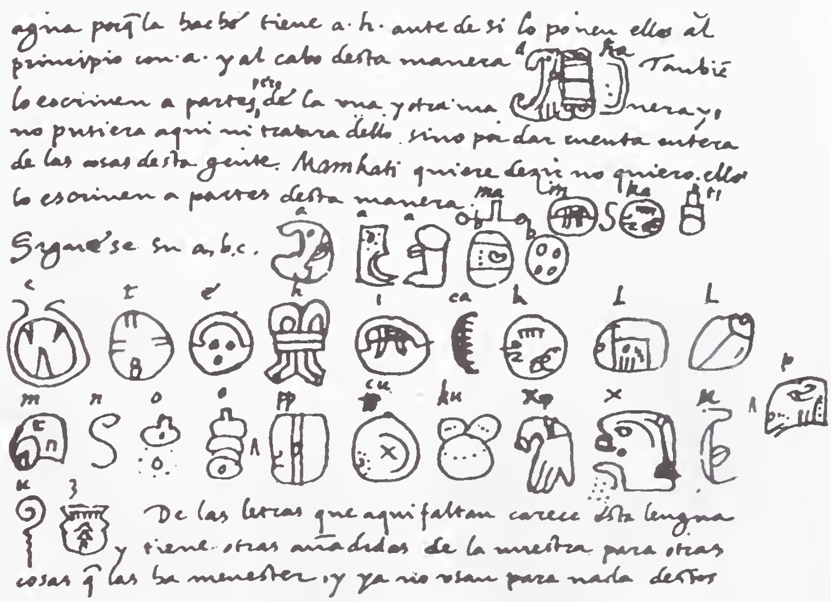
Landa's book, written in about 1566, gave a history of Yucatan from native sources, with descriptions of the Mayan calendar and ceremonies. It also included drawings of glyphs for the 20 days, 18 months, and claimed to be a key to hieroglyphic writing.

Brasseur published the book in French in 1864, just a year after its discovery. In his introduction, Brasseur described his Atlantean position.



agua porq la hache tiene a. h. ante de si lo ponen ellos al principio con a. y al cabo desta manera
Tambie lo escriven a partes de la una y otra manera
no pusiera aqui ni tratara dello sino por dar cuenta entera de las cosas desta gente. Mamhati quiere dezir no quiero. ellos lo escriven a partes desta manera
Siguese su a, b, c.
De las letras que aqui faltan carece esta lengua y tiene otras añadidas de la nuestra para otras cosas q las ha menester, y ya no usan para nada destos

Mayan glyphs for the days.

The first column on the right is from Landa's *Relaciones*, the second is from the Troano Codex. The remaining four are from the Book of Chilam Balam of Káua.

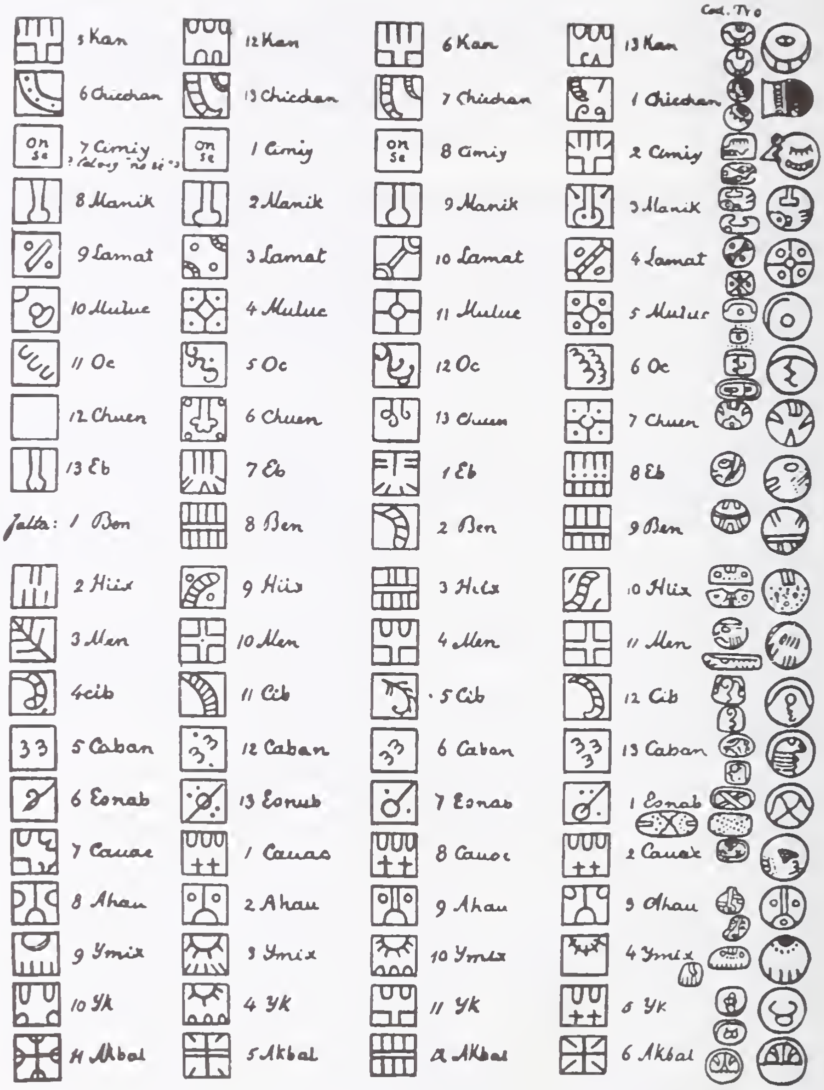
Operating on the premise that the Maya concocted composite glyphs with various meanings both symbolic and phonetic, Brasseur became overly sophisticated in the etymological nuances of meaning he attached to this or that position of a glyph. He thus got carried away by the momentum of his own notions about ancient Maya history.

Conversely, his history of Atlantis was built on a mixture of his interpretation of the Maya myths and of their hieroglyphs. Using Landa's basic interpretation of the glyphs, he read into those of the Troano Codex meanings which could substantiate the Atlantis legends.

His critics, anxious to put down Brasseur's linguistics, were equally delighted to put down his historical reconstruction of Atlantis, which did not fit their notion. Yet even Brasseur freely admitted the tenuous nature of his interpretation.

His critics, who considered him a better writer of fiction than of fact, believed his work was directed at proving preconceived ideas which they judged fanciful.

Later scholars, who discovered in the texts the most remarkable and sophisticated calendrical computers, could sympathize with Brasseur for his attempted readings in depth. He was on the scent but off the track. Brasseur believed the Troano Codex contained descriptions of part of a catastrophe which had resulted from the end of the last glacial period. He believed that the figures of the codex, though often gross in appearance and usually interpreted as the capricious efforts of superstitious genius, contain in fact the



identifying the twenty days of the month and the eighteen months of the year, as well as glyphs that personified various powers of nature, all of which was a steppingstone, but still not the Rosetta stone required for the unravelment of the mystery of the Maya glyphs.

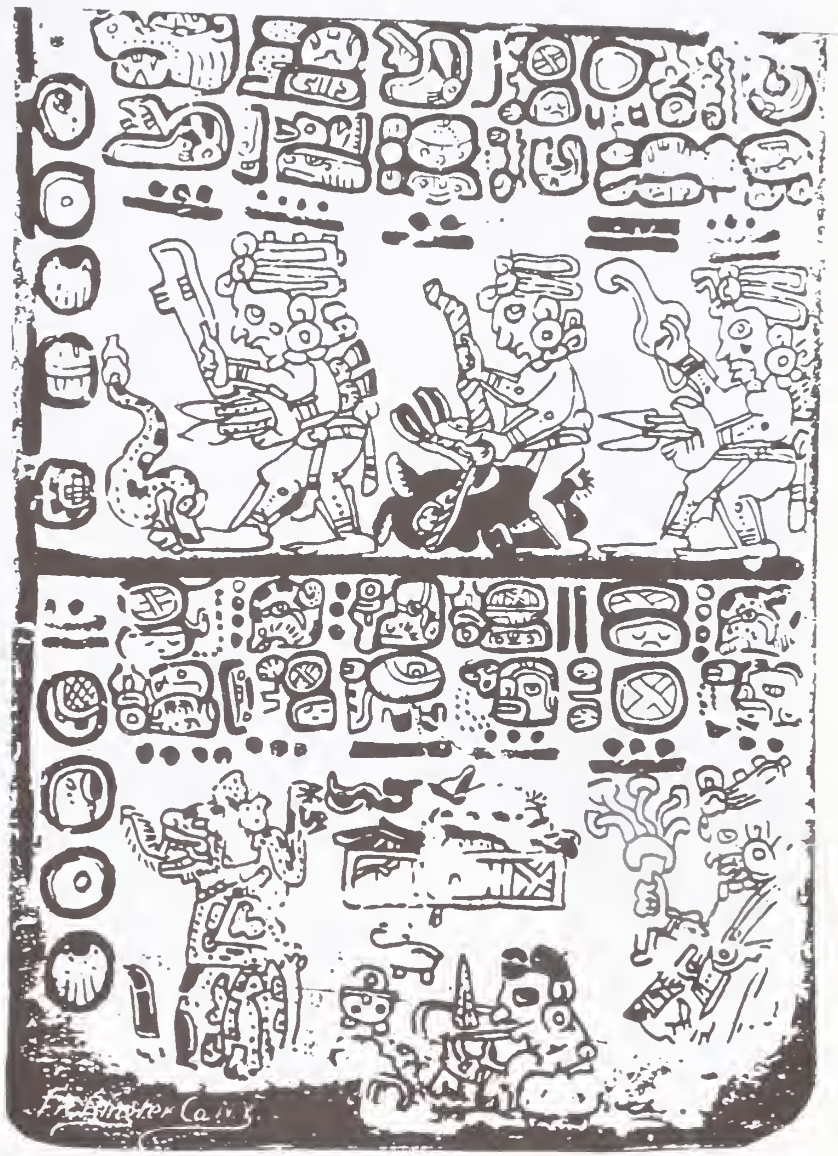
In Madrid Brasseur became acquainted with Jean de Tro y Ortolano, a descendant of Hernan Cortes, professor of paleography at the university, who showed him a document which had been in the family for centuries, a Maya book of divination first known as the Troano Codex till sometime later another half of it turned up and it became the Codex Tro-Cortesianus. In these early documents Brasseur found support for the myths still current among the natives of Mesoamerica that a great terrestrial convulsion had sunk an island in the Atlantic extending eastward in a crescent as far as the Canary Islands.

science of the ancient world; within the bizarre drawings he saw codified data about the geography, geology, and natural history of the ancients.

Brasseur believed that early migrations had been caused by passing comets, falling meteors, and other such calamities of extraterrestrial origin. He quoted Humboldt to the effect that primitive cultures were sometimes the debris of higher civilizations destroyed by natural catastrophes; and because he took seriously Humboldt's statement that myth could be history in disguise, Brasseur was accused of seeing history in every American myth.

Though he was derided for his method of attempting to unravel the secrets of the glyphs in this codex, he explained his reason for reading the manuscript from right to left with the sensible answer that the profiles of the figures faced in that direction. Modern experts have discovered that glyphs of the codices can be read not only up and down and left to right, but also diagonally to reveal sophisticated data.

The Codex is made up of two separate parts: the Troano, found by Brasseur in Madrid in 1864, consisting of 35 leaves or 70 pages which he chromophotoed in 1864, and the Cortesianus of 42 pages, which was found in Estremadura in 1867 and was believed to be a separate codex. The latter, refused by both the Royal Library in Paris and by the British Museum, was acquired by a private collector, José Ignacio Miro, who showed it to Leon de Rosny, discoverer of the "Paris" Codex. Unified into 112 pages, the full codex became the largest Mayan manuscript and was first displayed to the world in Paris in 1892.

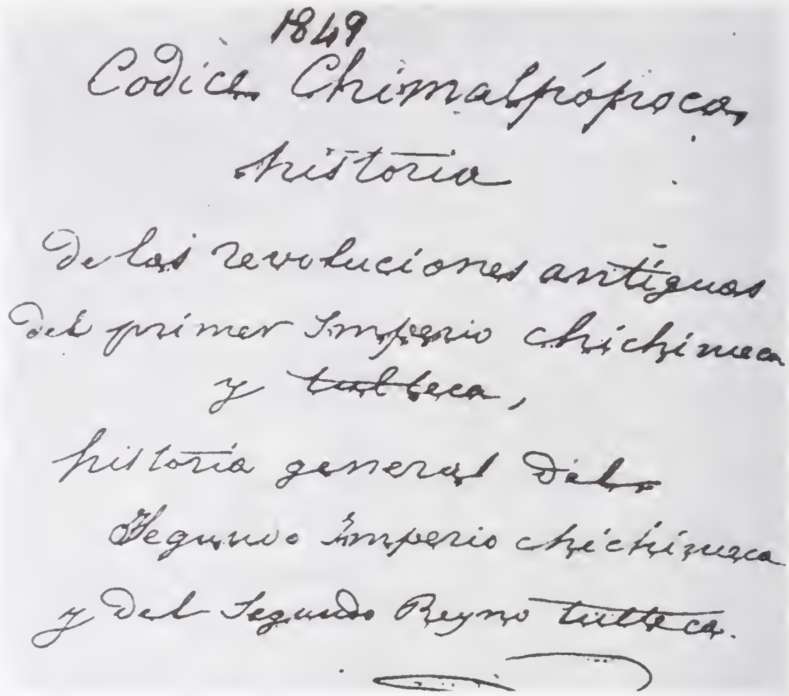


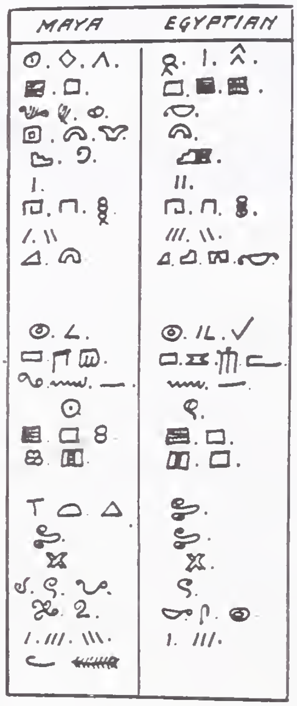
According to Brasseur, the Troano Codex placed the disappearance of this Atlantic continent in the year 9937 B.C. From this codex and from a Nahuatl manuscript purporting to be the history of the Kingdom of Calhuacan and Mexico, which Brasseur labeled the Codex Chimalpopoca, he deduced the revolutionary notion that civilization had originated not in the Middle East, as maintained by European historians, but in the West—in a large continent that stretched from America across the Atlantic, whence civilization had spread to Europe and to Egypt. Thus Brasseur explained the puzzling affinities he had found between the Mayan and the Quiché languages with Greek, Latin, French, English, and German. These languages appeared to him derivatives of Maya-Quiché.

Into the Nahuatl texts Brasseur read the story of a mighty cataclysm which had submerged the cradle of civilization

In the College of San Gregorio in Mexico City, Brasseur discovered a manuscript in Nahuatl to which he gave the name of Chimalpopoca Codex in honor of his teacher of Nahuatl, Faustino C. Galicia, who was a descendant of Montezuma's third son. Brasseur believed the codex to have been written in code so that each word had two or more meanings depending on the rhythm and cesura designed to enable the priestly scribes to conceal the history of the cataclysms and their cycles in a more banal and harmless-sounding text. From his translation of the Codex, Brasseur concluded that there had been not one cataclysm, as described by Plato, but a whole series which had shaped the world as it is today.

In his *Chronologie Historique des Mexicains,* Brasseur relied on the codex to say that in about 10,500 B.C. four periods of cataclysms had changed the world, and that each had been caused by a temporary shifting of the earth's axis.





A later comparison between Mayan and Egyptian alphabets.

millennia before Bishop Usher's still widely accepted Garden of Eden that dated back to 4000 B.C. From the text, Brasseur concluded that the American continent had originally occupied the Gulf of Mexico and the Caribbean Sea, extending across the Atlantic as far as the Canaries, but in some remote period it had been engulfed by a tremendous convulsion of nature. Subsequent upheavals, he believed, had restored parts of Yucatan, Honduras, and Guatemala to the surface.

Brasseur also traced the myth of Quetzalcoatl back to Plato's Atlantis and concluded that the Toltecs could have been descendants of survivors of that catastrophe.

Gradually Brasseur ascribed an increasing antiquity to the native cultures of Mesoamerica and came to believe that many of the truths of modern science had already been anticipated by the inhabitants of Mesoamerica many centuries previously. As he grew older, his cultivated notions grew out of step with those of his academic contemporaries. His penchant for seeing in the myths of antiquity explanations for what might have been actual history was too much for them. As one historian summed up the situation: "Unfortunately, as book after book appeared, his ideas grew more strange and his explanations more attenuated, so that serious leaders who had respected him increasingly lost confidence in his utterances."

Brasseur complained that no serious archeological work was being done in the Americas. That it was foolish to try to write world history leaving out one-half the world—the

Americas. He believed the Carians of Central America to have been the oldest known civilization, an industrious and commercial people who could handle metal and precious stones, great sailors and astronomers who had traveled the world, colonizing Atlantis, the Mediterranean, and ancient Egypt, whose astronomy, physics, and religious practices were similar, including a strong cult of Sirius, the Dog Star, and deification of the crocodile. From all of which Brasseur concluded that either Egypt had been a Central American colony or vice versa.

The American historian and bibliophile Hubert Howe Bancroft was to say of Brasseur that "In actual knowledge pertaining to his chosen subject no man ever equalled or approached him," but Brasseur's later writings were received by critics who were for the most part utterly incompetent to understand them; and more than a century was to pass before his prophetic intuition could be validated.

9. Reconquest of Mexico

William Hickling Prescott was born in Salem, Massachusetts, in 1796. His father was a lawyer; his grandfather, Colonel William Prescott, commanded at the Battle of Bunker Hill. Blinded in one eye by a crust of bread flung in the Harvard Commons, young Prescott was obliged to give up work in his father's law office in order to preserve his second eye, which had become paralyzed. So he devoted himself to literature, working in a darkened office with a noctograph, taking notes with an ivory stylus from what was read to him by a secretary. So proficient did Prescott's memory become that he could retain in his head the equivalent of sixty pages of printed matter, writing them and rewriting them as he walked or drove.

Meanwhile, William Hickling Prescott with his monumental *History of the Conquest of Mexico* had brought to the world the staggering story of the destruction of Montezuma's empire, making the exploits of Cortes common knowledge to the schoolboy. Using his family money to best advantage, and without ever moving from his native Boston, Prescott managed to accumulate the most extraordinary library of original data. First he gave large sums to a London bookseller to buy any book of interest that turned up on the subject of Mexico—no mean game, as Waldeck's, Del Rio's, Baradère's, and Catherwood's books each cost a fortune, and Kingsborough's nine folio volumes were coming off the presses at £150 apiece, or $3,500 the set.

Edward King, later Lord Kingsborough, an eccentric young Englishman who took seriously Humboldt's expressed desire that someone publish in book form all the known Mexican codices and manuscripts, hired an expert Italian draftsman, Agostino Aglio, and set about lithographing and hand-coloring reproductions of originals available in Europe, which had been brought back at various times since Cortes.

This was done between 1831 and 1848. Long commentaries in Greek, Hebrew, Latin, and Sanskrit, mostly in support of the theory that the Lost Tribes of Israel were the progenitors of the Maya, brought the opus to nine weighty and oversized folio volumes, one of literature's great tours de force, which no government had dared, and few individuals could have afforded or executed, but which executed its author because he too could not afford it. For failure to meet the price of the handmade paper on which the publication was printed, Kingsborough died miserably of typhus in a

Kingsborough took up the notion from Las Casas that the Lost Tribes of Israel had peopled Yucatan. Support for Kingsborough's version of the Mayan origin of the Lost Tribes of Israel also came from the Mormon story as told to the world by young Joseph Smith in 1827. According to Smith, in 1820, when he was 15 years old, a figure appeared to him in a vision claiming to be Moroni, son of Mormon, "sent from the presence of God."

During a second appearance, when Smith was 18, Moroni informed him where a number of gold plates were hidden containing writings in strange characters which Moroni termed as "revised" Egyptian. According to Smith's translation of these plates, the Israelites (progenitors of the Nephites, who were led by Lehi, a Jewish prophet of the tribe of Manasseh) had landed on the shores of Yucatan sometime after 600 B.C., when the tribe was divided.

The more unusual part of the Mormon version is that it tells how the Israelites came to America not via the Atlantic but via the Pacific.

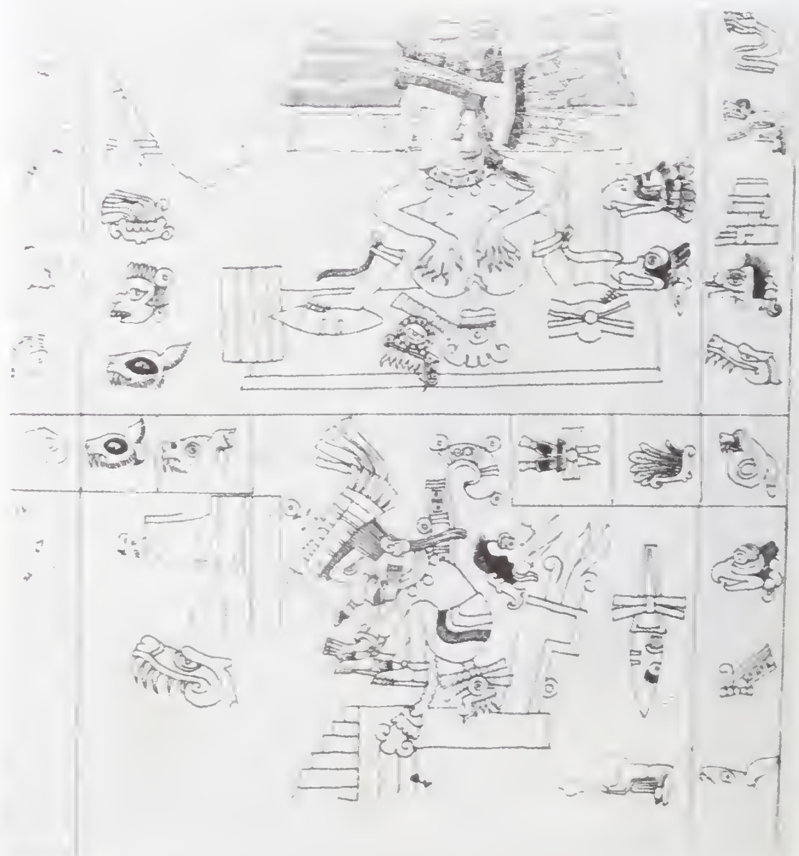
debtors' prison in Dublin, a demerit which prompted the British Museum to omit his name from its catalogue, mentioning only Aglio the artist. But Kingsborough, for his pains, did manage to force the world's societies of savants to focus their attention at last on ancient Mexico.

With such powerful but little-known ammunition, Prescott decided to corner the market and out-best-seller Stephens. From Boston, he persuaded a Spanish scholar living in London into ransacking the libraries of England, France, and Spain for material on Cortes. Taking advantage of a slightly more liberal spirit in the Spanish peninsula, Prescott then pulled his more stunning coup: he convinced the authorities to allow him to use the vast research accumulated by the official historiographer of the Indies, Juan Bautista Muñoz, who had died at the beginning of the nineteenth century before he could exploit the material. By special royal edict Muñoz had been allowed free access to the National Archives as well as libraries—public, private and monastic—in the Kingdom of Spain and its colonies.

To copy this material, Prescott hired a phalanx of scribes in Madrid under the supervision of a member of the Royal Academy of History, the German historian Friedrich Wilhelm Lembke. In Boston, Prescott received some eight thousand virgin folio pages of manuscript "on which," in his words, "the public breath had never blown."

Kingsborough's illustrations from the Codex Borgia of a strange figure representing Camaxtli, the Mexican god of fate, with the twenty day-signs attached to different parts of the body indicating different astrological effects they were believed to have on the various human organs. The interpretation is similar to Rodney Collin's thesis, detailed in his *The Theory of Celestial Influence,* that life energy is diffused from the sun through the various planets to the corresponding glands in the human body which they control.

Aware that noxious effects could also come from the cosmos, the Mexicans thus depicted their Goddess of Lust.



General Winfield Scott.

During his shorter conquest of Mexico for the U.S. Army in 1847, General Winfield Scott, known as "Old Fuss and Feathers," was accused by the Mexicans of having removed from the University of Mexico the remaining manuscript volumes of the works of Don Carlos de Sigüenza y Gongora, and of having transported them to Washington, D.C., where they were reportedly seen by the Mexican minister. A century earlier when Francisco Clavigero had consulted the remains of Sigüenza's works bequeathed to the Jesuit College of San Pedro y Paulo, he reported that only eight of the twenty-eight known volumes were available. A careful search in Washington, D.C., at the library of the Department of State, at the Library of Congress, and in the National Archives has so far been fruitless.

To this bonanza of unpublished material many learned historians from all over the world made contributions which helped Prescott produce his great *History of the Conquest of Mexico,* an instant success, quickly translated into scores of languages.

From the Kingdom of the Two Sicilies Prescott got more invaluable material: some from Count Camaldoli in Naples, more from the Duke of Senifalco in Sicily. In Mexico the incumbent representative of Cortes, the Duke of Monteleone, opened his family files, and the minister of foreign affairs, Don Lucas Aleman, gave Prescott his assistance both official and private, as did a man whom Prescott qualified as "a gentleman whose high and estimable qualities, even more than his station, secured him the public confidence, and gained him access to every place of interest and importance in Mexico," Don Angel Calderon de la Barca, minister plenipotentiary to Mexico from the court of Madrid.

Prescott, no longer able to read because he had nearly lost the sight of his remaining eye personally scrutinizing Stephens' four volumes on his travels in Yucatan and Central America, was obliged to produce his masterpiece from data read to him by a secretary in his Beacon Street studio, writing with a special case made for the blind which did not permit him even to see his own manuscript, the original draft of which he was never able to peruse or correct.

Knowing—as Humboldt had known from reading Careri—that descriptions of localities in Mexico only had that touch of verisimilitude when observed in person, Prescott relied for descriptions of living flora and fauna, and especially for details of such historic sites as the pyramids of Teotihuacan, on reports sent to him by Calderon de la Barca and, more especially, by Calderon's wife, Fanny. This Scottish lady had lived so long in Mexico that her book, *Life in Mexico,* based on letters to her family and friends, was used by the U.S. Army to indoctrinate the troops of "Old Fuss and Feathers" General Winfield Scott during his campaign against Mexico City in 1847, there being so little information available about the country.

Unfortunately, Fanny Calderon's description of the pyramids of Teotihuacan told more about herself and her style of living than it did about Mexico's antiquities.

As she approached San Juan Teotihuacan, the road, says Fanny Calderon, grew more picturesque and at length her attention was arrested by the sight of the two great pyramids, "which are mentioned by Humboldt and have excited the curiosity and attention of every succeeding traveler." Unfortunately, she adds, "our time was too limited to give them more than a passing observation."

Fanny Calderon de la Barca.

Fanny Calderon de la Barca and her husband, the Spanish minister to Mexico, set off at dawn on a spring day to visit the pyramids of Teotihuacan en route to a friend's hacienda. Their transport was a gilded calèche which had belonged to Charles X of France, drawn by six horses, driven by two coachmen with silver-buttoned and embroidered deerskin jackets, enormous sombreros and the high boots of a postilion, who produced wild shrieks to encourage the horses to gallop. For fear of bandits, several well-armed outriders galloped beside the calèche as it passed the cathedral of Guadalupe and crossed the marshy plain which had once been covered by the waters of Lake Texcoco. As Mexico had been for some years in the midst of a civil war, everywhere they saw the ruins of houses, whole villages crumbling, convents with broken-down walls, the abandoned country palace of a viceroy.

"Robbers" living in a half-ruined house helped them with a broken wheel, while several men with guns—"sporting looking characters, but rather dirty"—observed them but did not molest them, thanks to their own tough outriders.

Instead, the Calderons changed horses at San Juan and refreshed themselves on rancid sheep's milk and biscuits so hard that Calderon asked his host if they had been made in the same year as the church! The innkeeper, says Fanny Calderon, "seemed mightily pleased, and could not stop laughing till we got into the carriage."

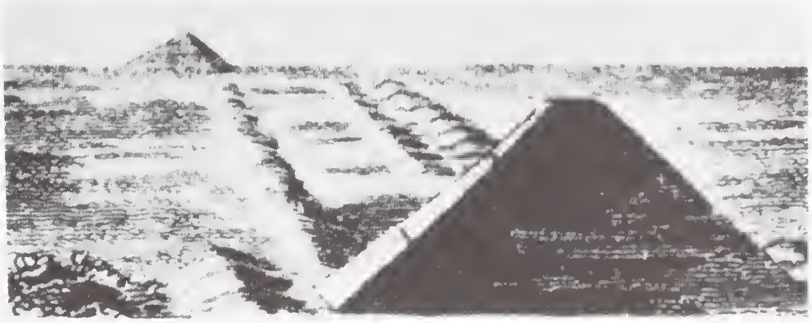
Mistaking Teotihuacan for Tenochtitlan, Fanny Calderon berated Cortes for his fanaticism in having ordered "the destruction of these bloodstained sanctuaries."

As a result, Prescott's description relied more on Humboldt than on Calderon, and is pleasingly atmospheric but none too correct.

> There are [wrote Prescott] no remains on the top of the pyramid of the sun. But the traveler, who will take the trouble to ascend its bald summit, will be amply compensated by the glorious view it will open up to him: towards the south-east, the hills of Tlascala, surrounded by their green plantations and cultivated corn-fields, in the midst of which stands the little village, once the proud capital of the republic. Somewhat further to the south, the eye passes across the beautiful plains lying around the city of Puebla de los Angeles, founded by the old Spaniards, and still rivalling, in the splendor of its churches, the most brilliant capital of Europe; and far in the west he may behold the Valley of Mexico, spread out like a map, with its diminished lakes, its princely capital rising in still greater glory from its ruins, and its rugged hills gathering darkly around it, as in the days of Montezuma.

Romantic Prescott! To have observed such a view from the Sun Pyramid, to have seen Puebla de los Angeles sixty miles to the southeast as the eagle flies, would have required a giant such as was described to the Spaniards by the Aztecs, or an airy Quetzalcoatl.

To describe the shape and condition of the steps of the Sun Pyramid, Prescott found himself with the conflicting reports of Bullock and of Henry Tudor, a barrister at law from London, who had visited the pyramids shortly after Bullock.



View for Prescott of the pyramids of Teotihuacan from Fanny Calderon de la Barca's book *Life in Mexico.*

Prescott went Humboldt one step further on the question as to whether the pyramids were built from outcroppings or from a flat plain. He compared them to the North American mounds and said they were built from scratch.

Tudor maintained that "it requires a particular position united with some little faith to discover the pyramidal form at all." Whereas Bullock contended that "the general figure of the square is as perfect as the Great Pyramid of Egypt."

As Tudor and his companions consumed—along with their picnic of turkey, tongue, and cold fowl—two dozen bottles of claret and Madeira, with which they "contrived to keep famine from the door," and then "rose from our rustic table like giants refreshed with wine" to visit the pyramids, it is perhaps Bullock's report that is the more sober.

Remarking that both men had been eyewitnesses, but that Bullock "has sometimes seen what has eluded the optics of other travelers," Prescott finessed the problem by taking refuge in a French lay to the effect that he was passing on information as he read it: *"Si com je l'ai trouvé éscrité/Vos conterai la verité."*

Relying on Humboldt, Prescott described the pyramids as being constructed of clay mixed with pebbles, encrusted on the surface with the light porous stone *tetzontli,* so abundant in the neighboring quarries. Over this, he said, the builders had placed a thick coating of stucco, "resembling in its reddish color, that found in the ruins of Palenque."

For a description of the hole found by Sigüenza in the south flank of the Moon Pyramid, Prescott relied on Charles Joseph Latrobe, former governor of Australia, who visited Mexico in 1834 in the company of Washington Irving and penetrated about fifteen feet into a gallery which he said was faced with unbaked brick, terminating in two pits or wells. Prescott mistakenly assumed these pits could have been "designed to hold the ashes of some powerful chief; like the solitary apartment discovered in the great Egyptian pyramid."

Like the first explorers of the mysterious passages and wellholes in the Great Pyramid of Cheops, Latrobe and a fellow-traveler, whom he referred to as McEuen, ventured into a snake- and scorpion-infested passage, the entrance to which has since been lost. "After undergoing a partial stripping," wrote Latrobe, "I proceeded to share in the glory and danger of the enterprise. I laid myself flat upon my face

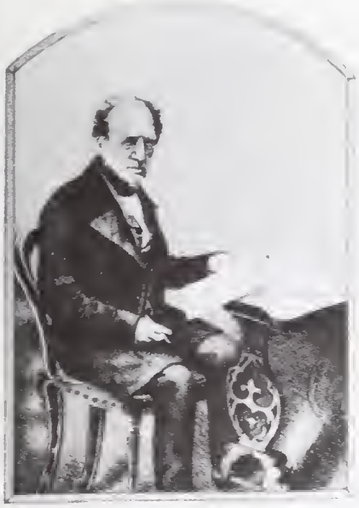
View of Tampico, where Charles Joseph Latrobe landed in 1834 to find everyone in the country armed to the teeth and bandits as plentiful as nopal bushes. From Mexico City, Latrobe lumbered off to San Juan Teotihuacan in a coach drawn by ten mules with faded trappings and brass-studded leather tailpieces. Looking back over Lake Texcoco, he saw the City of Mexico as a mirage, "the white edifices and colored domes of the capital appearing afloat, like a fleet of snowy sails, upon the blue surface of the water."

Between Lake Texcoco and Lake San Cristobal he noted that the 1500-foot dike and causeway, ten feet wide and four feet deep, which prevented the salty waters of one lake pouring into the other, had been built by forced labor with lassoed natives, hundreds of whom had died in the effort. He reported that in excavating for the building of the Guadalupe cathedral huge bones had turned up which he believed had belonged to mastodons used by ancient Mexicans to move great blocks for an earlier causeway.

Latrobe found Teotihuacan "emblossomed in shady groves irrigated by plenteous streams," and admired many moving pillars of dust as high as a hundred feet in the plain where "the great pyramids are perfectly distinguishable at a distance of many miles."

Climbing the Sun Pyramid, he found its surface to be a "stew of porous scoria and amygdaloid" and correctly estimated that the real base of the structure "lies below the level of the present soil, concealed by the wrecks cast down upon it."

In a hollow between two smaller pyramids at the foot of the House of the Moon, he described a large square mass with a sculptured face, saying the popular belief with regard to it was that anyone sitting down on it fainted.



Prescott gave the length of the Sun Pyramid as 682 feet, and its height as 180, which are Humboldt's figures translated into English feet, neither figure very correct. Prescott further compounded his error by comparing the size of the Sun Pyramid to that of the Pyramid of Cheops in Egypt, using Dominique Denon's figures obtained from *Egypt Illustrated,* which appeared in England in 1825, wrong by about thirty feet when compared with the almost perfect figures obtained by Jomard in 1799, of which Prescott was evidently unaware.

and ducking into the aperture squeezed myself blindly forward, with my candle, through a passage inclining downwards for about three yards when I found myself in an open gallery, at the termination of which, not many paces distant, I found two wells which I figured to be about the center of the pyramid." There Latrobe's companion McEuen "valorously allowed himself to be lowered by rope into the aperture on the left hand, to a depth of perhaps fifteen feet, without making any further discovery."

As Latrobe had been unable to find any other evidence of internal passages, what most preoccupied Prescott was to know who had built the huge structures. "Was it," he asked, "the shadowy Olmecs, whose history, like that of the ancient Titans, is lost in the mists of fable? Or, as commonly reported, the peaceful and industrious Toltecs, of whom all that we can glean rests on traditions hardly more secure? What has become of the race who built them? Did they remain on the soil, and mingle and become incorporated with the fierce Aztecs who succeeded them? Or did they pass on to the South, and find a wider field for the expansion of their civilization, as shown by the higher character of the architectural remains in the distant regions of Central America and Yucatan?"

Unable to find an answer, Prescott concluded, "It is all a mystery,—over which Time has thrown an impenetrable veil, that no mortal hand may raise. A nation has passed away,—powerful, populous, and well advanced in refinement, as attested by their monuments,—but it has perished without a name. It has died and made no sign."

The sign, had Prescott been able to see the pyramids, might have been before his eyes, a little more hermetic perhaps than in Egypt because of more crumbled walls, but evident nonetheless. At that moment in London the π proportion in the Pyramid of Cheops—that its height is to its perimeters as the radius is to a circle—was being worked out by a bookseller, mathematician, and amateur astronomer: John Taylor. But to extrapolate anything similar from the Teotihuacan structures would have required more careful measurements and scientific reconstruction, projects for which Mexicans were as yet unready and unwilling to expend a peso. They were bankrupt from half a century of civil war.

The liberal revolt, which had overthrown the last-gasp dictatorship of General Santa Anna and ushered in a movement known as the "Reforma" whose objective was the destruction of feudalism in Mexico, had turned into another civil war between conservative royalists and liberal constitutionalists, the latter under reformer Benito Juarez. In the process both sides had become heavily indebted to foreign countries and

Juarez.

Benito Juarez was born a mountain Indian. Orphaned as a child, he was brought to Oaxaca as a servant, where a Franciscan lay brother sent him to school. Quiet and reserved, but with a powerful logical mind, Juarez learned his Spanish and his lessons so well he got to law school. Elected to congress he became governor of the state of Oaxaca—which he found bankrupt and left with a 50,000-peso surplus.

As chief justice of the supreme court, Juarez succeeded to the presidency, but was obliged to flee the capital as the armed struggle renewed between the Catholic Royalists and the liberal republicans, the latter supported by Freemasons in both the Americas. Ironically, the policies of Juarez had been brought to the attention of U.S. readers by the London correspondent of the New York *Tribune,* an international exile by the name of Karl Marx. Juarez, in exile, received arms and supplies from New Orleans.

Early in 1861, after the most destructive war fought in Mexico, Juarez was able to enter the capital riding in a small black carriage. Known as "El Indio," he chose as his slogan "Nothing by force, everything through law and reason." But when the new Mexican congress narrowly chose Juarez president, the country was still in such turmoil that he was obliged to rule by decree, one of which expropriated all Church property and dissolved the religious corporations, leading to renewed civil war.

In the words of Manly P. Hall, the god of Juarez was "The Father of Freedom, served by a priesthood of liberation." His rebellion was not against God but against the theological institutions of Mexico.

The outlook of the higher clergy, who had accumulated and hoarded vast wealth, was authoritarian, monarchist, and anti-democratic, yet they felt bound to continue to interfere in politics.

The Mexican church continued to collect the high fees established under colonialism, higher than in any European Catholic country, as well as mandatory tithes. Marriage fees were so exorbitant that many of the lower classes could not afford them, and poor people raised stable families technically in sin without benefit of clergy.

The clergy refused to absolve, marry, or bury any Mexican who stood for the constitution of 1857. A priest, like an army officer, could not be tried in a civil court for civil crime. He went before an ecclesiastical court even if charged with legal debts. This infuriated Mexican jurists, because for sixty years the principle of equality before the law had been established in the advanced nations.

Vast numbers of monastics became idle, their missions defunct while the orders still retained large chapter houses and managed large estates. These monastics, says historian T. H. Fehrenbach, who had once been the finest, became "probably the most useless and corrupt of the Mexican clergy."

Napoleon III.

Wishing to emulate his uncle's cultural, archeological, and political exploits in Egypt, so as to unify the squabbling political parties of his empire "under a mantle of imperial glory," Napoleon III decided to take action in Mexico.

Jean-Frédéric Maximilien Baron de Waldeck.

When the French government insisted on paying Waldeck by the year instead of outright, because of his advanced age, Waldeck, already in his nineties, had the last laugh. Still an avid girl chaser, he used his yearly salary to entertain the beauties of Paris at government expense, and at the age of a hundred he married a 17-year-old—attributing his virility and longevity to a diet of horseradish consumed for six weeks every spring.

both had defaulted on their debts. Actually, Juarez had merely chosen to ignore an absurd French demand for 50 million pesos, plus 12 million in reparations, for a defaulted loan of a mere 750,000 from a Swiss banker who had subsequently assumed French citizenship. But Charles Louis Napoleon Bonaparte, as Napoleon III, was using the debt as a pretext to install by force a powerful Catholic and Latin empire in Mesoamerica under French protection.

To get a foot in the door, without upsetting either the Mexicans or his constituents in France, Napoleon capitalized on the publicity produced by Prescott, Stephens, Waldeck, and Brasseur to order his minister of public instruction, Eugène Viollet-le-Duc, to form a Commission for the Study of Mexican Antiquities, especially the pyramid complex at Teotihuacan.

Jean-Baptiste-Luis, Baron Gros, Napoleon's adviser on Mexico, who had visited the site and found a considerable analogy between the Mexican pyramids and those of Egypt, was put in charge of organizing a group of French experts to study the problem.

The French surveyors were to explore the site, establish the number of pyramids, as well as their situation and proportion, determine the nature of the blocks of which they were formed, and send some back to Paris. They were also to excavate interior galleries and ascertain whether there were any vaulted ceilings. Furthermore they were to record all the traditions preserved by the Indians in the vicinity, no matter how absurd or trivial those traditions might seem.

To produce some really prestigious works on Mexican antiquities, the French government commissioned Brasseur de Bourbourg to write a text to go with the engravings made in Yucatan by Waldeck, whom the government did not consider sufficiently founded academically to write his own text.

So Waldeck and Brasseur came together in the interest of Napoleon's grandeur.

To get more than a foot in the door of Mexico, Napoleon III overtly pressed the claim that Mexico's republican president, Benito Juarez, had defaulted on payment of the Swiss banker's loan. A military expedition was organized to collect the money, and a Catholic monarch, Archduke Maximilian of Hapsburg, brother of the Emperor Franz Joseph, was selected for enforcement on the Mexicans with the connivance of Mexico's royalist opposition to Juarez.

At noon of May 28, 1864, the Austrian warship *Novara* steamed into the harbor of Veracruz with the new thirty-two-year-old Emperor of Mexico and his twenty-five-year-old Empress Carlota, daughter to the King of Belgium.

Ferdinand Maximilian of Hapsburg and Carlota of Coburg.

Tall, blue-eyed, and blond-bearded, Maximilian was fundamentally a liberal interested in the arts and sciences who wanted to install in Mexico a government of honest ministers. Intelligent and hard-working, he had served well as royal governor and as head of the Imperial Austrian Navy. Carlota was an ambitious princess, daughter of Leopold I of Belgium. After the disaster that befell her in Mexico she went mad and lived in seclusion in Belgium until 1927.

Through practically deserted streets they were driven to the station of a rickety railroad that had been hastily built by the French to rush their troops out of the yellow fever area as far as Paso del Macho.There, Maximilian and Carlota transferred to old mail-coach *diligencias,* only to learn that Juarez' intrepid young republican general, Porfirio Diaz, was in the neighborhood with a body of guerrillas hoping to ambush the imperial suite. They too noted a countryside ravaged by forty years of civil war. For the steep ascent to the rocky plateau of Orizaba they transferred to horses, then back to coaches for a state entrance into Mexico City on June 12, an occasion sensibly celebrated by Maximilian with a general amnesty for all political prisoners.

10. Maximilian and Teotihuacan

Despite Maximilian's grand delusions, which included the hope of establishing a vast Hapsburg empire from the Rio Grande to the Rio Plata with the help of his younger brother, Ludwig Viktor, who was to marry one of the Brazilian princesses, Maximilian was fundamentally a liberal who honestly believed he had been called upon by the people of Mexico to end a civil war and set up an effective noncorrupt government based on "liberty and sincere love of progress."

He did not realize that in a country described by the London *Times* correspondent as "rotten to the core," where education was nonexistent, thieving and corruption general among all classes of officials, the Emperor of Mexico was no more than a prisoner of the reactionary group of clerical conservatives who had sought foreign intervention and the imposition of an autocrat on the people of Mexico solely to reverse the Juarez edicts which had secularized church property, suppressed religious houses, and abolished the privileges of the clergy. As for a mandate from the people, the situation was summed up by the British minister to Mexico, Sir Charles Wyke, who wryly observed that Maximilian might have had it in a few villages "possibly inhabited by two Indians and a monkey."

At the end of his first tour of the country Maximilian found its worst features to be the judicial functionaries, the army officers, and the greater part of the clergy. "None of them," he wrote, "are familiar with their duties, but live for money alone. The judges are corrupt, the officers have no sense of honor, and the clergy are lacking in Christian charity and morality."

To add to his problems, Maximilian promptly outraged Pope Pius IX, who had warned him in Rome that "the rights of the

Chapultepec Palace.

On "the hill of the grasshopper" on the outskirts of Mexico City, the palace of Chapultepec was built by Viceroy José de Galvez in the eighteenth century on the spot where the Mexica had first settled and where Montezuma had his summer quarters, surrounded by a garden enlivened by wild game under towering cypresses sixty feet round at the base. A powerful source of water which sprang from the hill had been tapped by the early Mexica and carried by aqueduct to the great city of Tenochtitlan, where its flow, according to Cortes, was as thick as a man's body.

people are great and it is necessary to satisfy them, but the rights of the church are greater and more sacred." By crossing the Pope and insisting on a separation of state and church, on freedom of religion, and on nationalization of Church property, Maximilian unwittingly signed his own death warrant.

Seeing himself as an enlightened humanitarian, he had quickly turned to improving the cultural and educational level of his adopted country and to cleaning up and beautifying its capital, wandering, like Montezuma, through the streets incognito to see that everything was progressing as it should.

With Carlota he first tried to live downtown in the Palacio Nacional, but the rooms were so small and cramped, leading from one to another like a railroad train, that he decided to move to the former viceregal palace on Montezuma's favorite spot, Chapultepec Hill.

There the young couple found the premises so filthy and in such poor repair that Maximilian had to spend his first night on the billiard table to avoid the vermin in his bed. More romantic in her outlook, Carlota was enchanted with the view over the city and the valley ringed by lakes, green fields, and the snowcapped volcanic peak of Popocatepetl in the distance, a view she considered superior to that of the Bay of Naples.

Childless—apparently because of a venereal disease communicated to her by Maximilian, who had contracted it from a Brazilian prostitute in his travels—the Empress had much time to devote to the affairs of state and to cultural pursuits. With her beautiful young Indian lady-in-waiting, Josefa Varela, a direct descendant of the Aztec poet king, Netzahualcoyotl, she visited many of the antiquities of Mexico, going as far as Uxmal, where she was struck by the extraordinary emblems of phallic worship, a painful reminder that her own lovemaking days were over. Whereas Maximilian, with the pick of the court at Chapultepec, was having a child by his gardener's wife at the Borda Gardens in Cuernavaca, a haunt he so favored that he had it linked to the capital by a better road, patrolled by French troops against bandits. Maximilian's taking of an Indian mistress, far from being frowned on by the Mexicans, was regarded as a token of his affection for his adopted country; but the result of the union was to have a sad consequence. Maximilian's son, named Concepcion Sedano y Lequizano, for his "legal" parents, grew up in France as somewhat of a wastrel who sported a beard like his father and took pride in being known as "the imperial bastard." On October 10, 1917, in Vincennes outside Paris he was executed by a firing squad as a convicted spy for the Germans.

To link the residence at Chapultepec with the Palacio Nacional in the Plaza Mayor, Maximilian directed the construction of one of the grandest avenues in the world, intentionally outdoing the Champs Elysées of his patron Napoleon III. First called the Calzada del Emperador, it was later more democratically renamed the Paseo de la Reforma.

On the first anniversary of his acceptance of the throne, Maximilian founded the Academy of Science and Literature, negotiating with a well-known Mexican book collector, José

Throughout Mayaland there is evidence of a former phallic cult similar to that of the Phoenicians, and to the cult of Osiris, which was concerned with life and death and fecundity in all its forms. Almost all the ancient races worshiped the yoni and the phallus as appropriate symbols of God's creative power. According to Manly P. Hall, the Garden of Eden, the Gate of the Temple, the Veil of Mysteries, the *vesica piscis*, or oval nimbus, and the Holy Grail are all important yonic symbols. Whereas the pyramid, the obelisk, the cone, the candle, the tower, the Celtic monolith, the spire, the campanile, the Maypole, and the sacred spar are all symbolic of the phallus.

An anonymous conquistador describing phallic worship in Mexico wrote, "In other provinces, particularly Panuco, they worship the member of the body which is between a man's legs: they have it in the mosque and also set in the square, together with figures in relief showing all the kinds of pleasure that can exist between man and woman and they have these pictures with legs raised in various ways."

Maria Andrade, for a magnificent 5,000-volume library of printed books and manuscripts relating to Mexican history and culture with which to form the nucleus of an imperial library for the use of the entire nation. He also established a national theater under the direction of the poet José Zorrilla, offering from his own private funds substantial prizes for the best plays written.

The National Museum was transferred from the university to the Palacio Nacional, where it stayed for exactly one whole century before it was moved to the modern Museo Antropologico. For the museum Maximilian sought to regain from abroad various relics such as Montezuma's shield and the original manuscript of a report from Cortes to Charles V, which had found their way into the imperial collection in Vienna. He also set about collecting the portraits of Mexico's former rulers, which had been scattered during the years of the civil war.

In the field of education Maximilian hoped to organize a system on such a scale that Mexico could "take its place by the side of the leading nations of the world." Of Brasseur de Bourbourg he thought so highly that he offered him the directorship of education and museums in his new government; but Brasseur, with a twinkle, declined, saying, "I never like to travel with the army."

So appalled was Maximilian by what he considered a shocking lack of interest demonstrated by Mexicans in the monuments of their own past, he organized the first genuinely scientific commission to study Mexican antiquities, with a

By careful astronomical observations the commission finally obtained more correct coordinates for both great pyramids. They set the Moon Pyramid north of the equator by 19 degrees, 41 minutes, and 52.8 seconds, and west of Paris by 6 hours, 35 minutes, and 18.32 seconds. The Sun Pyramid they placed 26 seconds of arc closer to the equator and 2 seconds of time nearer Paris. (The modern figures for the Sun Pyramid's latitude are: 19° 41′ 30″ north of the equator. Its longitude is 98° 50′ 30″ west of Greenwich.) The commission also established that the Sun Pyramid's west flank did not lie on the astronomical meridian running north-south, as Humboldt and others had suggested, but was angled about 15 degrees east of north. However, Almaraz noted that a line drawn between the vertices of the two pyramids did point very close to magnetic north, which did not particularly impress him, as magnetic north continually varies, but indicated to him that the pyramids' builders might have had a better notion of the apparent motion of the heavenly spheres, caused by the earth's rotation on its axis, than had previously been supposed.

Almaraz assumed that their error of a couple of degrees could have been due to the ignorance of the fact that the pole star is not, and was not, at the actual pole of the heavens, but circles around the pole at a varying distance, which in Almaraz' day was 1 degree 25 minutes.

particular emphasis on the ruins of Teotihuacan. The commission consisted of several eminent Mexican engineers under the direction of engineer Ramon Almaraz.

To reach the top of the Moon Pyramid, Almaraz found a stairway or zigzag ramp which started halfway up the facade, decreased proportionately, and ended in the center of the upper level; the zigzags were clearly visible on the plan he submitted. He also noted that the south facade of the Moon Pyramid had another pyramidal structure applied to it, or *adosado* as he called it, which reached a height of twenty-one meters.

At that level Almaraz found a deep excavation in the face of the pyramid, evidently Sigüenza's and Latrobe's hole, running north-south, with lateral excavations running in different directions, which he attributed to treasure seekers.

The only noteworthy feature appeared to Almaraz to be the square well which descended vertically within it, with walls formed of rows of volcanic brick held together by mud, only the southerly wall of which was slightly dilapidated.

So well preserved was this hole that Almaraz hoped to extrapolate from its measure the basic unit used by the builders of the entire complex. Very carefully he measured the well as being 1 meter 6 centimeters square.

In an intuitive flight of fancy, Almaraz suggested that as all the common units of measure in use in his time—the meter, the yard, the ana, the elle, and the vara—were more or less the same length, a similar unit might have been used at Teotihuacan. But wherever else he looked, Almaraz found

Teotihuacan pyramids with Moon Pyramid in foreground.

Almaraz described the Moon Pyramid as being on a rectangular base 156 meters long by 130 wide, covering a surface of 20,280 square meters, or 5 acres, which was within 2 percent of being accurate. He estimated its height as 42 meters, which is within a meter of the most sophisticated estimate to date.

Almaraz also saw the Moon Pyramid as originally being formed of three superimposed bodies, each about 10 meters high, only one level of which could be clearly distinguished at 21 meters from the base. He said he could see no evidence of levels on the east side, which had the aspect of an inclined plane with no break or fissure. Time, weather, and the hand of man, said Almaraz, had destroyed much of the original surfaces, causing crumbling and the obliteration of the ridges, so that the pyramids, without their original outlines, seemed at first sight to be hillocks rather than raised monuments.

To what was known of the exterior of the Sun Pyramid the commission did not add much, other than to confirm that it appeared to be divided into three stories and had a zigzag path leading to the summit, which was in better condition than the path up to the Moon Pyramid.

buildings too dilapidated and covered with rubble and earth to be accurately measured. At last in the ruins of a nearby mound, or *tlaltel,* as the Mexicans called it, Almaraz found a well-preserved piece of sculpture lying face down in the mud, which had preserved its sharp contours. Raising the statue, he found it to be a carved parallelopiped 3 meters 19 centimeters high with a square base of 1 meter 65 centimeters. This clearly gave it a height almost exactly three times the 1.06-meter width of the well, and a width 1 1/2 times that of the well.

But for some reason, instead of selecting this 1.06-meter unit, which varied no more than 6 percent from any one of the units in common usage, Almaraz chose 3/4 of that length, or 80 centimeters, which varied from all of them by more than 20 percent, on the theory that the statue was intended to be 4 units high by 2 units wide, instead of the more obvious 3 by 1 1/2 or possible 9 × 18 palms.

Almaraz also settled on the 80-centimeter unit because the distance between the Moon and the Sun pyramids was effectively 800 meters, giving a round 1000 units—a figure which pleased his francophile decimal point of view.

No attempt was made by Almaraz to compare this unit of 80 centimeters with any of the ancient units of measure found by Jomard to have been incorporated into the Great Pyramid of Cheops, presumably because Almaraz was unaware of the work of Jomard.

Because of earth and rubble around the base of the Sun Pyramid, it was difficult for Almaráz and his fellow engineers to even measure its length; but they obtained a figure of 232 meters along the west facade, very close to the 231 meters of the base of the Great Pyramid of Cheops, correctly estimated by Jomard. Though Almaraz also had no way of knowing this, as the correct length was not officially established until 1925, when the base of Cheops was cleared of a thousand years of accumulated rubble.

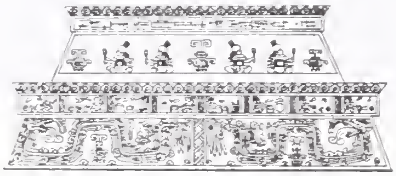
Scouting around the base of the Sun Pyramid, the members of the commission came upon a huge platform forty meters wide and six meters high which bordered the Sun Pyramid on the north, east, and south sides, forming a raised platform with *talud* facings.

South of the Sun Pyramid, in the area which the early Spaniards had called the Citadel, the commission found a similar platform twice as wide with walls ten meters high, except for the one facing the Way of the Dead, which was only five meters high. On these platforms were fourteen mysterious *tlalteles,* or mounds, symmetrically arranged, four each on the north and south sides, three on the east and west.

In the center of the large quadrangle formed by the platforms were the remains of another *tlaltel* with a stairway on the west face, and slightly ahead of it another smaller *tlaltel.*

Almaraz says that throughout the pyramid complex he found scores of smaller *tlalteles* that looked like hillocks, some built in a symmetrical pattern, others scattered with no apparent regularity. In the plaza before the Moon Pyramid he found a group of *tlalteles* which appeared to form a sort of circle around a central one. These had been much excavated, partly, says Almaraz, by searchers after archeological remains, but mostly by "rapacious and ignorant" persons in search of treasure. What most outraged Almaraz was the evidence that the entire area had been used as a quarry for stones for "the barbarous habitations" of the natives. In the houses of the village of San Juan he saw that many valuable carved stones had been broken up to form walls.

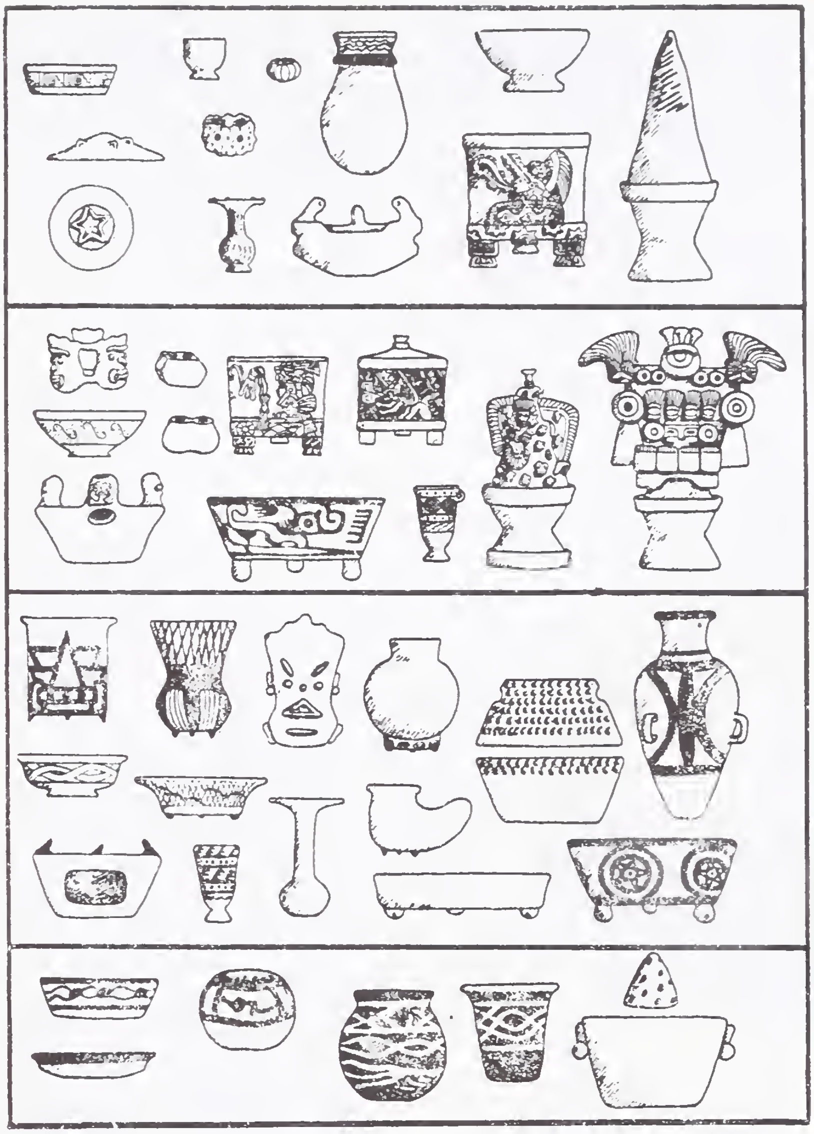
In one of the *tlalteles,* Almaraz found eight worked stones, also just over a meter wide, whose outer faces were carved to represent grotesque figures with the heads of serpents and tigers. The carving had apparently formed a circular monument just over five meters in radius, now chipped and broken, though one carving was sufficiently preserved for him to make a sketch. In the same *tlaltel* there were other sculptured stones in which Almaraz recognized the lineaments of a jaguar and a figure he could not make out.



Reconstructed *tlaltel* or platform temple.

Told that in an earlier excavation of one of the *tlalteles* a small stone coffer had been found containing a skull, various *cuentas,* and curious objects of beryllium, serpentine, heliotrope, and obsidian, as well as large quantities of gold dust in golden vases, Almaraz would have liked thoroughly to gut one of the *tlalteles,* and perhaps even dig a passage through the base of the two great pyramids, but was prevented from both endeavors by lack of personnel and funds. He also suggested that the entire area of ruined houses should be properly and thoroughly mapped, "as intelligent and respectable men have been suggesting for some time."

Almaraz says that at the very beginning of his efforts at Teotihuacan he decided not to draw conclusions about ancient times, but only to occupy himself with relating how he found things as they were. In the end he could not resist expressing an opinion—an opinion which only went to confirm that first impressions are inclined to be best. He said he first thought the pyramids had been intended to represent a system of planets, but in the end concluded they were merely temples and sepulchers dedicated to illustrious men. Almaraz also concluded that the ruins represented the work of several different epochs, because he had found buildings raised above the foundations and ruins of earlier buildings, as if to hide or protect the more ancient ones. It also appeared to him



Various styles of pottery found in Teotihuacan.

that many of the houses had been abandoned by their masons because of some great catastrophe.

Almaraz was greatly puzzled by the evident antiquity of the monuments and the mystery of the people who had built them, whose history was entirely unknown.

He marveled at the enormous work involved, the quarrying and moving of such great amounts of stone over long distances, all of which, he remarked with a touch of pathos, "did not even serve to keep alive the names of the architects, gods, or potentates in whose regime the structures were built."

As a final warning, he said he had to admit that all of what he had surmised was nothing but conjecture, without fundament or sort, resting on neither historical material, "which I did not have the means to consult," nor on archeological knowledge, "to which I did not have the opportunity of dedicating myself," but mostly on what he had picked up at the table from his mess companions.

Achille Francois Bazaine, born in 1811, served in Algeria, the Crimea, and Lombardy before coming to Mexico where he was made a Marshal of France in 1864. At Maximilian's court he developed a penchant for very young girls, one of whom he married in the presence of Maximilian, and was soon distracted from his military duties. To cover up his negligence and incompetence, Bazaine double-crossed Maximilian and left him in an untenable position both militarily and politically.

Responsible for the disastrous defeat of Napoleon III at Sedan in 1870, Bazaine was found guilty of negotiating with, and capitulating to, the enemy; but his sentence of degradation and death was commuted to twenty years in jail. In 1874 he escaped to Italy and thence to Madrid where he died in 1888.

For a truly scientific and detailed exploration of Teotihuacan, Almaraz said more money and more personnel were needed. But Maximilian's coffers had been emptied; the imperial government had been required to pay the full penalty for the defaulted Swiss banker's debt, all the costs of the French intervention, plus a thousand francs for every French soldier serving on Mexican soil; and the political and military situation had so deteriorated that no further attention could be paid to cultural pastimes such as the pyramids. The United States, resolutely determined not to acknowledge the existence of Maximilian's government, had continued to accredit its representative to the rival republican government of Benito Juarez. The moment the Civil War in the States was ended and it was clear that the Monroe Doctrine could once more be enforced, Napoleon III gave up his dream of a Catholic state in Central America and decided to cut his losses, leaving Maximilian in the lurch. He ordered his military commander, Marshal François Achille Bazaine, to secretly start withdrawing French troops from Mexico. Perfidiously, Bazaine even offered to sell large quantities of French arms for cash to the opposing

Diaz as a general in the republican army fighting against French interventionists.

Maximilian, Emperor of Mexico, was fetched from his quarters to be executed on a hillside outside Queretaro, on the morning of June 19, 1867, only three years after his arrival in Mexico.

Maximilian and his two remaining generals, Miramon and Mejia, were awakened to a fanfare of bugles and drums. When Maximilian asked Miramon, "Miguel, is this for the execution?" Miramon replied, "I cannot say, señor, as I have not been shot before."

General Porfirio Diaz, who had romantically escaped from prison in Puebla by lowering himself from a window on a knotted rope. When Diaz refused, Bazaine ordered the equipment destroyed rather than give it to Maximilian's weakened forces. At the same time Bazaine, despicably, persuaded Maximilian to save himself by issuing the infamous "Black Decrees," which ordered summary execution for all republicans caught in arms. That was the end. Though Maximilian had acquired adherents by his disarming manners and personal charm, he now found himself cornered. Juarez besieged him at Queretaro with the help of Porfirio Diaz. Betrayed into their hands, Maximilian was executed by firing squad on a nearby hilltop, dying like Hidalgo, crying "Viva Mexico!"

Again there was a dismemberment and disposal of valuable books and manuscripts about Mexico and its antiquities. Maximilian's confidant, Father Augustin Fischer, a Jesuit priest who drank heavily and was rumored to have numerous illegitimate children scattered about Mexico, tried to sell several of Maximilian's private papers.

It was an odd twist of fate, for Maximilian, as the natural grandson of Napoleon I, would have been closer by blood to the Imperial line of France than was his cousin Louis Napoleon III, who stood in line merely as the son of Napoleon I's brother Louis and of Josephine's daughter, Hortense. There is every indication that Maximilian's natural father was the Imperial dauphin, known as the King of Rome and more fondly as l'Aiglon, son of Napoleon I, and of the Austrian Archduchess Marie Louise. As the Duke of Reichstadt, the title by which Metternich insisted l'Aiglon be known at the Hapsburg court, he was much in love with and much loved by Maximilian's mother, the Archduchess Sophie, with whom he may also have fathered Franz Joseph, Emperor of Austro-Hungary, cuckolding his legal father, the dull-witted Archduke Francis Charles of Hapsburg.

The Andrade collection, which had not been paid for, was hastily packed up by its owner during the last days of the empire and transported on muleback to Veracruz, where it was shipped to Europe and sold at auction in Leipzig for $16,500. Many of the rare printed books and pamphlets on Mexico were acquired by the American historian Hubert Howe Bancroft and now form part of the Bancroft Library at the University of California.

Maximilian's execution put the quietus on further archeological speculation about Teotihuacan. Mexicans were more interested in the perils and possibilities of their own immediate future than in the wonders of their remoter past.

11. Foreign Intervention

The world's interest in Mexican antiquities might have withered during the next decades had it not been for the efforts of three Americanized Frenchmen, two of them adventurers, one of them a robber baron, Pierre C. Lorillard.

On vacation from teaching school in New Orleans in 1850, Claude Joseph Désiré Charnay, a young man in his early twenties, was so struck by the mysterious beauty of Mexico that he went back to France to induce Napoleon III's minister of fine arts, Eugène Viollet-le-Duc, to give him an assignment to photograph Mexico's ancient ruins with a recently developed camera obscura. Carrying the dark chamber on his

Désiré Charnay deep in the Mexican jungle with his camera obscura.

back and nursing the large glass plates on which to mix his own emulsion, Charnay got back to Mexico in 1858 for a three-year jaunt from Mitla to Monte Alban, to Chichen Itza, to Uxmal, and to Palenque. The result of these travels was a folio volume containing the first but certainly the drabbest photographs ever taken of Mexican antiquities, for which Viollet-le-Duc produced an equally drab academic text in which he came to the not surprising conclusion that an advanced civilization had once covered North, Central, and South America, well before the beginning of the Christian era, reaching its apogee several centuries before the Spanish Conquest, by which time it had broken up and fallen into decadence.

Charnay followed his folio volume with a personal memoir in octavo in which he entertainingly described the frustrations of trying to photograph Mexico under the most grueling and uncomfortable conditions. More of a vulgarizer than an academician, Charnay spiced the memoir with salacious anecdotes about the attractive Mexican maids he had encountered, telling of a sixteen-year-old who was highjacked from the coach in which they were both traveling to be raped by six tall bandits; of a sterile young wife whose Yucatecan husband, believing all foreign archeologists to be doctors, begged him to examine closely his wife's malfunctioning organ, for which Charnay successfully prescribed the dexterous use of astringent aloes and a camphorated candle; and in Mexico City of the whores who would reward a statue of the Virgin Mary with portions of their nightly earnings in return for a regular flow of clients.

In the hope that the government of Napoleon III might finance him on another trip to Mexico, Charnay unctuously dedicated his opus to "the Emperor whom nothing escapes

Charnay climbed Mount Popocatepetl, from which he was able to view simultaneously through the crystal air the shining cupolas of Mexico City and the belltower of Puebla sixty miles away.

of that which is useful, noble or grand, who knows how to honor merit and encourage modest work."

Unlike the Abbé Brasseur, whom he admired, Charnay was not averse to traveling with the army. As a result he got himself back to Mexico in 1864, only to be told to hurry up and wait, finally succumbing to the general debacle of Bazaine's army which followed Maximilian's execution in 1867.

Still determined to succeed, Charnay spent the next twenty years looking for a backer, until he managed to convince the Carolina tobacco tycoon Pierre Lorillard to underwrite for him, in conjunction with the French authorities, a proper research expedition to Mexico. Charnay complained, not altogether unjustly, that because most writers, especially North Americans, had taken to describing the ruins of Mexico more on the basis of what casual travelers told them than on any careful exploration of the sites, he wished to obtain permission from the Mexican government to actually dig in the soil for remnants of the past.

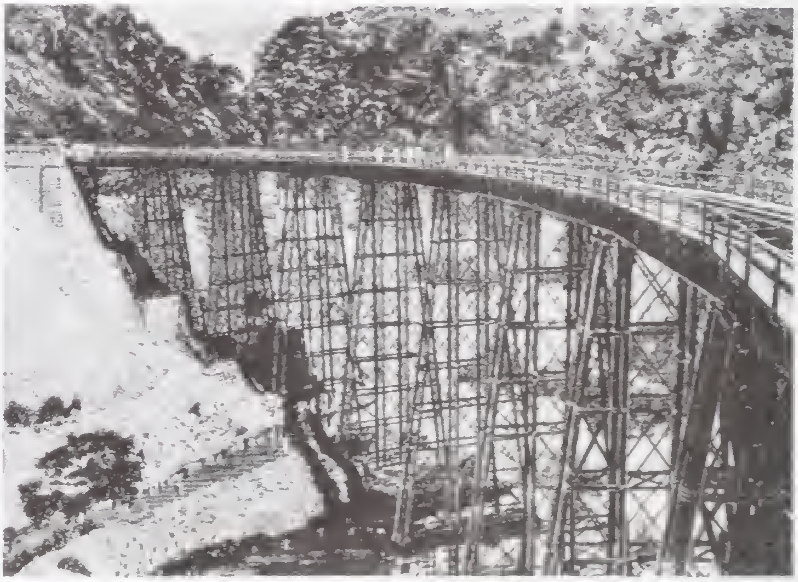
By the time Charnay returned to Veracruz, the port was being regularly serviced by motor sailors.

Exactly twenty-two years after his first visit to Veracruz, Charnay returned in April of 1880 to find the town much improved, houses freshly painted, steeples whitewashed, cupolas ornamented with pyramidal shapes, enameled in pink and blue.

The formerly squalid square, which had been crisscrossed by muddy watercourses, was now charmingly paved with marble and adorned by a park of shade trees in which squirrels gamboled. As much of a girl watcher as Waldeck, Charnay spent his evenings admiring the pretty women in checkered and phosphorescent *cucuyos* taking the air in the arcades with their "beautiful shops and magnificent cafes." Thanks to the influence of the French, the food had also improved. There was excellent fish, edible game birds, plenty of tropical fruits; and the wines were no more expensive than in Paris. Only the ubiquitous black vultures already remarked by Bullock were the same as on Charnay's earlier visit.

Thanks to some spectacular engineering by the British, Charnay was now able to travel to Mexico City all the way by train. It was a vast relief from his previous trip, when he had been obliged to use the rough post road, being jostled in one of the "chariots" drawn by fourteen mules which moved in convoys of a dozen, each headed by a majordomo. These convoys would set off at midnight, after the wandering bell-laden mules had been recaptured with lassos by groups of picturesque muleteers.

This time the train rose from the tropics into the temperate zone in serpentine leaps across barrancas more than a thousand feet deep, at the bottom of which the vegetation still remained tropical.



On the newly built railroad, Charnay ascended from sea level through grander and grander scenery, past coffee, tobacco, and banana plantations where little houses, embowered in orange groves and creepers, peeped out from enormous shade trees. Ahead were the silhouette outlines of the Sierras, dazzlingly bright and richly colored mountains dominated by the snowcapped volcanic peak of Orizaba.

As the train left the thick forests of the temperate zone, full of songbirds, changes in the scenery were brusque and varied. After crossing an arid desert, they entered mountains with deep ravines, perfect for armed robbery.

The only feature unchanged from the previous voyage was the prevalence of bandits, which obliged the train to travel with an armed escort.

At Apam the train loaded casks overflowing with "a yellowish, thick and stringy liquid, repulsive to the smell," the best pulque in Mexico, according to Charnay, "as superior to others as Chambertin is to ordinary claret."

When the train reached the plain of Otumba, it passed close to the pyramids of Teotihuacan, still covered in grass and underbrush.

On the outskirts of Mexico City Charnay noticed many pretty villas where once there had been only marshland. Inside the city, the principal square, or Zocalo, which had

Mexican bandits holding up a stagecoach.

In the brand-new railroad stations, rural guards armed to the teeth and adorned with large felt sombreros trimmed with silver, ribbons, and tassels lolled about waiting for bandits, whom they were expert at tracking to their hidden lairs, as most of them were converted ex-bandits. These were the famous Rurales of President Porfirio Diaz, whose method of recruiting them was to hold five bullets in his left hand and stretch out the other for a handshake. The recruit could make his choice.

been ill paved, had become a fine garden shaded by eucalyptus trees seven feet in girth and over a hundred feet high; beneath them spread a beautiful garden with a pavilion for concerts.

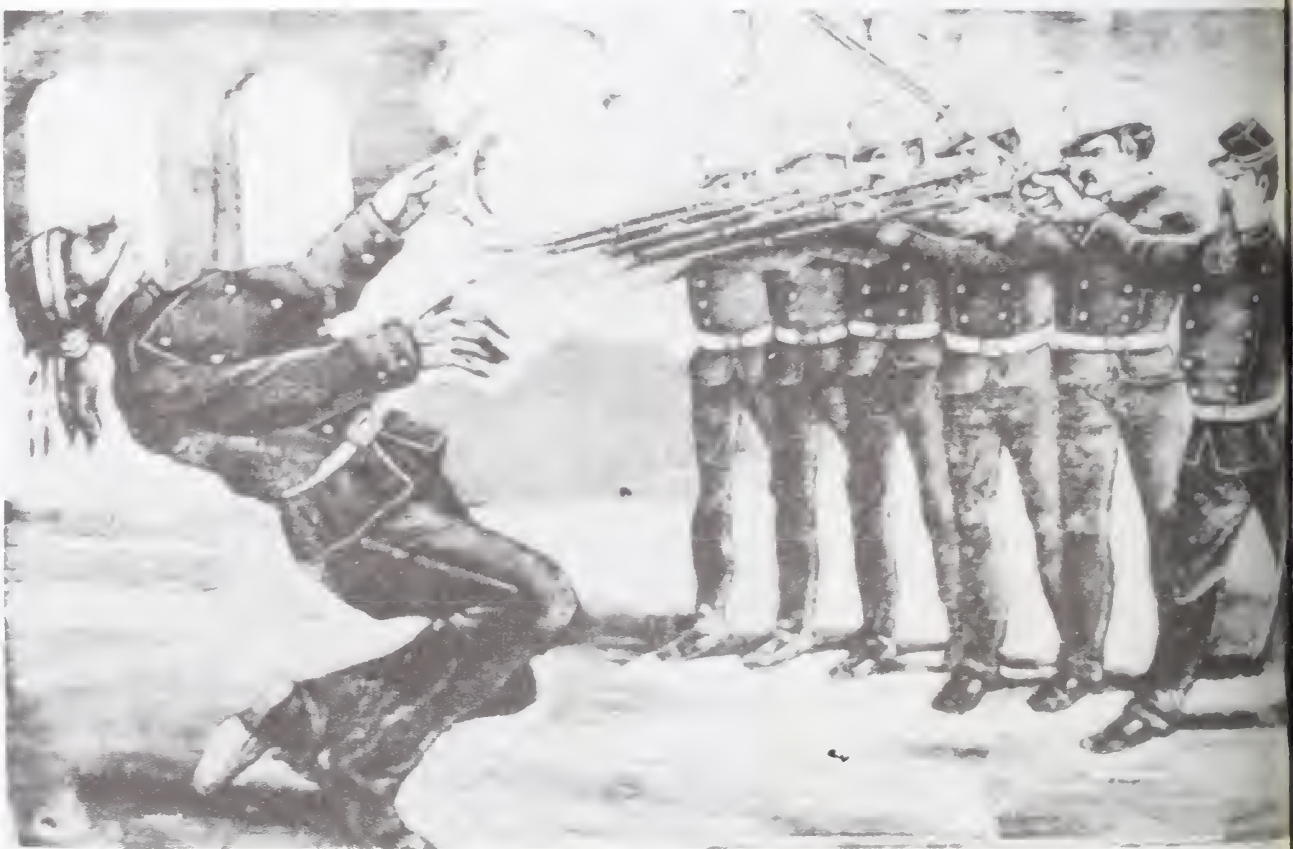
But the biggest change to Charnay was the absence on the streets of any priests. Since Juarez had entered the city in 1867, all the priests had vanished, going into exile or becoming private citizens, taking up business and getting married. Even the monks had taken wives or turned Protestant to serve the Bible societies from New York and Boston which had mushroomed with the influx of foreign capital solicited by General Diaz.

When the train reached Puebla, Charnay found it the cleanest and best-built city in Mexico, adorned with eighty belltowered churches decorated in faience of a thousand colors.

Operating on the theory that "two cats cannot live in the same bag," Diaz made himself supreme dictator of Mexico, a position he held for over thirty years by the simple expedient of disposing, one way or another, of any political rival. To those who helped him, he gave jobs, on the theory that "a dog with a bone neither barks nor bites."

Manuel Romero Rubio, originator of the *cientifico* minority to fight democracy in Mexico, became Diaz' minister of interior, head of the Rurales, and strong man behind the scenes. With funds from his illegal brothels and gambling dens he organized a gang of apaches who were paid monthly to do nothing but attack enemies of the system.

José Ives Limantour.
A skinny little man of French origin who considered Indians "dark, quarrelsome, lazy, thieving little men," he inherited his boss Rubio's mantle as head of the *cientificos* when Rubio died. As Minister of Finance, and power behind Diaz, he finally betrayed his new boss out of power.



Mexico's Cientificos.

While Charnay was in Mexico the *cientificos* concocted a law by which they were able to expropriate the public lands communally used by the peons so that some 50 million acres passed into private hands, often for as little as a centavo an acre. One beneficiary, Luis Terrazzas, had just become

owner of an estate of seven million acres, larger than New Jersey, on which he kept a million and a half head of cattle, while 95.5 percent of Mexico's rural families found themselves with no land. Ten million serfs were created, easily impressed into factories built by foreign investors, where the serfs were obliged to work for a pittance fourteen hours a day without even Sundays as automatic holidays. Recalcitrants, though technically free citizens, could be whipped for any infraction. Petty theft could draw two hundred lashes. Women were strung up and syringed with chili water.

If peons refused to give up the land, the Rurales and federal soldiers moved in, raping and murdering. Stubborn Yaquis, who showed title maps to their lands signed by the King of Spain, were rounded up and sold into slavery to Yucatecan sisal planters at seventy pesos a head—an extra profit for the *cientificos*. Many of the Yaqui women, like the Greek Suliotes in Byron's time, preferred to throw themselves with their babies into the sea.

Surviving Indians were left without woods, water, or any way of making a living off the land. In the United States, General U. S. Grant announced to investors that "seven million Aztecs are waiting to build railroads." Rockefellers, Aldriches, Goulds, Harrimans, Guggenheims, and McCormicks seized the opportunity to buy cheap land and hire dirt cheap labor to operate rail and mine concessions. The Creole *cientificos,* acting as middle men and legal advisers, amassed quick fortunes through large legal fees, stock manipulations, kickbacks, payoffs, and such subtle trickery as selling arms and ammunition to the Indian rebels that the government was officially exterminating.

Though millions vanished into the pockets of the *cientificos,* little of the wealth trickled down. Practically nothing was spent on schooling or education. Real wages were reduced to less than they had been a century earlier under the Spaniards.

Considering Mexicans too stupid for parliamentary democracy, the *cientificos* succeeded in making a farce of the electoral process, openly stuffing ballot boxes and intimidating voters with bands of armed Rurales. All appointments to congress, cabinet posts, or governorships were dictated by Diaz with the connivance of the *cientificos,* yet governors and judges could be removed by a simple majority of Diaz' rubber-stamp congress.

Labor organizations were outlawed, strikes put down by the army. Rebellious individuals conscripted into its ranks could be disposed of by the *ley de fuga,* "shot while trying to escape."

For opponents too much in the public eye, Diaz kept a stable of *pistoleros* who would challenge any required opponent to a duel, with usually fatal consequences. If jailed, the *pistolero* was promptly amnestied.

Judges did as they were told, and only official lawyers won their cases. The chief of police was Diaz' own nephew, Felix Diaz. Newsmen who came too close to the truth were beaten up or assassinated. One unwanted editor was sentenced to jail for material published in a fake issue of his own paper fraudulently concocted by friends of the sentencing judge. Mexican writers who sought asylum in the United States were extradited back to Mexico for punishment in return for grants to the U.S. such as the naval station at Magdalena Bay.

Foreign correspondents were subsidized to sing Diaz' praise to the world, with the result that the U.S. Secretary of State, Elihu Root, declared, "I look to Porfirio Diaz, President of Mexico, as one of the great men to be held up for the hero worship of mankind."

Here was the blueprint for a series of United States–financed dictatorships, from Mussolini to Trujillo to Franco, a system which was to pox the planet for almost a hundred years and which, though detailed by such authors as Carleton Beals, was to lead to bloodshed around the world.

Everywhere, Charnay says, he found a new spirit of initiative which had turned the governor's palace into a rendezvous for citizens, with the exception, of course, as he was quick to point out, of the vast majority of Indians. A thin veneer of progress was bandage to a running sore. In their cotton cloth and straw sombreros the peons were still not allowed on the main streets of the capital. They had to wear European trousers, which could be rented by the day from merchants on the outskirts of the city.

Considered too backward and too ignorant to govern themselves, Mexican Indians had been completely deprived of power or any say in the government by a group of Creole wheeler-dealers known as the *"cientificos,"* who thought they could "scientifically" transform Mexico into a Western state with foreign capital, operating as an elite behind the virtual dictatorship of Porfirio Diaz.

In this atmosphere of false prosperity Charnay tried unsuccessfully to rearouse the Mexicans to an interest in their historic ruins. He had developed the theory that there had once been a vast Toltec empire in central Mexico which had

Promenade of oak trees outside the cathedral in Mexico City's Plaza Mayor. In the evenings, "society" went there by moonlight, so the caballeros could make their conquests among beautiful women discreetly peeping out from behind their Spanish shawls.

spread its dominion from a legendary capital called Tollan as far as Teotihuacan, Toluca, Xochicalco, Cholula, and even Chichen Itza seven hundred miles to the south. From fragments of the works of Fernando de Alva Ixtlilxochitl—whom he considered every bit as trustworthy as Herodotus or Plutarch, and whose works were finally being prepared for publication by Charnay's friend, the Mexican historian Alfredo Chavero—Charnay had become convinced that the remains of the Toltec capital of Tollan were to be found in the subsoil of the modern village of Tula in the province of Hidalgo, sixteen leagues from Mexico City.

Armed with the necessary permit from a friend in the Ministry of Education, Charnay was at last able to board a train which took him past Tacuba, where he could still see the great solitary cypress under which Cortes had cried after the disaster of *La Noche Triste*. At Cuautitlan, armed with a powerful shotgun against bandits, which made his fellow passengers smile with reassurance, Charnay boarded a *diligencia* drawn by mules for a ride over a road so dusty and so rocky it caused all his fellow passengers to vomit.

At the foot of Mount Coatepetl, where the river winds through a narrow valley, the *diligencia* crossed its muddy waters at a gallop to deposit Charnay on what he believed to be the site of the once brilliant capital of the Toltecs—a quiet Indian village of 1500 souls—shaded by enormous ash trees. In the nearby fields there were only a few unpromising mounds overgrown with vegetation. But working with a gang of native diggers, Charnay soon came across large sculptured

Diligencia, or horse-drawn coach, passing Tacuba on the way from Mexico City to the town of Tula.

stones of black basalt more than two meters long and thirty centimeters in diameter, which appeared to him to be the feet of gigantic statues apparently used as caryatids (to which he gave the name "Atlanteans") designed to support a very large building.

There were also fragments of an enormous stone rattlesnake whose head had formed the base of a large column and whose tail had supported a capital much like the ones in Chichen Itza that Charnay had seen twenty years earlier. As in Chichen Itza, he also found a heavy stone ring almost two meters in diameter with a thirty-seven-centimeter hole, clearly part of a ball court.

As figures in the friezes found at Tula represented the same rulers and warriors as those at Chichen Itza, it appeared that both had been built by the same Toltecs.

Some distance away, Charnay found the remains of a large pyramid thickly covered in vegetation through which he could make out a surface with a thick coating of plaster. It was an exciting and important discovery, but even with labor so cheap that a man cost less to hire than a mule, to have tried to dig into the pyramid would have been more than Charnay could tackle with Lorillard's funds.

There was no doubt in Charnay's mind that he was on the site of ancient Tollan, and from the strong resemblance between its decorative motifs and those of faraway Chichen

View of Tula in the province of Hidalgo.

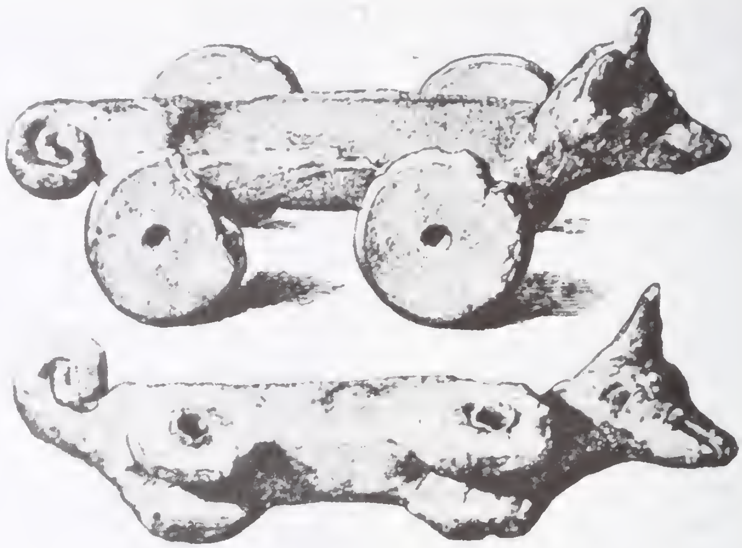
Told it was folly to look for ancient Tollan near the village of Tula, that the city was a fable which like Quetzalcoatl had never existed, Charnay was goaded into digging by the knowledge that twenty years earlier a poor shepherd boy scratching the moist ground of Tula had uncovered a vase containing five hundred ounces of gold, which he had sold for a few coppers.

In 1940 the Mexican archeologist Dr. Jimenez Moreno showed that Tula had indeed been a Toltec capital built about A.D. 900, well after the destruction and abandonment of Teotihuacan. Tula was in turn destroyed in the twelfth century by Aztec invaders who carried off much of its stonework and sculpture to build Tenochtitlan. Among the structures discovered at Tula by Charnay, the Mexican government eventually restored and reconstructed a 30-foot pyramid divided into five levels, beautifully decorated and frescoed, as well as several enormous 15-foot-high caryatids, known as "Atlanteans," armed with strange weapons.

Itza, he was convinced that a Toltec civilization had been the source of a high culture throughout Central America.

But the world of archeology, which considered Charnay unreliable and romantic, greeted his discoveries with the same reserve they greeted Heinrich Schliemann's contemporary discoveries of ancient Troy and Mycenae. They firmly denied Charnay had found Tollan.

As Charnay dug farther into the Tula fields, he found the remains of what appeared to be a whole palace, 62 feet long on one side, with an inner courtyard and garden altogether covering 2,500 square feet. On one wall was a bas-relief depicting two bearded men, which puzzled him, as they were clearly non-Indian.



On Monte del Fraile at 13,000 feet, from where he could view the Pyramid of Cholula, Charnay discovered a cemetery which he believed to be Toltec. Excavating its tombs, he came upon some chariots of terra cotta which he believed to be ancient toys that demonstrated Mesoamerican knowledge of the wheel. When told they were modern fabrications, he dropped the subject saying: "J'ai laissé tomber l'objection, qui serait une insulte à ma bonne foi." Later, more wheeled toys were found in Mesoamerica similar to the terra-cotta toy chariots modeled by the Phoenicians. The most appealing explanation for the Maya having known but not used the wheel comes from Stacy-Judd, who suggests that Yucatecan survivors from Atlantis took warning from the destruction of their former civilization engendered by over-indulgence in the wheel!

Not until the 1930s, when his excavations were finally reexamined by George C. Vaillant, who also laid the foundations for a systematic stratigraphy of central Mexico, was it realized that Charnay might have been correct. Vaillant was able to show that the artifacts at Tula placed it squarely with the Toltecs, just as Charnay had said, only at a slightly later date, between the eclipse of the great city of Teotihuacan, sometime in the eighth century A.D., and the arrival of the Aztecs in the thirteenth.

12. The First Real Digs

Charnay was surprised at the variety of human types portrayed on masks, often with considerable artistic skill: there were the features of Caucasian, Greek, Chinese, Japanese, and Negro; also Maya type heads with retreating foreheads, such as he had seen in Yucatan. They seemed to validate the theories of Viollet-le-Duc about an influx of Europeans and Asiatics, leading Charnay to comment that numerous races must have succeeded each other and amalgamated on the continent, "which, until lately, was supposed to be so new, and is in truth so old."

During fifteen years of investigation of thousands of pre-Columbian terra-cotta pottery heads and figures, art historian Alexander von Wuthenau found portraits of five different racial types: Mongoloid, Chinese, Japanese, Negroid, and all types of white people, especially Semitic types with and without beards.

Saddened by the treatment received from his contemporaries over the Tula digs, Charnay decided to attack the site of Teotihuacan to see if he could prove that it too had been a Toltec city comparable to Tula, a notion which found even less support.

Thanks to General Diaz' railway concessions, Charnay was now able to travel from Mexico City to San Juan Teotihuacan in the comfort of a railway coach in just over sixty minutes.

From San Juan, Charnay approached the pyramids on foot, his eyes falling on all kinds of fragments strewn across the fields: bits of pottery, masks, and small and large figures. There were ex-votos, idols, broken cups, stone axes, and all manner of fragments of obsidian, the volcanic glass, most often black, which could be worked into a hard cutting edge and had evidently served the ancient dwellers of the valley for cutlery, tools, and weapons. Crossing the river bed which runs through Teotihuacan, Charnay found countless obsidian pebbles of a grayish and opaque green color.

In a blistering sun Charnay climbed the larger pyramid, which he gauged to be angled at 47 degrees where the coatings of cement still adhered. It was a bright clear day, and from the summit of the pyramid Charnay was rewarded with a view of the lakes in the Valley of Mexico, the snowy peak of

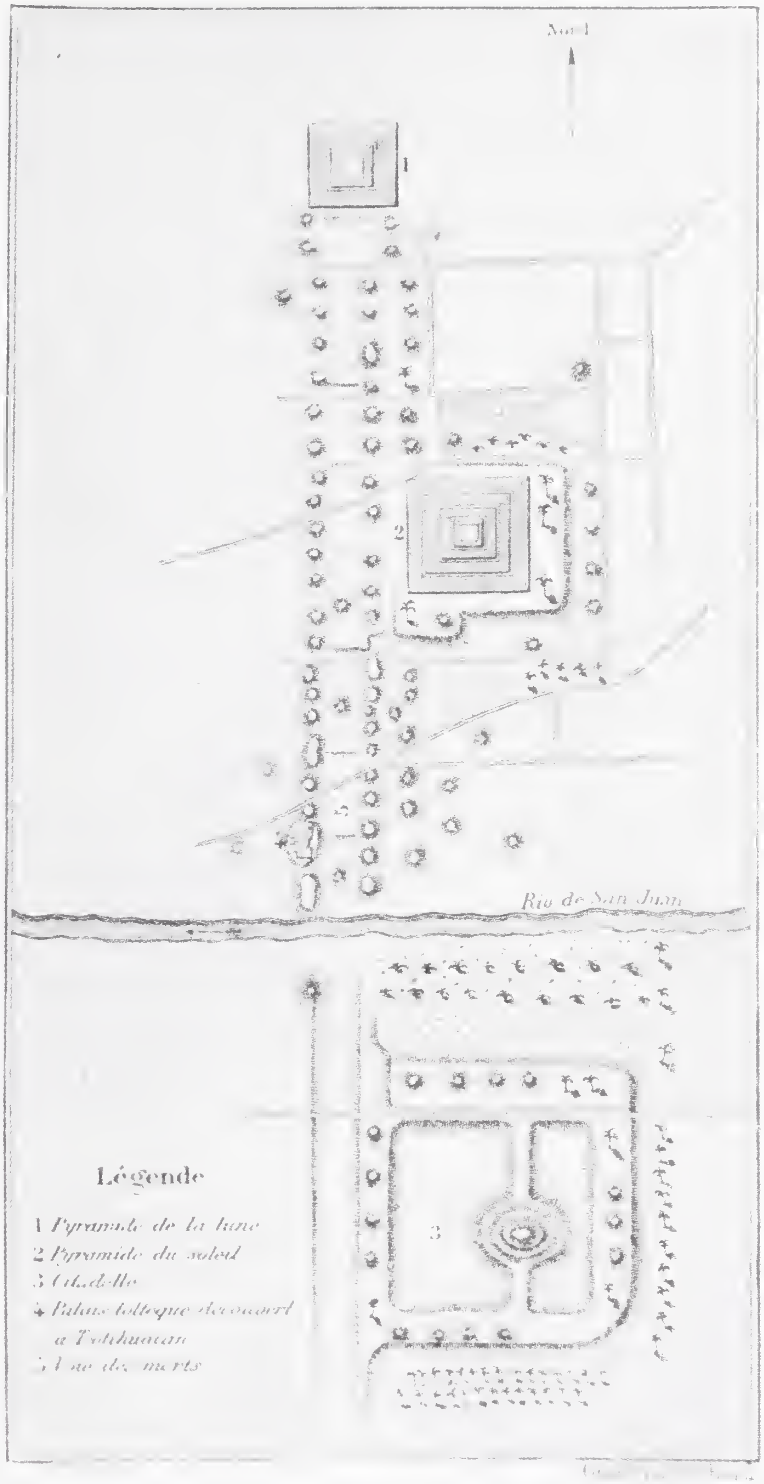
Like Humboldt, Charnay found the Sun Pyramid to be divided into four stories, three of which were still visible, but his description tallies so closely with the hearsay stories repeated by Humboldt that it hardly seems original. More vivid are his descriptions of finding atop the Pyramid of the Moon a perfect obsidian earring, thin as a piece of paper, brought to the surface by ants burrowing for a nest.

Iztaccihuatl towering above the Malacinga range, and, far, far away, the faint outline of the Cordilleras.

Going Prescott one better, Charnay pictured in his imagination a great dead city as it must have once surrounded the pyramid, recreating in his mind's eye its dwellings, temples, and smaller pyramids, "coated with pink and white plaster, surrounded by verdant gardens, intersected by beautiful roads paved with red cement, the whole bathed in a flood of sunshine."

With his Indian escort, Charnay next explored the remains of the mounds known as the "Citadel," which he poetically compared to a vast tennis court whose embankment he measured as 19 feet high and 260 feet thick. Noting fifteen medium mounds and a high one in the center, he intuitively concluded that the place must have been used for public ceremonies rather than as a citadel.

Two and a half miles west of the Pyramid of the Moon, Charnay was led by his guide to some cavernous quarries, or *cuevas,* from which much of the stone to build the pyramids appeared to have been dug. There Charnay found three narrow galleries, branching off in different directions at 45-degree angles, which led to different caves, one a conglomeration of large halls supported by incredibly thin pillars, another like a rotunda, filled with human remains, which he was told were attributable to brigands who used the cave as a burial place for their victims.



According to Charnay's guide, the caves extended three miles to the Pyramid of the Sun, and beyond, where the whole countryside was said to be undermined with caves.

As Charnay's prime interest was to dig, as he had at Tula, for remains of the ancient city of Teotihuacan, in the hope of finding remains of palaces or apartment houses to establish for the city a Toltec origin, and as diggers were needed for

Approaching the lovely baroque church at the end of a great avenue of well-watered poplars and cedars, Charnay was appalled by the way it contrasted with the hovels of the Indians, barely six feet square, within which whole families lay huddled on the beaten ground, half naked or in tatters, "suffocating in summer and freezing in winter, subsisting on a few beans and tortillas which the women ground from corn on *metate* boards kneeling in front of their hovels."

Noting in his diary that the children died mostly in their first year, and that a man earned barely a shilling a day to support a family of eight or nine, Charnay distributed a few coppers to the Indians to drink his health in pulque.

the purpose, he and his guide returned to the village of San Juan to muster volunteers.

With his accommodations in the village, Charnay was far from happy. The only place to sleep was on the floor of a bare-roomed building around a courtyard paved with brick. It was devoid of furniture, because, as he put it, "anyone who wished to, could lie beside you, and your ablutions have to be made at the well in the presence of half the village congregated in the yard."

Before the construction of the railway, Charnay remembered, the village had been a bustling relay point for mules plying to and from Mexico City, more than two thousand of them daily, when "the clapping of hands of the tortilleros was heard all day, along with copious libations of pulque." Now the village was a morgue.

Charnay attacked a terraced court fronting the Way of the Dead and found among the constructions and substructures stucco walls crisscrossing each other in all directions, over layers of ornaments, pottery, and detritus, which led him to conclude that a city had been built and rebuilt several times, and that when one building was demolished the new occupant, instead of clearing the ground of old rubbish, had simply smoothed it down and laid a new floor on the compacted detritus.

Charnay says he ate his dinner that night more to spare the feelings of his host than because he liked the menu, and also to insure by his good manners that the municipality would give him men on the morrow sufficient to start his digging.

Convinced that the village of San Juan covered part of the old city of Teotihuacan, Charnay decided to open four trenches right in the small square not far from the Plaza Mayor that was normally used for bull fighting.

The first two trenches produced no results. In the third the diggers came upon a dozen children's tombs and half a dozen adult tombs, the bones in which crumbled to dust as Charnay handled them.

The graves contained, along with a few obsidian knives, the remains of edible dogs and birds intended to feed the dead in their afterlife journey. The children were buried in circular vases with upright brims, the skeletons almost perfect, but the skulls, thin as paper, fell to pieces at a touch. From the fact that the bodies had not been cremated, Charnay deduced that he had struck a poor quarter of the ancient city.

Determined to show that Teotihuacan had been as flourishing as Tula, Charnay looked for a better spot to dig. North of the river he had noticed parts of walls, broken cement, and terraces. Settling on these, he managed in three days' digging to uncover ten rooms which formed part of a large house with inner courts, apartments on different levels, roofs supported by pillars, one chamber being 732 feet in circumference. The walls were nearly six feet seven inches thick, built of stone and mortar, incrusted with thick cement; at the

foot they sloped about three feet before becoming perpendicular.

Charnay labeled the house a "palace" because it had what appeared to be several reception rooms with stuccoed walls frescoed "like an Aubusson carpet" whose red, black, blue, yellow, and white markings were still discernible. Charnay would have liked to have unearthed a number of "sleeping accommodations" that he felt extended beyond the palace, but most of them were under an Indian's cornfield and could not be touched.

Manuel y Berra.

Convinced that he had only scratched the surface of a huge dormant city that might reveal great treasures, Charnay telegraphed messages to his friends in Mexico City, the historians Alfredo Chavero and Manuel Orozco y Berra, both professedly interested in Mexican archeology, urging them to join him to see what he had found, and to urge the Mexican government to initiate regular excavations at Teotihuacan. Neither government nor friend paid him the least heed. One friend sent word he had a headache, the other pleaded "a less poetic ailment."

As a consolation, Charnay was able to peel off some of the frescoes he had unearthed and send them to Paris, where they were put on display at the Trocadero, to arouse, in due course, enough interest among later archeologists to keep alive the prospect of further digs at Teotihuacan.

Determined also to make moldings of the stone reliefs at Palenque which he had been unable to photograph on his previous visit, Charnay finally managed to obtain the grudging approval of the Mexican government to travel elsewhere in the republic, including the rebellious areas of Yucatan, but only on condition that he take with him a colonel of artillery who was "to watch and share his labors and discoveries." Assuming, most probably correctly, that Charnay

Charnay crossing one of the more difficult Mexican passes.

Charnay's kitchen at Palenque. Unlike Stephens and Waldeck, who had subsisted on cornmeal and iguana, one of Charnay's dinners, thanks to Mr. Lorillard, consisted of soup of purée of black beans with snail broth, Valencian olives with Arles sausage, corn-fed chicken with garlic and red peppers, fried *morne* with chives garnished with hearts of palm and asparagus tips, black bean rissoles, crêpes, American cheeses, Bordeaux and Aragon wines, coffee and Havana cigars, with Xtabentun liqueur.

was doubling as someone's agent, the government selected an amiable veteran of the war against Maximilian, Don Perez Castro. To record whatever they might discover on their travels, the Mexicans also selected a young Frenchman born in Mexico, Albert Lemaire.

At Palenque the travelers found that a stranger could still pass within a few yards of the hidden city and not see it. Much of the Temple of the Cross had given way since Charnay had first seen it twenty-two years earlier, and many of the reliefs had disappeared, the work of both scavengers and vegetation. Roots removed by previous explorers had broken up the walls and caused them further to disintegrate.

"But my admiration for this massive place, these ruined temples, these pyramids," remarked Charnay, "is profound, nay, almost overpowering."

To obtain molds of the remaining reliefs, Charnay employed a system invented by a Monsieur Lantin de Laval of France which consisted of squeezing six layers of wet paper onto the friezes and allowing the pulp to dry. With this system Charnay was able to get 325 square feet of impressions for a weight of 500 pounds instead of the 30,000 pounds it would have weighed in plaster of paris.

But the work was not easy. Almost incessant rain obliged Charnay to redo scores of the impressions. The dampness penetrated to their bones and caused vegetable mold to grow on their hats. In the mud they slithered constantly, more often on their backsides than on their feet. At night drops of water trickled down their necks from the greenish moss on the walls.

By day they were prey to swarms of insects, mostly *rodadores* and *garrapatas,* the Mexican ticks. To offset malaria they now had the benefit of quinine, made from cinchona bark, discovered in 1820 by two Frenchmen, Caventou and Pelletier, whose use had been promoted by the wife of the Spanish ambassador to Peru.

Another improvement over Charnay's first trip to Palenque —when he had survived on frightful quantities of raw cornmeal soaked in water, along with snail soup from the river— were some delicious French dinners prepared by a sophisticated cook, complete with Havana cigars, coffee, and the local liqueur called Xtabentum.

Once the paper impressions of reliefs were safely packed off to France, Charnay and the colonel set off for Chichen Itza with a guard of fifty soldiers put at their disposal by the governor of Merida to protect them against the rebellious Yucatecans, still uncontrolled since their uprising in 1847, who made forays from their safe bases in the wilder parts of eastern Yucatan and Quintana Roo.

The castillo Kukulkan.

This 75-foot-high pyramid has four staircases of 91 steps for a total of 364; when the upper platform is added, the sum is 365, for the days in a year. The 18 larger steps represent the 18 months of a year. The 52 panels in the large steps give a Mayan century of 52 years.

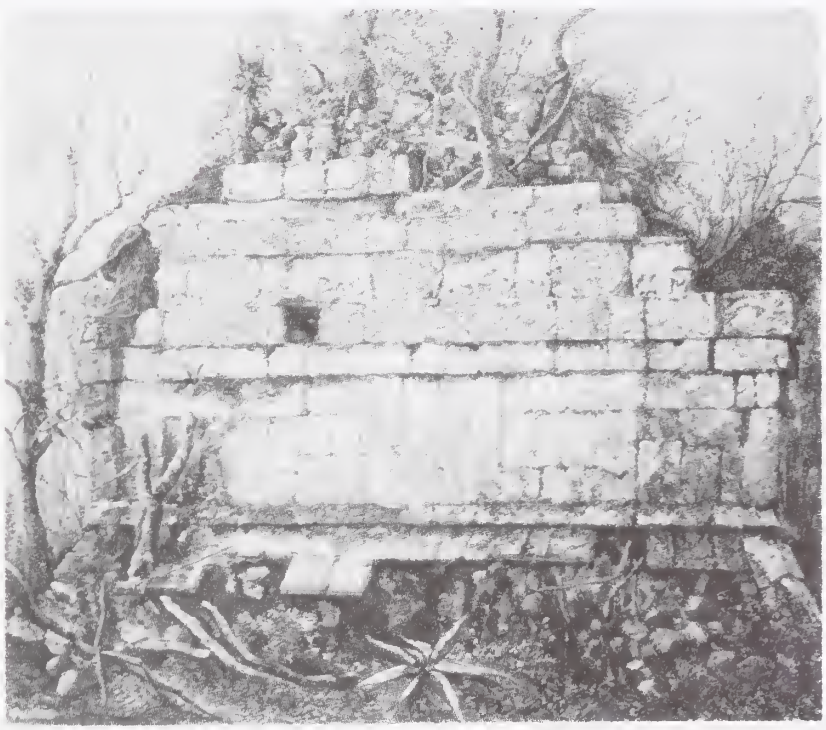
During the past decades most of the major cities of Yucatan had been burned by the rebels and half the population still lived with a weapon under one arm while the other half worked in the fields or slept.

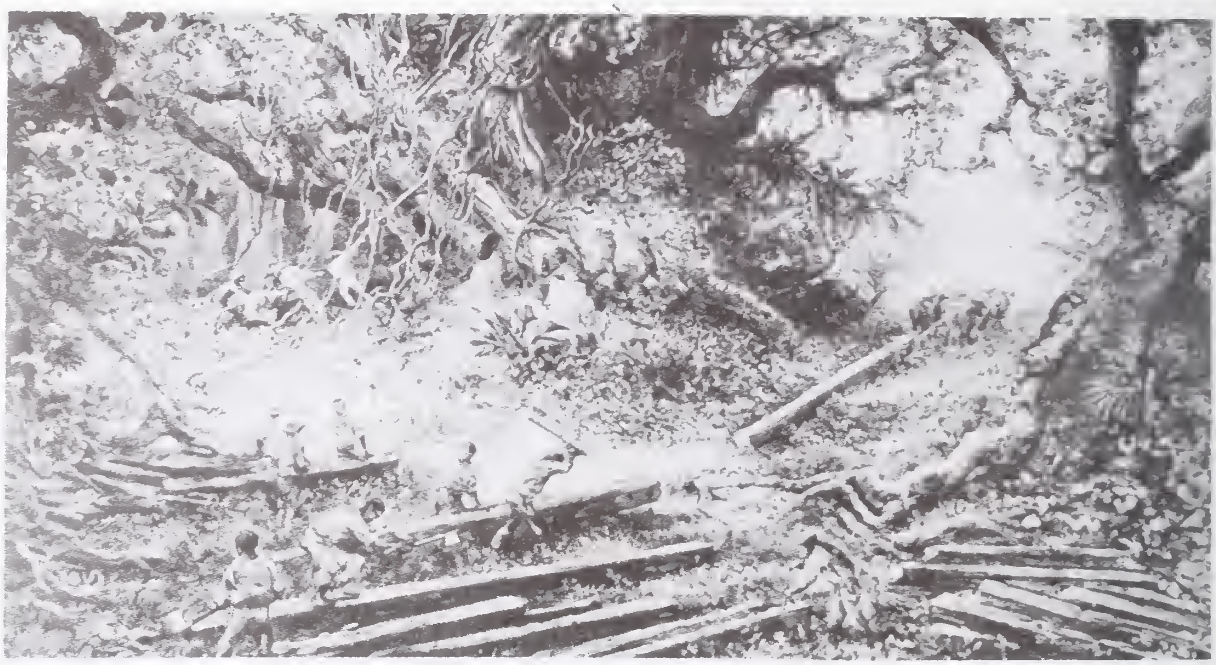
At Chichen Itza, Charnay and his military companions climbed to the top of the Castillo, which they found still overrun with vegetation, birds, snakes, and iguanas. To avoid being ambushed by the rebels, they ensconced themselves in the main chamber and set up regular sentries.

To Charnay there was something about Chichen Itza, especially the enormous figures of idols ornamenting the frieze around the Palace of the Nuns, that reminded him of Hindu art. At Izamal, barely sixty miles away, he had been reminded by the gigantic faces built into the side of a man-made pyramid of the Sphinx in Egypt. At Uxmal he had found a Greek influence in the governor's palace; at Palenque an Assyrian motif; at Mitla Chinese motifs. Other statuary reminded him of Malaya, Cambodia, and Java, where he had traveled in the interim between his trips to Mexico. He found the storied pyramids of Yucatan much like those of Angkor Thom and Angkor Wat. All of which validated for him the theories of his first patron, Viollet-le-Duc. But to please his present patron, Pierre Lorillard, Charnay wished to do something original; he wished to rediscover and name for Lorillard what was reputed to be the greatest and least-known of Mayan ruins, Yaxchilan, on the border of Guatemala, reported by Stephens to be a phantom city.

The nunnery of Chichen Itza, much more dilapidated and overgrown than when Stephens saw it for the last time half a century earlier.

With great difficulty Charnay mounted an expedition to make his way slowly up the Usumacinta River and was within a day's journey of his goal when he discovered he had been beaten to the mark by a solitary Englishman, Alfred



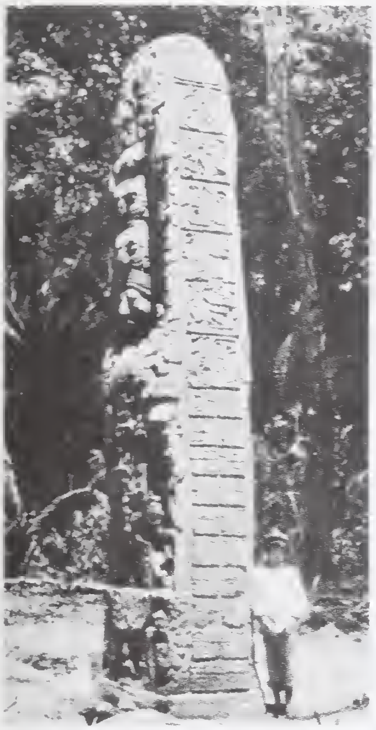


Remains of a temple at Lorillard.

Percival Maudslay, who was busy clearing the site and making remarkably beautiful drawings and photographs of its many stelae.

When Charnay finally arrived at Yaxchilan in a canoe sent down the river by Maudslay, the Englishman took one look at his expression and said with a cordial laugh, "It's all right. There is no reason why you should look so distressed. My having had the start on you was a mere chance, as it would have been mere chance had it been the other way. You need have no fear on my account, for I am only an amateur, traveling for pleasure. With you the case of course is different. But I do not intend to publish anything. Come, I have had a place got ready; and as for the ruins, I make them over to you. You can name the town, claim to have discovered it; in fact, do what you please. I shall not interfere with you in any way, and you may even dispense with mentioning my name if you so please."

After replying that he was deeply touched by the Englishman's kind manner, and "only too charmed to share with him the glory of having explored the city," Charnay proceeded to ignore his host. He named the city Lorillard "in honor of the munificent man who partly defrays the cost of the expedition," a name which hardly outlasted Charnay's stay in the Phantom City, and would have been unknown to the world except as an advertisement for tobacco had Charnay not devoted a chapter to it in *The Ancient Cities of the New World,* which he brought out on his return to France, a book more remarkable for its lithographs, mostly copies of the work of others, than for its pedestrian text. After one last



Employed by the British colonial service, Maudslay insisted he had come to Central America merely to escape the rigors of an English winter. Altogether Maudslay made seven expeditions to Central America, spending considerable periods at the ruins of Copan, Quirigua, Palenque, Yaxchilan, Tikal, and Chichen Itza. The results—in the form of casts, magnificent photographs of the ruins and particularly of the hieroglyphic texts, maps and plans, and the extremely good drawings of the glyphs, made by his companion Miss Annie Hunter—were published between 1889 and 1902, in a twenty-volume edition under the perhaps purposely vague title of *Biologia Centrali-Americana or contributions to the knowledge of the flora and fauna of Central America*.

Maudslay had struggled into Copan with a team of mules hauling tons of plaster of paris, determined to make molds of the stelae. When the molds eventually reached England they were ignominiously consigned to the basement of the South Kensington Museum.

At Lorillard City, Charnay found a stone lintel which he considered to be by far the most wonderful monument he had seen in America. Assuming it depicted a ceremony in honor of Quetzalcoatl, he interpreted the kneeling figure to be a priest passing a rope through his tongue. Charnay quoted Sahagun and Bishop Landa to the effect that priests did penance by running as many as four or five hundred sticks, twice as thick as a thumb, and fastened together in long cords, through their tongues, their ears, and their private parts. He also quoted Clavigero, who says the blood which flowed from these self-inflicted wounds was carefully kept on the leaves of a plant with symmetrical leaves called *acxoyatl.* The worshippers of Siva, the Hindu god of destruction, and those of his wife Kali, were wont to torture themselves by drawing a rope through their pierced tongues.

trip to Yucatan in 1886, Charnay retired to Algiers, where he wrote two romantic novels entitled *An Indian Princess* and *Across the Virgin Forest,* dealing with the beauty of the Indian and mestiza women of Mexico, whose "clear skin, beautiful flesh and thin embroidered shirts outlining their firm breasts" he could not get out of his system. One of them, "with ebony hair, a tunic of light gauze which barely disguised the beauty of her body, eyes full of timid promises," he admitted nearly having stayed to marry: "Only with great courage was I able to rouse myself in the night, saddle my mule, and make a rapid exit."

Before he died Charnay translated into French the letters of Cortes to Charles V and the *Histoire de l'Origine des Indiens* of J. F. Ramirez; but his main contribution was to have taken pick and shovel to the ruins of Mexico and shown that beneath the soil the remains of great cities were there for the digging.

13. Probing in Depth

On a reportorial and descriptive level, Charnay had walked in John Lloyd Stephens' footsteps. On a more philosophical and anthropological level, Brasseur de Bourbourg was followed by one of the most extraordinary and perhaps unjustly neglected of Mayaland adventurers, Augustus le Plongeon. The son of a French navy commodore who had married the daughter of the governor of Mont-Saint-Michel, Le Plongeon was neglected because his notions about the Maya and their possible connection with the lost continent of Atlantis became such anathema to academicians they were treated with the contempt reserved for the notions of his contemporary, Charles Piazzi Smyth, Astronomer Royal for Scotland, on the subject of the Great Pyramid of Cheops.

Both men, instead of propounding long-winded treatises on the available ignorance about their subjects, were bold enough to explore in the field notions outrageous to their blinkered Victorian compeers.

Alice Le Plongeon.

In New York in his middle forties, Le Plongeon married an English girl of twenty-two, then living in Brooklyn, Alice Dixon. Together they sailed for Central America in the spring of 1873 for what turned out to be twelve years in the wilds of Yucatan, most of it spent in the bush. In Merida, the capital, Le Plongeon learned to speak Maya before setting off for an intensive survey of the ruins of Chichen Itza, which had once more been engulfed by the jungle and was under attack from the Yucatan *sublevados*. When the army could no longer protect the Le Plongeons in the charred shell of the hacienda at Chichen Itza, they moved to a fortified church three miles away at Pisté. From there they walked each day to the site of the ancient ruins, where they surveyed scores of buildings,

Augustus Le Plongeon.

Born on the island of Jersey in 1826, the year that his idol Stephens discovered the work of Del Rio, young Le Plongeon's first adventure occurred at the age of 14 on his way to the Americas, when he became one of two survivors from a shipwreck. After a stint in South America learning Spanish, he found himself in California in time for the Gold Rush of '49. There he became county surveyor for the city of San Francisco, practiced law, and acquired the degree of doctor of medicine.

After some round-the-world traveling, he was back in Peru in the 1860s to set up a private hospital in which he applied electricity to medicinal baths for the poor and for victims of revolutions. In his spare time he studied the architectural ruins of the Incas and pre-Incas, producing a couple of religious books on Jesus and a manual on photography. His sensitivity to unorthodox but avant garde ideas was such that he concluded from the strata of oyster shells around the Bolivian ruins of Tiahuanaco that the great and mysterious city must once have been at sea level, foreshadowing by more than half a century the work of H. S. Bellamy.

took more than five hundred photographs, and made twenty careful sheets of mural drawings.

Because of his mastery of the Mayan language and his intrepid but gentle nature, Le Plongeon, who often ventured with his wife deep into the forest far from village or inhabited place, found the natives "always respectful, honest, polite unobtrusive, patient and brave." He attributed the ferocity of the *sublevados* to their reaction against a ghastly system of peonage enforced by the sisal planters of Yucatan, against which the natives had no redress but to revolt.

Gradually endearing himself to the Maya, who gave him the affectionate nickname of Great Black Beard, Le Plongeon got his new friends to confide in him much of the lore they normally kept rigorously secret from the hated Spaniards, lore for which many of their ancestors had been hanged or burned at the stake.

Like Carlos Castañeda in our day, Le Plongeon learned that the native Indians in his day still practiced magic and divination, that their wise men were able to surround themselves with clouds and even appear to make themselves invisible, materializing strange and amazing objects. Sometimes, says Le Plongeon, the place where they were operating would seem to shake as if an earthquake were occurring, or whirl around and around as if being carried away by a tornado. Sometimes they appeared to be bathed in bright and resplendent light, and flames seemed to issue from the walls only to be extinguished by invisible hands in the most profound obscurity where flashes of lightning made the dark appear darker.

Beneath the prosaic life of the Indians of his day in Yucatan, Le Plongeon concluded that there flowed "a rich living current of occult wisdom and practice, with its sources in an extremely ancient past, far beyond the purview of ordinary historical

Le Plongeon says that a third account of the sinking of Atlantis was written on the lintel of a door of the inner chamber at the southeastern end of the building at Uxmal called Akab-Oib, as intact in his day as when it was finished by the sculptor's chisel. The inscription, says Le Plongeon, "is a memorial commemorating the destruction of Mu, the Lands of the West, whence came the Sacred Mysteries." But his method of decipherment left much to the imagination.

Every day, all over the land, says Le Plongeon, working men in the haciendas were pitilessly and arbitrarily flogged by their overseers, then put in stocks overnight so as not to miss a day's work. Were they, says he, to lay their grievances before the owner of the hacienda, their only redress was to receive a double ration of lashes for daring to complain. If they lodged a complaint before a judge, "as by law they had the right," he, of course, "is the friend or relative of the planter. He himself may be a planter. On his own plantation he has servants who are treated in like manner."

Nor could Le Plongeon interfere on behalf of some poor man being whipped for some trifling cause, lest the victim receive a more severe punishment later.

research." He felt that occasionally the mask was lowered sufficiently for him to glimpse "a world of spiritual reality, sometimes of indescribable beauty, again of inexpressible horror."

From what he learned of the lore of the Maya it became clear to Le Plongeon that the pre-Columbian Maya had practiced mesmerism, induced clairvoyance, and used magic mirrors to predict the future. From a 150-year-old Indian, Le Plongeon learned that men still existed who could decipher meanings in the mysterious hieroglyphs scattered about the ruined cities of the Maya, which contained the history of the people who had inhabited the land.

From glyphs on the southeast wall of what Le Plongeon called the Gymnasium at Chichen Itza, he says he was able to interpret the word Chac-Mool and pinpoint a spot on which to dig for what he was lead to believe might be an effigy of this ancient character.

The undertaking seemed wildly implausible. The diggers descended painfully more than twenty-four feet, and they were about to give up when they struck a hard surface, revealing what Le Plongeon considered one of the greatest archeological discoveries of the Americas, an astonishing piece of sculpture, not in relief but in the round.

So impressed was he with his find that he wished to display it to the world at the centennial ceremonies in Philadelphia in 1876. Only how to get it there?

With nothing but his engineering ingenuity and some tree trunks and vines, Le Plongeon and his Mayan workers managed to raise the multi-ton monolith to the surface and drag it by oxcart through the jungle toward Merida. There the local authorities immediately claimed the trophy, only to be relieved of it by a warship from the central government, which decided it belonged to Mexico City, where it reclines to this day, still as

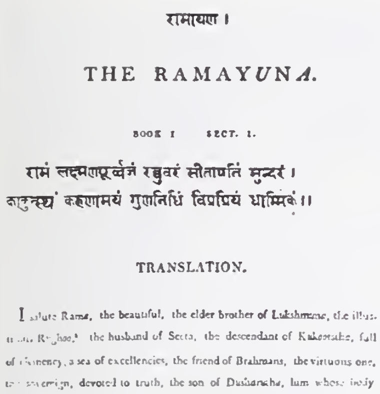
Augustus and Alice Le Plongeon with the Chac-Mool they unearthed from twenty-four feet beneath the soil at Chichen Itza, which they wished to exhibit at the 1876 Centennial.

Accused of promulgating notions on ancient America contrary to the opinion of men regarded as authorities on American archeology, Le Plongeon replied, "But who are these pretended authorities? Certainly not the doctors and professors at the head of the universities and colleges in the United States; for not only do they know absolutely nothing of ancient American Civilization, but, judging from letters in my possession, the majority of them refuse to learn anything concerning it. Can they interpret one single sentence of the books in which the learning of the Maya sages, their cosmogonic, geographical, religious and scientific attainments are recorded? From what source have they derived their pretended knowledge? Not from the writings of the Spanish chroniclers, surely. These only wrote of the natives as they found them at the time, and long after the conquest of America by their countrymen. The so-called learned men of our days are the first to oppose new ideas and the bearers of these."

enigmatic and unexplained as when it was dug up by Le Plongeon.

Disappointed, Le Plongeon sent a set of photographs and smaller artifacts to Philadelphia, but they too were waylaid and eventually fell into the hands of Stephen Salisbury, Jr., a wealthy bachelor and philanthropist from Worcester, Massachusetts, active in the American Antiquarian Society. As a result, though Le Plongeon failed to make his mark at Philadelphia, Salisbury agreed to publish reports from Le Plongeon in the society's journal. It was a pleasant association, for a while; but Le Plongeon's speculations were soon too much for his New England associates. Anyone who could speak of cycles of existence in more advanced planets and worlds than the present was likely to be in trouble with an establishment, many of whom still subscribed to a Biblical origin for the world sometime in the fifth millennium B.C.

Even Le Plongeon's notion that intimate communication had existed between the inhabitants of the Western Hemisphere and Asia, Africa, and Europe at a much earlier date than anyone else considered possible, though subscribed to by Sigüenza and by Brasseur, caused a lot of heads to shake.



रामायण।

THE RAMAYUNA.

BOOK I SECT. I.

रामं लक्ष्मणपूर्वजं रघुवरं सीतापतिं सुन्दरं।
काकुत्स्थं करुणामयं गुणनिधिं विप्रप्रियं धार्मिकं॥

TRANSLATION.

I salute Rama, the beautiful, the elder brother of Lukshmunu, the illustrious Rughoo, the husband of Seeta, the descendant of Kakootsha, full of clemency, a sea of excellencies, the friend of Brahmans, the virtuous one, the sovereign, devoted to truth, the son of Dusharutha, him whose body

One of several English translations of the *Ramayana*, printed with the original Sanskrit text.

The idea that the Phoenicians might have crisscrossed the Atlantic long before Columbus was shocking enough; Le Plongeon went further. He suggested as an explanation for the extraordinary similarities between the architecture, sculpture, and artifacts of Central America and those of Asia, Africa, and Europe, that Mayan colonists had sailed *westward* from Central America to develop civilizations in Polynesia, Indochina, Burma, India, the Persian Gulf, Babylonia, and Egypt, all of this several millennia before Christ.

In support of this revolutionary thesis he pointed to the Mayan legends of adepts known as Naacal, or "the exalted," who were reported to have set out across the world to teach others their language, architecture, and astronomy. Le Plongeon quoted the third-century B.C. Hindu sage-historian Valmiki's epic of *Ramayana* (in Hippolyte Fauché's translation) to describe the conquest of the southern parts of the Indochinese peninsula in remote antiquity by a people known as great navigators, terrible warriors, learned architects, famous for their beautiful women and inexhaustible treasures.

Valmiki is said to have received the information from Narana, high priest of the Rishi temple at Ayhodia, who read to him the ancient records, but Valmiki is also accused of having used poetic license in his own version.

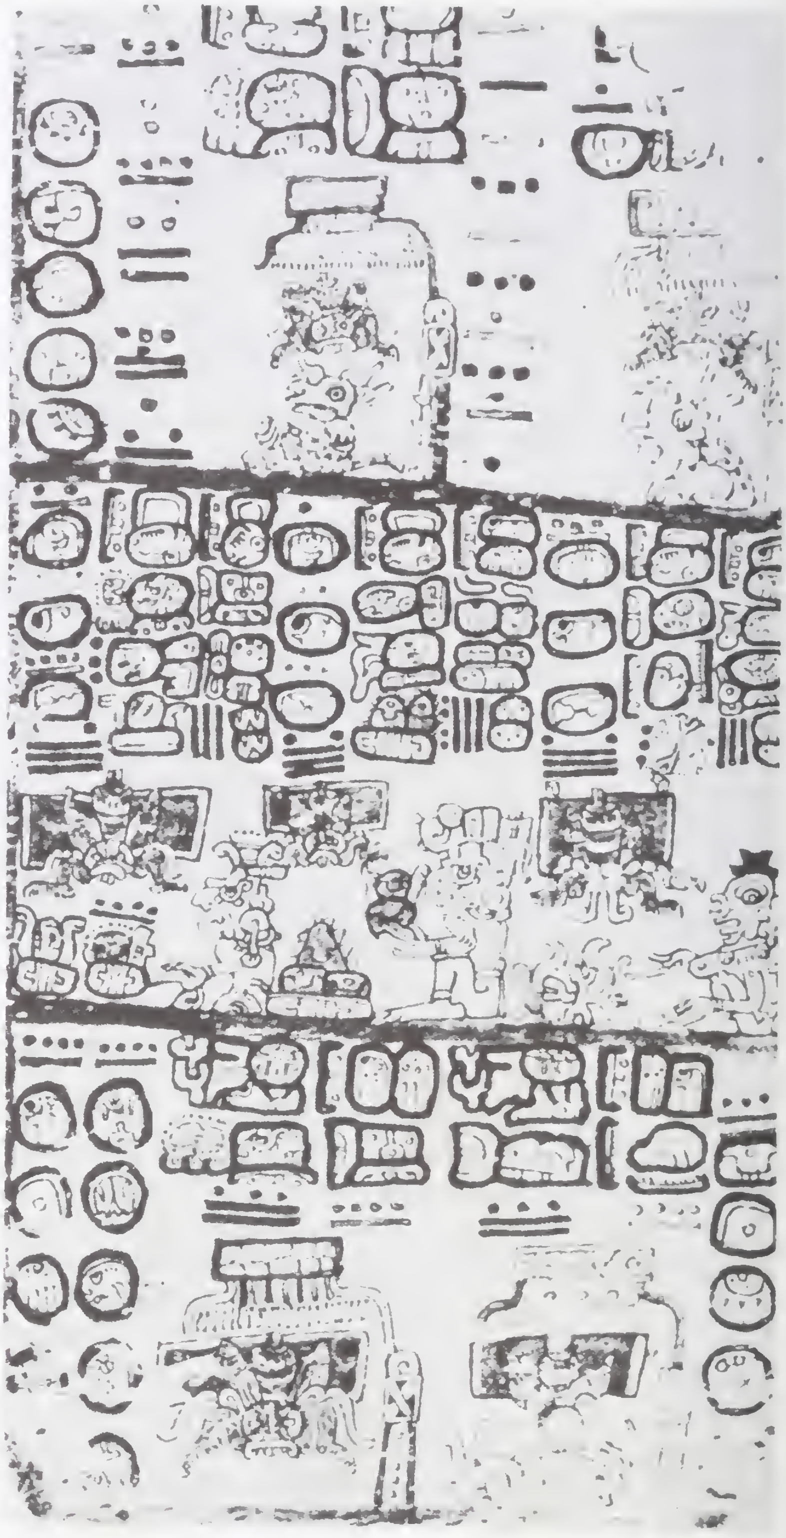
Le Plongeon suggested that Valmiki's Nagas were in fact the ancient Maya who traveled along the shore of the Indian Ocean, reached the Indus River, and then went north to Kabul. Others, he maintained, had continued westward across the Indian Ocean, to the Persian Gulf, whence they had reached Babylon, Syria, and finally Egypt. He quoted the Chaldean historian Berosus to the effect that civilization was brought to Mesopotamia by Oannes, who came from the Persian Gulf, pointing out that *oaana* in Maya means "he who has his residence in the water."

Le Plongeon added that the advent of the early Chaldeans in Mesopotamia was historically coincident with the origins of the art of writing, the building of cities, and the cultivation of the sciences, especially astronomy. He also pointed out that the Egyptians claimed their ancestors were strangers who arrived across the Isthmus of Suez to settle on the banks of the Nile, bringing their worship of the sun, along with the art of writing, several thousand years before the enthronement of Menes and the official inception of the history of Egypt. Among the many similar words in Akkadian and Mayan, such as *ma* for place, *naa* or *nana* for mother, and *tab* for tie, Le Plongeon pointed out that in both languages *kul* was the name for seat or rump and *kun* for the *mulieris pudenda*.

Not content with his blockbusting reconstruction of ancient history, Le Plongeon plunged into the even more controversial

One of the principal arguments against Le Plongeon was his apparently arbitrary interpretation of the Troano Codex. According to Le Plongeon, the author of the Troano manuscript devoted several pages at the beginning of the second part of his work to a minute description of the various phenomena attending the disastrous collapse of Atlantis, referred to in the text as the ten countries of Mu. Le Plongeon's version reads: "The year six Kan, and the eleventh Muluc, in the month of Zac there occurred terrible earthquakes which continued without intermission until the thirteenth Chuen. The country of hills and mud, the 'Land of Mu' was sacrificed. Being twice upheaved, it suddenly disappeared during the night, the basin being continually shaken by volcanic forces. Being confined, these caused the land to sink and rise several times and in various places. At last the surface gave way, and the ten countries were torn asunder and scattered in fragments: unable to withstand the force of the seismic convulsions, they sank with their sixty-four millions of inhabitants, eight thousand and sixty years before the writing of this book."

The fact that the cataclysm was said to have occurred on the thirteenth Chuen, says Le Plongeon, may account for the still lingering superstition about bad luck being attached to the number. According to Le Plongeon, it was as a result of this catastrophe that the Maya started computing their new calendar on a base thirteen with weeks of thirteen days, centuries of four times thirteen years, and a great cycle of thirteen times twenty or two hundred and sixty years. Was it chance, he asked, that the Platonic date of 9500 B.C. coincided so precisely with his date for the inception of the Maya calendar?



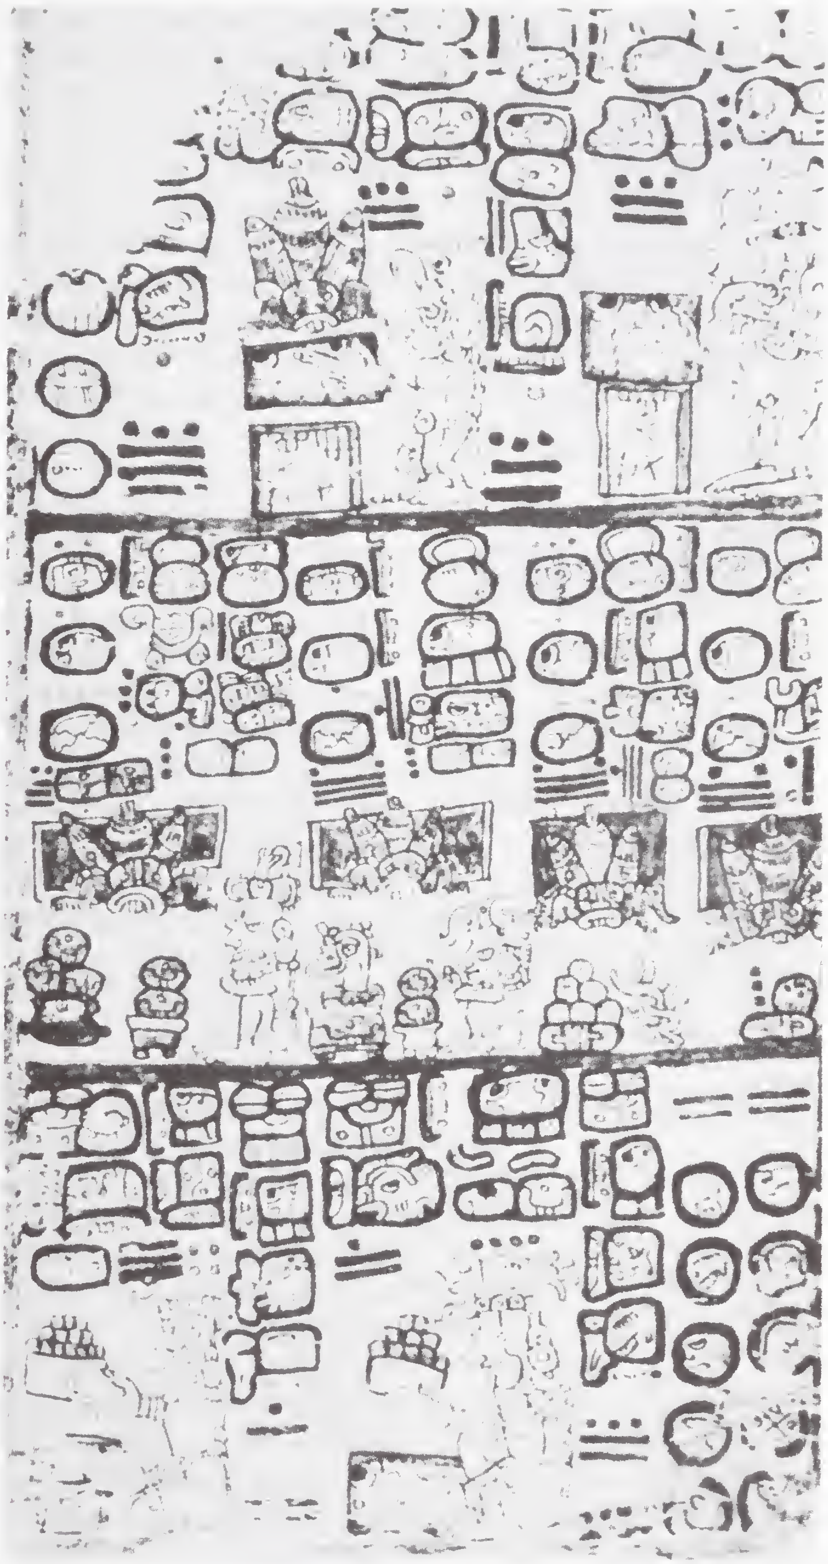
subject of Atlantis. At Chichen Itza he says he found a relief in a room sheltered from the elements which he deciphered as confirmation of Brasseur's "translation" of the Codex Tro-Cortesianus, saying it described in glyphs a cataclysm in which an island continent had sunk beneath the seas.

Later Le Plongeon claimed the discovery of a fragment of a

Le Plongeon quotes the Codex Cortesianus, which he calls more prolix than the Troano, to give further details on the collapse of Atlantis. "By his strong will, Homen caused the earth to tremble after sunset; and during the night, Mu, the country of hills and mud, was submerged." Homen, explains Le Plongeon, was the overturner of mountains, the god of earthquakes, the wizard who made all things move like a mass of worms, the volcanic forces anthropomorphized and then deified. "The Maya," says Le Plongeon, "deified all phenomena of nature and their causes, then represented them in the shape of human beings or animals. Their object was to keep for their initiates the secrets of their science."

Le Plongeon's translation—or, better, his interpretation—continues: "Mu, the life of the basin, was submerged by Homen during the night. The place of the dead ruler is now lifeless; it moves no more, after having twice jumped from its foundations. The king of the deep, while forcing his way out, has shaken it up and down, has killed it, has submerged it. Twice Mu jumped from its foundations. It was then shaken up and down violently by the earthquake."

According to Le Plongeon, one page of the Troano Codex depicts Queen Moo (held by the hair) falling into the hands of her enemies on the ninth day of the tenth month of the year Kan; the seventh Eb of month Yax, year Kan. He says the picture shows the queen traveling to the east across the sea. In the next panels Queen Moo is on her knees in supplication, and, symbolized as a black macaw bird, is losing hold of a Mayaland politically divided, as shown by the severed deer. Ingenious as Le Plongeon's interpretations may be, modern students dispute his identifications and suggest that the deer is more likely the symbol of a constellation.



mural painting on the walls of an apartment in one of the edifices at Kabah which to him again confirmed Brasseur's date from the Tro-Cortesianus manuscript describing the submersion of ten countries, among them the land of Mu, which to Le Plongeon might have been Plato's Atlantis. The codex, said Le Plongeon, also described the formation of a

According to Le Plongeon, this is a representation of Prince Coh in the heat of battle, overshadowed by the winged serpent, the genius of the Maya, who fights at his side and leads his followers to victory. Le Plongeon maintains that this is not a representation of Kukulkan, normally the image of the rulers of the country, but of the winged serpent Nonoca Can, the protective genius of the Maya, a confusion, says Le Plongeon, which authorities on the Maya were constantly falling into.

strangely crooked line of islands known to the Maya as the Land of the Scorpion, and to us as the West Indies.

Later still, at Xochicalco, Le Plongeon says he deciphered another inscription which appeared to memorialize the same catastrophe.

When Americanists disputed his and Brasseur's deciphering of these glyphs, Le Plongeon pointed out that until Brasseur had found the Codex Tro-Cortesianus, and then rediscovered Bishop Landa's work in Madrid, no Americanist even knew in what language the codices were written. He complained that none of the Americanists who claimed to be authorities on American paleography could even interpret with certainty more than a dozen Mayan glyphs and none could translate an entire sentence. In his opinion the greater part of what had been published in his day on the subject of Mayan writings could only be ranked with comic literature—not very amusing at that. "Even the beautifully printed papers of the Smithsonian Institution on the subject are as meaningless as they are pretentious; and I challenge any Americanist, authorized or not authorized, to disprove this assertion."

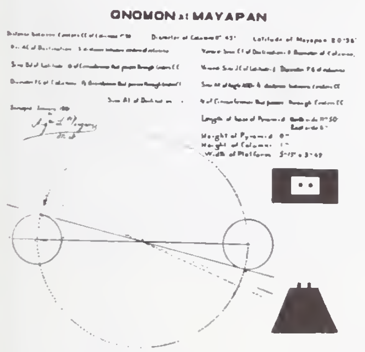
When a member of the Société Ethnologique de Paris warned Le Plongeon not to support Brasseur, "or you will kill your own reputation and lose the fruits of your labors: all authorized Americanists will condemn you as they have Brasseur," Le Plongeon replied in the words of Themistocles: "Strike me, but hear me!"

Anyone looking carefully at Le Plongeon's analysis of a set of tableaux which he found in what he called a mausoleum at Chichen Itza can readily appreciate his imaginative flights of fancy, but also cannot help but be impressed by the originality of his interpretation. From the writings of his opponents it is clear that, as was done to Emmanuel Velikovsky a century later, they usually did not even trouble to check what he had to say, considering his notions a priori too wild to be credited.

Le Plongeon's claim that he had deciphered the totem of Queen Moo as a bird eating hearts, and that of her brother-husband Prince Aac as a turtle, and that their story could be the source of the Egyptian myth of Isis and Osiris was too much for Americanists to swallow, especially when Le Plongeon suggested that Queen Moo had traveled from Mayaland to Egypt to be welcomed and made queen again by her former co-nationals.

When Le Plongeon declared that one-third of the ancient Egyptian words he had deciphered were the same as Maya words and that the grammatical forms of the two languages were similar, he finally got some support. Pierre Lorillard gave him a subsidy with which to decipher more ancient Mayan characters.

Le Plongeon says that the circle divided by a cross into four parts to which wings are added symbolized "the sacred four builders," the Dyan-Chohans of the Hindu occultists which are similarly portrayed in Egypt, Assyria, and in Guatemala. He says they are the Kabiri and Titans of Hesiod's theogony, the Amshaspands of the Mazdeans, the Elohim and Seraphs of the Hebrews, the Archangels of the Christians and Mohammedans, the four Canobs of the Maya, heavenly architects emanating from the "Great Infinite One" who evolved the material universe from chaos.



Most interesting to Le Plongeon, who was evidently a Mason, was his discovery of what he called evidence of Masonic rites in Mayan sculpture, from which he deduced that "the sacred mysteries" had been practiced in ancient Mayaland as early as 11,500 years before, and that modern Masonry was but a great-grandchild of these mysteries.

He also believed that he had learned at the fountainhead the meaning of several of the symbols indicating that the old initiation rites had been similar in all countries, designed to give a better understanding of the laws that govern the material and spiritual world, thus bringing man closer into contact with the deity.

Le Plongeon appears to have been the first to realize that buildings at Chichen Itza were used as astronomical observatories. From the design of a gnomon at Mayapan he concluded that the Maya had been able to calculate both latitude and longitude.

There was no doubt in his mind that the Maya had been accomplished mathematicians, astronomers, and navigators, familiar with plane and spherical trigonometry, which enabled them to compute the size of the world, estimate the distance from pole to pole, and calculate the length of a meridian. He believed they had embodied, as did the Egyptians, their cosmogonic and religious conceptions into their sacred buildings, particularly the pyramids.

When, from the measurements he made of various Mayan buildings, Le Plongeon found that only the meter appeared to give figures in round numbers, he deduced that the Maya may have divided the circle into 400 units instead of the 360 of the Egyptians, and had taken as their unit of measure a 40-millionth of the world's circumference.

In support of Le Plongeon, it is established that the Maya described the circle by three names: *ca-an* or "two-serpent" meaning the upper arch of heaven; *ca-bala* meaning "two occult," or hidden; and *can-bak* for a full circle meaning both "circular serpent" and the number 400.

Le Plongeon further noted that many of the pyramids of Yucatan were twenty-one meters in height and that their vertical planes appeared to be inscribed in half a circumference whose diameter formed the ground line of the sacred buildings; so he figured that esoterically these buildings represented the earth. In this he was also prophetically correct.

Outraged at the vandalism that was being perpetrated in Mayaland, often in the name of science, by individuals breaking up the carvings *in situ* and transporting them for sale to European and American museums, Le Plongeon worked for years to copy, photograph, and make moldings of as many glyphs and carvings as he could manage.

Returning to New York in 1885 after twelve years in Yucatan, blue-eyed and with a brick-dust complexion, but balding, and with a long snowy patriarchal beard, Le Plongeon settled in Brooklyn with his wife Alice.

The many moldings he had laboriously and expensively brought back from Mayaland he offered to the Metropolitan Museum, but the director, who had eyes only for classical European art, put them in the cellar "for want of space"; and there they remained.

Complaining that he and his wife had "lifted in part at least, the veil that has hung so long over the history of mankind in America in remote ages," Le Plongeon asked if it was to be allowed to fall again. "Will no efforts be made by men of wealth and leisure in the United States, to remove it altogether?"

The answer, for the moment, was no.

To arouse further interest in exploration in Mayaland, Le Plongeon hinted at the existence of old Maya books, the writings of the H'Menes, or wise men, of Yucatan, which he said had been buried long before the advent of the Spaniards lest they fall into the hands of the Nahuatl conquerors from Tula. He said he would see to their disinterment, but only on condition the U.S. government agreed to protect such treasures against arbitrary seizure by the Mexicans, something the Department of State was unwilling to consider.

The only real friend and supporter Le Plongeon acquired in New York was a young Englishman, James Churchward, whose ideas on the antiquity of civilization on this planet coincided remarkably with his own, except that Churchward's lost continent of Moo, or Mu, was in the Pacific, different from Plato's continent of Atlantis in the Atlantic. Like Le Plongeon, Churchward based his information on the decipherment of some very ancient tablets which he said had been written by the same Naacal priesthood mentioned by Le Plongeon but which Churchward said originated not in Yucatan, but in the

In Le Plongeon's analysis, this panel represents Queen Moo as a child seated on the back of a peccary, or wild American boar, under a royal umbrella of feathers which Le Plongeon says was the emblem of royalty in Chaldea, India, and Egypt, as well as in Mayaland. Queen Moo, says Le Plongeon, is consulting a H'Men, or wise man, who is revealing her fate by reading the tints of vapors rising from an armadillo shell that is being slowly cracked by the fire of a brazier.

Le Plongeon says that facing the Queen sits the soothsayer, whom he judges by the blue and yellow feathers of his ceremonial mantle to be a priest of high rank. The scroll issuing from the seer's mouth is seen as representing his prognosis, and the position of his hand is said to have a special significance for occultists. The winged serpent represents the protective genius of the Mayan Empire. Behind the priests, says Le Plongeon, are the Queen's ladies in waiting.

Here, says Le Plongeon, Queen Moo is no longer a child but a comely young woman seated under the royal umbrella accompanied by a suitor; she is consulting a priest, or H'Men, whose face is concealed by an owl's head. According to custom, says Le Plongeon, an old lady acting as spokeswoman tells the priest the young man sitting on the stool wishes to marry the queen. But the young queen refuses, as is indicated, according to Le Plongeon, by the reversed direction of the scroll issuing from her mouth.

Le Plongeon adds that it was the custom among the Maya, as among the Egyptians, Chaldeans, and Greeks, for girls of royal blood to marry their brothers, hence the impossibility of the present marriage.

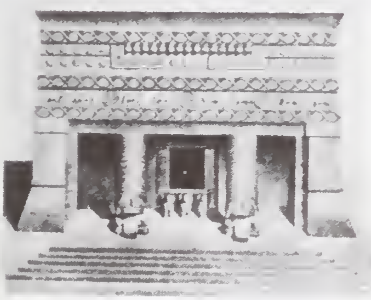
lost Pacific continent of Mu, mother country of colonists who had later developed Mayaland.

Churchward described having come across the Naacal tablets as a civil servant working for famine relief in India—though transparently an agent of British Intelligence. Churchward described entering a monastery in a valley near the headwaters of the Brahmaputra, where he was befriended by a high priest who eventually began to teach him to decipher inscriptions in a language the priest believed to have been the original language of mankind. Finally the old priest, then in his seventies, whom Churchward described as a "great master," last survivor of the Naacal priesthood, brought forth some sun-baked old tablets, written in the language of the Naacal priests, very dusty, which he said were records of the geology, history, and religion of Mu as well as of the cataclysmic disaster which had overcome that continent.

Le Plongeon's regard for his fellow Mason Churchward became such that he showed him much of his unpublished work on Yucatan and in the end bequeathed him his literary estate. As birds of a feather, Le Plongeon and Churchward became fair game for any academic with a shotgun.

In 1908, at the age of eighty-three, Le Plongeon died without anything having been done about the "hidden books" and without having been able to return to Yucatan. Twelve years later, in 1920, when his wife, Alice, realized her own death was imminent, she entrusted to a Mrs. Henry Blackwell the notes, photographs, and floor plans of the location of the Maya books in the ruins of Uxmal and Chichen Itza. But nothing was done with this tenuous lead, at least not for another twenty years; meanwhile the spiritual and intellectual achievements of the Mayas were once more ignored, and the archeological quest in Mayaland reverted to a materialist search for loot to adorn the world's museums.

Le Plongeon's chronology, which filled the gap between Plato's destruction of Atlantis in about 9500 B.C. and the historical record of Babylon and Egypt some five thousand years later, was too outrageous for his contemporaries, as was his



Le Plongeon's reconstruction of Chichen Itza building, from Stacy-Judd.

It was said of Le Plongeon that his "carefully detailed analyses and conclusions were founded upon conditions in the facade which never existed." It was a problem of restoration and reconstruction. According to Stacy-Judd, Le Plongeon mis-reconstructed the "Temple of the Tigers" at Chichen Itza and made several mistakes.

overtly expressed distaste for the endless bloodshed perpetrated on the planet by the Church in the name of Christ.

Disappointed in Le Plongeon, Stephen Salisbury, Jr., contrived with Charles P. Bowditch, the guiding light of the Peabody Museum of Anthropology in Cambridge, to send a more controllable young man to Yucatan to be their eyes and ears in Mayaland. To pay his way and insure him a free hand to explore, they hit upon the stratagem of having him appointed U.S. Consul to Yucatan and Campeche, using the influence of their fellow member, the senator from Massachusetts, George F. Hoar, to get the President to make the appointment.

Stephen Salisbury, one of the founders of the American Antiquarian Society.

Edward H. Thompson after he had been in Yucatan for almost a quarter of a century.

Ironically, the young man, Edward H. Thompson, a jovial blue-eyed six-footer, also from Worcester, Massachusetts, came to the attention of Salisbury because of an article he had written for *Popular Science Monthly* while still a student at Worcester Polytechnic Institute, pointedly entitled "Atlantis Not a Myth," in which Thompson suggested that the mysterious civilization of the Maya on the peninsula of Yucatan might have been a broken branch of the civilization that had once existed on the lost continent of Atlantis.

Fired by Brasseur's books, Thompson argued that although there was no proof of the Atlantis theory, a tradition so widespread and a legend so persistent must have some basis in history, which made it legitimate "to hold as probable the notion that at some time in the remote past a group of people representing a civilization of which we have lost all trace, made their influence felt upon the races indigenous to Mexico and Yucatan."

Thompson pointed to the traditions of widely separate peoples concerning a mysterious appearance on the shores of the Gulf of Mexico of the People of the Serpent, or Chanes. According to the legends, light-skinned beings, tall and blue-eyed, had landed at Tamoanchan, near Tuxpan in the Tampico district, wearing strange garments and emblems like entwined serpents on their foreheads. The sides of their vessels were said to have shone like the scales of serpents' skins. Thompson pointed out that the leaders of the "Ulmecas" were known as Chanes, or among the Mayas, as Canob, "Serpents' Wise Men," or Ah Tzai, "People of the Rattlesnake."

As the article appeared three years before Ignatius Donnelly brought out his best seller on Atlantis, Thompson's article attracted enough attention to get him the job as the youngest U.S. consul ever to be sent to Mexico.

With his bride and baby daughter, Thompson arrived in Yucatan in 1885, the year that Le Plongeon left for good.

Like Le Plongeon, Thompson threw himself into the job with enthusiasm, learned to speak fluent Mayan and took off

into the bush to hear from the natives firsthand their legends as they macheted their way along jungle trails, surveyed ruined cities, or squatted at night around campfires. Traveling light and living on the food of the Indians, Thompson soon visited over a hundred ancient cities and temple centers. In his own words he became "almost a Maya in the belief that a close study of the descendants of the ancient builders and cabinet makers might be of aid in reconstructing the ideas and methods of times long past."

Atlantean figure of a painted stone from Chichen Itza's upper Temple of the Jaguars.

But somehow Thompson either lacked the spark of Le Plongeon or did not make the proper contacts. He says he soon numbered among his friends members of the H'Menes, or wise men, of the modern Maya, and that he became an initiate of the Sh'Tol Brothers, one of the dominant secret societies of the Maya; but it was evident, even to him, that the society was no more "than a fading remembrance of some body among the ancients comparable to the Masons."

Unlike Le Plongeon, to whom the Maya had given one of the nicknames they reserved for those they admired, Ahmeexnal, "he of the long beard," Thompson was always respectfully referred to as Don Eduardo.

With neither the knowledge of Mayan glyphs nor the imaginative curiosity of Le Plongeon, Thompson had little basis from which to interpret the carved figures on the buildings he discovered. Yet the dry descriptions of the ruins he found and forwarded to Cambridge were evidently more satisfactory to his patrons than Le Plongeon's fanciful and potentially boat-rocking conceits.

Thompson was most adept at satisfying his patrons with the enormous efforts he expended on producing for them molds of the facades of buildings such as those at Labna, which measured more than a thousand square feet, the arrival

One of the intricate facades Thompson was requested to reproduce for exhibition in the United States.

of which in Boston only prompted them to ask for even bigger examples from Uxmal. This next job cost Thompson fourteen horrendous months in a fever-stricken area where one by one his forty workers turned into "yellow-skinned caricatures of their former selves." Delirious at the end, Thompson nevertheless managed to deliver to Chicago the enormous molds for their 1890 World's Fair. His reward was to be befriended by the meat magnate Allison V. Armour, who provided him with sufficient funds to achieve his life's ambition: to become the owner of the ruins of Chichen Itza. For the equivalent of about seventy-five dollars Thompson bought himself almost a hundred square miles of jungle and untold acres of prime Mayan ruins, the whole parcel accessible only by jungle footpath, along which on the night he took possession Thompson stumbled over the bones of the last inhabitant of the burned-down hacienda, murdered by the *sublevados.*

The ancient ruins were familiar to Thompson from having acted as Maudslay's assistant there two years earlier, surveying, measuring, and photographing, though no digging had

The Chichen Itza Cenote, alive with iguanas, is an oval-shaped opening in the rocky crust with a diameter of 180 feet, and craggy sides, which fall perpendicularly 60 feet to the rim of the water. Forty feet below the dark green surface is a layer of mud. One of the legends that spurred Thompson to submerge himself into this mud was contained in a report to Charles V from the mayor of the nearby Yucatan town of Valladolid written in 1579: "The Lords and principal personages of the land had the custom, after sixty days of abstinence and fasting, of arriving by daybreak at the mouth of the Cenote and throwing into it Indian women belonging to each of these lords and personages, at the same time telling these women to ask for their masters a year favorable to his particular needs and desires. The women being thrown in, unbound, fell into the water with great force and noise. At high noon, those that could, cried out loudly and ropes were let down to them. After the women came up, half dead, fires were built around them and copal was burned before them. When they recovered their senses, they said that below, there were many people of their nation, men and women, and that they had received them. When they tried to raise their heads to look at them, heavy blows were given them, and when their heads were inclined downward beneath the water, they seemed to see many deeps and hollows, and they, the people, responded to their queries concerning the good or the bad year that was in store for their masters."

been done other than what had been accomplished by Le Plongeon.

During the nearly three decades Thompson spent in Chichen Itza from 1885 to 1910 he somehow did not manage to produce as much data as had Le Plongeon in three months. He did, however, find a lintel with a date deciphered as A.D. 618, which was considered a coup. But most of his reports still lie unpublished in the vaults of the Worcester archeological library.

Thompson's main claim to fame was to end in his undoing: the dredging of the Sacred Cenote at Chichen Itza. Having read in Landa that the well was used for sacrificial offerings, both human and precious, Thompson was determined to produce from it artifacts to adorn the Peabody Museum in Cambridge. The prospect of descending sixty feet below the surface of the water into forty feet of pitch black mud meant getting some efficient diving gear and a certain expertise, both of which he obtained on Boston's Long Wharf from a Captain Ephraim Nickerson.

After years of dredging, and several almost fatal dives during which he ruptured his eardrums, Thompson eventually came up with enough gold, jade, and pretty artifacts to satisfy his Boston sponsors, to whom the artifacts were clandestinely smuggled and discreetly kept from public notice. Only when Thompson rashly publicized the results of his dives in the New York *Times* was the Mexican government aroused to sue him for the return of its chattels, placing a lien on Thompson's Chichen Itza property for a million pesos.

To collect back rent from his peasant tenants Thompson meanly threatened them with sterner measures and received in return a burned-down hacienda along with the destruction of his entire library and archeological collection. Obliged to return to Boston penniless, Thompson was kept alive by a subsidy from the Carnegie Foundation. Eventually, years after his death, the Peabody Museum obliged the Mexicans by returning them their artifacts, having kept them half a century.

Gradually, as archeology became a science, and the sale of *Kultur* became a means of feeding the academies, interest in the inherent meaning and value of the artifacts began to dwindle, giving place to an increasing appetite and market for looted artifacts around the world.

14. Batres' Archeological Pork Barrel

The first native Mexican to be impressed by Charnay's and Le Plongeon's approach to digging beneath the earth to discover the extent of Mexico's antiquities and treasures was one of General Diaz' ex-militiamen, Leopoldo Batres, who was able to approach such an offbeat and potentially expensive pastime because of his particular pull with the dictator, to whom he was illegitimately related. His natural father was Manuel Romero Rubio, who had become Diaz' top henchman by giving the fifty-year-old dictator his teenage daughter Carmen in marriage.

As a natural son of the leader of the all-powerful *cientificos,* Batres' venture into archeology was not such a wild idea; furthermore, he was astute enough to combine his interest in Mexico's hidden treasures with a wholesale and retail dealership in antiquities.

Struck by Ramon Almaraz' report on Teotihuacan that the smaller mounds paralleling the Way of the Dead contained treasure and gold dust which discreetly handled might prove of more than archeological interest, Batres got Diaz—whom he considered a brother-in-law—to appoint him "Inspector and Protector of the Archeological Monuments of Mexico," a sinecure which enabled Batres to poke about for treasure and have digs made wherever the fancy struck him—all at government expense.

To legitimize his efforts, Batres told the world he believed Teotihuacan to be "one of the most interesting cities in the world of archeology."

The Way of the Dead as seen by Batres from the top of the Moon Pyramid in 1884. Digging into a mound on the western side of the Way of the Dead, only a year after Charnay had been in the same area, Batres unearthed a perfectly preserved "temple" with a stairway facing west. Because its walls were decorated with mythological scenes, Batres argued that the building was neither a tomb nor a private dwelling, as had been assumed by his predecessors, but a religious center. Uncovering one mound after the other along the Way of the Dead, Batres showed them to be all "temples" built on platforms of adobe, or sun-baked brick, in groups of five or six around plazas with smaller temples in the center, none of which contained tombs or bodies. He therefore suggested that the entire forty-meter-wide esplanade between the terraces might have once been used for some sort of religious ceremony, and that the Way of the Dead should be renamed "La Via Sacra," or "Holy Way."

Whatever treasures or artifacts Batres may have found in these digs at Teotihuacan, little was heard of them publicly; yet his appetite for digging did not flag and he began to put out monographs to validate his endeavors.

In the rubbish near the Pyramid of the Moon, Batres found the monolithic statue of a woman of "colossal dimensions" known as the "sacrificial stone"; but he argued that the name had been inappropriately applied by the Spaniards, who were overly preoccupied with Aztec sacrifices. The earlier Toltecs, whose work Batres believed Teotihuacan to be, were reputed to have made sacrifices only of flowers, fruits, seeds, butterflies, and occasionally birds.

From the vestiges of pottery and artifacts he unearthed, and from the fact that nowhere did he find objects of war or fortifications, Batres concluded, like Charnay, that the city of Teotihuacan had been built by Toltecs, whom he believed to have been an eminently artistic and religious people, not the least warlike—deductions that turned out to be both facile and wrong.

Near the southeast corner of the Pyramid of the Moon, in the level plaza which fronts it, Batres came across a large mound of earth covered with underbrush. Digging into it, he uncovered a building with striking mural paintings depicting historical and religious personages, animals, butterflies, owls, beetles, human jaw bones, geometric forms, and concentric red and green circles with black outlines. The paintings were in various tones of red, or with green, yellow, blue, black, white, and gray pigment. As understood by Batres, the re-

Teotihuacan wall painting from the Temple of Agriculture.

ligion of the Toltecs was a "zoological mythology" in which the butterfly represented the soul's immortality, an idealized beetle called Pinahuiztli represented their astronomical system, and the owl, or Tecototl, was the demon of evil.

As well as temples, Batres found many more buildings such as had been unearthed by Charnay, evidently designed as dwellings, with large pillared halls connected by passages to smaller rooms, the main entrance being through a lobby supported by square pillars, the bases of which were painted red. On each side of the inner doorways, forty centimeters from the floor, Batres found holes which he assumed to have been used for leather thongs to tie back curtains.

These dwellings, all one-storied, had walls made of lava fragments held together with clay and mortar, faced with coatings of stucco, highly polished and painted red and white. Roofs were made of the same material, supported by wooden rafters ten or fifteen centimeters thick, so durable that they still resisted the blows of a crowbar.

Large jaguar heads carved in stone, with open jaws and large fangs, painted red, yellow, and blue, appeared to him to be symbolic of some power he could not identify.

A curious sculptured relief of lassos, coiled hawsers, and lambent flames, painted red, green, and blue, was interpreted by Batres as symbolizing the knot of years and the feast of the renewal of the sacred flame every fifty-two years.

Thousands of shards which came to the surface exemplified a great variety of pottery with or without feet—square, cylindrical, smooth, engraved, pierced, in monochrome or polychrome, on a fine white stucco base. But the great stylistic variety of these shards, found at different levels, and the fact that many of the buildings in and under which they were found appeared to have been built on the foundations of the previous ones, often many times, convinced Batres, as it had Almaraz, that reconstruction of the city's history would not be an easy job.

The dwellings appeared windowless, but each had a central patio thirty centimeters below the level of the main floor which could gather rainwater from the inward-sloping roofs, where it could either be held in a cistern or taken away through a central drain.

Everywhere Batres excavated he found a network of aqueducts covered by a layer of perfectly polished mortar through which water could flow, and still did flow from the many springs that gushed up from under Cerro Gordo.

He also found what he called an "underground" part of the city with rooms on different levels, the purpose of which he could not fathom, which he reinforced with steel beams in the hope that later archeologists might decipher their purpose.

Looking at the plain which stretched around the large pyramids, Batres found a great many more mounds, ten to fifteen feet high, whose arrangement led him to deduce that the ancient city must have once covered an area of some twelve square kilometers, four running north-south, three running east-west. On the south side of the city he considered the perimeter to be limited by the ruined edifices on the two low terraces known as the "Citadel."

The Way of the Dead and the north and east sides of the Sun Pyramid before Batres began his excavations.

Batres concluded that within the great city there had not been a single square meter not artificially paved with layers of small stones held together by mortar to a depth of ten to a hundred centimeters.

The most striking discovery made by Batres convinced him that some holocaust must have hit the city. Wherever he dug he found evidence of a great fire which had destroyed buildings "like a terrible Troy." He found that the upper parts of walls where they joined the flat roofs were charred, and that many rafters had fallen to the floor, where they lay carbonized.

Inside the dwellings he found the skeletons of men, women, and children in different positions, some still wearing necklaces of small stones which had withstood the heat.

It was hard for Batres to believe that anything but an earthquake followed by a fire could have so thoroughly destroyed a city; yet he kept encountering an extraordinary anomaly. In the excavations which he made he occasionally found roofs of houses perfectly preserved, the interiors filled with stones neatly fitted into place, joined one with another by claylike cement, forming a compact mass which he had to remove, piece by piece, with great care so as to avoid injuring the mural decorations. The anomaly set him to wondering: could the inhabitants of the great city have purposely destroyed it themselves? "Could those who had built it, fleeing before the invasion of barbarous tribes from the north, and with the hope of returning someday, jealous of the respect and veneration due their gods, have covered their sanctuaries with rubbish to protect them from the profanation of the sacrilegious?"

The conceit was stunning; it meant that the work of burying the city, along with all its temples, would have been as great as that of constructing it, a truly gigantic task, and one that required some pretty sophisticated explanation.

Batres would have liked to continue to dig at Teotihuacan to establish the truth of what had occurred, even hoping to unearth the whole city and its potential treasures, but his department ran out of funds. By 1890 it was clear to Batres it would take a million or more pesos to continue the job.

Skull of a grown man found by Batres in the House of the Priests, and skull of a sacrificial child found by Batres at the corner of the Sun Pyramid.

His benefactor, Diaz, at the end of his third term as president, was not yet sure of re-election. The country was in a financial crisis, the treasury empty, and bankruptcy threatened. Among the peons there was starvation, with epidemics of typhoid and smallpox, as well as insurrection among the Yaquis.

So Batres abandoned Teotihuacan and went off to look for greener sites in Mexico, potentially more profitable—also less of a burden on the national exchequer.

To justify his efforts and improve an unsavory image with the public, Batres produced—at government expense—a series of slick-looking illustrated booklets in which he said little of interest or value in very large print, mostly taking issue with opponents who attacked him in the press and accused him of purloining mountains of illicit gold from his digs.

Batres then had a row with Mexico City's Department of Sewers. They were digging new drains so stinking that no one else would go near them, but Batres insisted on spending long days underground with no one but his son Salvador, ostensibly, in Batres' words, to protect "treasure of inestimable value which would otherwise fall into the possession of negotiators who consider nothing but than their own pecuniary interest, destroying, like the horse of Attila, all that obstructs their way."

Each year Batres turned to a new site to exploit.

In 1902 he explored the ruins of Monte Alban, in 1903 the Valley of Mexico and "La Quemada," in 1904 Texcoco and El Garciclan, where he disinterred an enormous monolith. Of Monte Alban he wrote an inane book that attacked all other points of view but substituted nothing. His major complaint was against having had to supply sufficient water for all the diggers, which cost him two dollars for each barrel carried to the site by donkey.

La Quemada.

For the fifteen years between 1890 and 1905, virtually nothing was done at Teotihuacan except for the destructive efforts of an engineer called Antonio Garcia Cubas, who dug into the southern face of the Pyramid of the Moon on the theory that he would find an entrance to passages and chambers in approximately the same spots they had been found in the Great Pyramid of Cheops. He found no entrance, but seriously marred the structure.

Then, in 1904, better times appeared. Porfirio Diaz got himself re-elected president, this time for an extended term of six years. As he drove about the capital in his new Mercedes motorcar over well-paved, well-lighted and well-drained streets, the peons doffed their hats. As T. R. Fehrenbach put it in his spirited history of Mexico, *Blood and Fire,* "The first decade of the twentieth century appeared to be another of those calm, golden late-afternoons in which history seemed to pause."

But outward appearances were deceiving. "In the burning fields of Morelos and Yucatan, for men on their knees with bleeding fingers, and in the dismal mines and shops and airless factories, it was the worst of eras. Almost in hearing of the capital *pelados* still screamed and begged under the overseer's lash."

No sooner was Diaz inaugurated than Batres approached him with the idea that if Teotihuacan were made into a great national monument it might add to Mexico's national image, and that if the Pyramid of the Sun could be unearthed and restored to its former shape in time to commemorate the centennial of Mexico's liberation from Spanish rule, due in September of 1910, coincident with Diaz' eightieth birthday, it might cause enough of a splash to perpetuate the dictator in office.

The idea—which would assure Batres six uninterrupted years of well-funded digging—appealed to Diaz' vanity. Funds were provided, and on March 20, 1905, under the

North and east slopes of the Sun Pyramid before Batres began his excavations.

Batres discovers an arris line on the northeast corner of the Sun Pyramid.

auspices of the Secretariat of Instruction and Fine Arts, as part of the program to celebrate the centennial of liberation from Spain, Batres began a large-scale dig at Teotihuacan, with enough money, men, and authority to make a noticeable dent. To facilitate his work he took up residence on the spot in a small two-story fort with narrow slotlike windows. His commission was simply to uncover buildings and restore and consolidate their exposed surfaces; but political considerations indicated he concentrate on the Pyramid of the Sun in order to accomplish his ploy for Diaz and justify the money he was spending by uncovering and restoring a really grandiose monument.

To see if an architectural structure actually existed beneath the rough mound of earth, and thus to try to determine the purpose for which it might have originally been built, Batres realized that he would either have to peel off the entire mantle of dirt and rubble from the Pyramid of the Sun, or leave it as it was, a mute and dormant monster. No halfway measure was possible.

Batres assumed that under the dirt and rubble the Sun Pyramid would consist of a five-terraced structure diminishing in size as it rose to a height of sixty-three meters, half as high as the Pyramid of Cheops in Egypt, but on the same-sized base, with a staircase two meters wide zigzagging up one side to a sanctuary on top. Batres suspected that the outer faces might reveal surfaces plastered with mortar and lime, suitable for frescoes. He also suspected, with some justification, that such a pyramid would have been built little by little, beginning with a small central core, growing with successive layers of rock and earthwork to its final dimensions.

Batres' next problem was to figure out at what point to start peeling away the mantle of earth and debris in order to reach a recognizable surface of the shrouded architectural structure which could only vaguely be discerned as a quadrangular stepped pyramid with four apparent levels. After careful scrutiny of the whole mound he found a likely spot near the base on the northeast corner.

Probing to a depth of four meters, Batres exposed a wall made of stone and mortar; the wall had a perfectly defined edge which he believed to be the profile of the northeast arris. Using this wall as a starting point—though he admitted it would have seemed more sensible to start from the top—Batres launched upon his monumental job.

Wheelbarrows and dump wagons were brought to the scene, and eventually even a steam locomotive, whose tracks were laid right to the base of the pyramid. Batres' workers began to remove dirt at the rate of eighty to a hundred tons an hour. Even so, progress was slow. The entire operation

Batres' mule train.

required the removal of several hundred thousand tons before the dormant giant could begin to be liberated.

Critics promptly raised complaints at the unheard-of waste of government funds to remove one mountain of earth simply to reveal another, especially when hungry Mexican mouths needed feeding, which they did. Wags in Mexico City joked that "Señor Batres, excavating in the pyramid, has already gotten out of it two automobiles!" Batres, secure in the head man's approval, continued unperturbed. By modern standards, his operations were remarkably economical. His stonemasons received the equivalent of twenty-five U.S. cents a day; a donkey cost him two cents a day. For his own services, because they were so special, Batres received an expense of seventy-five cents per diem. He did employ what seemed to be an excessive number of guards to police the area day and night, but this was ostensibly to secure all kinds of recovered objects—pottery, ceramics, and sculpture—from the greedy hands of outside scavengers and souvenir hunters.

As the outermost layer of dirt began to be removed from the pyramid, Batres was happy to show that it was not just a pile of rocks and earth, but "a temple, perfectly constructed and planned." He even found surfaces plastered over with mortar and lime, hard and smooth, decorated with polychrome frescoes. To Batres it looked as if the pyramid might have originally been covered with cut stone, fashioned in the *talud tablero* style, that is, with sunken panels and entablatures enclosed in projecting slab cornices, built on sloping sides, anchored by projecting stones. Yet it was clear to Batres—if not to everyone else—that most of the original surface of the pyramid had been broken up, either purposely by some human hand, or by time and vegetation.

(Facing page)
Batres' 25-cent-a-day laborers working to uncover the southeast corner of the Sun Pyramid. With wheelbarrows they could remove a thousand tons a day, which was then carted away on specially built train tracks.

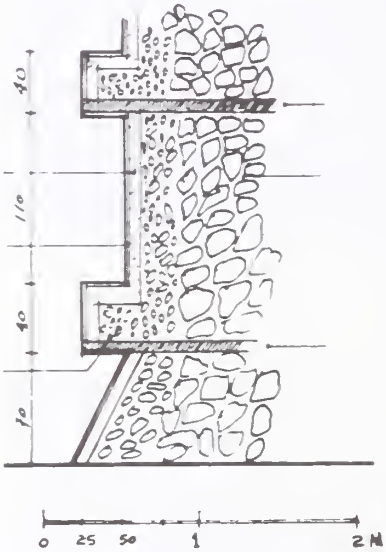
Southwest corner of the Sun Pyramid as the first two levels were exposed by Batres.

Again Batres even suspected that the whole structure might have been purposely hacked about and covered with earth to hide it from human eyes.

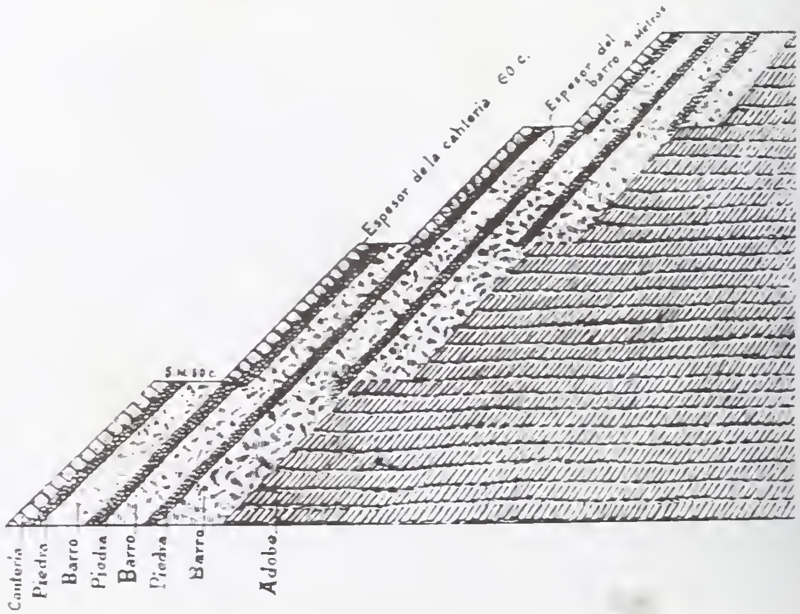
Then came trouble. The surface he was uncovering, clearly not the *original* outer surface, was made of adobe brick held together by mud. In heavy rain the mud began to dissolve, exhibiting plastic flow which threatened to destroy the whole edifice. Had it not been for the viscosity of the dissolving clay, which rendered disintegration slow enough to be arrested by hurried remedial measures, the whole surface of the pyramid might have been dissolved.

"As rainwater coursed downward from the heights of the pyramid in a veritable waterfall," wrote Batres, "it would have carried away completely the covering if I had not restrained the damage by establishing drains of wood to collect the water precipitated from the higher bodies which had not yet been uncovered, and, channeling this water with canals of wood, guided it away from the construction."

To prevent further damage, and to save the outlines of the structure as he uncovered it, Batres hit upon a method of



It was evident to Batres that the builders of Teotihuacan had everywhere employed the *talud-tablero* architectural motif of rectangular panels inset into sloping batters. Adobe bricks, measuring 40 by 30 by 10 centimeters, were laid horizontally for vertical stress and vertically for lateral stress. Over the adobe was laid a thick covering of crushed rock mixed with mud; on top of this was a layer of volcanic rock, four to six meters thick, followed by mixed concrete and mud, then the *tablero* or carved stonework, such as the colossal jaguars or hieroglyphs.

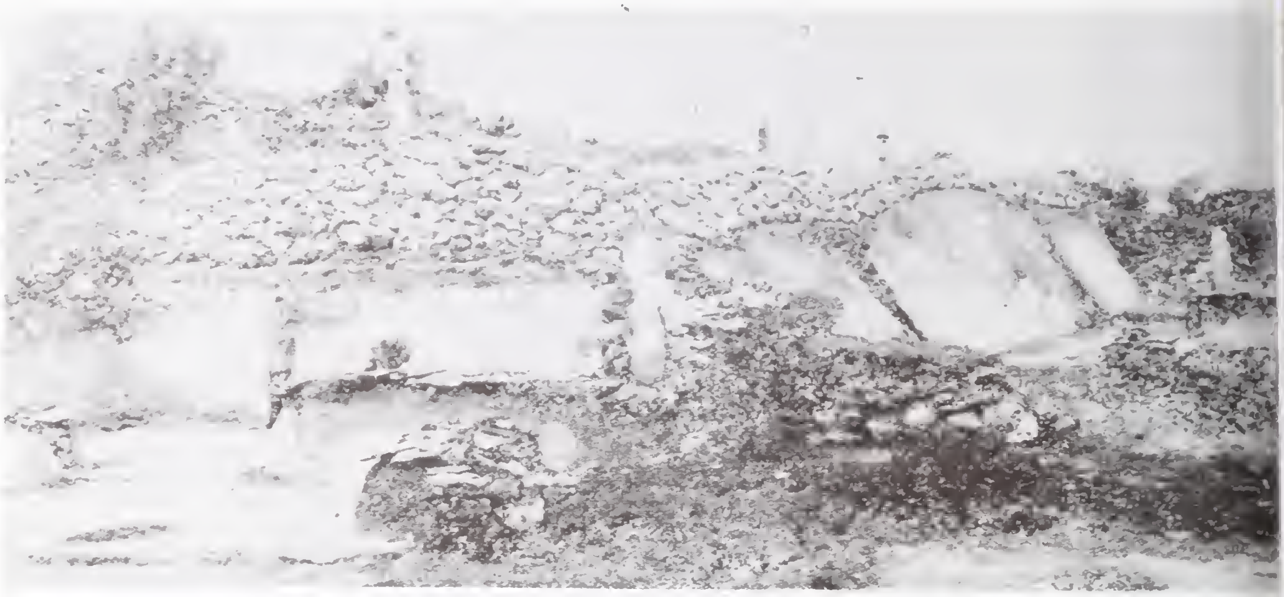


immediately introducing a mixture of lime and cement between the claybound bricks, reinforcing the mortar with fragments of volcanic stone. To this end he organized a group of skillful masons who dug with small spoons into the spaces separating the bricks to a depth of ten centimeters, removed the old mud, and, without moving the bricks from their position, rejoined them with the mixture of mortar and lava fragments.

During the excavation of the southeast corner, Batres found stone walls extending out from the surface like fins; these he assumed had been intended to hold the original surface in place; also there were some buttresses of stone and adobe, evidently intended to provide stability for the structure. This stonework was laid in diagonal rows, each series forming a braid of different widths.

As Batres continued to work upward on the pyramid, but at a slower pace because of the consolidating process, he decided to set other groups of men to digging around the base of the pyramid. At the foot of the west face they uncovered an immense mound fastened to the first level, whose outlines had been visible in the plan published by Maximilian's commission.

After removing a great deal of earth and rubble from a mound attached to the west side of the Sun Pyramid, Batres found atop the first level three temples, an enclosed room, and three stairways leading up to the next level. The central temple was like a three-stepped ziggurat, rising in shorter steps with angled faces. On the south side of the central temple, on its upper plane, Batres found a white and perfectly polished pavement, as well as a shallow cavity, oval in shape, which he believed had been a receptacle for some religious service. In the central temple, Batres found a carved stone with symbols in relief that seemed to be examples of a writing "more advanced than Mexican."



Northeast corner of the "House of the Priests" near the Sun Pyramid at Teotihuacan.

Meanwhile another gang began to explore the far western end of the platform surrounding the pyramid. Under a field of corn they discovered a large group of dwellings which, because it was only twenty meters from the corner of the Sun Pyramid, Batres named "House of the Priests."

Batres was amazed at the beauty of the walls which were uncovered, with massive carvings and polychrome frescoes, realizing they must have been striking when the colors were fresh.

Under a meter-thick layer of debris Batres found that the platform around the pyramid was 39.2 meters wide and 6 meters high, with sides in *talud tablero*. He believed this platform was designed to give stability to the pyramid and to prevent slippage at the base.

Batres' work had been in progress for a little over a year when money began to run out. To prime the pump, he decided to invite President Diaz to view the scene and see for himself that more funds were needed for what might be an imposing result.

At seven A.M. of April 6, 1906, General Porfirio Diaz took the train from Mexico City for the hour's ride to the San Juan station. There he and his company of ministers got into horse-drawn carriages and set off to see the sights under a riveting spring sun, raising great clouds of dust.

They were shown various frescoes and carved *tableros,* recently uncovered temples, and the platform around the base of the pyramid; then the party was invited to make a hot, sweaty climb to the top of the Pyramid of the Sun to admire the view. The retinue of ministers, impressed by Batres' work, were even more impressed by the "virile resistance" of their seventy-six-year-old "first magistrate," who climbed without

President Porfirio Diaz and members of his cabinet visit the pyramids at San Juan Teotihuacan in April of 1906.

visible effort to the top, perhaps because of the Zapotec blood from the Monte Alban hills which ran in his veins.

In the heat of the day the party descended from the pyramid and took refuge in one of the sixty-foot caves visited by Charnay, where they were served a typical Mexican meal. The guests were reported to be in very good spirits, exchanging historical anecdotes. At three-thirty the president took the train back to Mexico, "very gay and satisfied."

The next day newspapers gave details of the president's visit, noting that the caves in which he had lunched had been renamed the "Cuevas de Diaz." Controlled by the *cientificos,*

The older residents of San Martin recall how their grandfathers spoke of the times when the bandits who robbed the silver cargoes from coaches traveling south from Pachuca to Mexico City would disappear underground at Teotihuacan and emerge long after at Amecameca, sixty-five kilometers southeast.

Geologists report that the volcanic activity which took place in the Valley of Teotihuacan millions of years ago left tubular holes and bubble-shaped caves throughout the area. To the north of Cerro Gordo, lava flowed 6 million years ago. One of the giant underground bubbles left by the volcanic flow still lies to the east behind the Sun Pyramid, and is now called "La Gruta." Behind the Moon Pyramid a cave entrance leads to a tubular tunnel that was explored in 1964 and found to almost circle the pyramid.

the papers pointed out that in one year of work the two lower levels of the pyramid had been uncovered and consolidated, suggesting editorially that it would be very worthwhile if in a few years this extraordinary monument could be cleaned up and reconstructed in its original form.

To accelerate the work, and get it finished in time for the centennial of Mexico's independence, Batres said he would need to hire 400 more men and receive another 100,000 pesos. When the money was not forthcoming, Batres resigned in a huff and went off to explore the Mayan ruins in Yucatan.

15. Americans Good and Bad

At Chichen Itza, Batres found Edward H. Thompson busy diving for artifacts in the Cenote. Batres, though official Protector of Mexican Antiquities, made no objection to what Thompson was doing, indicating a certain honor among thieves.

By October, Batres had won his point in the capital: work could once more be resumed at Teotihuacan on the Sun Pyramid. In a few months the outlines of the structure began to be clearly discernible. While removing the debris, Batres found more strange artifacts and curios. From the south face he removed a whistle in the shape of a bird. Whistling into it and moving his fingers over four small holes cut into the back of the bird, he was able to produce seven notes of a scale different from that of our "well-tempered clavichord."

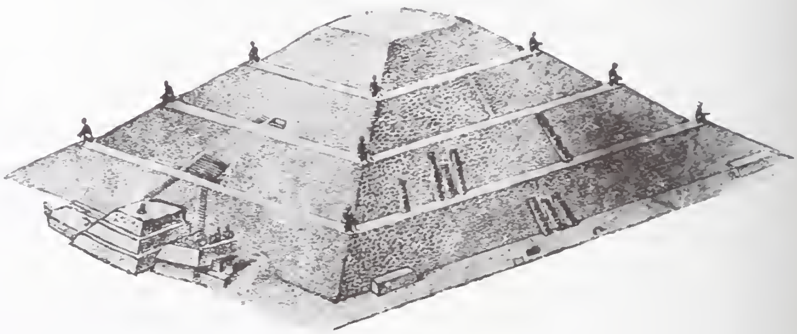
A more macabre discovery was made in the form of the skeletons of several six-year-old children, crouching, and purportedly buried alive, one at each corner of each level of the pyramid. Like the skeletons found by Charnay, they fell

The second level of the pyramid as uncovered by Batres was 16 meters high, sloping at an angle of 47 degrees, with a broad staircase 7 meters wide which provided access to a 3-meter-wide walkway on the next level which widened to 9 meters on the western facade.

A third body nearly 14 meters higher had a split staircase 5 meters wide either side of the center line. It also had more vertical fins held together by mud. A fourth body rose 6 meters higher, with a staircase on the center level, but at a steeper incline.

into dust as soon as they were uncovered, with the exception of one which Batres was able to preserve by immediately varnishing it.

On top of the pyramid, Batres found a horizontal platform with "the remains of a central temple," something no one else had noted since the eighteenth century. Three meters under the rubble he found a large number of clay figures carved out of jade, jasper, alabaster, and even out of human bone, as well as many shells of different sizes, also worked, and snakes of serpentine and obsidian. From these digs Batres deduced that what had been called the Pyramid of the Sun must, at an earlier time, have been dedicated to Quetzalcoatl, the plumed serpent, god of the air.



Batres' reconstruction of the Sun Pyramid with western *adosado,* and the skeletons of children on the various corners where he found them.

An unpublished find on the fifth level has never been adequately explained. While the Sun Pyramid was first being probed by Batres in 1906, an archeologist working with him reported a thick sheet of mica covering the top of the fifth body. This material was apparently carried away during the course of the restoration.

Coincidentally, a "Temple of Mica" was also found to the south of the Sun Pyramid about 350 meters down the Way of the Dead, where the local guard will still let one peek through a glass panel at the floor covered with mica slabs. Mica has two outstanding characteristics: high electrical resistance and opaqueness to fast neutrons. Hence it acts as an insulator or nuclear reaction moderator, which raises the question as to why two separate areas of Teotihuacan were covered with mica. By Batres the question was not even raised; the commercial value of mica was apparently sufficient to his purpose.

To complete the unveiling of the pyramid in time for the approaching celebration of the centenary of the war of independence, due on September 16, Batres pushed his workers to the utmost. His patron, General Diaz, about to celebrate his eightieth birthday on September 15, now allowed himself to believe he had become indispensable and should run for another six-year term. On his successful election depended further funds for Teotihuacan. By September of 1910 Batres had spent 566,798.06 pesos, or $45,000, to uncover the pyramid; more funds were essential to make the result grandiose enough to justify the expense.

In Batres' nearly completed reconstruction of the pyramid, none of its original covering remained, only the anchor stones of the central mass. Batres figured that altogether he had removed a mantle of 7 meters north-to-south and 4 meters east-to-west, leaving a pyramid that measured 225 meters north-south at the base and 219 meters east-west, with a height of 62 meters, 4 meters more than was found by Maximilian's commission in 1864. To finish the job, Batres had to await the re-election of his patron.

Francisco Madero.

Educated at the University of California, Francisco Madero was 32 years old when he tried unsuccessfully to oppose Diaz in the election of 1905. In 1908 Madero published a book—*La Succession Presidencial en 1910*—that was immediately suppressed by Diaz because of its reasoned statement of the problems of Mexico and its criticism of the Diaz regime for its unconstitutional method of ruling. After leading an armed rebellion against Diaz, Madero showed such notable generosity for the vanquished that he won the esteem of the people. After a six-month rule as provisional president he was elected by a large majority.

But Diaz, because of his own foolhardy gesture of saying he would allow the formation of an opposition to his regime, no longer faced a totally unopposed re-election. Opposition had concentrated around a rich landowner from the north, Francisco I. Madero, who although he had been trained at the University of California, was not taken very seriously by Diaz. Barely five feet tall, with a birdlike high-pitched voice, Madero seemed hardly *macho* enough for Diaz, who laughed at his penchant for vegetarianism and spiritualism.

However, when large crowds began to gather around Madero, Diaz quickly had him arrested, with 60,000 of his supporters, on a charge of inciting to riot. Madero, disguised as a mechanic, managed to escape across the border to San Antonio, Texas; elections were held without him.

On September 16 celebrations for the centennial of liberation from Spain and for Diaz' birthday commenced as scheduled, with grandiose festivities which cost the government 20 million pesos, or more than it spent in a whole year for social services. Pageants, viewed by half a million standees, depicted great moments in Mexican history, such as Cortes' confrontation with Montezuma. At Chapultepec Park 50,000 citizens attended a garden party. At the Palacio Nacional, under 30,000 electric stars, 2000 dignitaries banqueted on gold plate, consuming ten boxcars of French champagne served by 500 picturesquely costumed lackeys.

In the course of the festivities Diaz casually announced to the throng the results of the election—99 percent in his favor.

In a cheap hotel room in San Antonio, Francisco Madero and a few fellow conspirators declared, with some justice, that the election was fraudulent; they called for an uprising against Diaz to make him respect the will of the nation. Madero and his followers demanded effective suffrage, expulsion of the *cientificos,* and a law against a president following himself in office.

Diaz' rougher edges had been rubbed off by his wife, Doña Carmelita, who put him in white tie for ceremonies and taught him to use gold plate and bread instead of tortillas to scoop up his beans. In Chapultepec Palace they lived more regally than had Maximilian and Carlota.

To Diaz' surprise, all over the country disaffected citizens rose in rebellion. In various areas armed groups formed around such leaders as Doroteo Arango, better known as Pancho Villa, or Emiliano Zapata, a tall robust peasant with a big black mustache who had long complained about the misappropriation of peasant lands.

Diaz, who had systematically downgraded his army, weeding out officers of ambition and ability in favor of corrupt and docile servers, now found himself with gouty, rheumatic generals over eighty, colonels over seventy, lieutenants over sixty, and a roster half filled with straw men, paid, uniformed, and fed at regular rates, but in fact nonexistent. Even his

When Emiliano Zapata raised the cry of "Land and Liberty," he was quickly supported by an army of small dark *campesinos* in white pants and conical sombreros, armed with sharp machetes and icons of the Virgin of Guadalupe, ready to fight for the return of their stolen lands.

After the civil war, Zapata hoped independently to restore economic well-being to the ravaged state of Morelos but the newly elected president, Carranza, attacked him with federal troops. When the attack failed, Carranza fell back on treachery. A federal colonel, Jesus Guajardo, pretended to defect to the Zapatistas with 600 men. Although warned of the treachery, Zapata agreed to meet the colonel, each with only thirty men. The colonel showed up with 600, and when Zapata entered the hacienda there was a bugle call: the unarmed Zapata was shot to death.

vaunted Rurales (like the later militia of Mussolini's fascism) turned out to be better at gang-beating individual citizens than fighting as an organized group; they soon went down before the rebels.

When a mob gathered outside the palace on the Zocalo shouting for Diaz' resignation, the dictator ordered the presidential guard to open fire, machine-gunning two hundred demonstrators to death. Popular outcry could no longer be stemmed. The leader of the *cientificos,* José Limantour, who had inherited the mantle from Batres' father, deserted Diaz and made a deal with Madero, who was eventually installed as president. Half delirious with pain from a rotting tooth, Diaz

Batres replied to his critics that he had taken all the necessary precautions to preserve the Sun Pyramid while removing the rubble and earth which incrusted it, that "all structures in Teotihuacan" were formed of layers of construction, whether stone, adobe, or volcanic dust and mortar, and that even mural paintings were to be found, one beneath the other, like "colossal palimpsests." He argued that he had been obliged to peel off the outer layer of the pyramid so as to reveal its true shape.
He dismissed the accusations against him as being political, leveled at him by revolutionary enemies for having been a close friend and faithful servant of General Diaz. "Nothing," wrote Batres, "is easier than criticism when one does not have the noble proposition of illustrating, teaching or correcting, and such criticism is reduced to the venomous desire to damage another man personally, as in my case, without it mattering to the accusers the damage done to science and to history by attributing imaginary defects to our archeological monuments."

was hustled under guard to a train for Veracruz, where he was put on a ship for France, never to return to Mexico.

Diaz' exile, despite Limantour's efforts, brought to an end the reign of the *cientificos,* and with it, that of Batres. Deprived of his title of Inspector General of Monuments, Batres was quickly attacked for having gone about his work with more vigor and enthusiasm than care, of having peeled the Pyramid of the Sun "like an onion," for fear of not being able to reveal it in time for Diaz's birthday.

He was accused of having removed all the remains of the original covering of cut stone and of having left nothing but a disfigured core with a few projecting anchoring stones. He was further castigated for having cruelly mangled the pyramid by giving it five platforms instead of the "archeologically correct four," and of having grossly reduced its size, disfiguring its faces with irregular edges.

Bitter and disappointed, Batres retired from public view, leaving the field open to a young rival who had been groomed for the job by his opponents ever since 1906.

Batres' most determined antagonist in Mexico for over a decade had been an American lady, Zelia Nuttall, an amateur archeologist whom Batres had managed to outrage. Mrs. Nuttall, who was as well endowed intellectually as she was financially, had made some interesting discoveries on the Island of Sacrifices off Veracruz, for which Batres stole the credit. He also blocked Zelia Nuttall's friend Alfred P. Maudslay from excavating at Monte Alban, and took for himself the credit for work at Mitla done by Marshall H.

Archeologist Zelia Nuttall.

Gamio.

In 1917 Manuel Gamio, excavating off the main road from Mexico City to Cuernavaca, found an overgrown hill called Cuicuilco enveloped by prehistoric lava streams. It turned out to be an enormous ancient pyramid or truncated cone with four galleries and a central staircase.

Saville, even going so far as to have his own name carved in letters of gold on a lintel of the finest palace.

Savoring her revenge, Mrs. Nuttall now put into print what was common knowledge about Batres, that as a wholesale and retail merchant in antiquities he had rifled the nation of its archeological treasures, consistently smuggling antiquities from sites he was supposed to be guarding in order to sell them for export. At the same time Mrs. Nuttall exposed, with devastating particularity, the arbitrary and misleading nature of Batres' classification of archeological objects. In trenchant terms she showed that archeology in Diaz' dictatorship had been just another pork barrel at which the same old cronies could feed.

Batres was publicly accused of having grafted in illegal permits to take art objects out of the country, of having blown up an arch at Uxmal to steal a statue, of having faked many of the important pieces in the Mexican museum in order to sell the originals abroad, and of covering up his misdeeds by writing a pseudo-scientific book exposing the forgeries.

Zelia Nuttall pointed out that when the famous Codex Sanchez passed to the German minister to Mexico, Batres was shortly thereafter decorated with the high German order of the Red Eagle.

Batres' downfall, for which Mrs. Nuttall had been planning for years, was as complete as was her triumph.

For years she had been grooming as a successor to Batres a young Mexican named Manuel Gamio, for whom she had maneuvered a scholarship at Columbia University in New York, with the help of the head of the Department of Ethnology and Anthropology, Professor Franz Boas, an authority on Mexican antiquities, on the ground that what Mexican archeology most needed was a museum director thoroughly trained in the most modern methods of archeological research. By repeated intercession with high Mexican authorities Mrs. Nuttall had gotten young Gamio a leave of absence from his job in charge of historic items at the Museo Nacional to study at Columbia, expressing the hope that someday he would be made director of the archeological section of the National Museum and inspector of monuments instead of her *bête noire* Batres.

With the revolution of 1910 all of this came to pass, and the International School of American Archeology, subsidized by various U.S. academic institutions, got off to a start in Mexico with Gamio following Boas as director.

Unfortunately, not all United States efforts in Mexico were as beneficial as those of Mrs. Nuttall. The U.S. ambassador, Henry Lane Wilson, virtually a Guggenheim employee, considering his paramount concern to be the protection of the billion-dollar investment by North American capitalists in Mexico, decided to be rid of Madero.

Falsely reporting to Washington Madero's supposed addiction to radicalism, Wilson did his best to make Madero appear to be a Bolshevik. Madero, a good-hearted nineteenth-century liberal, more accurately described by historians as "a do-gooder whose honesty and charity were unassailable," merely urged compromise and reconciliation among all parties, insisting that all change must come through the legal process.

Exaggerating the destruction of foreign property during Madero's revolt against the Diaz regime and falsely arousing alarm in the United States that in Mexico "every north American citizen's life and property are in jeopardy," Ambassador Wilson conspired to replace Madero with a military figure, General Victoriano Huerta, described by one historian as "an immoral drunkard, devoid of loyalty or honor, supported by the Church and the Army."

U.S. Ambassador Henry Lane Wilson seated stage right of Porfirio Diaz and his thoroughly unpopular vice president, of whom Diaz said, "Ramon Corral is a faithful lad who does what I want him to without discussion."

Huerta falsely lured Madero's brother into a restaurant to a parley, where he had him savagely tortured to death. He then arrested Madero and had him brutally murdered. The same night Huerta met with Ambassador Wilson at the U.S. Embassy to receive his official support.

Surrounded by cronies, Huerta tried to run the country from a bar, until Pancho Villa and Zapata and other insurgents marched on the capital to avenge Madero. The result of Ambassador Wilson's intervention was a bloody civil war which lasted seven years, during which unbelievable atrocities were committed, often on both sides. Huerta's federalists refused to take prisoners; they hurled the Chihuahua governor under the wheels of a running train, and staked out men in anthills to be eaten alive.

Pancho Villa.

Oregon-born and Harvard-educated correspondent John Reed (whose body is buried in the Kremlin wall because of his *Ten Days That Shook the World*) became intimate with Pancho Villa during his coverage of the Mexican revolution. Reed described Villa as representing the peasant soul of a whole continent which had brooded over its bitter condition since the Spanish Conquest and since the Diaz sequestration of land.

Before he became governor of Chihuahua, Villa was a bandit for twenty-two years. At sixteen he murdered a government official, reputedly for the violation of his sister. Outside the law, Villa became a Robin Hood, stealing from the rich to feed the poor. In time of famine he drove off thousands of head of cattle from the Terrazzas' vast ranges, feeding whole districts and taking care of entire villages evicted by the Diaz soldiers in their land grabs.

Reed reported that Villa's great passion was schools, because he believed that land for the people and schools for their children would settle every problem in the country. When he came to power in Chihuahua, Villa established over fifty schools and would have liked to send his son to school in the U.S. but could not afford it.

When he took over the government of Chihuahua, Villa also ordered every Spaniard caught within the boundaries of the state in the next five days to be escorted to the nearest wall by a firing squad. When the U.S. consul reproached him, Villa replied, "Señor Consul, we Mexicans have had three hundred years of the Spaniards. They have not changed in character since the conquistadores. They disrupted the Indian empire and enslaved the people. We did not ask them to mingle their blood with ours. Twice we drove them out of Mexico and

allowed them to return with the same rights as Mexicans, and they used these rights to steal our land, to make the people slaves, and to take up arms against the cause of liberty. They supported Porfirio Diaz. They were perniciously active in politics. It was the Spanish who framed the plot that put Huerta in the palace. When Madero was murdered, the Spanish in every state in the Republic held banquets of rejoicing. They thrust on us the greatest superstition the world has ever known—the Catholic Church. They ought to be killed for that alone. I consider we are being generous with them."

When asked by Reed why he did not aspire to the presidency, Villa replied, "I am a fighter not a statesman. I am not educated enough to be president. How could I, who never went to school, hope to be able to talk to foreign ambassadors and to cultivated gentlemen of the Congress."

He believed that armies were the greatest support of tyranny. "There can be no dictator without an army." He suggested instead the resettling of veterans on the land, where they could farm and teach citizens the basics of soldiering so that "if the patria is invaded, we will just have to telephone from the Palace in Mexico City, and in half a day, all the Mexican people will rise from their fields and factories, fully armed, equipped and organized to defend their children and their home. It would be fine," said Villa, "to help make Mexico a happy place."

General Porfirio Diaz at the age of 81 at Veracruz about to go into permanent exile in Paris, where he was joined by Batres. Unwanted at home, Diaz managed one last fame-making action by diving into Lac Leman to save a girl from drowning.

It was a dismal period for archeology, one when most of the digging was done not for artifacts but to bury bodies. Manuel Gamio, one of a few determined spirits, continued working quietly through the years of the revolution. Applying the stratigraphic techniques he had learned at Columbia, he managed to establish by digging into layers of refuse around Mexico City, and carefully noting each stratum of residue, a record of human habitation in central Mexico going back over 1400 years. Working backwards from the top, Gamio found layers of Aztec and Toltec and then traces of an earlier civilization which he labeled "Archaic." It was a whole new field to be explored.

16. Mexicans for Mexico

Not until 1917, and the establishment of a representative democratic federal republic, was sufficient peace restored in Mexico to resume the search into its past. A new liberal constitution opened the way for the renaissance of native talent; such artists as Diego Rivera, José Orozco, and David Siqueiros appeared on the scene. Interest was aroused not only in Mexico's history but in its ethnic development and its general educational advancement.

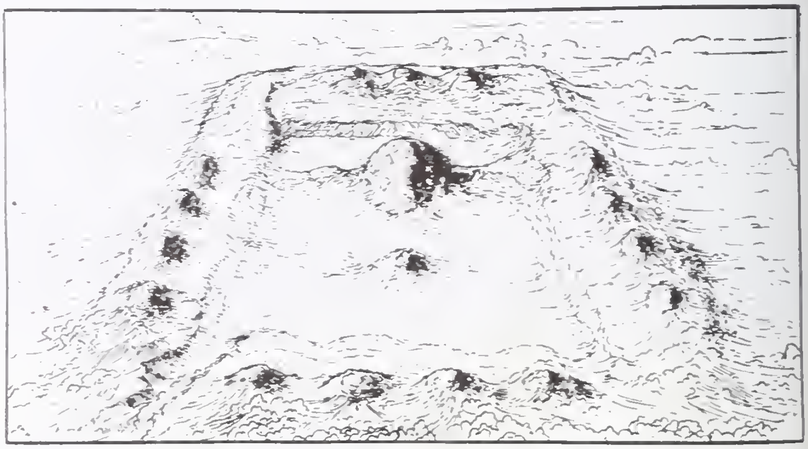
With Manuel Gamio as head of the Department of Anthropology at the Museo Nacional, a thorough study was decided upon not only of the ruins of Teotihuacan, but of the entire Valley of Teotihuacan, from a historical, geological, anthropological, and sociological point of view. For the first time in Mexican history teams of young Mexican scientists went out to make studies on the spot for a long-term investigation of Mexican antiquities. It was hoped that they would be able to reconstruct in detail the various cultures that had inhabited the Valley of Teotihuacan from remotest antiquity.

The earliest vestiges of human habitation found in the lava beds of San Angel were some adobe walls, given the name of Otomi. Gamio's students established that the earliest "archaic" metropolis at Teotihuacan had been built on a gently sloping plain irrigated by a network of crystalline springs which had their source in the volcanic mound of Cerro Gordo. Lava, abundant in the immediate surroundings, had been the main building material for this metropolis. The soil, known locally as *tepetate,* was heavily compacted and impermeable, which made it unnecessary to dig foundations for buildings; walls were not subject to deterioration from humidity.

Large deposits of hard, glassy volcanic obsidian, found in the northeast end of the valley, furnished the raw material for ancient arrowpoints, knives, and other weapons; also for jewelry and ornaments.

By February of 1918, Manuel Gamio was authorized by the secretary of agriculture to resume exploration of the ruins of Teotihuacan. In sixteen separate excavations he attempted to determine by stratigraphical studies the chronological development of the architecture he uncovered. Gamio believed the buildings of Teotihuacan antedated those of the lowland Mayas, which he believed to be two thousand years old; he assumed the earliest ruins of Teotihuacan might be five hundred or a thousand years older than that.

With the end of World War I, and renewed foreign interest in Teotihuacan, Gamio decided to attack an area of the city which he believed would reveal one of the most imposing ceremonial plazas in Mexico, the area known as the "Citadel."



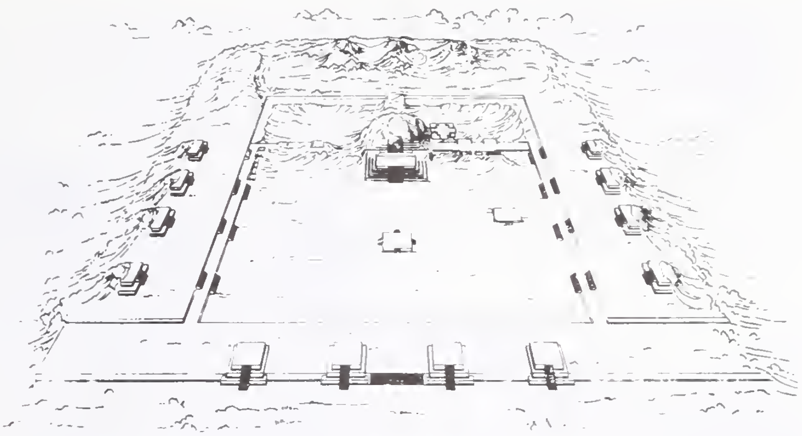
When Gamio first attacked the area of the Citadel, he found it entirely covered with a sheet of earth from under which its lineaments could only just be discerned. Setting aside the question of who could have covered it and why, Gamio decided to excavate what he could.

As with the Pyramid of the Sun—before Batres uncovered it—the Citadel's mounds and embankments, with one exception, were completely shrouded in earth on which flourished indigenous flora and many *pirul* (Peru) trees. The exception was a mound on the east side which had been partially unearthed by Batres to reveal a well-proportioned temple with the usual pyramidal base and *tablero* cornices.

As had been the case with Batres, Gamio realized that as soon as he uncovered a structure it would have to be protected or it would rapidly be disintegrated by rain or the germination of fresh vegetation in the clay mortar; it was also clear to Gamio that no one would be able to appreciate the original beauty of these ancient monuments unless they were restored into clear geometric lines.

Yet Gamio did not wish to incur the heavy criticism which had been heaped on Batres when he had lost the political support of Diaz.

The whole Citadel turned out to consist of a huge quadrangle, 1 mile in perimeter, or 400 meters on each side, covering an area of 36 acres. Facing the Way of the Dead, it had a 40-meter-wide platform 7 meters above the ground; on the other three sides similar platforms were 80 meters wide, around a central patio of almost 40 acres. Atop these platforms, symmetrically arranged, were fifteen mounds indicating the presence of temples. Within the patio were two more small mounds and one very large one. It was misnamed the "Citadel" by the Spaniards because of its high embankments, which they assumed were for military protection, but the true purpose of the complex remained a mystery.



To avoid a similar treatment, Gamio availed himself of the talents of an architectural draftsman of high repute, Ignacio Marquina, who made extremely careful renderings from the fragments of the walls, cornices, and stairways that came to light, recreating each monument as it might have looked in its original state. On the basis of these drawings Gamio concentrated on anchoring any parts of the original building that were found in place, or any part of the original concrete, immediately replacing the fallen rubble with fresh cement. Like Batres, he replaced weak mortar with cement, studded with volcanic fragments, but maintained that his method was more advanced than the primitive technique employed by Batres.

To limit the enormous amount of work such a project entailed, Gamio decided to uncover only the inward facing sides of the Citadel's embankments and temples, leaving the exteriors on the north, south, and east sides safely covered by their centennial or millennial coat of dirt.

Digging into the embankment around the central patio, Gamio found it to be a two-tiered affair with the usual *tablero* cornice, broken at regular intervals by stone stairways which led seven meters up to the flat platforms on which the fifteen temples were arranged. Those on the north and south sides faced inward, those on the east and west sides faced west, toward the Way of the Dead. Each temple had its own staircase leading to a flat top.

Mound in the center of the Citadel before Gamio attacked it.

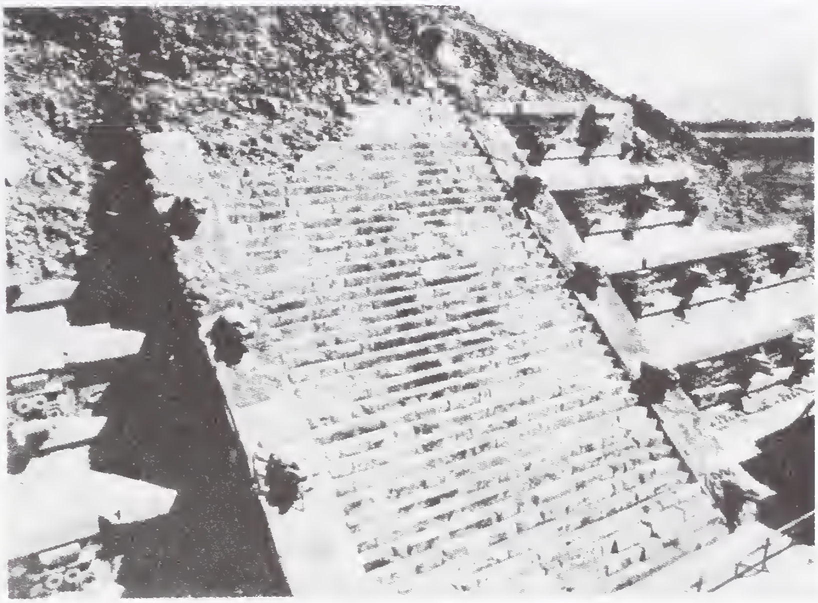
In the spring of 1919 the first soundings were made in the large central mound of the Citadel. By June it was excitedly reported to Gamio that huge sculptured serpents' heads were appearing from the mound, along with indications of other monoliths carved in the shape of curiously stylized animals which at first could not be identified. Unfortunately the rainy season had just begun, and it wasn't till September that Gamio was able to proceed with the excavations.

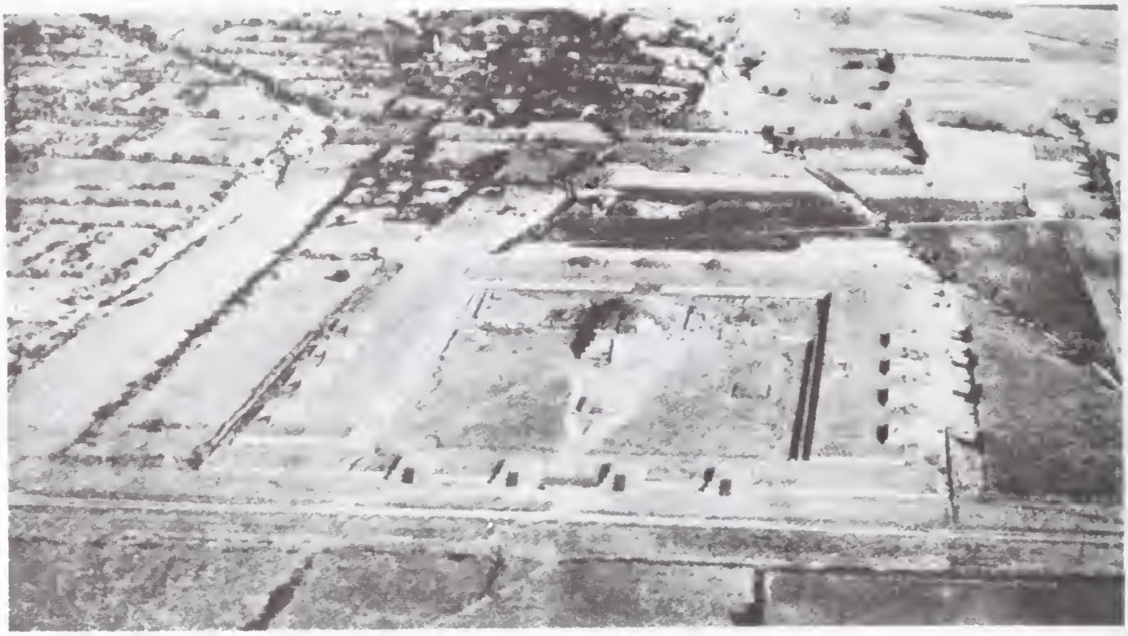
By carefully probing into the side of the mound, the diggers discovered they were dealing with two pyramids, one built up against the other, partly overlaying it. Gamio considered this to be corroborative evidence of two successive epochs having flourished at Teotihuacan. In order to reveal both pyramids it was necessary to make a passage between them. In the process part of the front pyramid had to be destroyed in order to reveal the facade of the back one, which Gamio found to be artistically finer and of an earlier period than the front pyramid; it appeared to have been superimposed during a later and more decadent era.

As earth was removed, an extraordinary sight was revealed; the rear pyramid, built on a base of some 25,000 square meters, rose in six stages to a height of 22 meters, each stage consisting of heavy stone cornices with polychromed sculpture of huge undulating serpents carved in relief with heads protruding from petaled collars to represent Quetzalcoatl. Each snake bore in the center of its body a large humanoid head with fanged jawbone, straight bar mustache, and circular orbs over its eyes, which, because of the sea shells and conchs that accompanied it, were interpreted to symbolize the rain god Tlaloc, though it could just as well have been interpreted as a jaguar representing Tezcatlipoca, the "smoking-mirror god of the rain of fire."

An imposing stairway, from which protruded the heads of plumed serpents, led to the uppermost terrace, where six graves were found by six deep wells containing large wooden pillars. Sculpture and stairway, which had been covered by the front pyramid, were in excellent preservation, considered to be the most successful integration of architecture and sculpture so far found at Teotihuacan. But the front pyramid,

Jutting from the facade of the Pyramid of Quetzalcoatl at regular intervals are great carved heads of feathered serpents, the symbols of Quetzalcoatl. Some of the eyes still glitter with polished obsidian insets. Alternating with the serpent is the symbol attributed to Tlaloc, the rain god, with circles inscribed around his eyes, more likely a representation of the jaguar Tezcatlipoca. Carved in low relief is an undulating design suggestive of waves. The intervening space is filled with carvings of seashells of Caribbean varieties.





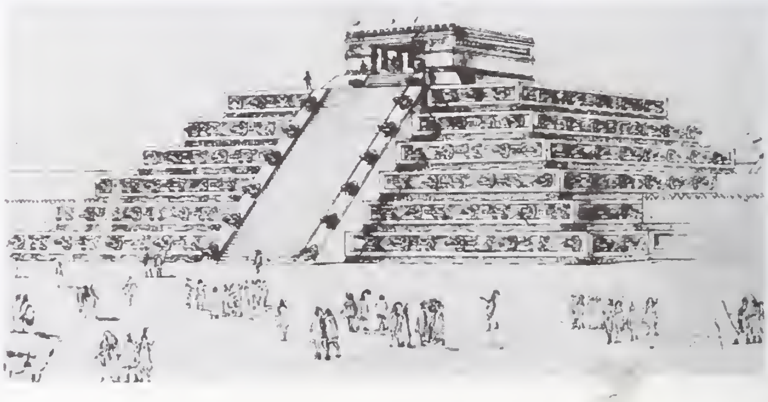
Batres contended that on the west side of the Citadel there had originally been three temple mounds atop the platform facing the Way of the Dead, but that Gamio and his department had leveled the mounds and the structures within them, arbitrarily replacing them—for symmetrical, or aesthetic, or whatever reason —with four "invented" mounds. Batres insisted he knew whereof he spoke, because several years earlier he had uncovered one of these temple mounds and had taken a photograph of it; and on the original survey made by Maximilian's commission only three mounds appeared. Batres accused Gamio and the Department of Anthropology of destroying large parts of the Citadel, literally razing them in order to build entirely arbitrary new buildings, which he called fantastic. Batres said he had devoted his life to the preservation of these monuments, and that now they were being destroyed beyond any hope of repair, to be replaced by "grotesque" reconstructions.

like most of the other mounds, had been largely despoiled of its stonework since colonial times, when the Citadel had been used as a quarry for stone to build churches and bridges.

In his attempt to remedy this vast spoilage Gamio got himself attacked by the man he had replaced. Batres, now old and crotchety, labeled Gamio's work a "savage destruction" of the Citadel, "done by men without understanding or conscience."

It was a serious accusation, but one that went largely unnoticed, as did the more fundamental issue of *arbitrarily* rebuilding ancient monuments. Both Batres' and Gamio's approach to their work had been more anthropological than scientific; they were looking for pretty temples to strange gods rather than to the possibility that the very dimensions of the buildings they were uncovering might contain scientific data.

The argument, often futile, which had been going on for several hundred years as to whether or not the base of the Great Pyramid of Cheops had been intentionally designed as



Ignacio Marquina's reconstruction of the Pyramid of Quetzalcoatl before the second pyramid was superimposed.

a scientific device for recording a fraction of the earth's circumference, thus to serve as a standard unit of measure, was not to be resolved until 1925, when the base of the pyramid was finally cleared of rubble and the British engineer J. H. Cole was able to pinpoint the length of the four sides to within millimeters. The answer, as classical writers had been saying for over two thousand years, was, of course, that the base of the Great Pyramid was an earth-commensurate eighth of a minute of arc, exactly 750 ancient geographic feet, or 500 cubits to the millimeter.

Unfortunately the difference in the length of the base of Mexico's Pyramid of the Sun, as found by Gamio and Batres, was still being disputed in meters rather than millimeters, so that as yet no rational system could be extrapolated from its measure.

If anything but an aesthetic thrill was to be derived from further unearthing of buildings at Teotihuacan, it would have to be done with a more scientific approach.

Ironically, whatever scientific shortcomings Gamio may have had, it was he who was credited with having initiated a new era of "scientific" inquiry at Teotihuacan. Soon the idea spread that the entire city might have to be explored.

But funds were lacking. North America's contribution to Mexican archeology came mostly through such foundations as the Carnegie Institute, whose new director in the field, Sylvanus G. Morley, was more interested in deciphering Mayan stelae in Yucatan than in any reconstruction of Teotihuacan.

He did gasp in wonder when Gamio showed him the freshly uncovered pyramid of Quetzalcoatl, and then took him to lunch in Diaz' grotto. Told that Batres had tried to disparage the accuracy of the work done on the Citadel, Morley gave an impassioned interview to the press in which he attacked Batres and praised the work of Gamio, saying that nothing in the New or Old World matched the ruins of Teotihuacan.

Gamio ond Morley at the Sun Pyramid of Teotihuacan.

Sylvanus G. Morley, a very short, slender Philadelphian, was known throughout Yucatan for the high and voluminous straw hat he sported. Described as a nearsighted bundle of energy, both lovable and exasperating, he had a high-pitched nasal voice and an odd Pennsylvania accent. His Spanish, though he had an extensive vocabulary, was considered atrocious, with mixed-up genders and tenses.

Inappropriately named Sylvanus, he loathed the jungle, especially the jogging on muleback over parched trails or through the smothering atmosphere of the rain forest. "Only liars and damn fools like the jungle," he said; but he stuck it out for twenty years to bring home what he called, "the epigraphic bacon." He was determined to find and decipher every possible dated stele with the long-term object of plotting the rise and fall of Mayan civilization, about which little or nothing was known.

At times only half conscious and afraid he would fall from the saddle, Van, as he was called by his friends, would tie his feet beneath the animal and plunge on despite sunburn, thirst, saddle sores, rock bruises, and cactus stabs. J. E.

Had it not been that the world was just then engulfed in a major depression, funds might have been forthcoming for further research at Teotihuacan. As it was, the site was allowed to languish until the economically solvent Swedes, who in the depths of the 1930s depression could still permit themselves the luxury of archeological exploration, financed Sigwald Linne to take up the spade at Teotihuacan.

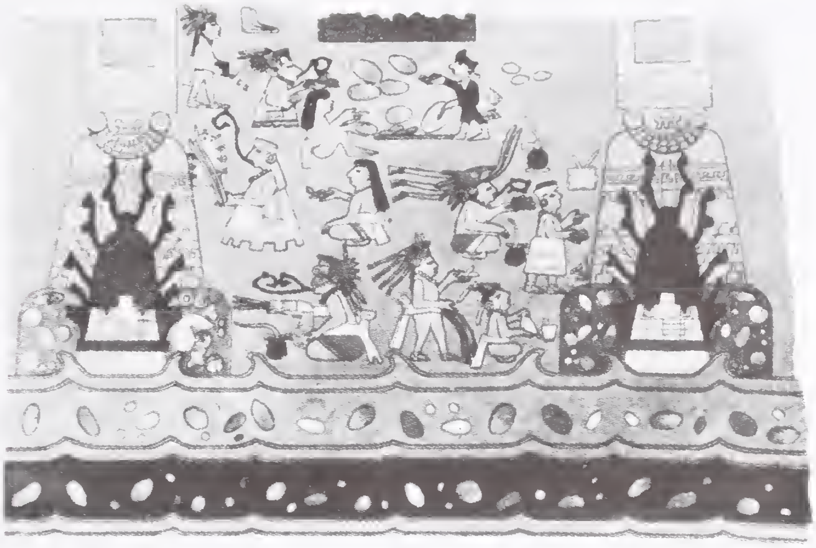
In a short time Linne showed a truly urban side to what had theretofore been considered primarily a ceremonial center. East of the Pyramid of the Sun, Linne discovered a large complex of small houses, interspersed with palatial residences. In one complex, encompassing a total of 4000 square yards, Linne uncovered a conglomeration of 175 rooms built around a network of corridors with twenty-one patios and five large plazas. Here, jammed between the more important religious edifices, were narrow alleylike streets leading off into residential areas where people had lived in crowded quarters separated by small courtyards and alleyways.

Along with the monumental religious structures there appeared the remains of public baths, theaters, and ball courts.

Linne found inner courts to houses with spacious basins for water complete with finely polished stone plugs to stop the drains, still *in situ*. Beneath the floors of these houses were graves replete with domestic utensils, jewelry, pottery, and

Thompson, who was to become England's leading expert on the Maya, describes Morley "squatting before a new-found stela to draw the glyphs, often with handkerchiefs around each wrist to keep the sweat from running down his arms onto the paper."

Eventually he learned to travel in greater comfort with a baggage train consisting of forty boxes, twelve kyacks, and over a dozen bundles of chairs, cots, and other luggage to make life along the trail as bearable as possible. In the bush he required thirty-four mules, two thirds of them for baggage and the remainder for personnel, who included a guide, four muleteers, and a Chinese cook.



obsidian artifacts. From the kitchen utensils, it was clear to Linne that the buildings had been used as dwellings.

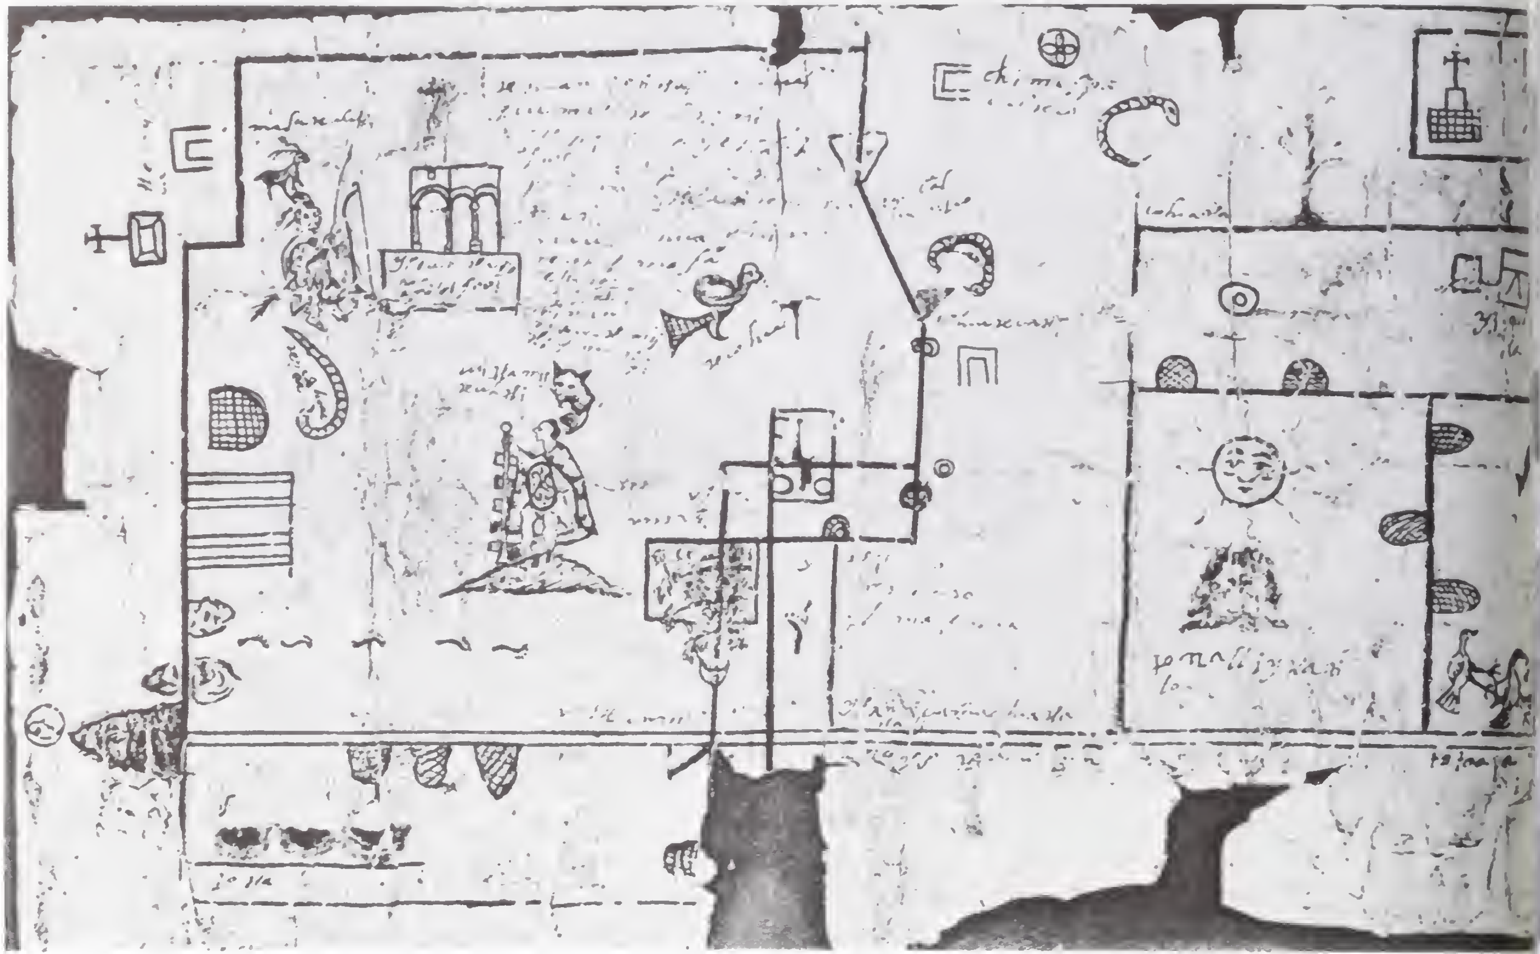
A second group of houses had forty-five dwellings around a rectangular patio surrounded on four sides by platforms, with an altar in the center. Some of the houses appeared to be designed like hotels, indicating the possibility of pilgrim quarters for thousands of visitors.

Linne was followed by Pedro Armillas, who, with money from a foundation called the "Viking Group," uncovered more buildings with frescoes which provided surprising information about the religious customs of the Teotihuacanos. Murals revealed the gods of Teotihuacan in impressive scenes.

Other paintings, made with mineral colors mixed with unfermented maguey sap painted on lime mortar, mixed with quartz dust to make the colors stand out, indicated to archeologists a civilization more of king-priests than of warrior-princes.

Still more gods, some of whom had also appeared in Tenochtitlan, were found on murals by Laurette Sejourné, a Mexican archeologist born in France. Digging into a bean field at Teotihuacan, she uncovered the ruins of a palace called Zacuala, covering 5000 square yards.

Yet all of this was desultory work. The mystery of when, how and why Teotihuacan had been built remained as deep as ever. To open up the ancient city a real financial shot in the arm was needed. It came in 1960 after the election to the presidency of Adolfo Lopez Mateos. A sharp economist, Lopez Mateos realized that a major effort at uncovering and restoring at least the ceremonial center of Teotihuacan might provide an attraction for both domestic and foreign tourists; they in turn might refill the state coffers.



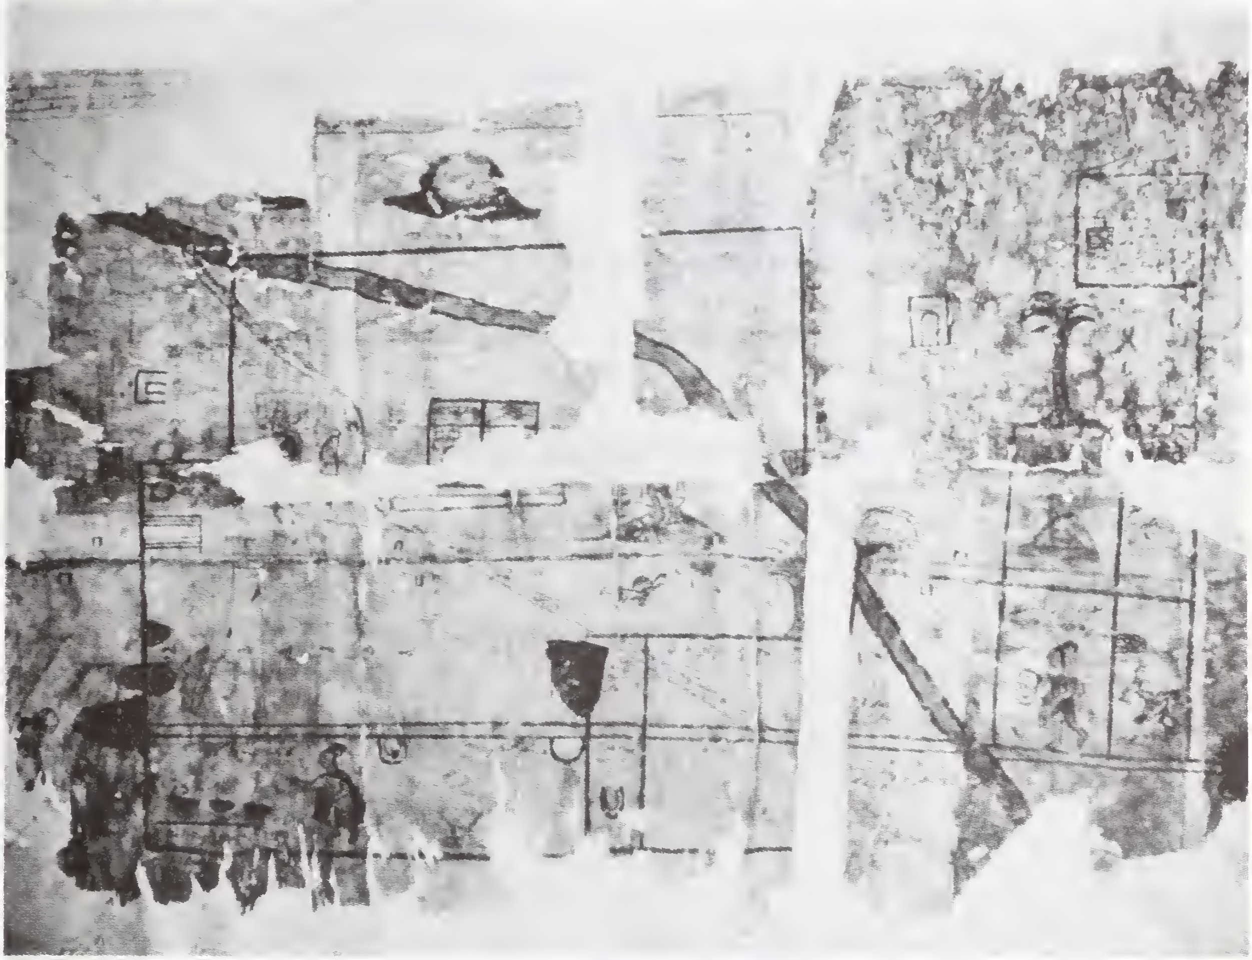
At Teotihuacan, Batres had found in a stone chest two manuscripts, one of which he gave to Marshall H. Saville, who presented it to New York's Museum of Natural History (where it is now stored on the shelves of Gordon Eckholm). The other, which he gave to Edward Ayres, is now in Chicago's Newberry Library.

Both maps, apparently made shortly after the conquest, contain unusual data and symbols not found elsewhere. Recent restoration of the Ayres manuscript revealed a backing paper with writing and the seal of Pope Urban VIII whose pontificate was from 1623 to 1644.

On the Ayres manuscript the Moon Pyramid is marked as "the moon house" and further down the Way of the Dead is "the place of the brilliant serpents." The Pyramid of the Sun, which is drawn in its proper position and correctly proportioned to the Pyramid of the Moon, is labeled "shining house."

Stansbury Hagar, Secretary of the Department of Ethnology at the Brooklyn Institute of Arts and Sciences, one of the first to realize the astronomical nature of Mexican monuments, suggested the smaller mounds could represent the planets or other stars.

Hagar believed the Way of the Dead, which was also known as the Way of the Stars, might represent the Milky Way; he pointed out that to Indians in the United States, the Milky



Way was known as the Path of the Dead because spirits were believed to pass to and from it, between earth and the land of the souls amid the stars.

Hagar suggests that Mixcoatla, the Mexican Cloud Serpent, might represent the Milky Way.

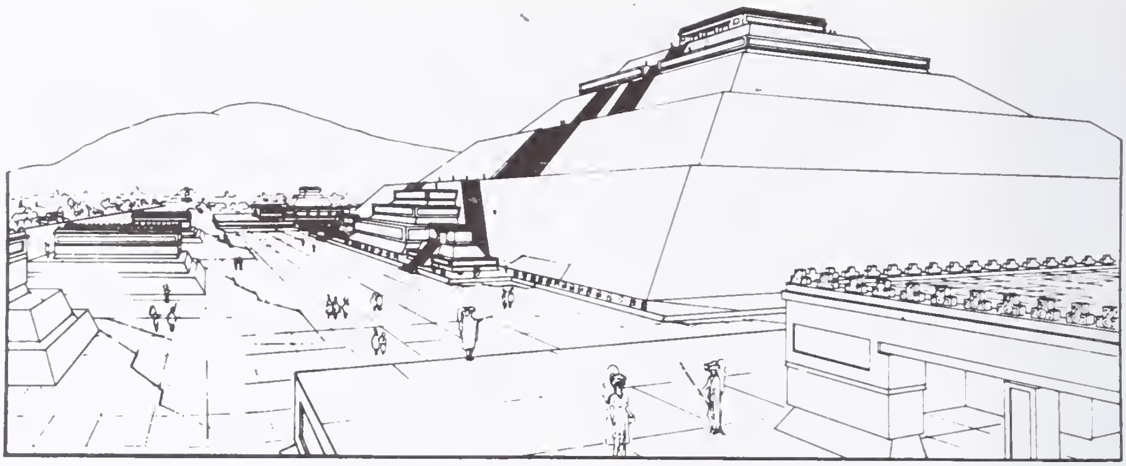
To Hagar, it appeared that Teotihuacan had been a sacred city because it reproduced on earth a supposed celestial plan of the sky-world "where dwelt the deities and spirits of the dead."

He believes the Citadel to have been a solar temple with two enclosures devoted to the solstices and equinoxes, and that its principal mound pertained to the sun and the summer solstice in distinction to the Pyramid of the Sun which was dedicated to the Sun as a celestial body. Hagar suggested that the great size of this zodiacal enclosure probably indicated a predominance of the cult of the stars over that of the Sun at Teotihuacan.

Hagar pointed out that footprints appearing on the maps could indicate the constellation of Capricorn at the moment of the December solstice. He interpreted the red and circular object outside the lower right-hand corner of the Citadel in both manuscripts as probably a tortoise, symbol of the summer solstice.

The word *itzquitla* in the margin he interpreted as a corruption of Dog, name of the day sign attached to the winter solstice.

The third enclosure of the Citadel containing two small mounds and two birds of equal size, one black and one white, Hagar interpreted as symbolizing the vernal equinox, which falls between the day sign Quauhtli, for eagle, and Cozcaquauhtli, for vulture. "Evidently," wrote Hagar, "we have not realised either the importance or the refinement, or the widespread distribution through ancient America of the astronomical cult of which the celestial plan was a feature, and of which Teotihuacan was at least one of the principal centers." But some time was yet to pass before further evidence was forthcoming on the astronomical functions of Teotihuacan.



Impressive but improbable reconstruction of the pyramids of Teotihuacan by Mexican architect J. A. Gomez Rubio.

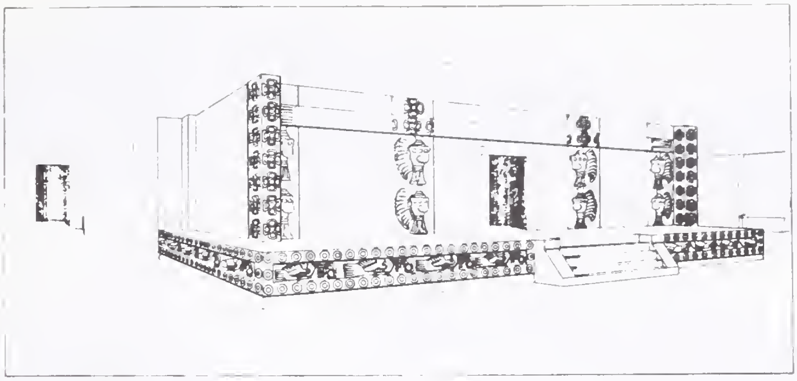
Seventeen million pesos were appropriated for a two-year campaign. Scores of archeologists were hired to supervise some six hundred spade diggers. It was hoped that dozens of the temples buried along the Way of the Dead might be excavated and restored so as to give visitors a more vivid sense of the ancient city's splendor.

Under the direction of Jorge Acosta, a Mexican archeologist born in Peking in 1904, whose digging at Tula had been responsible for confirming Charnay's contention that the ancient city had once been the seat of a prosperous Toltec kingdom, the area around the Pyramid of the Moon was first attacked. In a few months the plaza before the pyramid and three surrounding hectares were completely cleared of rubble. So was a large part of the Way of the Dead. The plaza in front of the Pyramid of the Sun could only be partially restored because of the damage done by previous excavators, including Batres' pet railway.

In the course of operations around the Moon Plaza, the remains were unearthed of a building with another large stairway with enormous snake heads leading to a patio with square sculptured columns, where Acosta found rooms with some of Teotihuacan's finest murals. This was the beautiful place of Quetzalpapalotl, the butterfly god.

Palace of the Butterfly God.

Substructure of the Palace of the plumed shells.

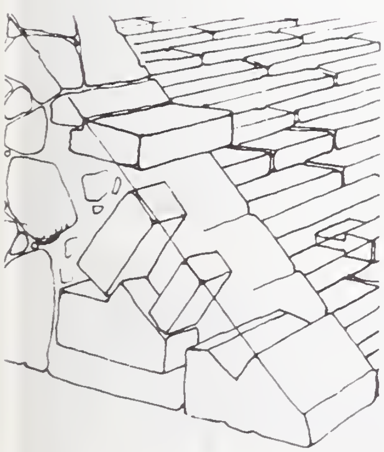


To analyze the enormous quantity of pottery, sculpture, tools, and ornaments dug up in these vast operations, a special scientific lab was created under the supervision of fifty-year-old Florencia Muller, a Mexican specialist in ceramics who had done her early schooling in St. Louis, Missouri.

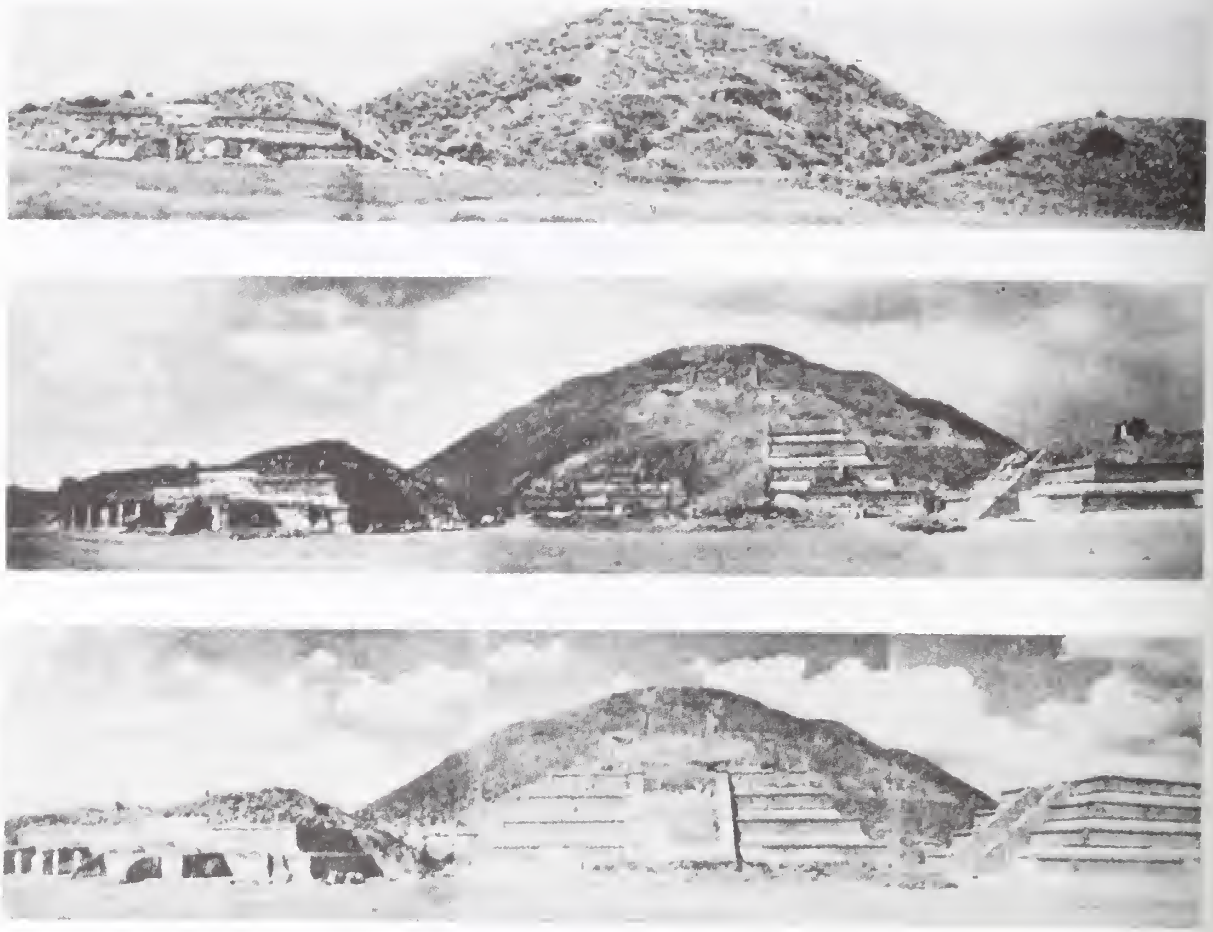
At which point another fifty-year-old Mexican archeologist, Ignacio Bernal, joined Jorge Acosta in the decision to embark on the major project of uncovering and reconstructing the remaining major monument at Teotihuacan, the Pyramid of the Moon.

Gamio had found it a mound covered with earth and vegetation, and so he had left it. Only a few portions of the external structure of the Moon Pyramid had been uncovered, showing the remains of a staircase, fifteen meters wide, on the south side, looking down the Way of the Dead, but largely destroyed by Garcia Cubas, who had left a hole of several thousand cubic meters in its center.

As Bernal and Acosta went about carefully uncovering the rest of the south face, four stages came to light, plus sufficient remains of a fifth stage for them to risk undertaking its reconstruction, in no way an easy job, even for twentieth-century archeologists, especially as no one could be sure that the building had not already been reconstructed two millennia previously. Not only had external stones subsided from their "original" positions and angles, but underneath the outer surface of the Moon Pyramid the archeologists found traces of two more "original" structures which might at one time have been external.



Thanks to some careful exploration by archeologist Ponciano Salazar, 565 original stones to the staircase were recovered from rubble around the plaza. One stone was still in its original position—luckily a cornerstone. From this stone it was possible to reconstruct the entire angle of ascent. As the whole staircase had been ingeniously designed with odd-shaped interlocking stones to prevent slippage, forty-eight courses could be reconstructed, which brought the top of the



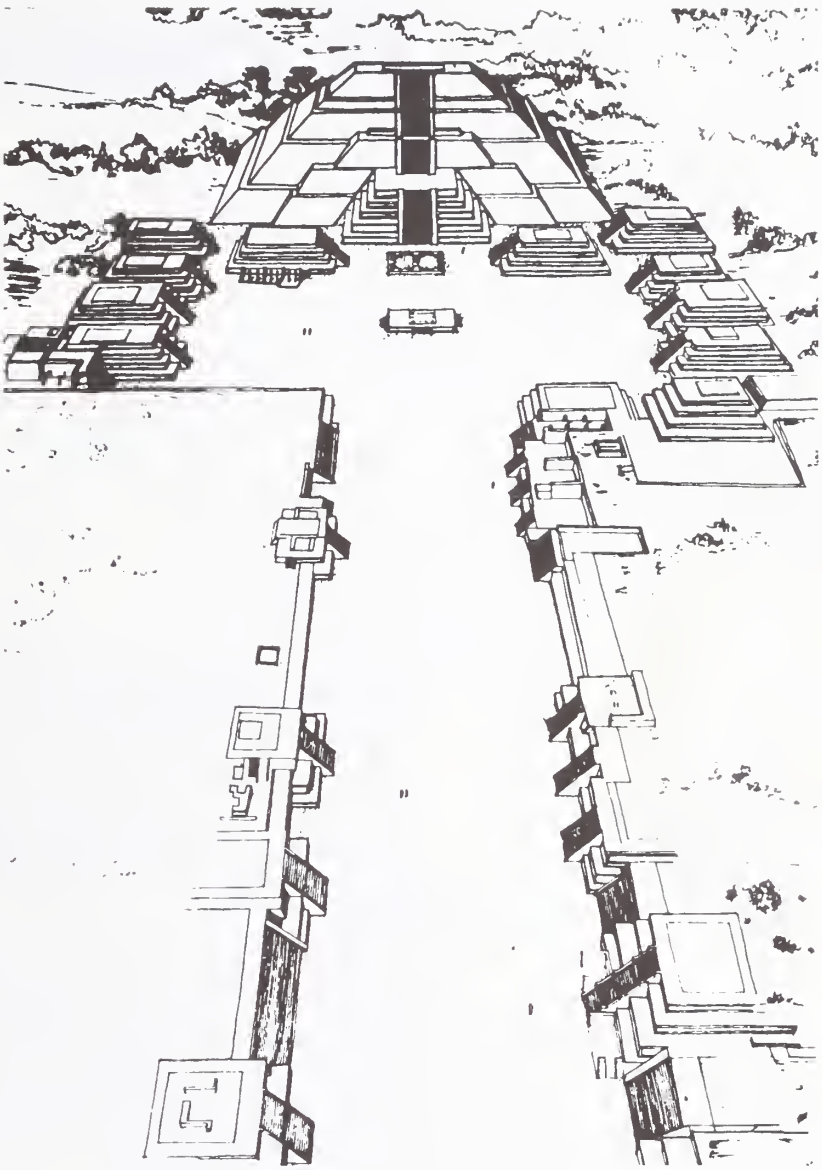
Pyramid of the Moon as Bernal and Acosta began to uncover and restore it.

staircase to a third of the way up the south face of the Moon Pyramid. Later reconstruction added three more staircases to the top of a fourth level.

As the workmen proceeded to clean up the rest of the ceremonial area, Bernal and Acosta were faced with the difficult choice of deciding whether to reconstruct buildings in the later, and to them inferior, Teotihuacan period, or to dismantle these remains in order to reconstruct the earlier, and more impressive, buildings beneath them. Mostly they decided to concentrate on rebuilding the city as it had been at what they considered the height of its glory. At the same time they left standing a number of buildings of the later, more decadent, period, when the city had apparently lost its role as a great capital and had become inhabited by peoples of "a lower cultural level," incapable, according to Acosta, of understanding the grandeur of the past.

Once the east and west sides of the Moon Pyramid had been cleared (leaving the north side in its original earth-covered state), visitors were afforded a spectacular sight of the great reconstructed pyramids joined by a temple-lined avenue prolonged to include the resurrected Citadel.

Theoretical reconstruction of the Pyramid of the Moon from Jorge Acosta's guide to Teotihuacan.



As had been expected, the lavish reconstruction of Teotihuacan caused an influx of tourists, both Mexican and foreign, which soon replenished the state coffers, to the delight of a government which still did not realize it had barely scratched the surface of the great city of Teotihuacan.

17. Imperial City

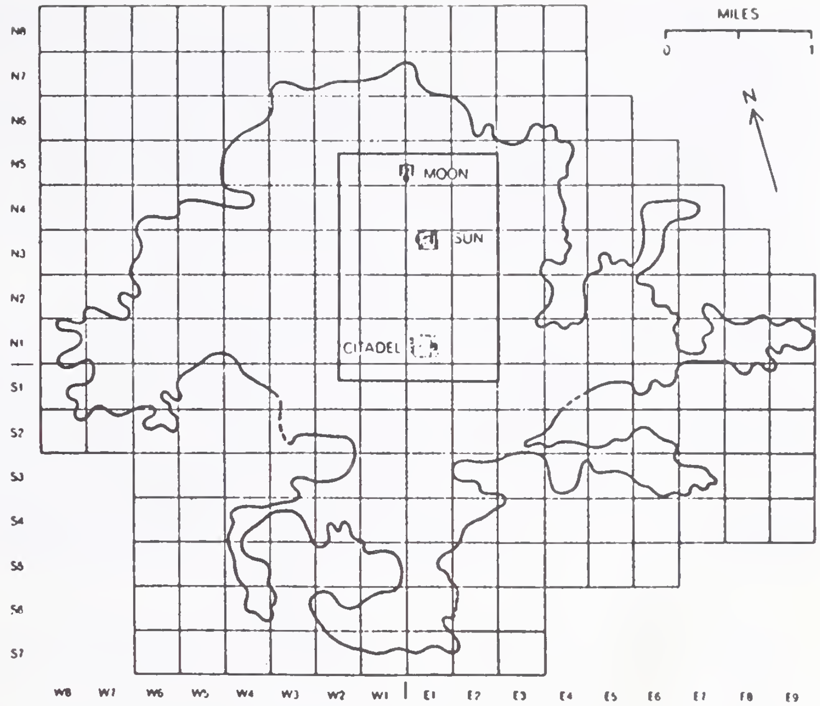
The person who was to spark the discovery of the true proportions of Teotihuacan turned out to be a young American of French origin, René Millon, who arrived in Mexico City in 1950, fresh from Columbia University. At the age of twenty-nine, Millon was so fascinated by what he saw and by how such a city as Teotihuacan could have risen in the Valley of Mexico that he came to devote his career to finding out its true dimensions.

After years of exploratory work at Teotihuacan and its surrounding valley he was able, in 1962, as a professor of anthropology at the University of Rochester, to obtain sufficient funds from the National Science Foundation in Washington, D.C., to start the preparation of a photogrammetric map of the entire area of Teotihuacan as a base for a comprehensive archeological survey to establish the exact dimensions of the ancient city.

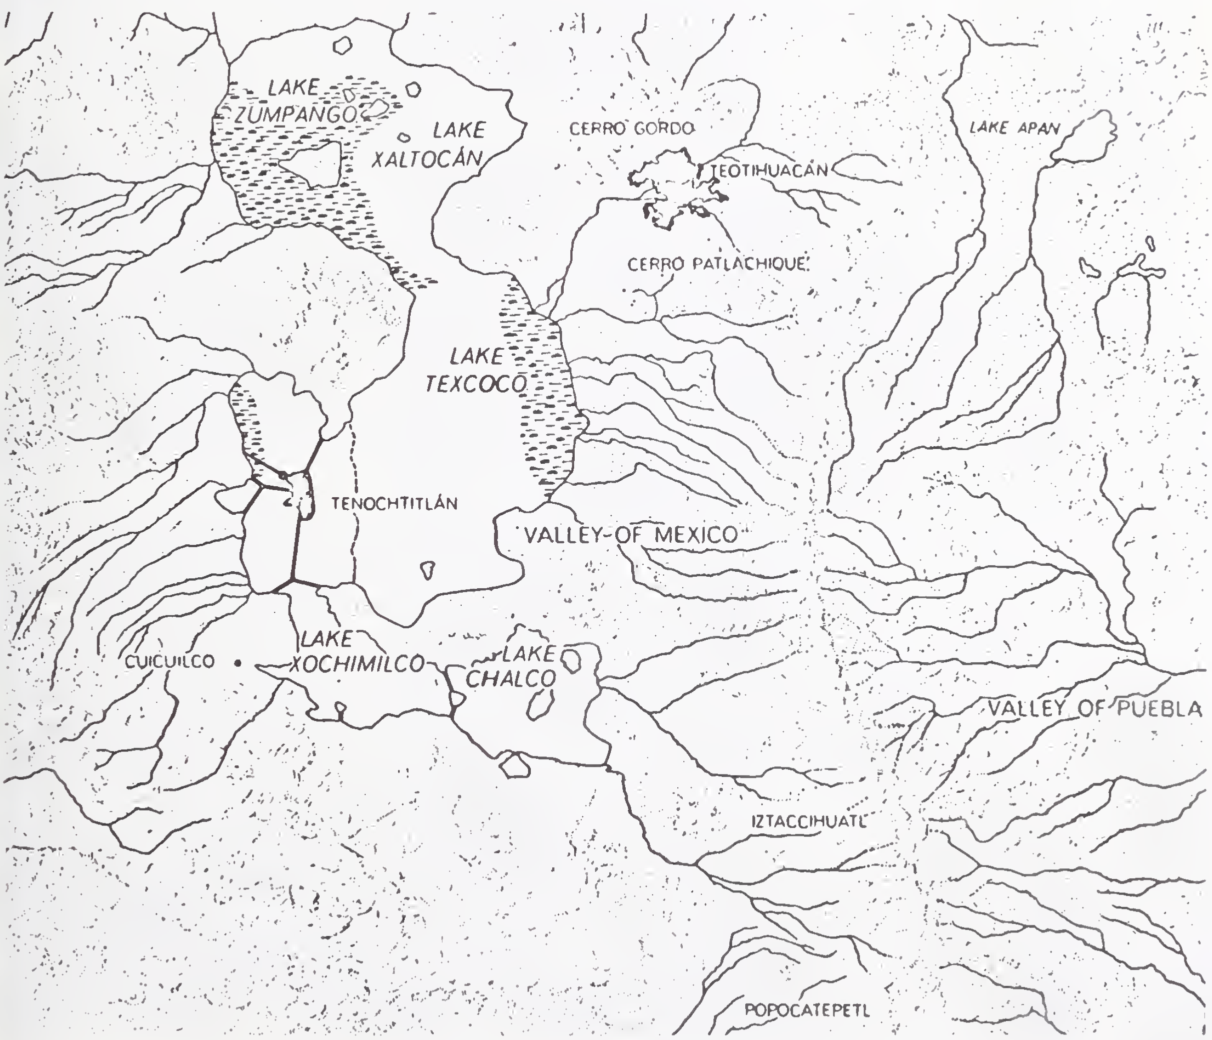
Until 1922 the only topographical map of the ceremonial center and heart of Teotihuacan had been the one prepared in 1865 by Maximilian's commission. In 1922 Gamio made a more detailed map of the same area, but did not even take it as far north as had Ramon Almaraz.

Millon decided that a proper map would have to show the full extent of the ancient urban zone so as to verify for density of construction and establish the way in which buildings had been disposed and related to each other.

To limit the area to be photographed, Millon and his colleagues first made a field survey to establish a neutral band, at least 300 meters wide, with no trace of a building in it. He first estimated that this would give him a city area of some 25 square kilometers. In the end he had to



Irregular boundary of Teotihuacan is shown as a solid line that approaches the edges of a grid, composed of 500-meter squares, surveyed by Millon's team. The grid drawn by Millon parallels the north-south direction of the Way of the Dead, the city's main avenue.



Teotihuacan was strategically located on the best route between the Valley of Mexico and the Valley of Puebla leading to the Gulf of Mexico.

cover 38 square kilometers, which caused a hiatus in his operations while more funds were sought to handle the enlarged project.

Once the funds were found, the job was to be carried out under the aegis of the Mexican Institute of Anthropology and History, whose new director was Ignacio Bernal.

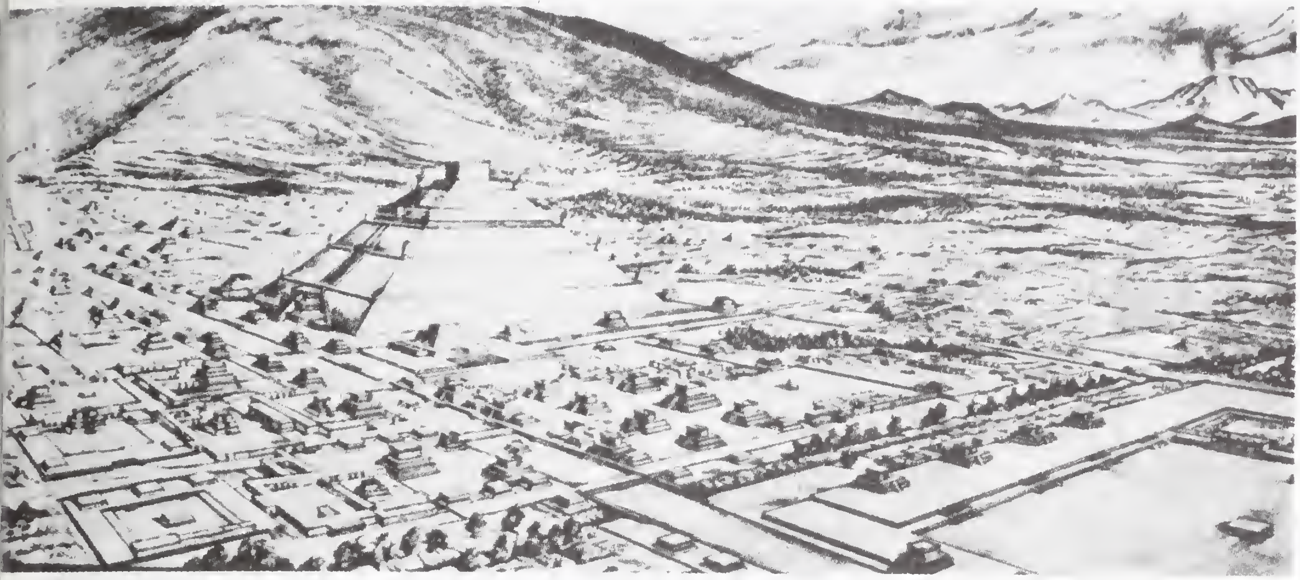
The map was to represent the most detailed surface study of so large a prehistoric urban area ever attempted. Photography took place in April of 1962, when the cloudless conditions prevailed that are essential for aerial shots from 4000 feet. Concurrently, a comprehensive archeological survey on the ground was undertaken to transform the raw photographic manuscript into a finished map containing all possible structural information of archeological interest. This was completed five years later, after various interruptions, in 1967. Overlay sheets would present a hypothetical reconstruction of what the city had looked like at the height of its development.

When the job was done, the results were staggering. From the jigsaw overlapping of photographs and the drawings made there appeared a fantastic view. At last it was clear to Millon that Teotihuacan had been an immense and well-planned city, laid out on a grandiose scale, teeming with life as early as 2000 years ago. There could no longer be any question about its having been only a ceremonial center. It appeared to be the first and most important urban center of the American continent, vaster than the area within the walls of imperial Rome of the Caesars, housing at the height of its development as many as 200,000 inhabitants organized into a most complexly stratified society. Teotihuacan had clearly been a religious, cultural, economic, and political capital, as well as the greatest known market center in Mesoamerica.

Millon realized that as a holy city, with thousands attached to its temples, Teotihuacan must also have been the seat of a religion with a wide appeal, possibly headed by a supreme pontiff, a city with the qualities of a Rome, Mecca, or Benares.

Economically it was clearly one of the largest pre-industrial cities in the world, with tens of thousands employed in crafts, and perhaps a hundred thousand involved in great markets at fixed intervals, a great attraction to visitors and traders, who had their own enclaves within the city.

Politically, Teotihuacan had evidently been the most influential center in Mesoamerica during the major part of the first millennium A.D., astride the major trade and access routes into and out of the Valley of Mexico, the seat of an increasingly powerful state that appeared to have extended its dominion over wider and wider areas.



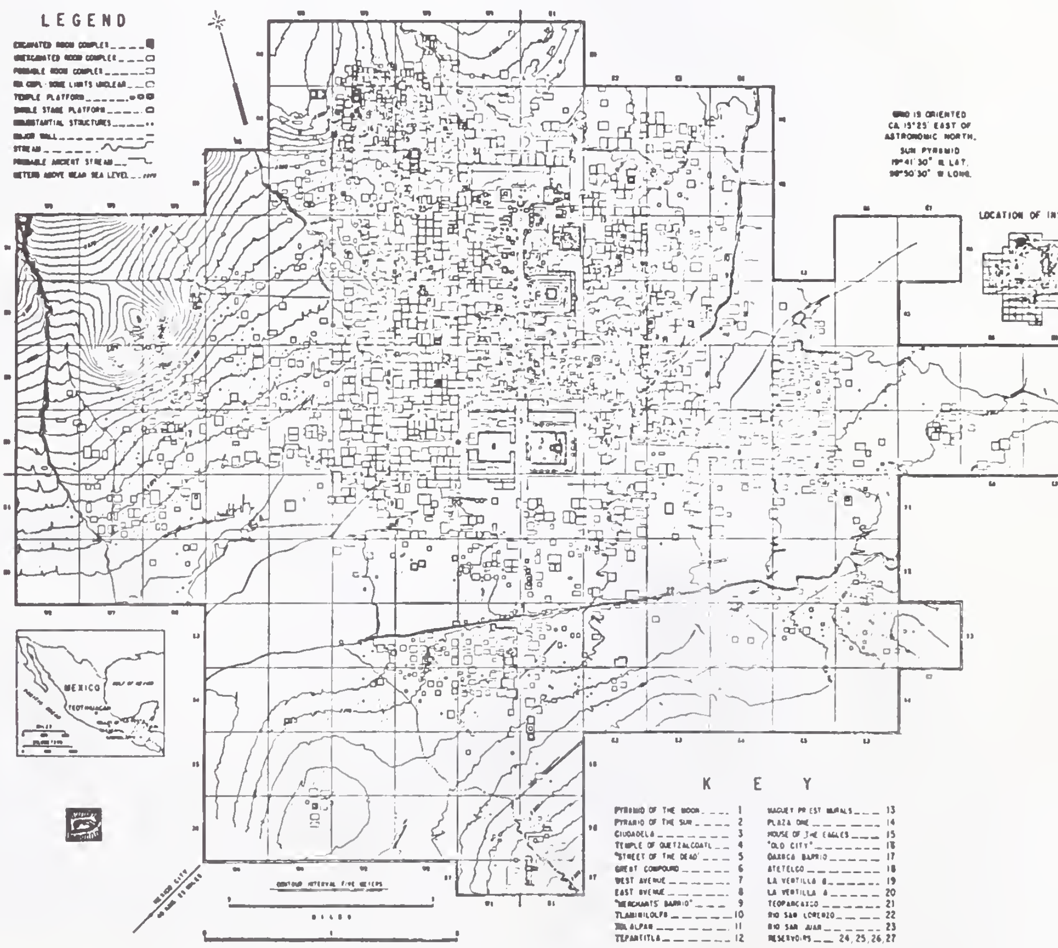
Reconstruction of the great city of Teotihuacan as imagined by Feliciano Peña of the National Museum of Anthropology.

Aerial photos revealed broad avenues to the east and west of the Citadel which had not been suspected, but which were quickly confirmed by surface reconnaissance. Other street patterns and clusterings of buildings into larger complexes, hypothesized through examination of the map, were also confirmed by field crews.

More than 2600 apartment compounds showed up, as well as other types of compounds, temples, platforms, and major structures. Of these larger stone-walled structures, more than 1200 manifested walls, floors, or other structural evidence *in situ*. In the course of surveying the city, more than 1800 floors and 1900 walls were recorded.

The outer walls of the apartment compounds turned out to be massive battered masonry or *taludes*, much thicker than interior walls, which made them easier to locate. High walls were on the exterior, without windows, giving onto narrow streets.

Millon estimated that sixty persons could have lived in one apartment compound of 3600 square meters, that thirty could live in a compound of 1600 square meters, and twelve in a compound of 600 square meters. Extrapolating from these figures, he obtained a possible population of 200,000.



Development of the great city of Teotihuacan from its inception in about 100 B.C. to its collapse in 800 A.D.

Between A.D. 450 and 650 the city, though it did not extend over twenty square kilometers, or twelve square miles, was, according to Millon's map, most densely populated, with more than 2000 apartment complexes. The city's peak of power and influence may have been reached about A.D. 500, and most of what is visible in Teotihuacan today is attributed by archeologists to this epoch.

By 650, some form of degeneration appears to have set in, and many inhabitants seem to have moved to the east side of the city. Yet the city still flourished, despite a slight drop in population.

The maps of Teotihuacan from 100 B.C. to A.D. 800 were prepared by Millon in 1967. Since 1966 additional data have significantly modified some of the areas shown. The maps are published with the permission of Professor René Millon, courtesy of the Sociedad Mexicana de Antropologia.

Ceremonial and/or administrative buildings along the Way of the Dead could now be clearly differentiated from residential areas on both sides of them. Surface survey and excavation indicated that Teotihuacan had been divided into neighborhoods or *barrios,* groups of buildings clearly set off from surrounding structures, forming easily definable units.

Inspection of the map showed the city to have been divided into quadrants. The north-south axis was formed by the Way of the Dead; the east-west axis, subordinate to it, was formed by two great avenues that determined the city's center, interrupted by the Citadel.

A striking feature of the northern and northwestern part of the city was its many walls and great precincts. Most of these massive long free-standing walls were identified in the field by locating ruined stretches of their two sides exposed on the surface, though excavation was often needed to reveal them.

Though Millon estimated that most of the inhabitants probably lived from cultivating the land outside the city, it was clear that a very significant part of the population was engaged in craft activities within the city, the vast majority being obsidian workers in some five hundred workshops.

Millon and his principal colleagues, Bruce Drewitt of the University of Toronto and George L. Cowgill of Brandeis University, also found evidence of over a hundred other types of workshops—for ceramic, figurine, lapidary, shell, basalt, slate, and ground-stone work. They infer that different crafts lived in separate neighborhoods and believe that many were employed in the building crafts, such as masons, plasterers, and carpenters.

From aerial photos, examined stereoscopically, Millon made another surprising discovery: a part of an immense platform opposite the Citadel, with a counterpart to the south of equal size. These two great platforms formed an enormous compound around a plaza that appeared to be larger than the main plaza of the Citadel. It seemed extraordinary to Millon that so large a structure could have existed and never have been observed. The next day he and his associates went into the field and easily found outlines of the two enormous platforms with remains of apartment compounds on them, "though no prominent structures."

Millon put forward the hypothesis that this great compound had once been the city's principal market place, a bureaucratic center with compounds built on the immense platforms. With the Citadel, these compounds evidently formed the religious and commercial center of the ancient city, a megacomplex surrounded by broad avenues and plazas, with more open space than in any other part of the city, a sort of island in its center. Millon considered the plan

TEOTIHUACAN
Topographic Map and Grid System

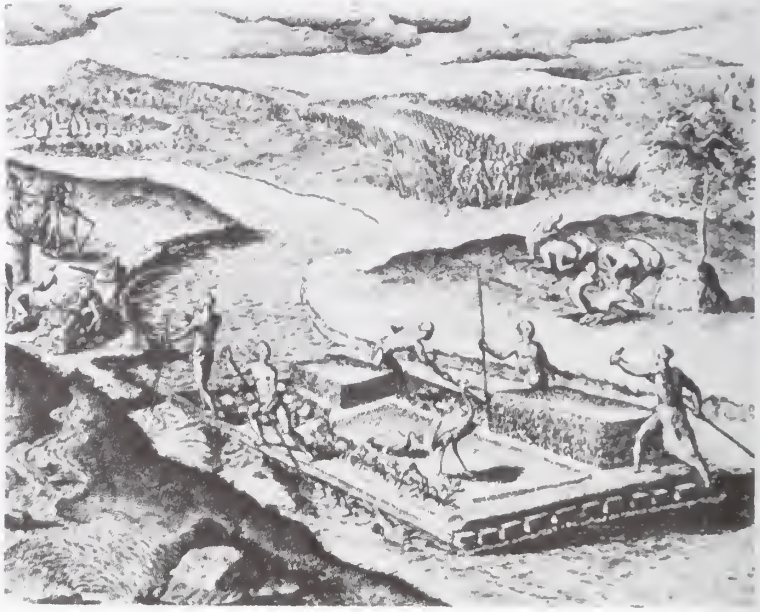
In the course of his explorations, Millon found that Teotihuacan had many carefully laid out canals and systems of branching waterways artificially dredged into straightened portions of a river fed by eighty permanent springs and its tributary streams, which altogether formed a network within the city and ran all the way to the lake, now ten miles away, but perhaps closer in antiquity. With these lakes and waterworks the ancient Teotihuacanos appear to have been able to feed a vast population with their system of chinampas, or so-called floating gardens, on which they could produce several crops a year.

Richard Ford of the University of Michigan analyzed plant remains of more than thirty superimposed kitchen floors and hearths in a "high status" apartment compound at Teotihuacan. He believes practically everything edible was consumed, including beans, squash, chili peppers, as well as an ample selection of wild plants such as sumac seeds. He found at least two varieties of goosefoot and portulaca leaves. He also found evidence of fish, deer, rabbits, and other game having been consumed.



one of the most majestic architectural achievements in the history of the pre-Columbian people of the New World.

Several more compounds revealed by the map, one west of the Moon Pyramid, and another immediately north of the Citadel, demonstrated that a great deal of planning had gone into the city. Millon concluded that the Way of the Dead must have been decided on very early in the history of the city, possibly before the construction of any permanent buildings other than the pyramids.

With the help of Millon's map it was now possible to recreate a tentative history of the development of Teotihuacan. Because the systems of scientific nomenclature devised by different archeologists to specify each historic period of Teotihuacan development are as confusing to the layman as they are unsatisfactory to scientists, the simplest way to date the development is by means of the Christian calendar.

From Millon's map and the shards that were excavated, it appeared that the Teotihuacan area had first been settled in the latter part of the first millennium B.C. when a handful of villages sprang up. The archeologists involved mostly agreed that it was during the period between 150 B.C. and the birth of Christ that Teotihuacan grew into a large settlement covering an area of more than six square kilometers, mostly in what was to become the northwest quadrant of the later city. In this area Millon found remnants of public buildings with stone walls and hard earth floors, the orientation of which was quite unlike that of the later city, an area that was to continue to be the most crowded throughout the city's later history.

The map survey revealed far more extensive residential areas covered with pottery fragments from the first century A.D. than previously believed. Since the same pottery was found on the Pyramid of the Sun, Millon concluded that the pyramids of the Sun and of the Moon probably were built in the earliest phase of the occupation of Teotihuacan, A.D. 1–150, rather than several centuries later, as had been assumed by Gamio and others. Early carbon dates were inconsistent, but later ones argued that the Sun Pyramid, or the greater part of it, had been built by A.D. 150.

Other archeologists hold that the city was flourishing as early as 1500 B.C., and a small group maintains that the construction of Teotihuacan goes back to an era before the eruption of the volcano Xitli, perhaps 6000 years ago.

Historians and anthropologists maintain that the cooperation of vast numbers of people would have been needed to build the two pyramids, and that this indicates the preexistence of a great metropolis with a stable society and strongly centralized authority. These experts envisage Teotihuacan as a planned city laid out by priest-architects.

Between the first and second centuries A.D., Millon sees the city as growing rapidly to a predominant position in the Valley of Mexico, covering an area of more than twenty square kilometers. During this period Millon found evidence of the construction of more than twenty temple complexes, mostly on either side of the Way of the Dead, which had grown so long it made it impossible for travelers or traders to pass through the valley without passing through the city.

Between A.D. 150 and 200 there is evidence that the city shifted to the south and east, partially abandoning the northwest. From Millon's mapping, it is clear that by A.D. 200 the city had been split into four squares or quadrants centered on a point along the Way of the Dead opposite the entrance to the Citadel. Based on excavations carried out as part of the mapping project, Millon believes it was in this period that the Citadel was first built in its present form and that the uppermost part of the Sun Pyramid was completed. He believes that the Citadel, which was developed over the next two hundred years, along with the Great Compound, formed the symbolic as well as the geographic, political, and religious center of the city, and that nothing approaching them in scale of conception is known anywhere else in the prehistoric New World.

Between 200 and 450, the evidence shows an enormous amount of building activity, and a revolutionary change in the settlement pattern. Permanent stone-walled residential compounds, mostly consisting of a number of apartments, appear to have been built in all parts of the city, replacing most

RENE MILLON 9/64 REVISED 7/71

of the earlier structures built of relatively impermanent materials. High faceless walls and narrow streets, says Millon, became the rule in most of central and north central Teotihuacan, and the city assumed the form it was to hold till its fall. From this era date such beautiful temples as that of the Plumed Shells with its monumental deeply carved stone columns.

During the latter part of this period, or from around 350–400, the influence of Teotihuacan appears to have spread to all other parts of civilized Mesoamerica; for four hundred years, says Millon, its political and religious dominance went unchallenged. This period also saw the culmination of its architects' dreams: the city grew into a great religious center with palaces for the clergy and the aristocracy, and large apartment compounds with communal dwelling areas for farmers, craftsmen and specialists.

Between 450 and 650, the city, though it did not extend more than twenty square kilometers, or twelve square miles, was, according to Millon's map, most densely populated, with over two thousand apartment compounds. The city's peak of power and influence may have been reached about A.D. 500, and most of what is visible of Teotihuacan today is ascribed by archeologists to this epoch.

By 650, some form of degeneration appears to have set in and some inhabitants seem to have moved to the east side of the city. Yet the city still flourished, despite a slight drop in population. Sometime around 750, some great holocaust hit the city. Charred areas around all or most of the city's temples and public buildings suggest to Millon that they were deliberately burned. Millon and others found considerable evidence that the city's center, after burning and collapsing, was never thereafter rebuilt.

But whether the city was sacked by invaders or destroyed by a great fire of accidental origin remained the unanswered question. The only evidence on which all agreed was that the collapse was sudden and catastrophic.

After 750, Teotihuacan was a ghost town. As Millon reconstructs the evidence, only a few people lived in what amounted to a village one square kilometer in area. Some refugees, fleeing the traumatic experience, appear to have settled closer to Lake Texcoco and at nearby Azcapotzalco, but what happened to the rest of the population remains a deep mystery.

To account for the sudden end of Teotihuacan, other than through the agency of some unknown cataclysm, major earthquake, or violent invasion, several theories have been propounded, including a drastic change in climate, sudden soil exhaustion, massive crop failure, dreadful epidemics of malaria, yellow fever, or typhoid, or the rebellion of the agricultural populace against too demanding rulers. On the fringes of science fiction, it has been suggested that the inhabitants were removed by spacecraft from elsewhere in the universe, during which operation the city and its pyramids were discreetly covered with earth to hide their whereabouts from other travelers from space.

Climatologists maintain that a gradual decline in annual rainfall brought the city to a semi-arid climate in the latter half of the first millennium A.D., that deforestation of the hills caused erosion and a decrease in soil moisture for crops. Certainly the valley around Teotihuacan had once been humid, with vast forests in which game was abundant, with lakes teeming with fish and aquatic birds. One archeologist suggests that the destruction of the surrounding forests was caused by the burning lime that was used to carry out the great building programs in the city. Others suggest that there were repeated invasions of barbarous nomads from the north, one horde of which overwhelmed the city.

Whether or not Toltec tribes could have destroyed the great city, by A.D. 850 they were settling in the area. Millon says that, although at a relatively late date the Citadel underwent architectural modifications which could have been defensive, there is no evidence, except for the slaughtered inhabitants found by Batres in the House of the Priests, of attackers, foreign or otherwise.

Millon and others have wondered whether tensions, antagonisms, and conflicts within apartment compounds—or among people in different compounds, neighborhoods, states, classes, or sectors of the Teotihuacan society—could have posed insoluble problems for the hierarchy in the city and played a significant role in the dissolution of Teotihuacan society. He points out that great clusters of apartment compounds in an urban setting did not survive the fall of Teotihuacan and never again were the basis for a continuing tradition of urban living in central Mexico.

Was it coincidence, archeologists ask, that toward the end of the ninth century some mighty crisis appears to have overcome all the classic civilizations of Mesoamerica, at which time the many gigantic ceremonial centers that were scattered throughout the area, such as Tikal, Uaxactun, Copan, and Palenque, were suddenly abandoned for no known reason, to be devoured by the jungle?

The ninth century has been described by historians as a period in Mesoamerica of degeneration, migrations, mass warfare, long and brutal invasions, followed by terrific confusion.

Toward the end of the century, Toltec tribes appeared in the Valley of Mexico to build on the remains of the Teotihuacan empire, only to vanish three centuries later and be replaced by the Aztecs, leaving the mystery of who the Teotihuacanos may have been and what may have become of them as shrouded today as when their great monuments were sighted by Cortes fleeing Tenochtitlan after the Night of Sorrows.

18. Mathematical Extrapolations

From Millon's map it was clear that the great city of Teotihuacan had been built by master builders according to a thought-out plan. The question remained as to whether such a vast complex with its massive temples might also have served a more special purpose, like Stonehenge, Cheops, or the Tower of Babel. Could Teotihuacan, like other great temples of antiquity, have served as a geodetic and astronomical marker to locate man in space and time, to fit him in the cosmos?

Unlike the Pyramid of Cheops, which has been measured to the millimeter, or the ziggurats of Babylon, for which cuneiform texts give the precise dimensions, no sound dimensional pattern had so far surfaced at Teotihuacan. Yet it was obvious that whoever laid out the city must have used some unit of measure as a yardstick, whether or not it was earth-commensurate as with the Pyramid of Cheops, whose base line of 500 cubits (or 750 Egyptian geographic feet) is exactly the distance traveled by the earth at the equator in half a second of time, there being precisely 86,400 seconds in one 24-hour day and 86,400,000 cubits in the circumference of the earth.

With the exception of Le Plongeon, none of the early diggers and reconstructors of Mexican antiquities since Almaraz—most of whom were intent on finding treasure and uncovering idols—appear to have been aware of the work of Edmé François Jomard, John Taylor, and Charles Piazzi Smyth, or of the controversy over the earth-commensurate dimensions of the Egyptian pyramids.

Unlike Cheops, with its chiseled corner sockets and trigonometrically reconstructable lines, the overgrown and dilapidated stone work at Teotihuacan made it difficult for archeologists to be sure exactly from what spot a piece of stone had been tumbled by vandals, crumbled by rain, bumped by an earthquake, or, indeed, replaced by some builder in remote antiquity.

Though the photogrammetric work of Millon's University of Rochester mapping project supplied a wealth of overall measurements, especially on a very large scale—distances of one to three kilometers—details were better shown in the drawings of Ignacio Marquina's *Prehispanic Architecture,* based on a careful survey of the Citadel area by Pedro Dozal, made with civil-engineering methods in the second and third decade of the century. Marquina considered this earlier data more reliable than the 1960 to 1964 information provided by maps in the files of the Mexican Institute of Anthropology, or even by the 1970 Rochester project.

Marquina, who had directed much of the rebuilding of the Citadel, pointed out that many of the dimensions, especially the longer ones of 150 to 200 meters, could only be considered accurate to within about 1 percent, which meant variations of over a meter.

With such margins of error, it seemed unlikely that a common unit of measure would emerge from Teotihuacan until in 1972 an American engineer, Hugh Harleston, Jr., who had lived a quarter of a century in Mexico and become obsessed with the beauty and challenge of Teotihuacan, hit upon a stratagem. Harleston decided to create a "mathematical model" to superimpose on the field measurement diagrams obtained by Millon and Marquina, on the theory that when and if a large percentage of points coincided with only a small margin of adjustment, a deliberate pattern of relationships might emerge.

To Harleston the key to resolving the problem lay in the *proportions of large measurements;* that is, if he divided the distance between the center of the Sun Pyramid and the center of the Moon Pyramid (almost 800 meters or over 2600 feet) by the overall length of the whole ceremonial zone from north to south (which is a little more than 2400 meters) the result, 2400/800, gives a ratio three to one, which changes very little if either of the distances is wrong by a few meters. Harleston reasoned that a comparison of *proportions* would show significant relationships despite any errors made in the reconstruction, especially if taken over large areas.

The first 3:1 relationship indicated to him to look for a system which might be organized in multiples of three. Taking as a supposition that errors of reconstruction or movements by earthquakes (though the geologists assured him that this had not happened) had shifted the centers between the two main pyramids by no more than 5 or 6 meters, which would make the distance between the top centers 806, instead of 800, and that if one side of the citadel were 402 meters instead of 400, the proportion of 806 to 402 would be 2.005 instead of 2.000, the result would be a proportion that varied by a mere 2/10 of 1 percent, a parameter within which Harleston could obtain valid results.

Already Millon had found what appeared to be a large recurring measure in both residential and semiresidential buildings with walled compounds which ran 57 meters to a side, twice that dimension, or a fraction of it. Longer streets also appeared to be measured off in multiples of 57 meters.

With a draftsman's compass, a pair of dividers, and all the maps he could find, Harleston set his dividers at 57 meters and began a search for further coincidences.

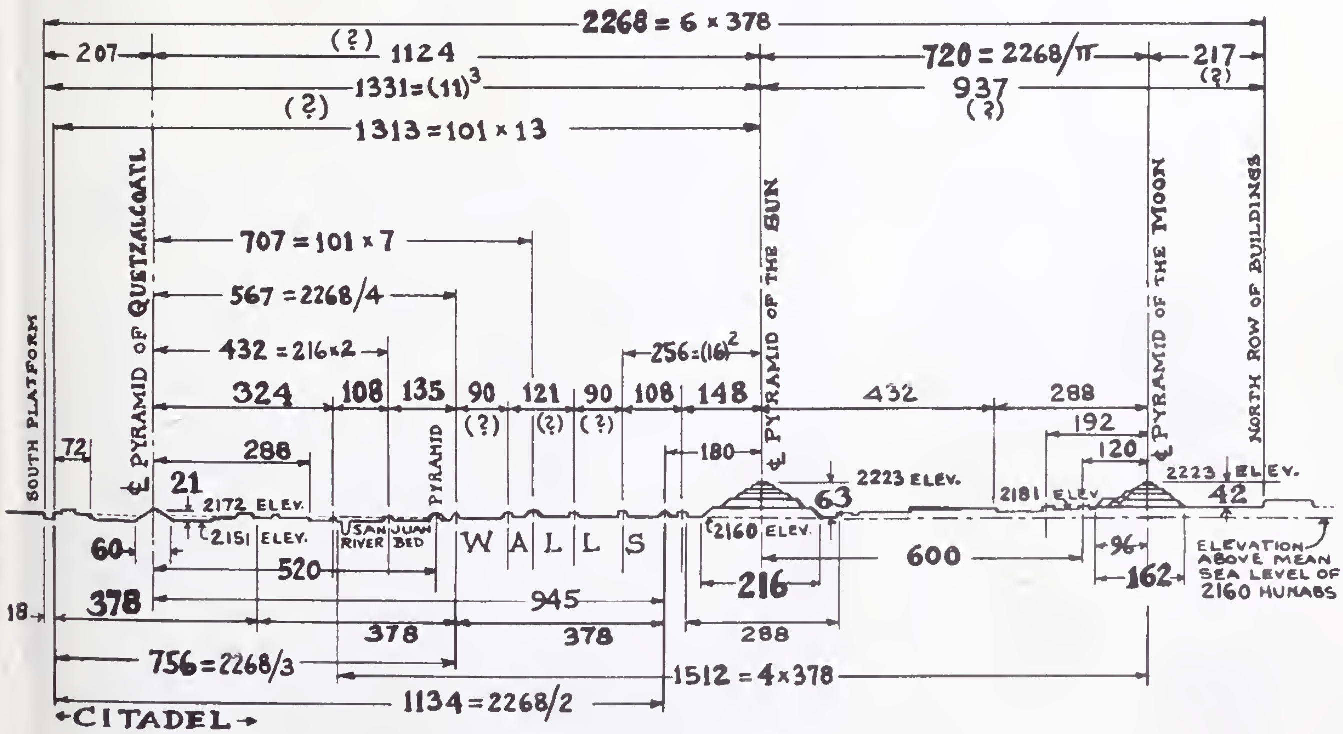
Almost immediately he saw that the north-south base line of the Moon Pyramid was 171 meters, or exactly 3 times 57. The base of the Sun Pyramid, marked on the map as 228 meters, was 4 times 57. The Citadel's wall of 399 meters was 7 times 57. Along the Way of the Dead, Harleston found markers at 114 and 342 meters, which is to say 2 and 6 times 57.

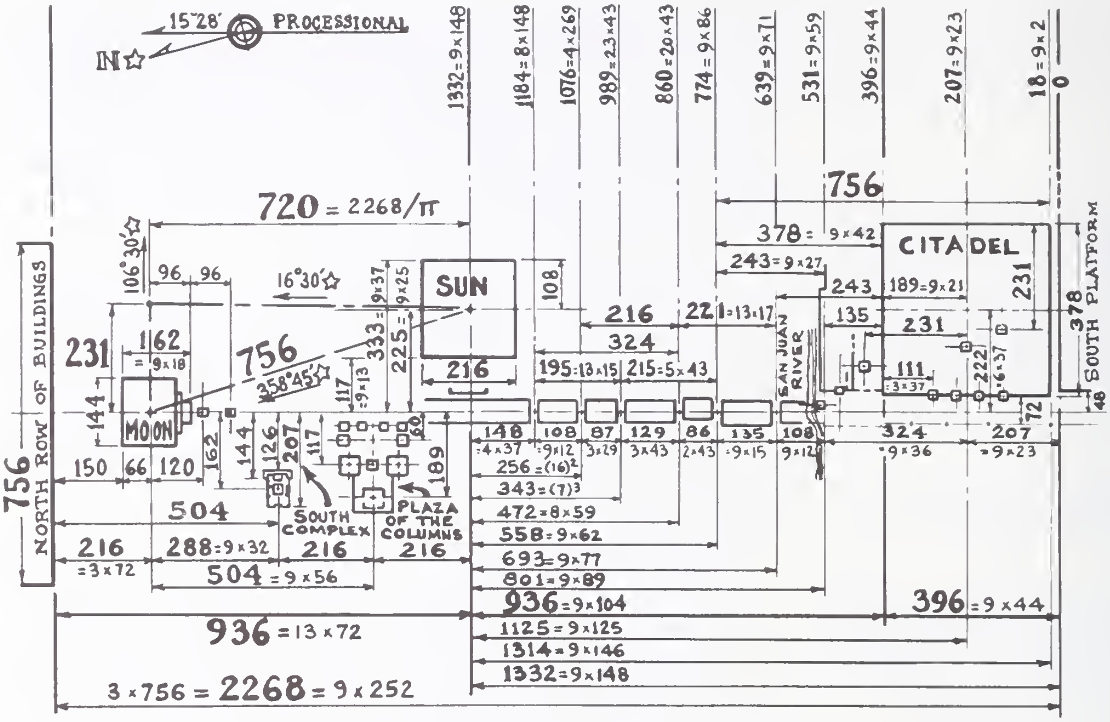
As 57 was clearly a recurrent measure, Harleston looked to see what fraction of it might give him a smaller proportionate measure. As 57 is only divisible by 3, he took the resulting 19 meters and searched with his dividers for any-

Harleston's view from the east of the Way of the Dead with the three major pyramids indicated in round-number distances marked by the center lines of the structures which produced such key numbers as:

162 for the Moon base
216 for the Sun Pyramid
378 for the Citadel.

The overall ceremonial zone of 2268, says Harleston, is equal to 6 Citadels, or 14 times the base of the Moon Pyramid. Individual walls along the way also show factors of 2268 including 2268/720 which is the direct line from the center of the Sun to the center of the Moon Pyramid or 3.15, evidently an easy figure for π, or the constant relation of diameter to circumference.





Sun Pyramid.

Harleston found that if he started at the Sun Pyramid and went south measuring walls, he got a significant set of numbers as far as the north face of the last big platform found and shown by Millon on his first map, which Harleston recognized as a clearly marked Ceremonial Avenue, 18 units beyond the Citadel wall. Measuring back from this point, Harleston was surprised to get a series of multiples of 9. This indicated to him some purposeful meaning which was only to become clear to him later. Meanwhile he noticed that most of the prime dimensional numbers in the Teotihuacan complex added up to 9: 162, 207, 216, 225, 369, 504, 531, 639, 720, 801, 936, 1125, 1314, 1332, etc.

thing that matched. In the Citadel and around the Moon Plaza he quickly found several platforms that were exactly 19 meters square. Assuming he might be on the right track, Harleston looked for a yet smaller measure. Dividing 19 by 3, the resulting 6.333 was at first sight unrewarding, until it struck him as being very close to the 6356-kilometer polar radius of the earth deduced by Sir John Herschel and Piazzi Smyth in their study of the geodetic values of the Great Pyramid of Cheops. Could the Teotihuacanos, Harleston wondered, have used as a basic unit of measure a fraction of the polar radius such as Herschel's and Newton's "sacred cubit" of .6356 meters, 10 million of which make a polar radius? The idea was intriguing, except for the fact that there seemed to be no other indication of a decimal system in the Teotihuacan figures: only 3s, 6s, and 9s.

Looking for a shorter unit, Harleston divided 6.356 meters by 6 and obtained a figure of 1.059, again a surprising result, for this was a very significant quantity in the realm of the mathematician, virtually the twelfth root of 2—a number which multiplied by itself 12 times gives a product of 2. Harleston wondered if the ancient builders of Teotihuacan might have arrived at such a basic unit by dividing the polar diameter of the earth not into 20 million parts as postulated by Herschel and Smyth for a unit of .6356 meters, but into 12 million parts for a unit of 1.059 meters. For neither one of these units was knowledge of the meter required; but Harleston had to use some conventional unit to work with

Moon Pyramid.

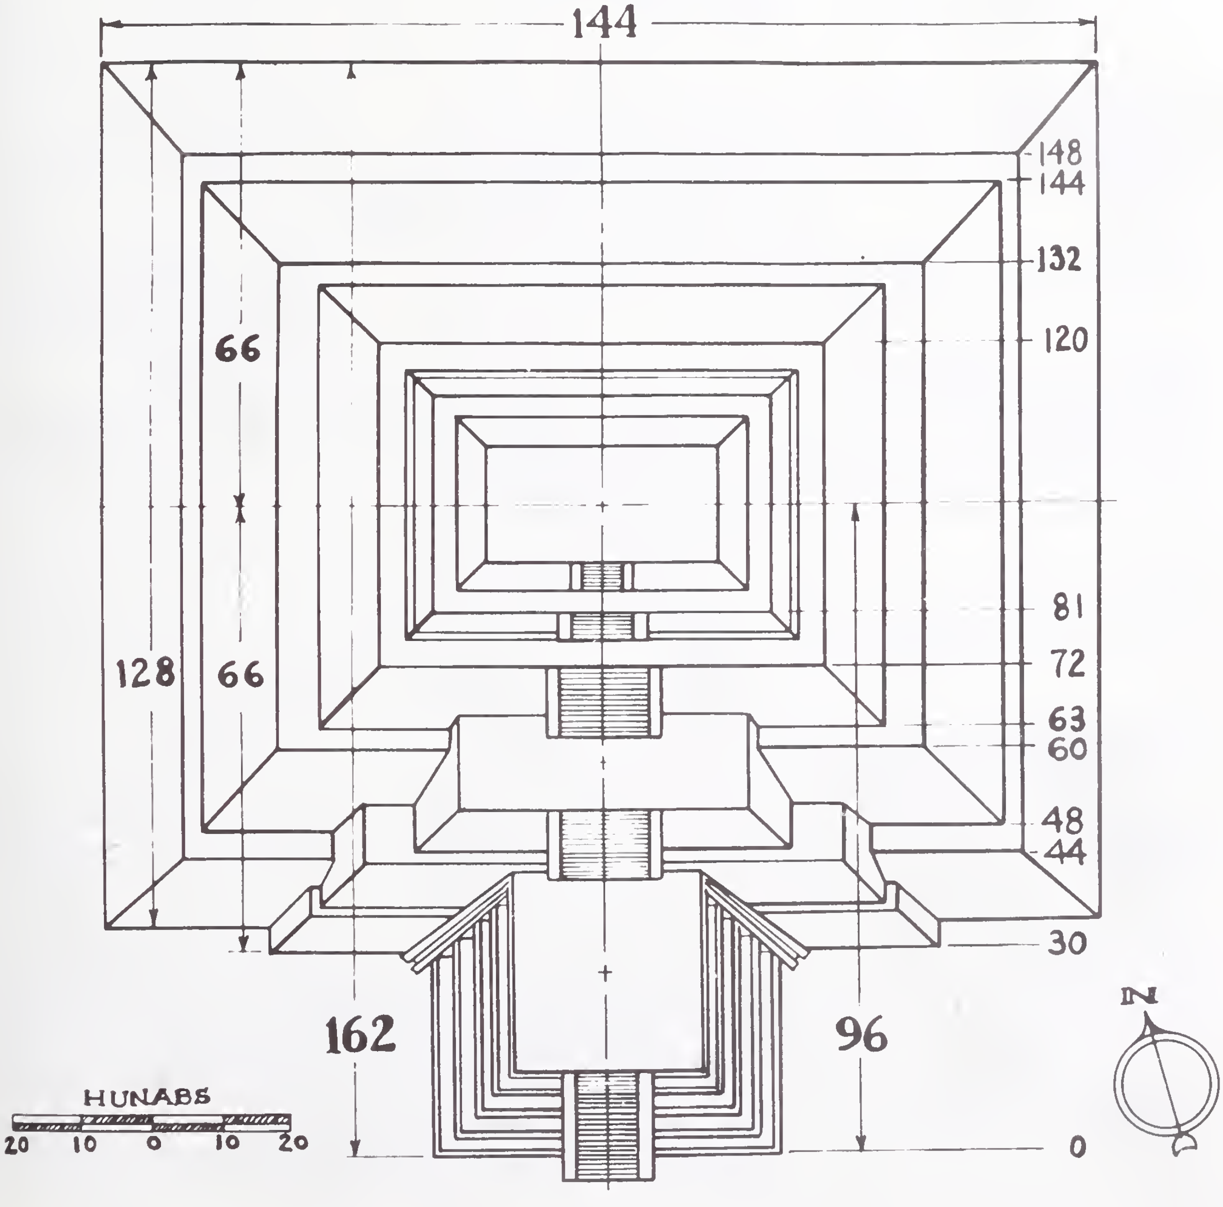
Harleston found that the edge lengths of the Moon Pyramid, from south to north, using the third *adosado*'s southern edge as a base zero point, repeated the same modules used at the Citadel and the Sun Pyramid: 30, 48, 60, 72, 81, 128, 132, and 162 STU. He found that the dimension 132 STU duplicates the distance from the center of the Quetzalcoatl Pyramid to the east edge of the Citadel, and can be factored into 11 × 12, 2 × 66, and 3 × 44.

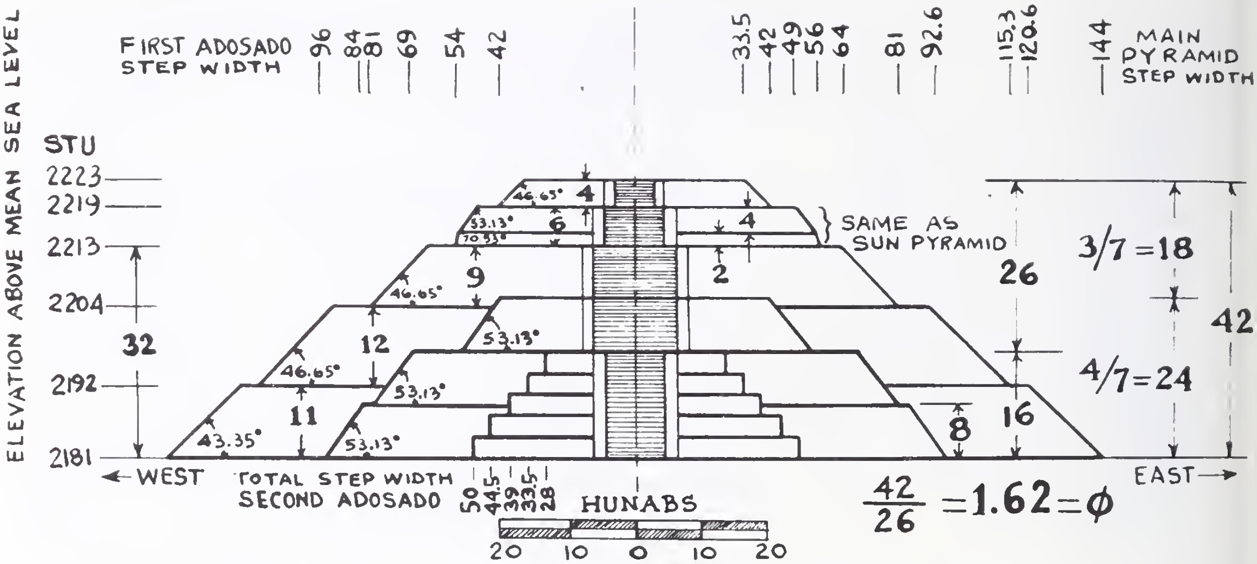
and choose to translate what he found in terms of the meter instead of the foot or the cubit, both of which are more inspired units, because the world has largely and unfortunately adopted the meter as its basic unit of measure.

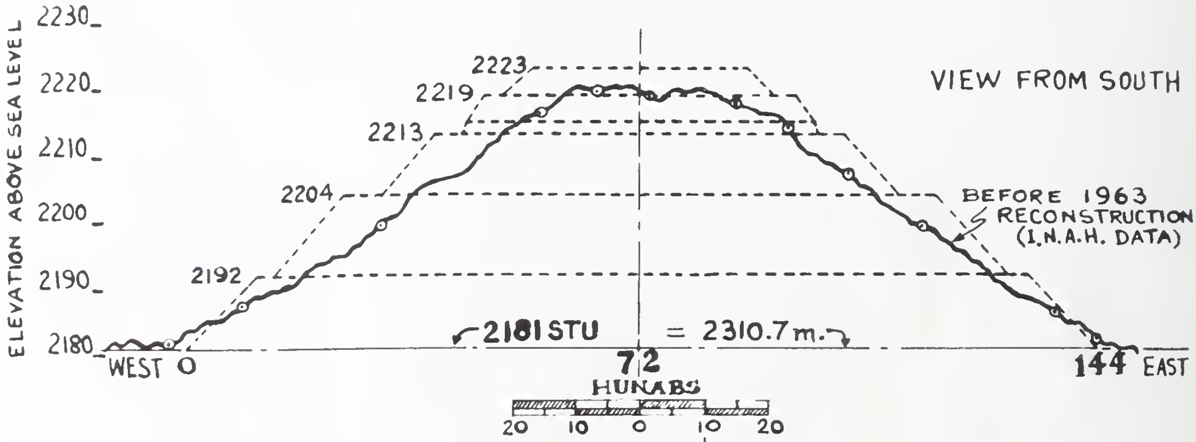
To check his theory that the Teotihuacanos had used a unit equivalent to 1.059 meters, Harleston set about measuring lengths of buildings, walls, and platforms on the basis of such a unit. Immediately he obtained modules of 18, 24, 54, 72, 108, 144, 162, 216, and 378, all in round numbers.

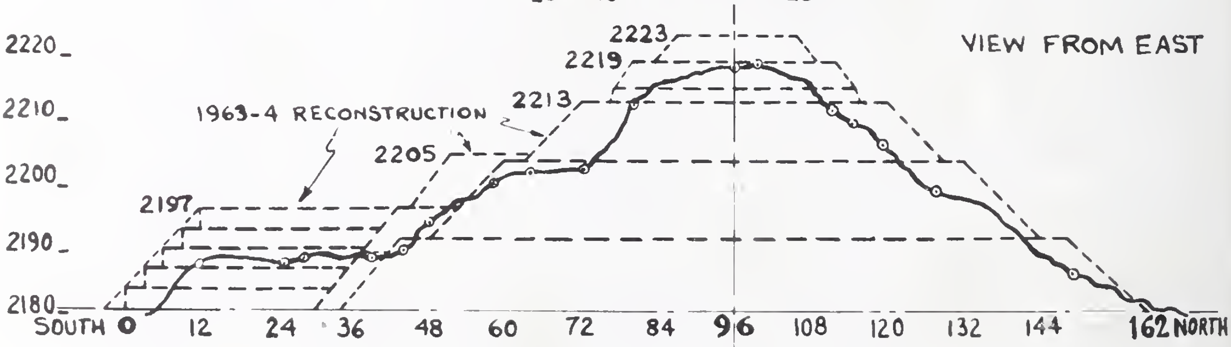
The Moon Pyramid, as carefully reconstructed by Salazar, gave Harleston lengths of 30, 48, 60, 63, 72, 81, 96, and 144 units, with a major north-south base of 162 units.

In the plaza at the foot of the Moon Pyramid, various temples each measured 18 by 18, for an area of 324 square units.









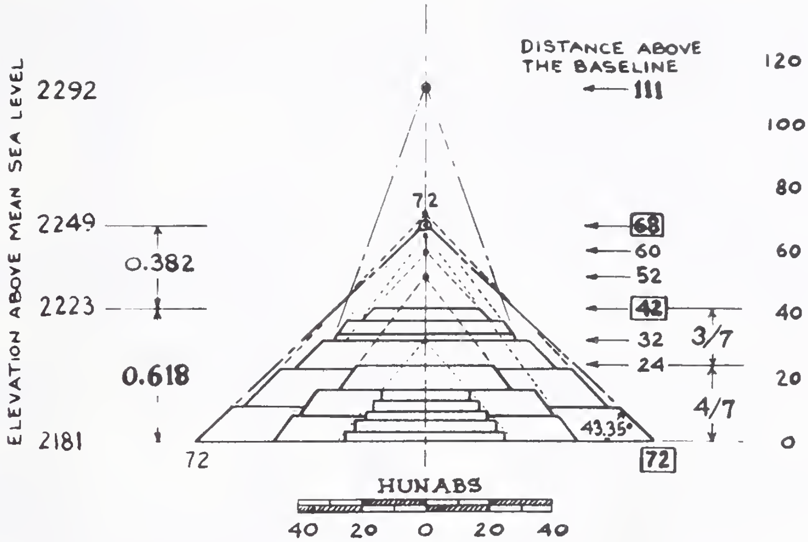
At the Sun Pyramid, measurements of the base and upper levels of each body duplicated measurements at the Citadel and the Moon Pyramid, indicating a logical series of 9, 12, 18, 27, 36, 54, 81 and 108, all multiples of 3. Lengths of 162 and 216 repeated lengths at the Moon Pyramid and the Citadel, adding up to 378, the overall length of the walls of the Citadel.

In his mathematical reconstruction of the Moon Pyramid, Harleston followed the basic principles of restoration outlined by Mexican archeologist Ponciano Salazar, who rebuilt the Moon Pyramid in 1964, maintaining the same lengths, heights, and original angles. But composite data yielded a more probable configuration with the top of the reconstructed Moon Pyramid at the same elevation above sea level as the Sun Pyramid, its base being higher than that of the Sun Pyramid. The Moon Pyramid is thus formed of thirteen basic components: the main pyramidal mass consisting of five bodies, the first *adosado* on the south side made up of three bodies, followed by a secondary *adosado* of five more bodies.

In Harleston's reconstruction, the first *adosado*'s height divides the Moon Pyramid vertically into 3/7 and 4/7, proportions shown horizontally by the west base line of the Quetzalcoatl Pyramid that cuts the Citadel into 162 STU to the east and 216 STU to the west. The north-to-south base of the Moon Pyramid, including the *adosados*, measures 162 STU and the base line of the Sun Pyramid is 216 STU, again giving the same proportions of 162/378 and 216/378 or 3/7 and 4/7.

The face angles of the Moon's first body are sloped at 43.35 degrees, the same as the Sun Pyramid. In Harleston's reconstruction, the projection of the sides to an overhead intersection point shows a triangular height of 68 STU. This means that the proportion of the 42-*hunab* truncated height becomes 68/42, again 1.62, the golden mean.

Combination of the heights of the Moon Pyramid's thirteen bodies gave Harleston values that cover a range of numbers from 2 to 42, reflecting major modules that appeared as significant factors throughout Teotihuacan matching other cosmic correlations.



$$\frac{72}{68} = 1.059 = \sqrt[12]{2} \qquad \frac{68}{42} = 1.62 = \phi$$

Along the Way of the Dead, boundary markers appeared at 378 and at twice 378, or 756 units. The overall length of the ceremonial zone was 6 times 378, or 36 times 63, the height of the Sun Pyramid.

The north-south length of the Moon Pyramid, the familiar 162, multiplied by 14 was also 2268, the length of the ceremonial area.

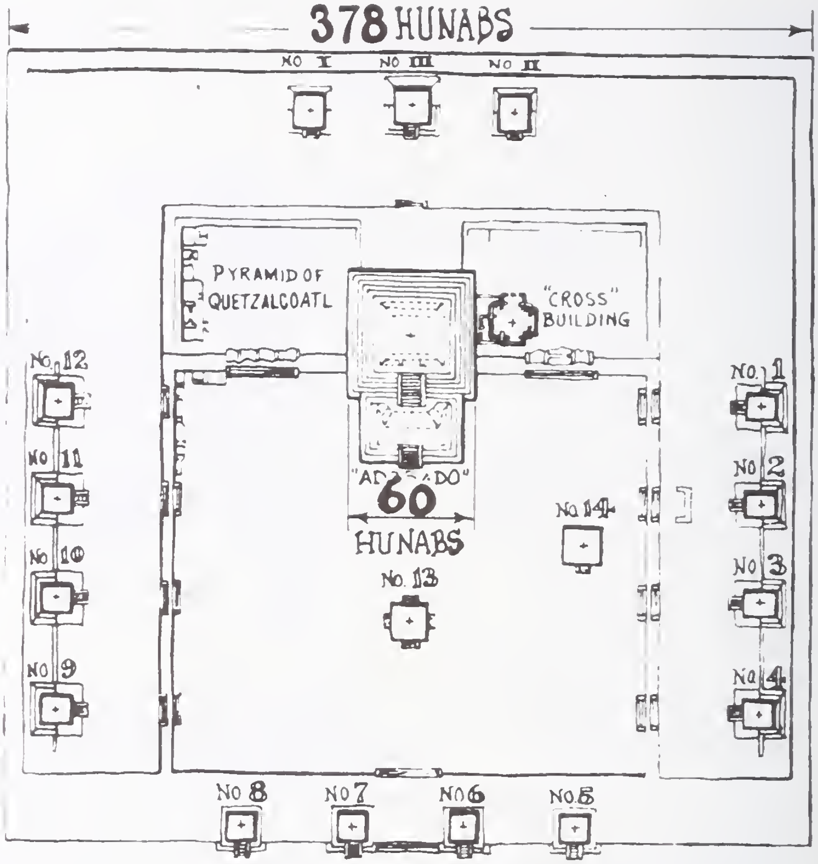
Behind the Moon Pyramid a row of buildings, almost perpendicular to the main north-south avenue, ran east and west. Harleston found that these boundary buildings ran 378 units both ways, totaling 756 units, twice the width of the Citadel, equal to the distance from the center of the Sun Pyramid to the center of the Moon Pyramid.

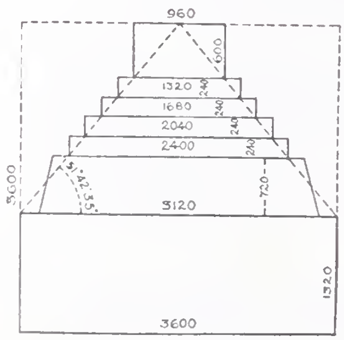
Convinced now that he had hit upon a possible Standard Unit of Measure or STU of the builders of Teotihuacan, Harleston named the unit a *hunab,* the Mayan word for "unified measure."

Studying the figures obtained from the Citadel, Harleston noticed that 378 times his basic unit multiplied by 100,000 gave a very accurate figure for the circumference of the planet, whose average spherical circumference is 40,049,589.35 meters. Harleston then found that the 60-unit base of the Quetzalcoatl Pyramid multiplied by 100,000 gave the polar radius of the earth. This led him to wonder whether the Pyramid of Quetzalcoatl, like the Pyramid of Cheops and the stepped ziggurats of Mesopotamia, could have been designed as a scale model of the earth, part of a citadel designed to incorporate mathematical, geodetic, astronomical, and possibly cosmic data.

Harleston decided the Citadel might include an earth-commensurate unit when he figured that the 378 *hunab* length of the Citadel divided by the 60 *hunabs* of the Quetzalcoatl Pyramid could represent the circumference of the earth divided by twice its radius, or 378 ÷ 120, which gives a value for π of 3.15.

But he overlooked the fact that the length of the Citadel wall is also 1296 Egyptian feet, or 864 cubits, lengths used by the Egyptians and Mesopotamians to compute the circumference of the earth.

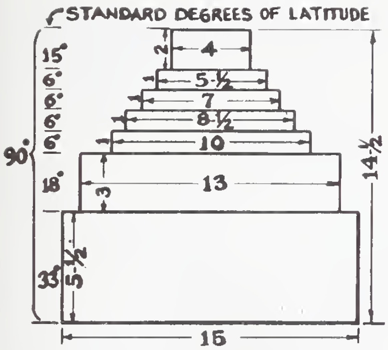




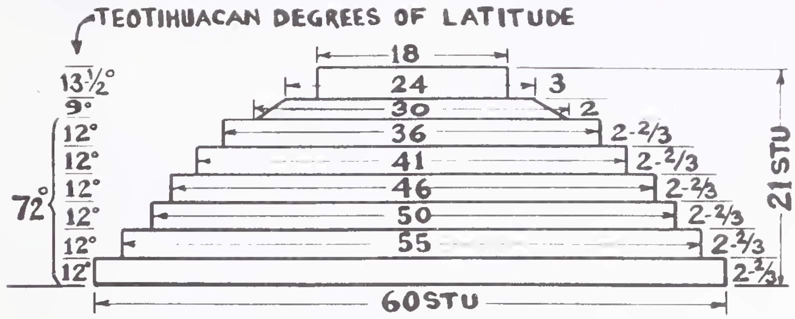
As with the ziggurats of Babylon, the square base of the Quetzalcoatl Pyramid covers exactly 3600 square units of Harleston's measure, equal to 43,482 square English feet, which is virtually an English acre. It also compares with the Mesopotamian land measure of 60 double cubits, as shown in the Babylonian ziggurats documented in the Smith cuneiform tablet.

As the Babylonians used each face of a stepped pyramid to represent a 90-degree quadrant or hemisphere of the earth, dividing the area between the equator and the North Pole into seven bands or zones, each diminishing in width to correspond to the shrinking degree of longitude, Harleston decided to check the reconstruction of the Quetzalcoatl Pyramid to see if the same system might apply.

The elevation plans of the Quetzalcoatl Pyramid made by the Mexican Institute of Anthropology show a structure rising in six tiers to 17 meters, on top of which rests a seventh structure of 5 meters, for a total of 22 meters, or 21 of Harleston's units. However, as the precise corners of the lower six levels have not been restored, it was necessary for Harleston to use the east-west values of the rebuilt horizontal face widths to arrive at a probable original length for each step.



BABYLONIAN ZIGGURAT
(RELATIVE PROPORTIONS)



PYRAMID OF QUETZALCOATL
(ACTUAL DIMENSIONS)

Temple of Jupiter Belus. The lengths of the seven stages of this Babylonian ziggurat were found inscribed on a palette by George Smith, F.R.G.S., according to which the area of the lowest section was 3600 × 3600 inches, or 12,960,000 inches.

The Quetzalcoatl Pyramid, as reconstructed by the Mexican architect and archeologist Ignacio Marquina in the 1920s, was also made in seven stages. The ziggurats at Ur, Uruk, and Babylon were as high as 300 feet (91 meters), equivalent to a 25-story building. This compares to Teotihuacan's Sun Pyramid at 18 stories. As Livio Stecchini has shown, the stepped pyramid, or ziggurat, transfers curved data to a flat surface in order to make a projection of an earth hemisphere with a minimum of distortion. Each main step face represents a 90-degree quadrant, and the levels can represent the zone between two parallels of latitude, in a series of mercator projections.

The Babylonians divided the area between the equator and the North Pole into seven bands, or zones, each diminishing in width to correspond to the shrinking degree of longitude. The base line corresponded to the equator, and the first step to the 30th parallel. The ziggurat in Mesopotamia raised the first step to a height corresponding to 33 degrees of latitude instead of 30 degrees, since 33 degrees was the location of Babylon. Thereafter each step rose in units of 6 degrees of latitude. By dividing the length of the step by 2/3, an easily remembered calculation of the cosine value of the latitude is obtained.

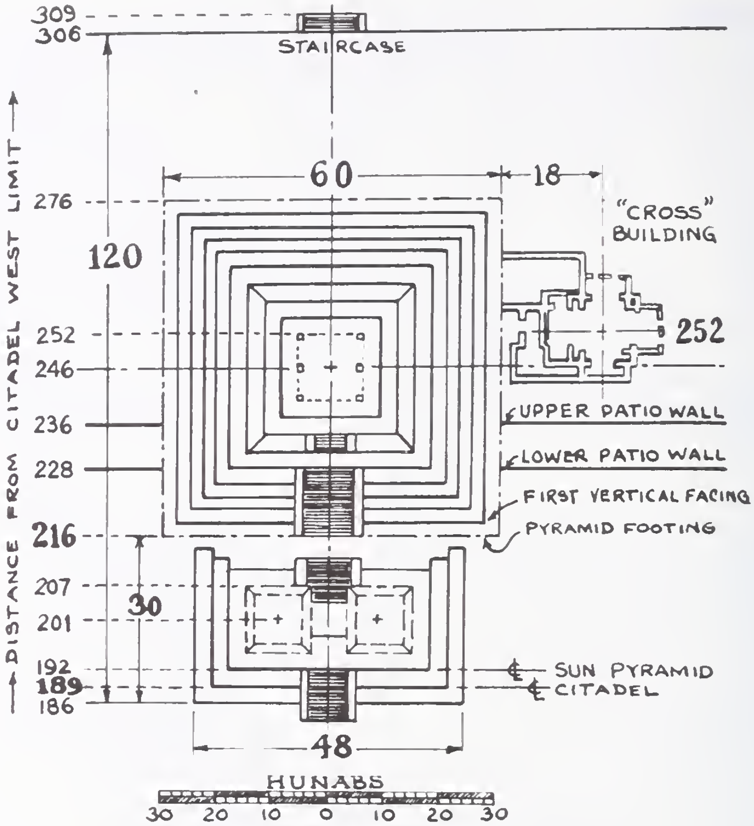
The Babylonian ziggurats incorporated a series of map projections several thousand years before modern cartography was refined in Europe during the eighteenth century. The Naba ziggurat at Barsipki was made in seven stages, and was said to have been painted with seven "planetary colors."

The Babylonians preferred counting in sixes, and their mathematical systems were hexagesimal and heptagesimal; that is sixes and sevens. This preference was apparently also characteristic of the Egyptians. Livio Stecchini shows how the degrees of latitude of a parallel represented by each ziggurat step can be obtained by multiplying the step height by 6. Thus 6 × 5 1/2 becomes 33 degrees of latitude for the first step.

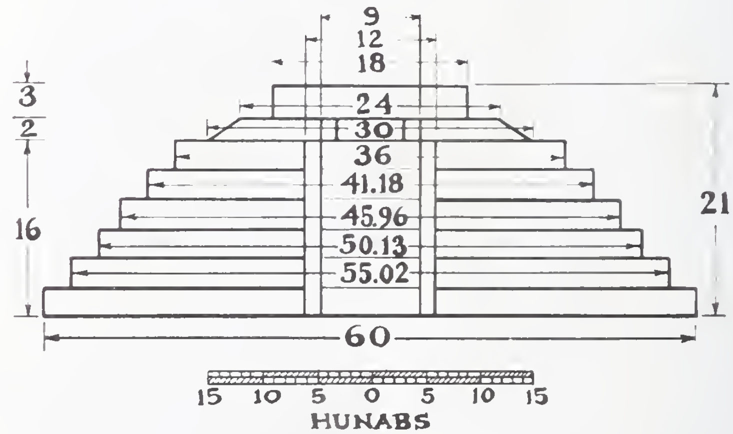
A similar system emerges at the Pyramid of Quetzalcoatl in Mexico. The elevation and plan views of the Mexican Institute of Anthropology allow converted measurements that show the height of the known steps in six tiers to total 17 meters, with a seventh structure of somewhat more than 5 meters on top. In Harleston's units each main vertical step becomes 2 2/3 *hunabs*, and the upper structure of 5 *hunabs* makes the pyramid 21 *hunabs* high, or 7 × 3. Since 21 *hunabs* represent 90 degrees of latitude, each step becomes 11 3/7 degrees of latitude.

Step No.	Step Length	Cosine	Latitude Angle, Std Degrees	Denotes
1	15	1.0000	00.00	Equator
2	13	0.8667	29.93	Thirtieth Parallel
3	10	0.6667	48.19	
4	8½	0.5667	55.48	°Lat. = °Long. (Equator)
5	7	0.4667	62.18	
6	5½	0.3667	68.49	
7	4	0.2667	74.53	Magnetic Pole

Harleston's reconstructed plan of the Pyramid of Quetzalcoatl with measurements in *hunabs*. However, when measured in Egyptian units, the width becomes a very interesting 204 feet, or 136 cubits, and its height 72 feet, or 48 cubits.

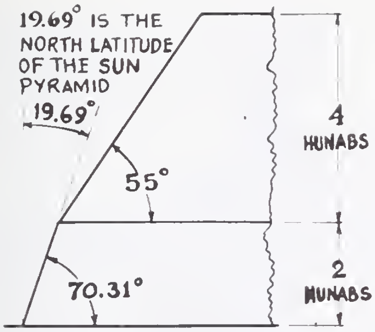


Harleston's reconstruction shows that the steps of the Quetzalcoatl Pyramid may have been designed to rise in lengths which indicated various important latitudes on the planet. When measured in *hunabs* the steps rise in increments of 2 1/3. But when measured in palms, they rise evenly in units of 24 from a base of 360 palms.



From the various figures given by the Mexican Institute, Harleston made several mathematical reconstructions until he arrived at one which seemed closest to what the original might have looked like.

To find the angle, or latitude, represented by the various steps, Harleston divided the length of each step by 60 to obtain the cosine of the angle of that latitude. The first step produced a result of 23.449 degrees, which corresponds to the latitude of the Tropic of Cancer. Other steps gave the latitude of the Arctic Circle, and the magnetic pole. The system appeared to be the same as that of the Babylonians.



Sun Pyramid's fourth body.

This still did not necessarily prove that Harleston's unit of 1.059 was the unit actually used by the builders of Teotihuacan; if the proportions were correct, the results would check out with whatever unit of measure had been used. But it did indicate that the Quetzalcoatl Pyramid had the measurements of an earth-commensurate model, like the ziggurats and pyramids of the Middle East.

To see what information might be keyed into the Sun and Moon pyramids, Harleston made composite reconstructions of them using minor deviations from the restorations made by the Mexican Institute of Anthropology. On the Sun Pyramid he replaced the amounts of missing material which the literature indicated had been removed by Batres from the first, second, and third levels.

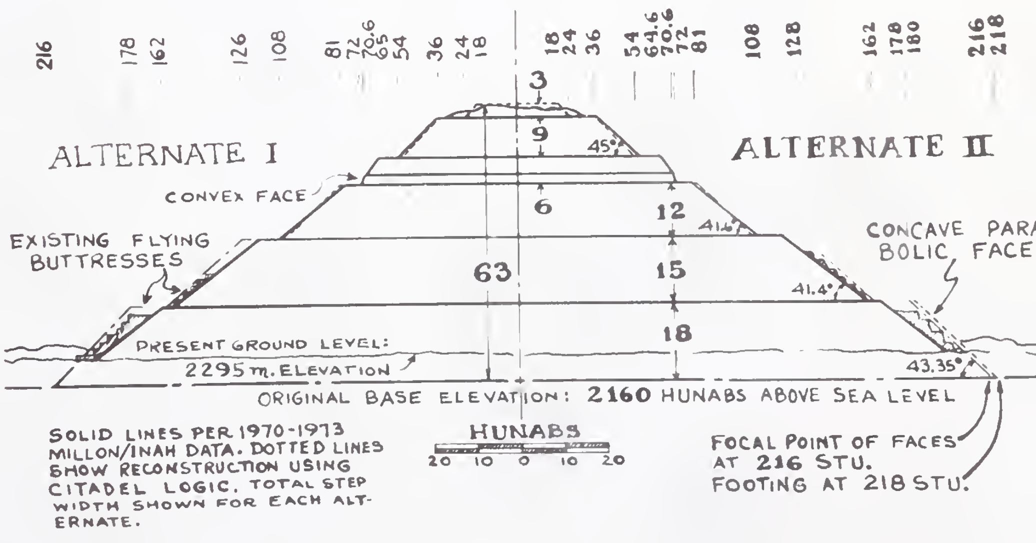
Immediately he noted a 1-2-3 relation between the Quetzalcoatl, Moon, and Sun pyramids, which turned out to be respectively 21, 42, and 63 units high, measured in his *hunabs*.

But it did not occur to Harleston that these same figures also gave 48, 96 and 144 of the ancient Egyptian cubit of .462 meters on which the great Pyramid of Cheops is built.

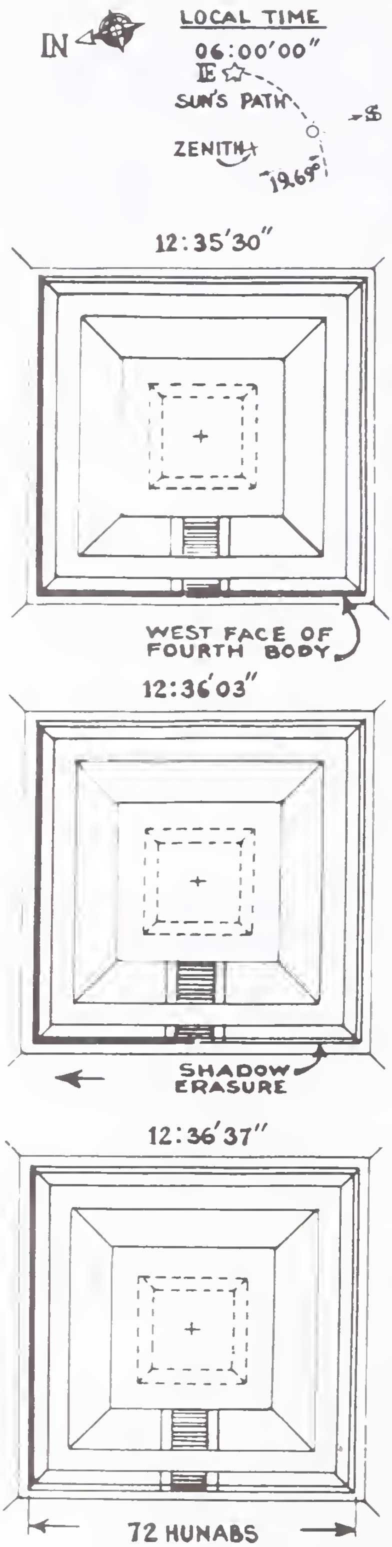
On the fourth body, Harleston felt that Batres had actually conserved practically the "original" positions of the stones (as he stoutly affirmed to his critics) and that the original design was close to what is seen today.

Noting that the lower portion of the fourth level was slightly convex and that it formed a triangle with an angle of almost 19.69 degrees to the vertical, it struck Harleston that this was also the latitude of Teotihuacan. This meant that when the sun crossed the pyramid at the equinox its rays would fall onto the north face of the fourth body at the same angle of 19.69 degrees to the vertical.

To observe what would actually happen at the equinox,



Conversion of the Sun Pyramid's metric measurements to *hunabs* is shown by Harleston's theoretical reconstruction. The solid lines indicate the restoration by Batres in 1906 to 1910, and by the Mexican Institute of Anthropology and History in 1963 to 1964. The dotted lines use the Citadel logic and are based on refilling almost exactly the parts left off. The flying buttresses formed retaining walls for the missing material that would have cost too much money and time to have restored in 1910. The mathematically sequenced lengths of the pyramidal bodies follow a series of increasing sums. The individual heights and also the elevations above sea level are factors of the number 3.



Manner in which the shadow on the lower part of the fourth body of the Sun Pyramid—a constant and boldly outlined feature of the structure—is eliminated at the equinox.

Hugh Harleston, Jr., showing lower fourth level in shadow. The only two shadows on the Sun Pyramid at midday on the equinoxes (March 21 and September 23) are on the western and northern faces, as seen in the above photograph of Hugh Harleston, Jr. The shadows appear only on the lower part of the fourth body. The shadow on the west face is removed by the advancing sunlight within a time lapse that suggested to Harleston that the designers divided a minute into 63 of their seconds (67 Newtonian seconds), the same number as the height of the Sun Pyramid itself in *hunabs*. The shadow on the north face is not removed until two days after the equinox, when it "flashes" on and off at midday, signaling the event and providing a calendar count correction twice a year, making of the Pyramid a living clock.

Harleston noted that the phenomenon in fact took place two days after the equinox. As the shadow did not wipe on the actual day, it meant the angle of the slope was 19.5 instead of 19.7, which could have been an error in reconstruction, or the angle was intended to convey some other meaning. However, observing the west face of the pyramid at the equinox, Harleston was able to witness a unique effect. As the sun crossed the zenith at 12:35′ 30″ (local noon at the longitude of Teotihuacan), the lower west part of the fourth face of the pyramid, which is in shadow during the morning, became illuminated as the sun's rays moved from south to north. The whole effect occurred in 66.6 seconds, a phenomenon which makes the Sun Pyramid a perennial clock, still transmitting its silent message, exactly as does the Great Pyramid of Cheops, or as does the south corner of the Castillo at Chichen Itza, each equinoctial day of the year. All these structures would have had to be designed by architects aware of the considerable astronomical and geodetic data required to achieve such effects—*before* the buildings were begun.

Harleston's analysis, interesting as it might be, remained

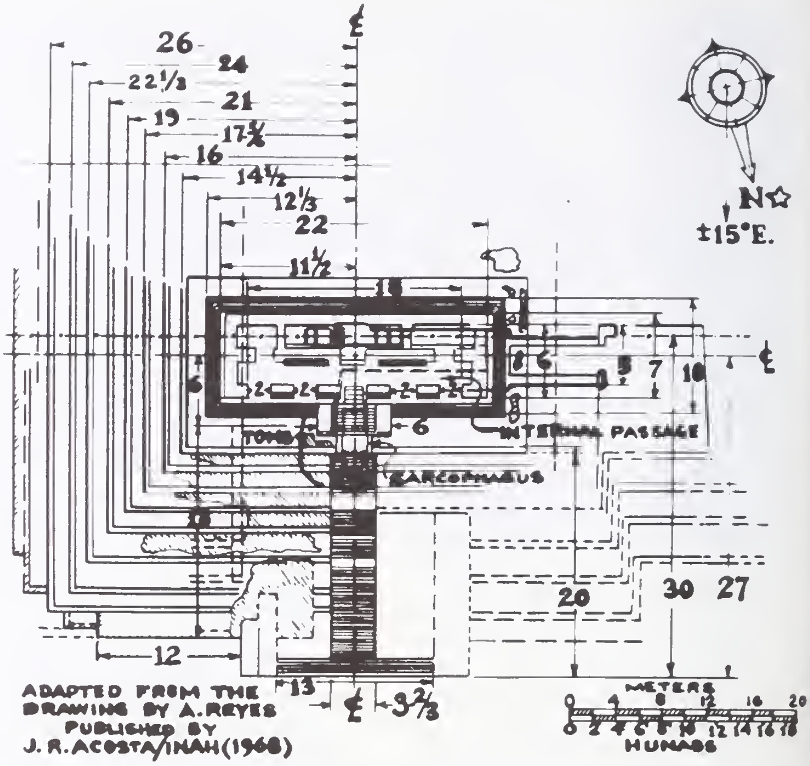
Harleston measuring Citadel.

circumstantial. There was no valid substantiation of his notion that the builders of Teotihuacan used the twelfth root of 2 as their constant, and it seemed hardly possible that they could have arrived at it as he had by means of the meter—or 1.059 thereof. Furthermore, as there appears to have been a great deal of intercourse between the Middle East and Mesoamerica, with a flow of technicians as well as religious and philosophical notions, it seemed reasonable to assume that any earth-commensurate unit used in Mesoamerica be related to the unit used in the building of the Great Pyramid of Cheops, or at least to have been derived from some common source. By applying to the Teotihuacan complex the ancient Egyptian geographic foot, of which there are 750 built into the base of the Pyramid of Cheops, the results were surprising. The most definite measure in the Teotihuacan complex is the width of the Citadel, given by Marquina as 399.48 meters (and by Harleston as 378 of his *hunabs*). Measured in the geographic feet of the Great Pyramid (or of the entire ancient world) 399.48 meters is 1296 feet or 864 cubits.

Here were the figures used by the ancients to define the circumference of the earth in both seconds of arc and seconds of time, the numbers from which they derived both their foot and their cubit. These two numbers, 1296 and 864, are basic to the entire ancient system of measures. Elsewhere in the Teotihuacan complex the foot and the cubit appear in easy and significant numbers. Harleston and Marquina's 800.6-meter distance between the Sun and the Moon Pyramids is 2600 ancient geographic feet.

The Quetzalcoatl Pyramid as measured by Harleston (on the basis of INAH's data) gives a width of 204 feet or 136 cubits. Its height comes to 72 feet or 48 cubits, figures that are every bit as significant as Harleston's. By his reconstructed measures, translated into geographic feet and cubits, the Moon Pyramid's height would be 144 feet or 96 cubits. Its reconstructed width, which is arbitrary, would be 558 feet or 372 cubits. The Sun Pyramid comes out to be 216 feet high or 144 cubits, all figures which Harleston considers significant. As there is still no known way of accurately measuring the base of the Sun Pyramid, of which only the northwest corner has so far been found, it may be idle to speculate on its length, but *if* it were to be the 218 *hunabs* postulated by Harleston, it would be almost to the millimeter the length of the Great Pyramid of Cheops: 750 feet or 500 cubits.

Even more startling is a transfer to feet and cubits of Harleston's reconstruction of the Palenque Temple of the Inscriptions. Whereas his measurements in *hunabs* come out to a mostly uneven 26, 21, 17 5/6, 14 1/2, 12 1/3, 11 1/2, Temple of the Inscriptions at Palenque showing measurements made by Harleston in *hunabs* of 1.059 meters, which come out in random fractions. Computed in Egyptian feet and cubits the same measures give an extraordinary progression of even numbers from 12 to 90.



3 2/3, when measured in the geographic feet of the Egyptians, these same numbers come out to a round 90, 72, 60, 50, 42, 40, and 12.

As the ancient foot and cubit were divided into palms and fingers and the Aztecs also had palms and fingers, the same divisions may have been used by the Teotihuacanos: if measured in palms all Teotihuacan measurement numbers would simply be increased by a factor of six, or by a factor of 24 if measured in fingers. The ancient Middle Eastern finger of .01925 of a meter is one of the most indelible measures: 96 fingers equal their fathom, 9600 fingers their stadium, and 96,000 fingers their mile; 21,600 of these miles, or 60 × 360, will take you around the world. The Arabs also divided their finger into 6 grains of barley or 36 hairs of a camel; thus their cubit was equal to 864 hairs of a camel, whereas the circumference of the earth was 86,400,000 cubits, or 100,000 times the Teotihuacan width of the Citadel in cubits.

Evidence for the use of finger, palm, foot, cubit, and fathom in Mesoamerica is solid as a pyramid.

Dr. Daniel G. Brinton, head of the Archeology Department of the University of Pennsylvania, in his *Essays of an Americanist,* published in 1890, is unequivocal about the unit of the Aztecs: "the foot measure was adopted as the official and obligatory standard both in commerce and architecture." To which he adds that there is ample evidence that it was "widely recognised, very exact, and officially defined and protected." Quoting Herrera, he shows that, just as in the Hebraic world, anyone in the Aztec world who falsified units of measure was considered a public thief, an enemy of the community, and severely punished.

After a long and careful study of the subject, Brinton concluded that the foot and the cubit (of a foot-and-a-half) had been the basic units of measure not only of the Aztecs but of the Maya and the Cakchiquels (among whom he includes the Quiche and the Tzutahil). To this he added that "the Aztec terms for lineal standard being apparently of Maya origin, suggests that their standard was derived from that nation."

The Mayan foot was the *oc*. Their cubit was the *cuc* or *noch cuc,* which Brinton describes as being about 18 inches, or a foot-and-a-half. Their fathom of six feet was a *zap* or *zapoul;* half a fathom or *betan* was their three-foot yard.

A *kaan* was 36 fathoms square, and 20 *kaan* made a *vinic,* the area of land needed by a man to support one family in corn. According to Brinton, the smallest Maya units of lineal measure were the finger breadth or *u nü kab,* and the thumb breadth *u na kab,* our inch or French *pouce.* The Maya also had three different spans of which the most used was the *nab,* from tip of thumb to tip of index; but they also had the *chi nab,* from thumb tip to little finger tip, and the *kok:* closed finger palm with extended thumb.

Father Thomas Coto expressly states that the cubit or *chumay* was the customary building measure among the Cakchiquels. "When they build their houses they use this cubit to measure the length of the logs. They also measure ropes in the same manner." Cakchiquel fields were marked off in fathoms of four cubits, and a three-fathom unit was a circle around a man with outstretched arms. The Aztecs also had the finger, span, and foot, as well as the cubit which they called *cemmolicipitl,* from *ce* = one and *molicipitl* = elbow. Their fathom was the *cemmatl,* and a half-fathom or yard the *cenyollatli.* For measuring longer lengths they used the *octacatl,* and though the unit has not been identified, Brinton believed that because *oc* is the Mayan for foot, it may have been a ten-foot length, a unit of which he found considerable evidence in the Americas.

Father Duran reports that along the Aztec highways, there were posts or stones erected with marks upon them showing how many of these stops there were to the next market town, a system employed throughout the Middle East. Unfortunately Duran did not measure or find out the distance between two such markers.

If it seems astounding that no one quickly established just what the Aztec unit of measure might have been, as related to European or any other measure, it must be remembered that it is a perennial and fundamental rule among conquerors to obliterate their victim's system of measures and place on the ruins of their sacred temples new structures built with an imposed system of measures.

It would have been pleasant to leave the matter there, but a possible complication may eventually lead to even further clarity. The Egyptians, or Middle Easterners, had a unit of 40 fingers called a *bema* whose length was .77 of a meter, 300 of which fit exactly into the base of the Great Pyramid; it was widely employed as a measure equal to ten palms.

If Harleston's *hunab* is divided into 60 fingers, a unit of .01765 meters is obtained, which is virtually the Aztec finger, as reported by V. M. Castillo in his *Unidades Nohuas de Medida,* ten of which make an Aztec *bema* of .706 meter. When applied to both the Teotihuacan and Palenque complexes, Aztec fingers, palms and *bemas* give even more significant results than Harleston's *hunab.*

The Quetzalcoatl Pyramid base, instead of being 60 *hunabs* becomes a more rational 90 *bemas* or 360 palms, and its steps rise in increments of 4 *bemas* instead of 2 1/3 *hunabs*. The perimeter of the Sun Pyramid becomes 12,960 *bemas* and its base length 1296 fingers. As the numbers 1296 and 864 were the key to unraveling the astronomical and geodetic secrets of the Great Pyramid, they may in due course resolve the mysteries of the Mesoamerican Pyramids.

Is it a coincidence that a circle of 1,296,000 units has a radius of 2,06,265 units and that 20.6264 is the length of both an English and Egyptian cubit, that the Hebrew shekel weighs 129.6 grams, and the English guinea 129.6 grains, and the measure of the Most Holy in Solomon's Temple is 1296 inches?

Not only was the number 129600 the numeric basis for astronomical measurements as far back as the records are traceable, it was also the favorite number in Plato's mystic symbolism. W. H. Wood, in his *Ideal Metrology,* says the multiples and submultiples of 12960, which are easily memorized—1728, 864, 720, 432, 360, 216, 180, 90, 40, 36, 20, 16, 10, 8, 5, 4, 2—were everywhere used as sacred numbers in the building of temples. The Babylonian tablet Igi-Gal-Bi contains all of them, plus 144, 162, and 810, which appear at Teotihuacan in both *hunabs* and cubits.

Wood points out that in the law of the Yoga, all periodic actions developed under the inspiration of the Invisible are measured by ideal cycles, expressed in geometric form by the number 1296 in thousands or thousands of thousands. The third stage of Yoga is represented by the third of 1296 or 432, which is considered the symbol of consecration, or standing in harmony with nature's beauty and order. The exalted life of a disciple of Buddha called for a cycle of 4320 million years.

Alan Watts in his *The Book* points to the Hindu myth which says that as time goes on, life in the world gets worse and worse, until at last the destructive aspect of the Self, the god Shiva, dances a terrible dance which consumes everything in fire—shades of Tezcatlipoca! There follows, says the myth, 4,320,000 years of total peace during which the Self is just itself and does not play or hide. And then the game begins again, starting off as a universe of perfect splendor which begins to deteriorate only after 1,728,000 years, and every round of the game is so designed that the forces of darkness present themselves for only one third of the time, enjoying at the end a brief but quite illusory triumph.

Charles Muses, writing on the origin of certain Babylonian numbers in a note in *Ancient Cultural Anthropology,* says the Chaldean priesthood of the ancient Sumero-Babylonian civilization was convinced, as were the later Pythagoreans, and indeed many physicists and cosmologists today, that embedded in cosmic structures lies a comparatively small "alphabet" of deeply fundamental numbers. As Muses put it, rephrasing Plato, "God not only geometricizes, but profoundly arithmetricizes."

Among those numbers still in great use today, Muses lists 360 degrees for a circle, 60 minutes for an hour, 60 seconds for a minute, and 24 hours for a day. He also notes our 7 days of the week, 12 months of the year. Taking the 4 states of matter, plus a quintessence, and adding to them unity and trinity, Muses makes a list of 1, 3, 4, 5, 7, 12, 24, 60, and 360; he proceeds to show how all of these numbers are simply and uniquely related to patterns of *circular arrangement.*

Using as an example a hostess with a round table of guests to be seated, Muses shows how the number of arrangements she can choose from jumps from 12 for 5 guests to 60 for 6 guests and to 360 for 7 guests. The seven guests, says Muses, represent the heavenly bodies of Babylon. Babylonian astronomy, which existed overwhelmingly for astrological purposes, was developed upon the 5 visible planets plus the Sun and the Moon.

These all appeared to revolve against the background of the stars in a comparatively narrow belt, changing the pattern of their place arrangement about what Muses calls "the great round table of the sky," overtaking each other because of their observably varying speeds. With 7 bodies, the number of arrangements was just 360. With 6 bodies, obtained by placing the sun in the center—the system standardly used for the interpretation of horoscopes—the number becomes 60. With 5 bodies, setting aside both sun and moon, the number is reduced to 12, or a division of the sky into the 12 zodiacal signs, or the twelve months of the year.

According to Muses, a twofold twelveness, or 24, comes from uniting the 12 signs of the zodiac with 12 hours of the day. Thus from 360, 60, and 24 came a circle for time of $24 \times 60 \times 60$, or 86,400 seconds; and a circle for space of $360 \times 60 \times 60$, or 1,296,000 seconds.

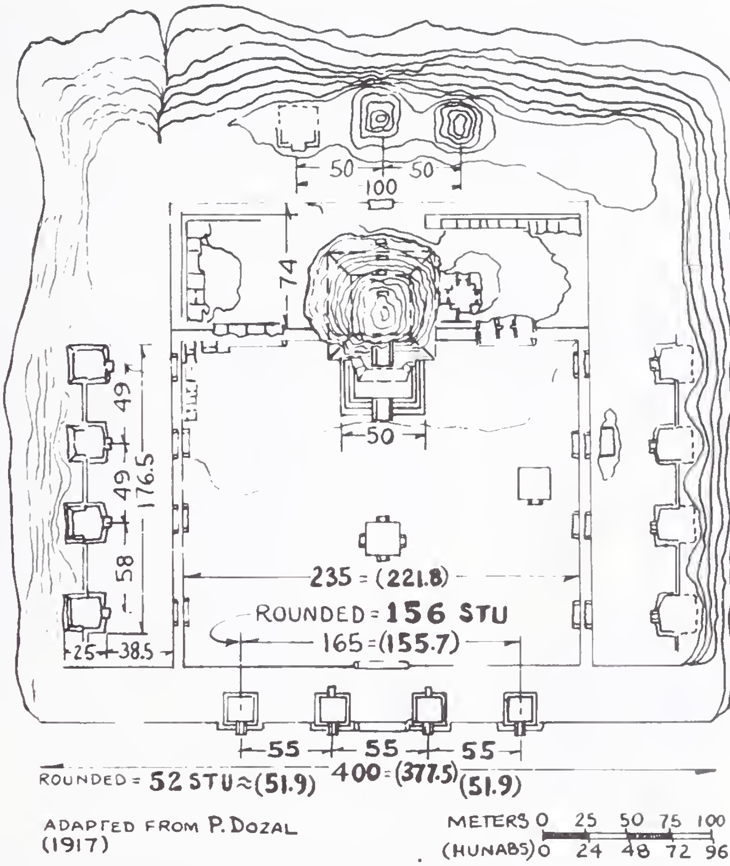
When a fellow engineer from Louisiana, Alfred E. Schlemmer, suggested to Harleston that he scan the Citadel for indications that it might have been used as a vast calendrical complex built around the numbers 13 and 52, Harleston realized that the four temples on the north, south, and west platforms of the Citadel, all the same size, plus one more, oddly placed within the patio, added to thirteen; all of them had thirteen steps on each of four sides for a total of fifty-two—the length of the Aztec century. Harleston noted that the distance between the centers of the western temples when measured in his units was 3 times 52, or 156.

This led him to conjecture that the builders of Teotihuacan could have celebrated ceremonies on various temples specially designed and arranged to incorporate the mathematics of their calendars.

He figured that if the Teotihuacanos had added one day to their calendar every 4 years, repeating the exercise thirteen times for a cycle of 52 years (perhaps using the four faces of their thirteen temples for a yearly ceremony), and then added another day at the end of three 52-year cycles (perhaps using the three larger temples on the east side of the Citadel for this 156-year cycle), they could have spread their calendrical ceremonies over a span of five human generations to obtain a calendar far more accurate than the Gregorian, correct to within 9/10 of a second per year, which would have needed no further correction for another 97,500 years.

For this the Teotihuacanos would, of course, have had to use a sidereal year, observing when a star reappeared in the same position in the sky at the end of 365.2564 days. With such a fraction of a day, just over the quarter, or .25, they would eventually have had to add another whole day over and above the leap years in order to keep their calendar correct; once every 156 years, to be exact.

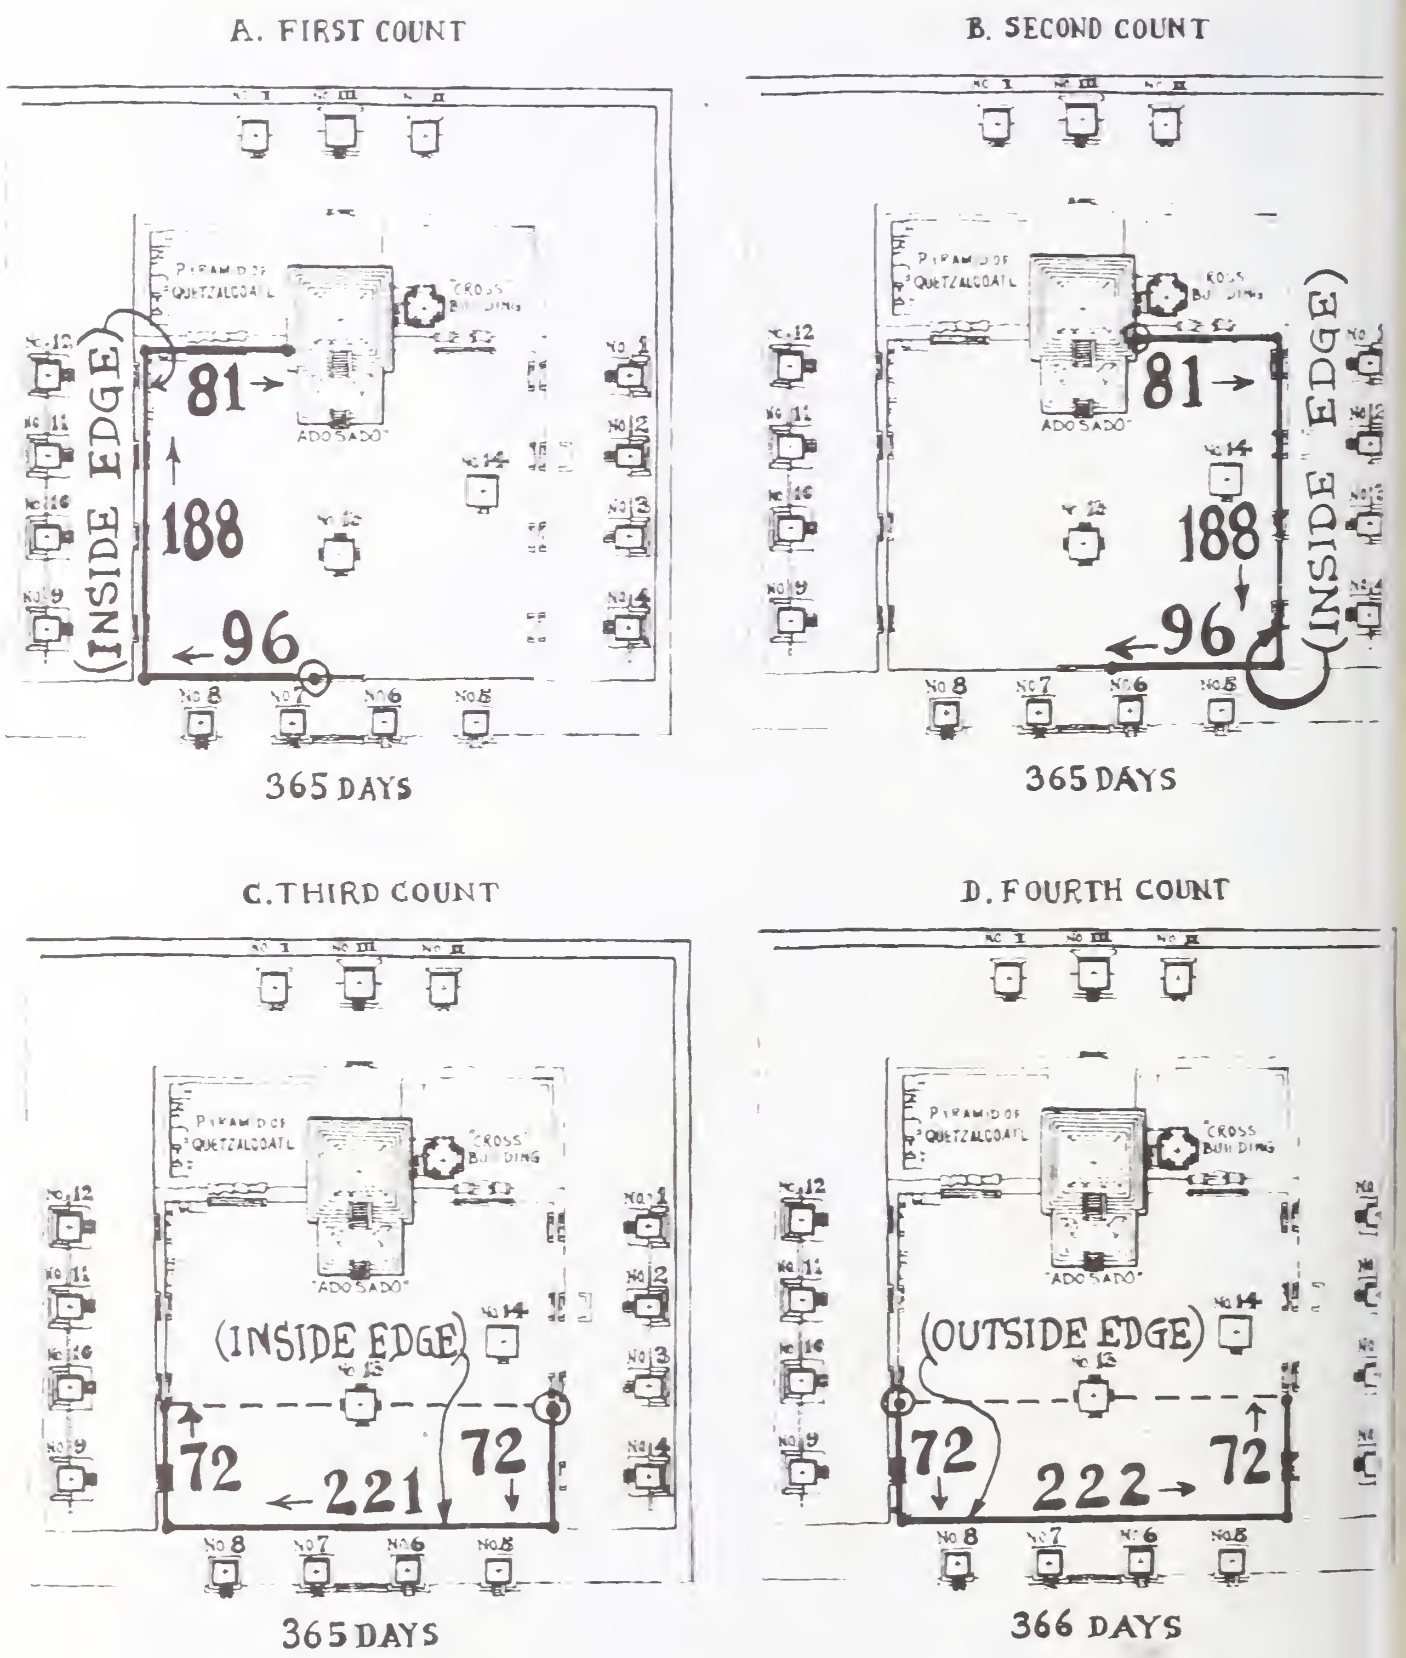
The four western platforms of the Citadel mark 156 *hunabs,* a distance that could represent a tricentennial time period of three 52-year "centuries."



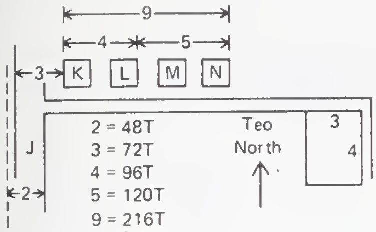
Spurred by the results of his hypothetical reconstruction, Harleston looked to see if there were other measurements in the Citadel to indicate a calendrical system. Starting at the entrance and moving clockwise around the perimeter of the patio, Harleston was surprised to obtain three counts of 365 and one of 366 units—clear indications of a yearly cycle—for a total of 1461 days, or units, identical with the Sothic cycle of the Egyptians.

Already in 1962 a similar notion had been advanced by George Kubler, author of *The Art and Architecture of Ancient America,* who suggested that the Citadel was "probably used for rituals of a calendrical nature." It struck Kubler that the three groups of four platforms round the Citadel plaza added to the Quetzalcoatl pyramid made thirteen ritual locations which could have been used for ceremonies dividing the calendrical cycle of fifty-two years into four parts of thirteen years each.

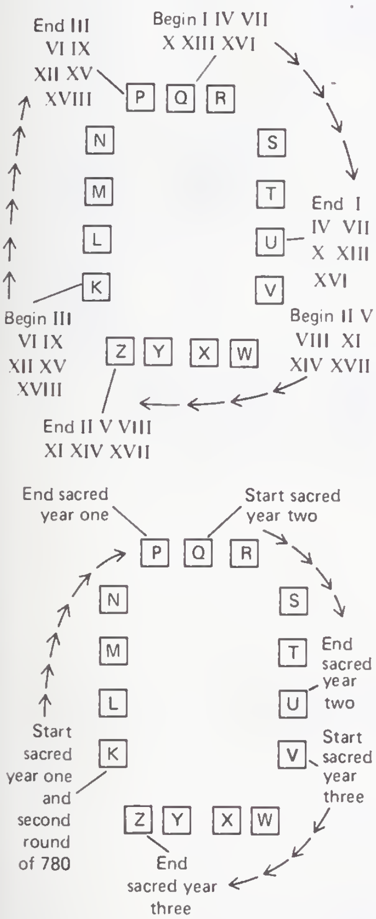
Kubler's idea was sustained and elaborated by David R. Drucker in a doctoral thesis for the University of Rochester. Drucker, who had worked on the Citadel as an assistant to Millon, suggested that the Teotihuacanos, fully conversant with the Maya technique of day counts in intermeshed calendars of 260, 360, and 365 days, could have used succeeding platforms in the Citadel to celebrate a constantly



Harleston's four-year calendar count.



Relationships among square platforms on F J and the Palace area expressed as simple whole numbers.



Drucker's calendar count in the Citadel.

Drucker took Platform Q as his starting point because it was the largest, and proceeded clockwise counting by twenties. He suggests there was a ceremony every 52 years on the Temple of Quetzalcoatl, and that each mound may have been surmounted by a temple with a flag or insignia on its roof to signify its role. Drucker says the system would have been perfect for recording a *tun,* or 360 days, as the last day would end on the main pyramid and start again.

unfolding day count for each of these rounds, plus the 584-day synodic return of Venus.

If, says Drucker, each Venus year were celebrated counterclockwise on the next platform immediately to the right, after 104 calendar years of 365 days (equal to 146 sacred years) a conjunction of the vague and Venus years would occur on the Quetzalcoatl platform where the ritual could be witnessed from the plaza.

Drucker furthermore believes that the Teotihuacanos laid out their whole city on the basis of a calendrical system that was most likely a heritage of the Olmecs (though it now appears that the Maya may have preceded the Olmecs). Drucker points out that the bearing of sunset at the beginning and end of the 105-days interval after the day of zenith was perpendicular to the Way of the Dead at the latitude of Teotihuacan, or 19° 42′.

Harleston concluded it might be worth investigating whether other geodetic, astronomic, or physical data could have been displayed in the actual geometry of the Citadel's buildings; if, for instance, there were triangles whose sides contained information deliberately encoded by the builders.

To eliminate the possibility of irrational or chance occurrences obtained from using any desired dimension to force answers, he put some elementary restrictions on his search. Any lines used had to fall on integral numbers defined by marker limits in the Citadel, such as walls, edges of platforms, centers of platforms, centers of pyramids, edges of staircases, and so on. Triangles had to be right-angled, and had to run north-south and east-west.

Within these parameters, Harleston soon found a score of Pythagorean right-angle triangles, and it was clear to him that the designers had a knowledge with exceptional accuracy not only of π, but of ϕ and ϕ^2—numbers which have a mathematically abstract relationship, and which appear to be basic to the construction of this universe.

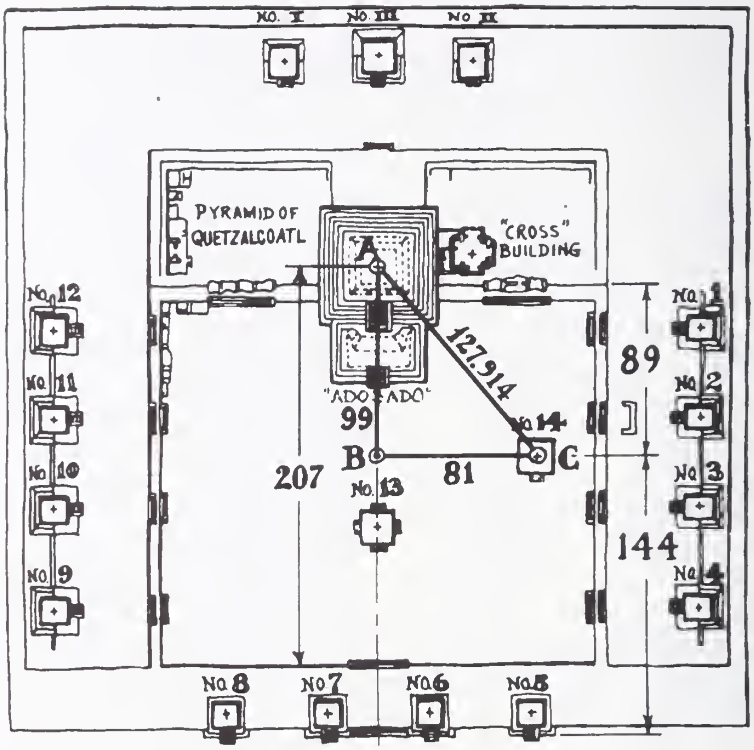
In the case of π, Harleston found nine integral triangles, all of whose sides included principal Citadelic dimensions such as 189, 222, 246, 147, 165, and 216 units.

Surprisingly, the triangle with the sides 216 and 165 units produced a hypotenuse of 271.810596, extremely close to the constant *e,* the natural logarithmic base 2.718281828 for Napierian logarithms. Twelve more triangles gave *e* with exceptional accuracy.

Harleston found that the probability of multiple reiterations of such numbers being strictly chance approached zero as the number of repetitive displays increased.

When Harleston saw that the Citadel's message might contain such "modern concepts" as the value for a logarith-

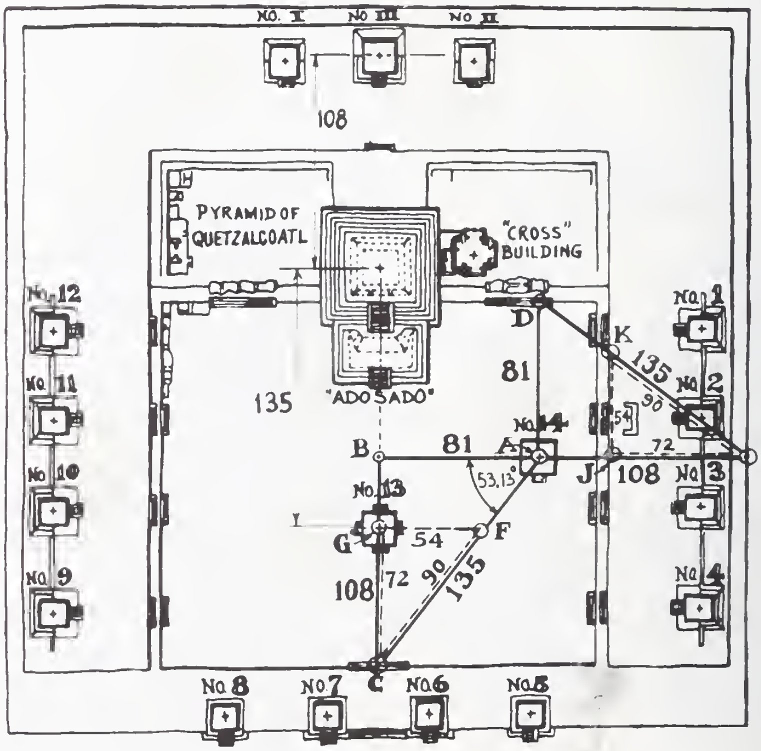
Harleston found the ϕ proportion in the Citadel, starting from the center of the Quetzalcoatl Pyramid. $207/127.9 = 1.618 = \phi$, and $144/89 = 1.618$. As with many classic and Renaissance structures, these ϕ relationships are aesthetically satisfying and account for the Citadel's extraordinary air of elegance.



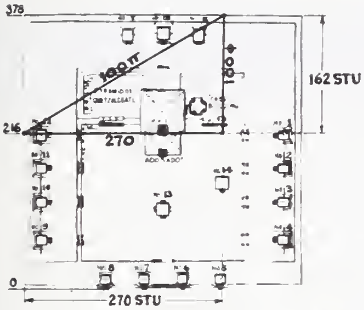
The constant, known to the ancients and designated by the Greek letter ϕ, is the proportion called "the golden mean." It has been found to be related in nature to the spiral growth in sea shells and other organisms. Mathematically the number is obtained in two ways: as the limit of a series of numerical divisions called the Fibonacci series (after the Italian mathematician), or simply taking the square root of 5, adding 1, and dividing the sum by 2:

$$\phi = \frac{\sqrt{5}+1}{2} = \frac{2.236068+1}{2} = \frac{3.236068}{2} = 1.6180339885\ldots$$

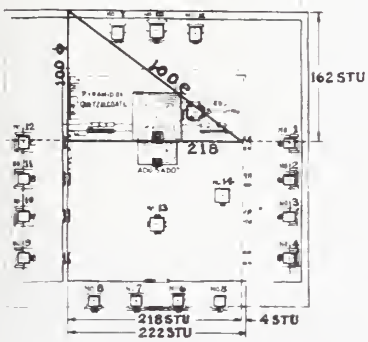
The number is usually shortened to 1.618, or further to simply *1.62*.



In the Citadel Harleston found several 3:4:5 Pythagorean triangles.



π and ϕ triangle in the Citadel.



e and ϕ triangle in the Citadel.

mic hyperbolic function, he wondered if there might not also be triangles which would give values for the other basic Einsteinian constant, the speed of light, which would have to be expressed as one-millionth of its value, namely 299.7925.

Harleston found that a triangle with sides 144 and 262 (which are 12^2 and $100\phi^2$) gave the speed of light within —1.0028, and another, with sides 162 and 252, gave a diagonal within 99.93 percent.

To Harleston, the correlative triangular information defined by the design of the Citadel's walls, platforms, and other delimiting structures was of such a complexity and interwoven exactness that he could only compare it to that of a computer program readout.

Here, said Harleston, was a design whose dimensional configurations provided accurately universal mathematical and other constants with a minimum of shared points. It was as if punch cards had been supplied for a four-dimensional advanced computer with the request to display an ideal architectural design that would incorporate major universal constants, geodetic, atomic, astrophysical, and other cosmic information in the minimum number of structures, all of which had to conform to right-angle Cartesian coordinates on an optimum scale model of the earth.

As the chances of the designers and builders of Teotihuacan having deliberately laid out such triangles to incorporate the values of π, ϕ, e, and the speed of light seemed remote, the more acceptable conclusion appeared to be that the designers could have been operating from some higher state of consciousness with the benefit of more cosmic and therefore simpler mathematics by means of which they could intuitively sense valid relations which would automatically include the basic constants of our three-dimensional math, which we, like blind men touching the elephant, can only describe with the squaredom of Cartesian coordinates.

Perhaps the pyramid complex was an intended hint to latecomers to expand their consciousness for a clearer view of the cosmos and of man's relation to the whole.

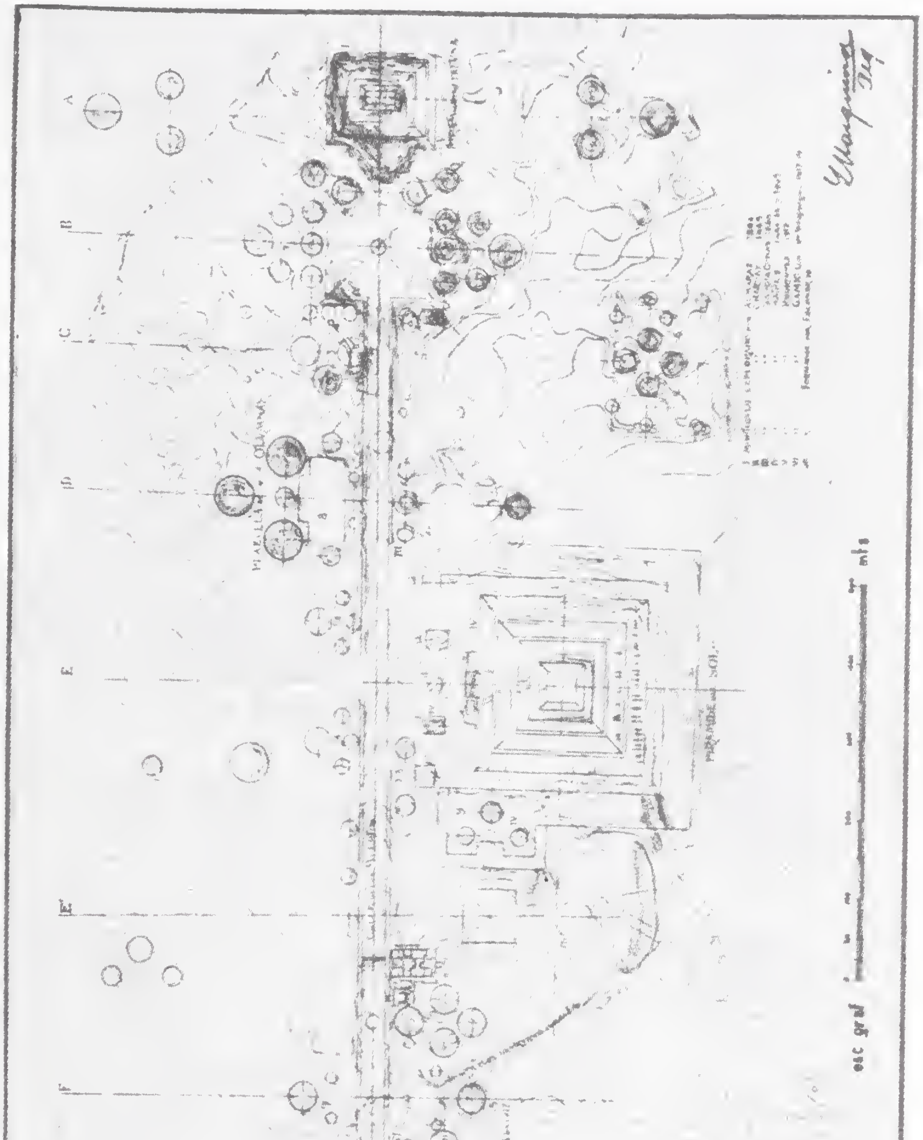
19. Cosmic University

Like a dog with a bone, Harleston continued to worry his *hunab* length and growl at any scoffers. If the Sun Pyramid had served its designers as a geodetic clock, and the Citadel as a gigantic calendar and repository of triangular data, what, Harleston wondered, was the function of the great north-south axis of Teotihuacan, misnamed the Way of the Dead? As he pursued his research, he began to get indications that it might have served as an enormous planetarium, a scale model of our solar system.

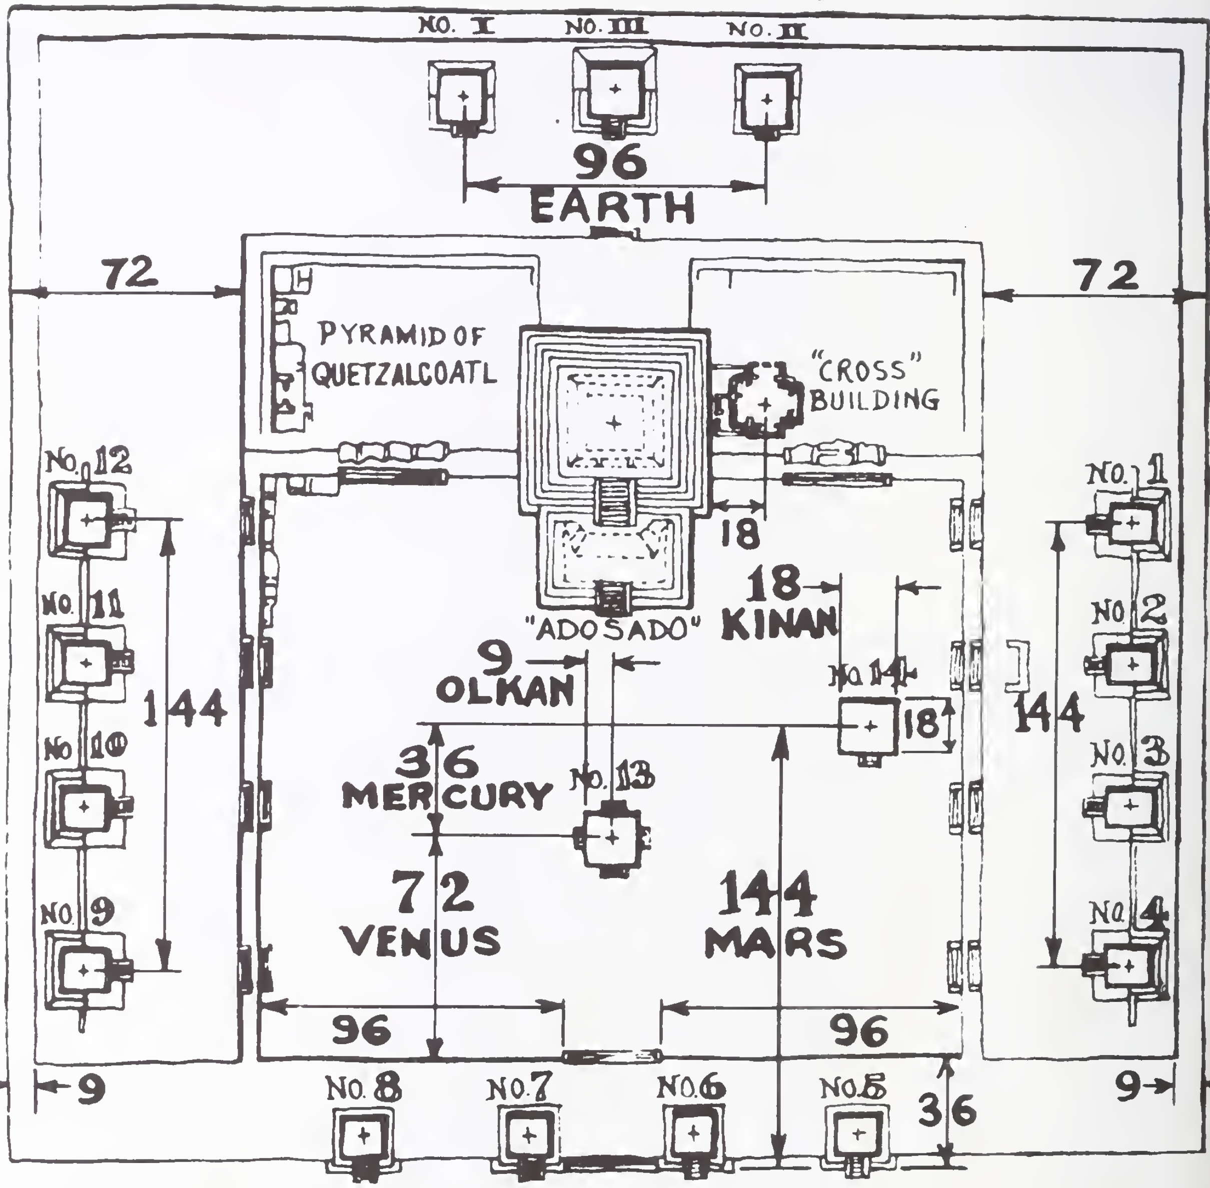
If one side of the base of the Pyramid of Quetzalcoatl of 60 units had been used by the Teotihuacanos to represent the radius of the earth, the radius of the sun would have been proportionately 6500 units, with a diameter of 13,000 units. Searching for such a demarcation, Harleston saw that this was roughly the distance across the Valley of Teotihuacan.

Rolled up and gathering dust in the vertical bins of the third-floor map and record room of the Mexican Institute of Anthropology, Harleston came across some old material considered to be strictly obsolete and only of academic interest, some of it still in the form of pencil drafts on squared graph paper, depicting the Way of the Dead.

Analyzing this material, Harleston saw that lengths between the walls with respect to the Sun Pyramid's center line provided integral proportions similar to the magnitudes already displayed by the Citadel and the Sun and Moon pyramids: lengths of 108, 144, 135, and 324 units. Already Millon had found a regular spacing of north-south streets, with definitely placed structures at fixed intervals not only along the Way of the Dead but along its prolongation north of the Moon Pyramid, and had suggested as a zero point for the ceremonial



Ignacio Marquina's early aerial map of the ceremonial area of Teotihuacan done while working with Gamio shows the areas explored by Almaraz in 1864, Charnay in 1885, Garcia Cubas in 1895, Batres in 1885–1905, Rodrigues in 1912, and Gamio in 1917–1919.



Orbits of the inner planets.

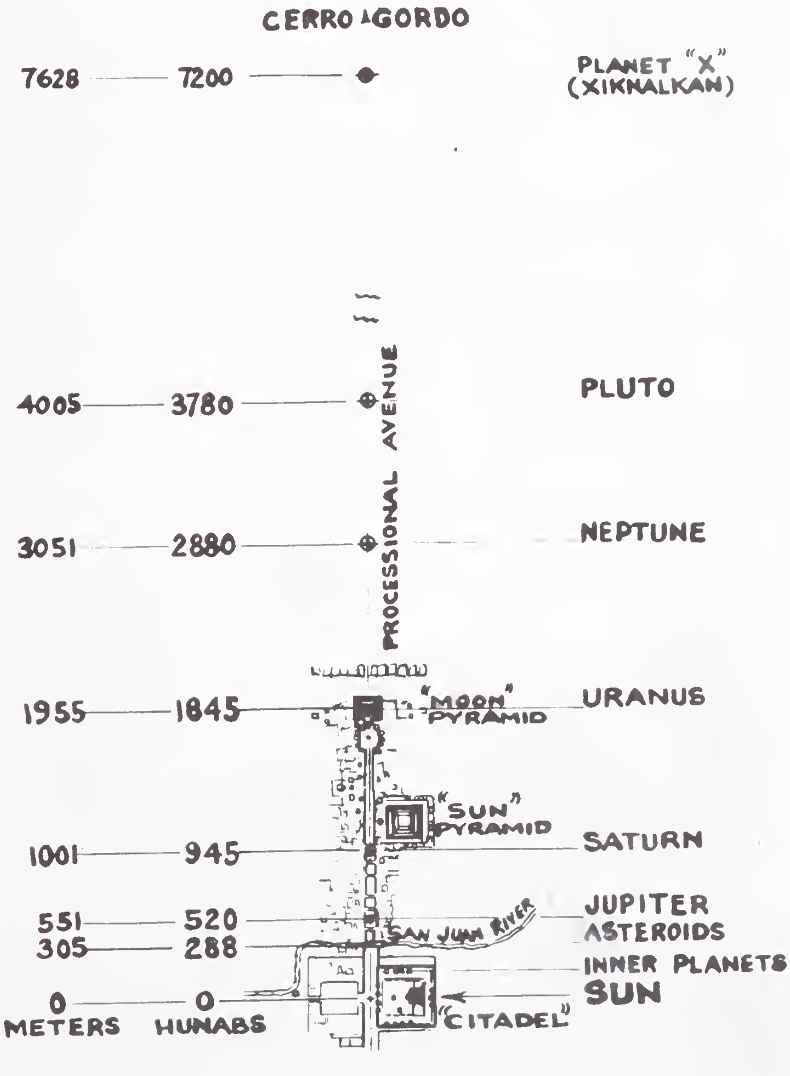
Harleston measured from the center of the Citadel to the edge of Platform 13 for a total of 9 units. He then realized that the values of the distances of the inner planets from the sun were displayed by the various walls and platform centers giving 9, 18, 36, 72, 96, and 144, which correspond to the orbits of Mercury, Venus, Earth, Mars, plus two additional possibilities closer to the sun than Mercury. These Harleston named Olkan and Kinan meaning "Sun Consciousness" and "Sun Spirit."

zone and approximate geographical center of the ancient city the intersection of the Citadel's center line with the axis of the Processional.

Taking this point as the center for a scale model of the solar system, Harleston was able to find markers along the Processional which to him gave values for the orbits of the various planets. Starting from the exact center line of the Pyramid of Quetzalcoatl in the Citadel, and arbitrarily assigning to the earth's orbit a value of 96 *hunabs,* the inner planets of Mercury, Venus, and Mars fell on their correct orbital values of 36, 72, and 144 units.

From the same starting point and traveling northward up the Way of the Dead, Harleston found that the canal of the San Juan River, apparently diverted from its original course by the ancient Teotihuacanos and made to flow under the Processional parallel to the Citadel, gave the average maximum orbital distance of the asteroids at 288 *hunabs,* or twice the orbit of Mars. This was only a vague indication. But still further, at 520 units, the remains of a pyramid corresponded to the average proportional distance of the orbit of Jupiter, as found by our astronomers, some 3 percent out of line from an ideally stable orbital shell.

Excited, but still doubtful, Harleston paced his way on up the Way of the Dead with a steel tape measure. At 1000 meters, or 945 *hunabs,* north of the Citadel's center line there is a spot where there had once been a platform, now obliterated. During the work of reconstruction carried out between 1962 and 1964 this section of the Way of the Dead had been paved over with asphalt to allow rubber-wheeled tourist trains to transit through the zone. By Harleston's calculations the spot could have been the demarcation for the average orbital distance of Saturn, which is now 9.55 astronomical units, about 2 percent further out than the ideal symmetrical orbital shell.



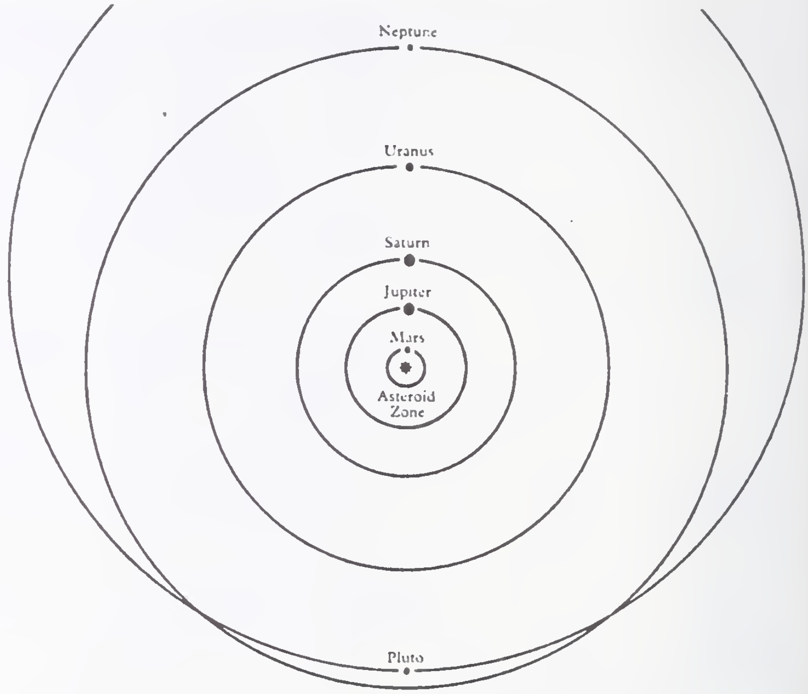
Outer planetary orbital distances

Starting with the center of the Quetzalcoatl Pyramid as a mark for the sun, and measuring northward up the Processional, Harleston found that all the known planets, plus another potential one, fell on definite markers which were symmetrically spaced in what appeared to be a binary progression beginning with the number 9: i.e., 9, 18, 36, 72, 144, 288. This is illustrated by the actual distances of Mercury, Venus, Mars, and the asteroids (9×4, 9×8, 9×16 and 9×32 units when the earth's orbit is assigned a value of 96, a number which is clearly displayed in the Citadel). It was here that Harleston concluded that the earlier indications of multiples of 9 appearing throughout the ceremonial area could have been intentional.

Starting from the premise that the law of angular momentum is valid for all the known universe, a Soviet named Schmidt, for whom the Institute of Geophysics in Moscow was named, formulated a theory of the harmony of the distances between planets by which the square root of the distance of planets from the sun increases from planet to planet by a constant amount. Schmidt's theory has now been verified not only for the planets of our solar system but also for the satellites of the larger planets.

In 1963 Lloyd Motz, then associate professor of astronomy at Columbia University, stated the view that planetary systems must appear and develop around stars of a given type as uniformly as the formation of salt crystals, which are always the same, whether they are formed on earth, Mars, or a planet millions of light-years away.

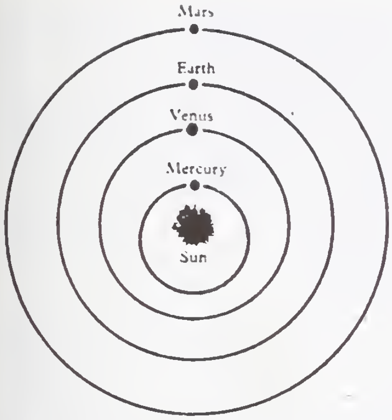
Until late in the eighteenth century, only five planets were known: Mercury, Mars, Venus, Jupiter, and Saturn. However, at the beginning of the seventeenth century when Johannes Kepler discovered that the orbits of the planets were slightly elliptical rather than truly circular, and that even these ellipses were irregular, the aberrations were attributed to some other as yet undiscovered planet or planets.



Next came the center point of the Moon Pyramid, corresponding to 19.2 astronomical units, or the precise orbital distance of the planet Uranus.

Encouraged by what he considered the extraordinary consonance of these processional markers, Harleston took off behind the Moon Pyramid and climbed the flank of Cerro Gordo to see what more he could find. At 2880 and 3780 *hunabs* from the Citadel, he came upon two typical temple mounds not yet reconstructed by the Mexican Institute of Anthropology and History. The first mound marked the correct orbital distance of Neptune at 30 astronomical units from the sun. Neptune was discovered in 1846. The second mound marked the distance of Pluto at 39 astronomical units. Pluto was discovered in 1930. Further up Cerro Gordo, at 7200 *hunabs* north of the Moon Pyramid's center line, Harleston came across the remains of an ancient temple known to the native residents as the Temple of Xochitl (or "Flower"), remains that were barely visible because treasure hunters had thrown most of the structure over the side of the ravine to cover up the traces of their pilfering.

Extrapolating from the previous Teotihuacan data, Harleston theorized characteristics at this location for an unknown planet "X," almost twice as far from the sun as Pluto. Naming it Xiknalkan (Mayan for "Flying Serpent"), Harleston attributed to it a mean orbit of 11,212,800 kilometers, or 75 astronomical units from the sun, a diameter approximately three times that of the earth, or 37,000 kilometers, and an inclination to the plane of the ecliptic of 4.74 degrees, compared with Pluto's 17 degrees.



In 1787 Sir William Herschel, Astronomer Royal at the Greenwich Observatory, realized that what was thought to be a star was actually a planet. First named for him, it was later called Uranus.

In 1845 a bright young Englishman, John Couch Adams, figured out where to look for a second new planet, but the local observatory paid him no no heed until a local Frenchman, Urbain Leverrier, reached the same conclusion by independent calculation and the planet Neptune was discovered during the night of the autumn equinox of 1846.

In 1930, at the observatory built in Flagstaff, Arizona, by wealthy Bostonian Percival Lowell, a young man, Clyde Tombaugh, got a picture of a new planet which turned out to be Pluto, a planet so eccentric in its orbit that in 1976 it moved in closer to the sun than Neptune.

Because such evidence indicates an overall system operating from the macrocosmic to the microcosmic, occultists have based their number systems on the time periods of the planets which are a direct function of their distance from the sun. To occultists the fact that twelve earth years is equal to one year of Saturn, leads them to conclude that 12 times 30, or 260, must be a significant number in the system.

There is, of course, considerable mention in occult literature of undiscovered planets in the icy regions of space beyond Pluto, and the Russian philosopher Georges Ivanovitch Gurdjieff maintained that we experience the influence from two such undiscovered planets beyond Pluto.

Physicists, philosophers, and psychics have all adduced data on the possibility of intra-Mercurial and extra-Plutonic planets as yet unofficially discovered. Several leading astronomers, including J. J. See, W. Peck, T. Gugril, and G. Forbes, have predicted planets with varying periods of orbit. But the weight of academic thought on their putative postions does not correspond with Harleston's locations. Dr. William H. Pickering, working out of his private observatory in Jamaica in the 1930s, postulated, on the basis of an exhaustive study of the perturbations of both Uranus and Neptune and of the period comets, the existence of two more planets beyond Pluto and predicted that the first of these, which he called "S," would have a sidereal period of 333 to 336 years, at a mean distance from the sun of 48.04 astronomical units, or half of Harleston's distance.

Pickering's figures agree remarkably well with those obtained by Dr. Charles Muses, a mathematician, physicist and cyberneticist who placed such a planet—which he suggested calling Pan—at 48.4 astronomical units from the sun with a period of 342 years. Dr. Muses obtained his data from two different approaches: by a refinement of the Bode-Titius law into a threefold law whose parts are related and mutually overlapping at their successive limits of application, and by a theory of cylindrical wave formation whereby the planetary orbits appear as rings formed by the comparatively dense matter of the planets in contrast with the light-filled bands of interorbital space in the solar system, as explained in his paper published by the National Research Council of Italy in 1965, and in a more popular version as "Why Do Celestial Bodies Rotate and Revolve?" in the *Journal for the Study of Consciousness*.

One other mathematician, Joseph L. Brady of Livermore, California, in an effort to explain the major irregularities in the orbit of Halley's Comet, has proposed a planet closer to Harleston's location, one that would orbit retrogradely in a period of 512 years, with a mass 300 times that of the earth, and tilt of 60 degrees to the ecliptic.

Within the Citadel's boundaries, where he believes the dimensions may indicate the orbits of the inner planets Mercury, Mars, and Venus, Harleston thinks that the dimensional system may indicate two more planets closer to the sun than Mercury, to which he has given the names of Olkan and Kinan, "Sun Consciousness" and "Sun Spirit."

Harleston's drawing represents his and Alfred Schlemmer's "far-out" notion derived from Aztec mythology of a flayed planet—the twin to Mars—called Quetzalcoatl or "Sumer," whose outer surface is conceived to have been deliberately "peeled off like an orange" by space people and deposited into the oceans of Terra in the form of the present continents, leaving the moon as a sterile core.

According to this reading, the damaged twin companion, Xipe Xolotl, the flayed Red God of the East, or Mars, retreated to a new position at a distance of 228,000,000 kilometers from the sun, its face cratered with the evidence of celestial bombardment confirmed by the Ranger space probes of 1976.

In this Velikovskian heavenly drama, Venus, the former twin companion of Earth, would have plunged into a nearly circular orbit at a symmetrical position of 108,000,000 kilometers from the sun, three-quarters the distance to her sister Earth. According to Harleston, the "arrow," that the Aztec said Venus launched, returned to her as a gravitational field, and she bounced sunward, stopped her clockwise spinning, and began to revolve backwards in retrograde rotation. Thereafter a dead planet, her incandescent atmosphere slowly cooled enough to have a temperature of boiling oil.

In this legend, Terra, the planet with the iron heart, was not light-headed like Quetzalcoatl, the hollow moon that arrived from the *west* (an orbit farther away from the sun), so she now deviated in her orbital circling only six percent. As Schlemmer reconstructs the tale, rotational rates may have varied, along with polar inclination, as the differences caused climatic changes, worldwide macroearthquakes, rains of meteorites, floods, and general havoc that remained engraved in the subconscious memories of the survivors.

Geoffrey Hodson, the psychic Theosophist, using what he calls "etheric vision," was able to spot an intra-Mercurial planet postulated under the name of Vulcan by astronomer Urbain Leverrier, who successfully predicted the discovery of Neptune. Using Hodson's and Leverrier's data, another astronomer, George Sutcliffe, was able to determine an orbital period for Vulcan. According to Sutcliffe, Vulcan can only be seen on very rare occasions of its transit as a small black disk over the sun's face because it radiates and reflects only deep infrared radiation.

In Dr. Muses' analysis there is room for just one such planet orbiting between Mercury and the sun, with a period of 42.9 days, but there has been little systematic search for Vulcan because of observational difficulties due to its proximity to the sun.

Surprisingly corroborative evidence for Harleston's figures then came from his friend Alfred Schlemmer, who for years had been analyzing the recurrence of large-scale earthquakes around the globe, keeping records of where they occurred and how big they were. From this accumulated data Schlemmer established to his own satisfaction that tornadoes and earthquakes repeat in cycles in a broad band around the world, cycles which he says are conditioned by the effect on the earth of the several motions of the other bodies in our solar system, motions called torsional because of the twisting effect they have on the earth as it rotates on its axis and revolves around the sun. When the moon, for instance, is at perigee (closest to the earth) every 27 1/3 days, its pull on the earth increases by 6 percent. The constantly differing patterns of planetary movements cause great torsional pull on the earth's crust, as does the sun's varying gravitational field, all of which cause earthquakes.

Curious to see if the periodicity of the earthquakes had anything to do with the length of the earth's rotation on its axis, measured in either tropical or sidereal years, Schlemmer came up with a list of thirty-eight numbers which appeared to be constants. By using a tropical year of 365.242189 days and dividing it by 1440, the number of minutes in a day, Schlemmer obtained the number 0.2536404097, by means of which he was able accurately to extrapolate orbital distances for the planets; he was also able to conjecture the theoretical existence of six additional planetary shells between Mercury and the sun, which may or may not be occupied by condensations called "planets" or merely by rotating fields, with the first three either non-condensed or burned out.

To Harleston and Schlemmer's surprise, nineteen of Schlemmer's constants coincided with numbers obtained by Harleston along the Processional at Teotihuacan. They found this so remarkable, as might any reader of Arthur Koestler's *The Roots of Coincidence,* that they concluded that if anything they had underestimated the scientific capacity of the Teotihuacanos and the reach of their overall mathematical display. It looked to them as if their Teotihuacan constant of 1.059 might provide an index of orbital distance, while ϕ, or 1.618, might be an index of time, both incorporated into the laws of celestial mechanics.

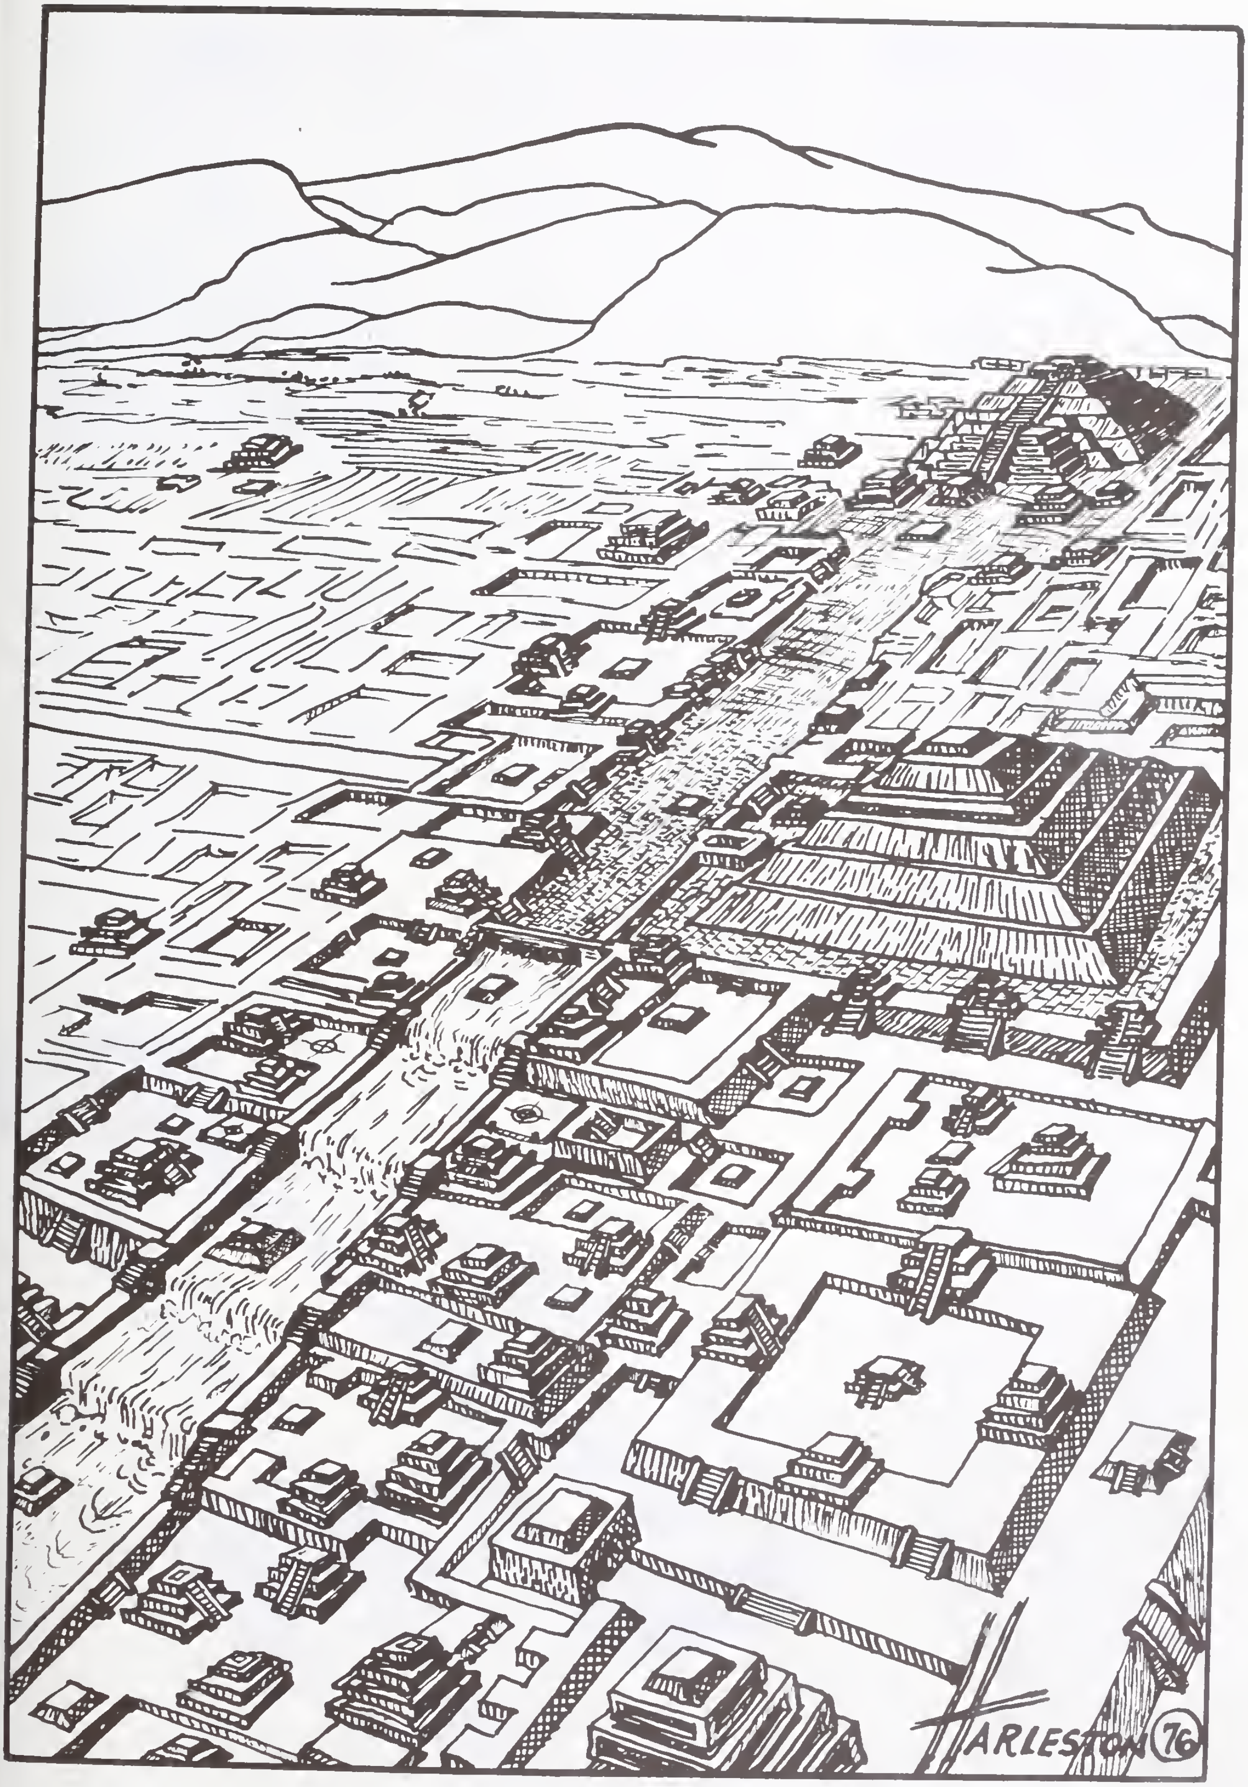
If repeating shell data could be validated by further outer space probes, Harleston figured there might be not one but two more planets beyond Planet "X," the first, Planet "Y," at 100 astronomical units, orbiting at an inclination of 2.09 degrees to the ecliptic, and Planet "Z" at 150 astronomical units, or 22 1/2 billion kilometers from the sun, at an inclination of 0.44 degrees.

A further clue to the possible layout of the Way of the Dead came to Schlemmer from watching a pan of oil on a tractor in which standing waves of a very particular shape were being engendered by the simultaneous spinning and vibrating motion of the tractor.

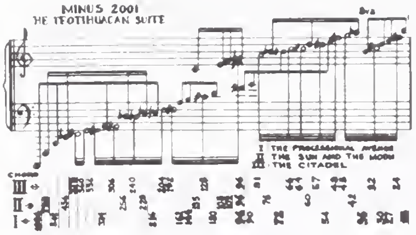
Schlemmer figured that if an earthquake in one part of our spinning globe can cause standing waves to form on a liquid surface right across the planet, then the several walled-off levels of the Processional, whose lengths coincided with his torsional constants, could have been used as a series of reflecting pools, falling down from the foot of the Moon Pyramid to the area in front of the Citadel, like the pools at the Royal Palace of Caserta, near Naples, harmoniously designed to enable Teotihuacanos to read from the standing waves formed on them the location and strength of earthquakes around the globe, enabling them to predict such an occurrence in their own area. Harleston then figured that at a time when earthquakes appear to have been more frequent and more devastating, knowledge of the characteristics of resonant vibration could have permitted the Teotihuacanos to use the several pools as long-range seismic monitors. It could also be an indication that the modern penchant for laying out reflecting pools, like the raising of obelisks, may be just a hangover from an ancient science no longer understood. Certainly a series of reflecting pools with the Moon Pyramid in the background would have been as impressive a sight as the Taj Mahal; and in support of Schlemmer's theory, one can still see sluices at the foot of each of the partitioning walls along the Processional.

Spurred by this conceit Harleston could no longer be restrained. He suddenly saw the Teotihuacan layout as possibly containing clues not only to the planetary orbits and telluric convulsions, but to much more hermetic data. It occurred to

Harleston's romantic reconstruction of how pools of water could have cascaded from one to another down the Way of the Dead, fed by springs from Cerro Gordo. When sluiced from below and used as reflecting pools, Harleston and Schlemmer believe that standing waves generated in the variously sized pools by distant earthquakes could have served the Teotihuacanos as a form of seismograph.



HARLESTON 76

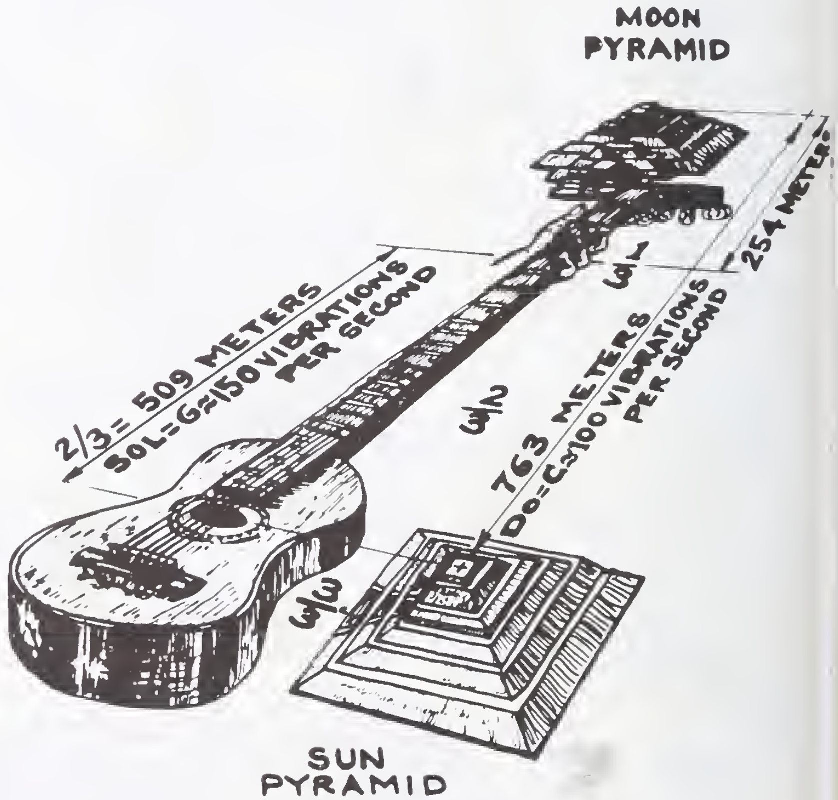


Harleston says the modular lengths of Teotihuacan can be compared with musical octaves. If the distance from north to south between the Sun and Moon pyramids were a huge guitar string 763 meters long, it can be imagined to sound a fundamental vibration, like a bass violin or the lowest note on the piano. He arbitrarily calls this tone C (or do). To sound the tone G (or sol) the guitarist would place a finger one-third of the way up the string 254 meters from the Moon Pyramid, and leave two-thirds free to vibrate. The string will oscillate one and a half times as fast as before.

Harleston found that the three chords overlap at one wavelength: 96 units, which he calls the relative orbital distance of the earth on the Teotihuacan planetarium. The orbital proportion of Mercury would then become what he calls the note B (or si) and one octave below it is Venus, while two octaves below represents Mars. To Harleston these are three base chords that might form the structure of a Teotihuacan suite.

When the proportional "notes" which corresponded to steps, walls, and buildings of the Processional, Citadel, and the Sun and Moon pyramids were converted to "chords" and diagrammed on paper, three great chords appeared, which, to Harleston's surprise, were just like the opening bars of Richard Strauss's *Thus Spake Zarathustra,* used by Stanley Kubrick as background for the opening of his motion picture *2001.*

Harleston that the Way of the Dead, as seen from the bird's-eye view of Acosta's mapping, might give the appearance of an enormous guitar whose frets were the walls of Schlemmer's reflecting pools. Could the Teotihuacanos, Harleston asked himself, have incorporated in their design of the great Processional an eight-note musical scale? Looking for "musical relationships" in the distance between the wall "frets," Harleston arbitrarily took as his note B (or *si*) the marker he had found for the relative orbital distance of Mercury. In this way an octave below it came Venus, and two octaves lower, Mars. But the distance of the markers did not quite work out, at least so long as he went by the frequencies of our "well-tempered clavichord," a scale worked out by Johann Sebastian Bach in which the mathematical frequencies are slightly corrected for the pleasure of Western ears and the convenience of orchestral scoring. Some of the notes were as much as four cycles lower than the mathematical frequencies displayed in the Teotihuacan measures. Then Harleston remembered that when he had first arrived in Mexico in the late 1940s he had been taken to the house of the Mexican composer Julian Carillo, who composed music in a different scale, one which he called "sound 13" because it divided an octave mathematically by means of the twelfth root of two, or what



Mexico's composer Julian Carillo.

Harleston says that as Teotihuacan yielded its secrets, one by one, he began to sense the sweep of its creator's vision. "At the lower level of the vibration, three major chordal sequences merge at a common note that symbolizes our planet's orbit: 96. At the intermediate range of the visible spectrum six balanced colors of light point toward the invisible vibrations beyond the range of our normal optical capabilities. And beyond this the sounds of our spiral universe are heard, as the evolution of an open-ended wave that becomes four-dimensional radial space and three-dimensional radial space and three-dimensional expanding time, the tetrahedron, and the sphere."

Harleston considered was the Teotihuacan constant, into thirteen equally spaced notes (or twelve intervals) with seven white keys and five black keys. In this system, each frequency multiplied by 1.059 gave the next half note, which, multiplied by itself, gave the next whole note.

Harleston found that Carillo's musical proportions, which produced a weird and exotic effect on the listener, turned out to be the closest approximations to the relationships of the measurements at the area of the Teotihuacan monuments.

Creation is certainly mathematical and harmonic, with physical relations such as the orbit of a planet, the pentagonal divisions of a fruit, the spiral growth of a vine, or the shape of a honey bee's cell, all expressible in mathematical terms: even the structure of bones, nerves, muscles, cells, molecules, and atoms, all appear to be governed by mathematical law.

Light, music, color, and even the table of chemical elements appear to be harmonically linked. Were the human ear capable of discerning sounds produced by chemical action, we might perceive a musical harmony, or better a symphony, in all forms of living. In the past, certain members of society may have had just such abilities.

According to Michael Heleus, an astrologer from St. Petersburg, Florida, who has developed a theory called "astrosonics," the actual motion of the planets as they orbit the sun makes sounds, or creates wavelengths, which affect a human being in different ways, more especially as they harmonize, or not, with the person's own birth chart.

By reproducing the various wavelengths of orbiting planets and raising these sounds sufficient octaves to be audible, Heleus claims to be able to produce in people astrological effects at will.

Like Orpheus, who was supposed to be able to charm any creature with his lyre tuned to the motions of the planets, Heleus says he can produce painful or pleasant sensations in humans. Gurdjieff also describes a broad gamut of musical effects, including the raising of boils on bodies with a tune.

Citing the stock example of a glass shattered by a singer's voice because it can only absorb so much energy on that wavelength, Heleus suggests that objects and especially buildings on this planet absorb and retransmit only if their proportions are earth-commensurate or harmonize with wavelengths from the cosmos. He believes the yard, the foot, and the inch are more in tune with telluric and cosmic forces than the inadequate meter.

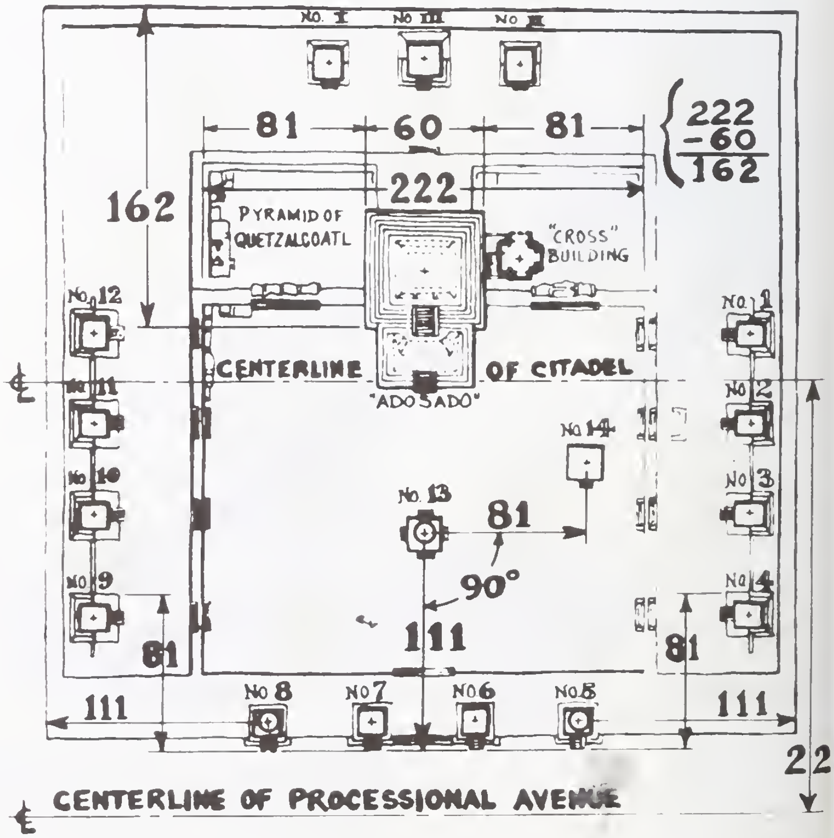
There may even be wavelengths and receptive shapes which together generate natural growth and reproduction—effects attributed to the ϕ proportion—as opposed to other wavelengths and shapes which restrict or enchain.

Harleston next saw the Teotihuacan layout as possibly giving clues not only to wavelengths of the structure of the immediate world of sound, heat, color, smell, and touch in which we live, but also to the wavelengths of light, the micro-universe of atoms, and the macrouniverse of galaxies.

Whether it was known or not to the designers of Teotihuacan, Harleston realized that the constant of 1.059 controls not only the frequencies of sound but those of light. If visible light is divided into six basic colors from ultraviolet to infrared, omitting the arbitrary indigo, the frequency of each succeeding color is obtained by multiplying by 1.059 or its square. The seventh frequency at either end of the band of light remains invisible. Harleston found other phenomena such as the fact that when the color orange is multiplied by 1.059 it gives the wavelength of the helium-neon laser.

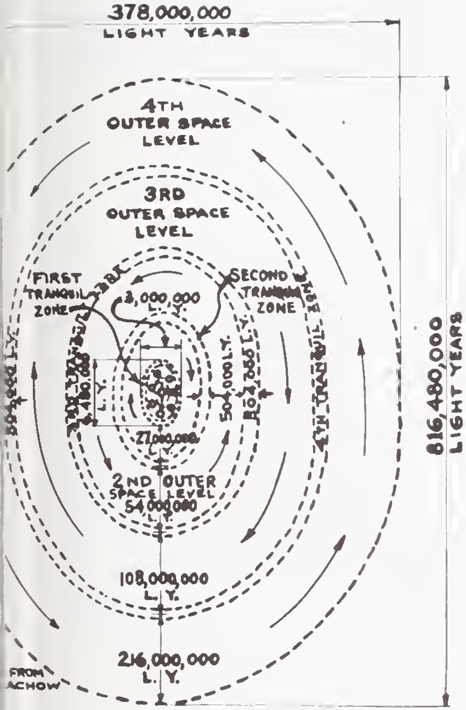
Schlemmer's symmetrical series for the orbiting distances of planets, says Harleston, can be reduced proportionately all the way down through the interior of the sun and finally to atomic configurations, indicating that Teotihuacan may also have been a display of cosmic data.

Of the whole numbers which Harleston considers to be deliberately displayed along the Processional, he was puzzled by 148 till he divided it by 4 for 37. Closer inspection of the



The Hydrogen Constant.

When a physicist tries to calculate the optical properties of a material or the way an object will behave in the presence of light, the hydrogen constant, or 1.37037037, enables him to make his experimental results fit theories which may be largely based on incorrect assumption. The constant, says Harleston, should be particularly useful when humans will have to cope with very large amounts of energy.



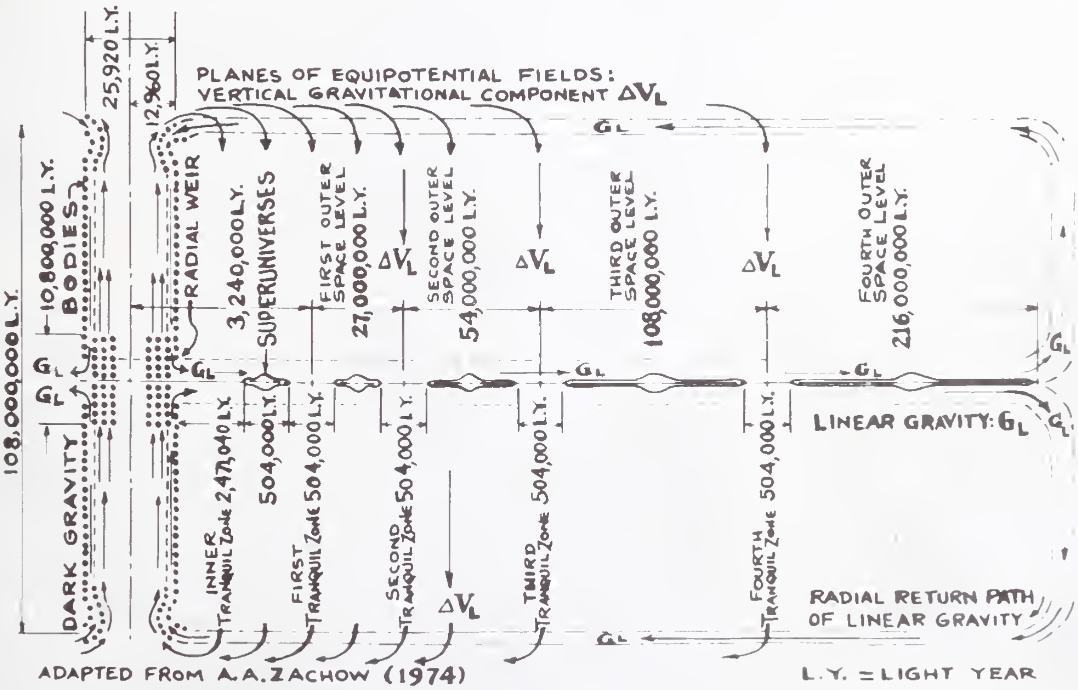
Harleston's adaptation of A. A. Zachow's logarithmic plan of the Grand Universe.

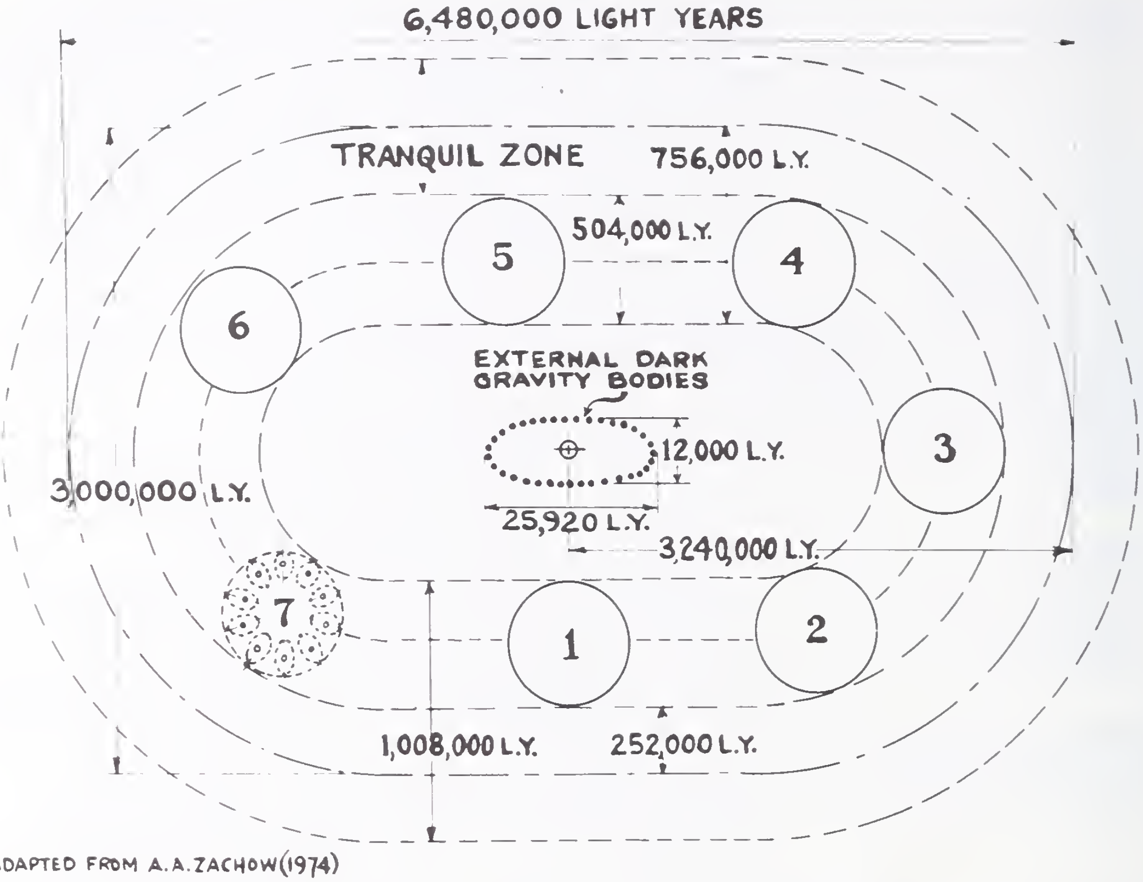
Citadel showed Harleston that the west platforms were located 111 *hunabs* from the north-south ends—that is 3 × 37—and the Citadel's central patio was 222 units or 6 × 37. Searching for some meaning to this apparently intentional indication, it was some time before the relationship of 37 to 27 came to him. In twentieth-century physics, 37/27 or 1.370370370, with the 037 continuing indefinitely, is the physical constant which forms the connection to the level of the atom. Multiplied by 100, this number is the average fine constant for hydrogen and deuterium, published in 1972 by the Bureau of Standards in Washington, D.C., a basic datum, says Harleston, for eventual macroenergy management.

Such a built-in datum appeared to him to be another indication that seen from another dimensional point of view the Teotihuacan complex contained vital physical data about the energetic and geometric makeup of the cosmos.

Harleston quotes the cosmology of A. A. Zachow, who postulates seven superuniverses that follow an elliptical path around dark gravity bodies, known as "black holes" by today's astronomers, to show that the Teotihuacan parameters could also relate to the structure of the *macro* universe. The cosmology of Zachow implies that the proper motions of nearby suns seem to indicate centroid positions that are "intelligently directed," and that this would suggest that stars, as well as star groups and galaxies, may be found to be located on symmetrically repeating orbital shells when future analyses permit the comparisons to be made. As each of Zachow's superuniverses contains seventy-two galaxies,

Zachow's transverse section of the Grand Universe.



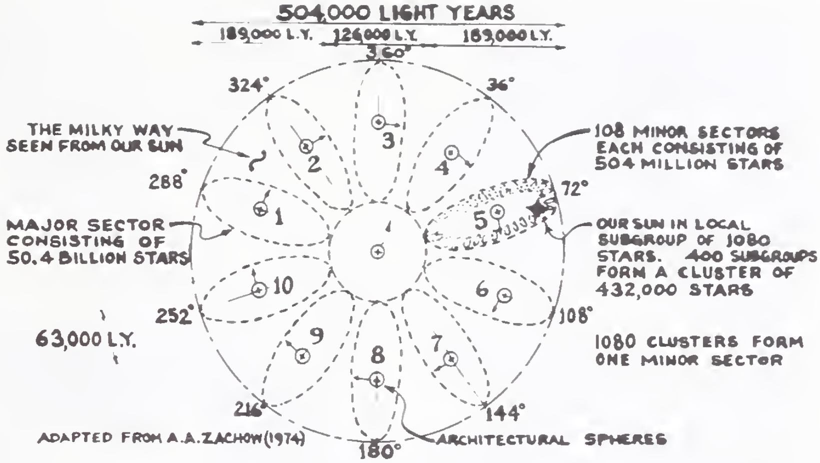


Zachow's plan of the Super Universes.

which cause our sun to experience seven distinct directions of motion through the superuniverse, Harleston surmises that the Teotihuacan standard unit of measure, or *hunab,* may be a natural unit of space-time. The selection of a measure that unifies space and time taken from a stable planetary dimension (such as its polar diameter), says Harleston, gives the advantage of enabling one to see cosmic relationships such as orbital symmetry in a simplified manner. He believes it most likely that the same proportion would exist on all planets, and suggests that the $\sqrt[12]{2}$ of the diameter would give a unit of measure appropriate for that orbit, correctly relating it to the unit and diameter of all other planets.

The angles and perspectives in the Teotihuacan layout appear to Harleston to show the framework of an integrated earth and heaven—along with the megaspace of the heavens above—as being the work of a master mathematician. To Harleston the messages of Teotihuacan point to a new way of looking at time and space, and to some new source of energy from the cosmos, some new field fabric that our science has not yet isolated. He believes that if Teotihuacan could express knowledge of cosmic relationships erected in the form of a ceremonial center, the whole complex could have served as a university. The ceremonial center, whose architecture exhibits

Zachow's view of our Super Universe.



information such as the rotational distance moved at the equator in a given time, plus positional latitudes and longitudinal distances of rotation, could have been used as an educational center for geodesy and navigation.

To Harleston the Teotihuacan messages are timeless concepts which could teach the student to reach beyond himself to a larger vision of the relationship of man to the cosmos and of man to himself as knower and perceiver. He says the overall information of Teotihuacan presents logical relationships so simple that the basic principles can be learned in a day; from these principles cosmic information can be deduced. "It is as if the Teotihuacanos," says Harleston, "had wanted to provide a method of teaching cosmic truths so simple that, once learned, the survivors of some unforeseen cataclysm could rebuild the knowledge from memory."

Harleston says that once the student at Teotihuacan learned the important values of thirds, sevenths, and ninths, and that squares and square roots were basic mathematical tools, the next step was to understand the relationship in space of two simple geometric solids: the sphere and the tetrahedron.

It was some time before Harleston found the clue to a tetrahedral geometry incorporated into the Teotihuacan complex, but he finally found it in the dimensions of the Pyramid of the Sun. Unlike the Pyramid of Cheops, which is a very exact scale model of the Northern Hemisphere (with the apex as the North Pole, the base as the equator, and its perimeter equal to one-half minute of arc), the Sun Pyramid does not fit such a system; it does, however, very accurately give the entire surface of the earth.

Harleston divided this surface into four great circles, making four great spherical triangles, each of which corresponded to the area of one face of the Sun Pyramid. This solution brought with it the question of how and why the Teotihuacanos should have chosen such an apparently complex system. That is where the tetrahedron came in.

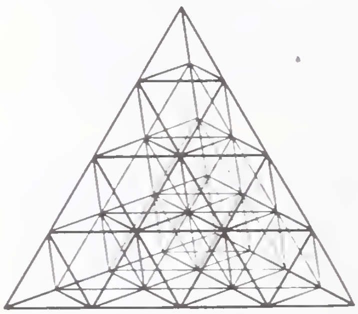
Harleston finds it significant that if you stand a tetrahedron on its nose at the South Pole it will form three triangles above the equator splitting the world into four equilateral great-circle triangles which will exactly divide into areas of 1/3 above and 2/3 below the equator.

A Teotihuacan sphere whose diameter is 12 will give an area of 144 π, a quarter of which is an easily reckoned 36 π, and so forth. Again all the numbers run in a 3, 6, 9, 12, 24 series, unique with a sphere of diameter 12.

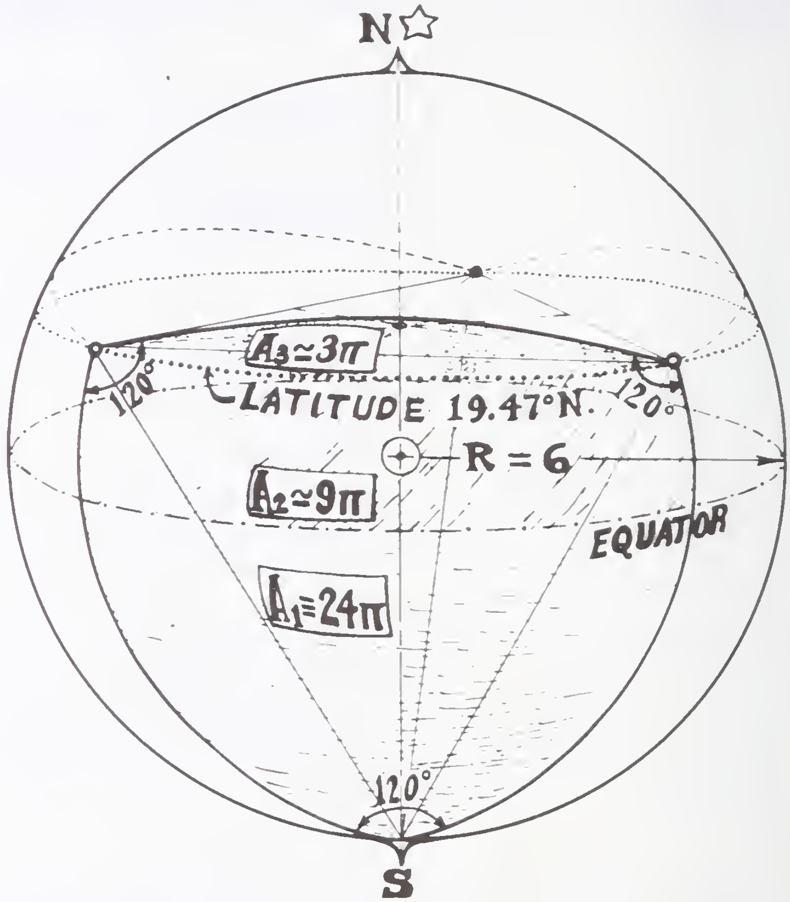
The tetrahedron, simplest of the five Platonic solids, is a perfect pyramid, a geometrical figure that represents the smallest number of points that will form a solid in three-dimensional space. It is constructed by uniting four identical equilateral triangles at their edges to form a body with four nodes, four faces, and six edges.

Harleston points out that the abstract properties of such a six-edged tetrahedron involve functions of 3, 6, thirds, square roots, and the number 1.06, all emphasized by the Teotihuacan displays.

When he inserts the tetrahedron into a sphere of diameter 12 some extraordinary relations develop. When the diameter of the circle is 12 (and therefore its radius 6), the ratio of the area of the sphere to the tetrahedron is 2 to 1. This is the only case in which this significant correlation occurs.



R. Buckminster Fuller's isotropic vector matrix.



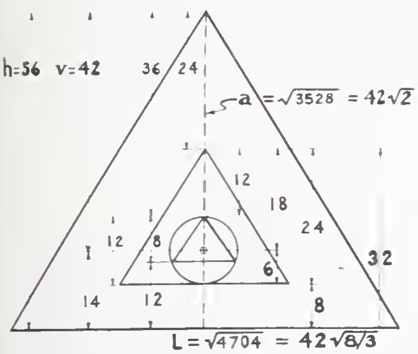
The four points at which the great circles meet form the nodes of a tetrahedron inscribed in a sphere. This apparently casual relation showed on closer inspection that an extraordinary and unique relation exists between a tetrahedron and a sphere whose diameter is twelve, one from which cosmic data ensues.

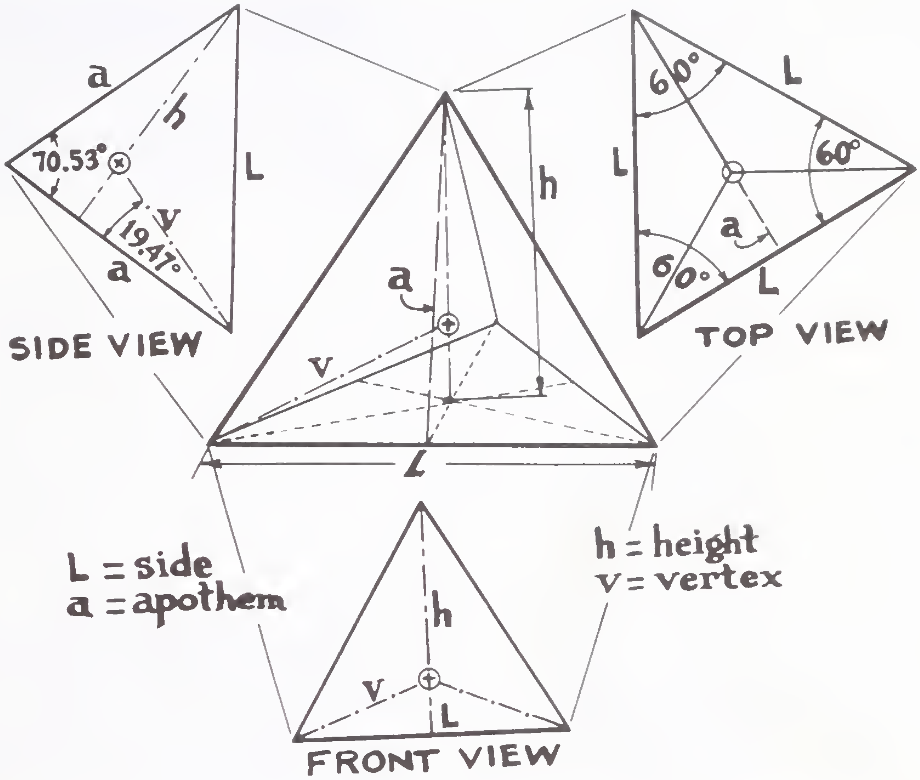
Oddly, or coincidentally, the relation between a tetrahedron and a sphere constitutes the thrust of the work of Buckminster Fuller, who, in his book *Synergetics,* maintains that the tetrahedron gives the basic mathematical blueprint for the universe.

From what he calls his "isotropic vector matrix" Fuller obtains a constant of $\sqrt{9/8}$, which comes to 1.06066, so close to Harleston's 1.059 constant that it fits the Teotihuacan complex virtually as well.

The difference between them—a mere one part in a thousand—produces a difference in length of less than 1 meter in the 800-meter overall distance between the Sun and the Moon pyramids, and less than 10 meters on the overall length of the entire Valley of Teotihuacan, differences easily absorbed by Harleston's own postulated margins of error.

The regular tetrahedron.





A tetrahedron whose height is 12 is demonstrated by Harleston to have a side that equals the square root of 216, the length of the base of the Sun Pyramid, which is 6 × 6 ×6 or 6 cubed.

The height of an equilateral triangle of 216 base will be the square root of 3 × 6 × 9, or 162, the length of the Moon Pyramid.

If a larger tetrahedron is selected so that the sphere exactly fits inside it with the surfaces of the sphere touching the centers of the four faces of the tetrahedron, then the characteristics of the superscribed tetrahedron will be exactly three times the values for the one inscribed within the sphere, and its height twice the diameter of the sphere.

Harleston is impressed by the fact that the side of the tetrahedron's apothem, or slant height, as well as its area and its volume, are all multiples of 216—the side of the Sun Pyramid in *hunabs.* The ratio of the volume to area of this tetrahedron equals 2 to 1, the same as for the sphere of radius 6 it encloses. All the above numbers are major Teotihuacan dimensions. Harleston considers the tetrahedron to be fundamental to the message of Teotihuacan. A tetrahedron inside a sphere will have linear properties that are 1/3 of the tetrahedron surrounding the sphere.

Pointing out that the carbon atom—which is the basic building block from which the material bodies of all living organisms are made—is a regular tetrahedron, and that the water molecule has characteristics that conform to the tetrahedral structure, Harleston concludes that the fundamental message conveyed by the Teotihuacanos is that the physical universe is tetrahedral from the microscopic level of the atom all the way up to the macroscopic level of the galaxies on a scale of vibrations in which man stands about the center. Man would thus have built into him, as suggested by Pythagoras and Plato, the tool for unlocking the geometry of the cosmos and recovering the knowledge of his role in the scheme.

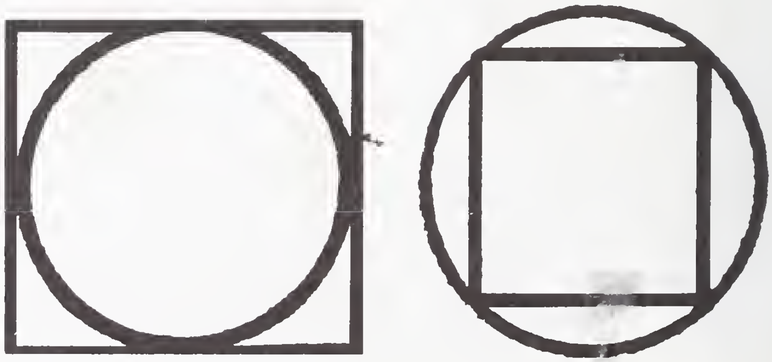
What evidence is there that the ancient inhabitants of Mesoamerica had sufficient physics, mathematics, and knowledge of the cosmos to leave such a message?

20. Wisdom of the Ancients

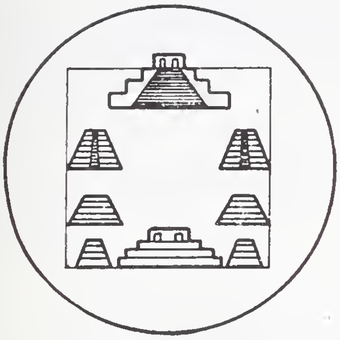
The most explicit Mesoamerican text on the origin and mechanics of their universe is the Quiche manuscript of Chichicastenango, better known as the *Popol Vuh,* which slips gently from a description of the physical world of men to a description of the spiritual entities and elementals which produced it.

In a carefully reasoned analysis of its text (which translates from the Spanish as *The Popol Vuh Is Right!*) the distinguished Maya linguist and philologist Domingo Martinez Paredes concludes that a very old and very highly developed culture existed on the American continents whose cosmogony agrees very closely with modern hypotheses about the origin of the universe and of its evolution.

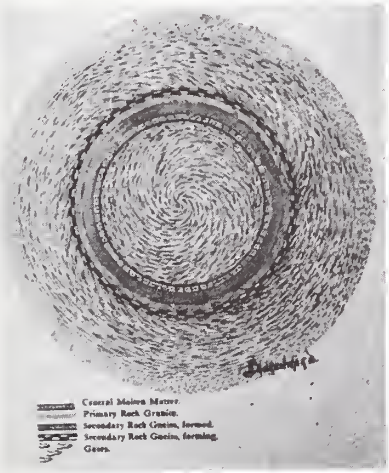
According to Martinez the Maya came to the mathematical certainty of the existence of a cosmic consciousness which they named "Hunab Ku," sole dispenser of measurement and movement, to whom they attributed the mathematical structuring of the universe. This divinity they represented by a circle in which was inscribed a square, just as did Pythagoras.



Hunab Ku, sole source of movement and measure, symbolized the universe for the Maya in the form of a circle with an inscribed square. The circle was the symbol of the infinite, the spiritual; the square of the material. Hunab Ku was thus a universal dynamism or that which motivates and stimulates life in its total manifestation as spirit and matter, the all in one. Martinez points out the similarity between the Mayan Hunab Ku symbol of a square in a circle and the Masonic symbol of the Great Architect of the Universe: the compass and the square. Martinez says *Hun* means sole or single in Mayan, *Naab* means measure, and *Ku* means giver.



According to Martinez, the central ceremonial area of a Mesoamerican pyramid complex was made in the form of a square circumscribed by a circle, symbol of Hunab Ku.



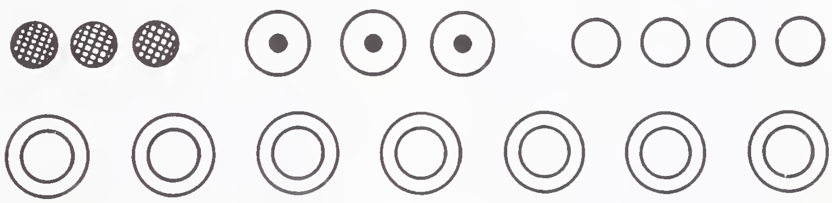
The Maya believed the world had been formed from a condensing nebula, here seen in Churchward's rendering.

The Maya believed that their supreme divinity functioned through a principle of dynamic dualism, or polarity, active and passive, positive and negative, masculine and feminine, by which, through the agency of four prime elements, air, fire, water, and earth (symbolizing space, energy, time, and matter) the whole material world was engendered.

The Maya conceived of the earth as having been formed from a nebula through the combination of fire, water, and gases which produced "solid" matter. Their name for the lesser deity of creative energy was Can or Kan; and Huracan was the rotary vortex which made possible the condensation of primordial elements by incorporating them into a nucleus, thus reintegrating elements disintegrated by Chaos. Gucumatz was water, Tepeu was fire, and the four elements symbolized by a square also represented matter in its four states: plasmic, gaseous, liquid, and solid.

The Maya considered every element in nature to be a cooperator in cosmic harmony, bound by its own vibrations into geometric form, a form which changed in type and quality as the vibrations changed. Modern science, Martinez points out, has found that no cell, no molecule, whether animal, vegetable, or mineral, escapes geometric form.

To the Maya the earth was not a corpse, it was neither dead nor inert, but a living entity intimately tied to the existence of man both physically and psychically; they knew that by laying their naked bodies on the earth they could revitalize their forces. They saw that trees and water constantly purified and revitalized man, as part of the cosmic order.

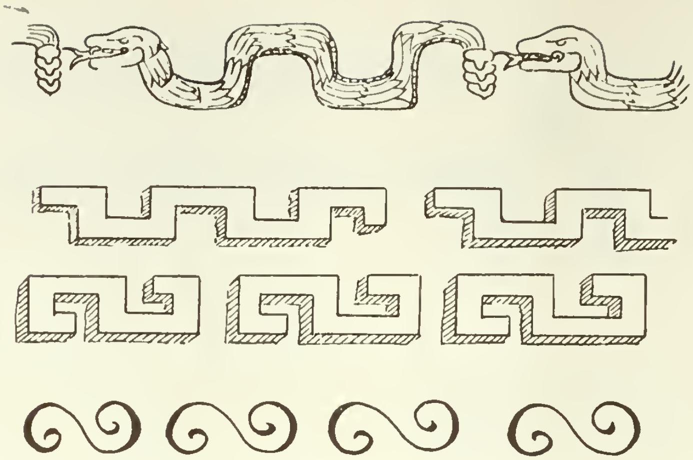


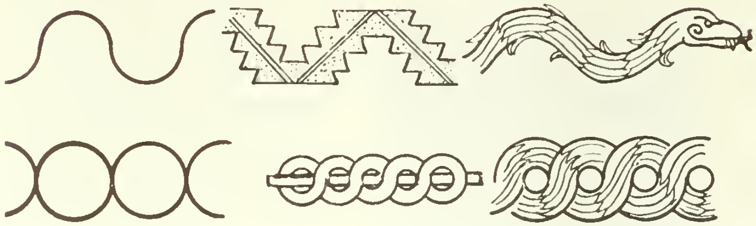
The Mexican mathematician Hector M. Calderon says that a people as sophisticated mathematically as the Maya would have had to incorporate its theogonic concepts into actual numbers, using the latter to express their ideas about the universe. He gives as examples Tzacol, the creator, as 1; Kukulcan as 2; Bitol, the fashioner, as 3; Alom, the female cosmic progenitor, as 4; Cajalon, the male progenitor, as 5; and Tepeu, the governor, as 6. All, were considered part of Hunab Ku, the primordial source of movement and measure.

Tzacol as 1, the creator, was considered a supernatural originator of energy, time, space, and matter. Creation, says Calderon, was considered foreign to the law of the conservation of energy, and nothing could be created or destroyed, only changed.

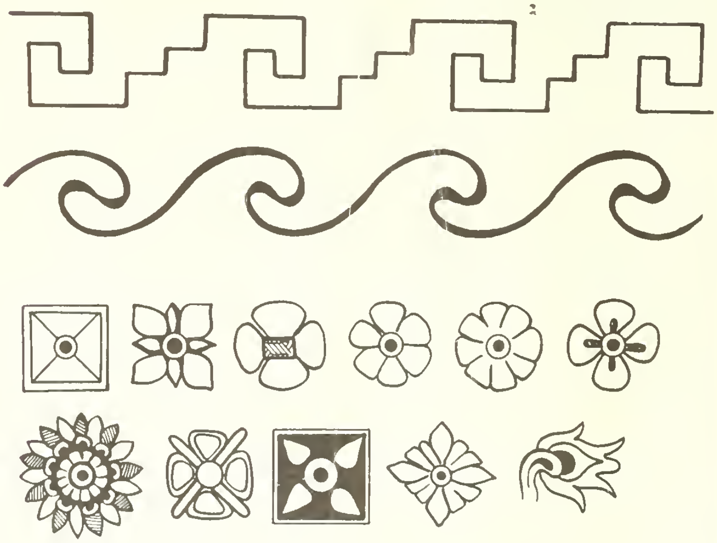
The Maya symbolized 1 by a point which, depending on its position, could increase in value to the infinite.

Number 2 was Gucumatz or Kukulcan or Quetzalcoatl, the airy plumed serpent symbol, the feathered part of which represented the spiritual and abstract, whereas the snake was the earthly and palpable. It represented the spirit-matter duality of the universe.





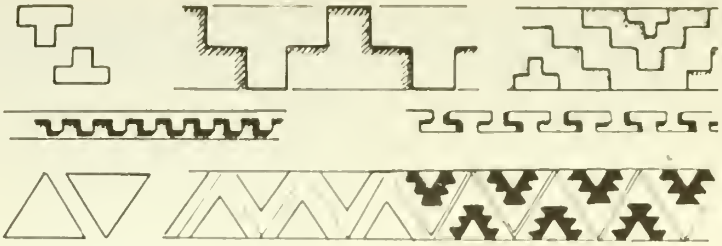
In all of nature the Maya saw countless combinations and manifestations of primordial forces which they incorporated into their architecture as geometric designs and represented by a host of nature spirits; yet they did not violate the basic notion of a single creative principle, a ubiquitous supreme dual god who created itself and all that exists.



Number 3 was Bitol, the Maya formulator, modeler of the clay of creation into countless evolutionary patterns of ever greater complexity. Its symbol was the wave, the basic giver of shape to the universe, a wave half evolution and half involution as it was represented by the Maya in their architectural designs. It symbolized the polarity or motor principle of the cosmos, which, from atom to star, is positive-negative—the latter not necessarily worse, just opposite, as gravity is to levity. Numerically, the 3 was derived from 1 plus 2.

Number 4 was Alom, mother of life, whose symbol was the flower, which receives the fecundating pollen; it is mother earth, which receives the grain of corn and the fertilizing rays of the sun. Its symbol is fourfold or a square. Cajalom, 5, is the father of life, or ⁚·⁚ the sun at its zenith, bathing the earth with fecundating energy. Its symbol is the celestial cosmic cross, four points with a central sun, which becomes ⁝·⁝, or 7, with the addition of East and West and the enlivening rain. For the Maya, 13 was the sun amidst the 12 constellations of the zodiac.

Calderon shows how Tepeu, the governor, who puts order into the furthest reaches of creation, was represented by the Maya as the number 6 or 3 and 3, a series of interlocked Taus, "as above so below," "synthesis and antithesis."



To the Mesoamerican everything was possessed by a "respected spirit." Not only the mineral, plant, bird, animal, and human kingdoms, but the mountains, clouds, and stars—all were possessed by invisible forces of life, the spiritual components of outer physical forms. These forces, or primordial images, were represented by men wearing strange anthropomorphic masks.

Itzamna, head of the Maya pantheon.

Kukulcan, the wind god.

Chac, the rain god.

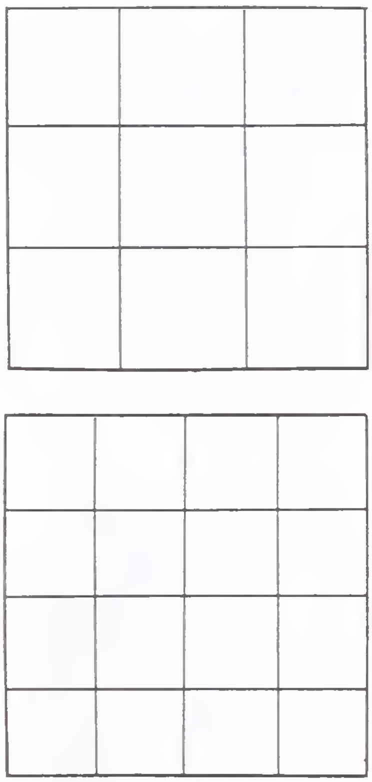
The god of sacrifice.

Like the Hindus, the Maya postulated rhythmic astronomical cycles as a result of which great civilizations appeared and disappeared, cycles that the priests maintained they were aware of and could understand through their mathematics, astronomy, and astrology.

The basic Mesoamerican chronology envisaged four great eras or world periods before the present or fifth world in which they lived. They believed that each of the previous worlds had been destroyed—the first by jaguars representing earth, the second by air, the third by fire, the fourth by a great flood. The fifth, they prophesied, would be destroyed by a cataclysm of earthquakes.

Ixtlilxochitl, writing in the sixteenth century, concluded from his study of Nahuatl sources that the creation of the Fifth Sun occurred in 3245 B.C. But the preponderance of modern experts on Maya chronology, following Herbert Joseph Spinden's correlation, project the beginning of the Great Maya Cycle back to August 12, 3113 B.C.; they interpret the Maya prophecies to indicate the end of this fifth world will come on December 24, 2011 A.D., when the earth is supposed to be destroyed by catastrophic earthquakes.

At the end of his remarkably erudite and sensitive book *Mexico Mystique, or The Coming of the Sixth World Consciousness,* Frank Waters has attached an appendix by an astrologer, Mrs. Roberta S. Sklower, who has computed the probability of the particular arrangement of the planets which occurred in 3113 B.C. taking place only every 4500 years. As for the arrangement in A.D. 2011, she estimates it can occur once in 45,200 years, which led Waters to remark, "From this extraordinary pattern we might well expect an extraordinary effect."



Calderon shows how the Mayans used a checkerboard or mat, lined in nine or sixteen squares, to perform the mathematical operations of addition, subtraction, multiplication, division, and the finding of square roots with a minimum of effort and without having to memorize a complex multiplication table.

The notion that the earth is periodically destroyed was not restricted to Mesoamerica. Heraclitus and Aristarchus both concurred, as did Hesiod, who recounted the destruction of previous worlds; Hindus, Tibetan Buddhists, and Persian Zoroastrians all shared the notion.

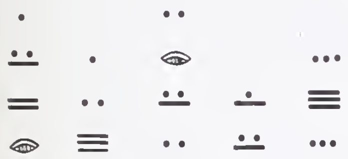
Convinced that nature was governed by cyclical laws, the Maya believed that everything could be foreseen—providing you understood the numbers which lay beneath the manifestations.

Nor were they mean mathematicians. Thanks to a checkerboard system, the Maya were able to handle very high numbers with little effort. Their system was so simple a child of four could multiply, divide, and obtain square roots without having to memorize a multiplication table; yet so versatile was the system that a housewife could manage her budget, and an astronomer could plot the centennial motion of the stars so as to calculate the arrival of a new eclipse.

The Maya knew our $+$, $-$, $=$, $\div$, and $\times$, but their zero was not a symbol for nothing: it represented completion and the seed from which all could be derived.

In his *La Ciencia Matematica de los Mayas,* Hector M. Calderon, a Mexican engineer who carefully analyzed the

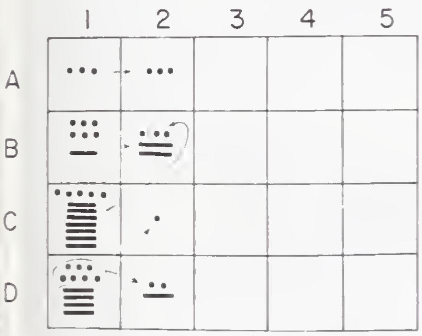
To add the following Maya columns of numbers:



11,000 455 16,142 127 1,503

add = 29,227

The Maya moved them all together by adding each column from the left, properly adding each square and moving upward any excess over 20.



The result

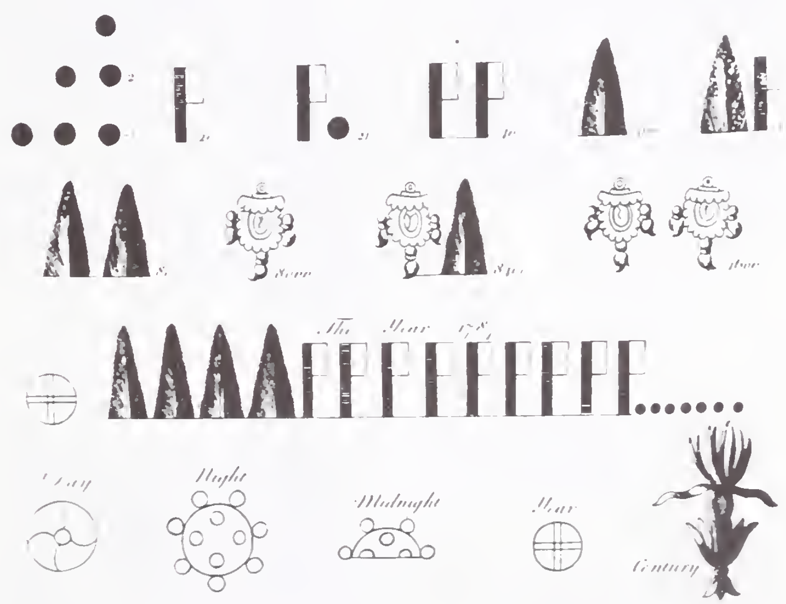
= 3 × 8000 = 24,000
= 13 × 400 = 5,200
= 1 × 20 = 20
= 7 × 1 = 7

29,227

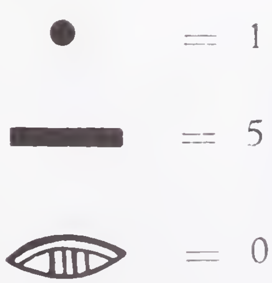
Mayan system of mathematics, says the Maya were able to resolve complex mathematical problems, perhaps several millennia before Christ, by means of a very simple system of grains of two colors to represent the numbers 1 and 5, placed in various positions on a checkerboard which they could draw on any flat surface. By means of these boards—represented on their monuments, paintings, clothes, and mats—the Maya were able to handle their chronology, astronomy, engineering, and architecture.

Calderon points out that what the Maya were using was a technique of metrical calculation only redeveloped in the middle of the past century, a system which for centuries was lost to humanity when the use of the checkerboard degenerated into sorcery, augury, and a simple game. He also points out that the universality of abstract numbers, a concept expressed with such insistence by the Maya in their ornamental boards, has only been repostulated in our century with dimensional analysis and the laws of similarity.

It is easier to picture numbers and their interrelationships with groups or sets of points than it is to do so with our symbolic figures.



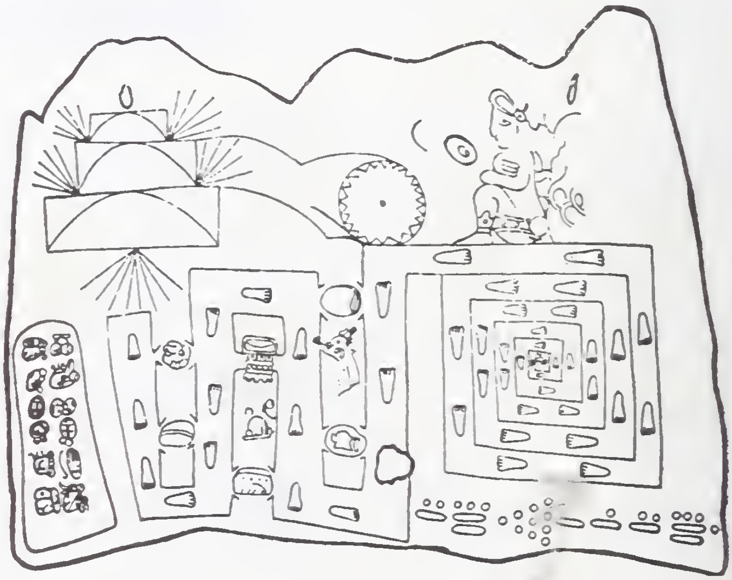
Aztec numbers.



Maya numbers.

Science, says Calderon, has now recognized that in the internal mechanisms of all phenomena there are certain mathematical relations which are independent of space, time, and the mass in which they are manifested. The recent rediscovery of this principle has made possible the deduction of several fundamental equations in every order of human knowledge. Thanks to these equations, says Calderon, there now exist hydraulic modules and constructional analogical computers for the rational compilation of statistical data. Now, for instance, it is possible to use a flow of water through an arrangement of levers and pivots to arrive at the results of a mathematical computation.

Calderon says the Maya identified man with the cosmos and created a school of philosophy based on the symbolism of numbers many centuries before Hermes Trismegistus or Pythagoras. Martinez says the Porrua Codex depicts the integration of man into the cosmos with symbols for one and zero to his right, left, and below him, in a square composed of calendrical hieroglyphs and numbers. The man holds a female serpent in his right hand and a male symbol in his left, interpreted by Martinez as man, time, and space.



Martinez points out how this "peregrination" from the Porrua Codex perfectly interprets the serpentine movement and the circle over the square, admirably depicting man and the cosmos. All took place within two geometric forms, the circle and the square.

Quipus, or knotted cords, used by Indians, Aztecs, pre-Incas, Mexicans, Egyptians, and Chinese as mnemonic devices like the rosary of the Catholic Church for recording and remembering long periods of history. The mathematical board with black and white pieces was used to make advanced mathematical calculations. Calderon says that throughout the Americas a similar if not identical system of mathematics, using colored beans or stones on a checkerboard, was employed before the Spanish conquest; he also points to the coincidence that our word for calculate comes from the Latin *calculi,* meaning little stones.

The great 260-day *tzolkin* calendar of the Maya known as *tonalamatl* by the Aztecs, showing grouping of lunar dates in three sections.

Intuitively considering the earth to be part of a whole, affected by the cyclical movements of the sun, moon, planets, and stars, the ancient Mesoamericans searched for the laws inherent in their recurring positions.

Well aware, long before the birth of Christ, that the foundations of chronology lay in the daily rotation of the earth on its axis and in its yearly revolution around the sun, Mesoamericans divided their year into 360 days plus 5 extra on regular years and 6 on leap years or 13 every 52 years.

On this point there is some discussion. Michael D. Coe of Yale University is categoric in his assertion that "there is no evidence that the Mesoamericans ever intercalated days or leap years." According to Coe, because the tropical year is 365.2422 days, the 365-day "vague" year simply gained on the seasons by a factor of 13 days every 52 "vague" years. But the fact remains that whatever system the Mesoamericans used, the result was a calendar more accurate than ours.

Calculating the orbit of the earth about the sun as 365.2420 days, the Maya marked the close of a year by the erection of a stone they called a *tun*. They did likewise for a twenty-year cycle or *katun,* a period they considered to be governed by the conjunction of Jupiter and Saturn.

Furthermore, they marked the passage of years by means of four distinct systems which acted as checks on all the others. Along with the year of 365 days and the more accurate tropical year of 365.2420 days there was a year of 365.25 days (the Egyptian Sothic year, whose .25 fraction was useful for the calculation of equinoxes, solstices, zenith passages, eclipses, and Metonic cycles), a lunar year of 354 days, and a very special "sacred" year of 260 days called *tzolkin* by the Maya, and *tonalamatl* by the Aztecs.

This special 260-day calendar, which has been called "one of the greatest jewels of human talent of all ages," was divided into 13 months of 20 days, and the multiples of 13 and 20 became the heart of a chronological computation "stunning in its simplicity and exactness."

On a monthly basis, twenty day names of the month were linked to the numbers from 1 to 13 to produce 260 different arrangements, such as 1-alligator, 2-wind, 3-house, 4-lizard.

A day with the same name and number could therefore recur only once every 260 days, forming a cycle which could repeat endlessly without regard to the actual movements of the sun and planets, which marked the natural time periods.

A greater cycle of 260 years was 13 consecutive Jupiter-Saturn cycles of 20 years, each one of which was considered to have a different quality depending on the series of angles formed between Jupiter and Saturn during each *katun*.

This sacred calendar was used as a divinatory almanac or *Book of the Good and Bad Days,* a *Book of Fate* rather than a calendar dependent on the seasons.

Each day of the *tzolkin* was governed by a deity who was thought to influence that day for good or evil, each separate day being regarded by the Maya as an individual god, whose glyph was a stylized portrait of his attributes. The numbers 1 to 13 were also personalized as the heads of the gods they represented.

A baby was given the name of the day on which he was born. The name of Cortes' mistress, La Malinche, for instance, was a corruption of Ce Malinalli, or "1-grass."

The imposition of this 260-day calendar was in no way arbitrary. The Mesoamericans had figured out correctly that 260 × 18 is the same as *360* × 13, that 260 × 7 is the same as *364* × 5, that 260 × 73 is the same as *365* × 52 and that 260 × *1461* (the Egyptian Sothic cycle) is the same as *365.25* × 1040.

To these calendars, which all fell into the 260-day pattern, were added more refinements for calculating the synodic returns of the moon and the planets.

In the latitudes of Mesoamerica the planet Venus looms in the dawn sky with extraordinary brilliance, and the astronomers of both the Nahua and Maya devoted particular attention to the planet, and especially to its heliacal rising.

Venus revolves around the sun every 224.7 days; but because the earth is moving along its own orbit, the planet appears at the same place in the sky in a little less than 584 days. As 5 × 584 is equal to 8 × 365, the Maya considered eight Venus years equal to five solar years. And as 365 × 104 is equal to both 146 × 260 and 65 × 584, the solar, sacred, and Venus calendars become coincident every 37,960 days, or 104 years, which was two Mesoamerican centuries of 52 years.

Actually the Maya knew the Venus cycle to be 583.92 instead of a round 584 days, so they dropped 4 days every sixty-one Venus years in order to compensate for the discrepancy and make a round number divisible by 260.

As astronomers are quick to point out, such an accurate knowledge of the cycle of Venus, whose revolutions are by no means regular, points to long and sustained observation.

The Mesoamericans furthermore devised a lunar calendar that would fit with the others. Calculating that 405 lunations or 11,960 days was exactly divisible by 260 (or 260 × 46), they obtained a lunar period of 29.53 days with a mere discrepancy of .112 of a day from what we know today. This would give them a lunar calendar accurate to within a day over a period of 300 years.

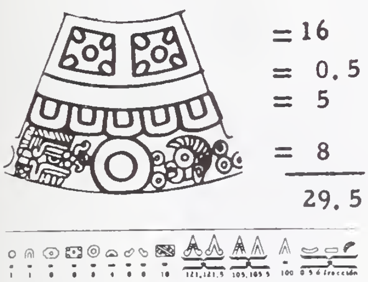
Hieroglyphic representation of an eclipse of the sun.

They also realized, as had the Athenian astronomer Meton in the fifth century B.C., that 19 Sothic years of 365.25 days were equal to 235 lunations, or 6940 days, which the Maya correctly figured to be one *katun* of 7200 days less one *tzolkin* of 260.

As a simple way to cope with the fraction slightly more than half a day over 29 for a lunar cycle, the Mayans reckoned their moons in groups of five or six, alternating between periods of 29 and 30 days. They could thus accurately state how many days after a new moon a date in question might be, how many moons of the group had been completed, and whether the actual moon, then running its course, was on a 29- or 30-day cycle.

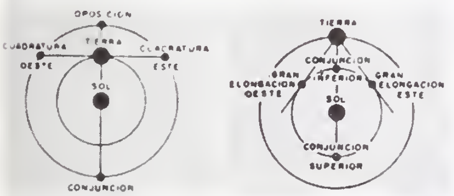
From a glyph they could tell how many days the date was after the full moon, which moon it was, and how long the previous moon had run.

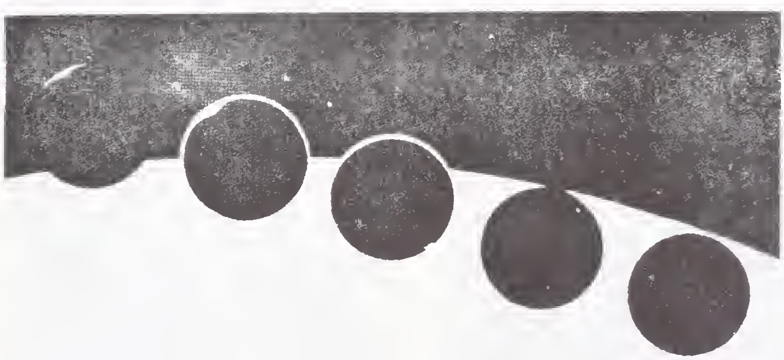
As for eclipses of both the sun and the moon, instead of being terrified by them as were their contemporary Europeans, the Mesoamericans calculated them accurately to use as a further check on the interrelation of returns of the planets.



Noriega's decipherment of the 295 days in the Aztec lunar cycle.

Raul Noriega's analysis of the Aztec Sun calendar of a 243-year period between passages of Venus before the sun.
121.5 + 8 + 105.5 + 5 = 243





The phenomenon, first calculated in modern times by Kepler in 1631, and first observed in 1639 by two Englishmen, William Horrox and Benjamin Crabtree, was seen in Mexico City in 1882.

The same phenomenon is recorded in the Tizoc stone in a slightly different manner.

In the early 1930s J. Antonio Villacorta, a Guatemalan lawyer, put together a set of books in which he reproduced the three main Maya codices—known for convenience as the Madrid, the Dresden, and the Paris—giving descriptions of their various glyphs and figures with whatever meaning for them he was able to glean from various sources. For the finely drawn copies of all the pages of the codices he enlisted his nephew, Carlos.

The effort itself did not bring much that was new to the art of decipherment, but the care with which the figures are reproduced, and the orderly manner in which they are annotated on opposite pages, made available to other researchers copies of the codices at a reasonable price to which they could apply their own talents of decipherment.

In the early 1950s a Soviet enthusiast, Yuri Knorosov, suggested that the Maya might have used two or three phonetic syllabic signs joined together to make a word. It was as radical an approach as Landa's, and met with as much opposition. Over the years, Knorosov produced a long book on the Maya and their hieroglyphs. He translated the *Chilam Balam* and other chronicles into Russian and added a short Maya dictionary along with reproductions of many of the glyphs—much as Thompson had done. Knorosov also reproduced Villacorta's drawings of the codices.

In the 1960s three Soviet mathematicians working in the Soviet Academy of Sciences Institute in Novosibirsk on the development of computer sys-

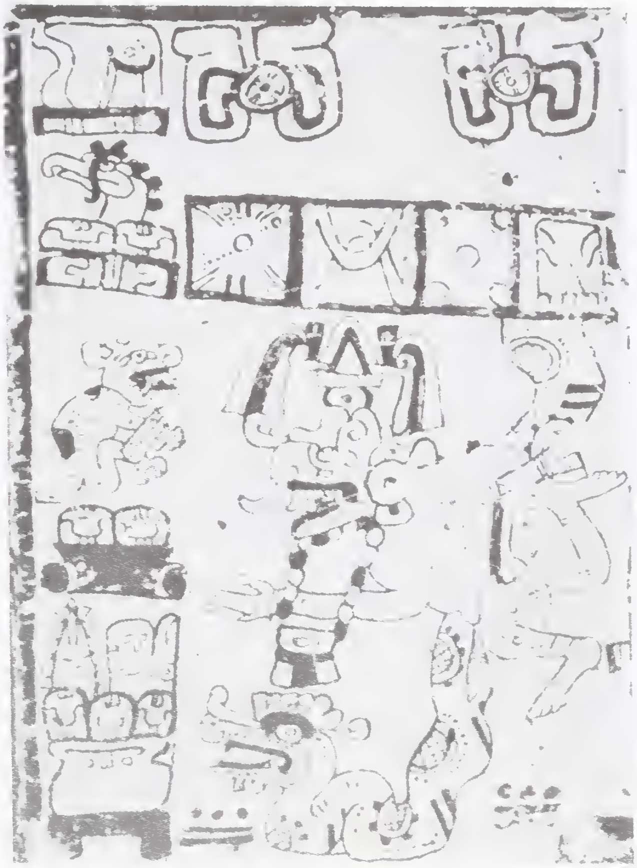
Villacorta describes the body of a large crocodile issuing from glyphs recognized as those of the planets Venus, Mars, Mercury, and Jupiter, from which hang all the glyphs representing the Sun and the Moon. From the crocodile's jaws pours a torrent of water which floods the earth, while a black god destroys humanity with a fistful of arrows.

Villacorta says that quite probably the Mayan priests wished to represent in this realistic scene the destruction of the world either in some distant future or possibly in the cataclysm produced by the flooding of the oceans as told in the *Popul Vuh*, when the gods wished to destroy humanity.

tems fell for the idea of using Knorosov's material in an attempt to decipher the Maya glyphs as a test project for a new large-scale computer they were designing. On the advice of Russia's most eminent mathematician—Soboliev, head of the Institute's mathematics department—the three Soviet computer experts, E. V. Evreinov, Yuri G. Kosarev, and V. A. Ustinov, fed into the computer all the known Maya glyphs, half glyphs, affixes, and prefixes they could find in the apprehensive expectation they might at last decipher the Maya texts. When all the data had been fed by number into the computer, the results filled four thick volumes with thousands of random phrases made up of Mayan words and syllables; but it did not do much toward an understanding of the Mayan writings.

J. Eric S. Thompson, the Polonius of Mayan hieroglyphics, accused Knorosov of doing violence to the language with his "disregard for all that is known of context and subject matter." Thompson was scathing in his criticism. "These numerous attempts to make silk purses out of Landa's sow's ear ended in disaster; the extravagances of the decipherers, growing with each failure, shrouded in clouds of fantasy the three or four reasonable decipherments."

In 1976 Knorosov brought out a new volume which was heralded by Reuters as a breakthrough; but Knorosov appears to have merely translated into Russian the random phrases put together by Villacorta, which were computerized by the mathematicians at Novosibirsk. Knorosov has promised a deeper analysis in a future publication. But the fact that the Russians have suddenly taken a distinct interest in the solution of the Mayan glyphs may indicate they suspect there is data of interest to be derived from them, or, indeed, may have already obtained such data.



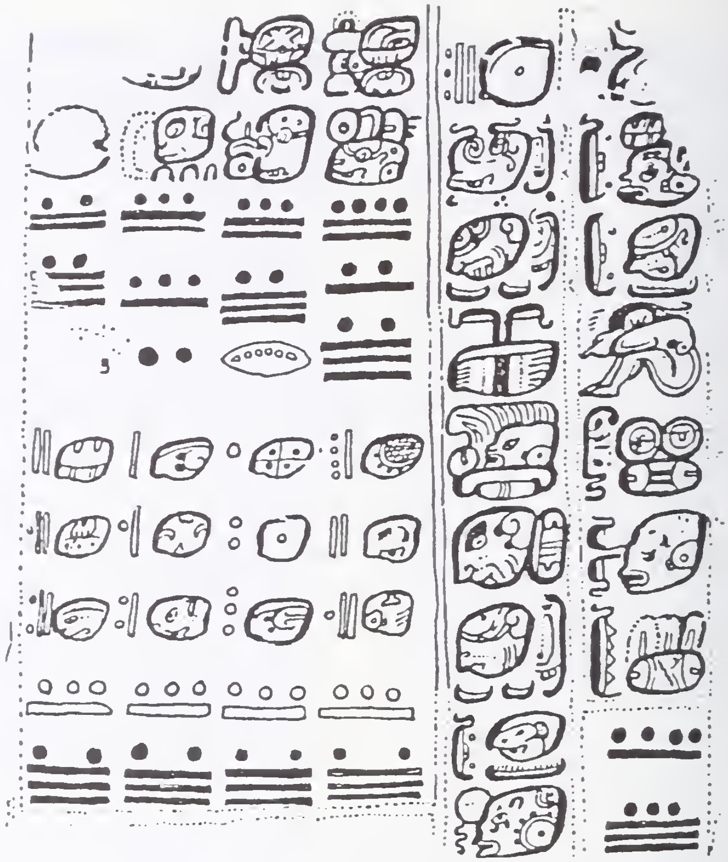
The boldest glyph recognized by Villacorta on page 12 of the Tro-Cortesianus Codex is that of the Sun surrounded by clouds producing tropical rainstorms. Immediately below, in four squares, are the glyphs for Mercury, Mars, Venus, and Jupiter. Villacorta says the large figure falling from under the four planets is the rain god painted in blue. Around his neck is a bag of copal painted red, yellow, and blue. Copal was burned as incense by the Maya with their prayers for rain. The large serpent entwined down the page has four Chicchan glyphs on his body each of which is interpreted as signifying "serpent." According to Villacorta the page is a prologue to the scenes depicted on the next seven pages (one of which is missing), where five large snakes (and possibly a missing sixth) represent time.

Page 60 of the Dresden Codex is interpreted by Förstemann as representing a "Battle of the Planets" including the Sun, Moon, Mars, Venus, Mercury, Jupiter, and Saturn, plus glyphs for an eclipse. In the top panel, according to Förstemann, the Sun is being threatened by the moon at an eclipse—symbolized by what he calls a dog under the platform about to devour the hieroglyph day-sign for *Lamat*. He believes the figure behind the moon to be Mars.

At the bottom of the page, Förstemann says the scene represents another struggle between the planets in their cyclical appearances, disappearances, and overtaking of each other. In this case, Sun, Moon, Mars, Venus, Mercury, and Saturn are shown.

Villacorta says the figure at the top left riding the snake represents Venus overcoming Mercury, whose eyes are bandaged—planets that alternate as "morning and evening stars."

Opposite them Jupiter is overcoming Saturn (with the black eye) and relegating it to a far corner of the sky.



In Vienna in 1739 the librarian of the Royal Dresden Library, Johann Christian Gotze, was given a mysterious 12 foot by 8 inch codex folded up like a fan into 39 sheets which he filed away with the notation, "A Mexican book with unknown characters and hieroglyphic figures written on both sides and painted in colors."

In 1813, Humboldt published a few pages of the codex in his *Vues des Cordilleras,* and Agostino Aglio copied it for Kingsborough's *Antiquities of Mexico,* which appeared in 1831. Yet little or nothing was understood of its 74 fig-bark paper pages illustrated with white, red, yellow, blue, and brown figures until they were chromophotographed by Naumann in 1880. With a working copy of the codex, Ernst Förstemann, director of the Dresden library and son of a Danzig mathematician, was able to study it more carefully and see in its glyphs an astronomical treatise. Over a period of fourteen years Förstemann was able to piece together the Maya long-count calendar determining the positions of five numerical signs with relative values of 1, 20, 360, 7,200, and 144,000. He then noted the appearance of zero in almost all the computations, established a Venus cycle of 584 days, and found the base date for a lunar calendar.

The next major step in deciphering the Dresden Codex was made by John Teeple, an American chemical engineer, who took up the study of Mayan codices to divert himself on long train trips.

Teeple saw how the Mayans had computed the synodic returns of Venus, which vary between 580 and 588 days, averaging 583.92. To offset the discrepancy between the rounded figure of 584 days, they added 24 days every 301 revolutions, reducing the error to one day in 6,000.

During World War I another German, Martin Meinshauser, was able to decipher in the codex a calendar of eclipses, and during World War II an attorney friend of Förstemann's, Paul Schellhaus, who was killed by the Nazis in 1944, described fifteen Maya deities who appear throughout the codex. The manuscript, kept in a wine cellar for safety during the bombing of Dresden, narrowly escaped being destroyed by fire and was somewhat damaged by water.

Subjected to tense scrutiny in the middle 1970s by the hieroglyphic section of the Institute of Maya Studies of the Miami Museum of Science, the codex can now be described as a highly sophisticated astronomical computer.

Pages 57 and 58 of the Dresden Codex provide a perpetual lunar calendar of 11,960 days consisting of 405 months divided into 69 groups of 177, 178, or 148 days. It is a very accurate lunar calendar, with a table for new moons for prediction of solar eclipses. 11,960 divided by 405 gave the Maya 29.5308 for the lunar cycle. Modern astronomers compute it at 29.5309. In the Dresden Calendar 11,960 divided by 69 gave the Maya 173.3333 as an average period between eclipses. 69 groups give the days when solar eclipses can occur as the new moons pass between the earth and sun.

Another calendrical device in the Dresden Codex is made by the serpentine pattern found by moving from one space up two rows and over one, then down two rows and over one. This produces an unending count of 91 days between each day-sign for a total of 20 cycles or 1,820 days. As each season of the year is divided from the next by the 91-day interval between the solstices and equinoxes, the calendar makes it possible to plot the sequence of equinoxes and solstices on the pattern beginning at any particular point of the 260-day sacred calendar, returning to that point to begin again in a perpetual cycle. To account for the discrepancy of 4.968 days every four years, the Maya added five days.

Newly Discovered Codex.

During 1971 a fourth Mayan codex surfaced in New York, where it was exhibited in June at the Grolier Club. As its anonymous owner did not wish to divulge its origin, the manuscript has become known as the Grolier Codex. It is now safely back in a Mexican museum. According to Dr. Michael D. Coe of Yale University, who helped prepare the exhibit, the codex, which is a painting on "bark cloth," dates from between A.D. 1400 and 1500. The manuscript consists of an eleven-page fragment of an original book of twenty pages, but unlike the other codices it does not have a profusion of complex hieroglyphs. On each page are columns of thirteen day-glyphs with relevant illustrative glyphs, each of which can now be read.

Like the Dresden Codex, which is a 400-year Venus calendar, the Grolier Codex is clearly a calendar of the phases of Venus, but displays a much more sophisticated system. Though it appears on the surface to be simply a 104-year calendar, it is described as "the world's first and only known perpetual calendar of Venus ever produced by any civilization." According to Charles H. Lacombe, "this ancient Mayan document must rank among the supreme intellectual achievements of human history."

The codex predicts the appearance and disappearance of Venus in a great cycle of 845 revolutions equal to 1352 years; and after completion, the cycle repeats itself endlessly by means of a shift in the order of the lines and the way they are to be read.

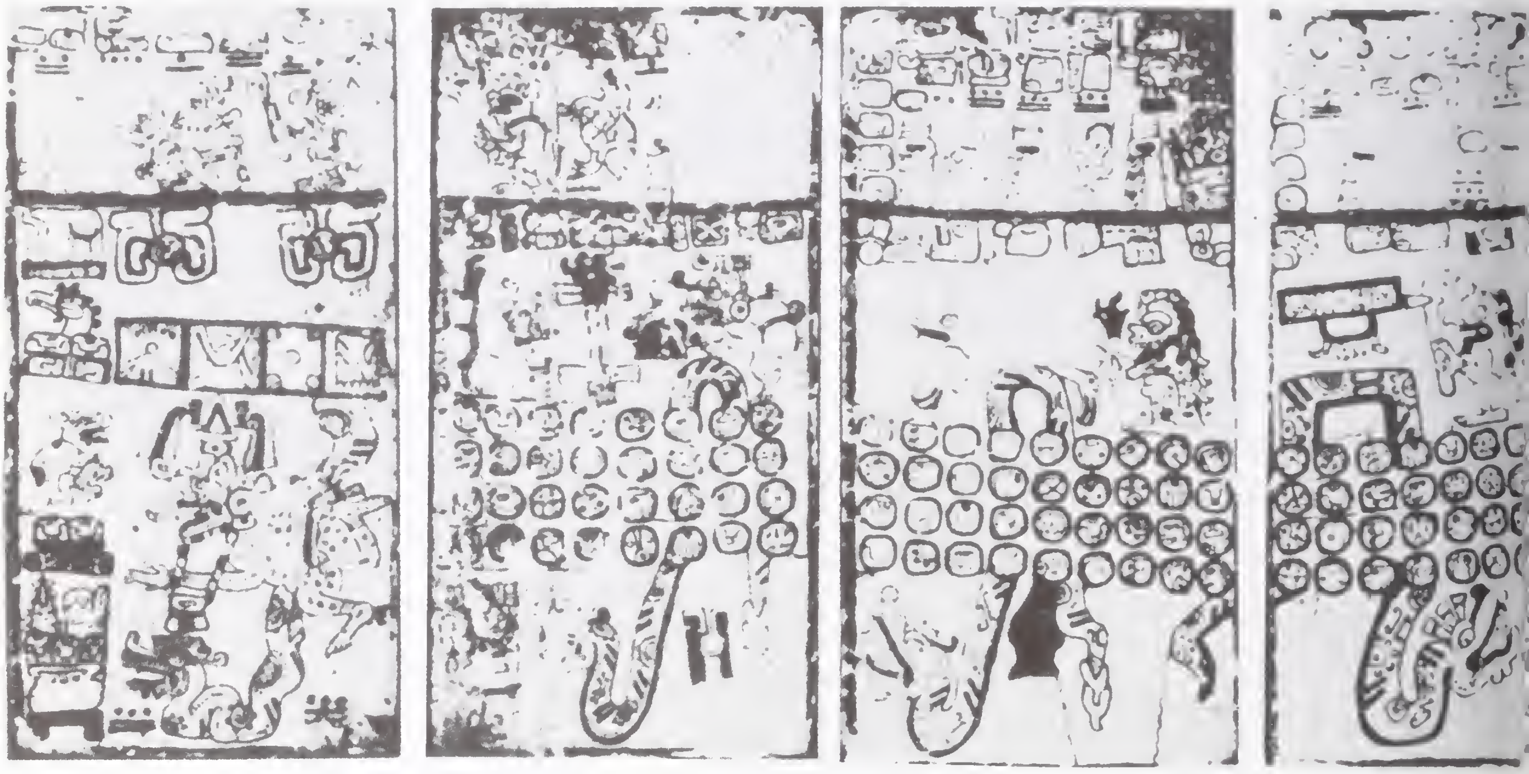
Viewed horizontally, each line of figures represents an 80-year cycle of the revolutions of Venus, and as there are 13 lines of figures, the chart represents 13×5, or 65 revolutions, equal to 104 years. But as each line moves up one place every 104 years and the top line goes to the bottom, every line is back in place at the end of 1352 years, at which point the process is repeated in an endless cycle for a perpetual calendar.

Curious as to why there appeared to be an extra 104 years in the calendar, Lacombe realized this was an essential correction built into the system to make it perpetual.

According to Dr. Douglas Duke, professor of astronomy at the University of Miami, Venus actually takes just 780 synodical revolutions, or 1247 years, to return to the exact spot at the exact time it started the cycle.

The Grolier Codex also supports the evidence for the Spinden and Makemson correlations, which place the date of the origin of the Mayan system in 3374 B.C.

To those who have suggested that this newly found codex could have been a fake, Lacombe replies that no forger could have been clever enough to fake such data for which there is no other source among Mayan scripts.



Tro-Cortesianus Codex.

Detailed analysis by the hieroglyphic section of the Institute of Maya Studies of the Miami Museum of Science, revealed that the illustrations function admirably as a computer for astronomical data.

In the words of Charles H. Lacombe, director of the hieroglyphic section, and Samuel S. Block, a Miami architect who has made several breakthroughs in deciphering the astronomical functions of Mayan hieroglyphs, this part of the codex is "unbelievable in its perfection and simplicity, instantly performing the incredible combination of mathematical functions required to program and retrieve the mathematical data."

The Mayan day-signs which run in columns of four from page to page of the codex are entwined with five serpents and a possible sixth which appears to have been on a page now missing. Read vertically, these day-signs provide a solar calendar of 365 days; as the sequences repeat themselves they provide a perpetual calendar of 4 times 13, or 52 years. The same day-signs read horizontally in groups of 5 times 13, or 65, give a Venus calendar (each of which takes 584 days), the equivalent of 104 years of 365 days, or two 52-year cycles.

Read diagonally in a succession of M's across the pages, or in what Block calls "a curious but fascinating economy of programming," the mechanism shows Venus appearing as the morning star, as the evening star, and in its superior and inferior conjunctions.

To identify two points on the diagonal separated by a Venus year, or 584 days, the computer shifts 65 spaces to the right, nine times, and one space to the left, for a total of $65 \times 9 - 1$ or 584.

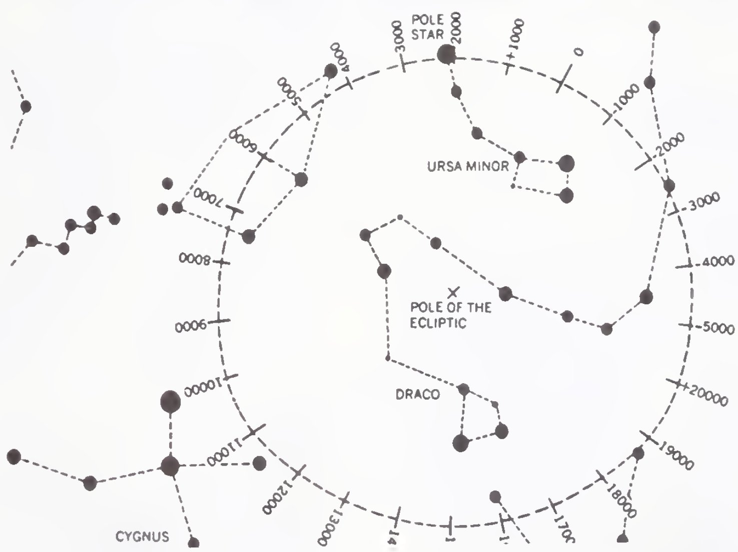
The five looped serpents entwined into the solar and Venus calendars are also arranged in such an exact manner, mathematically and geometrically, that they also function as a mechanism of the computer: they give the synodic cycles not only of Venus but of Mercury, Mars, and Jupiter. Explanatory panels across the top and bottom of the codex carry glyphs representing these planets as well as the long-nosed rain god Chac-Mool suspended over a serpent.

The first two serpent heads face left, the second two face right, and the fifth faces left, only in a reverse fashion, and each serpent intersects at four points. The total number of days covered in the intersections of all six serpents is 2600 days, or ten Mayan sacred *tzolkins.*

Lacombe and Block point out that the system is especially flexible in that the day-signs appear on the chart without the required numeral coefficient and can therefore be read up, down, or diagonally, producing readouts for different calendars, giving equinoxes, solstices, solar eclipses, and the days on which two or more celestial events can coincide.

After a great deal of careful observation, astronomer Marian Popenoe Hatch recently discovered that the various snake positions correlated exactly with the path of the constellation Draco as it would have appeared in the evening sky two thousand years ago.

Dr. Hatch noted that the star Eta of the constellation Draco was unique in that it alone among all the stars remained virtually unchanged in right ascension for the 2300 years between 1800 B.C. and A.D. 500, regularly transiting across the meridian at midnight of May 23rd and November 22nd with a variation of less than one degree. Thus the star Eta Draconis provided the Maya with an accurate measure of the sidereal year, and a yardstick for comparison between the tropical and the sidereal years, as well as an indication of the processional lag in the other stars.



Hatch found that the path of Eta Draconis, as it moved through the celestial orb in the course of the year, correlated perfectly with the pictures of the serpents on the pages of the Madrid Codex, each of which astronomically represents a rotation in the sky of 45 degrees per page. When Draco is visible in the western part of the sky, the appropriate serpent looks to the left, when Draco is in the eastern sky the serpent faces to the right.

Noting that the word *Tzab* in modern Yucatec Maya means both the rattle of a rattlesnake and the constellation Pleiades, Hatch was pleased to find that the rattle on the snakes also correlated with various positions of the Pleiades in the sky.

The glyph with crossed bands which appears in the Codex was interpreted by Hatch as representing the constellation Cygnus whose star Gamma, when it transited at midnight, used to announce to Mesoamericans the advent of the summer solstice.

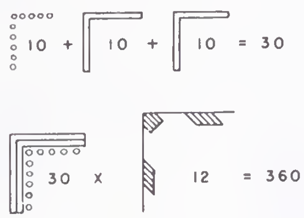
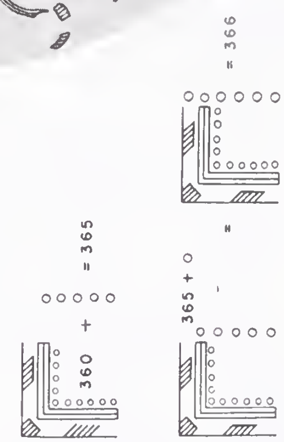
Noriega found a system of multiplication signs in the Sun calendar which he deciphered as follows:





Raul Noriega was able to achieve what Leon y Gama and Humboldt suspected but could not adequately accomplish: he demonstrated that the great Aztec monolith was a cosmic clock of extreme sophistication.

Noriega realized that with the exception of the obviously mythical figures, such as the twenty day-glyphs in the circle, and the four ages glyphs in the second circle, most of the other symbols carved into the great stone were purely mathematical, with algebraic functions, which could describe a great variety of calculations, harmonized into an aesthetic whole. With very few glyphs and some multiplication signs, the ancient Mexicans had been able to express at will either very small or very large astronomical-calendrical cycles, in days, weeks, months, years, and centuries.

Noriega found astronomical computations that showed an exact knowledge of the cyclical movement of the planets, calculated in their synodic (or apparent as opposed to sidereal, or actual) returns with an accuracy equal to our modern astronomers' five points of decimal.

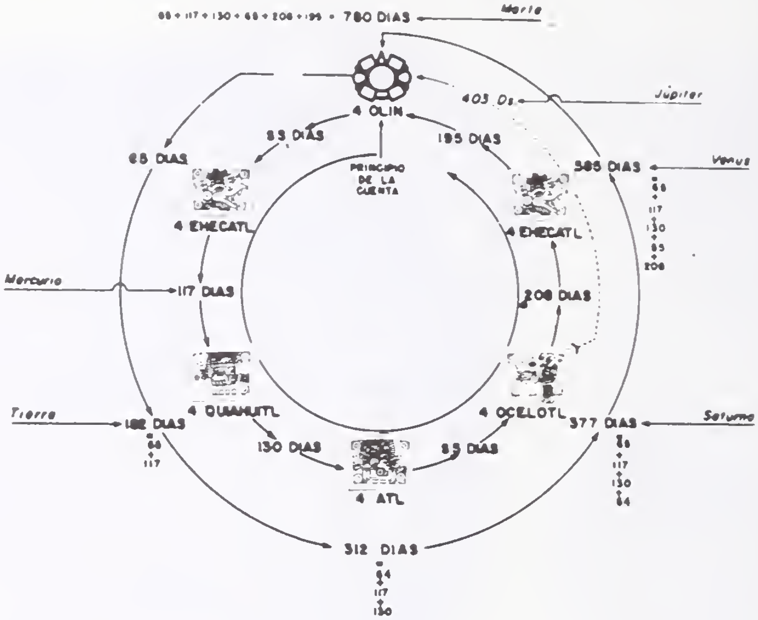
The calendar enabled its priests to compute the rhythmic cycle of solar and lunar eclipses, the passages of the sun at zenith, equinox and solstice, the furthest points reached on the horizon by the rising and setting sun and moon at different seasons, the phases of the moon, the heliacal rising of Venus, and the passage of Venus across the face of the sun (four times in 243 years), probably observed through fine sheets of obsidian or mica.

The third cycle of the calendar, says Noriega, will show a modern high school student how to determine the recurrence of planetary conjunctions going into the past or the future for thousands of years.

By locating in Oppolzer the 454 eclipses of the sun observable in the mid part of the North American continent from 1207 B.C. to A.D. 2161, Noriega was able to show the accuracy of recurrent periods of eclipses noted by the Ancient Mexicans in time lapses of 52, 104, 156, 208, 260, 416, 780, and 1248 years, all multiples of the Mexican century of 52 years.

The 1248-years cycle is quite remarkable. It is 12 centuries of 104 years each of 365 days. In that period the planet Venus makes as many synodic returns as there are days in a Mars revolution (780), and Mars makes as many revolutions as there are days in a Venus revolution (584). There are also exactly 1,752 calendars of 260 days in 1248 years.

Realizing that the earth was affected by the relative movements of the sun, moon, and planets, the ancient Mexicans, says Noriega, sought to master these cycles, by counting days, weeks, lunations, years, centuries, and synodic returns of the planets with the long-term object of being able to find the repetitive pattern in cataclysms, cyclones, tornados, earthquakes, floods, pestilence, and periods of relative serenity.



260 DIAS

Raul Noriega, a Mexican jurist and anthropologist who spent a lifetime researching Mexican calendar systems to produce an extraordinarily handsome and informative book, *La Piedra del Sol,* on the Mexican calendar stone, used the Oppolzer catalogue of eclipses of the sun and moon visible in Mesoamerica from 1204 B.C. to A.D. 2250 to find that almost all the eclipses related by a number of days whose factor was 260.

The planet Mars also fits this system admirably, in that one synodic return of Mars takes 780 days, which is exactly three sacred calendar periods of 260 days.

From an analysis of a score of Mexican calendar stones Noriega shows that the Maya (as well as the Aztecs) were able to calculate the synodic revolutions of Saturn, Mercury, and Jupiter with great precision.

One of the basic mysteries of the Mayan calendar now appears to have been resolved by one of the NASA technicians responsible for the Apollo flights, Maurice Chatelain, who was born in France but has lived twenty years in California. In his *Nos Ancêtres Venus du Cosmos,* published in 1975 by Robert Laffont, Chatelain worked out the basic calendrical system of the Maya which turns out to be similar to that of the Sumerians.

Chatelain got onto the solution while puzzling over the extraordinarily high number 195,955,200,000,000 which appears on one of the 30,000 Babylonian cuneiform tablets found in Assurbanipal's Nineveh library.

Chatelain says he got the shock of his life when he realized the number was 86,400 times 2,268,000,000, and that 2,268 million was the number of days in 240 precessions of the equinox (of 25,890 years each).

In other words, some ancient astronomer had counted 240 precessions not in days but in seconds, 86,400 being the number of seconds in their day. Then Chatelain began to realize why the Mesopotamians had gone to such lengths. He was even more surprised to discover that the huge Babylonian number was an exact multiple of all the planetary revolutions and conjunctions he could check, including those of satellites and comets, correct to four points of decimal! It made the 2,268 million years, or 240 cycles of precessions of 25,890 years, the basic constant or common denominator of the life cycles of the solar system.

Chatelain then resolved the riddle of the extraordinarily high Mayan numbers by looking not for a multiple of our earth and other planetary conjunctions, but at the conjunctions of the other planets with each other.

The Mayan cycle of 942,890 days, or 2,582 years, turned out to be 130 Saturn-Jupiter conjunctions. (It also covers

Noriega realized the four boxes around the central face of the calendar stone—4 Ehecatl, 4 Quihuitl, 4 Atl, 4 Ocelotl—together with the basic 4 Olin glyphs signalled the lapses of synodic revolutions of the planets.

Noriega deciphered the second ring of the calendar stone as an indicator of the synodic returns of the planets. Computed from 4 *Sun* to 4 *Hurricane* to 4 *Cyclone* to 4 *Water* to 4 *Ocelot,* all fit into a 260-day calendar, which gives the following time periods.

From 4 *Sun* to 4 *Hurricane* is 65 days or 1/4 of a sacred calendar, which is other cycles: 15 Neptune-Uranus, 1,555 Jupiter-Mars, 2,284 Mars-Venus, 6,522 Venus-Mercury, and 2,720 Sun-Mars.) Twice this cycle, or 5,163 years, is 260 Saturn-Jupiter conjunctions, which gives a grand cycle with the same number as there are days in the Mayan sacred year.

also 1/9 of a Venus and 1/12 of a Mars cycle. From 4 *Hurricane* to 4 *Cyclone* is 117 days, or one Mercury revolution (+ 1 day), the same as 1/5 of a Venus cycle. From 4 *Sun* to 4 *Cyclone* is 182 days, or 1/2 a terrestrial revolution (− 1 day). From 4 *Cyclone* to 4 *Water* is 130 days, or 1/2 a sacred calendar, which is 1/6 of a Mars cycle. From 4 *Sun* to 4 *Ocelot* is 377 days, or one Saturn cycle (− 1 day). Noriega points out that all the cycles are based on multiples or submultiples of 13, the fundamental Mesoamerican calendrical number, and that 44 lunations are counted as 1300 days, or 260 × 5. (The actual number is 1299.34596.)

To see where such a cycle would lead him into the past, Chatelain took the 18,630 B.C. date which appears in the Codex Vaticanus and moving forward in increments of 5,163 years (or 260 Saturn-Jupiter conjunctions) he lit upon 13,467 B.C., 8,304 B.C., and 3,141 B.C., the last of which coincided very well with the accepted beginning of the last Maya cycle of 13 baktuns.

Chatelain saw that this grand Saturn-Jupiter cycle of 5,163 years, or 1,885,780 days, could be divided into 13 baktuns of 397.2 years or (145,060 days) a katun of 19.86 years (or 7,253 days) each katun of which was divisible into 20 tuns of 363 days. He also calculated a grander cycle of 18,720 katuns or 135,776,160 days.

Next Chatelain realized that the next figure of 34,020,000,000 days which appears in the Mayan glyphs was 15 times the Nineveh constant of 2,268 million years, and that the even next higher number of 147,420,000,000 days in the Maya glyphs was 65 times the Nineveh constant. He also saw that 147,420 million days is 78,170 cycles of 260 Saturn-Jupiter conjunctions. It was clear to him that the Sumerians had used the same basic constant as the Maya, only multiplied by the 86,400 seconds of their day.

Furthermore, the Mesopotamians had linked their measures of time and space—in seconds of time and seconds of arc. 34,020 million days is not only the number of days in 3,600 Sumerian precessions of the equinox but 3,600 tenths of a degree—consisting of 36,000 Egyptian feet of .308 meter—is the circumference of the world in seconds of arc. The Mesopotamians had not only chosen as a unit of measure a foot that was earth-commensurate, it was also commensurate with the great Platonic year of 25,890 years. Odd would it be if the unit dispensed by Hunab Ku to the Maya were not equally earth-commeasurable. At Teotihuacan and at Palenque this ancient Middle Eastern foot fits Cinderella's shoe as neatly as it did at Cheops.

Frank Waters finds it useless to speculate on how the Mayan priest-astronomers "without telescopes, measuring apparatus, computers, and the use of fractions, could have achieved with such remarkable accuracy this immense and complex calendar system," and finds it even more incomprehensible that they could combine "the science of abstruse mathematics and astronomy with a metaphysical cosmology and mythology." The problem leads him to wonder whether "astrology, symbology and mythology could have been a shorthand to describe a galactic type of science of a different dimension from the conventional physics we use to describe earthly phenomena."

A clue as to how the Mesoamericans may have achieved such prodigious results was obtained in the 1950s by Geoffrey Hodson, the extraordinarily clairvoyant Theosophist, when he went into a semi-trance at the top of the Sun Pyramid of Teotihuacan. With closed eyes he was able to conjure pictures of the past. To Hodson it was clear that the ancient Mesoamerican priests had clairvoyant powers by means of which they could know when and where the various planets would be situated and from this knowledge deduce an accurate system of astronomy without benefit of high-powered telescopes. Such an accurate astronomy married to an accurately accumulated knowledge of the evident effects of planetary relations could have produced a valid science of astrology.

Hodson says that initiates were specially trained to detect combinations of planetary forces during astrological aspects. They could apparently feel or sense them, knowing when and where planets formed aspects like conjunctions, squares, or oppositions, which either strengthened or weakened stellar, zodiacal, or higher cosmic influences as they manifested on earth.

Hodson says the physical, astral, and mental bodies of the priests thus trained became sensitized to such a degree that they became human observatories, aided by physical recognition of the position of the planets.

The French astrologer Alexandre Volguine believes furthermore, that Mayan eyesight in those days was more powerful than today, though even with acute eyesight it would be difficult to account for how the Maya knew of 400 stars in the Seven Sisters constellation of the Pleiades, whereas today we can spot only 6 stars with the naked eye. Human senses appear to have degenerated rather than evolved under the influence of so-called civilization. Volguine says that illiterate natives in Oriental Siberia can still see the satellites of Jupiter. He adds that there is no reason to believe that the Maya were unable to see with the naked eye Uranus, Neptune, Pluto, and perhaps even the trans-Plutonian planet postulated by Harleston and others.

The Mayan palm, considered by Domingo Martinez Paradez to be the oldest continuous unit of measure, was known to the ancient Maya by the same word used for undulation: *naab*. Several Mayan palms were in use, one of which was about seven inches long.

An English radionic expert has found that every seven inches, or very close to that amount, the rotational polarity of a field of radionic energy extending from a magnetic compass reverses. This is shown by a change in the direction of rotation of a pendulum held over the horizontal plane in which the compass lies. According to astrologer Michael Heleus, this would imply that the ancient palm of nearly seven inches could have been a measure having a character intrinsically linked with the magnetic and radionic properties of the universe. Heleus suggests that the pendulum, sensing the magnetic undulation, reverses polarity at nodes whose distances are harmonic multiples of the palm, multiples whose sequence of alternation is reminiscent of the earth-commensurate palms in the ancient Greek (and Egyptian) foot and cubit.

Theoretical considerations supporting these observations are provided by D. B. Larson in *Structure of the Physical Universe*. In this work, Larson advances the hypothesis that the spacing of atoms, and indeed their production, is the result of the interplay of two opposing forces. The first, which he calls the space-time progression, moves outward from every point continually at the velocity of light, which he considers unitary. The second is rotation, which, where it exists, opposes the space-time progression, and if it exceeds that progression, creates an inward force giving rise to matter and gravitation.

21. Astronomical Observations

All the great temples of antiquity, as Livio Stecchini has abundantly shown,* served to locate man in the cosmos, both in space and time, bringing knowledge of the heavens to the earth.

According to the Chorti priests of Guatemala, their forefathers had divided the cosmos into a quadrangle. To bring this quadrangle down to earth, they picked as geodetic points the four corners on the horizon where the sun rests at dawn and sunset of the solstices.

The *Popol Vuh* says the surface of the earth was divided into four sections corresponding to the four points of the compass, each with its own colors, fates, and gods. Bishop Landa reports that towns in Yucatan were so designed, with four principal entrances in the form of a cross; and still today in Mayaland villages are laid out in the old pattern, the sun being observed at equinox and solstice in order to establish the points at which to put up stone markers.

The Dresden Codex shows that Mayan geodesy took into consideration both the cardinal points and the intermediate solstitial points, for which they eventually built complex observatories for determining the exact moment of the solstices.

A quote from the Roys book of Chilam Balam says, "When the eleventh day of June shall come, it will be the longest day, when the thirteenth of September comes, this day and night are precisely the same length. When the twelfth day of December shall come, the day is short, but the night is long.

* In his appendix to *Secrets of the Great Pyramid,* and other writings.

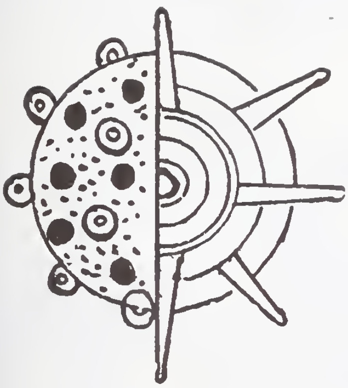
When the tenth day of March comes, the day and the night will be equal in length."

The discrepancy with our September 23 and December 22 is due to the shift of one day in seventy-two years caused by the precession of the equinoxes.

Diego Duran, Toribio Motolinia, and Fernando Ixtlilxochitl describe Mexican sun priests as spending long nights in systematic observation of the heavens, registering the movements of celestial bodies. With the use of the gnomon, they obtained accurate knowledge of the equinoxes and solstices.

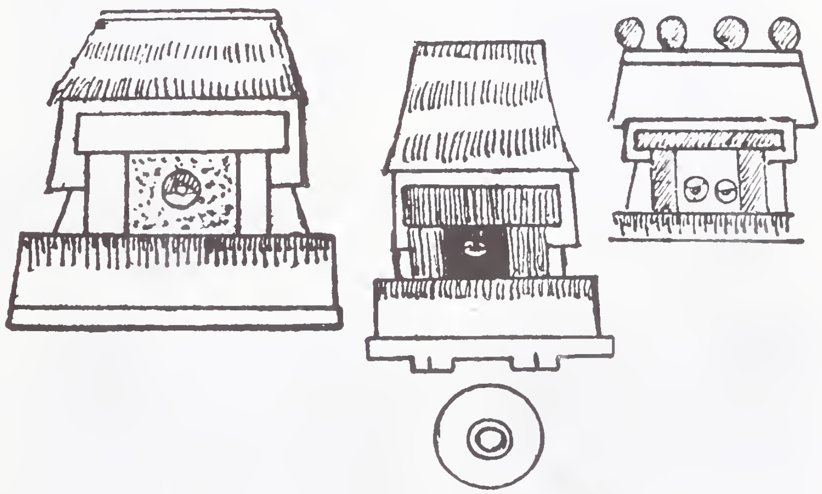
Motolinia says that in Tenochtitlan the festival called Tlacaxipeualiztli "took place when the sun stood in the middle of Huicholobos, which was at the equinox, and because it was a little out of line, Montezuma wished to tear it down and set it right." As part of his official duties Montezuma was required to rise regularly at midnight and offer incense to certain principal stars. Other priests watched for the appearance of certain stars at dusk, three A.M., and immediately before dawn, the time being heralded by drums and trumpets from the temples.

Zelia Nuttall demonstrated incontrovertibly, though little attention was paid her, that the ancient Mexicans not only employed carefully oriented temples and ball courts as astronomical observations, but also invented ingenious devices in and on these observatories for accurately registering the periodical appearances and disappearances of important celestial bodies: they had forked and bifurcated sticks, frets along the roofs of lined-up buildings, rows of upright sticks, and stelae carefully located several miles apart.



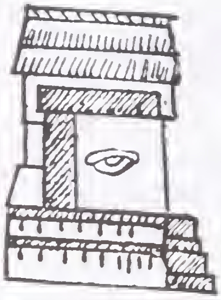
This circular figure with the sun symbol on the right and the star-filled sky on the left clearly shows an equal division of night and day—or the equinox.

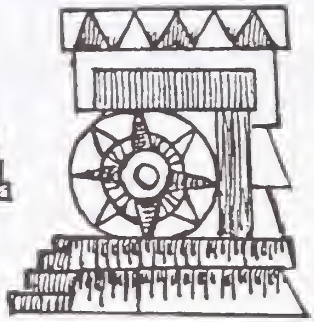
Figure 1. This illustration from the Codex Mendoza (reproduced by Kingsborough, volume V page 101) shows a seated priest whose vision is directed toward the symbol of the nocturnal heavens—an eye-filled hemisphere in which the eyes represent stars.

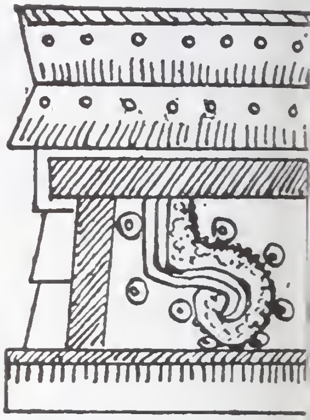


Figures 2 and 3 (Borgia Codex) show open doorways in the center of which float single stars. The first doorway shows the sky at dusk or dawn, the second at night. Below the second temple is a symbol for a great star or planet. The fourth figure shows twin stars appearing in the doorway.

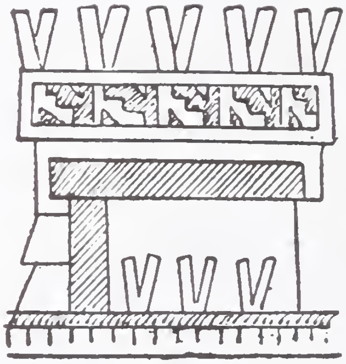
Doorways drawn in profile were the common conventional mode adopted by the native artists to represent temples. The first temple shows a single star, the second the sun, and the third an entire constellation in the form of a curved object studded with stars which is very similar to Scorpio.



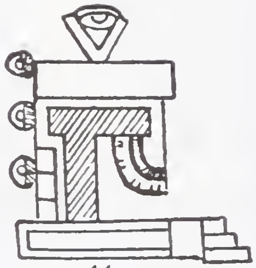




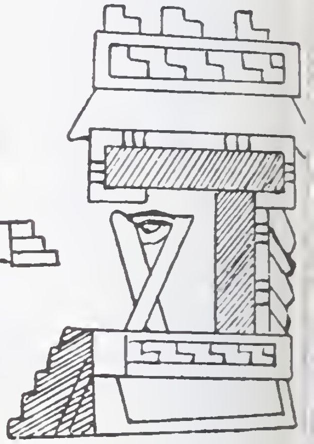
Ancient Mexican astronomers did not limit themselves to observing celestial bodies through openings in buildings. Figure 10 represents a temple on the roof and in the doorway of which stand rows of bifurcated stakes. Their purpose, says Zelia Nuttall, is revealed by figure 11, which is clearly designated as a star temple by three stars attached to the back wall. On the roof is seen a star in a bifurcated stake. Frets on the roof of the third temple indicate another method of lining up celestial bodies.

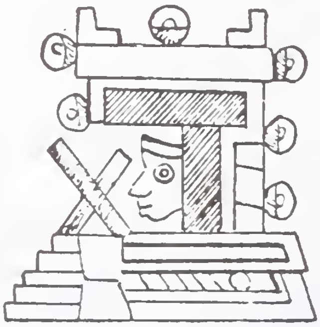


10

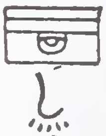


11



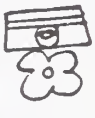


12

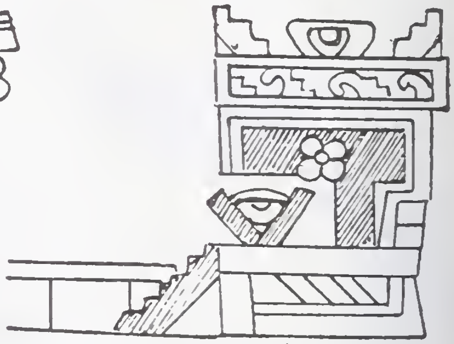


15

13

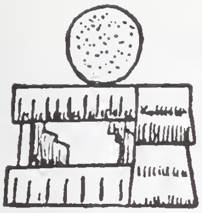


17



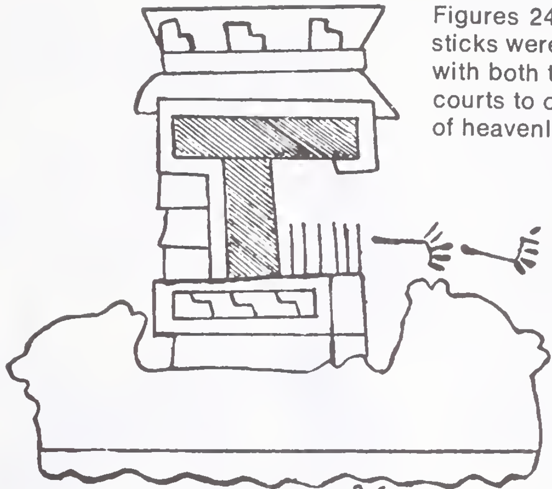
14

Figure 12. Here the temple walls and roof are studded with six stars, and a human face or mask is depicted peering out of the doorway through crossed sticks. Figure 14 shows a star lodged in the triangle of a forked stake erected on the summit of the temple stairway, while another large star rests on the roof exactly between the terraced corners of the edifice. On the lintel of the temple door is represented a four-petaled flower. Proof that this was the actual sign for a particular star is furnished by figure 17, which exhibits an identical flower on the band studded with stars, denoting the nocturnal heaven. Here in figure 15 a starband is painted above a footprint directed downward, near a seated figure accompanied by a day and year sign. Mrs. Nuttall believes this may have recorded the setting of some particular star on the date recorded. A similar footprint directed away from the temple in figure 14 suggests to Mrs. Nuttall that the doorway may have faced east, and that the footprint refers to the setting of the "Flower" star or of the adjacent constellation at a particular time of the year.

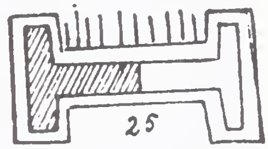


26

Figure 26 shows Venus atop a truncated pyramid without its winglike appendages, evidently at a different period of its revolution.

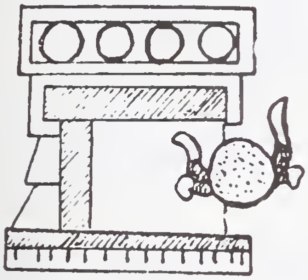


24



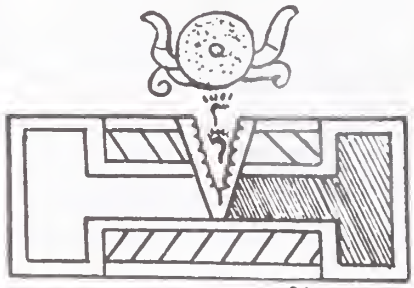
25

Figures 24 and 25 show that sticks were used in conjunction with both temples and ball courts to observe the motion of heavenly bodies.



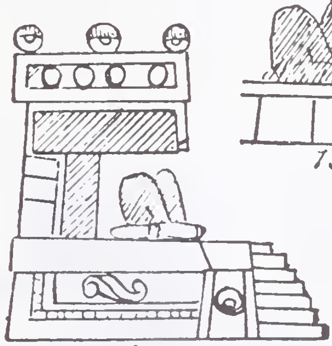
23

Figure 23 shows the planet Venus being observed by means of a temple.

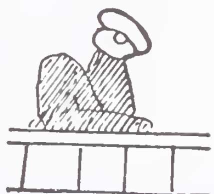


27

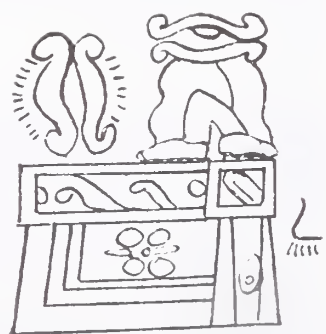
Figure 27 shows Venus as the morning star at its period of greatest brilliance, a large dish with two winglike appendages. It also shows that it was observed from the center of a ball court, where it is seen rising. The fact that half the court is dark may indicate a heliacal rising of Venus at the equinox.



20



19



22

Figure 22 shows a combination of the "Flower" star and a footprint directed downward, presumably for its setting. On top of the terrace is a curious device which resembles the drawn-up limbs of a seated human figure. It is even clearer in figure 19. Zelia Nuttall says the device serves the same purpose as a bifurcated stake, pointing out that the Nahuatl word signifying "on the knee" can be read as a homonym conveying the meaning "on the summit or head of the earth or land."

As early as the turn of the century Mrs. Nuttall found illustrations in the codices descriptive of methods used by Mesoamerican priests to observe stars and planets. The illustrations showed ancient astronomers, as in Babylonia and Egypt, observing certain stars from a dark cell or chamber through the opening doorway of the temple situated on an elevation.

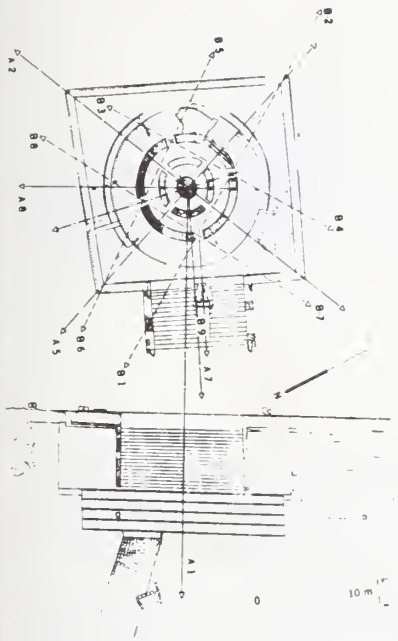
Zelia Nuttall also correctly suspected that the high dome of the Caracol at Chichen Itza constituted a gnomon which would be shadowless at noon on the days the sun crossed the

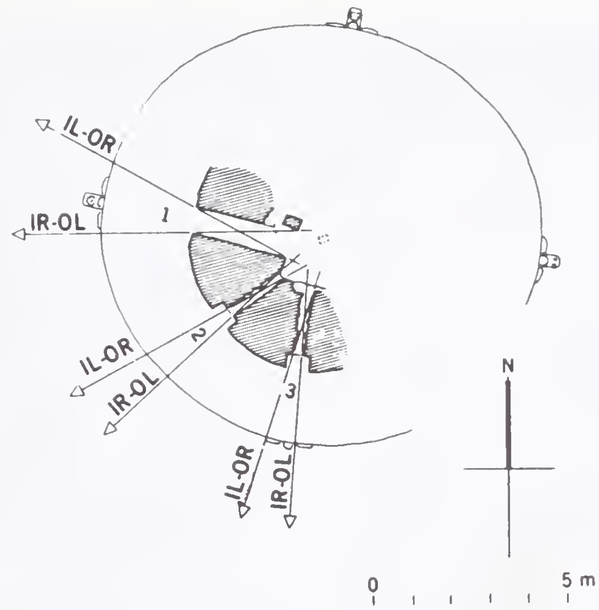
The Miztec manuscript known as the Codex Nuttall.

In Florence at the turn of the century Zelia Nuttall heard from Pasquale Villari, an Italian senator and ex-minister of higher education, that while he was doing research in the Library of San Marco some two years earlier he had been accosted by a monk with a strange manuscript. This was the turbulent period of the unification of Italy, and when the Library was taken over by the state the manuscript was sold to an Englishman living in Florence who gave it to a friend in England. Determined to recover the manuscript, Zelia Nuttall searched throughout England, eventually establishing that it had been given to Sir Robert Curzon, fourteenth Baron of Zouche. Among the papers of the fifteenth Baron, Zelia Nuttall found the manuscript where it had lain unopened for twenty-five years. It is now in the British Museum, and Zelia Nuttall's original facsimile of it, published in 1901, is available in paperback. The early history of the codex is doubtful, but it may have been among the prizes sent by Cortes to Charles V.

zenith in May and July (announcing to the populace the advent of the rainy season and the beginning of a new calendar year).

Luis Arochi, author of a new book on the astronomical orientation of the Castillo at Chichen Itza, also shows in a series of remarkable photographs that the steps of the building are so cunningly oriented and designed that only on the day of the vernal and autumnal equinox the sun's rays cause a great serpent (whose head is carved at the bottom of the steps) to slither up or down the stairway—up in spring and down in autumn, forming a set of seven perfect isoceles triangles patterned on the local rattlesnake, *Crotolus*.





(Above and right) Anthony Aveni's diagrams showing various astronomical alignments of the Caracol building at Chichen Itza.

Despite J. Eric Thompson, who is considered the foremost living authority on the Maya, but who disparagingly regards the Caracol as nothing more than "a two-decker wedding cake on the square carton in which it came," recent scientific investigation has shown this extraordinary building to be a sophisticatedly designed astronomical observatory and geodetic marker.

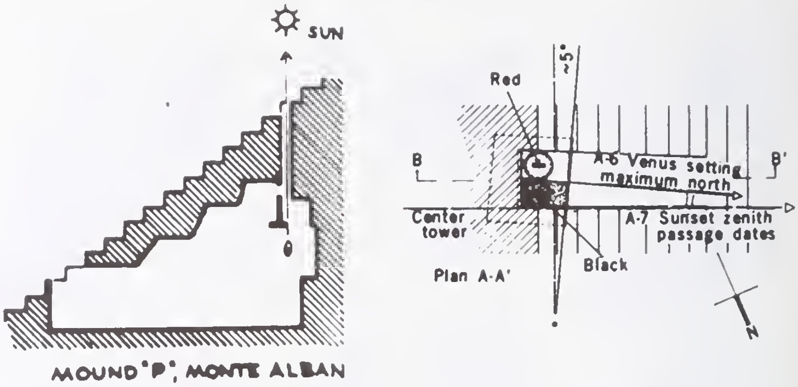
Anthony F. Aveni, an astronomer, Sharon L. Gibbs, a historian of science, both on the faculty of Colgate University in Hamilton, New York, and Horst Hartung, an architect on the faculty of the University of Guadalajara, Mexico, show that the diagonals of the main platform point to sunrise at summer solstice and sunset at the winter solstice, and that other astronomical observations could be made at different times of the year in different parts of the building by astronomer priests. In a paper presented to the forty-first International Congress of Americanists in Mexico City in 1974 they further suggested that many of the asymmetries built into the Caracol were intentionally designed to create alignments which would point to astronomical events.

(Left) Arochi's picture of a great snake with isoceles markings descending the steps of the Castillo at Chichen Itza at the equinox.

Hypothesizing that windows functioned as astronomical sighting chambers, and that one of them might have been deliberately designed to point to sunset at the equinoxes, the trio set themselves to observe the phenomenon and were able to see that the instant of the passage of the sun across the vernal equinox occurred within ten minutes of the movement of sunset. The edge of the setting sun lined up almost perfectly with a narrow opening in the window, enabling the sunset to be viewed through a slot.

As stellar observations are especially important at the time of the solstice or zenith in order to obtain greater ac-

Aveni's diagrams of stellar and solar methods of observation with Mesoamerican buildings.



curacy, they believe that weep holes, rectangular horizontal shafts of a width of from eight to twelve centimeters which pierce the tower at ground level both below and above the upper molding, may also have had an astronomical function. The trio found alignments for the heliacal rising of such major stars as Canopus, Castor, and Pollux, which led them to suggest that entire constellations such as the Pleiades could have been more carefully watched through the windows at important moments such as on the date of a Venus passage.

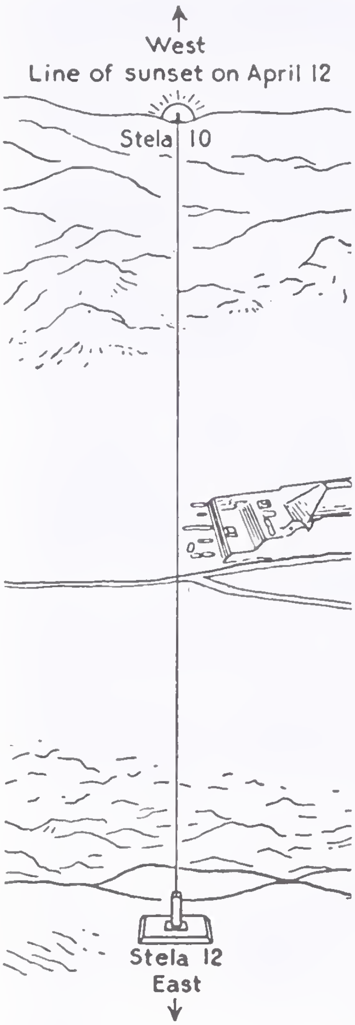
As Venus, which is exceeded in brilliance only by the sun and moon, reaches its greatest northerly and southerly extrema along the horizon at regular intervals of the calendar year, the trio suggest that the placement of the Castillo itself could have been determined by the setting position of Venus.

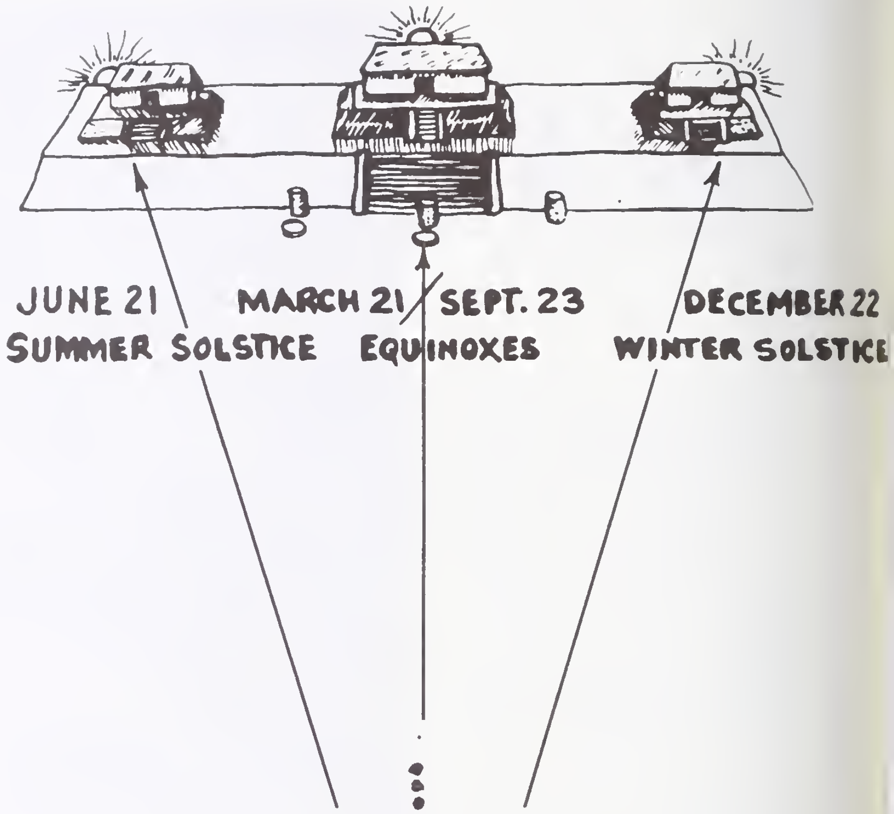
At Uxmal, the platform which serves as a base for the Palace of the Governor is oriented to the rising of Venus. For this, Thompson had the evidence of the elaborate Venus calendar in the Dresden Codex, believed to have been composed in the vicinity of Chichen during the Mexican period, which showed concern with the heliacal rising and setting of Venus. And the recent breakthroughs by the Hieroglyphic Section of the Institute for Mayan Studies at the Miami Museum of Science indicate that the codices contain sophisticated perpetual computer layouts for such ephemeral phenomena as the cyclical coincidence of heliacal risings of Venus in conjunction with eclipses of the sun.

Aveni, Gibbs and Hartung also found slots which point to the setting moon at its maximum northerly and southerly extremes. Every 18.6 years the full moon nearest the time of the winter solstice will be found to set at its greatest southerly extreme. This would have provided the Maya with a recurring cycle, such as the alignments at Stonehenge. The codices also contain refined data on various cycles of the moon.

Other round towers in Mayaland near Tulum, Ake, and Cozumel, also dedicated to Quetzalcoatl, are being analyzed for astronomical orientation.

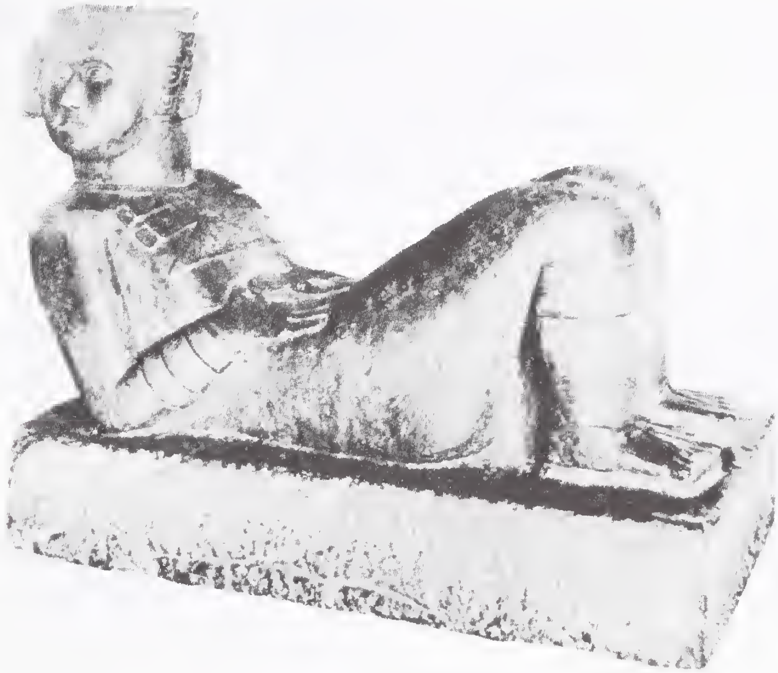
Aveni spotted a ceremonial center on a hill five kilometers by line of sight from the governor's palace at Uxmal—first noted by Stephens as Nohpat—which lined up with a pillar and Chac-Mool to indicate the maximum southing of Venus.





Equinox and solstice temples at Uaxactun.

Solar alignment of the "Sundial" stele at Copan, Honduras.



Chac-Mool.

The concave circular dish held on the stomach of the Chac-Mool first discovered by Le Plongeon, a copy of which has been placed at the top of the stairs of the so-called Temple of the Warriors at Chichen Itza, may well have been used as a receptacle for water or liquid mercury (with which the Maya were acquainted) on which to float a magnetic lodestone or compass point. The bowl could also have served as a mirror for watching the split-second transit of stars, the method still used today by the Naval Observatory in Washington, D.C., and at least 5000 years ago in the Great Pyramid of Cheops.

As the grid plans of a number of important sites in southern Mesoamerica possess orientations directed slightly east of astronomical north, close to the present compass direction, such as at Uxmal, Copan, and Ozibilchaltun, it has been suggested by Robert Furison in the *Annals of the Association of American Geographers* in 1969 that the Maya may have known the magnetic compass and used fragments of worked magnetite such as have been found and established as being pre-Columbian. There is no reason the compass, which was known in China a thousand years before Christ, could not have been brought to Yucatan by the Chinese explorers and Buddhist monks reported by Henriette Mertz to have reached Mexico in the second millennium B.C. and again in the fifth century A.D.

At Copan in Honduras a base line of 9 degrees north of west was established with a sundial to indicate sunset at the solstices and equinoxes. At Uaxactun three temples and two stelae give precise orientations of the sun's position at the solstices and equinoxes. At Xochicalco the great pyramid contains a vertical shaft down which the sun shines so as to cast a perfectly round shadow twice a year at the zenith.

Marquina and Ruiz suggest the setting of the Pleiades as a possible orientation point for the axis of the Teotihuacan and Tenoyocaca pyramids. Aveni says that at the time the Way of the Dead was constructed, the Pleiades would have touched the horizon point above the Cerro Colorado marker at azimuth 284° 40′, or 14° 40′ N of W.

Aveni says the Pleiades could also have served the function of "announcing" the first annual passage of the sun through the zenith of Teotihuacan, since the heliacal rising and the passage of sun through zenith occurred approximately on the same day—58 days after the vernal equinox.

The theory was supported by J. W. Dow in his *Astronomical Orientation at Teotihuacan* in *American Antiquity* in 1967. Dow suggests an east-west base line was fundamental to the layout of the city and that the Way of the Dead was oriented to it at right angles.

22. Geodetic Markers

Marker on the U.S.-Mexico border reported by Riva Palacios in 1889.

So far it has not been possible to establish precise dates when the markings could have been made. Were they inscribed as required alignment marks for the construction of the pyramids, sometime around the beginning of the Christian era, or earlier, maybe by many centuries, or much later, perhaps by observers attempting to re-establish solstitial and equinoctial lines of sight after the eighth-century fall of Teotihuacan?

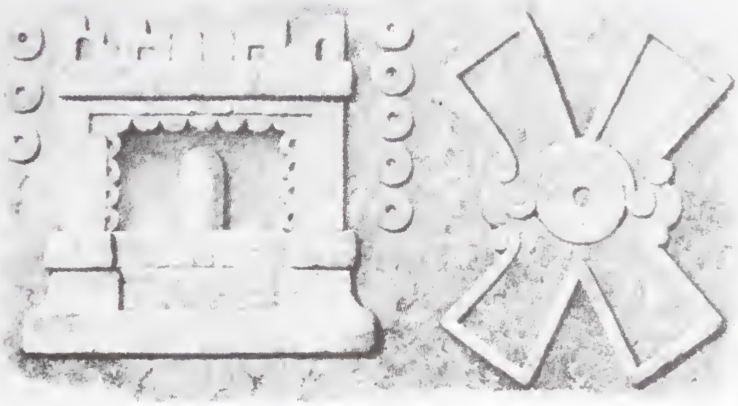
When the marker at Uaxactun from which the equinoxes and the solstices could be observed was first found by American archeologist Oliver G. Ricketson in 1937, he noted it was made in the shape of a cross formed by eighty-one holes. Many years earlier a similar marker had been used by Vicente Riva Palacio to illustrate his four-volume *Mexico Atraves de los Siglos*. But no one could figure out the purpose or significance of the eighty-one holes.

During the early 1970's, searching for temple sites on the hills around the Valley of Teotihuacan, Harleston and a group of amateur archeologists found a whole system of similar stone markers which clearly lined up with the Pyramid of the Sun, and other definite markers to indicate the rising and setting sun at solstices, equinoxes, and zenith passages.

The markers indicate that various buildings of the pyramid complex were used in conjunction with markers on the hills and mountains surrounding the valley for geodetic and astronomical sightings at least as early as the fall of the Roman Empire, and presumably much earlier.

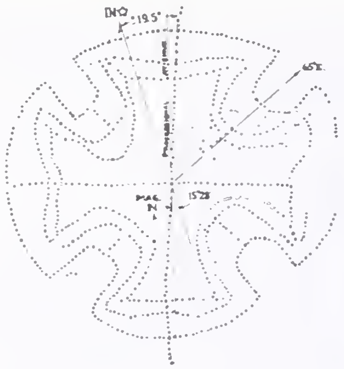
That the markers do just that was established by the researchers through repeated observation of sunrises and sunsets at Teotihuacan, where the markers line up with such fixed sighting lines as the corners of the Sun Pyramid to indicate the summer and winter solstices. Details of these discoveries and of the observed phenomena were presented at the forty-first International Congress of Americanists in Mexico City in September of 1974.

Petroglyphs found by Dupaix for which he could find no meaning.



The markers, some more than a meter in diameter, are in the form of crosses in single or double circles, or in triple cloverleaves. Small holes, a centimeter wide and about two centimeters apart, were pitted into solid volcanic outcroppings or into millennial mortar floors of lime and crushed volcanic rock in what appear to be mathematically significant numbers such as 4 legs of a cross of 20, plus a center of 1, for a total of 81, or 9 times 9. The series of holes either form angles of 90 degrees, or are aligned on specific azimuth readings from true north such as 48 degrees, 60 degrees, 66 degrees, 72 degrees, 144 degrees, or 228 degrees.The astronomical and geodetic functions of some of the azimuth lines have been deciphered by the researchers; others remain a puzzle.

The most complex of the markers, a triple cloverleaf around a Cartesian coordinate cross, was found on March 9, 1974,



Garcia marker.

In 1964 Mexican archaeologist Braulio Garcia, working on the restoration of the Processional Avenue's temples at a location called Area 7 some 300 meters south of the Sun Pyramid, uncovered a fourth-century A.D. concrete floor, on which were pitted two concentric circles and a Cartesian cross. The southern arm of the cross runs 19.5 degrees east of north. Garcia also found another configuration on the floor of the patio across the street in Area 6, and his colleague Alfonso Cuevas located a third marker in Area 8, some 83 meters to the south. The data on these markers were filed in the archives, but only the Garcia 7 marker reached publication.

by Alfonso Morales, an economist in hydraulic resource planning, who, like the other researchers, was anxious to accelerate archeological inquiry and the better preservation of Mexico's ancient monuments.

Morales found the marker under a loose layer of windblown earth and tourist detritus near the loggia of a patio west of the main Teotihuacan Processional axis, the so-called Way of the Dead, opposite the Pyramid of the Sun.

The cross contains 30 holes to each leg plus 1 at the center for a total of 121, or 11 squared: there are 63, or 9×7, holes per cloverleaf.

The north-south arm of the central cross was aligned 19.5 east of north. When the marker was shown to Harleston, he noted that one line of pitted holes indicated with special emphasis an azimuth which appeared to be almost 65 degrees.

To check this orientation with the greatest possible precision the researchers returned to the spot at noon of the vernal equinox equipped with a tripod and a pointer to center on the triple cross. They were then able to use the sun to trace a straight line across the marker without deviation from astronomical west to east, a line which was particularly accurate in 1974 because the sun happened to cross the equator at noon central standard time, which was also noon at Teotihuacan.

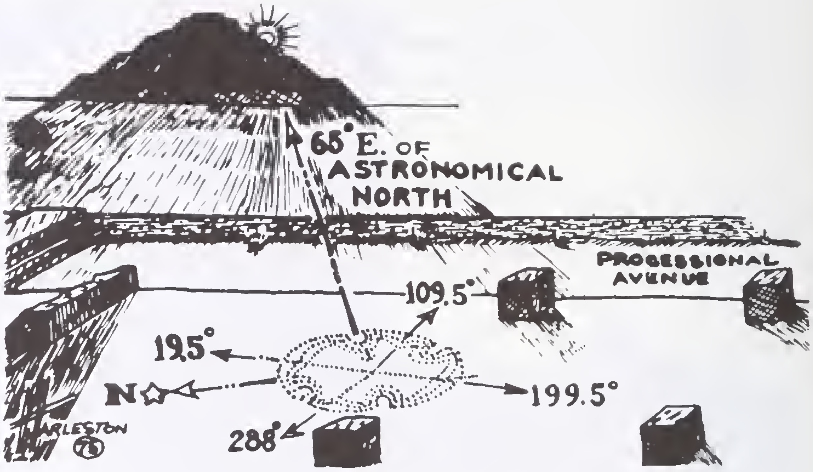
A perpendicular to this line gave the researchers a true north-south line from which it was possible to measure the azimuth marked out with holes on the mortar slab; it was precisely 65 degrees east of north.

By calculation, based on the latitude of Teotihuacan and the sun's declension, the solar azimuth on the morning of the summer solstice is 65.007 degrees.

To observe the actual occurrence of the phenomenon Harleston and Manuel Gaitan, a seventy-year-old professor of archeological restoration, who has been with the Mexican Institute of Anthropology for over thirty years, obtained permission from the institute to spend the night of June 20 in a tent on the Processional in preparation for the solstice of June 21.

During the night it rained on and off. The rainy season in the Valley of Mexico runs from June to September. But just after dawn on June 21, and shortly before sunrise, the rain stopped sufficiently for the two observers stationed by the triple cross to see the solstitial sun appear from behind the Sun Pyramid at the upper southeast corner of the third level in a way that was uniquely recognizable.

The phenomenon led the two observers to assume that another marker should exist from which sunrise could be accurately observed on the two mornings a year when the sun crosses the zenith above the Pyramid of the Sun—May 19 and



Sun at the summer solstice of June 21 as it appears behind the third level of the Sun Pyramid seen from the Triple Cross at Teotihuacan.

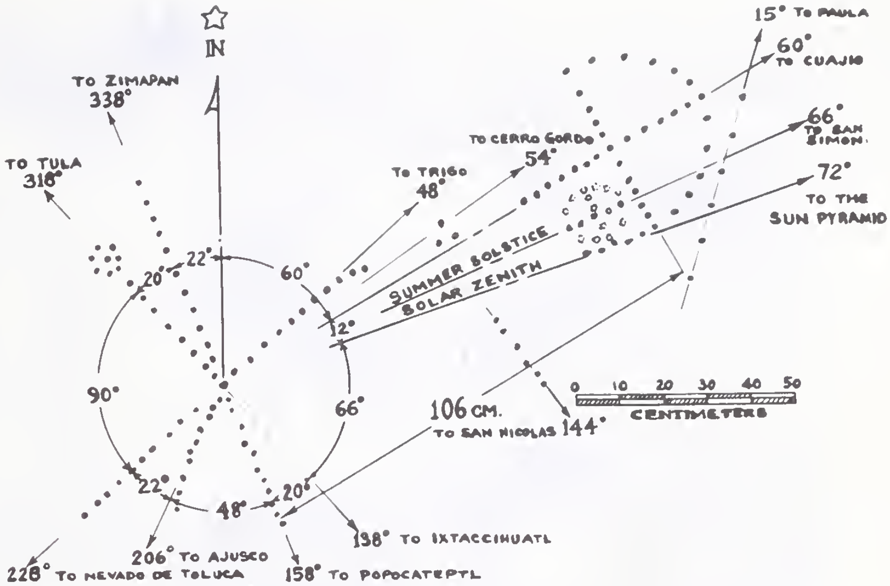
July 25 in 1974. Harleston calculated the spot where an observer would have to stand to be able to see across the top of the Sun Pyramid as being 14 kilometers southwest of the pyramid at an elevation of 2630 meters, forming an angle with the pyramid of 70.2 degrees east of north.

To be sure his calculations were accurate Harleston had them validated by three independent sources: by Mexico's leading geodesist, Manuel Medina Peralta, ex-director of the Geodesical School of Mexico's National University and author of *Elements of Positional Astronomy;* by Dr. Yogi Kondo, a NASA astrophysicist from Johnson Space Center in Houston, Texas; and by Dr. Paris Pishmish, an astronomer from Turkey. All agreed with his findings.

Three reconnaissance trips were made to the selected area near the summit of a hill called Chiconautla (the Place of Nine) 300 meters above the Valley of Teotihuacan and 2650 meters above sea level, but the trips proved fruitless; no marker could be found. Convinced that they had somehow missed the marker, Harleston and Gaitan spent the night of July 24 (which preceded the day of the zenith sunrise) at a campsite within half a kilometer of the calculated location. Again it rained, and the dawn was foggy and drizzly, but just at sunrise the clouds across the valley lifted enough for Gaitan to photograph the appearance of the solar orb above the Pyramid of the Sun, while Harleston, cussing the weather, ascended to the summit of Chiconautla, some sixty vertical meters higher than the encampment. He was then to be thankful for the rain.

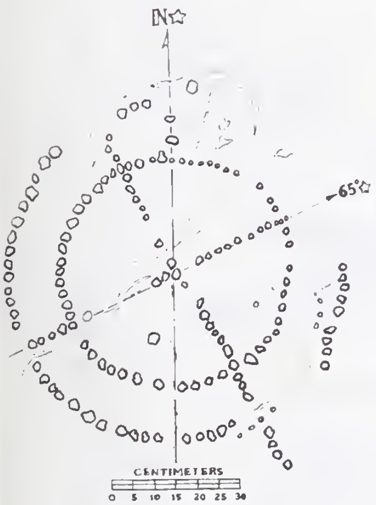
The wet shiny reflecting surface of the eroded lava outcroppings caused faint pittings of a multiangular marker to appear on the hilltop precisely at the calculated angle of 70.2 degrees and at an elevation of 2632 meters. The marker lined up perfectly with sunrise for that morning when the sun at noon stands directly over the Pyramid of the Sun at latitude 19 degrees 41 minutes.

Sunrise on May 19 and July 25, the days of the solar zenith at Teotihuacan, seen from the marker on the hill of Chiconautla.



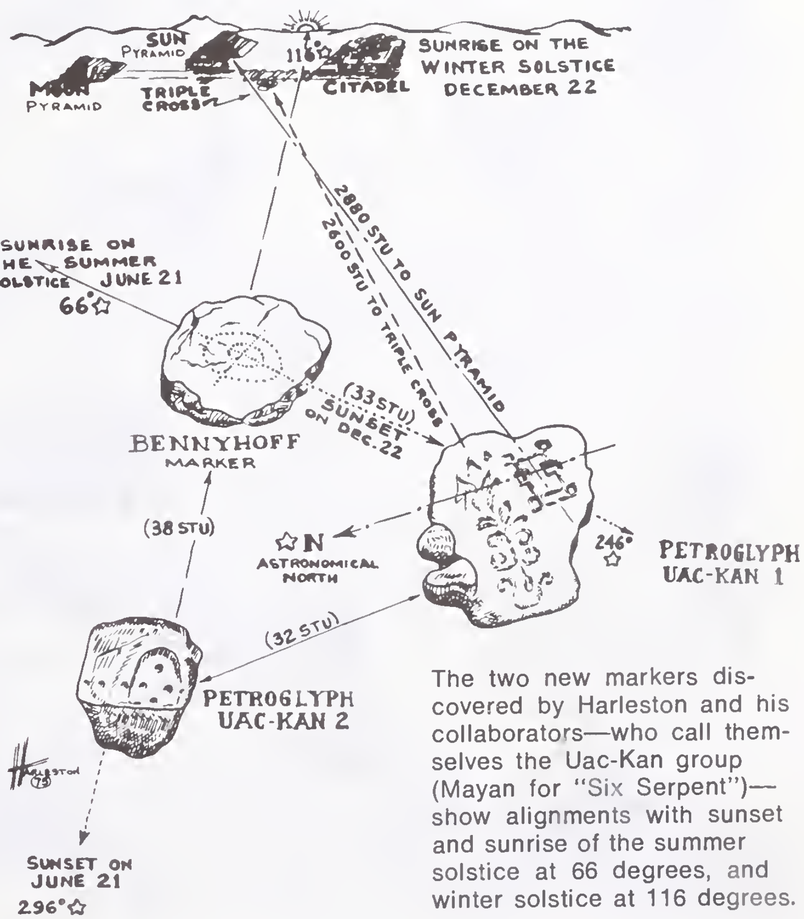
The marker named Uac-Kan Observatory No. 1 was located by Harleston thanks to an early morning rain that wet the surface and allowed the faint pittings to be seen. The pittings give angular directions to major mountaintops as well as alignments for the zenithal and solstitial sunrises, which strongly suggested to Harleston that the ancient Mexican geodesists used a system of 6-degree separations, the preferred Babylonian divisions.

Assuming that other markers would also have been placed for sighting the summer and winter solstices, the group found two more close to the marker discovered by James Bennyhoff, an American archeologist, in 1963. Used in conjunction, the markers form a triangle which enables an observer to sight along different legs to see sunrise and sunset on both summer and winter solstices.



Bennyhoff marker.

In 1963, when the survey was being made of the hillsides around Teotihuacan for Millon's mapping project, archeologist James Bennyhoff, while walking the sloping southern flank of Malinalli in an area called Colorado Chico, found an almost invisible stone marker. The marker consisted of two circles and a cross; its arms were aligned on 65 degrees east of astronomical north, a fact that was not to be noticed until eleven years later. Bennyhoff's find lay dormant until its publication in 1973 as part of the introduction to the *Teotihuacan Map*.



The two new markers discovered by Harleston and his collaborators—who call themselves the Uac-Kan group (Mayan for "Six Serpent")—show alignments with sunset and sunrise of the summer solstice at 66 degrees, and winter solstice at 116 degrees.

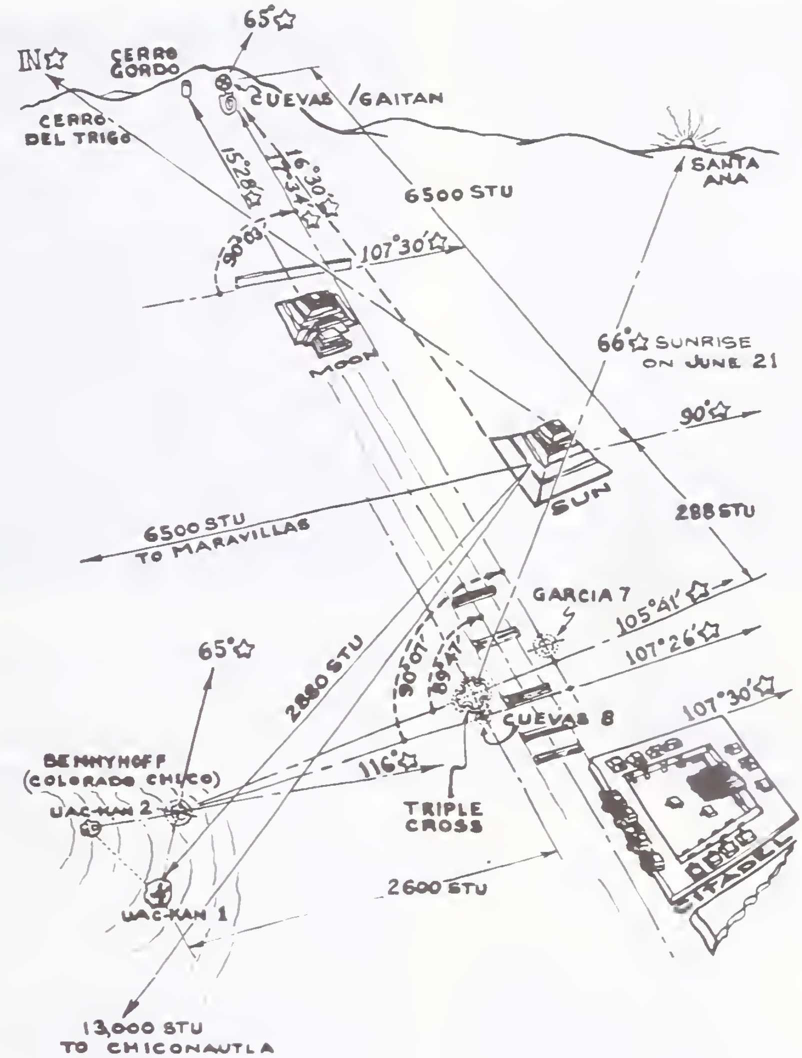
Other observatories.

The Uac-Kan Observatory No. 2 was located by Dr. Matthew Wallrath as a tumulus, the ruins of an ancient pyramid 1240 meters (1170 STU) northwest of the Sun Pyramid. The alignment of 116 degrees east is across the southwest corner of the fourth body, exactly opposite to the one used for the summer solstice from the Triple Cross. This pyramid appears on the 1973 *Teotihuacan Map,* but was not identified as an observatory when the map was made.

Further investigations revealed that at least eleven other pyramids to the west and east of the Sun Pyramid could be used as observatories. All the observatories are located within a two-kilometer radius of the Sun Pyramid, and six of them are at positions for observations of the solar solstices, equinoxes, and days of zenithal crossing, six being the total number of major solar events per year. Other observatories may have been for ceremonies on February 14 and October 29, later moved to November 1, the important All Saints' Day, still a major Mexican holiday.

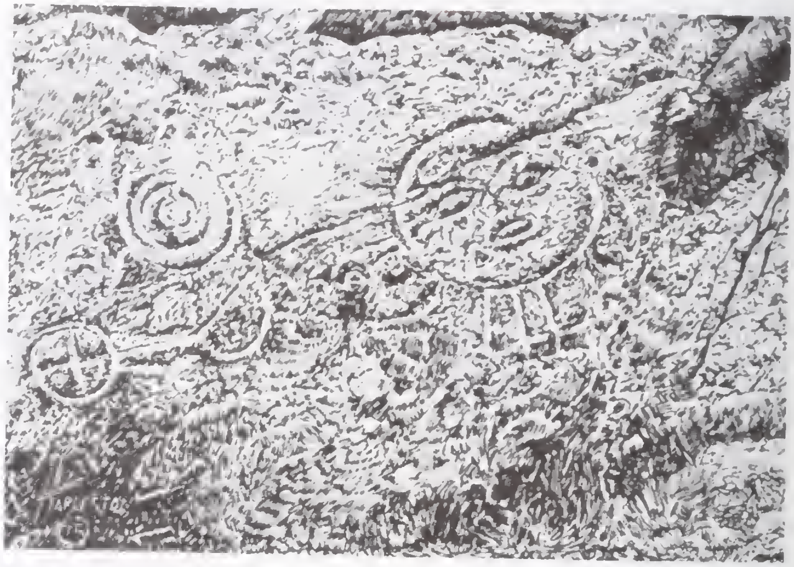
Further calculations led to the prediction and location of seven more observatories, including two that might have been destroyed and rebuilt as local land markers by the zealous clergy of the eighteenth century. These two markers are due east on Tepayo (U-K 11) and due south of the Sun Pyramid on Patlachique (U-K 12).



Convinced that another observation post must have been located closer to the Pyramid of the Sun from which to see the solar orb appear at the winter solstice, Harleston calculated it would have to be less than two kilometers from the pyramid, at an azimuth of 117 degrees, so that the mountains would drop away from the viewer, leaving only the pyramid to act as a mountain. With Dr. Matthew Wallrath, a Ph.D. in archeology who had worked with Millon's University of Rochester mapping project, they located a pyramid marked on Millon's map at 1200 meters from the Sun Pyramid, at exactly 117 degrees, from which the solstitial sun would appear above the second body of the southwest corner of the pyramid on December 22 or 23.

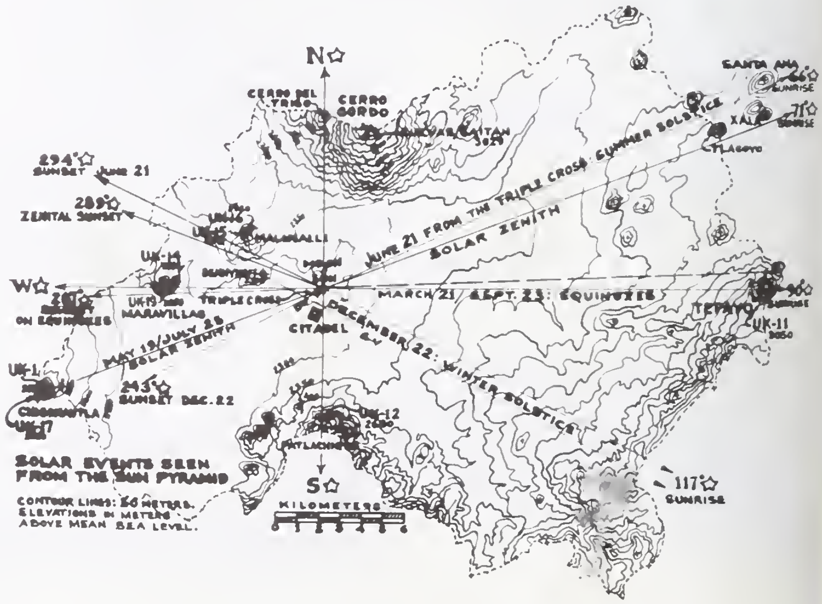
Further study of the Millon map revealed a whole series of remains of pyramids at different distances and angles, east and west of the Sun Pyramid, all within two kilometers. Azimuth angles for sunrise and sunset of summer and winter solstices, as well as of equinoxes and days of the zenith, were found to pass right through certain pyramids, indicating that

At the summit of Cerro Maravillas, Manuel Gaitan identified a marker named U-K 14 due west of the Sun Pyramid at an elevation duplicating the Bennyhoff stone. In addition to a circle and cross, this stone has an elliptical triple oval resembling the Garcia 6 configuration, and a circle with a face similar to designs already known at Teotihuacan, but with what appear to be shallow carvings of "sun rays" (not typical of Teotihuacan) believed to be the scratching of later visitors, perhaps the Aztecs of the fourteenth century, who could not resist the temptation to add their graffiti to the original.

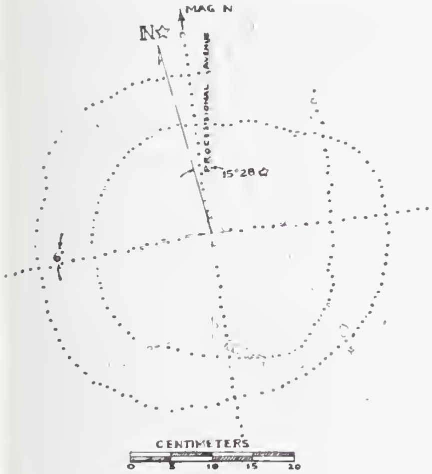


on these pyramids ceremonies may have been celebrated to mark important solar dates. From the location of many other pyramids scattered throughout the urban area it may now be possible to extrapolate the dates of other Teotihuacan celebrations marking lunar phases and stellar movements, such as the rising and setting of Sirius and the Pleiades.

From two other markers in the area southwest of the Moon Pyramid, it appears possible to sight across the third level of the Moon Pyramid and observe the maximum northward movement of the moon at the end of its nineteen-year Metonic cycle. If this is indeed possible, the Aztec attribution of "Sun" and "Moon" to the two great pyramids may be due to a vestigial tradition that they were once used for sighting the relative movements of these celestial bodies, a function which has only now been rediscovered.



The valley of Teotihuacan's solar events and marker orientations.

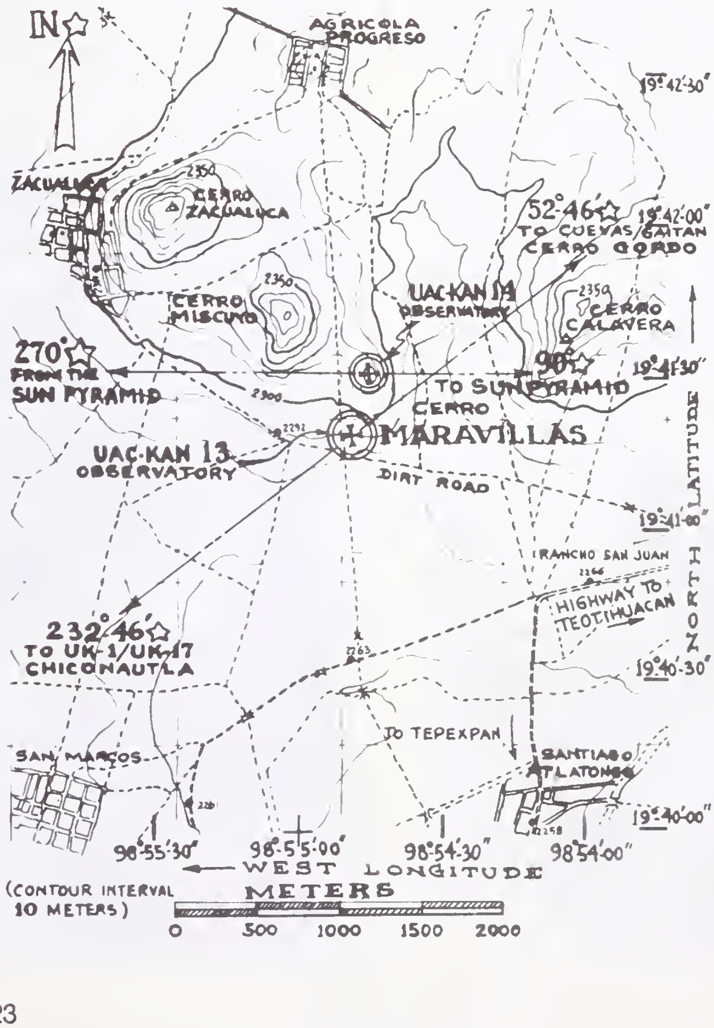


THE CUEVAS 8 MARKER

THE GARCIA 7 MARKER

THE GARCIA 6 MARKER

As in ancient Britain at midsummer, that is to say at the summer solstice, signals could have been sent with bonfires from the top of the Sun Pyramid, point to point over great distances; and it is noteworthy that Sahagun reported that Teotihuacan, as well as being known as "the place where men became gods," was also known as "the place from which the signals are made."



Markers on Maravillas showing angular relationships with other markers and with the Sun Pyramid.

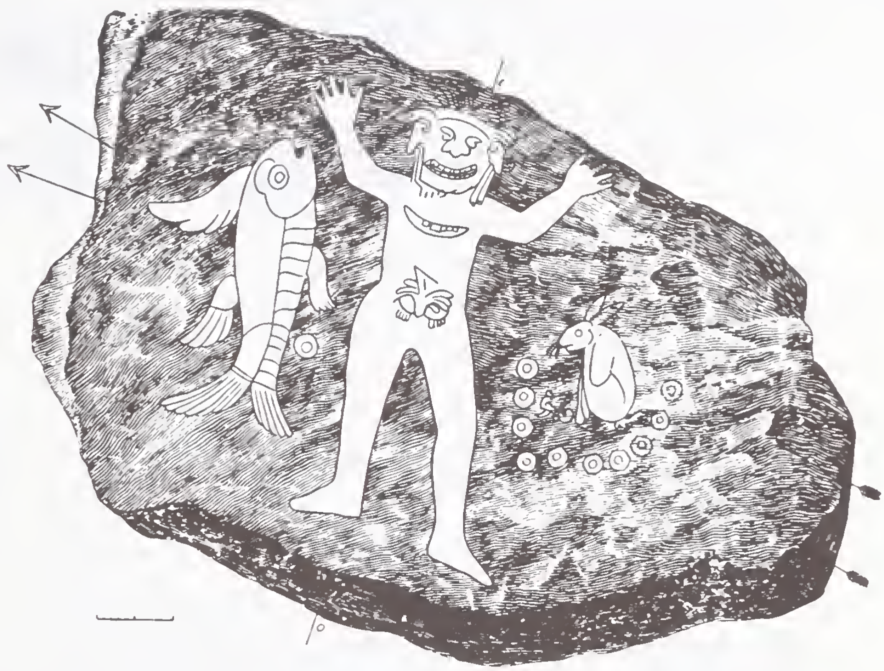
Similar stone marker designs have been found at distances on a great circle as far as 100 kilometers to the south of Teotihuacan and on the Mexico-U.S. border to the north. The coordinates of these stones permitted the prediction and location of previously unknown markers at telescopic distances from the Sun Pyramid, apparently used for the observation of astronomical events and for the definition of earth-commensurate distances and other cosmic information.

Surrounded by petroglyph murals, the egg-shaped omphalos of Observatory U-K 13 on Cerro Maravillas lies 7½ kilometers west of the Sun Pyramid. It not only provides a point from which to observe the sunset on the equinox directly aligned with the Sun Pyramid, but also has grooves for sighting the summer solstice at 66 degrees and three circles aligned on the winter solstice at 116 degrees east. An "astronomer's chair" on the west side allows the observer to lean back and comfortably watch a star cross the zenith. The backrest of the "chair" has the sculptured head of a combined man-serpent, with eroded fangs curled downward. The horizontal grooves and vertical lines of holes cut across the back of the serpent appear to have served as marks for a sundial that could be made by standing a 35-centimeter (1/3 of a *hunab*) wooden gnomon in a hole drilled to the right of the "astronomer's chair" in the main omphalos's body.

When the sun climbs skyward on the days of the equinox, the shadows of the west side of U-K 13 begin to move southward. The inclination of the chair is such that at ten o'clock A.M. the sunlight will start to illuminate the sculptured face. Within an hour, the chair has been converted into what Harleston calls "a vertical serpent of light, flying toward heaven, with the Sun Pyramid behind it: the symbol of Quetzalcoatl, the bird-serpent, which appears one week before and disappears one week after the day of the equinox!"

As the day wanes, the sundial shadow which had followed the line of holes up the serpent's back becomes a horizontal line at three o'clock, and then a vertical line by six P.M. At sundown the direct rays cross the omphalos stone to illuminate the Sun Pyramid, seven kilometers away, clearly seen through the V notch cut in the marker.

Dupaix found this stone giant (the figure is twenty-seven feet long) on the floor of a cabin near Orizaba. According to archeologist Daniel C. Brinton, who describes the giant as "an ogre of horrid mien," it is a depiction of Tzontemec Mictlanteculi, "the Lord of the Realm of the Dead, He of the Falling Hair." Brinton says "falling hair" represents the slanting rays of the setting sun at the winter solstice, and that the symbols convey a specific date: the winter solstice of the year 1 fish 10 rabbit.



This led Harleston to surmise that other ceremonial centers may have been built on what the English author Alfred Watkins called earthly magnetic "ley" lines at different azimuths from Teotihuacan, such as at Tupilco, 630 kilometers southeast of Teotihuacan, where a Mayan complex is presently being excavated.

Uaxactun, which was occupied by Teotihuacanos in the third century A.D., is 989 kilometers from Teotihuacan at an azimuth of 285 degrees, 30 minutes, forming a right angle to the Way of the Dead at almost 1000 kilometers.

Outside the ceremonial area at kilometric distances which appear to fit a module of 2268 of Harleston's *hunabs,* or 7800 Egyptian feet, other sites suggest that geodetic information was interlocked with the ceremonial zone's accurate display in what could be a global system of markers.

Additional information on a theoretical Teotihuacan geodesic system was presented at the Americanist Congress in Paris in September, 1976, that indicates a probable grid system that has been located by the Uac-Kan Research Group in the Valley of Tepoztlan, 85 kilometers southwest of the Sun Pyramid on the north-south alignment of 196° 30′.

23. Cosmic and Telluric Forces

John Michell, author of *The View Over Atlantis* and *City of Revelation,* is convinced that the Pyramid of the Sun at Teotihuacan, like the Great Pyramid of Cheops, is one of the fixed points in a worldwide geodetic system laid out on a vast scale with great accuracy by some former civilization with an advanced knowledge of science and what today is understood as magic. To lay out such a network of astronomical and geometrical lines across the face of the planet, says Michell, implies an advanced technology.

He believes that whoever built the system had "some remarkable power" with which to cut and raise enormous blocks of stone, vast astronomical instruments, pyramids, circles of pillars, cyclopean stone platforms, all linked together by a network of tracks and alignments, whose course from horizon to horizon was marked by stones, mounds, and earthworks, "a great scientific instrument sprawled over the entire surface of the globe."

From the evidence of old maps such as the portolanos, the Piri Reis, the Oronteus Fineus, and many others, it is clear that someone mapped this entire globe with a precision not reached again till the nineteenth century of our era. It is also apparent that they did not use Cartesian coordinates of latitude and longitude, but some system of spherical triangles, perhaps with some instrument by which they could follow earthly magnetic ley lines rather than a compass needle pointing to magnetic north.

Three Russian scientists, Nikolai Feodorovich Goncharov, Vyacheslav Moroz, and Valery Mokarov, have recently discovered evidence of faint magnetic lines which appear to run around the planet making of it a dodecahedron superimposed

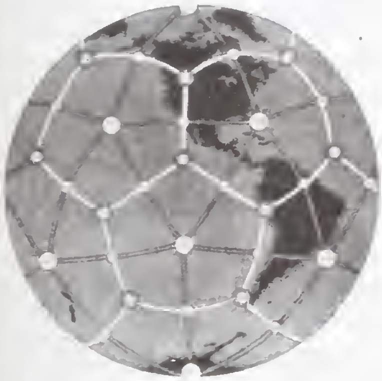
Alfred Watkins of Hereford (1855–1935), discoverer of the ley system.

on an icosahedron, as if the planet had once been a great crystal or was conditioned in its energetic nature by some crystalline core.

On a geographical map the Russians traced the seats of ancient cultures, which appeared to follow the magnetic or energetic lines of the icosahedron.

On metereological and geological maps they found that all the global centers of maximal and minimal atmospheric pressure occurred at the twenty nodes of the dodecahedral skeleton. These were the spots where hurricanes originate, or where there are gigantic vortices of ocean currents.

Christopher Bird reports that another Russian, Vitaly Kabachenko, while studying photos of the earth taken from space, found a deep-seated grid structure of the lithosphere, or upper hard core of the earth, which at times seems to "shine through." The phenomenon, says Kabachenko, appears as black streaks on the ocean, and in the sky as a barely noticeable network of nebulous streaks. Bird quotes another Soviet geologist and mineralogist, Dr. Vladimir Neiman, as suggesting a universal space-filling lattice which controls the position not only of planets and stars but of galaxies and intragalactic space. Like Wilhelm Reich, who suggested a basic ether or life force which traveled in spiral waves with matter forming where two spirals superimpose, Neiman substitutes for the idea of a primordial chaos a regulatory pulsation, with all matter—galaxies, stars, planets—being formed at the nodes.



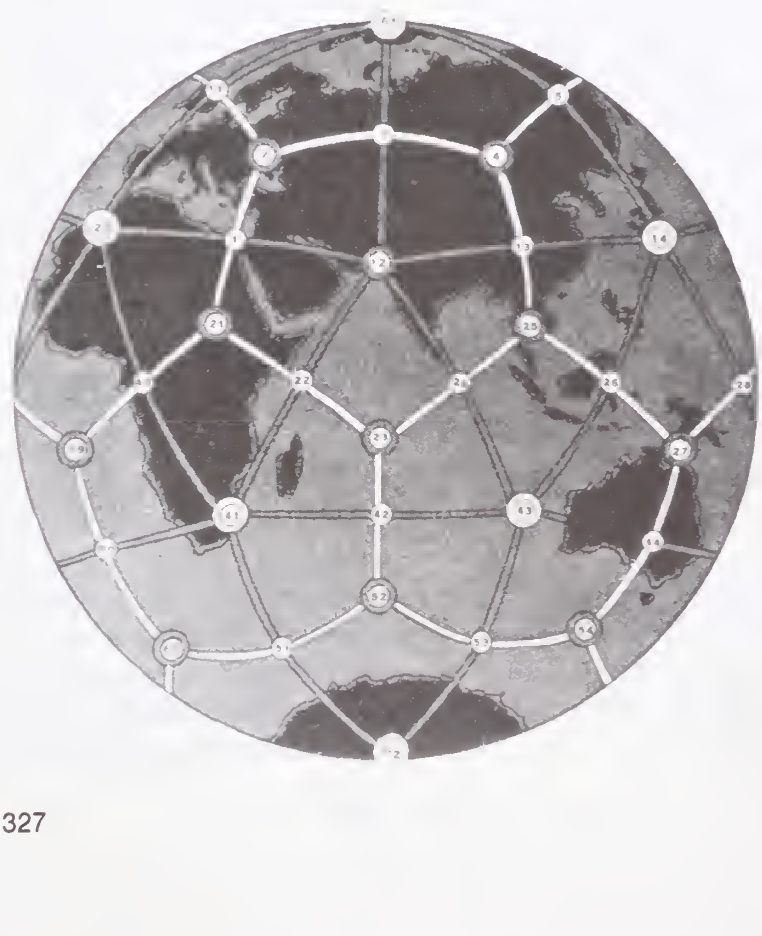
Soviet earth grid reported by Christopher Bird.

The thin lines of the grid form a dodecahedron solid with twelve pentagonal slabs. Plato has said that "the earth viewed from above resembles a ball sewn from twelve pieces of skin."

The thick lines form an icosahedron of twenty faces. The planet, therefore, appears to act energetically as if pulsating between one shape and the other.

The Soviets found that mid-oceanic ridges, core faults, and active zones occurred along the edges of these superimposed crystalline structures, and that such magnetically anomalous spots as the Bermuda Triangle fell on the nodes.

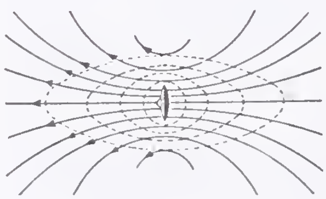
Ivan Sanderson, the professional biologist who founded the Society for the Investigation of the Unexplained, in Columbia, New Jersey, and fathered the vogue of the Bermuda Triangle, suggested nine more similar areas situated symmetrically around the globe, five above and five below the equator. To these the Soviets added the North and South Poles to obtain their dodecahedron.



Corroborative evidence for a lattice of ley lines on the earth comes from Aimé Michel, a French writer on UFO's, who says that sightings over the planet appear to run along similar magnetic lines, lines which Air Force pilot Bruce Cathy of New Zealand in his book *Harmonic 695* has drawn as a lattice covering the globe. Similar energized lines were obtained by Buckminster Fuller as great circles which define the lowest common multiple of his vector equilibrium triangles, of which there are forty-eight to a sphere. If one of the edges of Fuller's cuboctahedron lies along the equator, the intersection of three of his great circles will define the latitude of Teotihuacan to within a quarter of a degree.

From these approaches it appears that if the planet—as Goethe and Rudolf Steiner considered it—were a living breathing entity, it would take the form of a dodechahedron-icosahedron when compressed to its most compact stage. Medially expanded, it would take the shape of Buckminster Fuller's vector-equilibrium cuboctahedron. Fully expanded, it would have the shape of a truncated tetrahedron.

Wachsmith illustration. Part of a series showing a living breathing earth.



Suggested method of propulsion of UFOs along magnetic grid lines.

The ancients apparently considered the earth to be not only living but to have a nervous system related to its magnetic field, with nodes of power similar to the acupuncture points of a human body.

These straight lines running from node to node appeared to be involved with a power which was symbolized by a serpent or a dragon; the Chinese called these lines, which ran invisibly over the whole surface of the earth, lines of dragon current. The Chinese further divided the dragon current into two kinds, negative and positive, or yin and yang, represented by a white tiger and a blue dragon, symbols very similar to the jaguar Tezcatlipoca and the plumed serpent Quetzalcoatl.

The yang, or male current, was believed to run along mountainous ridges and ranges of hills, the yin, or female, along valleys, rivers, and subterranean channels.

These powers were also symbolic of cosmic and telluric forces which became creative in wedlock—such as the sun's rays impregnating mother earth.

Michell has no doubt that the dragon current is a natural flow of force related to the earth's magnetic field, something in the nature of the orgone energy rediscovered by Wilhelm Reich, which Reich postulated to be present throughout the universe in every particle of matter, every area of space, running in definite lines, and accumulating under specific circumstances, a force on the order of Franz Anton Mesmer's animal magnetism, Karl von Reichenbach's odyle, or what has now come to be known as *pyramid power.*

Like Reich, Mesmer, and Reichenbach, the ancients concluded the dragon power to be curative, invigorating, and

To Michell the mathematical rules of the universe are visible to men in the form of beauty: "The secret rules of poetry and aesthetics, which we now believe to be beyond rational expression, can be demonstrated in numbers, ratio and angles of the confluent lines of terrestrial geometry." Michell elaborates: "The key numbers are those which occur prominently in several different spheres and which express the element of unity or correspondence in phenomena apparently disparate in their nature and scale. The philosophers of the ancient world discovered that the peculiar qualities of these numbers could be discerned through measurement of the visible universe. Astronomers found these in the cosmic ratios, in the relative sizes of the heavenly bodies and in the intervals that separated them; mathematicians proved their relevance to the figures of regular geometry and discovered the magic squares and numerological patterns by which their geometrical relationships were further revealed. Musicians and artists observed that these same numbers and ratios were those that produced the most perfect harmonies and touched the deepest sources of human emotion. They contained in fact the secrets of magic."

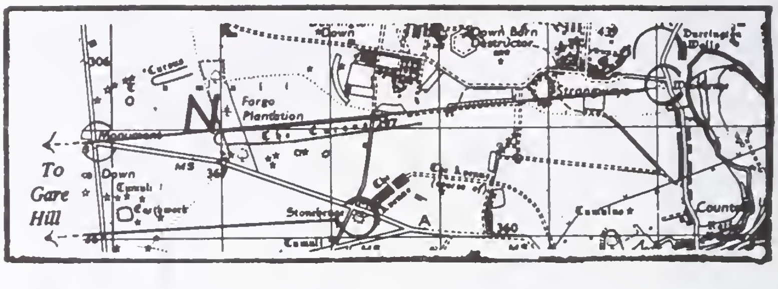
We all live within the ruins of an ancient structure whose vast size has hitherto rendered it invisible.

THE VIEW OVER ATLANTIS

John Michell

consciousness-expanding, a power which, as it passed down straight lines across the country, drew in its wake the fertilizing powers of life.

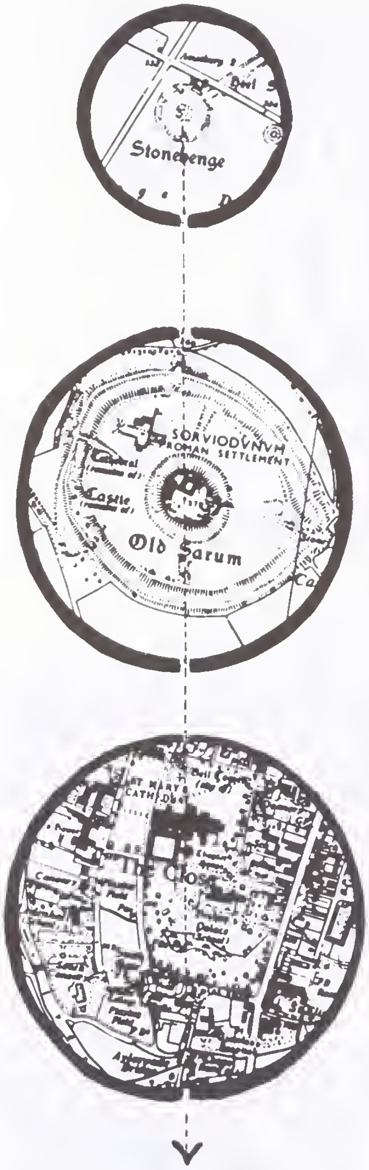
The most favored places were where two streams crossed. To find such spots, clairvoyants and dowsers were employed. Once found, temples and shrines were built on the spots, or great stones erected, linked by ley lines with other similar hot spots.



Michell says geomancers were used to detect these currents and interpret their influence on the land over which they passed, marking the course of the dragon power with alignments of mounds and stones, which then became the traditional paths of pilgrims from one holy place to the next.

According to Michell, the orientation of holy shrines and later of individual churches, including the details of their dimensions and architectural plans, was determined by these lines of current, of which the strongest spring was frequently located directly beneath the towers. At this spot the celestial influence was understood to combine with the terrestrial force to produce fusion.

Louis Charpentier, in *Les Mystères de la Cathédrale de Chartres,* says the cathedral stands on a large prehistoric mound over a buried chamber, which acts as a natural meeting place of several powerful streams of telluric current.



In *The View Over Atlantis,* Michell shows the remarkable ley-line alignment—noted by both Lockyer and Watkins—of Stonehenge, Salisbury Cathedral, and the prehistoric earth rings of Old Sarum, former site of the cathedral. The unit of measure appears to be the furlong of 220 yards.

From Stukeley's *Stonehenge.*

According to W. Y. Evans-Wentz there seem to be favored places on the earth where its magnetic and even more subtle forces are most easily felt by persons susceptible to such things. Carnac in France is said to be such a spot, as is Glastonbury in England, Iona in Scotland, and Fata in Ireland.

In ancient Britain, and once all over the world, buildings and stones were placed in landscapes according to a magic system by which the laws of mathematics and music were expressed in the geometry of the earth's surface.

Experts on geomancy such as Michell say the strength and activity of the magnetic currents is influenced by the composition of the ground over which it passes. Over firm, flat country it is said to be placid and regular; over rocky, broken land it becomes violent and disturbed, reacting with the elements that cause magnetic storms or polar lights. Near geological faults or volcanoes the magnetic flow is said to become particularly agitated because of springs of current which at these places burst through the earth's crust.

The strength and direction of the currents of the magnetic field, which is said to flow over the whole surface of the earth, are apparently influenced by such factors as the proximity and relative positions of the other bodies of the solar system, chiefly the sun and the moon, the sun imposing a daily rhythm modified by such influences as the lunar cycle, the moon exerting the same influence on the invisible magnetic flow as it does on the tides.

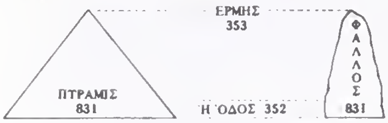
That is why, says Michell, the ancients were so preoccupied with lunar eclipses, which have no apparent physical influence on the earth other than on the level of magnetism.

At certain seasons the lines were believed to become animated by a current of invisible energy, reaching a peak on certain days, which could have a fertilizing effect on the land.

A dowser in the south of France, killed by the Germans during World War II, developed a machine whereby he could monitor cosmic forces which entered the soil, affected minerals, and then exited from the earth at other definite spots as telluric forces. By channeling these forces into his patients, he was able to cure humans of many varied diseases.

A young English engineer, Michael Watson, who worked on the construction of the Concorde, managed to salvage the Frenchman's notes, and claims with their help to have been able to photograph what he assumes to be the fourth state of water, or water in its plasmic state. He believes such elements as plasmic water have programmed goals which they follow like earth-encompassing genies, something close to the formative forces described by such authors as Gunther Wachsmith, and postulated and believed in by the ancient Mesoamericans.

SYSTEM OF SPIRITUAL ENGINEERING BY MEANS OF PYRAMID, STANDING STONE AND MAGNETIC PATH



From John Michell's *The View Over Atlantis.*

Michell infers a magnetic relation between pyramid and obelisk, or erect stone marker, saying that "Standing stones, which in many parts of the world are still regarded as the phallic instruments of fertility, are linked by the one mercurial principle with the Great Pyramid at the central storehouse of terrestrial current."

Michell quotes Iamblichus, the fourth-century theurgist, on the use of phallic stones as markers by means of which native geomancers directed the flow of magnetic current to fertilize the countryside.

"We say that the erection of Phalli is a certain sign of prolific power, which, through this, is called forth to the generative energy of the world."

Michell adds that an analysis of cabalistic numbers reveals a definite association between the terrestrial current and lunar influence.

The Austrian scientist and mystic Rudolf Steiner made numerous experiments which revealed the extent to which planetary influences affect not only the magnetic currents of the earth's surface but the layers of mineral ore deep below. The minerals within the rocks, says Steiner, are never inactive, but subject to regular cycles of motion in accordance with the orbits of the particular planet to which they chiefly respond. He says that at certain seasons they become charged with energy which they gradually release into the soil, and this allows seeds to germinate and stimulates vegetable growth.

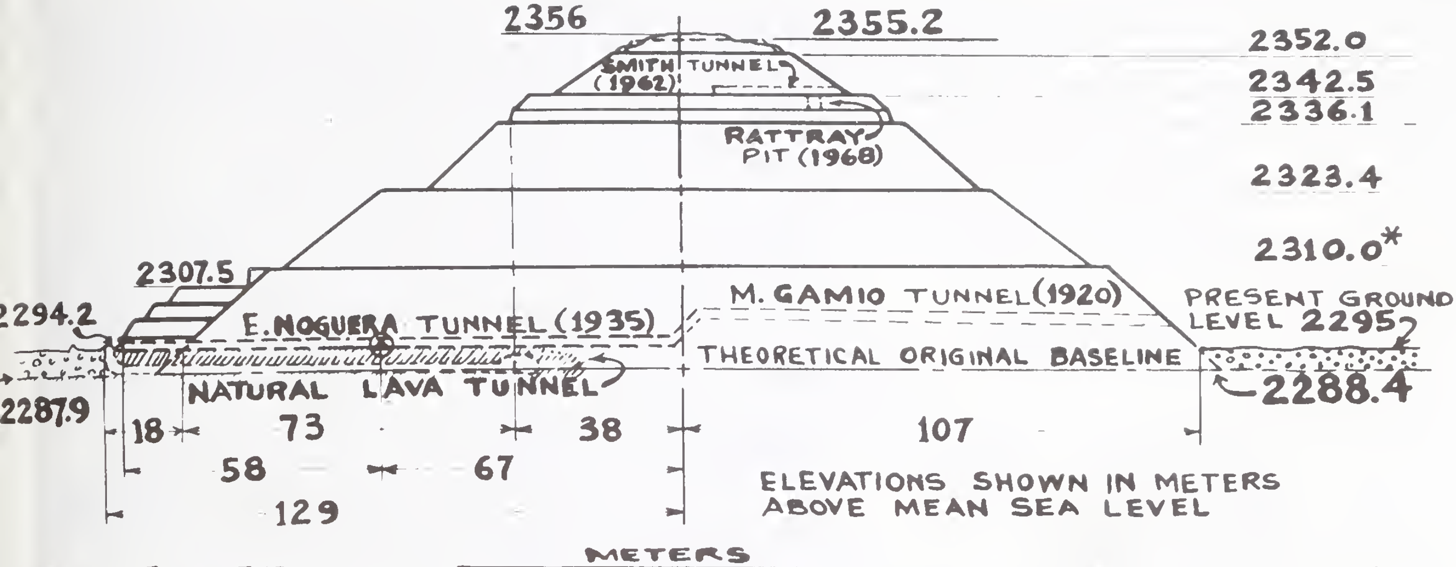
It is possible that seasonal feasts and "dragon processions" may have produced the vibrations of music and magnetizing effect, a sort of orgonomic injection, to increase vitality in humans and to stimulate the growth of plants, the plants on which the ancients survived and flourished, and which today we poison with toxic sprays and debilitating "fertilizers."

One of the most sacred locations where the ancients believed the most powerful telluric and cosmic forces met in a creative intercourse was in a cave with a natural spring under a pyramidal mound.

In 1930 a French dowser, Paul Berger, who styled himself "a prospector at great distance," dowsed a photograph of the Pyramid of the Sun at Teotihuacan and said he had found the hidden entrance to yet another gallery at an approximate depth of three meters from the base of the first level. Berger, who said he had specialized in locating mineral deposits while prospecting in Switzerland, Canada, and the United States, claimed the entrance had been plugged but that beyond the barrier a tunnel ran to the center of the pyramid, where it opened into a room closed on all sides, except for a small gallery on the right and another room on the left in which he could distinguish six articles in a row which appeared to him to be of gold. Berger offered to indicate the precise spot of the opening of the gallery so as to reduce to a minimum the necessary work of finding it.

When the editor of *Art and Archeology,* Arthur Stanley Riggs, tried to check on Berger's data with the Secretary of Public Education in Mexico City, he was told by the director of archeology, Don José Reygadas Veritz, that he had no knowledge of any such tunnel, nor did he believe it existed.

Unaware of this dowser's report, René Millon continued to be convinced that some sacred structure existed beneath the bulk of the Sun Pyramid, despite the failure of either Manuel Gamio or Eduardo Noguera to find it with their tunnels. Finally in 1959, Millon secured enough funds from the National Science Foundation in Washington, D.C., to organize a group



ADAPTED FROM THE R. MILLON DATA (1959) AND THE TEOTIHUACAN MAP, 1973, VOL. 2.

* SAME AS THE BASE ELEVATION OF THE MOON PYRAMID

Ⓐ STONEWORK FOUND IN NOGUERA TUNNEL (1959)

The tantalizing question of what might be buried either deep within the great pyramids or underneath them was first seriously broached by Manuel Gamio in 1917, when he decided to tunnel into the base of the Pyramid of the Sun. Starting just above ground level on the east side, he pushed a tunnel about two meters high and not quite as wide horizontally toward the center at a slight upward slope.

Gamio's main purpose was to establish whether any major interior structure of stone lay within the pyramid which would indicate that it had been built in stages. Leaning toward the theory that the pyramid had been built all in one piece, Gamio found no evidence of previous structures. When the tunnel reached a hundred meters he quit, satisfied that he had proved his point.

Second thoughts on the subject were had by an engineer called Eduardo Noguera some seventeen years later; so he obtained permission to drill a tunnel from the west side of the pyramid to meet Gamio's in the center. As the entire base of the Sun Pyramid would thus be traversed, he hoped to prove or disprove Gamio's theory. The entrance to Noguera's tunnel was slightly below present ground level, protected from rain by a masonry extension to the *adosado,* or lower structure, attached to the west facade. The tunnel ran to the center of the pyramid about 6 meters below the level of Gamio's tunnel and was offset about two meters to the north. A connecting staircase joined the two tunnels, which together ran 218 meters.

Though Noguera searched diligently, he found no signs of an earlier pyramid on which the later structure could have been superimposed, nor any internal strengthening features; so he concluded that the only way the great mound was held together was by the tensile strength of the outer skin of 15 to 20 centimeters of mortared adobe and stone.

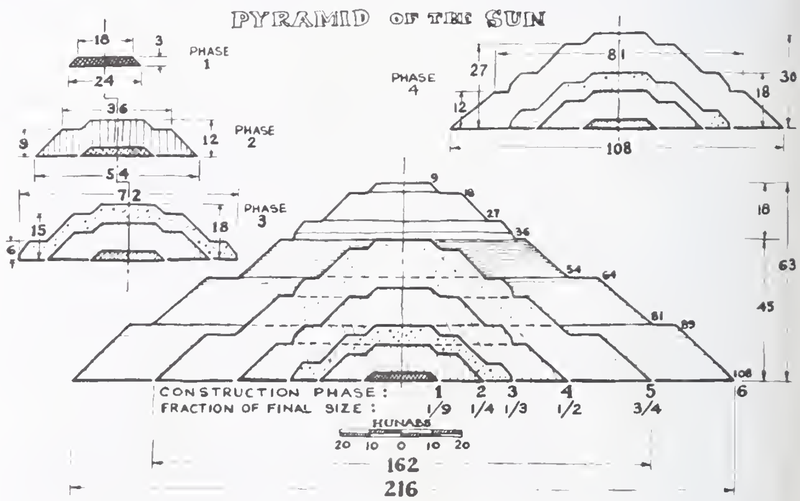
What Noguera did find were some 35,000 pottery shards, all of the earliest period of Teotihuacan development, called by the experts Archaic, or Teotihuacan I, or Tzacualli, which indicated that the pyramid had been built about the time of Christ or earlier.

If this seemed to settle the dating of the pyramid, it failed to settle the question of inner structures.

In 1962, Smith, with the help of the Peabody Museum, put a tunnel almost to the center of the east face of the fifth body of the Sun Pyramid, going west. Six years later Dr. Evelyn Rattray, working with Millon, excavated on the south side of Smith's tunnel till she ran onto a giant *talud* sloping wall, two meters high, indicating an earlier inner structure. Based on Dr. Rattray's papers, Harleston figured this wall to have had a slope up from north to south of 70.5 degrees, showing an earlier stage of construction similar to the one on the fourth level reconstructed by Batres—validating his claim of having learned to reconstruct more accurately as he approached the top of the pyramid. Since the wall was on the north side, its angular inclination could have served the same purpose as the present lower part of the fourth stage for shadow observation on or about the equinox.

to make a closer search in the tunnels for remains of earth and clay structures which might have eluded both Gamio and Noguera. Millon's group was interested in finding out what kind of fill had been used in the construction of the pyramid and in what way adobe bricks had been used.

At about fifty-five meters into Noguera's tunnel, the new investigators found evidence of adobe walls. Then, by running smaller branch tunnels north and south, near the center of the pyramid, they came across what Millon hoped they would find: the remains of what could have been a major structure, possibly a tomb of immense proportions. Here was a pyramid of much older construction, with an earth nucleus covered with adobe bricks, faced with uncut stones and cobbles, much of it destroyed. They also found evidence of what might once have been a huge pit. Millon still believed the additional blocked passages would reveal a mammoth tomb.



Hugh Harleston's Theoretical Construction Sequence of the Sun Pyramid.

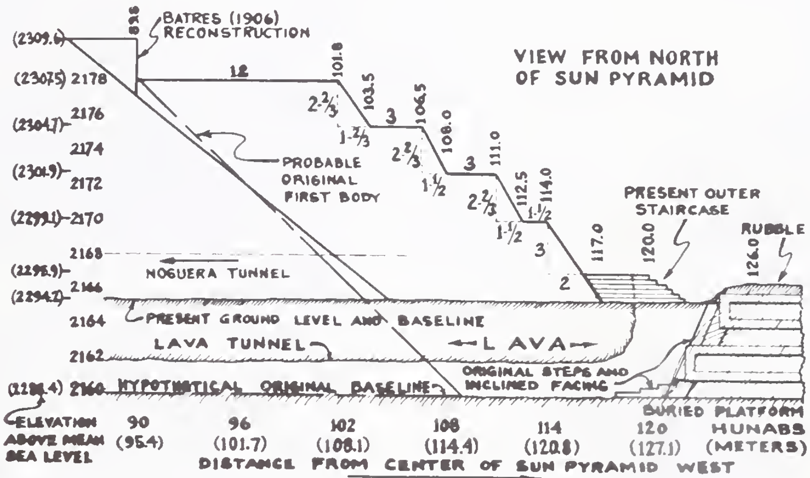
If the Sun Pyramid had been built in stages, by first building the sixth level on the ground, then superimposing on it a structure equivalent to the fourth and fifth levels, the upper outlines of the pyramid could have been progressively raised, maintaining a constant outline. Harleston suggests that the 70-degree angle of the third phase was used to obtain the day of the equinox. It could thus have been repeatedly in use till it was raised to the fifth level. Harleston suggests the builders may have built the stages in four 52-year cycles, constantly maintaining the shadow devices.

While Millon and his colleagues wrote papers on the results of these finds to be digested by the academic community and interested archeologists, a whole decade passed and nothing of interest was forthcoming for the laity. Then, in the fall of 1971, a heavy rain squall caused a deep depression at the foot of the main stairway of the Pyramid of the Sun. Examining the depression, Ernesto Taboada, locally in charge of the archeological zone, found the remains of an ancient and semi-destroyed stairway. As debris was removed, Taboada found steps that led six meters down into a pit to the entrance of a natural cave, two meters high, leading horizontally into the bedrock beneath the pyramid.

Jorge Acosta, in charge of all digs at Teotihuacan, was summoned to view the site and immediately took charge of clearing and consolidating the find. Ironically, it was he who had spotted a section of the same staircase six years earlier, but he had been obliged to cover the find for lack of funds with which to clear the pit. Now he determined to follow the cave or tunnel wherever it might lead.

As the entrance coincided with the center of the pyramid's main stairway, Acosta realized the cave entrance must have been known before the construction of the pyramid was started, which led him to surmise that its presence might even have determined the site for the construction of the pyramid.

Harleston's rendering of the entrance to the cave below the Sun Pyramid beneath the *adosado*.



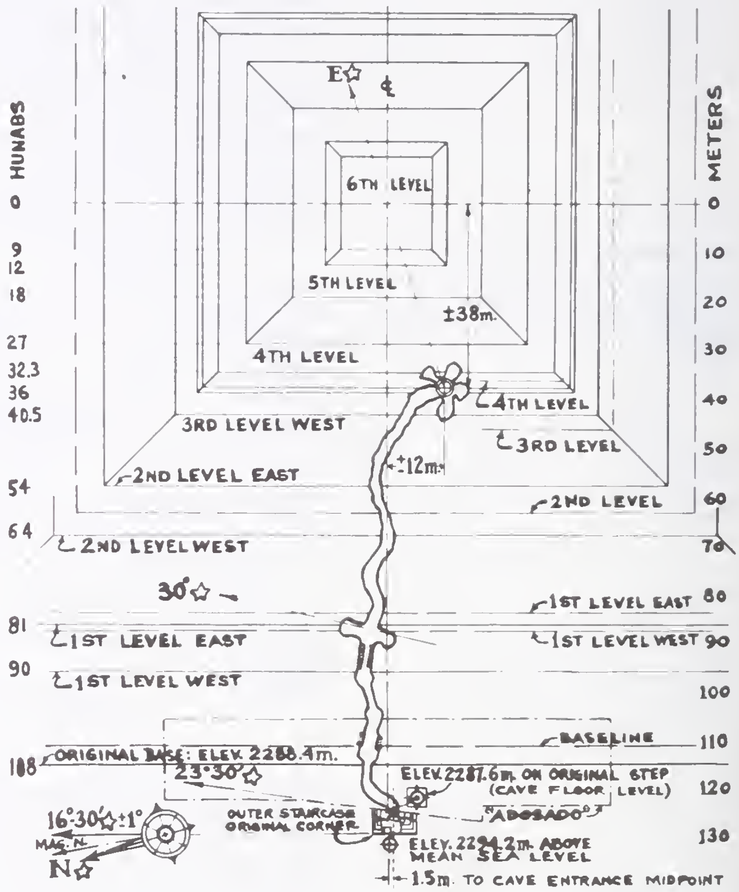
Entering the cave with a group of archeologists, Acosta found it to be a natural structure, two meters high and almost as wide, leading in an easterly direction. Frederick Mooser, a geologist of the Mexican University's Institute of Geology and a consultant to the Institute of Anthropology, said that in his opinion the cave was a natural formation, the result of lava flow that occurred more than a million years ago. The cave had been adapted by man for some purpose in that its walls were plastered with mud, and heavy stone slabs had been laid in the ceiling, some of them still in place.

As the group progressed along the subterranean canal by torchlight, they suddenly found themselves blocked by a wall of adobe and mortar which filled the cave with the exception of the top right-hand corner, which had been breached, apparently by vandals or by previous explorers, possibly much more recently than anyone cared to admit.

As the party advanced slowly down the tunnel, they encountered twenty-eight more blocking walls, all pierced. They also noted that the mortar on these walls was smoothed off between the adobe bricks only on the outer, westerly, side, evidently by masons *moving out.*

One hundred and three meters down the tunnel, the archeologists came upon an extraordinary sight: an arrangement of caves in the shape of an irregular four-leaf clover. Each chamber, which was ten to twenty meters in circumference, appeared to be of natural formation, deliberately enlarged by the hand of man.

Aerial view of tunnel beneath the Sun Pyramid, as drawn by Harleston from data collected in 1974 by the Uak-Kan group. Dotted lines are Batres' 1906 reconstruction. Solid lines show Harleston's hypothetical reconstruction.



Doris Heyden, an archeologist from New Jersey who moved to Mexico after World War II to study art at the University of Mexico and marry her anthropology teacher, joined the Mexican Institute of Anthropology and History, and seized on the cave theme to write several articles and a doctoral dissertation on the *Social, Economic and Religious Symbolism of Caves in Ancient Mexico.*

Heyden first wondered whether the chamber caves beneath the Pyramid of the Sun could have been a prototype tomb, such as was found in the Temple of the Inscriptions in Palenque, placed beneath the pyramid to intentionally hide its contents from the eyes of men, a tomb long since rifled by intruders.

She then suggested that the caves could also have been for the ritual of burying children as offerings to a water deity. Brother Motolinia describes certain offerings to Tlaloc in which four children were sacrificed and their bodies placed in a cave whose entrance was sealed until the following year when the ceremony was repeated. Sahagun tells of a rite in which the victim was flayed, and after the priest had worn the victim's skin for twenty days, it was placed in a cave "in the pyramid called Yopico." This cave was said to be at the foot of a pyramid stairway, "in an underground place . . . which had a moveable doorway."

Heyden also pointed out that there are many indications in Mexico of oracles taking place in caves. In Morelos a rock carving dating from circa 600 B.C. shows a figure in a cave with enormous speech scrolls by his mouth, indicating, says Heyden, that he is saying something of great importance.

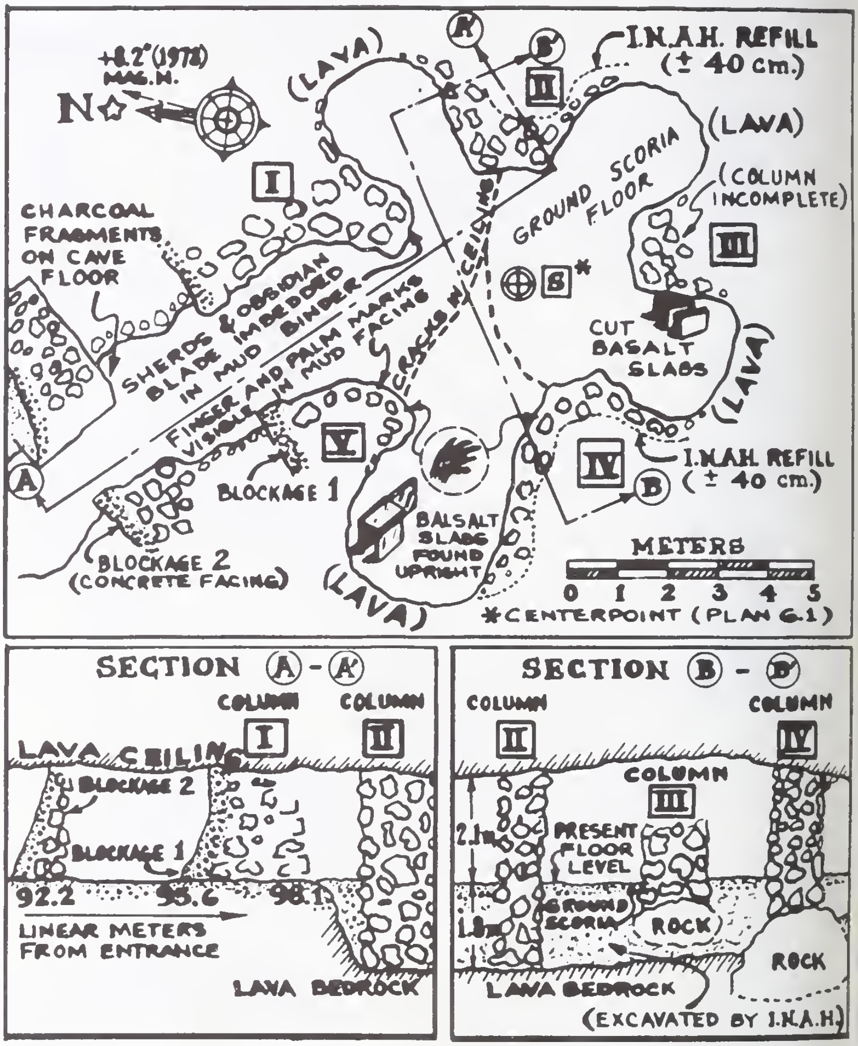
Historian George Baker's diagram of what was found at the end of the tunnel under the Sun Pyramid, indicating that at some time someone had built reinforcing walls to avoid additional cracking from earth movements; there were also indications of continual use of the chambers after the construction of the pyramid. Finger and palm marks were still visible in the millennial adobe, possibly made by violators.



On the compacted floor the searchers reported finding numerous crudely worked vessels, together with slate disks beautifully engraved with anthropomorphic figures, one dressed in jaguar costume, another as a bird. Acosta wondered if they could have been funerary offerings, but could find no trace of skeletal material or evidence of cremation.

Bits of mirror found on the floor of the cave indicated their possible use, as at Delphi, for prophetic reasons, mirrors having been used for divination in antiquity. More interestingly, Zelia Nuttall says the priests "of the below," the personifications of Tezcatlipoca, or "Shining Mirror," employed an actual mirror of polished obsidian as an aid in pronouncing final judgment on criminals, apparently using it as a crystal ball to reach the powers beyond.

Though there was no evidence of any spring or course of water, usually associated with underground shrines, such as at Lourdes, broken pieces of interlocking segments of drainpipes made of carved rock indicated they may once have been used to channel the flow of an underground stream. A thin line of vegetation stemming from beneath the pyramid, visible to Millon on his aerial maps, indicated the possibility of a former underground watercourse, which may have dwindled to a trickle.

Altogether the tunnel and cloverleafed caves presented a major and baffling discovery, the news of which the experts decided to sit on to give themselves time to conjecture on the possible uses and original function of their discovery. Caves, they knew, had from the remotest antiquity been of key importance in the religious history of Mesoamerica—a symbol of creation and of life itself.

Springs, they also knew, had been regarded as openings to the underworld and to the earth gods, the unnumbered spirits of the earth. Many of the legends spoke of gods or of extraterrestrials creating men in their present mold inside labyrinths of caves.

Zelia Nuttall maintains there were two basic rituals in ancient Mesoamerica: one by sun worshipers, with male overtones, performed on the steps of and atop the great pyramids; another, with female overtones, dedicated to the earth mother and to the powers of darkness, which took place at night and in caves.

Of the night ceremonies Nuttall says that the dangers and evils attendant on the earth cult became irretrievably associated with the female sex, so that "the votaries of Heaven naturally came to regard women as a source of temptation and degradation." Eventually, in Yucatan, says Nuttall, because of an unbridled use of pulque during the night ceremonies, the nocturnal cult of the female principle degenerated into such abominations that the incensed population actually rose in revolt, murdered the high priests, and scattered the votaries.

On the other hand, for what might have actually occurred during the sun ceremonies atop the pyramids, Geoffrey Hodson's clairvoyantly witnessed account is chillingly affective. He describes the evocation of earth forces, and of the Kundalini in particular, together with forces from the sun and from what he calls the higher planes. Hodson says he could observe the solar forces as they were made to pass rapidly down the head and spine of the officiants and others at the ceremonial to meet the ascending earth forces. These, says Hodson, combined to make a very powerful concentration of solar and planetary forces in the bodies of those present and of "associated Intelligences within and about the Great Temple of the Sun."

Hodson believes the ancient Mesoamericans considered—as indeed do modern Theosophists—that the constellations, stars, suns, and planets were governed by intelligences and

Geoffrey Hodson and the Theosophists claim that Kundalini, or the Serpent Fire, has the power of giving or transmitting Life, in a contradistinction to Prana, or vitality, which has the power of organizing Life, and Fahat, or cosmic electricity, which has the power of manipulating Life. To Theosophists, these three cosmic forces "ensoul" all substances.

Fahat, or cosmic electricity, Hodson calls the universal constructive force in all creation. Coiled in the center of the earth, it is a storehouse for solar Kundalini. When specialized and enclosed within the spinal cord of man, it is called Kundalini, or Serpent Fire, "the power that moves in a serpentine path." As the Godlike force within man, coiled at the base of the spine, it needs to be set free. When fully aroused either by Yoga or as a result of evolutionary progress, Kundalini is said to flow up an etheric canal in the spinal cord, vivifying and awakening the individual to self-conscious awareness in superphysical worlds. Kundalini is also said to give the power of astral travel.

The force opens up knowledge of the oneness of life, direct intuitive spiritual perception. It enhances the powers of clairaudience and clairvoyance, of being able to leave and return to the body at will without any break in consciousness.

Hodson says that the cerebrospinal system of man, when occultly vivified by Kundalini, resembles in many ways a TV set with superphysical broadcasts projected on the screen of the mind-brain.

The symbol of Kundalini is the caduceus, staff of the god Hermes: a rod entwined by two serpents. The winged sphere represents the freed soul of man who has awakened and learned to use his hidden powers. Hodson adds that like all the basic forces in nature, Kundalini is the manifestation of an intelligence, of an archangelic power.

powers which the priests in Mesoamerica had learned to contact without mediation, especialy those of the sun, Venus and Mars.

Hodson thinks the colors of the priests' robes and the paintings of their temples were designed to be in mutual resonance or harmonious vibration with these superphysical forces and intelligences.

The high priest and his helpers, says Hodson, evidently knew full well of the Kundalini, the fiery serpent force in the center of the earth and in man, for they employed certain ceremonies, postures, and words of power to evoke the earth Kundalini and cause it to flow along the spines of officiants and others present.

Hodson says the chief officiant at the ceremony at the temple on the summit of the Sun Pyramid at Teotihuacan seemed to be what he calls in Theosophical terms an "Initiate of the Fourth or Atlantean Root Race"—a tall man with reddish-brown complexion, very clear-cut features, large aquiline nose, eyes full of power, and a facial expression of sternness and great strength. As Hodson describes him, he wore a high feathered headdress and beautiful robes of many hues, the chief colors being red, yellow, green, and purple. His neck, arms, and legs were ornamented with jewels.

Hodson says that high in the air above Teotihuacan he observed a great circle, at least a mile in diameter, of golden Devas or angels hovering above the Sun Pyramid at a height of several thousand feet. "Their auras kept touching to form the bowl of a Deva chalice filled with solar 'wine,' a form of energy derived from a higher plane."

He says the stem of the great chalice built of intelligences and forces passed down through the temple and the pyramid into the ground while a large number of other Devas moved about high in the air above the rim of the cup, and one very great Atmic Deva supervised the proceedings, having apparently been in charge of the religion and area for many centuries.

This temple, says Hodson, was a spiritual center for the whole region, and at least three great ceremonies were regularly performed there, at sunrise, high noon, and sunset, high noon being the most important. Hodson notes that the very moment of high noon was measured by means of a vertical staff above the topmost temple, now demolished.

He says some of the people had psychic powers enabling them to see the auras of the leaders, which were brilliant and large, and that it was this direct experience which assisted in the maintenance of order throughout the land.

At the special time of the ceremony, performed when the sun was at its meridian, the summit of the pyramid seemed to become superphysically on fire, with "astro-mental flames" reaching out for a hundred yards or more above and on all sides. This, Hodson said, represented sun worship at its greatest and purest, because it was produced by the responses to invocations to the Solar Logos and the Solar Devas.

Whereas to the average citizen and even to the average scientist the sun appears to be part of a strictly mechanistic universe, to the Theosophists the sun is the visible aura of a mighty solar consciousness, part of a living, pulsing universe, an all-pervading Divine life in which we all live and move and have our being. To the Theosophists, all the entities within the Solar System, regardless of their kind, are subservient to what they call "Cosmic Vitality"; they give as a parallel the case of the human being. "Each of us," says L.

Gordon Plummer in his *Mathematics of the Cosmic Mind,* "is composed of myriads of subservient entities, better known among which are the cells of our bodies, which include the blood cells. Every one of these is a living organism, highly complex in itself; yet they all function within the dominance of the vitality of the man while he is alive."

The Theosophists say that just as in human bodies there is a constant circulation of vital essence via the blood and nerve fluids, so in the solar system there occurs an incessant interchange of vital essences along electromagnetic patternings, with every planet contributing to every other planet and to the sun, which, like a beating heart, revitalizes the system.

Man, they say, is an integral part of the universe which environs him, to which he must return parts of his vitality, a notion which could give meaning to the Aztec sacrificial ritual in which, while blood is shed, a spirit is freed from the body. Like the Theosophists, the Aztecs believed that vast hosts of other-dimensional entities in all degrees of development, from atoms to gods, inhabit the system, moving from body to body along the electromagnetic pathways of the universe.

Georges Ivanovitch Gurdjieff in New York in 1924.

Georges Ivanovitch Gurdjieff held that cosmic emanations in the form of matter or substance were, and are, transmitted by the planets, the solar system, the stars, and the suns of the Milky Way, on out to the ultimate principle he refers to as the "Absolute." Emanations of matter from the Absolute, upon meeting the stars, the solar system, and the planets, says Gurdjieff, change in density according to an order which corresponds to the musical notes do, si, la, and so on up the scale through different octaves.

According to the Ancient Wisdom, the Galactic Universe in its totality is a sort of living being, "an entity of such mighty power that nothing short of a universe could possibly represent it." A pretty conceit which Theosophists qualify by pointing out that the "space" of the scientist is in fact an illusion produced by our consciousness, not that it does not exist, but rather that we do not perceive it for what it truly is.

PART VI PREHISTORI

EAPPRAISAL

24. Origins of the Maya

Hodson's re-creation conjures up the picture of a spiritually evolved priesthood, descendants of Atlanteans, performing still vital ceremonies on the pyramids of Mesoamerica. Does such a picture fit with what is known of the Teotihuacanos, Olmecs, or Maya? Sylvanus G. Morley, who, though he died some decades ago, is still North America's leading authority on the Maya, would have one believe that Mayan civilization developed suddenly, springing fully armed like Athena from the brow of Zeus.

"The ancient Maya . . ." as he puts it, "emerged from barbarism probably during the first or second century of the Christian era." To make his point he used what he believed to be the earliest Mayan stelae erected at Tikal and Uaxactun, but failed to account for the fact that these stelae incorporate not only a developed Mayan system of writing and numerals but a calendrical system so sophisticated that it alone indicates centuries if not millennia of previous careful astronomical observation.

Opposing experts—such as the California architect Robert B. Stacy-Judd, who spent fourteen years exploring Yucatan to produce a beautifully styled book, *Atlantis, Mother of Empires*—maintain that the Mayan civilization arrived in Central America already developed, its origin having taken place elsewhere—in his opinion Atlantis, or the island of Antillia, the last large surviving segment of the Atlantean Empire, approximately what is now the Grand Bahama Bank.

As there are no historical records contemporary with the appearance of the Maya in Central America, but only the archeologists' interpretations of the buildings, stelae, sculptures, and pottery found in a fraction of what may be hun-

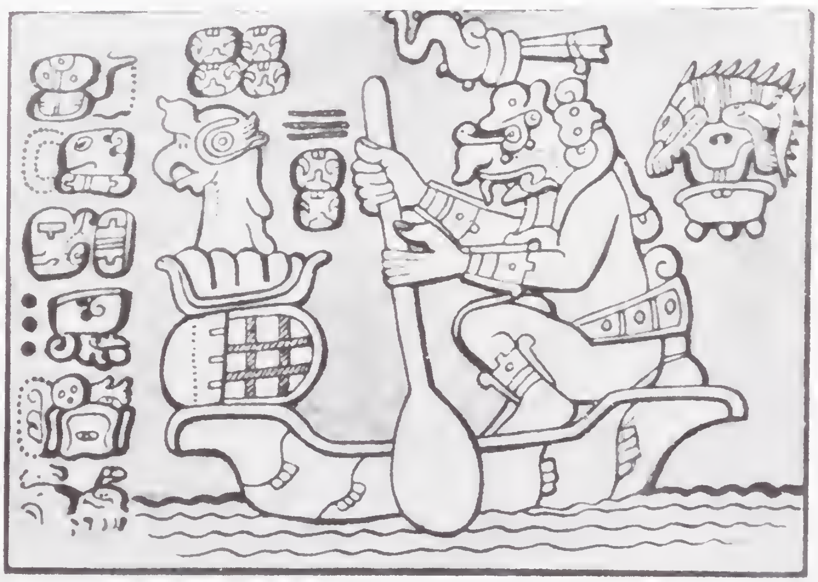
dreds or even thousands more undiscovered Mayan sites, the next best information derives from native sources, from the books concocted from memory by the Quiché and the Maya such as the books of Chilam Balam and the *Popol Vuh,* rediscovered and publicized by Brasseur de Bourbourg.

The books of Chilam Balam relate that the first inhabitants of Yucatan were the Chanes, "People of the Serpent," said to have come from the east in A.D. 219 in boats across the water with their leader Zamna, also known as Itzamna, "Serpent of the East," a healer who could cure by laying on of hands, and, like the Therapeuts, revived the dead.

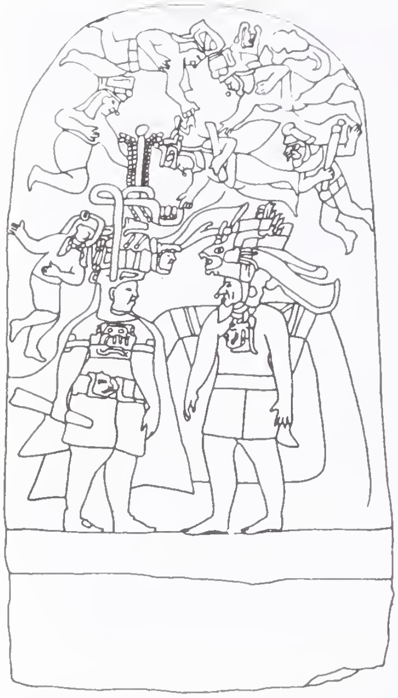
The Chumael book of Chilam Balam is even more specific. It speaks of the first inhabitants of Yucatan, known as Ah-Canule, or "People of the Serpent," having come across the water from the east in boats to locate on the island of Cozumel off the coast of Yucatan. As their population grew, these Itza moved to the mainland and built cities, altogether 150, including Chichen Itza (the "Mouth of the Wells of the Itza"), Izamal, Ake, Uxmal, and Mayapan.

The *Popol Vuh* is vaguer but more poetic: "Then they came; they pulled up stakes there and left the East . . . Each of the tribes kept getting up to see the star which was herald of the sun (Venus). This sign of the dawn they carried in their hearts when they came from the East, and with the same hope they left there, from that great distance, according to what their songs now say . . ."

The history of Zodzil, by Juan Darreygosa, incorporated into one of the earliest reports from the Spanish conquerors, the *Unedited Documents Relating to the Discovery and Conquest of New Spain,* picked up the same legend: "The most ancient people who came to this land were those who populated Chichen-Itza . . . and were the first after the Flood."



Drawing of Itzamna sailing from the east, taken from one of the codices.



Reconstruction of stele found near La Venta showing an exotic Middle Eastern figure known to archeologists as "Uncle Sam."

From Bishop Landa's reports it is clear that the strangers did not come, as Morley suggests, from the *south*east overland, but from across the seas: "Some of the old people of Yucatan say they heard from their ancestors that this land was occupied by a race of people who came from the east and whom God had delivered by opening twelve paths through the sea."

Morley maintains the Mayan area had been inhabited from two to three thousand years earlier by Maya-speaking peoples whom he labels as nomadic, but of whom he can say no more.

Archeologists then discovered remains of another whole civilization on the east coast of Mexico, just north of the Maya, complete with hieroglyphics, calendar system, and pyramidal religious complexes which appeared to antedate Morley's "civilized" Maya by almost a thousand years. For lack of a better name, the archeologists called these people Olmecs, or the "Rubber People"—though no one knows what these people might have called themselves.

When archeologists were digging in the soil of a swamp-surrounded island about twenty miles inland from the Gulf of Mexico, close to the western border of the state of Tabasco, known as La Venta, they came upon a fourteen-foot stele, seven feet wide and three feet thick, with two figures in apparent conversation. When the mud was cleaned from the carvings, the diggers discovered a tall, handsome figure with a commanding look, high-bridged nose, and flowing beard, in conversation with a smaller man. So much did the figure resemble Uncle Sam that he was so dubbed by the astonished archeologists. The features of the figure were clearly not those of an Indian. Furthermore, the figure was wearing a long gown, elaborate headdress, and shoes with oddly upturned toes.

Fascinated by this stylistic anomaly, Constance Irwin, who pursues the riddle of ancient seafarers to the New World in her controversial book *Fair Gods and Stone Faces,* asked herself who in the world was wearing upturned pointed shoes in the first half of the first millennium B.C., the date assigned by the experts to this stele.

After considerable research she traced the upturned shoes to either the Hittites or their successors and imitators, the Phoenicians, renowned as great seafarers, who regularly wore long clinging double robes, turbans with ribbons, pointed beards, and upturned shoes.

So impressive is the evidence accumulated by scholars to the effect that the Phoenicians reached the shores of both North and South America, it is hard to understand why it continues to be shunned.

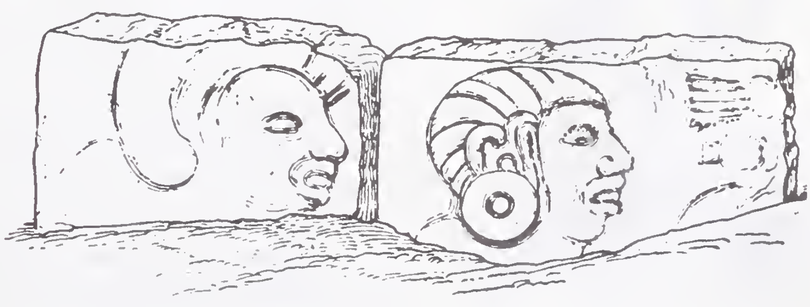
Support for a Phoenician land fall on the east coast of

At La Venta, on the east coast of Tabasco, 50 yards into the jungle, diggers came upon a huge hemispherical stone, vine-sheathed and almost unrecognizable till they dug further and revealed a colossal head eight feet high with broad nose and thick lips. Three more heads, all facing east, surfaced nearby, one of them 8 1/2 feet high and 22 feet in circumference. Later, several more were found further along the coast, many of them mutilated. One had a singularly Egyptian feature: a speaking tube that ran from a giant ear to emerge between two great stone lips through which the voice of a priest could have spoken. Nearby a huge pyramidal mound was discovered rising 100 feet above a base 300 feet square close to a colonnade with tightly fitted columns.

Mexico appeared in the form of enormous stone heads with marked Negroid features and what looked like baby caps or football helmets dug up from the subsoil of La Venta, dated to about 500 B.C. by the experts.

Pointing to other Phoenician carvings of black slaves wearing just such helmets, Constance Irwin suggests that nothing could have been more natural for Phoenician traders than to have picked up African Negroes on the west coast of Africa and sailed with them across the Atlantic to Mexico.

Further evidence of the presence of men with Negroid features accompanying bearded Semites also turned up farther west in Oaxaca.



Colossal heads in low relief found near Oaxaca.

Hugh Fox in his *Gods of the Cataclysm* says the association with the yogic trance is especially evident in these Monte Alban figures because the designs portrayed on the dancers' bodies are chakras, "the mystic centers connected with successful meditation."

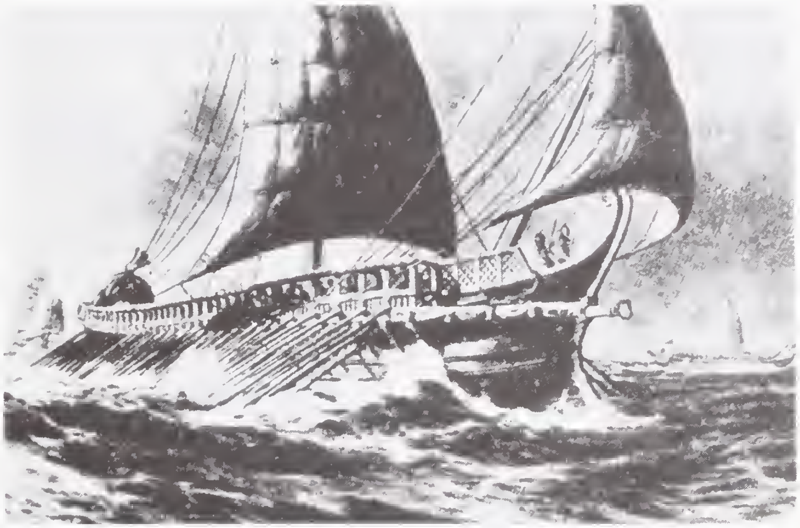
Like the Olmecs, the earliest known settlers of Monte Alban had a hieroglyphic system of writing, a calendar, and a mathematical system of computing by bar and dot. These settlers left some extraordinary cyclopean rocks built into buildings which portray life-sized Negroid dancers with flat noses, round faces, and thick lips. Alongside them are Old Testament types with hooked noses and spatulate beards, all very un-Indian. Archeologists date these finds around 500 B.C. and attribute the ruins to the Olmecs.

Startlingly Semitic figures found throughout Mesoamerica.

Fox points to the ecstatic face of the Mochica coca-taker with its inward-turned eyes, frozen, fixed, expressionless face, and compares it to the world of yoga ecstasy.

Among the institutions and customs shared by the Phoenicians of the first millennium B.C. and the inhabitants of Central America during the same era, Constance Irwin has listed several items starting with an advanced knowledge of mathematics and astronomy (which the Phoenicians picked up from the Babylonians). In common with the Maya, the Babylonians were the only known ancient civilization that had a place value in their mathematics, the concept of zero, and the ability to express large numbers—as indicated by the cuneiform text found in Mesopotamia with the now no longer so mysterious number 195,955,200,000,000. As C. W. Ceram points out, it was not until the nineteenth century that the concept of a million became common in the West. Like the Maya, and their possible predecessors the Olmecs, the Chaldeans had records of stars going back 370,000

The Phoenicians, whose origins are vague, are known to have sailed north from the Pillars of Hercules to Britain for tin, and even farther to Scandinavia for amber. Southward, they sailed down the coast of Africa, planting colonies as close to the equator as Dakar. At one point, in the employ of the Egyptian Pharaoh Necho, in 600 B.C., they appear to have circumnavigated the entire continent of Africa—2000 years before the Portuguese next accomplished the feat. Westward the Phoenicians sailed as far as the Azores and the Canaries, jumping-off place for Columbus, where the favoring trade winds blow from the east, and the northerly equatorial current along the fortieth parallel will thrust a boat irresistibly toward the Antilles and the Mexique Bay. Diodorus Siculus wrote of a land which lay far to the west and was known to none but the Phoenicians and Carthaginians. The Tyrians, he says, at the time when they were masters of the sea, proposed to dispatch a colony to it.

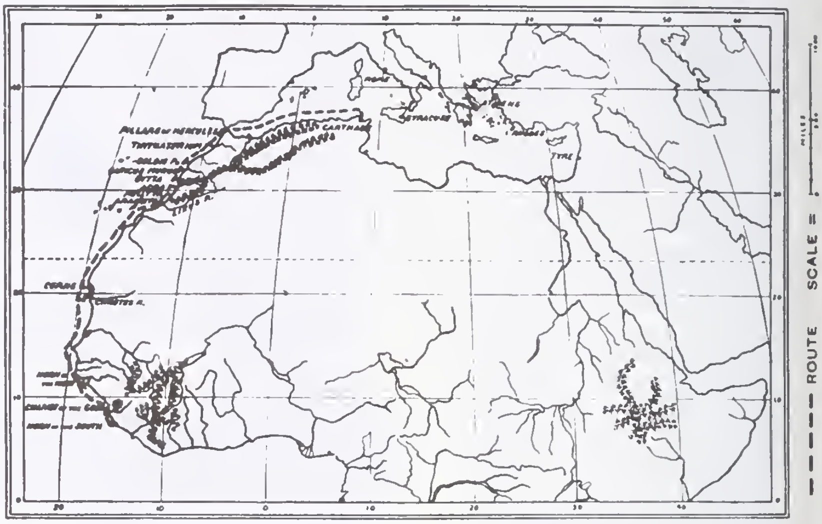


At Tula, the Toltec capital, shoveling rubbish from the remains of a house, Désiré Charnay found many curios, such as huge baked bricks, filters, curved water pipes, and what appeared to be small Phoenician seals, and a vase with a bearded, robed, mustachioed Tlaloc holding a bolt of lightning.

years, while the Babylonians kept the nativity horoscopes of all children born for thousands of years, from which to calculate the effects on humans of the various planets and constellations. Like the Maya, the Babylonians measured the year in 360 and 365 days; and they estimated the period of the moon's return to within a matter of seconds. Unlike the Romans, who thought the morning and evening star were two different bodies, Lucifer and Hesperus, the Babylonians and the Maya both knew them to be the same body: Venus.

Further traits held in common by the Phoenicians and their contemporaries in Central America were hieroglyphic writing, the custom of deforming the heads of newborn children, infant sacrifice, the use of incense, phallus worship, the depiction of deities floating horizontally over the heads of mortals involved in conversation, twisted rope borders on sarcophagi and seals, pyramidal temples that rose in terraces to a truncated top where they were used as astronomical observatories, worship of the sun and the moon, to whom temples were raised, the use of gnomons to measure the sun's shadow and determine latitude, the manufacture of clay figurines depicting dwarfs, and, most astonishing, representation of the rain god Tlaloc in Central America by the figure of a white man with a handlebar mustache and long beard, holding a thunderbolt of lightning—just as did his Phoencian counterpart. (See Charnay's vases.)

When the Phoenician stronghold of Tyre fell to Nebuchadnezzar the Great in the sixth century B.C., Carthage succeeded as the wealthiest city in antiquity. Founded by the Phoenician Queen Dido in 825 B.C. near what is now the city of Tunis, Carthage became the most important outpost of Phoenician civilization in the western Mediterranean, with a population of close to a million within its walls. As an



The periplus of the Carthaginian Captain Hanno describes a flotilla of 60 ships of 50 oars and 30,000 men and women setting off in about 500 B.C. down the west coast of Africa with enough provisions to travel 3500 miles from Carthage and 2500 miles beyond the Pillars of Hercules to found new colonies as far south as Senegal and Gambia—curiously named "Chariot of the Gods."

Archeologist Hugh Fox sees a profound religious link between the early Mesoamericans and the early Mesopotamians, a link that was forged by travel to the west of Phoenicians and Carthaginians. In his *Gods of the Cataclysm,* Fox has concluded that Huitzilopochtli, though an amalgam of various gods or god-qualities, is actually a Phoenician version of Zeus, or to be more exact, a Carthaginian version —a Jupiter Haman. He points out that there was human sacrifice to Zeus, including the ritual of flaying, and that in many Middle Eastern rites "worshippers were clad in the skins of animals sacrificed." He sees in Xipe Totec, the Aztec flayed God, an Adonis or Osiris or Dionysus or Baal Haman—all fertility gods. Flaying was a favorite method of torture among the Carthaginians.

outlet for this burgeoning population, and to insure its continued existence, Carthage sent out colonists to sail past the pillars of Melkarth (as they called them) down the coast of Africa, carrying their knowledge and their cults.

From that latitude these Carthaginians, like their Phoenician predecessors, could well have sailed to the New World and made landfalls in Yucatan, Tabasco, or Chiapas, giving substance to the tale of Votan. For the return journey to the Mediterranean, as is recounted in the *Odyssey of Votan,* the Gulf Stream would have swirled them clockwise around the Atlantic, eastward along the 39th parallel, to where the prevailing westerlies would drive a ship to the Azores, and home to Africa and Europe. On Corvo, the northwesternmost island of the Azores, just over a thousand miles from the shores of North America, a cache of Carthaginian coins was found dating from the fourth and the third centuries B.C. In 1975, stones were found on the Atlantic coast near Cape Cod inscribed in a southern Iberian alphabet attributed to Hanno and dated between 480 and 475 B.C.

Nor does the tale of travel to the West stop there. After the Phoenicians and the Carthaginians, Greeks, Romans, Irish, Welsh, and all manner of Scandinavians left tales and evidence of travel to the Americas. Books with information on these voyages fill several shelves in the stacks of the Library of Congress, some with specific studies like those of Professor Cyrus Gordon, others, popular summaries, such as Charles Michael Boland's *They All Discovered America.*

There is equally intriguing evidence of travel to America across the Pacific from the west. As an explanation for the abundance of Indians in Mexico with pronounced Chinese features, Henriette Mertz in her book *Pale Ink* tells of two Chinese expeditions to America, one in the fifth century A.D.

According to Fox, whereas Judaism developed away from human sacrifice, toward surrogate animal and then cereal and then symbolic sacrifice, "the Aztecs caught up the Canaanite religion in its most primitive phase and developed it almost solely along its cannibalistic/human sacrifice lines." He points out that the Phoenicians were the great child-sacrificers, and that in the Old Testament the gods were only appeased by blood sacrifice. Wherever the Phoenicians went they left behind a heritage of blood and sacrifice.

To the Phoenician mind, says Fox, whether in Syria, Palestine or North Africa "the whole sacrificial system was based on an attempt to prevent another—and final—Great Cataclysm."

Fox found Tanit-Baal-Haman, the god-goddess, at the very top of the Aztec Pantheon, and saw her as the Aztec version of Kali, the great Indian mother-goddess, destroyer-creator, and the simultaneous beginning and end of the whole.

To Fox, the benign, benevolent life-giving *mater magna,* mother of heaven and earth, may have become a malevolent destructive force as the result of some great cataclysm. It is clear to him that when the Mayas killed a victim and offered his heart to Venus, the Evening Star, they were offering it to the Phoenician Venus, Tanit, out of fear. He adds that the Hopi were Phoenicians, or strongly influenced by the Phoenicians, and that the Olmecs were black African Phoenicians or escaped Phoenician slaves.

Summing up, he puts the rhetorical question: "If this whole religion was Phoenician, as it certainly seems to be, and if the oldest memory of Aztec theological sources reached back to Teotihuacan, then didn't that make Teotihuacan a Phoenician colony? And the original Quetzalcoatl a Phoenician priest?"

and another much earlier in the twenty-third century B.C., both of which are in the Chinese records.

The fifth-century expedition is described by Hwui Shan, a Buddist monk who reported on the travels of five Buddhist missionaries to a country far to the east called "Fu-sang," which Henrietta Mertz and several other modern historians identified as Mexico, overall from Los Angeles to Yucatan, and specifically around Chichen Itza. Fu-sang was so named by the Chinese because of its trees, which looked like bamboo but produced an edible fruit, pear-shaped, and reddish in color, which could be preserved for a year without spoiling. At the beginning of the Christian era, corn in Mexico was only about three inches long, wider at the base, like a pear, with reddish kernels.

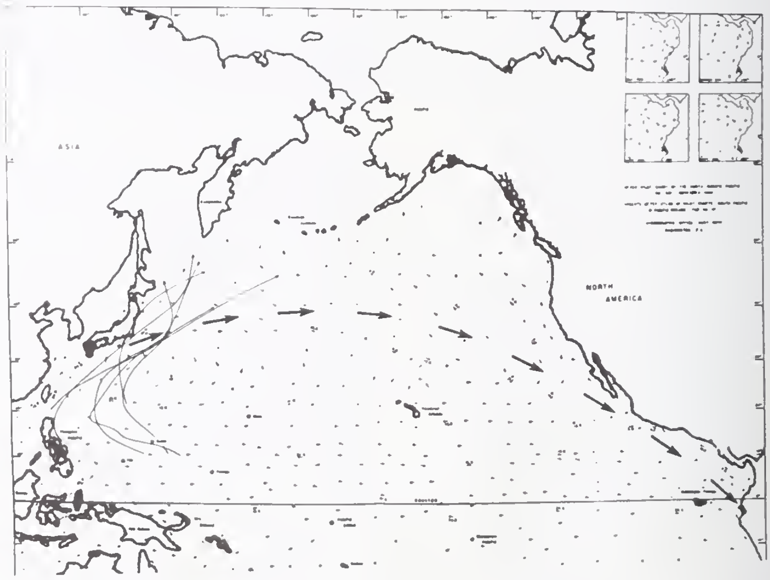
Hwui Shan describes finding a civilized people in Fu-sang who knew writing, which they did on paper made from a plant, and who, though they had no iron, had plenty of gold and silver. According to Mertz, this fifth-century visit to Mexico changed the entire course of Mexican history. In Hwui Shan's story, a Chinese nobleman of the first rank was called "Tui-lu," and the Mayan books of Chilam Balam tell of a leader who came from the west, from Tulupan, who had the title of "Tutul Xiu." Mertz describes Tutul Xiu as a Chinese Quetzalcoatl who contributed to the Mexicans Oriental knowledge of the calendar, astronomy, metallurgy, agriculture, jade carving, and the compass.

The earlier report of Chinese travel to America, known as the *Classic of Mountains and Seas,* is the record of a series of journeys about the globe compiled in 2250 B.C. at the request of the Emperor Shan by a man called Yu, his minister of public works, who later became emperor himself. The Chinese travels describe mountains and rivers across the Pacific, or the "Great Eastern Sea." This classic Chinese periplus, known as the Shan Hai King, or oldest Chinese geographical work, though severely truncated, miraculously survived the repeated burning of Chinese libraries and the emasculation of less interested or accurate Chinese historians, and Dr. Mertz believes it "will be found to be the most astounding ancient document detailing geographical phenomena that has ever been written."

The periplus tells of great rocky mountain ranges beyond the sea and names and describes a series of peaks stretching 2200 miles from Manitoba in Canada to Mazatlan in Mexico. With great pains Mertz has followed the record of the Chinese peregrination, whose geographical details described in vivid language are as recognizable today as when they were noted in the third millennium B.C.

As she puts it, "We can do no more than to stand with bowed heads before the intrepid Chinese who mapped those jagged snow-capped peaks over 4000 years ago."

At about the same period, the Japanese appear to have explored the west coast of South America. Both Japanese and Chinese histories abound in stories concerning boatloads of thousands of people sailing out across the Pacific Ocean in search of a promised land. From careful analysis of pottery on the Ecuadorian coast, which compares very closely with Japanese pottery of 2500 B.C., Betty J. Meggars and her husband, Clifford Evans, were led to the conclusion that the Japanese had reached Ecquador thousands of years ago.



Route taken by Japanese to reach Ecuador before the Christian era, from Betty J. Meggers.

These reports of voyages to the Americas from both east and west take the story back to the third millennium B.C., but much earlier remains of buildings, often extremely sophisticated, have been found in North, Central, and South America, and various authors have hypothesized advanced civilizations which long preceded the Mayan and the Olmec. However, as there are no known historical records for such early periods, and no sure system for dating the remains, these stories float in a limbo between fact and fiction.

Their cumulative evidence, however, is too evocative to be ignored.

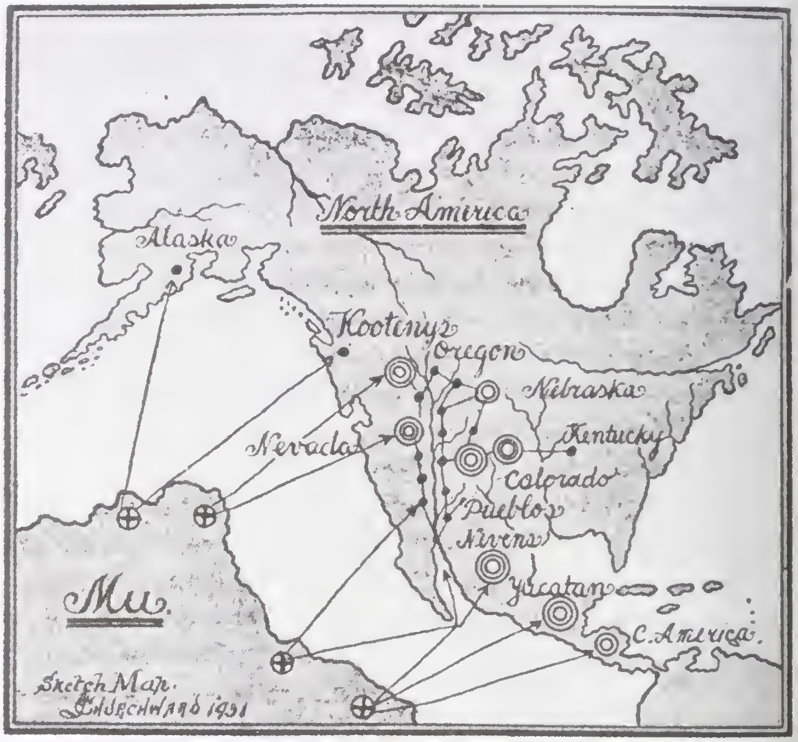
25. Prehistoric Mexico

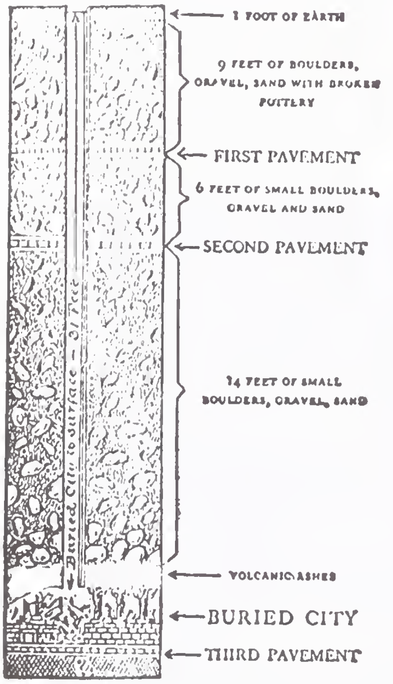
One indication that a far earlier civilization existed in the Valley of Mexico than was reached by Manuel Gamio's spades comes from the tantalizing discoveries made in the Mexican highlands by a Scotsman, William Niven. As a mining engineer working for a Mexican corporation, Niven described coming upon the remains of two separate prehistoric civilizations at depths of from six to thirty feet below the present level of the Valley of Mexico. These discoveries, made between 1910 and 1930, have hardly been considered by the "scientific world," partly because they fit into none of the preconceived notions, and partly because they were used by an even more unorthodox author, James Churchward, to validate his, to them, even wilder hypothesis—the existence of a vast continent in the Pacific Ocean which he called Mu, mother, says he, of several colonial civilizations which spread around the globe.

Churchward's efforts, though very popular with aficionados of Atlantean and Lemurian tales, and often prophetically exact in certain details, have, because of Churchward's unsupported and highly improbable notions, been thrown out by an establishment which may have discarded, along with Churchward's Lemurian bath water, some living, screaming babies.

Being befriended by fellow Freemason Churchward was of no greater help to William Niven than it had been to Le Plongeon, except that with the thousands of copies of Churchward's books sold around the world Niven was rescued from oblivion. When he died in 1937, his obit in the *American Historical Review* listed him merely as a professor who had been engaged for several years in mineralogical research, an

Churchward's rendering of prehistoric North America with part of his great continent of Mu in the Pacific.





Niven's Mexican Buried Cities
Now 7000 feet above level of sea. Mountains 5000 feet higher intervening

In the several strata clearly revealed by the pits, Niven says he found traces of what he describes as three well-preserved concrete floors or pavements at depths from about 6 to 25 feet. Above the first pavement there was a deposit of small boulders, pebbles, and sand, covered with a foot-thick coating of rich valley soil. Everywhere in the first layer of debris, Niven found fragments of broken pottery, small clay figures, diorite beads, spear- and arrowheads, spindle whorls, and other artifacts, mostly broken.

honorary life member of the American Museum of Natural History and various other such scientific societies who had become involved in Mexican archeology, nothing more. Nothing to indicate he might have made the most controversial archeological discovery of the Western world.

Actually, Niven had been exploring in Mexico since 1889. While digging among the ancient ruined cities in the unknown and uninhabited portion of the state of Guerrero, southwest of Mexico City in the Acapulco area, he began to receive periodic visits from local Indians who came to him with terra-cotta figurines and other objects for sale. Though the Indians pretended to have found these objects at the pyramids of the Sun and Moon at San Juan Teotihuacan, Niven realized that the source of the artifacts must be nearer; with a bribe of five pesos ($2.50 at that time) he managed to discover the actual spot.

Between Texcoco and Haluepantla, hamlets just north of Mexico City, he came across hundreds, if not thousands, of pits dug into the sand, clay, and tepetate used for material by the builders of Mexico City for more than three hundred years. Exploring these pits, which Niven says cover an area of about ten by twenty miles in the northwest corner of the Valley of Mexico, he came across vast layers of what appeared to be very ancient ruins, whole prehistoric cities lying as deep as thirty feet below the plain, which appeared to have been overwhelmed by a series of cataclysmic tidal waves, perhaps at several-thousand-year intervals, which, In 1920 William Niven (in light suit) was exploring a passageway in the Pyramid of the Moon with an enthusiastic Sunday archeologist, Charles Beeching, a bridge-building civil engineer from Boston, Massachusetts, when the latter fell into a well-like hole. Beeching described the event in a letter to his daughter Mariana Beeching de Prieto, a writer of children's books now living in Miami, Florida. "I fell feet first through a hoie and tumbled into blackness. One moment I was walking along a dim corridor, the next I was plunged from Aztec into a pre-Aztec or Teotihuacanic era. My undignified drop turned out to be a valuable archaeological discovery. I had fallen into the chamber of an ancient race. As soon as I could collect myself I let out a yell. Niven was within earshot. The only escape from the chamber was through a narrow opening which I myself had punctured in the roof. Niven lowered a rope and hauled me bruised and shaky out of the place.

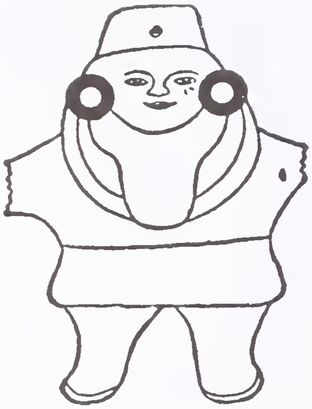
"While waiting for rescue, my eyes became accustomed to the darkness . . . in the corners of the stone-walled rooms there were heaps of images, tablets and pieces of pottery."

From Beeching's report it appears that passageways, wells, and hidden chambers, such as were reported by Ewing and Latrobe, still existed in 1920 before they were obliterated by a massive restoration of the Moon Pyramid.

as Niven described them, had left telltale strata of boulders, sand, and pebbles. By their depth beneath the surface, Niven estimated the oldest remains might go as far back as 50,000 years.

Four to six feet below the first pavement, Niven says he encountered a second "concrete floor," but in the intervening space failed to find a single piece of pottery or other trace to indicate that humans had once lived there. Beneath the second pavement, he describes coming upon what he considered "the great find of my many years' work in Mexican archeology."

Niven discerned, beneath a well-defined layer of ashes from two to three feet thick, analyzed as being of volcanic origin, traces of innumerable buildings, large, but regular in size, the remains of a vast city which appeared uniformly at the same level throughout more than a hundred clay pits. In one of the houses—most of which were crushed and ruined, filled with ashes and debris—he says he found an arched wooden door which had turned to stone. The walls of this house were bound together with white cement, harder than the stone itself. In one



Niven believes the figure of a Chinaman, which he found thirty feet from the surface in a pit which he had dug at San Miguel Amantla, near Haluepantla, nineteen miles from the national palace in Mexico City, had been buried thousands of years earlier. Niven says the oblique eye slits, padded coat, flowing trousers, and slippers make the statuette clearly Chinese. He explains the lack of a queue by pointing out that the Chinese did not have the queue till they were conquered by Tartar hordes from the north in the seventh century. The statuette is seven inches high, of friable clay, which on the outside has turned to stone. It is three and a half inches wide at the chest and one and a half inches through the abdomen. The ears are ringed; the skull cap has a button in the center like the caps of mandarins of the empire.

uncrushed room, about thirty feet square, full of volcanic ash, with a flat roof of concrete and stone, Niven says he came across many artifacts and human bones, which "crumbled to the touch like slaked lime." According to his detailed report, a complete goldsmith's outfit was still on the floor with some two hundred models of figures and idols molded in clay turned to stone, each model thickly coated with iron oxide, bright and yellow, presumably there to prevent the molten metals adhering to the patterns while in the casting pot.

Niven says the ornaments were unlike any found in Palenque or Mitla or anywhere between. The work was fine, beautifully polished, demonstrating an advanced degree of civilization. On the walls Niven found paintings in red, blue, yellow, green, and black, which he says compared favorably with the best he had seen from Greek, Etruscan, or Egyptian works of a similar sort. The ground color of the wall was a pale blue; six inches down from the fourteen-foot ceiling a frieze painted in dark red and black ran around the room, glazed with some native wax which had perfectly preserved the color and pattern, which depicted the life of some person, apparently a shepherd, from birth to death.

Beneath the floor Niven found a tomb three feet deep, lined with cement, in which were seventy-five pieces of bone, all that was left of a skeleton. A large fragment of the skull contained the blade of a hammered copper axe, which appeared to have been the cause of death, for it had not been removed. Niven also found in the tomb 125 small terra-cotta idols, manikins, images, and dishes, some with features strongly Phoenician or Semitic, one sitting crosslegged with a hollow movable head set on its neck by a cleverly devised truncated tenon fitted into a mortise at the base of the skull.

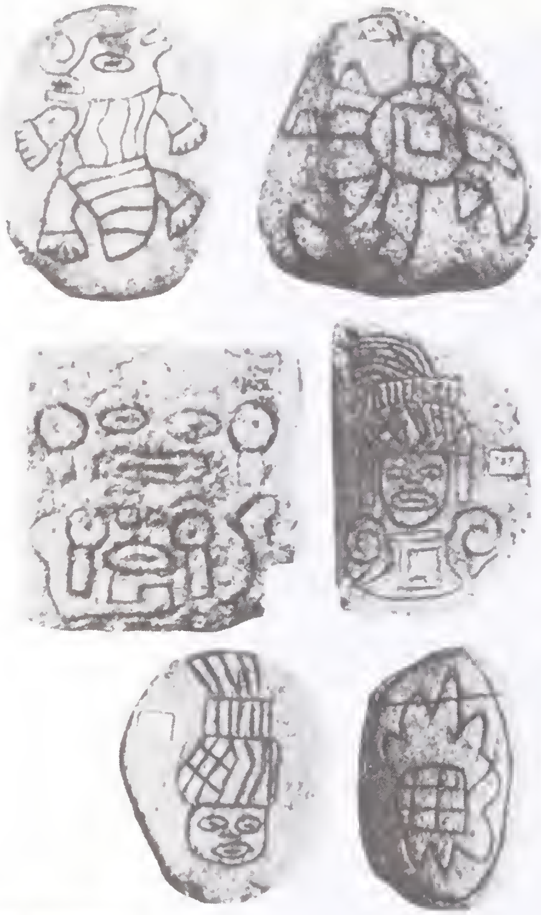
Less than three miles away Niven found an ancient riverbed in the sands and gravel of which he says were thousands of terra-cotta and clay figures with faces representing "all the races of southern Asia."

Then, in 1921, in the course of excavations at Santiago Ahuizoctla, a hamlet contiguous to Amantla, about five miles northwest of Mexico City, Niven came across a discovery so startling he says it opened up for him a whole new field of archeological research. At a depth of twelve feet Niven described coming across the first of a series of stone tablets with very unusual pictographs. Systematically exploring other clay pits and tepetate quarries within an area of twenty square miles, he claimed he was able to unearth during the course of the next two years 975 more tablets. In the end he says he found more than 2600. Though there was nothing in these tablets by which he could determine their exact

Niven's showcase number 6 containing a portion of his collection of carved stones from the Valley of Mexico. When William Niven died in Austin, Texas, in 1937, the New York *Times* described him as a distinguished mineralogist and archeologist who had discovered buried prehistoric cities beneath the Valley of Mexico. He was also noted as the discoverer of four new minerals including cytrialite, thorogon, and nivenite. According to the *Times*, Niven donated to the Mexican government the best of the relics he found in Mexico, keeping for himself some, which he sold to finance further archeological expeditions. With what was left over there were enough pieces to establish in Mexico City a private museum of 30,000 exhibits.

or even approximate age, Niven deduced from the depth at which they were buried and the accumulation of debris on top of them that they were over 12,000 years old and more likely closer to 50,000.

The tablets, which Niven carefully numbered in the order in which he found them, had no particular shape. They appeared to be water-worn stones with smooth surfaces on which the figures had been carved, often to conform with the shape of the stone, much like the so-called Cabrera stones found almost contemporaneously in Peru, which depict strange human beings with four-fingered hands in combat with dinosaurs, though such prehistoric creatures were



In the 1920s the American Museum of Natural History in New York was given a collection of artifacts by a man who informed the curator that many of them had been bought from Niven. In 1976 the curator of Mexican archeology, Gordon F. Eckholm, said the museum still possessed a collection of objects from Guerrero sold to them by Niven, but that he did not know what had become "of the famous Niven tablets."

thought to have been extinct many millennia before the appearance of man on the planet.

When Niven showed tracings of the tablets to "informed professors both American and foreign," including Sylvanus G. Morley, he was told the symbols were unlike anything they had ever seen. No prominent archeologist was able to decipher a single one of the tablets. So Niven went to the not inconsiderable trouble of making tracings of each and every tablet, which he sent to his old friend James Churchward for comment. And so Pandora's box was opened.

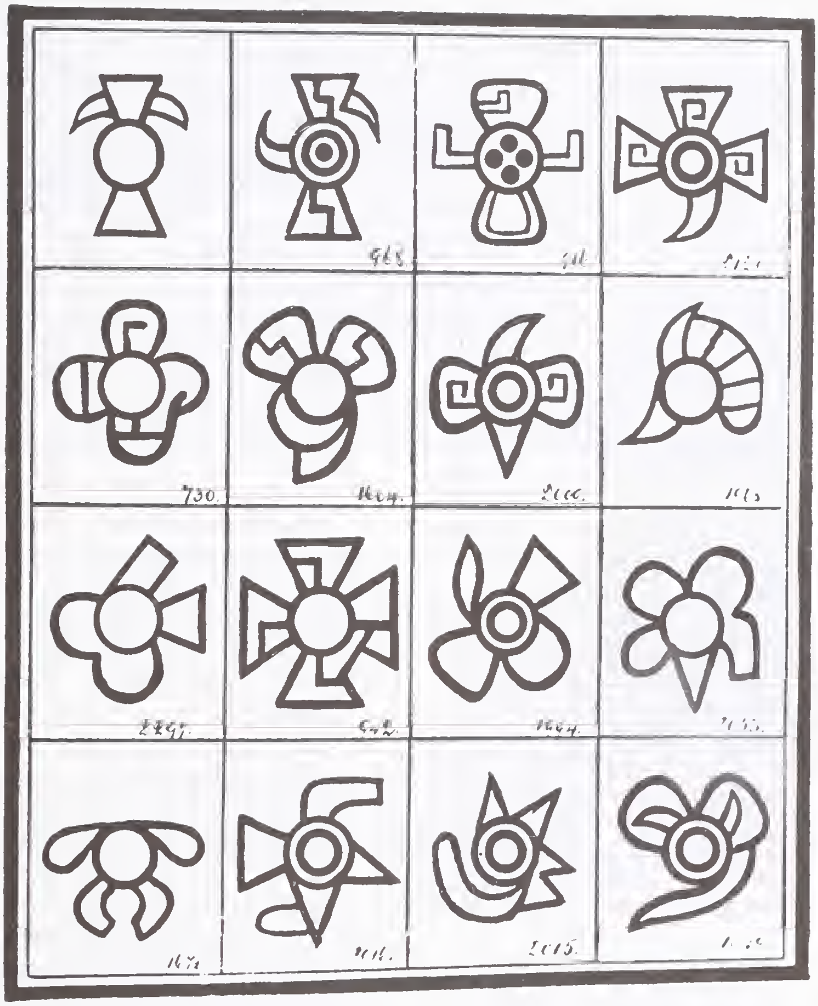
Churchward said he was not the least surprised that none of the archeologists could decipher the tablets. He, on the other hand, recognized in Niven's tablets symbols and designs similar to the ones he had been shown on tablets in a monastery in Tibet known as the Naacal tablets, which, Churchward said, contained "Sacred Inspired Writings" originating in the lost continent of Mu, which had sunk into the Pacific Ocean about 12,000 years ago at about the same time the last remnant of Atlantis had gone down in the Atlantic.

On closer study, Churchward said that Niven's Mexican tablets confirmed data he had derived from the Tibetan Naacal tablets, filling in many missing gaps.

From the intimate links in the content of Niven's tablets, Churchward concluded that they were the work of members of a colony of Mu which had been established in the Valley of Mexico, thousands of years before the birth of Christ.

This priestly brotherhood, said Churchward, had been sent out from Mu to teach the sacred writings, which contained the religion and science of the mother country, to colonists in southeast Asia. From there they had moved to India, where eventually the brothers had taken refuge from persecution in the mountain fastness of Tibet.

Stone carving of men fighting dinosaurs, part of a collection of twenty thousand such stones recently found in Peru by Dr. Cabrera, who believes them to be over fifty thousand years old. The collection includes an anatomical library accurately showing man's inner organs and an extraordinarily sophisticated series of heart transplants.



Designs found on Niven's Mexican tablets which Churchward said confirmed data he had obtained from Naacal tablets in India. According to Churchward the figures represent the "Four Great Primary Forces of Nature."

According to the tablets, as interpreted by Churchward, they took the history of man back 200,000 years. Archeologists threw up their hands; they not only refused to countenance Churchward but decided on a similar treatment for Niven. Undismayed, Churchward incorporated Niven's data to bolster his own thesis.

Churchward's books on Mu received a new impetus in the Aquarian age when the Paperback Library of New York reprinted his five books, plus one of explanation and support entitled *Understanding Mu,* by Hans Stefan Steffanson.

Then in 1970 Paperback Library went further: they published a thin volume, *Mu Revealed,* by Tony Earll, in which the author described recent excavations at Niven's site by a Professor Reesdon Hurdlop, who reported the discovery of a stone sarcophagus under the floor of a small temple found by Niven. The sarcophagus was said to contain sixty-nine scrolls or leaves of papyrus bearing strange writings.

Professor Hurdlop was described as well known in archeological circles for his work at Johore Lama, the site of the ancient city of Singapura, and at Kota Tinggi, where he followed up the work started by the late Dr. Gerald Brosseau Gardner, who discovered the original site; and he was said to have been advised in his work by Sir Richard Windstedt, British general adviser in Johore at that time.

By 1964, wrote Earll, the scrolls had been deciphered sufficiently to reveal that they held the intimate details of life on the continent of Mu (which the scrolls called Muror) over a period of years prior to its destruction; and Professor Hurdlop dated the scrolls at 20,000 to 25,000 B.C. The scroll writings, which purported to be the diary of a young priest called Kland, were said to include descriptions of homes and families, temples, transport, wars, elections, crimes and punishments, household accounts, and personal letters.

Though Professor Hurdlop had considered Churchward's discoveries deserving of further investigation, "little did he realize," wrote Earll, "that this was going to lead to one of the greatest discoveries of our time, comparable to Schliemann's discovery of Troy and Evans' work on the Minoan civilization."

Earll says he followed Hurdlop to Mexico from India via Egypt and England, where they talked with directors of the Marquina-Jolicoeur Institute in London in preparation for an expedition to dig at Niven's old site in Mexico, apparently the first to do so. The rest of Earll's book describes how the scrolls were worked on with probes and tweezers, opened a fragment at time, and the broken fragments pieced together. Carbon-dated at 23,000 years, the text, says Earll, was translated with the help of Dr. Eward Stich of Boston.

Unfortunately, Tony Earll turned out to be an anagram of "Not Really," who in real life is Dr. Raymond Buckland, a Canadian of Weirs Beach, New Hampshire, now deep into witchcraft. Professor Reesdon Hurdlop never made the dig near Niven's site, and never found a sarcophagus with the diary of a priest called Kland written on ancient papyrus. He is an anagram for Rednose Rudolph, the reindeer. So: *caveat* the *emptor* of quickie paperbacks, and let him beware of taking on faith the unqualified data of the precursors and followers of Erich von Däniken. There is no indication whatsoever on the covers—front or back, or anywhere between them—that Earll's work, which advertises itself as "the archaeological discovery that rewrites earth's history," is spurious. And that's the world we live in, not much better than the sixteenth century, when the Jesuits pirated important works such as those of Paracelsus to replace them with bowdlerized editions, spreading the notion that Paracelsus was a phony, a notion which lasted till the present century

One of the reasons Niven may have failed to receive the attention he deserved was his discovery of indications of both Masonic and phallic worship in the figurines he unearthed, both of which were subject to being glossed over. In lava fields dated at over ten thousand years, Niven found figurines with one hand pressed to the lips and the other resting on a muscle or against the head—gestures which he recognized as being similar to those still practiced in his day by Masons. Nor was Niven shy about pointing out that "these miniature figures, both masculine and feminine, in these secret mysteries, show the genital organs in a perfectly nude condition as if such rites had some relationship with those of phallicism."
Niven further noted that the female figures "reveal

the pudendum or vulva with every detail; and here is something more wonderful, there is an object which seems to be falling, which at first appears to represent a small timbrel, but on closer inspection is seen to be the representation of a drop of semen oozing from the feminine organ of generation."

Niven adds that in the Jonuta work of relief (number 26 in the gallery of monoliths in Mexico's Museum of Archeology) the symbols of the male organ of generation, which are portrayed in the manner of projecting cloves around the head of the priest of the temple, are evidently "ejecting semen."

when a couple of Swiss researchers finally produced a sounder version of his works.

Was Churchward a phony? Did he invent the Naacal tablets? And what of Niven's tablets?

At last some serious attention is being paid to Niven by Robert Wicks of the University of Washington in Seattle, who is preparing a book on Niven and his tablets. In correspondence with leading academicians in the field of Mexican antiquities, Wicks has managed to obtain their admission that negligence of Niven's work may have been an error.

In due course not only Niven but Churchward may be revalidated, as have been Mesmer and Paracelsus, who for centuries were treated with vituperative denigration. More digs on Niven's sites and a closer look at Mu may be in order, for beneath the ancient myths, as Humboldt and Brasseur averred, some history may surface yet.

Colonel James Churchward (1850–1936), of an old Devonshire family, was educated at Oxford and Sandhurst Military College: he served in India with the Royal Engineers and as colonel of a regiment of Lancers. When his marriage broke up he resigned his commission to become a tea planter and amateur painter, an exponent of the proverb: *"Les aventures arrivent aux aventuriers."*

After many adventures in many lands he settled in the United States, where he became renowned as an angler and a teller of tall stories.

Above medium height, sturdy, with an aquiline nose, the eye of a hawk, and a firm mouth which constantly broke into a smile, he is described as a man of affairs and culture, cordial and candid, a great lady killer, who, though charming, had a "thirty-third-degree efficiency in the art of making enemies."

After working as a civil engineer with the railroads and traveling to sell his own patented inventions, he made a killing in the steel business organizing the Churchward International Steel Corporation and

26. Churchward: Fantasy or Fact

On the basis of his interpretation of the Niven tablets, Churchward rewrote the text of his book *The Lost Continent of Mu* and dedicated it to Niven. In the book he describes the land of Mu as having been a large continent between America and Asia, its center lying somewhat south of the equator. Its area he bases on remains still above water, on rocky islands scattered over the Pacific, where there are still great cyclopean walls, stone-lined canals, paved roads, and enormous monoliths and statues such as those discovered on Easter Island.

Churchward saw Mu as having been about 6000 miles from east to west, and about 3000 north to south, a vast stretch of rolling country, extending from Hawaii to the Fijis, divided into three land areas separated by narrow seas.

He describes it—whether intuitively or on the basis of actual information—as a beautiful tropical country, with vast plains covered with rich grazing grasses and tilled fields, shaded by luxurious growths of tropical vegetation, a true Garden of Eden, teeming with gay and happy life, over which 64 million human beings reigned supreme, grouped into ten tribes, a white or olive-skinned race with large soft dark eyes and straight black hair, a yellow-skinned, a brown, and a black people, each distinct, but all under one government, builders of great temples and palaces of stone, navigators who took their ships around the world leaving inscriptions and legends from China to the Middle East, in both directions.

Churchward says that, according to the tablets, when a colony had advanced enough to govern itself it was turned into a colonial empire; one branch of colonization ran from Mu to Central America, thence to Atlantis, thence to the developing a nickel-chrome-venadium alloy, excellent for armor-plating. But he soon tangled with the magnets of steel and high finance who quickly disposed of him. Churchward accused the large mills of having "milked me dry of all I could show them, stolen my patents, tried to kill me by dumping tons of white hot steel on me, and were in cahoots with the Navy Department and fellows in there, to unload my steel on Uncle Sam at fabulous prices."

His attorney, Percy Tate Griffith, who at first considered the statement preposterous, later said: "Events proved that far more of it was true than I was willing to credit, and much that even the suspicious Colonel had not visioned."

Churchward claimed to have learned the truth about the dirty dealing in the steel industry from highly placed friends in Masonry. Churchward's brother Albert, a medical doctor and inventor, was a prolific writer on Freemasonry and its relation to primitive mankind.

As a comeback from his debacle in the steel business, Churchward turned to the story of Mu, bringing out *The Lost Continent of Mu* in 1930, *The Children of Mu* in 1931, *The Sacred Symbols of Mu* in 1933, and *Cosmic Forces as They Were Taught in Mu,* in 1934.

In the late 1930s his attorney, Percy Griffith, wrote a fourteen chapter, two hundred page biography of Churchward in which he set himself to validate much of Churchward's career, intimating that Churchward had solid data on which to base his fabulous tales of Mu. Unfortunately, only six chapters of the biography were salvaged by Griffith's daughter Joan, and the mystery of Churchward's sources remains to be revealed.

Mediterranean and Asia Minor; another branch ran from the west coast of North America down the east coast of South America, traceable as far as Argentina.

Before Mu went down, a great civilization existed in South America, in the area of Tiahuanaco, says Churchward, adding that the Inca are not a prehistoric people but a mixture of Quichés who emigrated to Peru from Guatemala, settling among the local Aymaras.

Among the tablets Churchward was shown in Tibet, he says some described an extended history of Atlantis; one included a map two feet square showing Atlantis with the contour of the lands around the Atlantic Ocean, vastly different from today, Atlantis being not an island but joined to America, Europe, and Africa, at a time "when great monsters roamed the earth and seas were filled with monstrous forms."

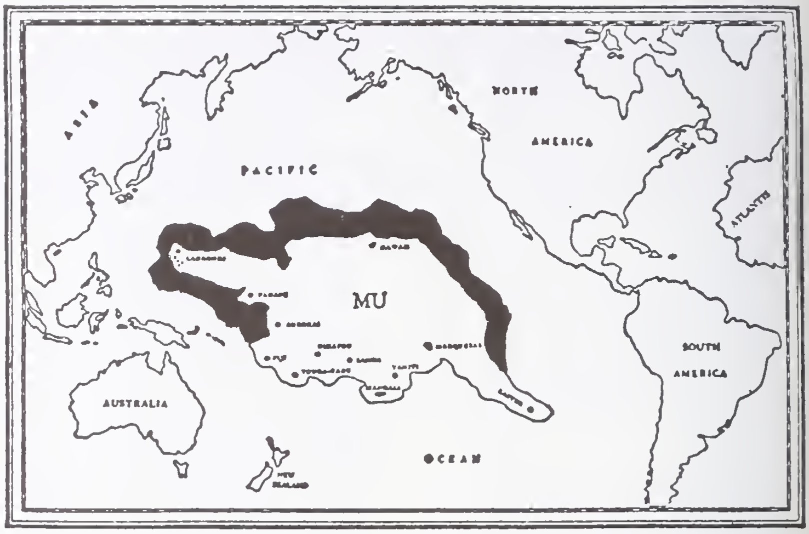
The tablets, says Churchward, also tell of Osiris being born in Atlantis, whence he traveled 20,000 years before Christ to Mu to become a master, so as to return to Atlantis to eliminate the "extravagances, superstitions, misconceptions and inventions that had crept into the Atlantean religion." Osiris is reported as having reinstalled in Atlantis an original religion of love and simplicity, of which he became high priest. From Atlantis, says Churchward, the Osirian religion was carried to Egypt by Toth about 16,000 years ago, a religion, Churchward says, which reportedly contained word for word and sentence for sentence the same teachings as those of Jesus, and from which Moses fathered his doctrine of monotheism.

In the other direction, westward from Mu, several lines of colonization are described; the best known ran from Burma to India to Babylon and upper Egypt, thus resolving the apparent conflict in legends about Egypt having been settled by strangers arriving from both east and west.

Churchward says lower Egypt was settled by colonists from Mu, via Mayax and Atlantis, both of which lay to the west, whereas the upper Egyptians came to Egypt from Mu, via Burma and India, which lie to the east.

The latter, as described by Le Plongeon, were known as the Nagas. Hindu records tell of the central parts of India (the Deccan) being first colonized by a white race who came to India via Burma from a motherland one moon's journey toward the rising sun, east of Burma, where now are the Polynesian islands. Churchward dates this migration as having taken place more than 15,000 years ago. The same Nagas are credited with starting the civilization of Babylonia, whose recently discovered cuneiform tablets contain religious concepts identical with those reported in the Naacal tablets.

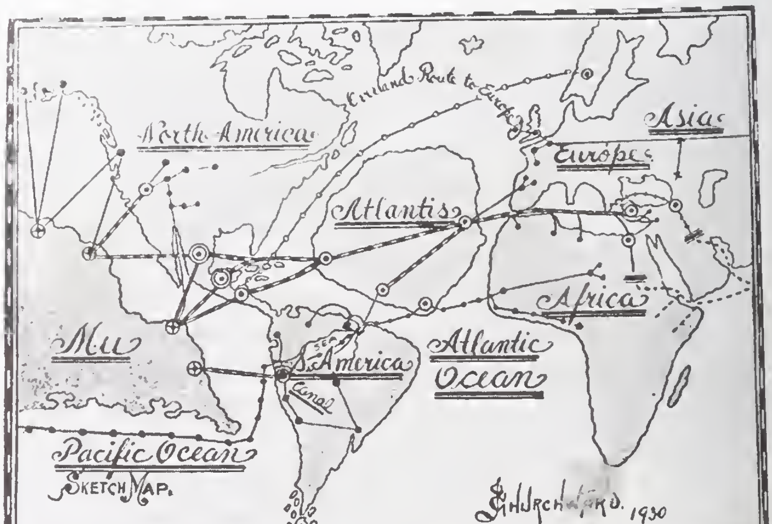
In support of the theory that numerous Pacific island groups form the last remnants of a once large continent, Stacy-Judd says the natives of Easter Island in the Pacific, 2000 miles west of Chile, state that their ancestors did not come from Lemuria but that they *are* Lemurianas living on a peak of a Lemurian holy mountain, the only portion of Lemuria remaining above the water.



Comparison of Easter Island glyphs (right columns) with those of the Indus valley.

Easter Island is known as one of the world's geodetic navels, or omphali. Barbieri says that a few years after the catastrophe which destroyed civilization on the island, missionaries found wooden tablets with hieroglyphs similar to ones found in Mohenjo Daro by the Hungarian Guillaume de Hevesy, and also to the archaic Chinese characters of the epoch of Chang as described by Dr. Hervé Geldren. One of the tablets was translated by W. J. Thompson in 1886 as saying "This (little island) was once part of a great continent of land, crossed with many roads . . ."

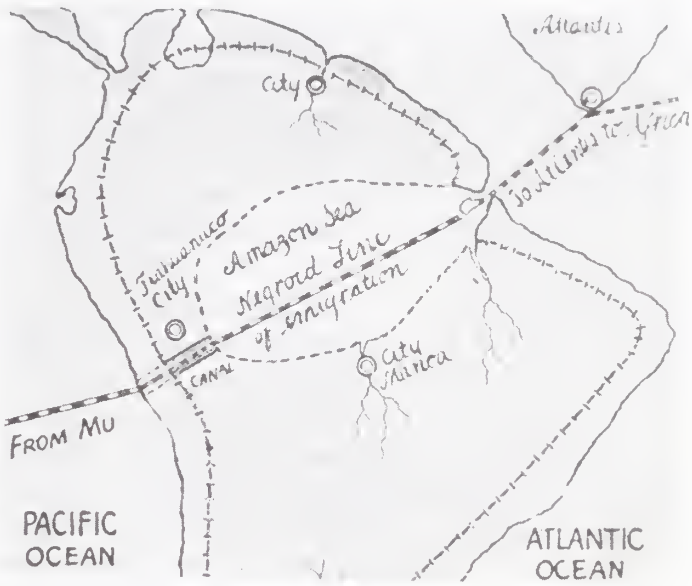
There are some twenty such tablets with Easter Island script scattered among the museums of the world.



Churchward's rendering of communications from Mu through North and South America to the Mediterranean via Atlantis.

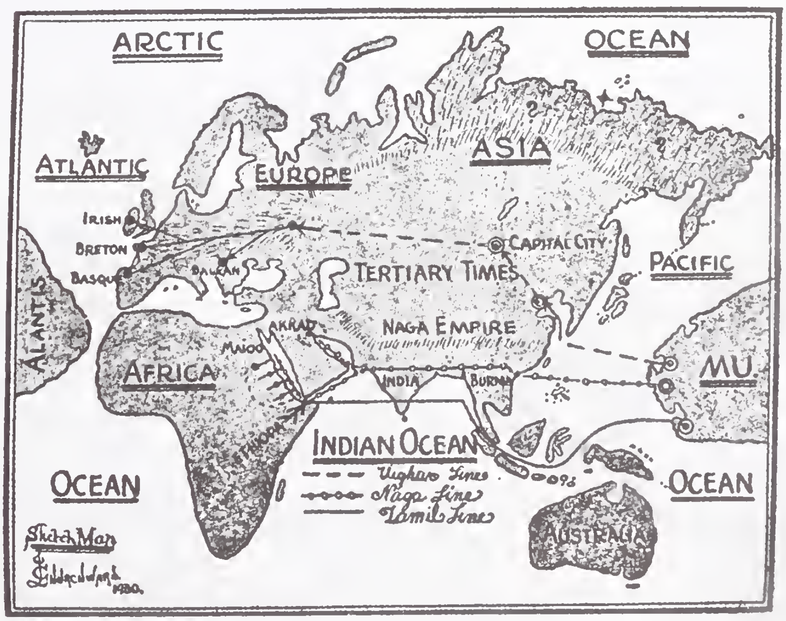
Amazon Canal.

This canal, and the Amazon Sea, are shown on a map of South America which Churchward says he found on a tablet in a monastery in Western Tibet on his last trip there. He says the date of the map was marked by the position of certain stars in certain constellations, and that astronomers told him it was twenty-five thousand years ago when these stars were in the positions given.



Churchward says that when he compared the writings of the old civilizations with the legends of Mu, he established to his satisfaction that the civilizations of the early Greeks, Chaldeans, Babylonians, Persians, Egyptians, and Hindus all derived from the civilization of Mu.

As for the Israelites, he says that when they were captives in Babylonia, they were able to study in the colleges of the Chaldi (or Chaldeans) where they learned the cosmic sciences. "The Chaldi," says Churchward, "were open and free to all who wished to come to them for learning. There was no expense to the student, and the slave was as welcome as the prince. Directly the threshold of the Chaldi was passed, everyone was on an equality. They were symbolically at the feet of the Heavenly Father, and became in fact brothers in truth.

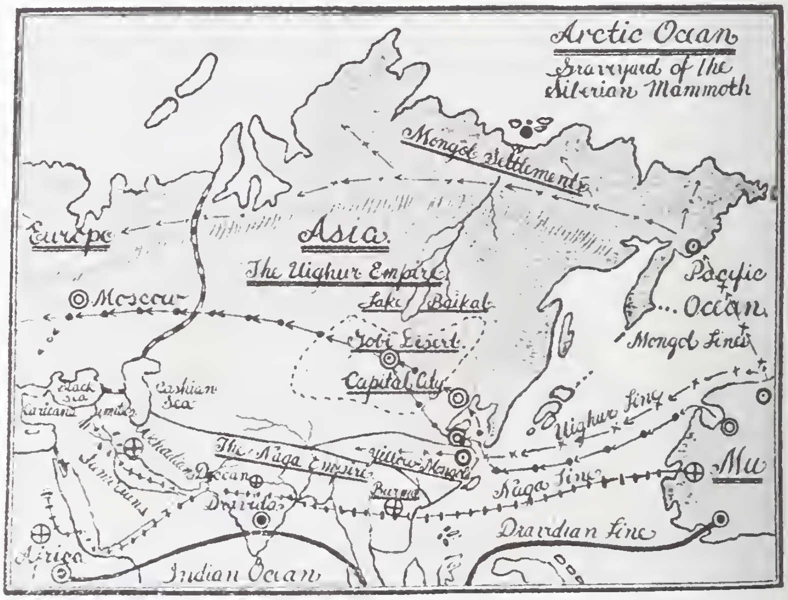


Westward lines of communication from Mu, according to Churchward.

These Israelites, although in bondage, attended the Chaldi and became Masters."

A secondary line in Churchward's scheme ran from Mu to the Malay islands and thence to southern India, called Dravida, and from India to Africa, where they settled south of Nubia, becoming the ancestors of the Ethiopians.

To the northwest of Mu the predecessors of the Japanese became a colonial empire; and on the mainland of Asia, says Churchward, was formed the largest and most important colonial empire ever derived from Mu, the great Uighur Empire, which stretched from the Pacific to Moscow, with outposts in Europe as far as the Atlantic, where the British Isles, at that time, 17,000 years ago, were still attached to Europe. This colony, whose southern borders were formed by Cochin China, Burma, India, and part of Persia, was said to have been destroyed partly before the cataclysm which ended Mu and partly afterward; its history, to Churchward, is the story of the Aryan races.



The Great Uighur Empire, which Churchward believes to have existed in the Tertiary Era, stretching from the Pacific to what is now the British Isles.

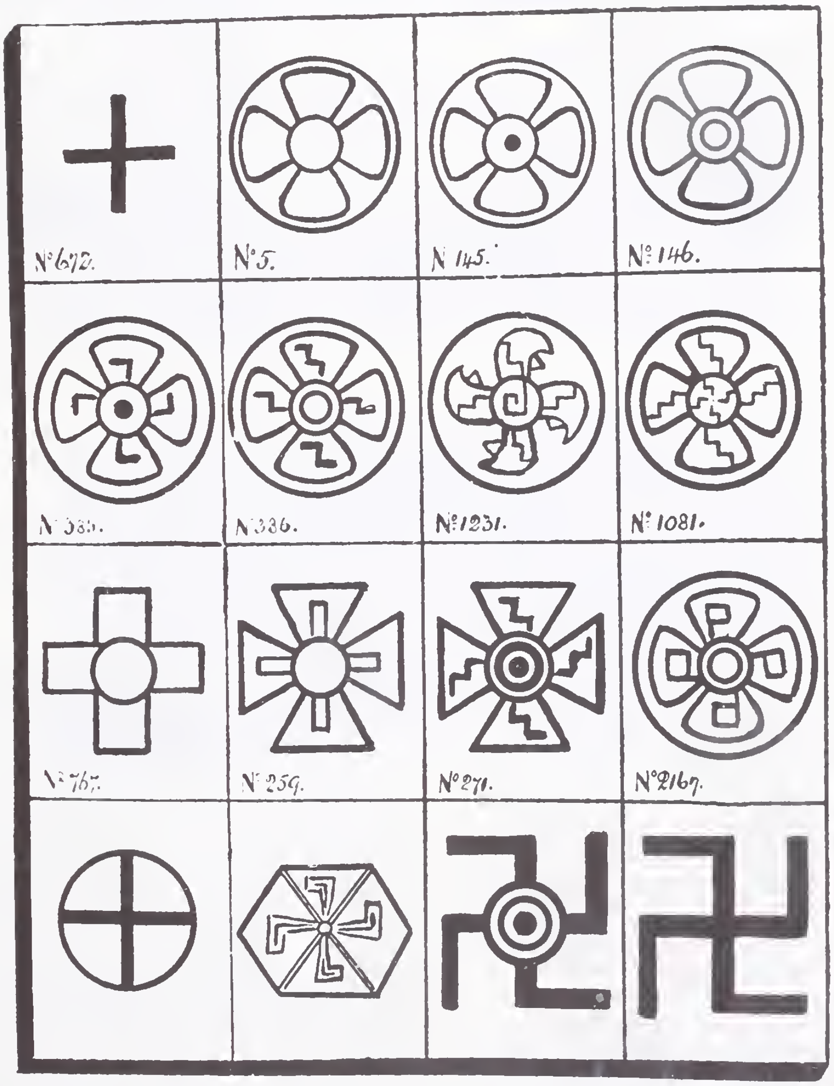
To the various colonies and colonial empires, says Churchward, the sacred writings of Mu were carried by a body of trained masters known as Naacals, who formed colleges in each country where priest-teachers could be taught religion and the sciences, the priesthoods in turn teaching the people.

As reconstructed by Churchward, the religion of Mu was without dogma, taught in the simplest and most easily understood language that the most unschooled mind could grasp. Confusion, he says, set in only after the collapse of Mu, when bigotry and impossible theologies were developed. "At various times in the history of man, unscrupulous priesthoods have caused the downfall of religion by introducing into it vicious systems of theology made up of inventions, extravagances, and immorality as well as false translations from the Sacred Writings from which all religions sprung, for the purpose of inspiring superstitious fears, to ensnare people body and soul into slavery to the priesthood." Having accomplished this, says Churchward, it did not take long for the priesthoods to acquire wealth and to become all powerful.

The Vedas, says Churchward, were stolen from the Naacal writings and changed by the Brahmins to be foisted on the world as sublime thoughts of their own, whereas the Brahminical theology became, as it was intended, a breeder of superstition and awe, dragging the nation down from a pinnacle of civilization to the lowest rung of the ladder.

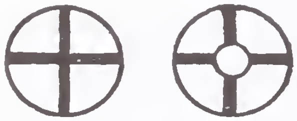
The priesthood in Egypt, says Churchward, caused a "cataclysmic wave of false gods, idolatry and spiritual degradation to sweep over the land."

Churchward maintains that the Naacal tablets he was shown in Tibet contain religious concepts and a cosmology of a very high order. He says the civilization which produced the tablets was in no way primitive, even though some of the workmanship of the tablets appears crude. According to his interpretation, their knowledge of the cosmic forces of "energy" was remarkable, and the tablets were the exposition of the knowledge of a profound science, "which is only dawning on the scientific world of today, and which has not been learned and mastered by modern man."

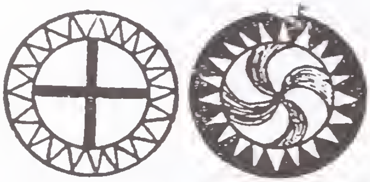


Group 6.
Ancient symbols of the Sacred Four.

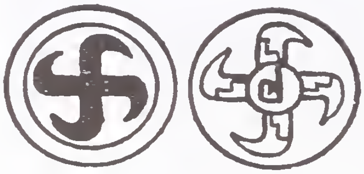
Churchward's interpretation of the Four Forces proceeding from the source.



And the Four Forces within the absolute.



Rays proceeding from the Four Forces.



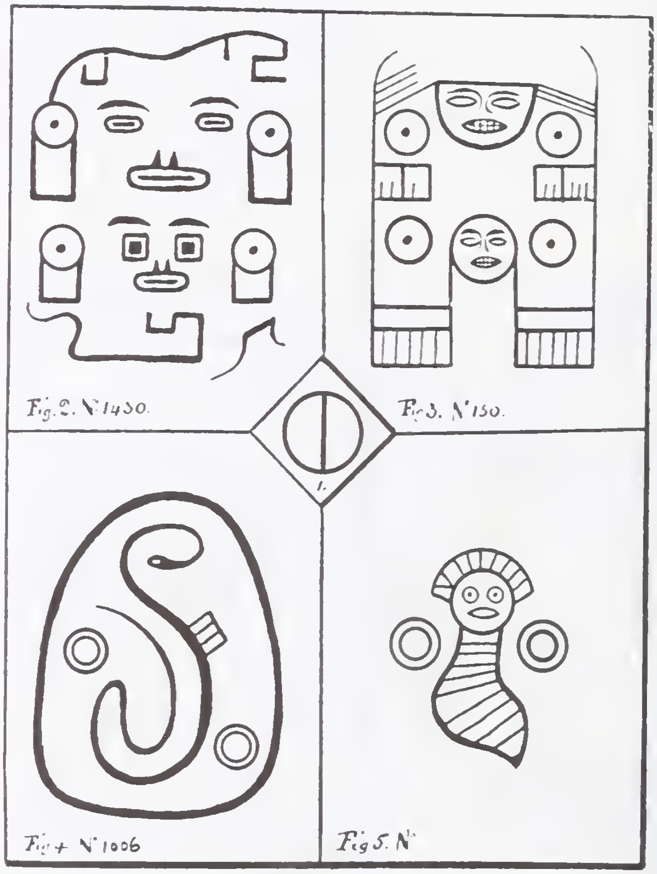
The Four Forces working from east to west.

A group of four tablets which Churchward says symbolize the dual principle of creation. Churchward says the alphabet of Mu consisted of sixteen letters and many diphthongs, each letter of which had three different glyphs to express it. According to Churchward, the first was the hieratic letter, which also carried a hidden meaning known only to the priests, and not even to all of them; the second was used in the body of words; and the third was an adjective for emphasis. He says the bulk of the tablets contained extracts and sentences from the Sacred Inspired Writings of Mu, and in most cases the esoteric or temple glyphs were used. He believes the ancient Mexicans obtained their cosmogony from the Sacred Writings of Mu, the fountainhead.

Churchward's interpretation of the Naacal and the Niven tablets indicates a much earlier awareness of where man had come from, why he was on earth, and how the universe is governed and controlled.

The tablets, says Churchward, tell of how originally the universe was all soul or spirit.

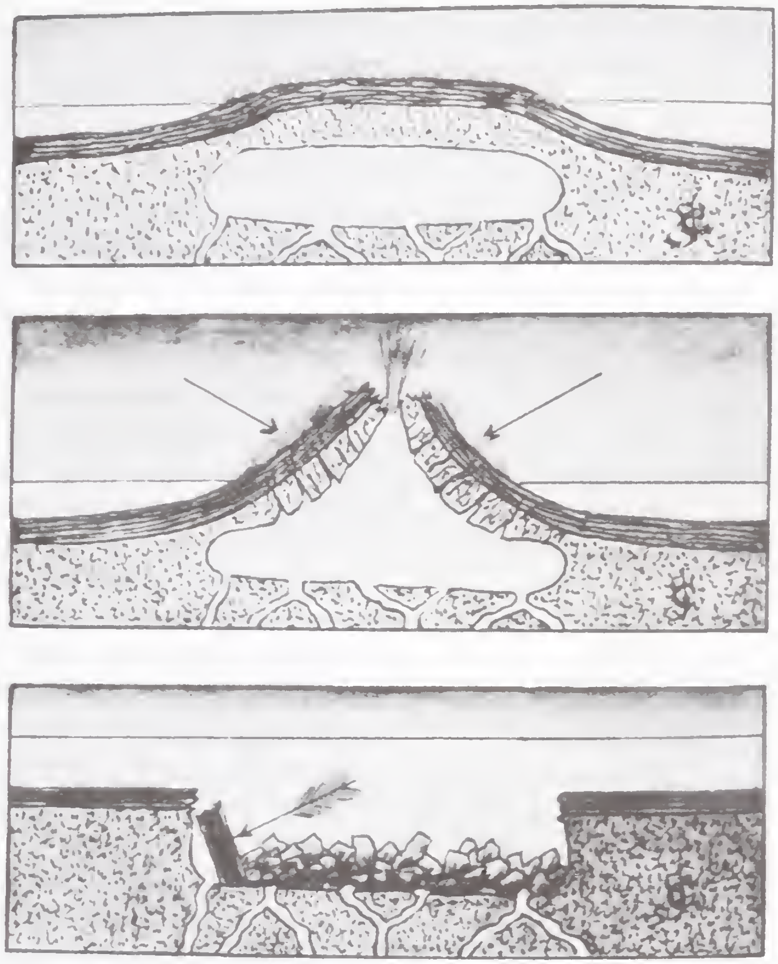
The principal symbol of the tablets was the sun—a monotheistic or collective symbol of the Creator; later it was given many attributes, each of which was also symbolized, though it was stressed that these attributes were only powers of the One Supreme.



According to Churchward's interpretation of the tablets, two cosmic forces were required for creation; thereafter, the first four gods were the four primary forces which evolved law and order out of chaos, creators of all that is physical throughout the universe—or what in the Christian and Moslem worlds would be termed the four archangels. Churchward adds that Pythagoras taught that the number four referred to the Great Creative Forces. In Steinerian or anthroposophical terms, these forces could manifest as the force fields behind hydrogen, oxygen, nitrogen, and carbon.

Later in the history of man, according to Churchward's analysis, the disembodied souls of men were added to the list

The raising and collapsing of mountains by the action of great subterranean gas belts, which, according to Churchward, occurred in more recent times than geologists are ready to accept.



Churchward's depiction of a mountain rising from a plain.

of gods. The formulator of this theology, says Churchward, knew that man at his creation was given cosmic forces under the control of the soul, and that when the soul leaves the material body it carries the cosmic forces with it, eventually back to the originating power.

Churchward claims the symbols of Mu reveal an origin of Freemasonry far older than in Egypt 5000 years ago. He also claims the sacred writings of the Naacals, which contain many Masonic symbols, evidently going back to Mu, perhaps as far back as 70,000 years, constitute the first known religious teachings, of which the present Masonic doctrines are but fragments outlining a monotheistic religion of All-in-One, with love for the Creator as Heavenly Father, and love for mankind as brothers, handed down from generation to generation since the collapse of Mu 12,000 years ago. Ever since, says Churchward, man has lived many lives in many places, not always of this world, with between each life a veil of darkness breached only in some daydream or casual thought of previous circumstances, all of which in the end will be revealed.

Churchward's most improbable explanation for the evident tidal wave which swept across the Valley of Mexico, a mere 5000 feet above the sea, is to suggest that the valley was once at sea level and that vast mountain ranges were pushed up by the explosion of subterranean gases in a relatively recent period, not more than 12,000 years ago. He suggests a similar explanation for the abundant evidence indicating that Tiahuanaco in the Bolivian Andes, now at 9000 feet, was also once at sea level, ignoring H. S. Bellamy's theory that the waters of the oceans once reached up to these levels when held by the attracting force of earth satellites which preceded our moon and which caused cataclysmic tidal waves when these satellites disintegrated onto the earth, releasing enormous girdles of water accumulated around the equator. Though each suggestion seems farfetched, either, and especially Bellamy's, is at least an attempt to explain remarkable evidence for which geologists cannot provide explanations.

This story of Mu does give a background to the influx of peoples to Central America and fill some gaps in a rational way, but as no one other than Churchward appears to have reported on the Naacal tablets, and as he produces

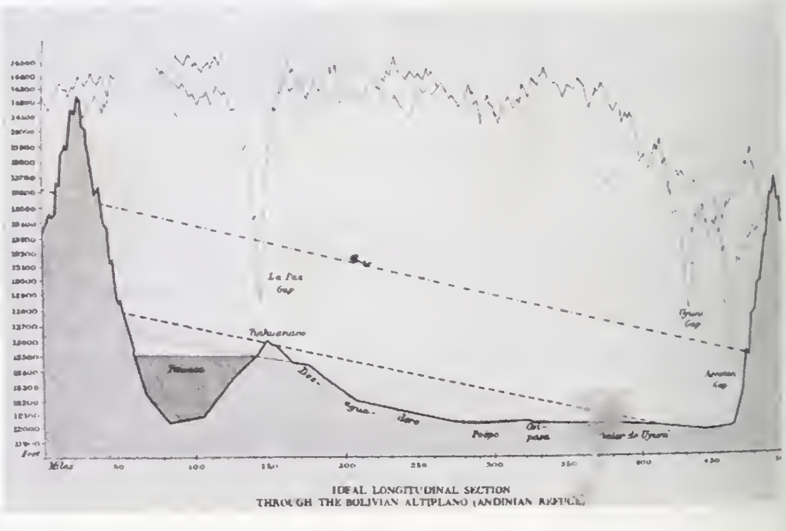


Illustration from H. S. Bellamy showing level of oceans on Andean Altiplano as held by his postulated satellite predecessor of Luna.

illustrations of only very few—and none of these in photographs—his word can only be taken by those who wish to believe him.

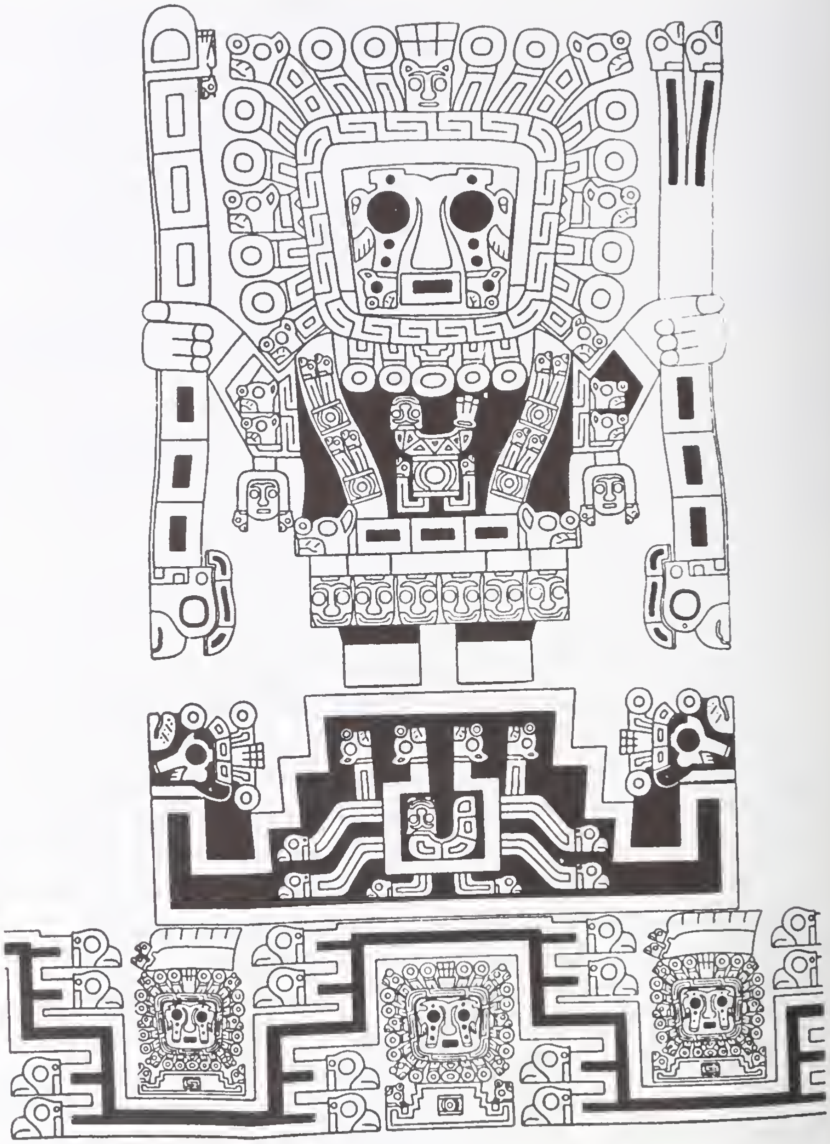
It might therefore seem foolhardy to dwell on the geological possibilities of a sunken continent in the Pacific were it not for a great deal of solid data recently put forward by a group of Soviet academicians. Soviet author N. F. Zhirov, who lucidly marshaled the data in his scholarly *Atlantis,* fully subscribes to the opinion of V. V. Belousov, who writes in *The Geological Structure of Oceans:* "It may be asserted that very recently, partially even in the age of man, the Pacific Ocean grew considerably at the expense of great chunks of continents which, together with their young ranges of mountains, were inundated by it. The summits of these mountains are to be seen in the island garlands of East Asia."

Zhirov also quotes from an interesting paper read by George H. Cronwell at the 10th World Pacific Congress on the discovery of coal on Rapa Island (Rapaiti, southwest of Mangareva Island) which "provides irrefutable testimony of the fact that there was a continent on that part of the ocean." The flora on the island likewise dates back to remote antiquity. On the basis of these discoveries, which, Zhirov says, passed virtually unnoticed, Cronwell assumed the existence of a vast submerged land area in and south of the region of Polynesia.

A comparison of island and continental lava led R. Furon to surmise in *Sur des trilobites dragnés à 4255 de profondeu par le "Talisman"* that the Hawaiian Islands were once part of a Pacific continent. "We believe," says Zhirov, "that in the not very distant past the submarine Hawaiian ridge was a large land area—Hawaiis; perhaps the sinking of its remains was witnessed by man—let us recall the Polynesian legend of a happy motherland named Hawaiki about whose location there are the most diverse guesses." Zhirov adds that at one time Hawaiis may have been a chain of islands or even a large land mass over which man (possibly Mesolithic and Neolithic pre-Ainu and Mongoloid tribes) migrated from Asia to America and southward to Polynesia.

North of New Guinea there is also the vast submarine Carolina plateau, over which are islands of the same name. This region is the home of an enigmatic Megalithic culture about whose origin and people there is little trustworthy data. The cradle of this culture, says Zhirov, was on Ponape with its remains of a huge mysterious port carved into basalt cliffs, Nanmatal, sometimes called the Venice of the Pacific. This port of the western Pacific is now virtually

Solar-year part of the great calendar at Tiahuanaco, Bolivia, from H. S. Bellamy.



inaccessible to archeological and oceanographic investigation because of U.S. naval and air bases—possibly the cause of such detailed interest by the Soviets in a lost continent of Mu.

Edgar Cayce (1877–1945), America's "Sleeping Prophet" was a medical diagnostician by clairvoyance whose 30,000 "readings" while entranced gave detailed medical and spiritual advice to thousands of individuals, often thousands of miles away from Cayce's office. The stenographic records of these "readings" are now at the Association of Research and Enlightenment in Virginia Beach, Va., along with hundreds of affidavits from satisfied patients and physicians who followed Edgar Cayce's prescriptions.
As a psychic observer, Cayce also described geological changes in the remote past of this planet, and calmly prophesied catastrophes for the future, believing, as he did, in endless cycles of life in which spiritual entities occupy one body after another.
From Cayce's description of the "past lives" of his patients, going back several millenia, it has been possible to create or recreate a picture, sometimes hodge-podge, sometimes lucidly rational, of what might have occured on this planet, for which there is little historical data but for which recent geological and archaeological research has adduced some startling verification.

27. Cayce's Mesoamerica

There is one strange source corroborating Mu. In the voluminous "readings" given by America's foremost psychic, Edgar Cayce, over a period of a quarter of a century, he describes in broad strokes and fine lines the same sinking of two great continents, Mu in the Pacific, Atlantis in the Atlantic; he also outlines an inspired religion very similar to that exhumed by Churchward from the Mexican tablets of Niven.

Cayce's data is extracted from "past life" readings of several hundred individuals whose incarnations in Atlantis, Mu, and their various colonies he describes in such fascinating detail that, as the Italians say, *"se non è vero è ben trovato."*

Mu, which Cayce calls short for Lemuria, he describes as a continent covering a large area of the southern Pacific which sank beneath the sea even before the end of Atlantis. The arrival of fleeing Lemurians to the Yucatan peninsula, says Cayce, had its part in changing the civilization already established there by the Atlanteans, though it was the Atlantean civilization which was the most powerful influence in shaping the earliest culture in Yucatan. According to Cayce, at the time of the final destruction of Atlantis much of the land area of Yucatan also sank and was covered by the sea so that the land assumed its present outline.

Again it might seem idle to pursue such tenuous leads as the psychic readings of Cayce were it not that many of the same eminent Soviet geologists quoted by N. F. Zhirov support the thesis that a large continental body sank into the Atlantic in relatively recent times. Furthermore, the University of Miami's top geologist, Cesare Emiliani, is categoric, on the basis of corings in the Gulf of Mexico, in his description of the flooding of Yucatan about 12,000 years ago. He says that at the end of the last great ice age a flood of icy water poured down the valley of the Mississippi to raise the waters of the Gulf of Mexico some 130 feet. Pointing to Antillia on the map, he is quite specific: "That's where the last of Plato's Atlantis could have been submerged."

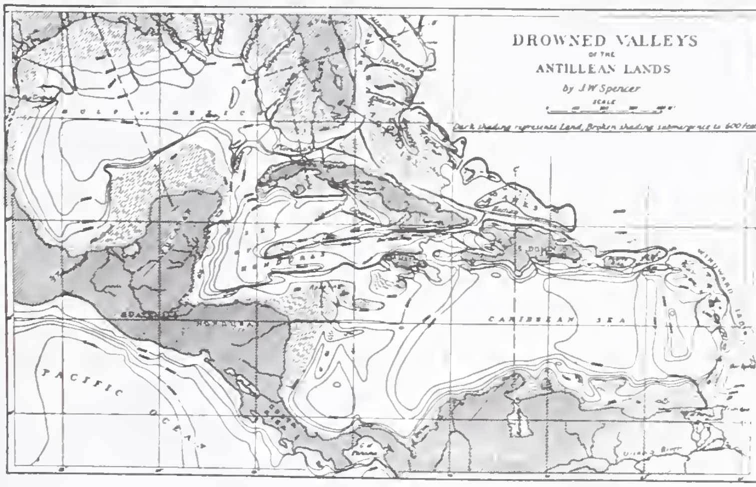
The lost continent of Atlantis, which Cayce places just about where Plato placed it in the Atlantic, went down, says Cayce, in three successive disasters. The readings claim that many lands have risen from or collapsed into the seas in a series of cataclysms over hundreds of thousands of years, shifting the poles repeatedly, causing tropical areas to freeze while frozen ones became warm and fertile.

Antillia (B) and Atlantis (A).

No definite date is mentioned for the first destruction of Atlantis, though 50,722 B.C. is given as the time of a meeting held to discuss how to rid the earth of a menacing horde of prehistoric beasts; the first destruction is presumed to have occurred not too long thereafter.

The readings tell of a few Atlanteans leaving before the first destruction, going to South and Central America, Egypt, and to what are now Spain and Portugal as places of refuge.

Cayce describes a struggle on Atlantis between two main groups, the "Sons of the Law of One," who believed their bodies to be a temple to the living God, with whom they could communicate by meditation, and the "Sons of Belial," who opposed the Law of One, using their creative forces for self-aggrandizement and the control of others. Cayce attributes the



J. W. Spencer's map showing coastal areas of the Caribbean islands, Florida, and Yucatan that were above water before the flooding of the Mississippi, estimated by geologists to have occurred at the end of the last ice age about 12,000 years ago.

catastrophes which overcame Atlantis partly to the noxious thought forms of the Sons of Belial and partly to misjudgment by the others in the use of power.

In the first destruction of Atlantis, a large portion of the area of the Sargasso Sea is said to have gone under, inundating a huge land mass that "would be considered a large continent." The breakup apparently produced large islands "with intervening canals, ravines, gulfs, bays and streams."

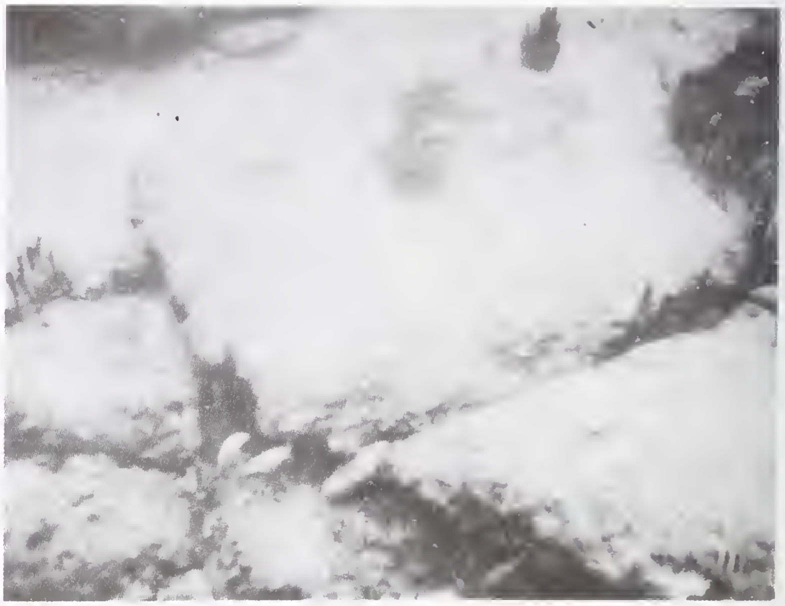
Prior to the breakup, Cayce speaks of the earth's rotation about the sun being different, revolving around Arcturus and the Pleiades. As the earth's axis shifted, people rose up and there were great movements toward the south during which the enormous animals which threatened to overrun the earth were fortuitously destroyed by the changing of the poles.

The second period of disturbance is given by Cayce as "some twenty-eight thousand years before Christ." In this catastrophe he tells how representatives of Atlantis fled the land and settled in what is now Yucatan. According to the readings, they fled in airships as well as water craft.

Elsewhere Cayce describes aircraft "lifted by gases," and pleasure vehicles "that pass along close to the earth," as well as craft that traveled on and under the water.

To power these craft at a distance, Cayce describes a mysterious cylindrical glasslike stone placed in an oval building where it could be activated by the sun's rays to produce phenomenal energy, which the Atlanteans had apparently learned to broadcast.

Cayce says that knowledge of how to construct such a "mighty firestone" was taken to Yucatan, where it was preserved, the records of the manner of the construction of the stone being secreted in three places in the earth: "in the sunken portion of Atlantis, or Poseidia, where a portion of the temples may yet be discovered, under the slime of ages of the sea water—near what is known as Bimini . . . And in the

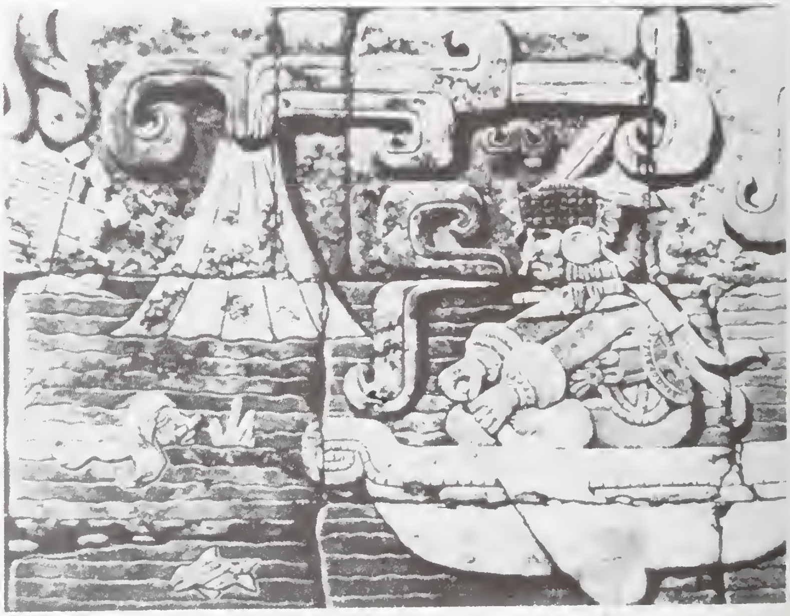


Controversial part of the so-called Bimini Wall believed by some first-rank European geologists to be a man-moved megalithic structure, but which Florida geologists believe to be a natural formation of beach-rock. Now in about eighteen feet of water, it appears from recent corings by geologists to have been above water some eight thousand years ago.

temple records that were in Egypt . . . Also the records that were carried to what is now Yucatan."

Much of Cayce's evidence is either corroborated or complemented by the research of Robert B. Stacy-Judd, who belives that the people of the Cro-Magnon invasion of Europe in 23,000 B.C. were also Atlanteans, and that another large wave came about 14,000 B.C. He says the Cro-Magnons were a tall well-built people with long skulls, fine foreheads, of light brown or red complexion, "one of the finest peoples, mentally and physically, that the world has ever known."

According to Stacy-Judd, the Cro-Magnons brought with them to Europe a mixed bag of assets, including the art of pyramid building, witchcraft, the cult of the phallus, and wor-



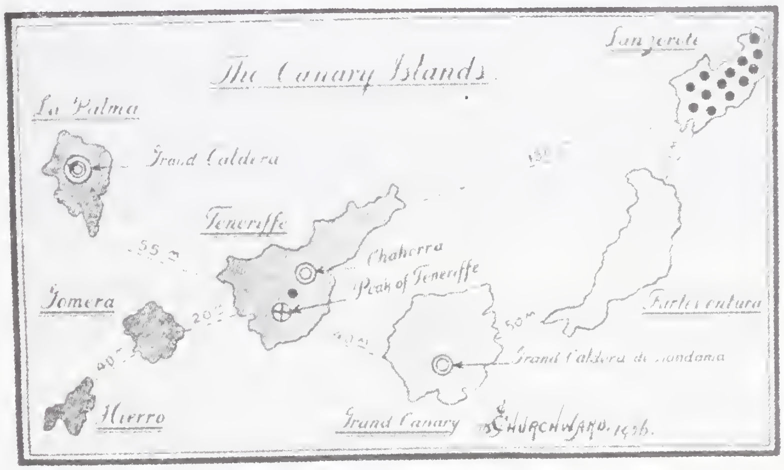
Teobert Maler obtained this depiction of an Atlantean cataclysm from a bas-relief in a remote and, at that time, unknown spot deep in the jungle of Yucatan. The relief shows a volcano erupting, a pyramidal temple crumbling, land sinking, men drowning, and a survivor fleeing by boat. The original of the photograph is in the possession of Robert B. Stacy-Judd, who suggests that when, between 200 and 500 B.C., the last of a great Atlantean empire vanished beneath the waves of the Atlantic Ocean, the remnant of her highly cultured people, last of the root Atlanteans, fled hurriedly to Yucatan and Central America, bringing with them—among numerous other expressions of a great civilization—the highly developed art of symmetrical pyramid building, and were thereafter known as the Maya.

ship of Osiris. He says that all the ancient races of Europe, with the exception of the Negro, claim that their ancestors arrived in boats from a land which sank beneath the waters toward the setting sun or west, and that with each successive subsidence of the disintegrating Atlantis, escaping hordes invaded the shores of the Mediterranean, slowly pushing their way eastward toward the fertile lands of Egypt, already settled by colonists of their own mother country.

To Cayce, the escape from Atlantis was not a random scattering but an organized movement to colonize lands that were carefully chosen. Several readings indicate there were already inhabitants in the Yucatan area when the Atlanteans first arrived, though these were less developed than the newcomers.

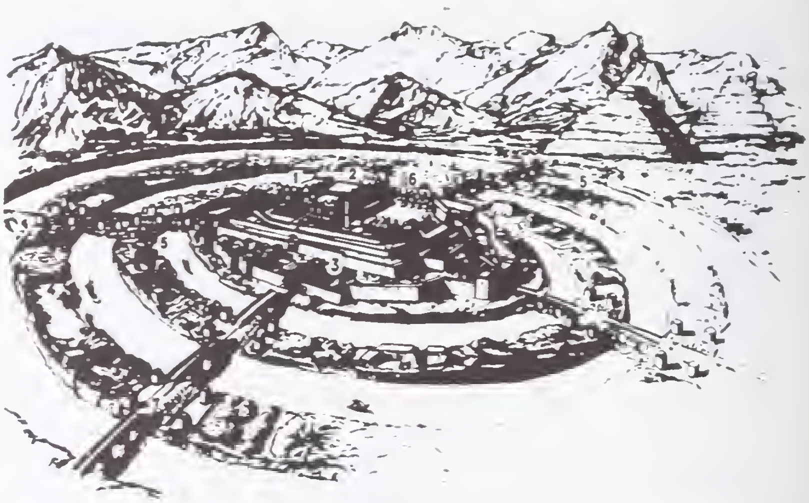
Cayce refers to considerable temple activity in Yucatan by the refugee Atlanteans, with temples set up to propagate the original faith and to preserve the "knowledge that would make for a unifying of the understandings as to the relationships of man to the creative forces." From Cayce's readings it appears that the Atlantean civilization was well advanced and that their art reappeared in Yucatan as a full-blown accomplishment.

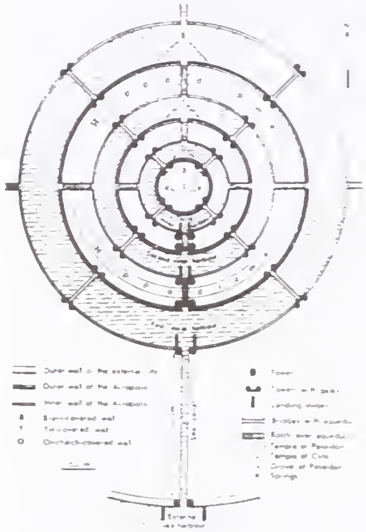
The Canary Islands as depicted by Churchward.



Stacy-Judd believes that fleeing Atlanteans became the Cro-Magnons who settled on the Canary Islands. Humboldt and Bonpland searched for remains of ancient Atlantis among the extinct volcanoes of the Canaries.

Plato described the capital of Atlantis as being divided into alternate zones of land and water.





Plan of the Atlantean capital as it appears in Soviet geologist N. F. Zhirov's book *Atlantis*.

Cayce tells of a leader named Iltar with a group of followers, "members of the worship of the One," who came westward and entered what is now a portion of Yucatan to develop their civilization as it had been on Atlantis. He says the first temples that were erected by Iltar and his followers were destroyed at the period of the final collapse of Atlantis, when there were great physical changes also in the contours of Yucatan. In one of his readings he adds that these temples built by the Atlanteans in Yucatan were being rediscovered in the 1930s, saying that many of the second and third civilizations may never be discovered because to do so "would destroy the present civilization in Mexico."

Corroborating Le Plongeon, Cayce says that ruins of temples still stand in Yucatan which contain secrets pertaining to the occult. As for the temple of Iltar, he says it is located on a portion of the land that now rests beneath the waters, but may yet rise again.

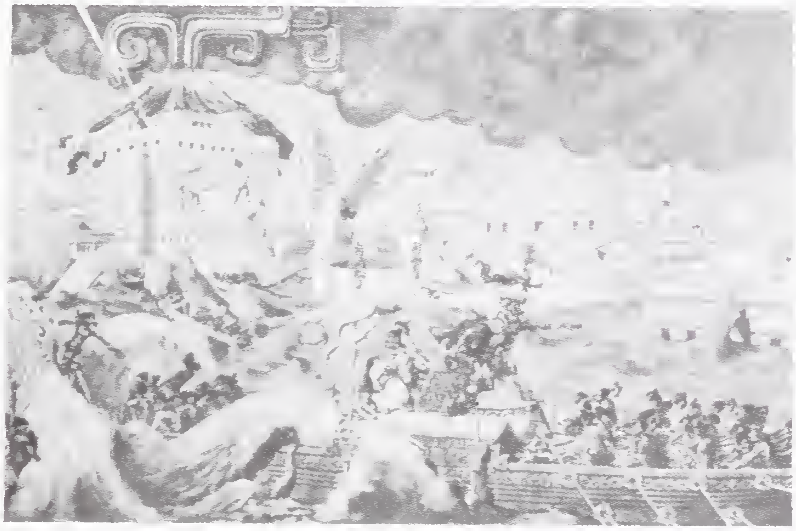
Cayce categorized the two types of remains from Atlantis as "stones that were circular" and "altars upon which there were the cleanings of the bodies of individuals." The readings state that the altars were not for human sacrifice. Instead, the bodies of those to be "cleansed" were placed on the altars so that such undesirable qualities as hate, malice, and self-indulgence could be removed "through the rise of initiates from the sources of the light."

The altars apparently served as focal points for spiritual forces brought from "the source of light," the cleansing being accomplished through a sort of spiritual healing.

Partly corroborating Le Plongeon, Cayce says small numbers of Egyptians also came to Yucatan, where they prepared "The Temple Beautiful" in which song and music were used to make "for losing even the association with the body" except for the body's vibrations which "make for light, then become color, then become tone, then become activity . . ."

With the music, there was dance which "enabled those with the disturbing forces and influences to become more erect, upright in body, in thought, in activity . . . being in the world, yet not of the world . . ."

Cayce says the "children of the Law of One" could concentrate their thoughts for the use of the universal forces, with the guidance of what today would be called the saints. Through concentration of the group mind, they were able to reach a higher level of consciousness which brought them into a fourth-dimensional consciousness, an out-of-body experience.



Stacy-Judd's romanticized version of the collapse of Atlantis. And Edgar Cayce's description of the events told in the strangely archaic language which issued from him when he fell into a trance.

The records in Egypt, says Cayce, contain "A record of Atlantis from the beginnings of those periods when the Spirit took form or began the encasements in that land, and the development of the peoples throughout their sojourn, with the record of the first destruction and the changes that took place in the land, with the record of the sojournings of peoples to the varied activities in other lands, and a record of the meetings of all the nations or lands for the activities in the destructions that became necessary with the final destruction of Atlantis and the buildings of the pyramids of initiation." According to Cayce, the Great Pyramid of Gizeh in Egypt was completed around 10,000 B.C. to be used as a temple of initiation for the White Brotherhood.

He speaks of the Atlanteans being able to transpose "those materials that did not pertain to themselves bodily, by that ability lying within each to be transposed in thought and body." He suggests that Atlanteans were not only able to move matter about the universe, but could move themselves in consciousness beyond the earth plane.

He speaks of the "full consciousness of the ability to communicate with or to be aware of the relationships of the Creative Forces and the uses of same in material environs," adding that during the age of Atlantis and Lemuria (or Mu) this brought destruction to man because of selfish use.

As for the Lost Tribes of Israel, Cayce confirms that a portion of them came into the southernmost portion of the United States, mixing with the refugees from Mu, then moved on to Mexico and Yucatan, but mostly to the central part near what is now Mexico City. He says they came much later than settlers from Atantis or Mu, but did add their influence, as rerecorded by the Mormons, to the cultural melange that had been gathering in Central America for thousands of years. He says they too came by boat, setting sail during those periods

Barbiero's Atlantis in Antarctica, with shifted pole.

By some ardent fan, Atlantis has been placed almost everywhere on the globe. It has even been placed in Antarctica in the area bathed by the Weddell Sea. In the book *Una Civiltà sotto Ghiaccio,* Italian author Flavio Barbiero maintains—with some cogent evidence—that the earth was struck by an asteroid or comet about 12,000 years ago, just about when Plato said that Atlantis sank. The ensuing cataclysm, says Barbiero, shifted the poles and caused Antarctica to be shrouded in a mile-thick mantle of ice. The same event, says Barbiero, caused the melting of the great Wisconsin icecap and the melting of the icecaps over parts of Scandinavia, Russia, Germany, Britain, and the Alps.

Taking as historic fact Plato's description of the sinking of Atlantis in a single night under the action of earthquakes and tidal waves, and as scientific evidence the carcasses of mammoths congealed with springtime food in their stomachs, Barbiero suggests that the cataclysm would have had to be sudden.

Barbiero postulates that a vast civilization with a high technology and a fleet of great trading ships flourished in Antarctica before the catastrophe; he believes the survivors from this civilization got away in ships to create colonies elsewhere. According to Barbiero, neolithic culture was not a civilized advance but a regression of Atlantean survivors who landed in various areas, gradually losing their original know-how. Barbiero believes that sophisticated Atlantean artifacts will be found beneath the icecap of Antarctica.

A preface to Barbiero's book by the director of the Italian Polar Geographic Institute, Silvio Zavatti, attests to the seriousness with which the thesis was received.

when there was the breaking up of the Tribes of Israel, and while "the rest were enslaved in the Persian land."

Several tests of the veracity of Cayce's prophecies have already turned in his favor. His prophecy about the recovery of the Quamran papers is quite breathtaking.

Though all of this is highly speculative material, hardly the makings of history, the data adduced by Churchward, Niven, and Cayce makes so much more sense and resolves so many apparent incongruities in what passes for history and prehistory that it should perhaps be pigeonholed rather than discarded a priori.

More tests are in the making. Between now and 1998, Cayce envisages another shifting of the poles with great upheavals. The earth, says Cayce, will be broken in many places, which he lists for the benefit of those who wish to listen to his

Barbiero's ancient Atlantean Continent.

Barbiero maintains that 15,000 years ago the seas were 130 meters lower and that the missing water was heaped up on what is now Europe and the northern part of the United States in the form of 80 million cubic kilometers of ice.

He rests his thesis primarily on the evidence of geologists that a large celestial body precipitated into the North Atlantic 10 to 12,000 years ago, and quotes Austrian geologist Otto H. Much to the effect that the body which weighed 2 billion tons landed near Florida, breaking into two large fragments. According to Much, this event occurred on June 5 of 8496 B.C. at 2000 hours local time.

Barbiero further maintains that because of the pull of the moon, the earth cannot maintain its axis of rotation constant to the ecliptic. He says the moon's pull makes the earth's tilt vary from 15 to 20 degrees over a period of about 20,000 years, causing more or less ice on the poles and glaciations that occur in cycles. Ten to twelve thousand years ago, says Barbiero, the earth was tilted no more than 4 to 5 degrees from the ecliptic.

Professor Cesare Emiliani, head of the Department of Geology at the University of Miami, has worked out a graph from deep-sea core samplings taken in the Gulf of Mexico which indicate glaciation and deglaciation in cycles of about 20,000 years over the past 700,000 years, with the last major deglaciation occurring in 11,600 B.C. when ice water pouring down the Mississippi Valley from the melting Wisconsin icecap caused the waters of the Caribbean to rise about 130 feet, at precisely the date given by Plato. Emiliani postulates that the ensuing flooding of low-lying coastal areas, many of which were inhabited by man, gave rise to the deluge stories common to many traditions.

warnings. If any more of the events he has predicted come to pass, a closer look may be given to Cayce's descriptions of events purported to have occurred on this planet in remote antiquity. And an even closer look may be given to his descriptions of the spiritual religion of the Atlanteans, remnants of which were passed on to Yucatan and Central America for the avowed purpose of finding a better way to handle man's affairs upon this planet.

28. Therapeutic Theater

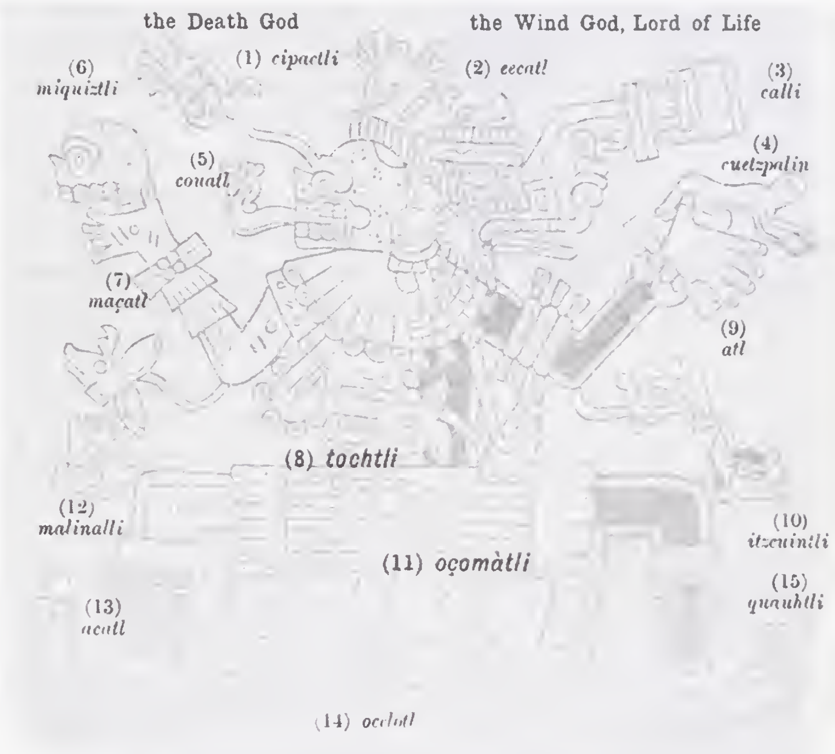
From the first reports of the Spaniards in Mexico it was evident that the stepped pyramids they encountered had been used for religious rituals but had long since degenerated into monuments of senseless slaughter. The Spaniards also found that the stadiumlike ball courts of the Indians appeared to have once had astronomical and cosmic overtones.

Edmond Bordeaux Szekely, philosopher, psychologist, and author of many books on ancient cultures, whose brilliantly intuitive work on Mexico is described in the prestigious *Handbook of Latin American Studies* as a "compendium of misinformation with unsubstantiated conclusions to explain Toltec, Aztec, and Maya cosmology," has, in fact, delved deep into the philosophy of ancient Mexico to produce a convincing analysis of the pyramid and ball-court rituals which indicates they were originally designed by initiate priests for religious dramas to convey to large audiences religious truths of cosmic import.

Edmond Bordeaux Szekely.

A Sanskrit and Aramaic philologist, whose Transylvanian forefather, Csoma de Körös, compiled the first grammar of the Tibetan language, Szekely claims to have deciphered the hermetic symbolism of the ancient Mesoamericans to show that their pictographs incorporate a philosophy of life similar to the world picture of the Sumerians and Persians, which interpreted the realities of the universe and gave expression to the strange forces within and surrounding man.

The predecessors of the Aztecs, says Szekely, believed that everything in the cosmos, including life and human consciousness, was brought about by a struggle between the two cosmic principles of Life and Death: a system similar to that of Zoroaster, or Zarathustra, in which Ormuzd, or Ahura Mazda, The Life and Death sides of a single deity as they appear in an Aztec codex, with the symbols for the Aztec days of the month.



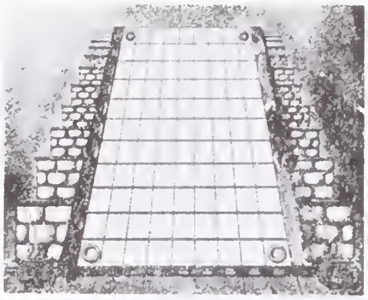
the holy spirit of Light, and Ahriman, the evil spirit of Darkness, waged war for man's soul—a war that constituted the history of the world.

In Mesoamerica, says Szekely, the spirit of Light and Life was symbolized by the plumed serpent Quetzalcoatl; his opponent, the spirit of Darkness and Death, by the jaguar or tiger called Tezcatlipoca.

At the center of this struggle, man, created free, could partake of either Life or Death, could make himself accessible to the influences of either good or evil. By his actions man could render service to, and thus strengthen, one or the other protagonist.

Aztec Tezcatlipoca.

Aztec depiction of Quetzalcoatl.



Ball Courts.

Both Brinton and Troncoso observed that the game of ball was intended by the Mesoamericans to represent the idea of the perpetual motion of the heavenly bodies. Tezcatlipoca, Lord of the Shining Mirror, Lord of the Nocturnal Heaven, was reflected in a myriad of mirrors each night throughout Mesoamerica. His priests, who called themselves "sons of the night," were associated with the divination of human destiny, which was linked with the movement of the stars.

Nuttall draws attention to the fact that the courts were called *tlach-tli,* which literally means "the looking place" or observatory, and the *tezca-tlachtli* is the obsidian mirror-observatory. The double tau-shaped courtyard or enclosure surrounded by a high wall with battlements, which at night was employed for observation, was employed by day for the national game of ball by figures depicted with obsidian mirrors.

Mexican astronomers extensively used black obsidian mirrors as an aid to astronomical observation by means of reflection. Nuttall says that besides mirrors on the summits of temples and mountains, the codices depict square columns, placed on an elevation, faced with a broad band of polished obsidian. The latter, says Nuttall, if properly oriented, would have served as an admirable means of registering the periodic return of

To dramatize the struggle for man's soul between the forces of "good" and "evil," the ancient Mesoamerican priests, according to Szękely, devised a religious ritual to be enacted on the steps of the great pyramids, a ritual that was not mere pageant, but combined a knowledge of the science of the time, of astronomy, philosophy, psychology, and of social organization.

All the pyramids in Mesoamerica so far discovered, says Szekely, contain symbols of the two cosmic principles of Life and Death: in Mexico, Yucatan, Guatemala, and Honduras all the stepped pyramids leading to the sky contain representations of the plumed serpent and of the jaguar.

Later the ritual was transferred to the flat surface of a ball court, gradually degenerating into a mere display of athletic prowess or bloody sacrifice. As Szekely reconstructs the original ritual, largely on the basis of the extant codices, the pyramids were divided into eleven horizontal levels and nine vertical ones, which produced ninety-nine squares. Larger pyramids consisted of multiples of this basic system, a pattern which was then transferred to the flat ball courts.

planets, stars and constellations to certain positions; they would have been reflected on the polished surface, as in a frame. Thus the obsidian mirror became the symbol of Mexican Star Cult adherents. Small mirrors of polished pyrite—used to concentrate rays of the sun to light sacred fires at noon on the days of the vernal equinox and summer solstice—were the symbol of the Sun Cult.

TLA  MAN

Father Duran's depiction of various masks and costumes worn by Mexican dancers for rituals, the original purpose of which was lost.

(Facing page)
Szekely's arrangement of players on the pyramid steps.

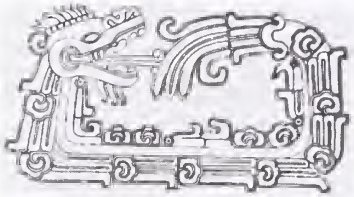
As with Protagoras, who proclaimed that man was the measure of all things, so in ancient Mexico man stood at the center of the pyramid (on the sixth horizontal and fifth vertical position) represented by a priest wearing a human mask. Szekely shows that in the codices the numbers representing the rising steps were written horizontally and those representing the squares were written vertically. On the various squares stood the twenty basic characters of the religious drama, ten representing the forces of Life, ten representing the forces of Death, each wearing an appropriate mask symbolizing the force or power represented. Szekely says the masks, which are still worn by dancers at festivals in central and south Mexico, are survivals of these ancient pyramid rites, whose original significance has long been lost.

The object of the drama, in which actions had deep symbolic meaning, similar to the rituals of Freemasonry, was for man, at the center of the stage, to rise toward the summit of the pyramid, aided by the forces of Life embattled against the forces of Death, which tended to drive him down and off the bottom rung of the pyramid.

If man could triumph over the forces of Death and destruction so as to reach the summit of the pyramid, the spiritual part of him could then triumph over the force of gravity and he would become transfigured into the light of Quetzalcoatl, the evening star.

The pyramids, says Szekely, were invariably designed in such a way as to have a level which formed an angle with the motions of Venus. In this game, man's ceasing to be subject to planetary gravity meant a true return to the stars, a reunion with the cosmic ocean of life.

According to Laurette Sejourné, when the internal war in the human heart was resolved by reconciliation of the two opposite forces symbolized by water and fire, man "could bud and flower" from fleshly matter into spirit, finally freeing himself from duality—a shedding of man's earthly clothing to free his spirit from his mortal body.



To Sejourné, Teotihuacan was the place where the serpent learned miraculously to fly, that is, "where the individual, through inner-growth, attained the category of a celestial being."

From the scant remains of two palaces within the Citadel area, recently excavated and measured by Drucker, he suggests that there may have been two rulers at Teotihuacan, one the head of the rite of the feathered serpent, or Quetzalcoatl, who lived in one palace, and a second ruler, presumably identified with Tezcatlipoca, who lived in what Drucker euphemistically calls the "other" palace.

In Szekely's analysis, if man were brought downscale and forced off the bottom of the pyramid, he would be devoured by jaguars and disintegrated, losing his individuality and having to start another cosmic cycle.

Like the Persians, says Szekely, the Mesoamericans believed that at death a body disintegrated and returned to "the reign of gravity"—the entropy of modern science. But each birth of an individual or organism was considered by the Persians to be a triumph of Life over Death. In Mesoamerica, Quetzalcoatl was considered the germ, the cause of germination in a seed, of the birth of an animal or a child, of the production of ever more abundant life. He was the Attis, Adonis, Thammuz, Bacchus, Dionysus, Osiris, and quite possibly the Pan of the Western World.

Quetzalcoatl was also seen as a unifying symbol which could achieve the union of opposites: of heaven and earth, morning and evening star, matter and spirit, light and darkness, male and female, good and evil, which, in their separate forms were Quetzalcoatl and Tezcatlipoca. The conflict between them, says Indianist Frank Waters, and their reconciliation, were what gave movement and life to man and the universe.

Out of the interplay of these opposing forces rose the world of being, change, and movement, conceived as the continuous transformation of one force into the other.

In Szekely's reconstruction of the ritual on the Mexican pyramids, a priest, wearing the mask of man, or *tla,* as the Aztecs called him, would go up or down the steps, depending on whether his thoughts and actions supported the forces of Life or Death. If his thoughts and actions had favored Tezcatlipoca, he would go downscale; if they had favored Quetzalcoatl, he would move upscale. On the face of the pyramid, man could only move slantwise, like the rays of the sun, because it was believed that Ollin, the sun, was the source of all movement, and thus of the power behind both Quetzalcoatl and Tezcatlipoca.

According to Szekely's reconstruction, the deathly priests of Tezcatlipoca occupied the higher steps of the pyramid, attempting to force man down, whereas the life-giving forces of Quetzalcoatl occupied the lower steps, hoping to raise man higher.

Coatl, the serpent, represented energy moving in spirals—the Kundalini of the Tantras or the wavelengths of modern science, which views the entire universe, from the smallest vibration in the atom to the longest wavelength in the super-galaxies, as fluctuating within a gamut of a mere 144–151 octaves.

Moving and undulant, the serpent in Mesoamerica symbolized life, power, planets, suns, solar systems, galaxies, ultragalaxies, and infinite cosmic space. The plumes, says Szekely, were an added symbol of the levity with which birds can overcome gravity better than other creatures. When the plumes were depicted folded within the circle formed by the snake's body, they signified matter in its latent form, potential, as it was before the creation of stars and solar systems. If the plumes were fanned out from the serpent, they represented the universe in manifestation, with all its created worlds, each plume symbolizing a basic element in the strength of nature—fire, earth, water, air.

Depicted with its tail in its mouth, the serpent represented infinity, eternity, no beginning, and no end. The symbolism was comparable to that of the Hindu cosmic cycles of Brahma. When Brahma sleeps the material universe is nonexistent. When Brahma wakes, all of creation comes into existence. When, after eons, Brahma sleeps again, the planets, solar systems, and all the energies of the cosmos revert to nothing.

The power of gravity and disintegration was represented by the jaguar Tezcatlipoca, who brought everything back to the kingdom of Death.

As with Goethe, the ideal of the Mesoamericans was the triumph of levity over gravity. The pyramids were the symbols of this triumph, of the ascension of man from the kingdom of Tezcatlipoca in dark caves under the earth, step by step, up to the light and wisdom of Quetzalcoatl, high above the earth.

In a ritual which expressed the cosmic life of man living in a universe governed by the absolute laws of Karma, every good move tended to free man from the slavery of gravity, leading him to levity, from which the jaguar could no longer hold him back.

To Irene Nicholson it was clear that the bloody ritual sacrifices of the Aztecs were a distortion of what must have once been an extraordinary vision of the place of man and of organic life in the universe.

She sees Quetzalcoatl as the wind god representing spirit freed from matter, yet in his totality as a composite figure

The lively world of Quetzalcoatl in Szekely's interpretation of ten of the Aztec day-signs.

THE WORLD OF QUETZALCOATL

	ATL	RAIN	WATER

"describing the many orders of matter in creation; a kind of ladder with man at the center, but extending downward into animal, water and mineral, and upward to the planets, the life-giving sun, and the god creators."

On the lowest rung of the pyramid, the first Quetzalcoatl supporter of man, according to Szekely, was what the Aztecs called *malinalli,* or grass, because grass grows on the surface of the earth where the basic life-giving elements of air, water, earth and sun are united. Grass also revives perennially, so it was considered the source of renewed vitality, a giver of sustenance to all creatures, which permitted them to take the first step in the conquest of gravity.

In opposition to grass, on the top level of the pyramid stood a skull or death's-head, representing disintegration and the return to gravity. Man was depicted as seesawing between these parameters.

The second negative or downward force was represented by the crocodile, known to the Aztecs as *cipactli,* a creature which lounges in the sun, creating nothing. On the other hand, because life has both the aspects of creation and preservation, a small adobe house, known as *calli* to the Aztecs, represented the values of conservation, of planting, of watering gardens, of painting pictures, of building new things, of preventing deterioration, deterioration being symbolized by a vulture, quick to spot death and corruption.

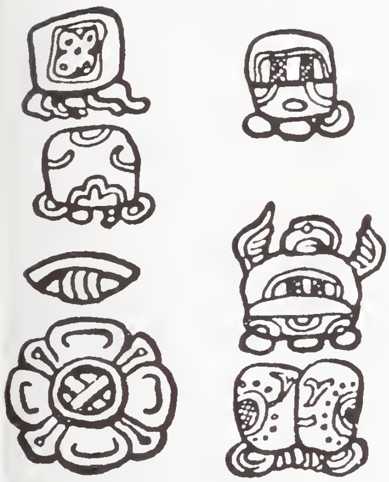
A stylized flower, *xochitl,* was considered gaily positive: its color, shape, fragrance, and the lovely effect it had on humans, representing joy. Its reverse was the cane, representing vacuity.

Disinterested love and devoted affection were symbolized by the dog, *itzcuintli.* In Mexico, where there were few domestic animals before the arrival of the Spaniards—no cows, horses, donkeys, or mules—the dog was man's most constant companion, the only possession which accompanied a Toltec to the next world.

In opposition to the dog was *ocelotl,* the meanest of killers, enemy to all animals, obliged to make a kill every day to survive.

To symbolize peace, the Mesoamericans had *mazatl,* the deer, an animal which eats only plants and vegetation, never attacks other animals, is pacific, inoffensive, and the ideal of a tranquil life.

For inferior humanity the symbol was a monkey, for weakness a rabbit, for fertility a lizard or newt, because it was also considered alchemically close to the basic elements of earth, water, air, fire. For sterility the Aztecs chose the flintstone; for wisdom, because of its high point of view and its airiness —Quetzalcoatl's favorite element—Mesoamericans chose



As Frank Waters put it: "The tonalamatl may thus be seen as a four-sided pyramidal structure of twenty day-signs arranged in five terraces of four steps each, symbolically showing the process of creation—the birth of spirit in matter, death to the world of forms, and the ascent of the spirit to a higher plane as was exemplified by Quetzalcoatl."
An interpretation of the Mayan procession of days as symbolizing man's cycle of birth, death, and resurrection is also given in Irene Nicholson's *Mexican and Central American Mythology.*

The ten Aztec day-signs of the deadly world of Tezcatlipoca, according to Szekely.

THE WORLD OF TEZCATLIPOCA

SYMBOL	AZTEC NAME	ENGLISH NAME	SYMBOLIC MEANING
	MIQUIZTLI	SKULL	DEATH
	CIPACTLI	CROCODILE	IDLENESS
	COZCAQUAUHTLI	VULTURE	SPOILER
	ACATL	CANE	EMPTINESS
	OCELOTL	JAGUAR	HATRED
	OZOMATLI	MONKEY	INFERIOR MAN
	TOCHTLI	RABBIT	WEAKNESS
	TECPATL	FLINT	STERILITY
	EHECATL	WINDSTORM	VIOLENCE
	QUIAHUITL	RAINSTORM	EMOTION

the eagle. Violence and ignorance were symbolized by the pointlessly destructive force of *ehecatl,* the hurricane. Water, considered the font of life, was symbolized by three drops of water; its opposite, a devastating torrential rain, by *quiahuitl,* the monsoon. Such is Szekely's interpretation of the ancient symbols. With just ten positive ones the Mesoamericans were able to represent the Life powers of vitality, creativity, conservation, gaiety, love, peace, power, fertility, wisdom, and eternal life; on the negative side stood the ten deadly forces of sloth, corruption, vacuity, hatred, inferiority, weakness, sterility, violence, and ignorant destructiveness.

The purpose of each ritual on the pyramid steps was to drum into the audience what was considered an essential moral: the fact that as man faces each and every problem in life, the result depends entirely on his own thoughts and actions; it is up to him whether he rises toward the stars or slips to the underworld. The audience was shown that with freedom of choice man has responsibility for his own actions, that a man's past actions affect his future, and that man, subject to the inviolable laws of the universe, determines his destiny by his thoughts and actions, by his positive or negative output. Man can create more abundance, or more destruction, he can be full of appreciative joy, or empty as a reed. He can love or hate. He can have fertility, wisdom, and the font of life, or sloth, corruption, and death.

Szekely reconstructs the ritual in which a high priest, positioned on a platform on the summit of the pyramid, announced to the accompaniment of drumbeats to the crowd below the movement of each character from square to square on the pyramid steps, drums and voice being loud enough for an audience a mile away to participate in the ritual. Zelia Nuttall describes two kinds of drums: a large *huehuetl,* which emitted a loud, deep tone heard for miles, and a smaller portable drum suspended from the neck, which emitted a shrill piercing note employed as a signal.

At the opening of the drama, man would be in the center of the field; his object was to rise to the eleventh level and to avoid being pushed below the first. The ritual, says Szekely, was an actual trial of man for his good and evil deeds. Whereas today a man is judged for a crime by a judge and jury according to a labyrinthine code of laws, in Mesoamerica man was judged by the sum of his past deeds, good or evil, as searched out by two high priests, one looking for his deeds in support of Quetzalcoatl, the other for his deeds in support of Tezcatlipoca. If a man had watered a tree, mended a wall, or saved a bird, he got points for the Quetzalcoatl team; if he had killed, maimed, or hated, he got points for Tezcatlipoca.

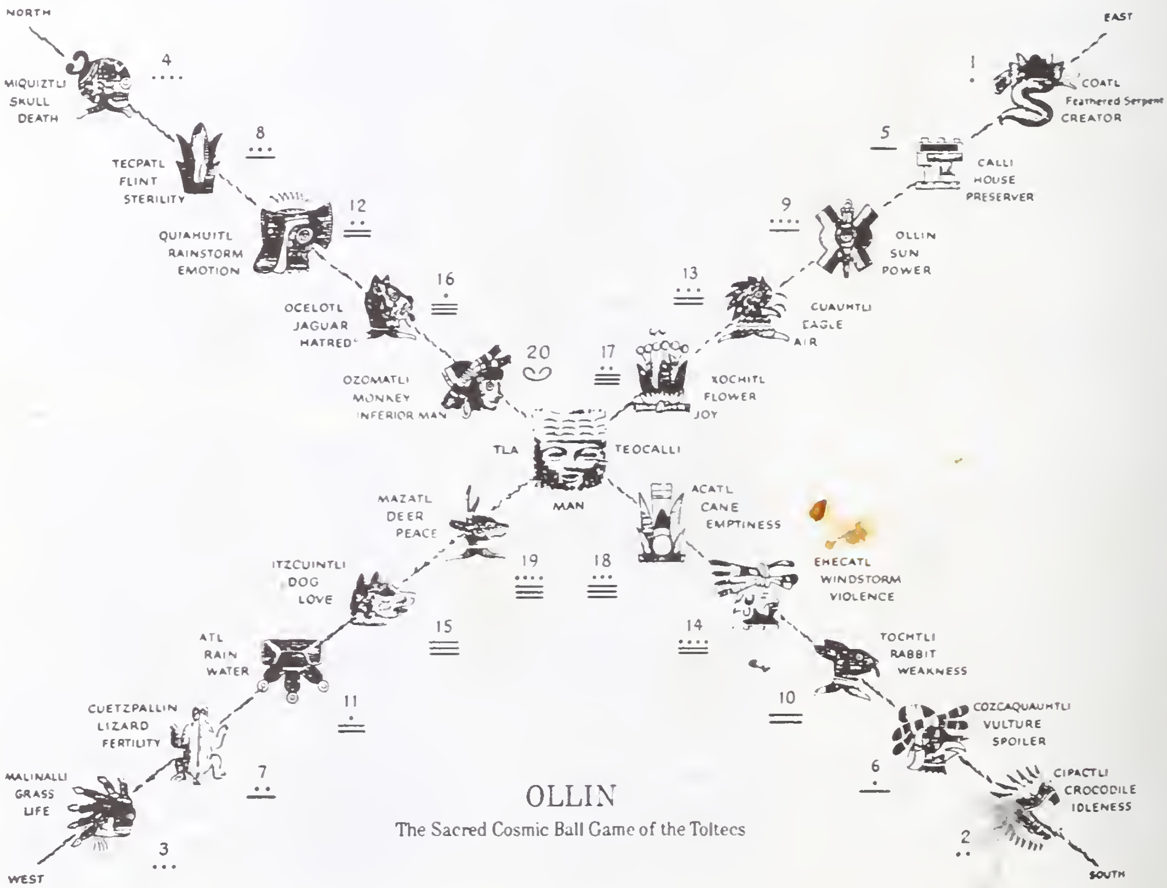
For each point, a man was entitled to a small round object, or *pelota,* originally made of stone and then of rubber, with a hole in the center so it could be strung on a thong. The *pelotas* were given to the players on the team with which he had cooperated.

In the ritual, when a masked player was reduced to a single ball he would have to retire from the game and could no longer help man either up or down. If a man had cooperated very little with the forces of Tezcatlipoca, that team would have few *pelotas* and would be forced to disappear from the stage, allowing the man to rise rapidly to the top.

With such a clear-cut world picture of Karmic law, it was easy for a man to harmonize his acts. Szekely says that during every moment of his experience the early Aztec, Toltec, Mayan, and presumably Teotihuacano would ask himself if what he was doing was in harmony with the positive, constructive principles of Quetzalcoatl or with the negative, destructive principles of Tezcatlipoca.

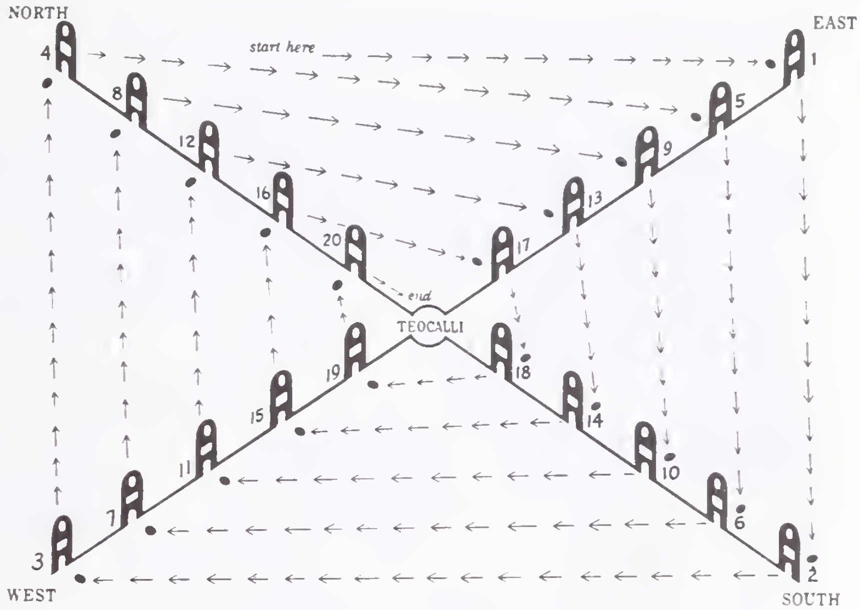
With just twenty symbols, says Szekely, it was easier for the priests of Mesoamerica to instill a moral code into society than it is for a modern judge to handle contemporary man with thousands of volumes of codified law.

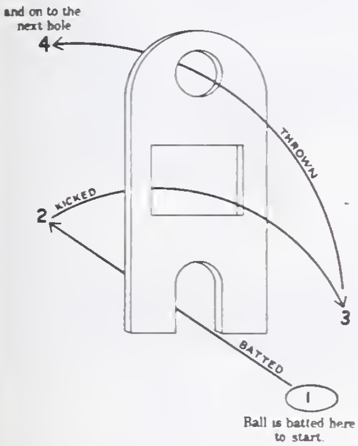
Szekely's depiction of the horizontal ball game of King Netzahualcoyotl.



OLLIN
The Sacred Cosmic Ball Game of the Toltecs

Order in which the ball had to be moved to the winning goal at the center of the horizontal ball game, according to Szekely.





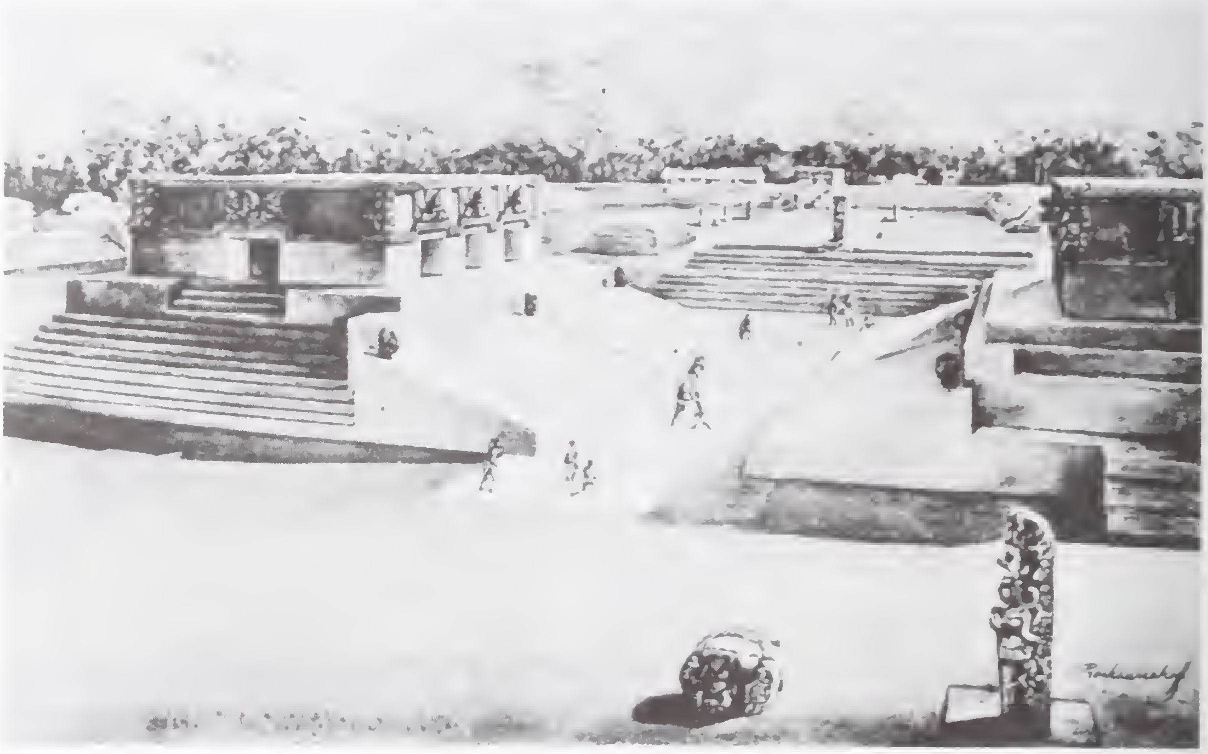
In Szekely's reconstruction of the game, the player had to bat, kick, and throw the ball through the apertures in a stone marker.

In due course the pyramid ritual was transferred to a level court that retained the pyramid format only when seen from a bird's-eye view: a cross with a central point, symbolizing the rays of the sun. In this ritual man still stood in the central position, symbolizing his fundamental unity with the creator. Here man was like a pawn on a checkerboard moved backward or forward by the force of his own past actions.

In different areas the ritual varied, says Szekely, until King Netzahualcoyotl, poet, philosopher, and lawgiver, compared by Szekely to King Solomon, synthesized the four games of Teotihuacan, Monte Alban, Tula, and Tenayuca into a single new game. In Netzahualcoyotl's game the twenty classical symbols were erected on the ball court in the form of stone stelae with three separate holes through which a ball had to be batted, kicked, and thrown.

Played with a rubber ball, the game was the evident prototype of several of our modern games, a mixture of croquet, baseball, soccer, and basketball, with scoring similar to golf, depending on the number of strokes it took to finish. This game, says Szekely, constituted "one of the most advanced judicial systems in the history of man." It took into account not simply the crime committed, but the entire past history of the person accused.

Whenever a person violated the law, a priest would go to his home and neighborhood, talk to his friends, neighbors, and family, and objectively collect accounts of his good and bad deeds. With sixty holes in the game to contend with, sixty good deeds could get the accused to the center of the field safely into the *teocalli,* "home of the gods." Anything less would bring him punishment, no matter how well he played.



Ball court in Copan as it is estimated by archeologist Proskouriakoff to have existed in A.D. 600.

The beauty of the game, as described by Szekely, is the emphasis placed by law on the pursuit of good deeds rather than the punishment of evil, with an extra incentive for keeping physically fit in case of a trial.

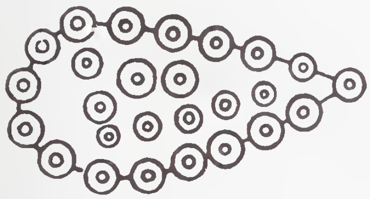
Eventually the game degenerated into a spectacle, with professional ballplayers touring the country to give exhibitions of their skills and engender a fever for gambling.

Sometime earlier it may have been an even more sensational exhibition of paraphysical prowess.

Stephan Schwartz, author of *Psychic Archeology,* and Dr. Lindsay Jacob, a psychiatrist in Pittsburgh, both students of the Cayce readings as well as of the archeology of Mayaland, surmise from the reliefs on the walls of Chichen Itza that there may have been more to the game of Tlachtali than described by conventional archeologists. They suggest that the original ball in play may have been of a substance more subtle than rubber, a sort of plasma on the order of a static electric thunderball, or orgone, requiring a high degree of initiation to move around the court and pass through a ring high on the wall, possibly by means of such developed talents as those described by Carlos Castañeda in his quatrilogy on the metaphysical feats of the Yaqui bruja. Failure to control such a fireball could have resulted in an out-of-body experience, which, carried to excess, might have left the body fulminated.

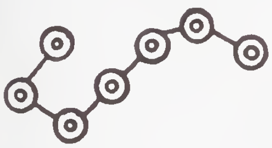
Archeologists concur that the game had deadly implications and that the losers could forfeit their lives as easily as they did on the pyramids. This too could have been a corruption of the original sport.

Several researchers have linked the ball courts with maps of the heavens. According to Livio Stecchini, the great ball court at Chichen Itza displays on its walls a cylindrical mercator projection of the path of the planets around the zodiac, a 14-degree swath 7 degrees above and below tne ecliptic along which the planets move, a sort of ball court for the gods, in which to dribble the planets.



Aztec depiction of the Pleiades according to Sahagun.

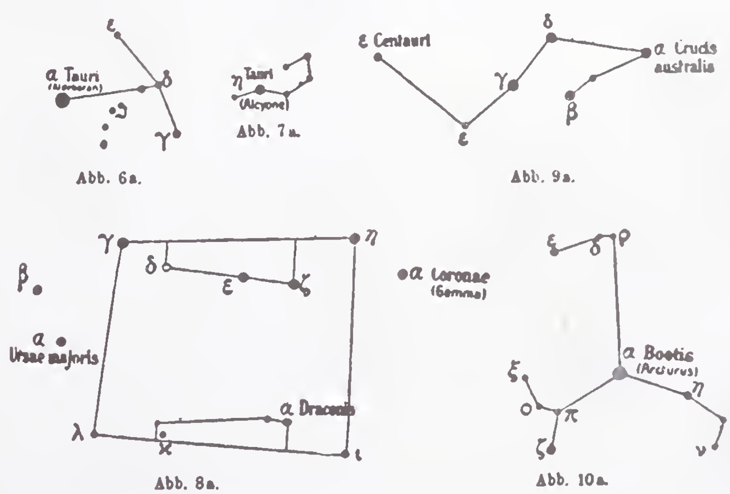
Other researchers have suggested the ball courts dramatize a bigger game, the game of life in the entire universe, symbolizing the various levels at which spirit creates and handles matter. They suggest that the ring through which the ball must pass may have represented the spot in the heavens whence travelers came to this planet from their previous cosmic home.



The big dipper in an Aztec codex.

Whereas the pyramid ritual appears to have been a dramatization of man's earthly struggle between the poles of spirituality and materiality, between gravity and levity, the ball-court games may have dramatized the space adventures described by modern science-fiction writers—the exploits of spirits operating bodies, robots, and spacecraft to and from planets orbiting various stars in various galaxies—exploits which appear less fictional since man has landed on the moon, and since UFOs have been validated by tenured academics.

L. Ron Hubbard, originator of Dianetics and Scientology, produced fine data on such "space games" by regressing individuals in reverie back on the time track to remote periods during which they described invasions of this planet by extraterrestrials. Hubbard added to this data from his own out-of-body exploration of the universe and from his own travel along the track of time. In the early 1950s



Ball-game arenas among the constellations, according to Szekely.

he used the electropsychometer—a galvanometer refined by Olin Mathieson—much like the standard lie detector, only more sensitive, and calibrated for longer trips, to probe the Jungian memories of the race going back thousands and thousands of years.

Delicate movements of the electropsychometer's needle subtly and fleetingly reflect the thought patterns of the subject, enabling the questioner to probe for memories heavily charged with emotion. These, when contacted and reviewed by the subject, appear to run in almost endless chains, revealing three-dimensional dramatic scenarios with full color, sound, and sensation, set in the most exotic surroundings, scattered through time and space. By this technique, any subject can become a potential Edgar Cayce, capable of projecting his point of view throughout the cosmos, a technique which enabled Hubbard to produce one of his more unorthodox but startling books: *A History of Man.*

In the "space opera" of the twilight world between science and fiction there is said to flourish a group of extraterrestrials known as the Brotherhood of the Serpent, familiar in terms of Mayan history. They are described as members of a Great White Brotherhood who arrived on earth from bases they had established on Mars and the moon during the Atlantean and Lemurian periods to set up mystery schools to teach humans how to free themselves from mortal coils. These Serpent People are described as a pro-evolutionary group, on whose instructions the original pyramids in Egypt and Central America are said to have been built.

G. I. Gurdjieff in his *Beelzebub's Tales to His Grandson* claims that the beings responsible for the occult school in which he was instructed in Central Asia—the ones who developed the Sufi movement—also had a base on Mars.

Psychics have described certain temples in Atlantis as being used by priests to encase spirits in human bodies so they might better learn to care for them, a process which apparently degenerated into a state of identification with the body in which they forgot who they were: a condition only to be remedied by other initiate priests who could get them out of their bodies to recognize the game—through initiation.

From the accumulated data on the rites of initiation in the mystery schools, it is clear that the initiate was led to see and be and know without a body, facing certain out-of-body terrors as illusions that could be handled by postulate and will. Initiation was a rebirth to the world of levity and the realization that no harm can befall a spirit other than that which it does to itself, mostly by willing harm to others, or by restricting, for the perverse enjoyment of the sensation, its own unlimited powers. Once initiated, a person could be in this world but no longer of it, see it as an entrancing game in which a player can be trapped by believing he is a body, or by agreeing he must hurt when the body hurts, or die when the body dies, despite the fact that such a notion is easily disproved by a hypnotist in twenty minutes, when pain can be seen to be a subjective imposition on the body, and that one can be and see without the bonds of space and time.

Any Indian taking peyote can tell you that all are one, and each is but a point of view. Out of body, anyone can see, and be, like Edgar Cayce, a thousand or a million miles away.

Frank Waters, in his *The Book of the Hopi,* says the Hopis still claim that the Maya were helped by extraterrestrials or intersteilar people. He says the Cochines also claim to have come from outer space and to have helped the Maya.

Dogon tribesmen in central west Africa have reported contact with blue-skinned men, purportedly extraterrestrials from Sirius—a fascinating subject dealt with in great detail by Robert K. G. Temple in his *The Sirius Mystery.* All over the world and throughout history there have been reports of blue-skinned men who are somehow related to the star Sirius. There were blue-skinned gods in the Vedas, blue-skinned men of northern Japan and the Marianas, blue-skinned men of Wales.

Sirius is a blue-white star, bigger and hotter than our sun, thirty-four times as bright, with eight times the mass. In occult literature, it is said to act as a cosmic throat center for this area of the galaxy, whereas the Pleiades act as the heart.

Lao Russell, wife of the extraordinary mystic writer Walter Russell (described as a modern Leonardo da Vinci), says she was in touch with a group who said that Sirians had come to Atlantis about 20,000 years ago and left important records which, with the sinking of Atlantis, were entrusted to Phoenicians who took them to Brazil, where they remained sealed in a cave in the cliffs marked by great Phoenician petroglyphs.

Sensitives say the Serpent People are due to return to earth in 2011 to help create a world government. But all is not so simple. In opposition to the Brotherhood of the Serpents, the grand opera of space has its heavies: members of the "Marcab Confederation." Marcab, or Markab, is a star in the constellation Pegasus. It is located in the same general direction as the stars belonging to the group reconstructed in a three-dimensional model by Marjory Fish from Betty Hill's hypnotically described star maps of the area seen while aboard a space ship.

Those spacemen are said to be monitoring this planet preparatory to manifesting themselves en masse, and to be sending ahead scouts in human bodies to prepare the way.

Some individuals, when regressed or out of body, describe the Marcabs as having been in existence some 200,000 years, operating meat bodies and androids, or robots modeled to look like human beings, but who have lost the power to crawl out of their present condition. In this semi-degenerate state they can apparently only try to control others and drag them to their level.

Subscribers to the Marcab-Serpent People theory envisage a struggle between extraterrestrials for the souls, minds, and bodies of terrestrials, with the Marcabs using control methods to keep humans ignorant and enslaved while the Serpent People use initiatory methods to help humans recover the knowledge of their true spiritual identity.

Identity with a body can lead to easy blackmail by a controller who wishes to enslave an individual simply by guaranteeing the requirements of shelter, food, sex, and security. Hence the various attempted routes of escape via fasting, abstinence, free love, and vagabondage. Hubbard's remedy is to recover the certainty of one's spiritual essence and and learn to operate, successfully and at will, with or without a body.

Ball, hole, and body games seem to predominate in this particular corner of the universe.

Much of the violent history and pre-history of this planet could rationally be accounted for by such a hypothetical conflict between the Marcab-type "controllers" and the Serpent People "liberators," or the roles could be reversed.

For those who find it hard to postulate the existence, even in space, of friend and foe on the Quetzalcoatl and Tezcatlipoca order, it is suggested that a cosmic game, just like any earthly game, requires levels of "friend" and "foe," stacked in alternating harmonics, otherwise the layers will coalesce until eventually everyone will be on one side—and the game will end.

As Hubbard points out, to have a game you must have barriers and delimitations—arbitrary limits. One can hardly kick a goal where there are no goalposts. To have surprise and variety, there must be something one does not know, or temporarily hides from oneself. To have a contest there must be opponents. To have a winner, someone must suffer defeat. Thus games can lead to falls, and harder falls to forgetting it's a game and who invented it.

If all this sounds grossly farfetched, far from the point of a pyramid, it is no further than the substance of all myth and of most organized religion: it is the perennial subject of great art and literature; it is as much the source of *The Magic Flute* as of *A Midsummer Night's Dream*.

But whereas in Renaissance England the Ancient Wisdom was still preserved hermetically in the Temple and the Inns of Court to be dramatized for the Globe in Shakespeare's plays, elsewhere on the planet the prospect was less brilliant. In Spain and New Spain, with rack and pillar and stake, the Holy Office cast itself to eradicate the vestiges of wisdom, and those reflections of the game of life still dramatized upon the local temples—on the pyramids and ball courts of Mexico and Mesoamerica.

Index

TRAVEL/HISTORY/OCCULT

"An interesting, beautifully illustrated book. . .of interest to general readers who wish to look at its illustrations and want a well-written introduction to a wide range of speculations concerning the cosmic importance of ancient pyramids."
—*Choice*

In *Mysteries of the Mexican Pyramids,* bestselling author Peter Tompkins probes the history, origin, and purpose of the pyramids in the Valley of Mexico, the Yucatan, and Central America, with emphasis on the Pyramid of the Sun and the Pyramid of the Moon near Mexico City. He recounts the history of these structures from their first sighting by Cortes as rubble-covered mounds through four centuries of efforts to solve the mystery of their existence. He follows the adventures of Humboldt, Stephens, Brasseur de Bourbourg, and other explorers and scholars. He shows what theories have been advanced concerning the design and dimensions of the pyramids as mathematical computers, astronomical observatories, and foci for cosmic and telluric forces. He also speculates on why and how the Mayan and the Mexican pyramids were built and what links there may have been between their builders and other historic and prehistoric societies, like that of the lost continent of Atlantis.

Peter Tompkins has visited the complex of ruins at Teotihuacán and other Central American pyramids on numerous occasions and has spent half a dozen years gathering and analyzing information from scientists and archaeologists and studying hundreds of published and unpublished documents on early Mexican civilizations. He has selected more than 500 illustrations from rare books and other sources and obtained special drawings from Hugh Harleston, Jr., René Millon, and Edmond Bordeaux Szekely. In addition to this book's companion volume, *Secrets of the Great Pyramid,* on the Great Pyramid of Cheops, he is the coauthor of *The Secret Life of Plants* and several works of history and biography.
